To establish a uniform decision process concerning what to do about sediment contamination, Ecology shall develop guidelines for deciding whether existing sediments that exceed the sediment standards developed under element P-2 should be capped, excavated or otherwise treated, or whether no action should be taken. In developing the guidelines, Ecology shall consult with agencies and parties with expertise in these issues and provide a public education and public involvement program. Development of the guidelines shall include consideration of deadlines for making decisions on cleanup actions. As a guide in deciding whether to wait for natural processes to cap or dilute the sediments or to undertake cleanup actions, the guidelines shall also include consideration of a time by which surface sediments should no longer have adverse effects. Because of the high cost of treatment or removal of contaminated sediments, the guidelines shall include a process and criteria for establishing priorities for such actions, including consideration of the cost of cleanup. Development of the guidelines should include a process for ranking sediments with high levels of contamination by relative potential risk posed to human health and the environment.

Target Dates: Guidelines for sediment cleanup decisions are contained in the sediment management standards adopted in 1991. Implementation of the guidelines shall be ongoing.

S-8. Investigations and Cleanup of Contaminated Sediments

This element constitutes an expansion of the ongoing EPA and Ecology program of investigations and pollution source-control efforts in urban bays and other areas of the Sound where sediment contamination is known or suspected. This element deals with sediment contamination in three tiers. In subelement 8.1, specific sample locations that exceed sediment standards are inventoried. In subelement 8.2, Ecology uses the inventory and other information to identify bays or other similarly sized areas for further investigation under subelements 8.3 and 8.4. In subelement 8.6, Ecology identifies specific sites that should be considered for cleanup actions under subelements 8.6 and 8.7, using ranking criteria developed in subelement 8.5.

VOL 12 2 3384

R0056679

Element P-13 in the Municipal and Industrial Program provides additional detail on the Urban Bay Action Program.

Although this element contains specific directives and assignments, the Authority intends that the EPA, Ecology and other agencies and local governments exercise flexibility in resolving contaminated sediment problems. The EPA is requested to continue or increase existing support for this effort through various programs including the national funding for estuary programs, federal Superfund activities and federal funding for Ecology's water quality and hazardous waste programs. To organize and coordinate the program, Ecology, in cooperation with the EPA, shall undertake an integrated program consisting of the guidelines called for in element S-7 and the following components:

8.1. Inventory of Locations with Contaminated Sediments

To provide information to the Authority and the public and to allow for tracking of increases or decreases in the extent of sediment contamination, Ecology shall maintain an inventory of points or locations in the basin where sediment samples have been taken which violate the sediment standards developed under element P-2. The inventory should consist of graphic displays with locations of contamination indicated. All available sources of data, including monitoring, permit applications and published research studies, should be used in developing the inventory. The inventory shall be integrated into the Puget Sound Geographic Information System (GIS) and used to update the Puget Sound Environmental Atlas if possible. This inventory shall be updated every two years and made available using the data transfer formats developed under element M-4. The Authority shall assist in distributing the inventory and include a summary of the inventory in the State of the Sound Report. As an aid in targeting pollution source-control activities, Ecology's inventory shall identify the chemicals or other characteristics for each location that causes it to be on the inventory.

Target Date: Establish computerized inventory and make data available to the Puget Sound GIS annually or when required for specific projects.

8.2. Contaminated Sediment Area[6] Priority List and Investigation Schedule

Ecology shall develop decision criteria for identifying areas of Puget Sound where locations with sediment contamination have been identified or are suspected and where investigations should be undertaken to control sources and consider cleanup actions. These criteria will be used to establish a priority list of areas to be investigated, allocate resources for contaminated sediment investigations, and establish a schedule for these investigations. (Under element P-13, Ecology is to prepare a long-term implementation plan for the Urban Bay Action Program.) Every effort should be made to investigate each area on this priority list within five years of its first appearance on the list. Ecology shall reevaluate both the area priority list and the investigation schedule every two years. Ecology shall provide the Puget Sound Estuary Program

6 An "area" is a bay or similar-sized region where sediment contamination might be studied and an effort made to control sources of contamination. A "site" is smaller than an "area" and defines a specific "hot spot" that might be caused by a single source and considered for cleanup action.

VOL 12 2 3385

R0056680

Management Committee an opportunity to review and comment on the priority list of areas.

Although this element focuses urban bay action programs on areas with sediment contamination, Ecology may include other factors in selecting areas for inclusion in the plan for urban bay action programs.

Target Date: The priority list of areas to be investigated is to be completed within 12 months of final adoption of sediment standards under element P-2.

8.3. Investigations of Contaminated Sediment Areas

Ecology, in cooperation with federal and state agencies and local and tribal governments, shall carry out investigations of contaminated sediment areas identified and listed under element 8.2. Investigations shall be designed on a case-by-case basis using Elliott Bay and Commencement Bay studies as the models. The investigations shall include reviews of existing information on contamination and sources as well as field investigations designed to refine information on levels and distribution of contamination and probable sources.

8.4. Action Teams and Source Control

For each contaminated sediment area being investigated, Ecology, the EPA, local governments and other appropriate agencies will form a team of investigators to work on source controls. The teams should include Ecology regional office inspectors and permit writers who normally handle the area. The DNR shall participate in each urban bay action team as part of its efforts to reduce contamination of state-owned aquatic lands. Each team's activities shall be integrated with the Municipal and Industrial Discharges Program by focusing activities under that program in areas associated with contaminated sediment areas. Also, in some urban bays, bay wide planning efforts are being promoted by the Department of Natural Resources. Bay-wide planning is encouraged as a tool to balance cleanup, habitat development and other water dependent activities. Because the urban bay action teams include representatives of many of the appropriate parties, the bay wide planning efforts shall be integrated with the activities of the urban bay action teams. The lead for a baywide planning initiative however, might be a public port or the Department of Natural Resources.

Urban bay action teams shall carry out various source control, cleanup and investigative actions including:

- Review existing discharge permits and compliance with them.
- Reopen and modify discharge permits of sources in the vicinity to control toxicants identified at problem levels in the sediments.
- Search for unpermitted discharges and take enforcement actions.
- Investigate contamination in storm drains or ground water and search for sources of such contamination.

VOL 12 2 3386

R0056681

- Take other actions to control sources of sediment contamination by seeking to achieve full compliance with applicable laws and regulations in locations that drain into the contaminated area.
- Identify sites within the area that should be considered for cleanup.
- Assist in ensuring that cleanup actions take place.
- Develop urban bay action plans for each urban bay. (The development and adoption of action plans is described in element P-13.)
- Coordinate with applicable baywide planning efforts.

Ecology and the EPA are encouraged to make use of industry scientists, engineers and other experts to assist in these efforts.

8.5 Ranking Method Study

[This subelement has been completed.]

8.6. Sediment Site-Cleanup Actions

Following the guidelines developed under element S-7, when sites with high levels of sediment contamination are identified, Ecology shall consider the feasibility and reasonableness of sediment cleanup actions, coordinating with the DNR on actions that affect state-owned aquatic lands. Ecology, as part of this element, shall develop decision criteria for determining when sediment cleanup actions should be taken pursuant to laws regulating water quality and discharge permits (sediment restoration activities) and when cleanup actions should be taken pursuant to the Model Toxics Control Act (sediment remedial actions). If sediment cleanup actions are necessary, funds for such actions will be sought first from responsible parties and then from public sources. All cleanup actions shall be consistent with the guidelines developed under element S-7. Ecology shall maintain a priority list of specific sediment sites where cleanup will be considered.

Target Date: Establish initial priority list of sites by January 1, 1995.

8.7. Responsible Parties

The Authority recognizes that identifying the parties responsible for sediment contamination is generally difficult. Often neither the underlying property owner nor the abutting property owner is responsible for the contamination. But cases have occurred and will occur where responsible parties can be identified. Where treatment or removal of contaminated sediments is recommended, Ecology shall attempt to have such cleanup actions, including investigations and feasibility studies, undertaken and paid for by responsible parties, whether they are dischargers under water quality laws or liable persons pursuant to the Model Toxics Control Act. The DNR shall utilize state proprietary authority to secure, to the extent possible, site cleanup, natural resource damages, and cost recovery from responsible parties whose contamination is located on state-owned aquatic lands. Every reasonable attempt will be made to recover cleanup costs from responsible parties, including study costs.

VOL 12 2 3387

R0056682

Target Date: Ongoing activity.

S-9. Public Involvement, Education and Technical Assistance

Ecology shall increase staffing for public involvement for sediment program issues including sediment standards (element P-2). A staff person will be assigned to coordinate Ecology's public outreach and education on sediment issues and improve the response to technical inquiries. This element will be coordinated with the development of educational materials on sediments under element EPI-3.1.

Target Date: Establish staff position by December 1995.

MAJOR PUBLIC ACTIONS FOR AUTHORITY REVIEW

1. Changes to PSDDA recommendations adopted by reference in element S-3.
2. Adoption of sediment management standards which include the sediment quality standards (element P-2) and maximum allowed cleanup levels and site-specific cleanup requirements (element S-7 and subelement S-8.6).
3. Adoption of disposal standards for contaminated sediments (element S-4).
4. Priority list for investigation of contaminated sediment areas (subelement S-8.2).

LEGISLATION REQUIRED

New legislation may eventually be required to allow the establishment of multi-user disposal sites for dredged material.

ESTIMATED COST

Full implementation of the Contaminated Sediments and Dredging Program is estimated to cost close to $5 million during the 1995-97 Biennium and $4.5 million during the 1997-99 Biennium. The program's largest cost, comprising over 80 percent of the total, is the investigation and cleanup of contaminated sediments (element S-8). Funding at this level would allow some progress on site investigations and source control but does not include public funds that might be needed to clean up contaminated sediments. Such costs could run in excess of $100,000 per acre for removal or treatment and at least $5,000 per acre for capping. Estimates of costs to dredge and dispose of sediment hot spots in Commencement Bay ranged from $8 to $79 per cubic yard depending on the type of disposal required.

Large public and private sector costs are currently associated with dredging or disposal of dredged material. In 1984, dredging and open-water disposal of clean material cost only $2 to $3 per cubic yard. Now testing of material suspected of being contaminated has cost an additional $1 per cubic yard. In addition, disposal fees have increased and will increase more in the future. Disposal of dredged material that cannot go to open water now costs anywhere from $15 to $40 per cubic yard. Disposal of highly contaminated material has been estimated, as discussed above for cleanup actions, at up to $79 per cubic yard. Since annual dredging volumes are in the hundreds of thousands of cubic yards, most of it clean material, these are significant costs for the region.

Private sector costs associated with investigating and dealing with contaminated sediments sites may also increase. This would occur when responsible

VOL 12
2
3388
R0056683

parties are required to investigate and remedy sediment hot spots resulting from their discharges. These costs are not included in the overall cost estimates.

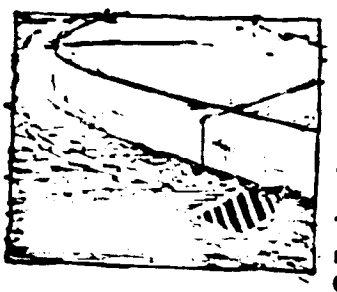
PROBLEM DEFINITION

Storm Water



Storm water, or urban runoff, is defined as rainfall that falls on impervious surfaces and is routed into natural or artificial drainage systems.[1] Pollutants in storm water can include sediments, nutrients, bacteria, oils, grease, metals and other toxicants. These contaminants can harm biological populations, destroy fish and wildlife habitat, contribute to restrictions on shellfish harvesting and swimming, and contaminate sediments. Sources include motor vehicles; fertilizers, pesticides and herbicides; runoff from urban development; construction sites; businesses and industries; pet feces; and poor management of other wastes.

The potential for significant pollution from storm water has been increasingly recognized. The Environmental Protection Agency's (EPA's) 1992 Water Quality Inventory (Clean Water Act Section 305b) stated that urban runoff impairs 43 percent of estuarine miles, 11 percent of river miles, and 24 percent of lake acreage in the United States. The average stormwater concentrations exceeded chronic water quality criteria for cadmium, copper, lead, nickel and zinc. The concentrations of metals did not appear to be different among the three basic land-use types sampled—residential, commercial and industrial.

Runoff from freeways, however, was consistently higher for most metals. Compared to effluent from secondary sewage treatment, urban runoff in Bellevue contained higher concentrations of lead and zinc. Runoff data from the Nationwide Urban Runoff Program[2] showed that average concentrations of total suspended solids, chemical oxygen demand, and nitrate/nitrite were higher

1 Impervious surfaces include rooftops, driveways, streets, parking lots and highways. Lawns are found to be almost as impervious as some paving.

2 The Nationwide Urban Runoff Program was a five-year study (1978-82), sponsored by the EPA and many cooperating federal, state, regional and local agencies, which addressed the quality of urban runoff, the significance of the urban runoff problem, and the effectiveness of best management practices.

R0056685

VOL 12 2 3390

than the annual mean concentrations in secondary treated effluent from the Renton treatment plant.

Runoff is greatest in urban and suburban areas due to population density and the high percentage of impervious surface area that prevents absorption. The atmosphere in urban areas contains particles and associated contaminants from cars, factories and wood stoves. When it rains, these particles—and pollutants—may be deposited on the water, or they may be deposited on the land and washed into the nearest stream, lake, or bay. Not surprisingly, storm water is a significant source for pollutants concentrated in the sediments of urban bays. Some storm drains in Seattle were found to be major sources of lead and PCBs (a group of industrial compounds banned in the 1970s) in the sediments of Puget Sound.

Without controls, stormwater volume and peak flows can impair the ability of anadromous species to migrate through obstructions and changes in flows. Peak flows scour gravel beds needed for spawning. Natural and artificial wetlands are being used to store and treat storm water. Preliminary data from Puget Sound Wetlands and Stormwater Management Research Program shows that unmanaged storm water has a detrimental effect on wetlands in certain areas.[3]

Population in the Puget Sound basin is projected to grow by more than one million people by the year 2010. Development associated with this growth requires adequate stormwater control. Without proper management, storm water will continue to degrade water quality and harm biological resources.

Combined Sewer Overflows (CSOs)

Combined sewer systems collect sanitary sewage, industrial waste water and storm water in a single sewer system. During large storms, part of the system's effluent is discharged before being treated because the system's pipes and sewage treatment plant cannot handle the full volume of waste water. Nine cities around Puget Sound have combined sewer systems that discharge directly into Puget Sound during large storms. Metro (King County Metropolitan Services) in King County handles waste water from combined sewers but does not own a combined system.

Except for Metro and Seattle, basic information about frequency, quantity and effects has been lacking for most CSOs discharging into Puget Sound. In an average year, Metro and Seattle have discharged about 2.8 billion gallons of raw sewage, untreated storm water and industrial effluents from about 110 CSOs in the Seattle area. This volume is approximately six percent of the annual discharge from the West Point treatment plant. Although the volume of effluent of CSOs is relatively small compared to the discharge of sewage treatment plants, CSO discharges are untreated and many are in close proximity to sensitive shoreline areas. Metro and Seattle are working to reduce their CSO discharges.

3 Puget Sound Wetlands and Stormwater Management Research Program, 1993. Research Summary V1. Sensitive Plant Communities in the Puget Sound Region: Forested Wetlands, Bogs/Fens, and Sedge Meadows.

VOL 12 2 3391

R0056686

The discharges from CSOs frequently contain large amounts of fecal coliform bacteria, nutrients, suspended solids, and sometimes toxicants. Sediment samples around the Denny Way CSO in Seattle showed highly elevated concentrations of heavy metals and organic toxicants. Metro has since capped those sediments. The biota around the CSO was harmed by the discharge, and the area is closed to swimming due to high concentrations of fecal coliform.

INSTITUTIONAL FRAMEWORK

Since the mid-1950s, the U.S. Environmental Protection Agency's (EPA) policy, and standard engineering practice, has been to install separate sanitary and storm sewers for newly developed areas. CSOs are now regulated under the National Pollutant Discharge Elimination System (NPDES) program, with discharges required to meet all applicable requirements. In 1985, the Washington State Legislature passed a law requiring all municipalities with CSOs to develop plans for the greatest reasonable reduction at the earliest possible date. Implementation of those plans is under way.

In 1986, a handful of local governments had established stormwater utilities based on their general legal authorities, but at that time storm water was primarily addressed as an issue of water quantity in permits. The 1987 Clean Water Act reauthorization and subsequent revisions established new procedures, requirements and deadlines for regulation of storm water. The Department of Ecology (Ecology) established a stormwater program in 1988.

The federal Clean Water Act, and state statutes RCW 90.70 and RCW 90.48 establish federal and state authority for stormwater management in the Puget Sound basin. Ecology administers (NPDES) stormwater permits for municipal and industrial dischargers, and the state Department of Transportation. The EPA issues NPDES permits to federal facilities and tribal lands located in the state. The Authority, under RCW 90.70, directs local governments to adopt stormwater regulatory programs. Ecology developed minimum standards for stormwater programs, a technical guidance manual and a model ordinance for local governments implementing stormwater programs.

AUTHORITY'S APPROACH

The Authority recognized that because of the pervasiveness of stormwater problems, any viable solutions would require the cooperation of diverse segments of society: the development community, government, businesses and individuals. Programs to control and prevent storm water needed to be developed at the local level, with guidance and assistance from state and federal agencies.

The 1987 Puget Sound Water Quality Management Plan (Plan) called for: (1) stormwater programs to be developed in urbanized areas of the Sound in a phased program, starting with the largest cities; (2) all cities and counties to develop operation and maintenance programs, adopt ordinances for new development, and develop stormwater education programs; and (3) all cities with CSOs to develop and implement plans providing for the greatest reasonable reduction of overflows each year.

VOL 12 2 3392

R0056687

The Plan called for Ecology to develop technical manuals, guidelines, regulations and model ordinances; the Department of Transportation to develop a program to control highway runoff; and the EPA to include stormwater controls in NPDES permits issued to federal facilities.

Revisions to the Plan in 1989 added no new program elements; effort was focused instead on implementing existing elements. However, amendments to the 1991 Plan included several key changes, including: recognizing the importance of implementing the most effective best management practices; calling on Ecology to include minimum requirements in its "stormwater technical manual"; coordinating stormwater programs with Growth Management Act planning; and increasing technical assistance and outreach to local governments.

The 1994 Plan calls for the departments of Natural Resources and Fish and Wildlife to adopt the stormwater technical manual, adds performance criteria for BMPs (best management practices) to help track performance, emphasizes coordination among watersheds, addresses vactor waste, and better integrates stormwater controls with Growth Management Act (GMA) requirements.

PROGRAM GOAL

To protect shellfish beds, fish habitat and other resources; to prevent the contamination of sediments from urban runoff and combined sewer overflows; and to achieve standards for water and sediment quality by reducing and eventually eliminating harm from pollutant discharges from storm water and combined sewer overflows (CSOs) throughout Puget Sound.

STRATEGY

The pollution control strategy for achieving the program's goal is to implement the most appropriate best management practices first, assess their effectiveness, and as necessary, require further water quality controls.

The implementation strategy for achieving this goal is to: (1) require that all cities and counties meet minimum requirements for a basic stormwater program; (2) develop stormwater programs in urbanized areas of Puget Sound in a phased program starting with the largest cities; (3) develop NPDES permits for municipal storm water that incorporate the Plan's stormwater requirements and federal requirements, and phase in additional NPDES permits for municipal storm water for smaller jurisdictions as further U.S. Environmental Protection Agency EPA regulations are promulgated; (4) schedule the development of additional Puget Sound stormwater programs on a priority basis; (5) provide technical assistance to both local governments and businesses; and (6) require all cities with CSOs in the Puget Sound basin to develop and implement plans which provide the greatest reasonable reduction of CSO events.

VOL 12 2 3393

R0056688

PROGRAM ELEMENTS

SW-1. Basic Stormwater Programs for All Counties and Cities

The pollution control strategy for achieving the program's goal is to implement the most appropriate best management practices (BMPs) first, assess their effectiveness, and, as necessary, require further water quality controls.

1.1. Minimum Requirements for Basic Stormwater Programs

All cities and counties shall adopt stormwater programs which include the minimum requirements for new development and redevelopment[4] and other basic stormwater controls contained in the Plan and in guidance developed by Ecology. All counties and cities in the Puget Sound basin shall adopt ordinances requiring stormwater controls for new development and redevelopment.

The basic stormwater program shall include ordinances that address, at a minimum: (1) the control of off-site water quality and quantity effects; (2) the use of best management practices for source control and treatment; (3) the effective treatment, using best management practices, of the storm size and frequency (design storm) as specified in the manual for proposed development; (4) the use of infiltration, with appropriate precautions and maintenance, as the first consideration in stormwater management; (5) the protection of stream channels, fish, shellfish habitat, other aquatic habitat; and wetlands; (6) control of erosion and sedimentation for new construction and redevelopment projects; and (7) local enforcement of these stormwater controls.

Local governments should monitor compliance with stormwater requirements and publish the results of the monitoring in watershed "report cards" or in other forms.

Ecology shall publish guidance, as required under element SW-4, for meeting these requirements.

This program shall not affect Ecology's authority to require appropriate corrective action (pursuant to Chapter 90.48 RCW) whenever existing facilities cause or contribute to violations of state water quality standards.

1.2. Operation and Maintenance Programs

Each county and city shall also develop and enforce, within local governments' authority, operation and maintenance programs and ordinances for new and existing public and private stormwater systems. Each county and city shall maintain records of public and private storm drainage systems and appurtenances. Counties are responsible for the stormwater programs in unincorporated residential, commercial and industrial areas. Ecology's guidance shall ensure that all appropriate areas are included in these programs.

All programs and ordinances developed under this subelement shall be consistent with the plan guidance and model ordinances developed under elements SW-3 and SW-4. Each city and county shall adopt ordinances consistent with

4 Ecology shall define re-development in the technical manual.

VOL 12 2 3394

R0056689

the model ordinances (element SW-4) requiring stormwater controls for new development and redevelopment and requiring and enforcing maintenance of privately owned stormwater systems.

1.3. Technical Manuals

In conjunction with the runoff control ordinances for new development and redevelopment, each jurisdiction shall adopt a stormwater management manual containing best management practices. A local government may adopt the manual prepared by Ecology under element SW-3 or prepare its own manual as long as it has substantially equivalent technical standards to those in Ecology's manual. Ecology shall review alternative manuals of local governments for substantial consistency with the Plan and Ecology's manual and guidance.

When Ecology updates its manual, local governments must, within one year of receipt, make any appropriate changes to their manuals.

1.4. Education Programs

Basic stormwater programs should include education programs to inform citizens and businesses about storm water and its effects on water quality, flooding, and fish/wildlife habitat, and to discourage dumping of waste material or pollutants into storm drains. When possible, these program should coordinate with the Education and Public Involvement Program the Household Hazardous Waste Program and the Nonpoint Source Pollution Program. Compliance and monitoring "report cards" (subelements SW-1.1 and SW-3.1.2) should be used to publicize progress in controlling storm water.

1.5. Growth Management Planning and Interlocal Coordination

Each city or county which adopts a comprehensive land use plan and development regulations under the provisions of Chapter 36.70A RCW (the Growth Management Act) shall incorporate its local stormwater program into the its comprehensive plan and shall incorporate the ordinances required by this program into its development regulations. Accordingly, cities and counties shall also incorporate and implement the provisions of the stormwater program through: ordinances to protect critical areas, capital facilities plans, concurrency strategies, watershed action plans, drainage or basin plans, urban bay action tasks, the State Environmental Policy Act (SEPA) reviews, environmental priorities, or utilities. Any utilities which are developed should be designed to address a broad spectrum of stormwater- and nonpoint source pollution-related water quality problems.

Consistent with the Growth Management Act and RCW 90.70, and in keeping with the intent of Chapter 39.34 (the Interlocal Cooperation Act), each local jurisdiction in the Puget Sound basin shall cooperate with neighboring jurisdictions in stormwater, growth management, and basin or watershed planning. Jurisdictions sharing common watersheds should cooperate in analyzing the effects and control of stormwater runoff and adopt coordinated and compatible programs for stormwater management. This coordination should also achieve the most efficient and effective protection of fish, shellfish, aquatic habitat, wetlands, and other aquatic resources within their shared watersheds.

VOL 12 2 3395

R0056690

In setting priorities for stormwater control, cities and counties should consider the list of critical watersheds prepared by the Department of Fish and Wildlife (WDFW) under subelement SW-7.2 as well as information from approved, watershed action plans, basin plans, and urban bay action plans. Based on these priorities, cities and counties should identify sensitive areas that may need even stronger stormwater controls.

Ecology, the Authority, and the Department of Community, Trade and Economic Development (DCTED) shall provide local governments with technical assistance on managing stormwater runoff during the growth management planning required under the Growth Management Act.

1.6. Compliance Monitoring

Ecology shall monitor compliance with these requirements, reviewing the status of city and county basic stormwater programs every two years to ensure consistent and adequate implementation and report to the Authority. When Ecology finds that a local program is not in compliance with these requirements, Ecology is encouraged to provide technical suggestions to improve implementation and to allow maximum flexibility and creativity for local governments to resolve site-specific stormwater problems in accordance with their land-use and other local policies.

1.7. Enforcement

If local governments fail to prepare and implement the required programs under this element, the Authority shall follow procedures in RCW 90.70 and request written explanations for the shortfalls, together with their proposed remedies. After monitoring compliance under subelement SW-1.6, Ecology may take enforcement actions against stormwater discharge violations under RCW 90.48 (the State Clean Water Act) or by issuing NPDES discharge permits (see subelement SW-2.3).

Target Date: All cities and counties shall incorporate the Puget Sound Plan's stormwater considerations into critical areas ordinances, countywide policies, comprehensive plans and implementation regulations; adopt ordinances and stormwater manuals, and comply with the basic stormwater program requirements by January 1, 1995. By the same date, cities and counties with ordinances and operation and maintenance programs predating Ecology guidance under element SW-4 shall bring their ordinances and programs into compliance with provisions of this element. By May 1, 1997, Ecology shall complete the first round of biennial reviews.

SW-2. Comprehensive, Urban[5] Stormwater Programs

Starting with the larger cities in the basin that are named in the EPA stormwater NPDES regulation and eventually expanding to cover all urbanized areas, each city and unincorporated urbanized area shall develop and implement a stormwater management program consistent with the requirements of elements SW-1 and SW-2, guidance under element SW-4, and appropriate

5 Urbanized areas are as defined by the United States Bureau of the Census. Counties are responsible for the comprehensive, urban stormwater programs (element SW-2) in unincorporated urbanized areas. Ecology shall ensure that all appropriate areas are included in these programs.

VOL 12 2 3396

R0056691

stormwater NPDES regulations. This program shall not affect the Ecology's authority to require appropriate corrective action (pursuant to Chapter 90.48 RCW) whenever existing facilities cause or contribute to violations of state water quality standards. The local government stormwater program shall be submitted to Ecology for review for consistency with the Plan and compliance with stormwater NPDES regulations. Ecology shall provide appropriate assistance to correct local program deficiencies. Ecology shall schedule the development of stormwater management programs by the remaining cities and counties.

The pollution control strategy for achieving the program's goal is to implement the most appropriate best management practices first, assess their effectiveness, and, as necessary, require further water quality controls.

2.1. Purposes of the Urban Stormwater Program

The purposes of the comprehensive programs for managing storm water in urban areas shall be:

1. To control erosion and manage the quantity and quality of stormwater runoff from public and private activities and to protect stream channels, aquatic habitat, wetlands, fish, shellfish, and other aquatic resources.

2. To protect and enhance water quality, and achieve water quality and sediment quality standards.

3. To reduce the discharge of pollutants and eliminate harm to the environment.

4. To protect beneficial uses, as described in Washington state's water quality standards, 173-201 WAC.

5. To achieve purposes 1 through 4 in a manner that makes efficient use of limited resources to address the most critical problems first.

2.2. Scheduling

Ecology shall use the following ranking criteria to schedule development of additional stormwater programs for urbanized areas:

1. Population size.

2. Rate of growth, in absolute numbers.

3. NPDES regulations developed by the U.S. EPA for storm water.

4. Water quality and quantity considerations, including but not limited to, sediment quality, beneficial uses of clean water, shellfish protection, priorities identified by watershed action plans developed pursuant to WAC 400-12 and other watershed planning programs, groundwater management areas, aquifer protection areas, sensitive areas for fish, shellfish, and other aquatic resources, wetlands, or flooding (see subelement SW 7.2).

R0056692

Ecology shall notify affected jurisdictions at least one year prior to the scheduled start date. Comprehensive programs for managing storm water in urbanized areas shall be completed and fully implemented within five years after notification by Ecology to proceed.

2.3. Coordination with Stormwater NPDES Permits

Starting with the Puget Sound areas designated under the EPA's NPDES Permit Application Regulation for Storm Water Discharges (40 CFR Parts 122, 123 and 124), Ecology shall review permit applications and write watershed-based permits for urbanized areas of Puget Sound that are consistent with these regulations and the requirements of elements SW-1 and SW-2. Permits will be issued using procedures identified in the state's permit writers manual (see element P-5). Additional permits shall be written and phased in as EPA issues additional stormwater regulations under NPDES.

Ecology will assess the federal regulations and the requirements of the Plan and determine whether the state's NPDES rule should be amended or a new rule written to implement these requirements.

When EPA promulgates stormwater regulations for smaller jurisdictions, Ecology shall write NPDES permits for these jurisdictions consistent with the state's permit writers manual, federal regulations, and element SW-1 and SW-2 requirements.

Ecology shall write permits for stormwater discharges associated with industrial activities, including land-disturbing activities of five acres or more, according to requirements of the EPA's NPDES regulation for storm water. These permits shall be consistent with procedures under Ecology's state permit writers manual (see P-5).

2.4. Program Requirements

Each urban stormwater program shall seek to control the quality and quantity of runoff from public facilities and industrial, commercial and residential areas, including streets and roads, consistent with manuals and guidance provided by Ecology under elements SW-3 and SW-4. Where local programs are not effectively solving stormwater problems, Ecology shall ensure compliance with elements SW-1 and SW-2 through its oversight role or through issuance and enforcement of individual or watershed-based NPDES permits.

Ecology shall coordinate development of its stormwater program with other state programs and activities affecting storm water, i.e., the Coastal Nonpoint Pollution Control Program, wetlands protection, floodplain management, nonpoint source pollution programs, underground injection control, growth management planning, and the sediment management-standards program.

Each city or urban area shall have the flexibility to design its own program, but the content, priorities and deadlines for compliance with the program shall be subject to review by Ecology for consistency with provisions of the Plan and the NPDES regulations.

In addition to the provisions of element SW-1, each urban stormwater program shall, at a minimum, include:

VOL 12 2 3398

R0056693

a. Identification and ranking of significant pollutant sources and their relationship to the drainage system and water bodies through an ongoing assessment program.

b. Investigations and corrective actions of problem storm drains, including sampling.[6]

c. Programs for operation and maintenance of storm drains, detention systems, ditches and culverts.

d. A water quality response program, to investigate sources of pollutants, and respond to citizen complaints or emergencies such as spills, fish kills, illegal hookups, dumping, and other water quality problems. These investigations should be used to support compliance and enforcement efforts.

e. Assurance of adequate local funding for the stormwater program through surface-water utilities, sewer charges, fees or other revenue-generating sources.

f. Local coordination arrangements within watersheds, such as interlocal agreements, joint programs, consistent standards, or regional boards or committees to address the requirements of subelement SW-1.5.

g. Ordinances requiring implementation of stormwater controls for new development and redevelopment as defined by elements SW-3 and SW-4.

h. A program aimed at educating residents, businesses and industries in the urban area about storm water.

i. Inspection, compliance and enforcement measures.[7]

j. An implementation schedule.

k. If, after implementation of the control measures listed in a-j, there are still discharges that cause significant environmental problems, retrofitting of existing development and/or other water quality controls of discharges from new and existing development may be required.

The quality of storm water in public stormwater systems in commercial and industrial areas shall have a high priority in city and county programs. Ecology shall determine, in compliance with EPA regulations and in consultation with local governments, the appropriate approach to controlling stormwater discharges from industrial and commercial facilities that are not currently required to have stormwater NPDES or point-source discharge permits.

Jurisdictions which annex an area from another jurisdiction shall manage stormwater runoff consistent with the standards designated for the area prior to the annexation. Any new development or retrofitting of existing systems shall

6 The Elliott Bay Revised Action Program: Storm Drain Monitoring Approach, March 1988, Tetra Tech, for EPA Region 10 presents an approach particularly suited to industrial areas.

7 Local governments may request Ecology's assistance with enforcement measures.

VOL 12 2 3399

R0056694

meet the most stringent standards. Areas that incorporate shall adopt standards at least as strict as those in place prior to incorporation.

Target Dates: Schedules for stormwater NPDES permits are established by the EPA. By the year 2000, all urbanized areas in the Puget Sound basin identified by Ecology shall implement urban stormwater programs. Ecology shall review and track the ordinances, manuals and other program requirements for each city or county program for substantial progress toward implementation of the elements listed above within two years of its initiation and report to the Authority every two years.

SW-3. Technical Manuals and Assistance on Stormwater and Erosion Controls

3.1. Technical Manual

Ecology shall maintain a technical manual that implements the requirements in elements SW-1 and SW-2 for use by local jurisdictions in stormwater planning. In updating this manual Ecology shall use existing information where possible. The technical manual shall also incorporate the requirements of the Coastal Nonpoint Pollution Control Program and shall provide technical guidance and define minimum requirements for implementing local programs (elements SW-1 and SW-2). The technical manual shall include, but is not limited to:

a. Best management practices for controlling erosion and sedimentation from construction sites, including guidance for operation, maintenance and inspection procedures.

b. Procedures for hydrologic analysis, including selection of design storms and estimates of runoff.

c. Design, operation and maintenance standards for public and private retention/detention facilities and conveyance systems. Emphasis shall be placed on systems that will maximize water quality benefits as well as water quantity control, such as the inclusion of biofiltration techniques where practicable.

d. Techniques for reducing or eliminating pollutants in runoff from problem land uses.

The manual should encourage the use of innovative technologies which have been adequately tested. The manual shall be closely coordinated with the guidance and model ordinances for stormwater programs (element SW-4). Ecology shall review the manual and revise it as needed. Ecology is encouraged to publish supplemental guidelines relating to new technologies for managing storm water when new information becomes available between manual revisions. Ecology shall promptly notify local jurisdictions of changes

R0056695

VOL 12 2 3400

to the manual and shall provide technical assistance on its contents to local jurisdictions, citizens and businesses.

Updates of the manual shall incorporate performance standards (percentage of pollutant removal) for best management practices for stormwater runoff and information on the effectiveness of BMPs. The performance standards are intended to promote the most effective stormwater controls through selection, design, operation and maintenance. The failure of a best management practice to meet its performance standards may indicate the need for additional controls, but should not be considered a water quality violation.

Ecology shall establish a review board or use appropriate existing groups composed of representatives from interested and affected entities to review innovative BMPs, and to provide feedback on the manual, its revisions and its implementation.

3.1.1. Vactor Waste

Ecology shall incorporate into the manual a workable, coordinated program for stormwater maintenance (vactor) waste disposal for local governments, the Washington State Department of Transportation (WSDOT), private contractors and others. Ecology shall include reasonable, affordable disposal options for jurisdictions in both sewered and unsewered areas. The program should address testing, classification, disposal and reuse of decant water and solids from stormwater systems in sewered and unsewered areas. Ecology shall seek to resolve any conflicting regulations. The vactor waste program shall be developed in consultation with state, local and tribal governments, and contractors. Local governments shall implement Ecology's guidance on vactor-waste disposal procedures. Ecology shall provide technical and financial assistance to local governments for the handling and disposal of vactor wastes.

3.1.2. Monitoring Guidance

Ecology shall incorporate guidance into the manual on how to monitor stormwater runoff compliance and the effectiveness of best management practices. Ecology shall provide technical assistance to local governments and private industry. The guidance shall be developed using EPA and other related guidelines in cooperation with local governments and private industry. Monitoring guidance should be coordinated with NPDES requirements and be targeted to respond to specific local concerns about water quality and to minimize administrative burdens and costs. When appropriate, the guidance shall include protocols that are consistent with the Puget Sound Ambient Monitoring Program (PSAMP) and related data entry methods. The guidance should include recommendations on publicizing the resulting information, including the use of watershed "report cards" (subelement WP-7.2).

Local governments are encouraged to submit stormwater monitoring results and data on the effectiveness of best management practices to Ecology and the University of Washington Center for Urban Water Resources.

VOL 12 2 3401

R0056696

3.1.3. Stormwater Manual Concurrence and Regulatory Streamlining

To ensure state coordination and to simplify requirements, Ecology shall submit drafts of the manual for review and approval to the departments of Fish and Wildlife, Health, and Natural Resources. This review and approval is to ensure that the manual is adequate to protect fish and shellfish habitats, wetlands, and other aquatic habitats and resources and to prevent sediment contamination from stormwater runoff.

After consulting with interest groups, and other agencies, Ecology shall include in the manual, guidance to state and local stormwater permitting agencies, on how to coordinate stormwater permits. The guidance shall minimize overlapping or differing requirements for industrial and municipal NPDES permits, Hydraulics Project Approval permits (HPAs), aquatic land-use authorizations, and local permits. Ecology, the Authority, and the Department of Community, Trade and Economic Development (DCTED) shall also develop guidance to encourage coordinated requirements within a shared watershed, as outlined in subelement SW 1.5. Local governments and other permitting agencies shall make every effort to follow this guidance and defer to other agencies' permits when those permits already provide adequate stormwater controls.

3.2. Stormwater Assistance Service for Local Governments

Ecology shall develop a technical assistance service for storm water. The service should assist local governments, tribes and private industry with: (1) the design and implementation of stormwater programs at the local level; (2) current best management practices for storm water; (3) local basin characteristics; (4) coordination with local government growth management planning activities; (5) vactor waste handling; and (6) habitat protection. The service should be staffed with people who have up-to-date, hands-on experience.

The Authority, Ecology, the Department of Fish and Wildlife, and other agencies, as appropriate, shall offer briefings to elected officials, citizens and other interested and affected groups on the effects of stormwater runoff on stream channels, wetlands, fish and other aquatic habitats and resources.

Ecology, in consultation with local governments, the Association of Washington Cities, the Washington State Association of Counties, the Center for Urban Resources Management, the County Road Engineers Group, and other interested parties, shall develop curricula to train local government and Ecology staff. Training shall include an explanation of state requirements, development and implementation of local programs, and use of the state technical manual. Ecology shall provide the curricula to interested public and private schools.

3.3. NPDES Coordination

Ecology shall provide technical assistance to local governments that are required to obtain stormwater NPDES permits, and to WSDOT and industrial stormwater permittees. Technical assistance shall cover coordination of federal stormwater requirements, the Plan's Stormwater and Combined Sewer Overflows Program, and Ecology's watershed permits for storm water, as well as coordination with other related programs such as HPA permits, the Coastal Nonpoint Pollution Control Program, and locally developed watershed action plans.

R0056697

VOL 12 2 3402

Ecology is encouraged not to require stormwater permits for Puget Sound cities or counties unless the following apply: (1) they are subject to the element SW-2 program; (2) a specific water quality problem related to stormwater runoff is identified; or (3) federal laws or regulations require a permit. Ecology shall give each city or county adequate notice of its intent to require a permit. Where Ecology chooses to include more than one local government in a watershed-based permit, it should give the affected local governments a reasonable time to negotiate interlocal agreements.

Target Dates: Ecology completed the first stormwater manual in June 1992 and shall regularly update the manual as necessary. The Vactor Waste Program shall be established by June 30, 1995. Technical assistance is ongoing.

SW-4. Guidance and Model Ordinances for SW-1 and SW-2

Ecology shall review and update guidance and model ordinances for the basic stormwater programs for all cities and counties (element SW-1) and for comprehensive urban stormwater programs (element SW-2) consistent with the Plan.

Ecology shall consult with cities, counties, the Association of Washington Cities, the Washington State Association of Counties, the Municipal Government Research Center, developers, citizens' groups, and other interested parties when it updates the guidance and model ordinances. The guidance shall provide minimum program requirements and shall be consistent with NPDES requirements. Ecology shall develop, as appropriate, additional supplemental guidance for stormwater programs to remain consistent with applicable NPDES requirements. The model ordinances shall be developed with local government assistance and shall be accompanied by useful methods and examples which will assist local governments in adopting these minimum requirements into their regulations. Ecology shall also provide technical assistance to local jurisdictions (element SW-3) during preparation and implementation of their stormwater programs.

Ecology's Water Quality Financial Assistance Program shall ensure that stormwater-related projects are awarded state grants only if they are consistent with the goals of this program and include design elements that implement best management practices consistent with Ecology guidance. The Authority encourages Ecology to offer financial assistance to projects that meet these criteria.

4.1. Guidance for SW-1 and SW-2

The guidance for elements SW-1 and SW-2 shall include:

a. Procedures for developing local programs, including procedures for review of programs and manuals.

b. Minimum requirements for runoff controls and system maintenance required in local ordinances.

c. Minimum requirements for control of private sector maintenance of private drainage systems.

VOL 12 2 3403

R0056698

d. Minimum requirements for the operation and maintenance programs, including record-keeping for new drainage systems and facilities, and handling of vactor waste.

e. Methods to assure practical and appropriate disposal procedures for decant water, solids and other substances from cleaning out and maintaining drainage systems. Methods shall address catch basins, oil/water separators, pipelines, swales, detention/retention basins, and other related drainage elements.

Additionally, the guidance for the comprehensive, urban stormwater programs (element SW-2) shall include:

f. Procedures for identifying and ranking significant pollutant sources and their relationship to the drainage system and water bodies.

g. Procedures for source-tracing investigations, including sampling of problem storm drains.

h. Procedures for investigations, implementing spill control measures, enforcement, and remedial actions.

i. Methods to assure adequate local funding for the urban stormwater program.

j. Provisions for agreements with neighboring jurisdictions when storm water and watersheds do not follow jurisdictional boundaries.

k. Requirements for public education programs.

l. Requirements for retrofitting and/or treatment measures, if necessary.

m. Procedures for inspection, compliance and enforcement measures.

n. Requirements for implementation schedules.

o. Methods to coordinate stormwater management with other watershed, habitat protection, and growth management activities.

The guidance shall lay out approaches to control storm water from new development and redevelopment, such as water quality policies for use in SEPA, NPDES and other permit decisions; density controls to limit development in sensitive areas; development standards to limit the amount of impervious surfaces; regional detention ponds; oil separators or other treatment facilities; grading and drainage ordinances; erosion control programs; buffers next to waterways; preservation of wetlands; and other appropriate elements.

In the guidance for elements SW-1 and SW-2, Ecology shall address the issue of responsibility and procedures for dealing with direct discharges of storm water from industrial and commercial facilities into the waters of the state.

VOL 12 2 3404

R0056699

4.2. Model Ordinances

The model ordinances for elements SW-1 and SW-2 should describe how local governments can meet or exceed the minimum requirements and shall include at least the following elements:

1. A drainage element which: (a) sets policy; (b) defines the role of surface-water management; (c) defines water quality criteria and standards; (d) provides local enforcement authority; (e) provides for inspection and maintenance of private drainage facilities; (f) authorizes administrative development of operation and maintenance standards, development standards, and spill response procedures; and (g) generally integrates the management of surface waters with other appropriate codes affecting water quality (i.e., the Uniform Fire Code, public health codes, and land-use codes).

2. A clearing and grading element which defines authority to control erosion and provides for inspection and enforcement.

3. An element which ensures protection of streams and wetlands.

Target Date: Ecology has completed the guidance and model ordinances. Regular updates are required as necessary.

SW-5. Puget Sound Highway Runoff (WSDOT)

The Washington State Department of Transportation (WSDOT) shall carry out a program to control runoff from freeways and highways in the Puget Sound basin. This program shall continue to be consistent with Ecology's Puget Sound Highway Runoff Rule (Chapter 173-270 WAC) as described below.

Ecology shall maintain the rule for the Puget Sound Highway Runoff Program and shall continue to coordinate with the WSDOT in its development of a runoff program. Ecology shall provide technical assistance to the WSDOT and local jurisdictions during development and implementation of this program.

Any revisions to this rule shall maintain requirements for:

a. Controlling and/or treating runoff from highways in the Puget Sound basin.

b. Implementing best management practices (BMPs) and/or treatment facilities for new construction.

c. Using BMPs that address the control of water quality and quantity using pesticides in highway rights-of-way, and using de-icing chemicals.

d. Complying with Ecology and local stormwater programs. Ecology shall seek to provide consistent requirements for the highway program in different jurisdictions.

e. Phasing in the runoff program. A priority ranking system will be developed in consultation with Ecology and local and tribal governments for retrofitting water quality BMPs so they factor in vehicle use and site-specific constraints of implementing best management practices. Additional criteria

R0056700

VOL 12 2 3405

may be considered. Opportunities for public involvement in the process shall be provided.

f. WSDOT funding of construction and operation and maintenance of local or private stormwater systems receiving highway runoff. Such funding shall be in accordance with RCW 90.03.525, which governs financial contributions from state highway rights-of-way to stormwater facilities. The WSDOT is encouraged to negotiate its appropriate share of specific or private stormwater facilities receiving highway runoff, as allowed for in RCW 90.03.525.

g. Determining site-specific constraints in implementing best management practices and/or treatment measures for existing highways.

h. An implementation schedule.

Ecology shall, consistent with federal stormwater regulations, write a general Puget Sound basinwide permit for the WSDOT highway system to implement the requirements of the Puget Sound Highway Runoff Rule.

Ecology shall evaluate the WSDOT's existing operation and maintenance programs to ensure that measures are taken by the WSDOT to implement high-priority measures first.

Target Date: Puget Sound Highway Runoff Rule (Chapter 173-270 WAC) was completed June 21, 1991. Implementation is ongoing.

SW-6. Runoff from Federal Facilities

As part of the state certification process under Section 401 of the federal Clean Water Act, Ecology shall require that all NPDES permits for federal facilities, including military bases, written by the EPA contain stormwater controls that: (1) are at least as stringent as those required for industrial facilities in Municipal and Industrial Discharges Program (element P-5), including all toxicant and particulate limits and requirements for monitoring, spill control and public notice; and (2) are consistent with the wetlands protection policies under the Plan. The EPA shall review existing EPA-issued permits and modify any permit as necessary to include such limits and requirements. (See Municipal and Industrial Discharges Program elements P-5 through P-11.) Before considering a Clean Water Act Section 401 certification for a federal facility permit, Ecology shall seek to be familiar with the facility site through joint site visits or inspections with the EPA or through other means (for discharges of waste water from federal facilities, see Municipal and Industrial Discharges Program, element P-11).

Target Date: Ongoing as federal permits are prepared.

SW-7. Stormwater-Related Research and Sensitive Areas

Ecology shall conduct a comprehensive search of the literature to identify and rank stormwater research needs, in collaboration with the Research Program (see element R-1), and report the results.

VOL 12 2 3406

R0056701

7.1. Stormwater-Wetlands Research

Using the expertise of state universities and local governments as appropriate, Ecology, in coordination with the wetlands inventory element, shall continue to fund and participate in research on short- and long-term effects of stormwater quality and quantity on wetland values and functions. Ecology shall cooperate with state and local agencies that are participating in the Puget Sound Wetlands and Stormwater Management Research Program developed by King County, and in the Urban Water Resources Management Program. Ecology shall encourage a research program designed to obtain the data necessary to develop and support policy and regulatory decisions regarding water quality and the management of stormwater discharges entering wetlands that are consistent with wetlands protection policies in the Plan. Results from this research shall be integrated in the updates of the technical manual (element SW-3) and the model ordinances (element SW-4).

7.2. Stormwater-Related Habitat Damage and Sensitive Areas

The Department of Fish and Wildlife, in consultation with the departments of Health and Natural Resources, local governments, and tribes, shall periodically prepare a listing of habitats of fish, shellfish and other aquatic resources that have been damaged by stormwater runoff and combined sewer overflows, and shall identify the most sensitive areas for stormwater and CSO controls. Where possible, sensitive areas should be identified by stream segment. The Department of Fish and Wildlife shall provide this information to the Authority, Ecology and local governments.

7.3. Stormwater, Wetlands, Fisheries, Growth Policy Assessment

In consultation with the EPA, the state departments of Ecology, Transportation, Fish and Wildlife, Natural Resources and Community, Trade & Economic Development, and local and tribal governments the Authority shall promote the development of policies to resolve conflicts regarding competing stormwater management, wetlands protection, and fishery protection program mandates.

Target Date: Ecology's participation in the wetlands research project is ongoing. The Department of Fish and Wildlife shall provide the first listing of sensitive areas by June 30, 1995, and update it as frequently as necessary.

SW-8. CSO Reduction Guidelines

The goal of the guidelines for reducing CSOs shall remain to achieve the greatest reasonable reduction of pollutants from both storm water and sanitary sewage in CSOs. If local governments choose stormwater separation as a CSO reduction technique, best management practices, including a pollution source-control program, shall be required and the effects of storm water on receiving waters shall be monitored by the municipality as required by Ecology. Ecology shall also update the guidelines as necessary and provide technical assistance to local governments implementing the guidelines (element SW-9).

SW-9. CSO Reduction Plans by Cities (or Sewer Districts)

As required by the state Clean Water Act (RCW 90.48.480), each city, sewer jurisdiction or other entity with CSOs[8] shall carry out its plan to achieve

8 Deadline set by current state law. All CSO deadlines in this program are based upon the need to comply with current state law requiring CSO reductions. Cities known to have CSOs, and therefore affected by this requirement, are Seattle (and Metro), Anacortes, Bellingham, Bremerton, Everett, Mount Vernon, Olympia, Port Angeles and Snohomish.

R0056702

VOL 12 2 3407

greatest reasonable reduction of CSOs consistent with Ecology guidelines. The plans should include priority ranking of CSOs, implementation schedules, and provisions for funding the corrections. Ecology will continue to review the plans, develop compliance schedules and modify NPDES permits.

Target Dates: The controls are to be implemented according to a compliance schedule negotiated between Ecology and each jurisdiction. Ecology will ensure compliance as necessary.

MAJOR PUBLIC ACTIONS FOR AUTHORITY REVIEW

1. Ecology guidance for urban stormwater programs (element SW-4).

2. Ecology's model ordinances and guidance (element SW-4) and technical manual (element SW-3).

3. Program for Puget Sound highway runoff (element SW-5).

4. Compliance with the Stormwater and Combined Sewer Overflows Program by local governments, tribes, businesses, industries and federal facilities.

5. Listings of sensitive areas and damaged habitats under subelement SW-7.2.

LEGISLATION REQUIRED

None.

ESTIMATED COSTS

The incremental cost beyond other Clean Water Act requirements of fully implementing the Stormwater and Combined Sewer Overflows (CSOs) Program is estimated to be $90.8 million during the 1995-97 Biennium and $130.8 million during the 1997-99 Biennium. This makes it the most expensive program in the Plan. It should be noted that local governments, industry and business have already made substantial investments to address their stormwater problems. The costs are greatest for elements SW-1, Basic Program and Ordinances, SW-2, Urban Stormwater Management Program, and SW-5, the Puget Sound Highway Runoff Program. Most of these costs are borne by local governments and the state department of transportation.

Although some of the local costs may be supported by the Centennial Clean Water Fund, the bulk of the costs are expected to be funded through the formation of local drainage or utility districts. Comprehensive control of storm water from non-NPDES permitted industrial or commercial facilities is a potentially expensive task, not currently included in cost estimates for the stormwater or municipal and industrial discharges programs. Some additional costs would be borne by private industry and developers ranging from a few thousand dollars for simple erosion and source controls to hundreds of thousands of dollars for stormwater detention and treatment systems.

CSOs

The CSO control programs are expensive. Metro, Seattle and Everett estimated the costs of eliminating their CSOs. Total costs for these cities to control

VOL 12 2 3408

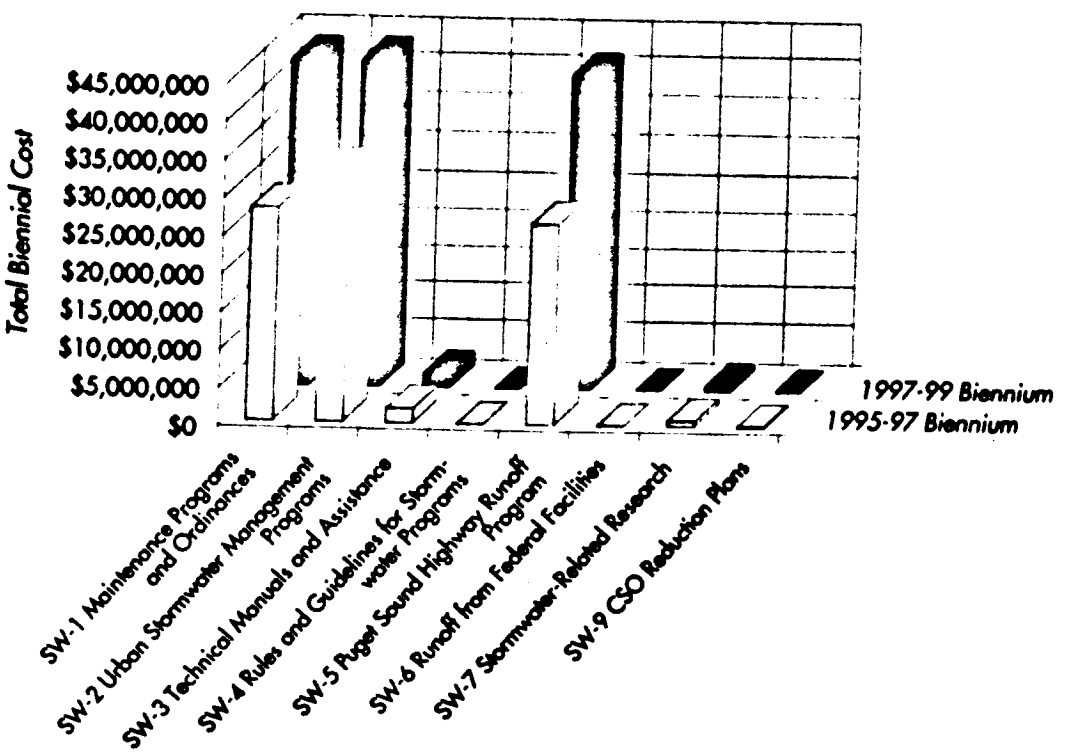
R0056703

CSOs to the ultimate goal of one overflow per year would be approximately $425 million, of which $289.5 million would be for Metro. Ecology estimated the cost of eliminating CSOs in other cities at $230 million. These costs are a result of existing legal requirements; this Plan does not impose new requirements on CSOs.

Growth Management and NPDES

Many of the costs associated with the Stormwater and Combined Sewer Overflows Program are also called for in growth management planning requirements and under the stormwater NPDES permit program. Both of these factors have resulted in more jurisdictions using Ecology stormwater guidance to comply with the Puget Sound Plan stormwater requirements.

Stormwater and CSOs Program Implementation Estimates



R0056704

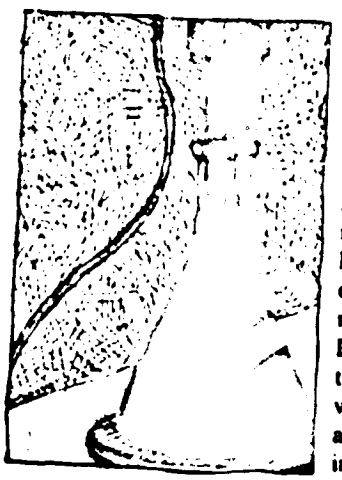
VOL 12 2 3409

LABORATORY SUPPORT PROGRAM

PROGRAM ELEMENT DIRECTORY

L-1. Laboratory Certification Program 234
L-2. Laboratory Capacity 234
L-3. Puget Sound Estuary Program Protocols and Guidelines 235
L-4. Quality Assurance/Quality Control 236

PROBLEM DEFINITION



Many of the programs in the Puget Sound Water Quality Management Plan (Plan), such as Monitoring and Shellfish Protection, depend on accurate and timely laboratory analyses. Laboratories provide information on the presence, concentrations and effects of contaminants in Puget Sound. Lab information is needed to design programs that remedy the effects of contaminants and prevent or limit future contamination.

Many lab analyses are conducted pursuant to federal, state or local laws designed to prevent water quality degradation and threats to human health. For example, the federal Clean Water Act requires routine monitoring of municipal and industrial wastewater discharges. The state Department of Ecology (Ecology) and the U.S. Environmental Protection Agency (EPA) rely on lab results to assess compliance with the law and specific permit requirements, and to determine whether enforcement action is necessary. The state Department of Health (DOH) relies on results of water quality and shellfish tissue analyses to determine whether levels of fecal coliform bacteria are within specific levels designed to protect human health. Laboratory analyses also are conducted for routine ambient monitoring to establish trends and for investigations associated with specific research projects.

Standardized protocols (procedures) for collecting and analyzing many types of environmental samples within Puget Sound exist, but their use is not uniform. The Puget Sound Estuary Program Protocols and Guidelines (PSEP Protocols and Guidelines) were developed to standardize sample collection and analysis within the Sound so that data may be compared and long-term environmental trends determined. Although many agencies increasingly are using the protocols and guidelines, data are still collected that are not comparable.

Standardized, clearly defined quality assurance and quality control (QA/QC) procedures are necessary for many types of analyses. However, when they exist, there is no method for determining the extent to which they are followed, or whether the procedures are uniformly applied across different programs and among different agencies. Consequently, lab results may come into question and may not be helpful.

Analyses of environmental samples within Ecology are performed or contracted by Ecology's environmental laboratory at Manchester. Improvements have been made in sample tracking, management systems, turnaround time, information flow and training of lab users and personnel at the laboratory. However, additional improvements are needed in areas such as predicting how many employees are needed. Samples exceeding laboratory capacity are sent to private (and sometimes public) laboratories for analysis.

VOL 12 2 3410
R0056705

AUTHORITY'S APPROACH

The 1987 Plan called for developing a laboratory certification program to certify the accuracy of laboratory sample collections, and laboratory support for agency sampling programs. A laboratory certification plan would be developed to certify labs in a phased manner.

Revisions to the Plan in 1989 and 1991 directed the Authority, with EPA and Ecology, to develop Puget Sound protocols to assure quality and consistency in handling samples. In addition, Ecology was directed to develop a QA/QC plan and program for sampling and analyses and establish a QA/QC work group to provide continuing oversight.

PROGRAM GOAL

To assure the quality and timeliness of physical, chemical and biological laboratory tests necessary to support the protection and enhancement of the waters of Puget Sound.

PROGRAM STRATEGY

The strategy for achieving this goal is to: (1) establish a laboratory certification program administered by Ecology that will review the capability of environmental laboratories to generate data of known quality; (2) assure that adequate laboratory support exists for agency and other sampling programs; (3) develop and update protocols and guidelines to standardize data collection, analysis and transfer within Puget Sound, and to encourage their use uniformly for all data collected in Puget Sound; and (4) develop and encourage the use of uniform quality assurance guidelines for data collected under all Puget Sound programs.

PROGRAM ELEMENTS

L-1. Laboratory Certification Program

[Completed portions of this element have been deleted.]

Ecology shall continue to implement a laboratory certification (also referred to as "accreditation") program. As a part of the certification program Ecology shall adopt rules requiring all certified laboratories to use approved field and laboratory protocols and to comply with specified quality assurance and quality control procedures. Ecology shall inform all certified labs that the use of adopted PSEP Protocols and Guidelines (element L-3) is required for many Puget Sound plan programs. Ecology shall implement the PSEP Protocols and Guidelines in the Ecology laboratory at Manchester.

Target Dates: Ecology is to continue its ongoing efforts to carry out the lab accreditation program.

L-2. Laboratory Capacity

Ecology shall prepare a biennial laboratory plan that addresses the short- and long-term needs, capacity, and data management of Ecology and other state agencies and of local and tribal governments, and make recommendations regarding means to rectify shortfalls in the ability of the labs to support agency programs. The plan shall: identify target turnaround times and specify accept-

R0056706

VOL 12 2 3 4 11 11

able holding times[1] for analyses; assess available means to assure that all samples are analyzed within those times while meeting the highest possible quality standards; describe sample tracking and data management systems; include a consideration of the need for additional staff, including night shifts, to fully utilize existing agency lab equipment and facilities; and fully explore the use of lab capacity possessed by other agencies and the use of contract labs before recommending establishment of new lab facilities.

Ecology shall biennially submit to the Authority an updated laboratory plan that includes: (1) a revised estimate of the number and types of analyses needed to support Ecology programs, (2) a review of the services provided by Ecology laboratories including holding and sample turnaround times, data quality and data management during the preceding two years; and (3) an updated analysis of the additional laboratory capacity needed to carry out these analyses within the target turnaround times which Ecology shall specify.

In preparing the laboratory plan, Ecology shall consult with other state agencies, including the departments of Health, Agriculture, and Labor and Industries, and tribal and local governments to incorporate their laboratory needs and capabilities related to the Puget Sound Plan in the reports.

Target Dates: Ecology to submit biennial updates to the laboratory plan.

L-3. Puget Sound Estuary Program Protocols and Guidelines

Ecology, in consultation with the EPA and the Authority, shall develop and implement a process for the review and adoption of PSEP Protocols and Guidelines (element L-1). The process shall provide for development of new protocols and guidelines, for review and revision of existing protocols and guidelines, for assignments to agencies with expertise, and for formal adoption of the protocols and guidelines.

The development and review of the protocols and guidelines shall be assigned to agencies and organizations with technical expertise in fields relevant to the individual protocols and guidelines. The technical experts shall prepare recommendations which shall undergo extensive peer review. Experts from federal and state agencies, local and tribal governments, the private sector, the academic community, and the public shall review protocol development and revisions. In addition, the review group shall outline QA/QC needs for the use of each updated protocol. Ecology shall recommend the PSEP Protocols and Guidelines to the Puget Sound Estuary Program Management Committee for adoption.

New protocols and guidelines shall be developed and existing protocols and guidelines revised as needed and reviewed biennially.

Target Dates: Ecology shall ensure that the existing Puget Sound Estuary Management Protocols and Guidelines are reviewed and revised by July 1995.

1 Turnaround time is the time between submittal of sample to laboratory and receipt of results (after quality assurance) by the requester.

R0056707

VOL 12 2 3412

L-4. Quality Assurance/Quality Control

Ecology has prepared a Quality Assurance Management Plan that addresses quality assurance and quality control issues related to the collection of environmental data in support of Ecology programs and projects. The plan shall be used to ensure uniform quality assurance practices are incorporated into all of Ecology's activities to develop data. Implementation of the plan should include requirements for (1) QA project plans; (2) training in, and technical assistance with, QA/QC principles and practices; and (3) QA audits of selected projects. Ecology QA project plans shall require the use of PSEP Protocols and Guidelines and of data qualifiers and formats for data transfer specified in element M-4 where appropriate.

The QA/QC program shall include the following:

- Establishment of guidelines for the preparation of quality assurance project plans as required by the state/EPA agreement.[2] The guidelines shall include establishment of specific objectives and development of sampling and analysis plans commensurate with objectives for major surveys.
- Audits of data quality (based on selected QA project plans), including checks that sampling and analytical procedures have been correctly performed, and reviews of data to verify that they meet user requirements including data-quality objectives.
- Training for Ecology staff, including training needed to determine the appropriate number and type of samples and analyses for areas of investigation commonly encountered. Training needs will build upon information gained during the planning process and during implementation and oversight of the resulting program.
- QA/QC assistance to the Ecology staff, including guidelines for use by regional office and industrial section staff in reviewing discharge monitoring report (DMR) data, guidelines for use by regional and environmental investigations staff in their evaluation of environmental laboratories, and technical guidance to Ecology staff concerning QA/QC in general.
- Other appropriate measures resulting from issues identified during the planning process.

Target Dates: Ecology provides annual reports on the implementation of the Quality Assurance Management Plan to the Authority beginning July 1, 1994.

MAJOR PUBLIC ACTIONS FOR AUTHORITY REVIEW

1. Revisions to Ecology's QA/QC management plan (element L-4).

LEGISLATION REQUIRED

None.

2 An agreement negotiated annually between the Department of Ecology and the EPA (known as the State/EPA agreement).

R0056708

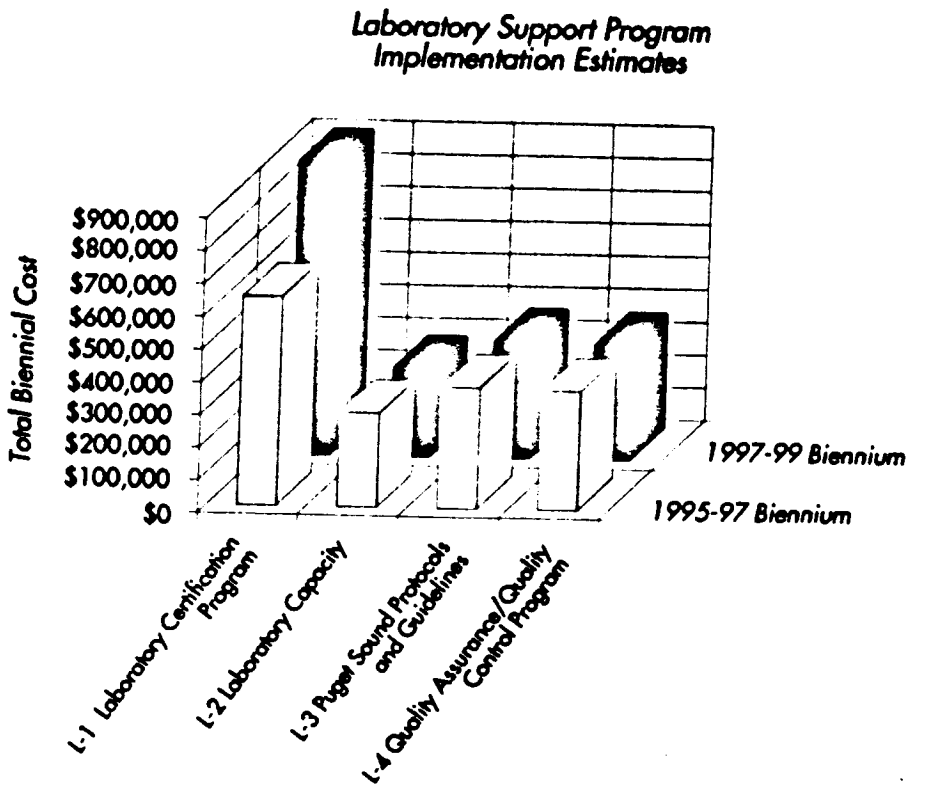
VOL 12 2 3413

ESTIMATED COST

To fully implement the Laboratory Support Program would cost an estimated 1.7 million during the 1995-97 Biennium and $1.9 million during the 1997-99 Biennium. This money will cover the lab accreditation (certification) program, conducting an ongoing assessment of the needs for laboratory capacity and making recommendations on how to provide for this, and maintaining and updating lab protocols and a quality assurance and quality control program.

Ideally the costs for conducting the certification program (element L-1) will be raised charging fees for lab accreditation reviews. These fees currently generate about $1.3 million statewide. Any increase in fees will be subject to Initiative 601 limitations.

The laboratory certification program may entail private sector costs (beyond the certification fees) to those NPDES (National Pollutant Discharge Elimination System) permit holders not participating in an EPA-approved quality assurance program, to private laboratories and to others who utilize private laboratories. These costs will vary depending upon several factors, including the current quality of the equipment and staff of the lab applying for certification and the protocols called for in the certification program.



R0056709

VOL 12 2 3 4 1 4

Chapter 3.
The Unfinished Agenda

INTRODUCTION

The action plan contained in Chapter 2 of this document represents a comprehensive program to protect Puget Sound. The Plan consists of 13 programs that address the major threats to the Sound. A number of other issues affecting the health of the Puget Sound environment were reviewed by the Authority as part of the initial scoping of the Puget Sound Plan and during public reviews of the 1989, 1991 and 1994 Puget Sound Water Quality Management Plan. This chapter contains a complete list of unfinished agenda items to be considered by the Authority and the public in the future.

UNFINISHED AGENDA ISSUES, DECISIONS AND CURRENT STATUS

The following topics have been identified as issues the Authority should consider for possible inclusion in future Puget Sound plans:

Aquaculture

Aquaculture in the state of Washington involves the controlled cultivation and harvest of aquatic animals and plants such as shellfish, finfish and edible "sea vegetables" (marine algae). This industry utilizes a number of different methods to produce a wide variety of species, including tideland cultivation, off-bottom culture (for oysters), open-water suspension, net-pen rearing, and pond or tank culture.

There has been substantial public controversy over some aspects of the aquaculture industry, particularly over the floating culture of salmon, shellfish and nori. Opposition to the siting of these aquaculture facilities has focused on potential conflicts with boating, fishing and aesthetic values (such as residential views). Other concerns are related to the potential effects on water quality and bottom organisms. There have been some additional questions about the introduction of disease, antibiotics and competition with natural fishery stocks.

VOL 12 2 3 4 1 5

R0056710

Contamination of the Sea-Surface Microlayer

The sea-surface microlayer, located at the interface between the water and the air, is only about 0.002 inches (50 micrometers) thick. It is composed of a complex mixture of natural and (sometimes) synthetic substances which float on the surface of the water. The sea surface is a highly productive habitat, supporting an abundance of bacteria, microalgae and planktonic animals that feed on these sources of food. At certain times in their development, the eggs and larvae of many marine animals (e.g., crabs, sole, flounder, cod and hake) are buoyant and may be exposed to contaminants in the sea-surface microlayer.

Contaminants with low solubility in water and contaminants associated with floating particles can become concentrated at the sea surface. Concentrations of contaminants can be orders of magnitude greater in the microlayer than the concentrations of the same contaminants in the underlying water. Substances that have been found to concentrate in the microlayer in Puget Sound include both natural and anthropogenic PAHs, PCBs, pesticides, metals, oils, greases, inorganic nitrogen compounds, and bacteria. Sources of contamination to the sea-surface microlayer may include the atmosphere, petroleum or fuel spills, disposal of dredged material, recreational and commercial boating activities, stormwater runoff and other nonpoint pollution sources, and the water column (e.g., floatable oil and grease and organic matter from wastewater treatment plants or industrial outfalls).

The Environmental Protection Agency (EPA) sponsored a microlayer workshop in 1989. Since being released, the results of that workshop have guided further research.

Effects of Air Pollution on Water Quality

Examples of sources of air pollution include industrial smokestacks, motor vehicle exhausts, woodstoves, aerial spraying of pesticides, evaporation from waste treatment plants, slash burning, landfill gases, incinerator emissions, and release of volatile substances from dry cleaners. Pollutants may enter Puget Sound waters through precipitation or direct fallout. Pollutants may also enter Puget Sound via surface-water runoff that picks up air pollution contaminants that have been deposited on the ground.

Recent studies indicate that atmospheric deposition is a major pathway by which toxic pollutants, such as metals, pesticides, polycyclic aromatic hydrocarbons (PAHs), and polychlorinated biphenyls (PCBs) enter the upper Great Lakes. In some coastal areas (such as the southern California Bight) measurements show that up to half of the PAHs and particulate metals entering the water come from direct atmospheric deposition. An EPA-funded study to evaluate atmospheric deposition of toxic contaminants to Puget Sound was completed in 1991 but no immediate actions were recommended.

Freshwater Use and Availability

There are many competing interests for the use of fresh water. Some interests require that water remain in the streams or rivers. For example, fish production depends on adequate in-stream flows and habitat conditions. Hydroelectric power and some recreational activities (such as boating and fishing) also depend on adequate in-stream water supplies. Other activities require diver-

VOL 12 2 3416

R0056711

sion of the water for out-of-stream uses. Industrial, commercial, residential and agricultural users compete for the water that is withdrawn from the stream.

Authority activities have been limited to reviewing and commenting on significant activities, such as the recommendations of the Joint Select Committee on Water Resource Policy and the Water Use Efficiency Study Committee.

Groundwater Contamination

Contaminated groundwater can carry pollutants to the waters of Puget Sound. Groundwater basins can be hydrogeologically linked both to surface waters in the basin and to the Sound itself. Thus, pollutants in ground water can affect water quality in the Sound. Contaminants can reach ground water from a variety of sources including improper disposal of solid or hazardous wastes, failing on-site sewage disposal (septic) systems, spills and accidents, and other activities that allow potential contaminants to migrate underground.

Ground water carrying contaminants to Puget Sound has been confirmed in Commencement Bay, Eagle Harbor and Budd Inlet. Both sites involve wood preserving operations where creosote and other organic compounds have built up in the ground over time and are now visibly seeping into Puget Sound. The direct link between contamination of surface water and ground water is illustrated in the Nooksack River where applications of the pesticide EDB to farm fields has contaminated both surface and ground water.

Hazardous Materials Spill Prevention and Response

Large quantities of petroleum and other hazardous substances are produced, stored and used in the Puget Sound basin. There are thousands of shipments of these substances every year by barge and tanker on Puget Sound, and by air, tank, truck, rail car, and pipeline over and around the Sound. Although the Plan's Spill Prevention and Response Program was revised in the 1994 Plan, the issues related to upland spills have not been addressed in the Plan.

Human Health Risks

Human health risks associated with Puget Sound and its resources can be categorized into two general areas: (1) human health implications associated with direct physical contact with the shorelines or waters of the Sound and (2) health implications associated with the recreational and commercial harvest and ingestion of sea vegetables, shellfish and fish from the Sound.

Concentrations of biological and chemical contaminants are typically highest in urbanized embayments around the Sound. Algae, shellfish and groundfish living near these polluted areas have been found to contain high levels of certain contaminants. While most of the seafood captured in the Sound is probably consumed with no unpleasant or dangerous side effects, the routine ingestion of large quantities of contaminated seafood over a lifetime may pose a health risk to a consumer of Puget Sound resources.

Northwest Straits Marine Sanctuary

By direction of Congress, the National Oceanic and Atmospheric Administration (NOAA) is conducting a study of northern Puget Sound for possible designation as a national marine sanctuary. The study area under consideration

VOL 12 2 3411

R0056712

includes, in general, the waters surrounding the islands of San Juan County; waters off Cherry Point and Lummi Bay in Whatcom County; waters surrounding Cypress Island in Skagit County; waters surrounding Smith and Minor islands and Partridge Banks in Island County; waters surrounding Protection Island in Jefferson County; and waters up to the high-water mark in Discovery Bay, Sequim Bay, and Dungeness Bay and surrounding Dungeness Spit in Clallam County. The proposed western boundary of the study area follows longitude 123° 10' west to the Canadian border. Some or all of the study area could be included if a sanctuary is established.

Title III of the Marine Protection, Research and Sanctuaries Act of 1972 authorizes the Secretary of Commerce to designate specific marine areas as national marine sanctuaries to protect their distinctive conservation, recreational, ecological, historical, research, educational, and aesthetic qualities. The Act is administered by the NOAA through the Office of Ocean and Coastal Resource Management, Marine and Estuarine Management Division.

The planning process for a national marine sanctuary involves the preparation of a draft environmental impact statement/management plan (DEIS/MP) and specific regulations. The DEIS/MP will examine the impacts of designation of northern Puget Sound as a sanctuary, including an analysis of alternatives for protecting and managing the proposed sanctuary's resources. Subsequent steps in the designation process include public hearings on the DEIS/MP and preparation and submission of a prospectus to Congress. If the prospectus is approved by Congress, the final step will include the preparation of a final management plan/environmental impact statement and the development and issuance of sanctuary designation determination and findings. All final terms of the plan must be approved by the governor of Washington.

The proposed boundaries of the Northern Puget Sound Marine Sanctuary lie within the planning area of the Puget Sound Water Quality Management Plan. These overlapping state and federal jurisdictions raise a number of important questions regarding management authorities, responsibilities, and coordinating functions.

Nutrient Effects

Sewage effluent discharged into the fresh and marine waters of the Puget Sound area contains high levels of both organic and inorganic forms of nitrogen and phosphorus. Other sources of excess nutrients include fertilizers, animal wastes, and on-site sewage disposal systems. These nutrients can, in certain instances, stimulate the growth of phytoplankton, sediment microalgae, macroalgae, kelp, seagrasses, and marsh plants, particularly in vertically stratified bays and inlets and along shorelines where nutrients might otherwise be limiting. Excessive phytoplankton growth from human-caused introduction of nutrients can lead to oxygen depletion in the bottom waters. Fish kills and other biological effects may occur as a result of this depleted oxygen.

Although there have been few recent reported fish kills in the marine waters of the Sound, there may be other biological effects from nutrient enrichment that are currently not well understood or are not being detected. For example, there is some evidence that the growth and population dynamics of the plank-

VOL 12 2 3418

R0056713

tonic dinoflagellate *Gonyaulax catenella*, the organisms that causes paralytic shellfish poisoning (PSP), may be influenced in some cases by anthropogenic additions of nutrients. Nutrient inputs may shift the natural population patterns of phytoplankton species and have effects further up the food chain. In addition, macro-algal growth may be enhanced by nutrient additions in the nearshore and shoreline areas of the Sound.

Nutrients may be contributed to the Sound from a variety of sources other than sewage treatment plants. These include storm water, on-site sewage disposal systems, nonpoint runoff from heavily fertilized agricultural and forestlands, industrial discharges (e.g., pulp and paper mills), and atmospheric deposition.

The increased population projected for the Puget Sound area will result in increased nutrient loadings to Puget Sound. Nutrient effects in shallow, stratified bays and inlets around the Sound may increase unless sources of excess nutrients are detected and controlled.

Plastic Debris in Marine Waters

Because of their durability, plastics are causing substantial pollution of marine waters. Plastics have become the most common objects sighted at sea. They typically comprise one-half to two-thirds or more of all surface objects sighted. Studies have indicated that the coasts of Oregon and Washington have one of the highest concentrations of marine plastic debris in the world. In fact, a Japanese survey concluded that the Washington coast had a higher percentage of floating debris than anywhere else in the Pacific.

The most serious concern of plastic debris in marine waters, however, is the harm to marine life though entanglement or ingestion. Entanglement can lead to drowning, starvation, strangulation or predation. Loss of limbs through infection from entanglement is also common.

In December 1988, the Marine Plastic Debris Action Plan for Washington state was released by the Department of Natural Resources. Prepared by the Marine Plastic Debris Task Force, it contains 20 action recommendations for how to reduce and respond to plastic marine debris. The Authority is committed to continuing work on this issue, including possibly adding program language in future plans.

Transboundary Pollution

Washington state and the Canadian province of British Columbia share the Strait of Juan de Fuca and part of the Strait of Georgia. Contaminants entering British Columbia's waters from point and nonpoint sources often end up in the Strait of Georgia and can be transported into Puget Sound. It is unclear exactly how much pollution is transported either way between British Columbia and Washington, but the 1994 report of the B.C./Washington Marine Science Panel identifies increasing threats to the marine waters of British Columbia and Washington.

Treatment of Domestic Wastes

Many elements of the Puget Sound Plan and regulatory programs administered by Ecology and the EPA deal with the treatment of domestic wastes. Howev-

R0056714

VOL 12 2 3419

er, there are a number of issues that deserve further review. Some of these include: the production, treatment, use, and disposal of domestic sludge; the use and effects of chlorine in the wastewater treatment process; and water reuse.

Municipal sewage sludge is the semi-solid material left over after treatment of sewage, while septage is the semi-solid material pumped from septic tanks and marine holding tanks. Sludge may be treated to reduce its volume and to lessen risks to public health and the environment. Treated sludge is a useful fertilizer, and most sludge in the Puget Sound area is applied to the land for silviculture, land reclamation, and composting. Certain risks are associated with the use of sludge due to its contamination with heavy metals, pathogens, and toxic organic compounds. Cadmium in sludge can be taken up by plants and potentially could poison animals or humans. Excessive use of sludge can also contaminate ground water or surface water with nitrates.

Chlorine is applied to waste water in the final stages of treatment to kill bacteria, viruses and protozoans that may be harmful to humans. However, chlorination of sewage effluent may create other problems in the fresh and marine waters where treated waste water is discharged. Chlorine can chemically combine with organic substances in the effluent and form highly toxic chlorinated organic compounds. Chronic toxicity effects have been detected in fish exposed to low concentrations of residual chlorine compounds in water.

Chlorination may kill the microbial organisms (usually fecal coliform and fecal streptococci bacteria) that serve as indicators of the potential presence of harmful organisms while allowing pathogenic viruses and other microorganisms to pass through the treatment process unharmed by the chlorine and undetected (depending on the degree and type of chlorination treatment used). Researchers have found that chlorine-treated wastewater effluent may contain viruses even though no fecal coliform bacteria are present. This is a public health concern because viruses cause many of the diseases that are spread through the presence of domestic waste water, and most of the more dangerous viruses cannot be easily measured with existing technology.

Urban water supply and disposal systems generally take in drinking water from the mountains or from ground water and, after treatment, discharge it to salt water. This water bypasses the rivers, streams, wetlands, lakes and aquifers of the freshwater system with poorly understood effects. Additional consideration should be given to opportunities for reuse and for putting treated wastewater back into the freshwater system.

INCENTIVES

As environmental regulations have become more common, their cost has become apparent to two major groups. Businesses have found that it is very expensive to comply with regulations, particularly when they are very rigid, allowing for little in terms of innovative responses. Government regulators have also found that enforcement of the regulations and the monitoring of compliance is costly. In fact, inadequate resources to fund these activities is a chronic difficulty for government.

R0056715

VOL 12 2 3420

This situation has caused many regulators, environmental planners and business groups to seek new approaches to environmental policy that are at least as effective as traditional regulatory approaches to preventing degradation of the environment. One approach is using market-based incentives to reach predetermined pollution abatement goals. Environment 2010 prepared an issue paper on this topic.

This approach, also called environmental economics, is a way of harnessing the forces of the marketplace in order to most effectively and efficiently achieve specific environmental goals and standards. Government regulators (and the public) establish specific environmental goals. Then mechanisms are brought into play which take advantage of the forces of the marketplace in our economy.

Two types of market-based incentives that have been used or proposed elsewhere are subsidies, to provide a positive inducement to do something, and taxes or fees, which provide a negative incentive.

Subsidies

Subsidies can be both direct and indirect. Government can provide direct financial backing or technical assistance to businesses as they work to develop more efficient and cost-effective practices which generate less waste. This direct form of assistance can be tailored so that it will not be provided unless the business first makes a "good faith" effort on its own. The proposal for a university-based institute to develop pollution control technologies included in the Municipal and Industrial Discharges Program (element P-27) represents a proposed state subsidy of technology development. Indirect subsidies can be provided through various sorts of tax breaks for costs associated with waste reduction. Washington state provides tax benefits for pollution control equipment in certain cases.

Taxes and Fees

Taxes and fees are a way of providing a negative incentive so that a business will be motivated to seek a way of decreasing the amount of wastes that are being generated. The fees would be levied by government in addition to the costs that have to be paid for treatment, storage, or disposal of the waste. Economic theory would hold that this fee or tax should be high enough that it would reasonably cover all of the social costs incurred as a result of the long-term environmental effects of the existence of the waste. The business decision to produce, or continue producing, the waste would then be based on the true costs controlled by the decision. Many of these costs are not normally accounted for today.

It is important to recognize that a market-based incentive system cannot be successful without a major commitment by regulators to enforce the program. Since permits would be for a set quantity of discharge, and the marketable system gives a significant economic value to the exact quantity discharged, monitoring the exact amount discharged by each outfall would be more necessary than with the current technology-based permit system. The method also includes an assumption that it is the total quantity discharged, regardless of its location or form, that affects the environment. Yet in Puget Sound we

VOL 12 2 3421

R0056716

have a pattern of sediment "hot spots" associated with individual discharge points. So a system of marketable discharge permits for Puget Sound would need an additional mechanism to account for the locations of discharges.

OTHER ISSUES

Other issues that have been identified include the special needs of islands, improved and expanded public access to Puget Sound shorelands, protection of sole-source aquifers, and the issue of fecal coliform bacteria contamination generated by seal populations.

VOL 12 2 C. 3 3424

Appendix B. Glossary

ACUTE TOXICITY
Any toxic effect that is produced within a short period of time, generally 96 hours or less. Although the effect most frequently considered is mortality, the end result of an acute effect could be any harmful biological effect.

AEROBIC
Living, active or occurring only in the presence of oxygen. For example, soil microorganisms which degrade sewage effluent from septic systems need oxygen in order to function.

ALGAE
Aquatic, nonflowering plants that lack roots and use light energy to convert carbon dioxide and inorganic nutrients such as nitrogen and phosphorus into organic matter by photosynthesis. Common algae include dinoflagellates, diatoms, seaweeds and kelp. An algal bloom can occur when excessive nutrient levels and other physical and chemical conditions enable the algae to reproduce rapidly.

AMBIENT MONITORING
Monitoring that is done to determine existing environmental conditions, contaminant levels, rates, or species in the environment, against which future conditions can be compared. This type of monitoring occurs in waters not located in close proximity to direct discharges of pollutants.

AMPHIPODS
Small shrimp-like crustaceans such as sand fleas and related forms. Many live on the bottom (i.e., are benthic) and feed on algae and detritus.

ANADROMOUS FISH
Species, such as salmon, which hatch in fresh water, spend a large part of their lives in the ocean, and return to freshwater rivers and streams to reproduce.

ANTHROPOGENIC
Effects or processes that are derived from human activity, as opposed to natural effects or processes that occur in the environment without human intervention.

APPARENT EFFECTS THRESHOLD (AET)
The highest sediment concentration of an individual chemical contaminant which is not associated with adverse biological effects. Samples with concentrations of contaminants above the AET have always shown adverse biological effects.

AQUACULTURE
The controlled cultivation and harvest of aquatic plants or animals (e.g., edible marine algae, clams, oysters and salmon).

AQUIFER
The underground layer of rock or soil in which ground water resides. Aquifers are replenished or recharged by surface water percolating through soil. Wells are drilled into aquifers to extract water for human use.

AROMATIC
A chemical substance characterized by the presence of at least one benzene ring. These substances may have a strong smell and are often persistent in the environment due to the stability of the benzene ring.

BASELINE STUDY
A study that documents the existing state of an environment to serve as a baseline against which future changes are measured.

BENTHIC ORGANISMS
Organisms that live in or on the bottom of a body of water.

BEST MANAGEMENT PRACTICE (BMP)
A method, activity, maintenance procedure, or other management practice for reducing the amount of pollution entering a water body. The term originated from the rules and regulations developed pursuant to Section 208 of the federal Clean Water Act (40 CFR 130).

BIENNIUM
The Washington State Biennium. WA adopts a two-year budget, which runs from July 1 of odd-numbered years to June 30 of the next odd-numbered year.

BIOACCUMULATION
The process by which a contaminant accumulates in the tissues of an organism. For example, certain chemicals in food eaten by a fish tend to accumulate in its liver and other tissues.

BIOASSAY
A test procedure that measures the response of living plants, animals or tissues to potential contaminants. For example, marine worms have been exposed to the sediments of Puget Sound, and their responses have been used to determine areas in the Sound where the sediments may be harmful to life.

BIOCHEMICAL OXYGEN DEMAND (BOD)
The quantity of oxygen-demanding materials present in a sample as measured by a specific test. A major objective of conventional wastewater treatment is to reduce the biochemical oxygen demand so that the oxygen content of the water body will not be significantly reduced. Although BOD is not a specific compound, it is defined as a conventional pollutant under the federal Clean Water Act.

BIODEGRADATION
The conversion of organic compounds into simpler compounds through biochemical activity. Toxic compounds can sometimes be converted into nontoxic compounds through biodegradation. In some cases complex compounds are first converted into intermediate substances that can

VOL 12 2 3425

R0056720

be more toxic than the original substance.

BIOMAGNIFICATION
The process by which concentrations of contaminants increase (magnify) as they pass up the food web such that each animal in the food web has higher tissue concentrations than did its food. For example, concentrations of certain contaminants can increase as they are passed from plankton to herring to salmon to seals.

BIOTA
The animals, plants and microbes that live in a particular location or region.

BIVALVE
An aquatic invertebrate animal of the class *Bivalvia*. Bivalves, such as clams and oysters, have two shells (valves) and most are filter feeders.

CARCINOGENIC
Capable of causing cancer.

CENTENNIAL CLEAN WATER FUND (CCWF) also known as the WATER QUALITY ACCOUNT
In 1986, legislation was passed creating the Water Quality Account in the state treasury (RCW 70.146). The purpose of the account is to provide financing of water pollution-control facilities and activities. The account receives revenue from a tax on tobacco products. The Department of Ecology, in adopting rules for administration of the account, has named it the Centennial Clean Water Fund.

CERTIFIED SHELLFISH BED
An area where commercial shellfish harvesting is approved by the Washington Department of and Health (DOH), based on measurements of fecal coliform bacteria in the overlying waters. Fecal coliform bacteria are used as an indicator of pathogens that could pose a human-health risk.

CHRONIC TOXICITY
Any toxic effect on an organism that results after exposure of long duration (often 1/10th of the life span or more). The end result of a chronic effect can be death, although the usual effects are sublethal (e.g., inhibited reproduction or growth). These sublethal effects may be reflected by changes in the productivity and population structure of the community.

CLEAN WATER ACT (CWA)
Also known as the federal Water Pollution Control Act (33 U.S.C. 1251 et seq.).

CLEANUP ACTIVITIES
Actions taken by a public agency or a private party to correct an environmental problem. Activities generally consist of the treatment or removal from the environment of contaminants introduced by past practices (for example, capping part of a public park contaminated with carcinogenic compounds or digging up and incinerating soil contaminated with dioxin).

CODE OF FEDERAL REGULATIONS (CFR)
The compilation of federal regulations adopted by federal agencies through the rule-making process. For example, pretreatment regulations are found in 40 CFR 403.

COLIFORM BACTERIA
A type of bacteria that is coil or helix shaped. Fecal coliform bacteria are those coliform bacteria that are found in the intestinal tracts of mammals. The presence of high numbers of fecal coliform bacteria in a water body can indicate the recent release of untreated waste water and/or the presence of animal feces. These organisms may also indicate the presence of pathogens that are harmful to humans. High numbers of fecal coliform bacteria therefore limit beneficial uses of water such as swimming and shellfish harvesting.

COMBINED SEWER OVERFLOW (CSO)
A pipe that discharges untreated waste water during storms from a sewer system that carries both sanitary waste water and storm water. The overflow occurs because the system does not have the capacity to transport, store or treat the increased flow caused by stormwater runoff.

COMBINED SEWER SYSTEM
A wastewater collection and treatment system where domestic and industrial waste water is combined with storm runoff. Although such a system does provide treatment of storm water, in practice the systems may not be able to handle major storm flows. As a result, untreated discharges from combined sewer overflows may occur.

CONFINED DISPOSAL
A dispositional method that isolates dredged material from the environment. Confined disposal may be in aquatic, nearshore, or upland environments.

CONTAMINANT
A substance that is not naturally present in the environment or is present in amounts that can, in sufficient concentration, adversely affect the environment.

CONVENTIONAL POLLUTANT
Conventional pollutants as specified under the Clean Water Act are total suspended solids, fecal coliform bacteria, biochemical oxygen demand, pH, and oil and grease. Today a large number of nonconventional and toxic contaminants are of concern in addition to the conventional pollutants.

CUMULATIVE EFFECTS
The combined environmental impacts that accrue over time and space from a series of similar or related individual actions, contaminants, or projects. Although each action may seem to have a negligible effect, the combined effect can be severe.

DETENTION
The process of collecting and holding back storm water for delayed release to receiving waters.

DISCHARGE, DIRECT OR INDIRECT
The release of waste water or contaminants to the environment. A direct discharge of waste water flows directly into surface waters while an indirect discharge of waste water enters a sewer system.

DISINFECTION
The destruction of infectious agents such as bacteria or viruses.

VOL 12 2 3426

R0056721

Most wastewater treatment plants use chlorine or bromine for disinfection.

DISPOSAL
Methods by which unwanted materials are relocated, contained treated, or processed. Unless contaminants are converted to less harmful forms or removed from the material before disposal, they may be released again into the environment.

DISSOLVED OXYGEN
Oxygen that is present (dissolved) in water and therefore available for fish and other aquatic animals to use. If the amount of dissolved oxygen in the water is too low, then aquatic animals may die. Waste water and naturally occurring organic matter contain oxygen-demanding substances that consume dissolved oxygen.

DOMESTIC WASTEWATER (SEWAGE)
Human-generated waste water that flows from homes, businesses and industries.

DREDGING
Any physical digging into the bottom sediment of a water body. Dredging can be done with mechanical or hydraulic machines, and it changes the shape and form of the bottom. Dredging is routinely done in many parts of Puget Sound in order to maintain navigation channels that would otherwise fill with sediment and block ship passage.

ECOSYSTEM
A community of living organisms interacting with one another and with their physical environment, such as a rain forest, pond or estuary. Damage to any part of a complex system, such as Puget Sound, may affect the whole. A system such as Puget Sound can also be thought of as the sum of many interconnected ecosystems such as the rivers, wetlands, and bays. Ecosystem is thus a concept applied to communities of different scale, signifying the interrelationships that must be considered.

EFFLUENT
The liquid that flows out of a facility or household into a water body or sewer system. For example, the treated liquid discharged by a wastewater treatment plant is the plant's effluent.

ENVIRONMENTAL IMPACT STATEMENT (EIS)
A document that discusses the likely significant impacts of a development project or a planning proposal, ways to lessen the impacts, and alternatives to the project or proposal. EISs are required by the national and Washington state environmental policy acts.

EROSION
Wearing away of rock or soil by the gradual detachment of soil or rock fragments by water, wind, ice and other mechanical and chemical forces.

ESTUARY
A coastal water body where ocean water is diluted by out-flowing fresh water.

FECAL COLIFORM see *COLIFORM BACTERIA*

FECES
Waste excreted from animals.

FOREST PRACTICE
Any activity conducted on or directly pertaining to forestland related to growing, harvesting or processing timber. These activities include but are not limited to: road and trail construction, final and intermediate harvesting, precommercial thinning, reforestation, fertilization, prevention and suppression of disease and insects, salvage of trees, and brush control. Forest practices are subject to regulation by the Washington Department of Natural Resources.

FULL-TIME EQUIVALENT (FTE)
The work one person does in one year—used to estimate costs and people needed to perform certain actions.

FUNGICIDE
A substance that destroys or inhibits growth of fungus.

GEOGRAPHIC INFORMATION SYSTEM
A computer system that allows the display and analysis of geographic information. A GIS could, for example, display wetland boundaries on a city map.

GROUNDFISH
Fish (also known as bottomfish) that live on or near the bottom of water bodies, for example, English sole.

GROUND WATER
Underground water supplies stored in aquifers. Ground water is created by rain that soaks into the ground and flows down until it is collected at a point where the ground is not permeable. Groundwater then usually flows laterally toward a river, lake or the ocean. Wells tap the ground water for use. (See AQUIFER)

GROWTH MANAGEMENT ACT
The state law (RCW 36.70A) that directs local governments to adopt revised comprehensive land-use plans and development regulations. Local governments can incorporate many water quality and habitat protections into their growth management program.

HABITAT
The specific area or environment in which a particular type of plant or animal lives. An organism's habitat must provide all the basic requirements for life and should be free of harmful contaminants. Typical Puget Sound habitats include beaches, marshes, rocky shores, the bottom sediments, intertidal mudflats, and the water itself.

HAZARDOUS WASTE
Any solid, liquid or gaseous substance which, because of its source or measurable characteristics, is classified under state or federal law as hazardous and is subject to special handling, shipping, storage and disposal requirements. Washington state law identifies two categories, dangerous and extremely hazardous. The latter category is more hazardous and requires greater precautions.

HERBICIDE
A substance used to destroy or inhibit growth of vegetation.

VOL 12 2 3 4 2 7 1
R0056722

HOLDING TANK
An enclosed container used as part of a sewage disposal system on a boat. The tank is used to temporarily store sewage for later pumpout at a marina pumpout facility.

HUMAN-HEALTH RISK
The risk or likelihood that human health will be adversely affected. Estimating health risks is a complex and inexact practice.

HYDRAULIC PROJECT APPROVAL (HPA)
Under the Hydraulic Code Rules, approval is required from Washington State Department of Fish and Wildlife for certain activities in state waters that support fish life. A project approval is required for activities affecting state waters such as certain forest practices; culvert construction; bridge, pier, and piling construction; bulkheads; boat launches; dredging; etc.

HYDROCARBON
An organic compound composed of carbon and hydrogen; for example, petroleum compounds.

HYDROLOGIC CYCLE
The continual cycling of water between the land, the sea and the atmosphere through evaporation, condensation, precipitation, absorption into the soil, and stream runoff.

IMPERVIOUS SURFACE
A surface that cannot be easily penetrated. For instance, rain does not readily penetrate asphalt or concrete pavement.

INSECTICIDE
A substance, usually a chemical, that is used to kill insects.

INTERFERENCE
A contaminant can interfere with the normal sewage treatment plant process by diminishing the efficiency of the treatment process. For example, a toxic chemical can kill the beneficial bacteria in a treatment plant and interfere with the biological treatment process, thus causing the release of excessively contaminated effluent.

INTERTIDAL AREA
The area between high and low tide levels. The alternate wetting and drying of this area makes it a transition between land and water and creates special environmental conditions and habitats.

LAND USE
The way land is developed and used in terms of the types of activities allowed (agriculture, residences, industries, etc.) and the size of buildings and structures permitted. Certain types of pollution problems are often associated with particular land-use practices, such as sedimentation from construction activities.

LEACHATE
Water or other liquid that has washed (leached) from a solid material, such as a layer of soil or debris. Leachate may contain contaminants such as organics or mineral salts. Rainwater that percolates through a sanitary landfill and picks up contaminants is called the leachate from the landfill.

LIVEABOARD
Those using a boat, other than a houseboat, as a primary dwelling.

LOADING
The total amount of material entering a system from all sources.

MARINE SANITATION DEVICE (MSD)
A device installed on a boat to treat or hold sewage. Section 312 of the federal Clean Water Act requires all vessels with installed toilets to have approved MSDs. Federal regulations describe three types of MSDs: Type I and Type II MSDs are treatment devices, while Type III MSDs are holding tanks.

MARSH
A wetland where the dominant vegetation is non-woody plants such as grasses and sedges, as opposed to a swamp where the dominant vegetation is woody plants like trees.

METABOLISM
All chemical processes occurring within an organism, including both synthesis and breakdown of organic materials.

METALS
Metals are elements found in rocks and minerals that are naturally released to the environment by erosion, as well as generated by human activities. Certain metals, such as mercury, lead, nickel, zinc and cadmium, are of environmental concern because they are released to the environment in excessive amounts by human activity. They are generally toxic to life at certain concentrations. Since metals are elements, they do not break down in the environment over time and can be incorporated into plant and animal tissue.

MICROLAYER, SEA-SURFACE MICROLAYER
The extremely thin (usually estimated as 50 microns) layer at the top of the water. Contamination of this layer is of concern because many contaminants, such as oil, grease, organic toxicants and pathogens, are buoyant in seawater and therefore may concentrate at much higher concentrations in the microlayer than in the water column. The atmospheric deposition of toxicants into the microlayer is also of concern. These contaminant concentrations may pose a danger to fish eggs and other organisms that may come into contact with the water surface.

MICROORGANISMS
Microscopic organisms, (e.g., bacteria, viruses and protozoans) that are not visible to the unaided eye. Some cause diseases in humans, animals and plants; some are important because they are involved in breaking down and stabilizing sewage and solid waste.

MODEL ORDINANCE
A sample ordinance which contains elements and language necessary to achieve a desired regulatory effect.

MONITOR
To systematically and repeatedly measure conditions in order to track changes. For example, dissolved oxygen in a bay might be

VOL 12 2 3428
R0056723

monitored over a period of several years in order to identify trends in concentration.

MUNICIPAL DISCHARGE
Effluent from a municipal sewage treatment plant.

NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM (NPDES)
A part of the federal Clean Water Act, which requires point-source dischargers to obtain discharge permits. These permits are referred to as NPDES permits and are administered by the Washington Department of Ecology.

NONPOINT SOURCE POLLUTION
Pollution that enters water from dispersed and uncontrolled sources (such as surface runoff) rather than through pipes. Nonpoint sources (e.g., forest practices, agricultural practices, on-site sewage disposal, and recreational boats) may contribute pathogens, suspended solids, and toxicants. While individual sources may seem insignificant, the cumulative effects of nonpoint source pollution can be significant.

NUTRIENTS
Essential chemicals needed by plants or animals for growth. If other physical and chemical conditions are optimal, excessive amounts of nutrients can lead to degradation of water quality by promoting excessive growth, accumulation, and subsequent decay of plants, especially algae. Some nutrients can be toxic to animals at high concentrations.

OXYGEN-DEMANDING MATERIALS
Materials such as food waste and dead plant or animal tissue that use up dissolved oxygen in the water when they are degraded through chemical or biological processes. Biochemical oxygen demand (BOD) is a measure of the amount of oxygen consumed when a substance degrades.

PARALYTIC SHELLFISH POISONING (PSP)
An illness, sometimes fatal to humans and other mammals, caused by a neuro-toxin produced by a type of plankton called *Gonyaulax*. During certain times of the year and at certain locations, these organisms proliferate in "blooms" (sometimes called red tides) and can be concentrated by clams, mussels, and other bivalves. The nervous system of affected shellfish is unaffected. Consumption of the shellfish can cause acute illness in humans and other mammals.

PARAMETER
A quantifiable or measurable characteristic. For example, height, weight, sex and hair color are all parameters that can be determined for humans. Water quality parameters include temperature, pH, salinity, dissolved oxygen concentration, and many others.

PATHOGEN
An agent such as a virus, bacterium or fungus that can cause diseases in humans. Pathogens can be present in municipal, industrial and nonpoint-source discharges to the Sound.

PELAGIC
Associated with or living in the water column as opposed to the bottom or the shoreline.

PERCOLATE
To pass through a permeable substance. For instance, septic effluent and rainfall percolates through soil.

PERSISTENT
Compounds that are not readily degraded by physical, chemical, or biological processes.

PERSISTENT MARINE DEBRIS (PMD)
Plastic, glass, metal, rags and other refuse accidentally or purposely put into the marine environment. The plastic component is often referred to as Marine Plastic Debris (MPD). Marine debris can injure or kill marine life and threatens the safety of swimmers, divers and watercraft.

PESTICIDE
A general term used to describe chemical substances that are used to destroy or control pest organisms. Pesticides include herbicides, insecticides, algicides, fungicides, and others. Many of these substances are manufactured and are not naturally found in the environment. Others, such as pyrethrum, are natural toxins which are extracted from plants and animals.

pH
The degree of alkalinity or acidity of a solution. A pH of 7.0 indicates neutral water while a pH of 5.5 is acid. A reading of 8.5 is alkaline or basic. The pH of water influences many of the types of chemical reactions that will occur in it. For instance, a slight decrease in pH may greatly increase the toxicity of substances such as cyanides, sulfides and most metals. A slight increase may greatly increase the toxicity of pollutants such as ammonia.

PHOTOSYNTHESIS
The process by which plants use light energy to make simple sugars and carbohydrates from carbon dioxide and water.

PLANKTON
Small plants (phytoplankton) and animals (zooplankton) that are suspended in the water and either drift with the currents or swim weakly.

POINT SOURCE
A source of pollutants from a single point of conveyance such as a pipe. For example, the discharge pipe from a sewage treatment plant or a factory is a point source.

POLLUTANT
A contaminant that adversely alters the physical, chemical or biological properties of the environment. The term includes pathogens, toxic metals, carcinogens, oxygen-demanding materials, and all other harmful substances. With reference to nonpoint sources, the term is sometimes used to apply to contaminants released in low concentrations from many activities which collectively degrade water quality. As defined in the federal Clean Water Act, pollutant means dredged spoil, solid waste, incinerator residue, sewage, garbage, sewage sludge, munitions, chemical wastes, biological materials, radioactive materials, heat, wrecked or discarded equipment,

VOL 12 2 3429

R0056724

rock, sand, cellar dirt, and industrial, municipal and agricultural waste discharged into water.

POLYCHLORINATED BIPHENYLS (PCBs)
A group of manufactured chemicals including about 70 different but closely related compounds made up of carbon, hydrogen and chlorine. If released to the environment, they persist for long periods of time and can biomagnify in food webs because they have no natural usage in the food web. PCBs are suspected of causing cancer in humans. PCBs are an example of an organic toxicant.

POLYCYCLIC or POLYNUCLEAR AROMATIC HYDROCARBONS (PAHs)
A class of complex organic compounds, some of which are persistent and cancer-causing. These compounds are formed from the combustion of organic material and are ubiquitous in the environment. PAHs are commonly formed by forest fires and by the combustion of gasoline and other petroleum products. They often reach the environment through atmospheric fallout and highway runoff.

PRETREATMENT
The treatment of industrial wastewater to remove contaminants prior to discharge into municipal sewage systems.

PRIMARY TREATMENT
A wastewater treatment method that uses settling, skimming and (usually) chlorination to remove solids, floating materials, and pathogens from waste water. Primary treatment typically removes about 35 percent of the BOD and less than half of the metals and toxic organic substances.

PRIORITY POLLUTANTS
Substances listed by the EPA under the federal Clean Water Act as toxic and having priority for regulatory controls. The list currently includes 12 metals, two inorganic compounds, and a 111 natural and artificial organic compounds (111). The list of priority pollutants includes some substances which are not of immediate concern in Puget Sound, and it does not include all known harmful compounds.

PROTOCOL
A standardized procedure for field collection, laboratory analysis, and/or interpretation of samples. Good protocols improve the quality of data and make data from different sources comparable. The Puget Sound Estuary Program protocols were developed under contract to EPA to standardize sample collection and analysis within the Sound, allowing for comparability of data and determination of long-term environmental trends.

PUGET SOUND, WATERS OF
As defined in RCW 90.70.005, all salt waters of the state of Washington inside the international boundary line between Washington and British Columbia, and lying east of 123° 24' west longitude (east of Port Angeles).

PUGET SOUND WATER QUALITY AUTHORITY (AUTHORITY)
The state agency which is responsible for development and oversight of the Puget Sound Water Quality Management Plan.

REGULATED WETLANDS
See section W-2.1.

REGULATORY FRAMEWORK
A particular set of laws, rules, procedures, and agencies designed to govern a particular type of activity or solve a particular problem.

RESOURCE CONSERVATION AND RECOVERY ACT (RCRA)
The federal law that classifies and regulates solid and hazardous waste.

REVISED CODE OF WASHINGTON (RCW)
The compilation of the laws of the state of Washington published by the Statute Law Committee. For example, the law that created the Puget Sound Water Quality Authority is incorporated in the code as Chapter 90.70 RCW.

RIPARIAN HABITAT
Riparian ecosystems include the transitional areas between aquatic and terrestrial environments and contains all of the environmental elements that directly contribute to the structural and functional processes of a body of water..

SALINITY
A measure of the quantity of dissolved salts in water.

SALMONID
A fish of the family Salmonidae (as distinct from a salmonoid which is merely a fish that resembles a salmon). Fish in this family include salmon and trout. Most Puget Sound salmonids are anadromous.

SANITARY WASTE WATER
Waste water which includes domestic sewage and may contain pathogens. Sanitary waste water is not sanitary.

SECONDARY TREATMENT
A wastewater treatment method that usually involves the addition of biological treatment to the settling, skimming, and disinfection provided by primary treatment. Secondary treatment may remove up to 90 percent of BOD and significantly more metals and toxic organics than primary treatment.

SEDIMENT
Material suspended in or settling to the bottom of a liquid, such as the sand and mud that make up much of the shorelines and bottom of Puget Sound.

SEPARATED SEWER SYSTEM
A wastewater collection and treatment system where domestic and industrial waste water is separated from storm runoff. A separated system consists of independent sanitary wastewater and stormwater systems. The storm water is generally discharged directly into open water and the sanitary waste water goes to a treatment plant.

SEPTAGE
The sludge and scum material that is pumped out of a septic tank.

SHELLFISH
An aquatic animal, such as a mollusc (clams and snails) or crustacean (crabs and shrimp), having a shell or shell-like exoskeleton.

R0056725

VOL 12 2 3430

SHELLFISH CONTAMINATION
The contamination of certain bivalves (clams, mussels, oysters) which filter water to feed and tend to collect or concentrate waterborne contaminants in their tissues.

SHORELINE DEVELOPMENT
As regulated by the Shoreline Management Act (Chapter 90.58 RCW) the construction over water or within a shoreline zone (generally 200 feet landward of the water) of structures such as buildings, piers, bulkheads, and breakwaters, including environmental alterations such as dredging and filling, or any project which interferes with public navigational rights on the surface waters.

SHORELINE MANAGEMENT ACT (SMA)
The state law (90.58 RCW) that requires local governments to develop a shoreline master program, and requires permits for water and associated land uses. Many local governments promote the protection of wetlands, habitat, and water quality through their shoreline master program.

SLUDGE, WASTEWATER TREATMENT SLUDGE
Semi-solid matter resulting from the treatment of waste water. Some of the contaminants (especially toxic metals) that were in the waste water remain in the sludge after treatment. The treated waste water can be discharged to the Sound, but the sludge must be disposed of elsewhere. Sludge is usually at least partially dried before disposal and if relatively uncontaminated may be added to soil to increase plant growth.

SOLE SOURCE AQUIFER
The single source of ground water for human use in any one area. Areas with a sole source aquifer have no other source of ground water; any contamination of the aquifer could contaminate the entire water supply.

SOURCE CONTROL
A practice, method or technology that is used to reduce pollution from a source; for example, best management practices or end-of-pipe treatment.

STATE ENVIRONMENTAL POLICY ACT (SEPA)
A state law (Chapter 43.21C RCW) that requires state agencies and local governments to consider environmental factors when making decisions on activities, such as development proposals over a certain size, and comprehensive plans. As part of this process, environmental impacts are documented and opportunities for public comment are provided.

STORM DRAIN
A system of gutters, pipes or ditches used to carry storm water from surrounding lands to streams, lakes or Puget Sound. In practice storm drains carry a variety of substances such as sediments, metals, bacteria, oil and antifreeze which enter the system through runoff, deliberate dumping or spills. This term also refers to the end of the pipe where the storm water is discharged.

STORM WATER
Water that is generated by rainfall and is often routed into drain systems in order to prevent flooding.

SUSPENDED SOLIDS
Organic or inorganic particles that are suspended in and carried by the water. The term includes sand, mud and clay particles as well as solids in waste water.

TECHNOLOGY-BASED STANDARDS
Technology-based effluent standards are developed by considering the effluent quality that can be achieved using various process or treatment technologies, and the costs of those technologies, rather than basing effluent standards on the environmental effects of different loadings of pollutants.

TIMBER/FISH/WILDLIFE AGREEMENT (TFW)
An agreement between timber, fish and wildlife interests that promotes the monitoring and protection of fish and wildlife resources as an integral component of forestry management practices.

TOTAL SUSPENDED SOLIDS (TSS)
The weight of particles that are suspended in water. Suspended solids in water reduce light penetration in the water column, can clog the gills of fish and invertebrates, and are often associated with toxic contaminants because organics and metals tend to bind to particles.

TOXIC
Poisonous, carcinogenic or otherwise directly harmful to life.

TOXIC SUBSTANCES AND TOXICANTS
Chemical substances such as pesticides, plastics, detergents, chlorine and industrial wastes that are poisonous, carcinogenic or otherwise directly harmful to life.

TREATMENT
Chemical, biological or mechanical procedures applied to an industrial or municipal discharge or to other sources of contamination to remove, reduce or neutralize contaminants.

TRIBUTYL TIN (TBT)
An organic-metal compound used as an additive in many marine antifoulant paints used to prevent algal and barnacle growth. Tributyl tin is highly toxic to many marine organisms.

TURBIDITY
A measure of the amount of material suspended in the water. Increasing the turbidity of the water decreases the amount of light that penetrates the water column. High levels of turbidity are harmful to aquatic life.

UNCONFINED, OPEN-WATER DISPOSAL
Discharge of dredged material into an aquatic environment, usually by discharge at the surface, without restrictions or confinement of the material once it is released.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY (EPA)
The federal agency which administers many federal environmental laws. EPA Region 10, which includes Puget Sound, is headquartered in Seattle.

VOL 12 2 3431
R0056726

UPLAND MANAGEMENT AREA
A mandatory unharvested area for wildlife use and protection in a forest clearcut. These areas typically represent two percent or more of the clearcut area. This term originated from the Timber/Fish/Wildlife Agreement.

VOLATILE
Can be readily vaporized at a relatively low temperature.

WASHINGTON ADMINISTRATIVE CODE (WAC)
Contains all state regulations adopted by state agencies through the rulemaking process. For example, Chapter 173-201 WAC contains water quality standards.

WASHINGTON DEPARTMENT OF ECOLOGY (ECOLOGY)
The state agency which is responsible for developing, implementing, and enforcing many environmental protection laws and policies, including the state Clean Water Act and the Shoreline Management Act. Note that the abbreviation DOE is confusing because the federal Department of Energy uses the same term. Ecology is the preferred term for referring to the Department of Ecology.

WATER COLUMN
The water in a lake, estuary or ocean which extends from the bottom sediments to the water surface. The water column contains dissolved and particulate matter, and is the habitat for plankton, fish and marine mammals.

WATER QUALITY ACCOUNT see CENTENNIAL CLEAN WATER FUND

WATER TABLE
The upper surface of ground water or the level below which the soil is saturated with water.

WATERSHED
The geographic region within which water drains into a particular river, stream or body of water. A watershed includes hills, lowlands and the body of water into which the land drains. Watershed boundaries are defined by the ridges of separating watersheds.

WELLHEAD
The immediate area around the top of a well. Contamination of the aquifer may occur from surface water if the wellhead is not sealed to prevent flow down the well casing.

WETLANDS
Wetlands are defined on the first page of the Wetlands Protection Program.

ZONING
To designate by ordinances areas of land reserved and regulated for different land uses.

Links between the Growth Management Act and the Puget Sound Plan

Growth Management Act (direction on water quality)	1994 Puget Sound Water Quality Management Plan Element (direction on land use)
Comprehensive Plan "Where applicable, the land-use element shall review drainage, flooding and stormwater run-off in the area and nearby jurisdictions and provide guidance for corrective actions to mitigate or cleanse those discharges that pollute waters of the state, including Puget Sound or waters entering Puget Sound." (RCW 36.70A.070) Identify lands useful for public purposes, such as stormwater management, and a list of lands and their estimated acquisition dates, all to be reflected in the capital budget. (RCW 36.70A.150) Identify open space corridors, including lands useful for wildlife habitat and connecting critical areas. (RCW 36.70A.160)	Wetlands 2.1—Guidance on protecting wetlands through comprehensive plans. Nonpoint 2—Guidance on using the GMA to protect water quality from nonpoint pollution and for incorporating watershed action plans into comprehensive plans. Storm Water 1.5—Guidance for incorporating the local stormwater program into the comprehensive plan. Shellfish 2—Guidance on using comprehensive plans to protect commercial and recreational shellfish areas.
Development Regulations Each county and city shall adopt development regulations that protect critical areas, including wetlands, critical aquifer-recharge areas, fish and wildlife habitat conservation areas, frequently flooded areas, and geologically hazardous areas. (RCW 36.70A.060) Critical areas are to be designated by adopting a policy statement and locating them (classifying, describing general distribution, location and extent) or describing them through performance standards and identified during the permit process. (WAC 365-190-040)	Wetlands 2.1—Guidance on adopting development regulations to protect wetlands. Nonpoint 2—Guidance on implementing watershed action plans by using development regulations. Storm Water 1.5—Guidance for incorporating local stormwater programs into development regulations. Shellfish 2—Guidance on protecting commercial and recreational shellfish areas through development regulations.
Public Involvement Counties and cities shall involve the public in classifying and designating critical areas. (WAC 365-190-040)	Public Involvement 1—Guidance for local governments on public involvement in implementing the Puget Sound Plan.

VOL 12 2 3439

Growth Management Act (direction on water quality)	1994 Puget Sound Water Quality Management Plan Element (direction on land use)
Interjurisdictional Coordination "The comprehensive plan of each county or city...shall be coordinated with, and consistent with, the comprehensive plans...of other counties or cities with which the county or city has, in part, common borders or related regional issues." (RCW 36.70A.100)	Nonpoint 2—Guidance for jurisdictions sharing common watersheds to cooperate in analyzing the effects of pollution coming from diffuse sources and to adopt coordinated and consistent programs. Storm Water 1.5—Guidance for jurisdictions sharing common watersheds to cooperate in analyzing the effects of stormwater runoff and to adopt coordinated and consistent programs for managing storm water.

Section 6217 Coastal Nonpoint Management Measures Addressed through the Puget Sound Water Quality Management Plan

Management Measure	Related Puget Sound Plan Elements*
Agriculture	
Sediment/erosion control	AG-1, AG-3, WP-2, WP-4, WP-5, WP-6, EPI-2, EPI-8
Confined animal facility	AG-1, AG-2, AG-3, WP-2, WP-4, WP-5, WP-6, SF-2, SF-8, EPI-2, EPI-8
Nutrient management	AG-1, AG-3, WP-2, WP-4, WP-5, WP-6, EPI-2, EPI-8
Pesticide management	AG-1, AG-3, PS-2, WP-2, WP-4, WP-5, WP-6, EPI-2, EPI-8
Livestock grazing	AG-1, AG-3, WP-2, WP-4, WP-5, WP-6, EPI-2
Irrigation	AG-1, AG-3, WP-2, WP-4, WP-5, WP-6
Forestry	
Preharvest planning	FP-1, FP-2, FP-3, WP-2, WP-4, WP-6
Streamside Management Areas	FP-1, FP-3, WP-2, WP-4, WP-6, H-4
Road construction/repair	FP-1, WP-2, WP-4, WP-5, WP-6
Road management	FP-1, WP-2, WP-4, WP-6
Timber harvesting	FP-1, FP-3, WP-2, WP-4, WP-6
Site preparation/forest regeneration	FP-1, FP-3, WP-2, WP-4, WP-6
Fire management	N/A
Revegetation of disturbed areas	FP-1, FP-3, WP-2, WP-4, WP-6
Forest chemical management	FP-1, FP-3, WP-2, WP-4
Wetland forest management	WP-2, WP-4, WP-6
Urban	
New development	SW-1, SW-2, SW-3, SW-5, WP-2, WP-4, WP-6, SF-2
Watershed Protection/Site Development	WP-1 through WP-7, SW-1 through SW-5, SF-2, SF-8, FP-2, FP-3, NP-2, EPI-8
Construction erosion/sediment control	SW-1, SW-2, SW-3, SW-4, WP-2, WP-4, WP-6, EPI-5
Construction site chemical control	SW-1, SW-3, WP-2, WP-4
Existing development	SW-1, SW-2, SW-3, SW-4, WP-1 through 7, SF-8
New on site treatment systems	OS-1, OS-3, OS-4, OS-5, SF-2, WP-2, WP-4, WP-6, NP-2
Operating on-site treatment systems	OS-1, OS-2, OS-3, OS-4, OS-5, SF-8, WP-2, WP-4, EPI-2, EPI-5, EPI-8
Pollution prevention	EPI-1, EPI-2, EPI-5, EPI-8, HHW-1, HHW-2, OS-2, OS-3, PS-1, PS-2, WP-2, WP-3, WP-4, WP-6

* See Appendix C. Alphabetical Guide to Elements on page 257 for a description and location of element numbers.

R0056736

Management Measure	Related Puget Sound Plan Elements*
Siting roads, highways and bridges	SW-5
Construction projects for roads, highways and bridges (RHBs)	SW-5
Construction-site chemical control - RHBs	SW-5
Operation/maintenance for RHBs	SW-5
Runoff systems for RHBs	SW-5
Marinas & Recreational Boating	
Marina flushing	MB-2
Water quality assessment	MB-2, MB-7
Habitat assessment	MB-2, MB-7
Shoreline stabilization	N/A
Stormwater runoff	MB-2
Fueling station design	N/A
Sewage facilities	MB-2, MB-3, MB-4, MB-5, EPI-8
Solid waste	MB-3, MB-4, EPI-5, EPI-8
Fish wastes	N/A
Liquid material	MB-3, MB-4, EPI-2, EPI-8
Petroleum control	MB-4, EPI-2, EPI-8
Boat cleaning	MB-2
Public education	MB-1, MB-3, MB-4, EPI-1, EPI-2, EPI-8
Maintaining sewage facilities	MB-2, MB-3, MB-5
Boat operation	N/A
Hydromodification *Channel modification (dams, dikes, dredging, etc.)*	
Physical and chemical characteristics of surface waters	W-3, H-5, WP-2, WP-4
In-stream and riparian habitat restoration	W-8, H-2, H-5, H-6, SW-7, WP-2, WP-4
Dams	
Erosion and sediment control	N/A
Chemical and pollutant control	N/A
Protection of surface water quality and in-stream and riparian habitat	N/A
Streambank and Shoreline Erosion	
Streambank and shoreline erosion	W-1 through W-9, H-1 through H-6, M-2, WP-2, WP-4
Wetlands	
Protection of wetlands and riparian areas	W-1 through W-9, WP-2, WP-4
Restoration of wetlands and riparian areas	W-8, H-2, WP-2, WP-4
Engineered vegetated treatment systems	SW-3, SW-7, WP-2, WP-4

* See Appendix C. Alphabetical Guide to Elements on page 257 for a description and location of element numbers.

TO: All Holders of Volume 3 of the Urban Storm Drainage Criteria Manual

FROM: Chief, Master Planning Program

SUBJECT: Comments and Address Changes

DATE: September 28, 1992

Although much effort was spent on compiling this manual and in checking it for accuracy, invariably errors and inconsistencies were likely missed. Should you discover what you believe to be errors or would like to suggest changes, additions or improvements, we as you to write us at:

Urban Drainage and Flood Control District
2480 West 26th Avenue, Suite 156B
Denver, Colorado 80211-5500

Attention: Chief, Master Planning Program

As corrections and changes are made to this manual, the District will send them to all manual holders of record. Should your mailing address or the name of your organization change, please be sure to notify us. Most of the revisions will be sent to you free of charge, or for mailing cost only. But we will need your current address in order to provide you with our updates to this manual.

PREFACE

The purpose of Volume 3 of the *Urban Storm Drainage Criteria Manual (USDCM)* is to provide design guidance for local jurisdictions in selecting and designing best management practices (BMPs) for stormwater quality improvement. The guidance is intended for use by the public, local governments, builders, and land developers in commercial and residential areas and, to a somewhat limited degree, for use in industrial areas.

This volume of the USDCM covers an array of topics related to stormwater quality BMPs and is arranged to contain the following:

- An introduction to stormwater quality management that includes an overview of the manual and explains the selection and use of nonstructural and structural BMPs
- A discussion on stormwater quality and hydrology, urban runoff, and pollutant loadings
- Technical criteria for the structural BMPs recommended for consideration and use in developing residential and commercial areas in the Denver metropolitan area and other areas with similar climate and meteorology
- Technical guidance for structural BMPs that can be used in light industrial and certain commercial establishments (to be developed)
- A description of various nonstructural BMPs and how they may be implemented
- A collection of example structures and their details that could be used in stormwater quality facilities (to be developed)
- Guidance in the selection and use of erosion control practices during construction
- A section discussing ancillary uses of stormwater facilities and potential issues surround them (to be developed)

R0056750

The combined Bibliography section for this volume includes references for each chapter to show where additional materials on the topics presented in this manual may be found

The first volume of structural BMP criteria described in this manual is targeted at developing and redeveloping residential and commercial areas. As a result, the 1992 edition of this manual does not address BMPs for light industrial, or other types of land uses, which are being permitted directly by the State of Colorado or the U.S. Environmental Protection Agency. However, as BMPs for these land uses are evaluated and refined, or are promulgated by the State, they may be added to this manual. As a result, Volume 3 is expected to grow and change as the technology of stormwater BMPs matures and is refined over the coming years.

The format of Volume 3 was selected to permit incorporation of revisions and additions as they occur in the future. You can help by sending to us your comments about any changes or additions you would like to see and any corrections that need to be made. We look forward to hearing from you. In the meantime, we hope you find this document useful and of a benefit in your stormwater management endeavors.

The Urban Drainage and Flood Control District

VOL 1 2 2 3 4 5 9

ACKNOWLEDGEMENTS

The Urban Drainage and Flood Control District (District) wishes to acknowledge all individuals and organizations that contributed to the development and publication of the first edition, dated September, 1992, of the *Urban Storm Drainage Criteria Manual, Volume 3 - Best Management Practices (Manual)*. The list is too numerous to acknowledge everyone individually, for which we apologize. In addition to the organizations listed here, technical guidance and review were provided by many of the members of the Joint Task Force (see list) working or advising on, or assisting with, the preparation of municipal separate storm sewer discharge permit applications for the City and County of Denver, City of Aurora and City of Lakewood. We wish to acknowledge the assistance rendered by the members of this group, not only in the preparation of the *Manual*, but in helping to formulate an approach in how to pursue the development of municipal stormwater discharge permit applications.

The District specifically acknowledges the following organizations and individuals who contributed to the development and publication of this *Manual*:

Urban Drainage and Flood Control District - *Manual*

Ben R. Urbonas, P.E.	Editor-in-Chief and co-author of *Manual*
L. Scott Tucker, P.E.	Overall review of *Manual*
John T. Doerfer	Co-author - *Erosion Control* Lead author - *Nonstructural BMPs*
William DeGroot, P.E.	Technical and editorial review of *Manual*
David Lloyd, P.E.	Review - *Erosion Control*
Mark Hunter, P.E.	Review - *Erosion Control*
David Bennetts	Review - *Erosion Control*
Galene Bushor	Word Processing - *Nonstructural BMPs* and *Erosion Control*
Jay Carlson	Final camera-ready assembly of *Manual*

1. STORMWATER QUALITY CHARACTERISTICS AND SOURCES

1.1 General

Urban runoff contains many types and forms of pollutants – some occurring in higher concentrations than found in runoff before development and some that are not naturally present in surface runoff from undeveloped land. Runoff from undeveloped basins contains sediment particles, oxygen-demanding compounds, nutrients, metals, and other constituents. Once developed, pollutant loads increase because surface runoff volumes increase and the sources of many of these pollutants also increase. Also, additional sources of pollutants exist in a basin and find their way into runoff. They may include the following:

- Metals, lubricating compounds, and other constituents originating from vehicles, machinery, and industrial and commercial activities
- Pesticides, herbicides, and fertilizers
- Household solvents, paints, roofing materials, and other such materials
- Pet litter, garbage, and other debris
- Suspended solids washed off impermeable surfaces
- Increased soil erosion during construction activities

A phenomenon termed *first flush* has been discussed for a number of years resulting in mixed conclusions. The first flush represents the higher levels of initial concentrations of constituents that are washed off from a surface at the very beginning of a rainfall event. Some reports include a first flush because of atmospheric fallout that accumulates before a storm occurs. Other reports conclude that there is no first flush, or an insignificant first flush of pollutants in separate, namely, not combined sewer, stormwater runoff. However, by designing facilities to capture and treat the majority of runoff events, first flush becomes irrelevant because it will be captured if it exists. At the same time, most storms will be captured in total if it does not exist.

R0056761

1.2 Typical Constituent Concentrations in Urban Runoff

The most recent urban stormwater runoff data for the Denver metropolitan area were collected under an Environmental Protection Agency (EPA)-funded effort by the U.S. Geological Survey (USGS) in 1979 and 1980 (EPA, 1983). The summary of findings is reported in the Denver Regional Council of Governments report, *Urban Runoff Quality in the Denver Area*, dated September 1983. Table 1-1 summarizes the findings for the average event mean concentrations (EMCs) for 15 constituents from residential, commercial, and undeveloped land uses. These results may be somewhat different in stormwater runoff sampled today and will probably need to be revised when new data are available.

2. OVERVIEW OF BEST MANAGEMENT PRACTICES

2.1 Nonstructural and Structural BMPs

Urban stormwater runoff has been documented to contain a variety of constituents that originate from a number of different sources. When certain constituents are present in harmful amounts, the potential exists for adverse effects on receiving waters.

Studies such as the Nationwide Urban Runoff Program (EPA, 1983) and the Denver Regional Urban Runoff Program (DRCOG, 1983) have documented concentrations of various constituents in urban stormwater. To reduce the concentrations and the loads of these constituents that reach the receiving waters, various BMPs have been suggested. These BMPs fall into the following two primary categories that include erosion controls during construction:

- Nonstructural–Including the subcategories of pollution prevention BMPs and source control BMPs
- Structural–Including facilities constructed to passively treat urban stormwater runoff before it enters the receiving waters.

The most cost-effective nonstructural BMP is to prevent the disposal of pollutants on the urban landscape and to minimize the migration of pollutants offsite from the point where they are being used, stored, or otherwise being exposed to stormwater. Measures that can prevent deposition of pollutants include public education to reduce improper disposal of household toxics, trash, pet droppings, and used oil. Nonstructural source controls include administrative programs, preventing and controlling erosion during construction, street sweeping, and modified street maintenance practices. Nonstructural source controls used to isolate pollutants from stormwater include covering contaminated areas such as service center gasoline pump islands. Source control BMPs are sometimes termed as "good housekeeping" measures because a clean site will produce less stormwater contamination than will a dirty one. These and other nonstructural BMPs are further addressed in a separate section of this volume.

Structural BMPs are facilities used to reduce runoff and/or remove pollutants from runoff. Examples of structural BMPs are erosion control and sediment entrapment facilities during construction, water

R0056764

quality detention (both dry basins and wet ponds), wetlands, porous pavement, and the use of vegetated zones. These BMPs may treat small volumes of stormwater on development sites or serve larger regional drainage areas. Removal is accomplished by adsorption, settling, precipitation, infiltration, filtration, and/or biological activity.

2.2 Stormwater Quality Management Strategy

The selection of the most appropriate BMP categories within a municipality is, for the most part, determined by whether development is in place or has yet to occur. In areas with existing development, relying on nonstructural BMPs is most cost-effective because retrofitting structural controls into a developed area can be very expensive; that is, $3,000 to $20,000 per acre of tributary watershed. Structural controls are more appropriate for new development and significant redevelopment, particularly when they are integrated into the initial planning and design of municipal infrastructure and private development. Figure 2-1 provides a decision flow chart to help one decide when to consider structural and nonstructural BMPs.

Structural BMPs are most cost-effective when included in the planning stages of development. It is recommended that the structural BMPs presented in this manual be integrated into stormwater management planning by public entities and into the site planning process by land developers. Structural BMPs can also be used, in a cost-effective manner, whenever redevelopment or significant improvement occurs within fully developed areas.

An effective strategy for reducing stormwater pollution loads is to use multiple BMPs, including nonstructural measures, source controls, and structural BMPs. A single practice and/or facility cannot generally provide significant reductions in stormwater pollutant loads because these pollutants come from many sources within a municipality. Also, multiple BMPs can provide complementary water quality enhancement to achieve desired results. A multilevel BMP approach, schematically depicted in Figure 2-2, deals with the many pollutant and runoff sources throughout a watershed and shows that whenever feasible, combining most effective BMPs in a series can be an effective strategy to reduce pollutant loads being transported to the receiving waters by stormwater.

2.3 Erosion Control During Construction

Control of construction activities are critical in stormwater quality management. During the relatively short period of time when land is converted from undeveloped to urban uses, a significant amount of

R0056765

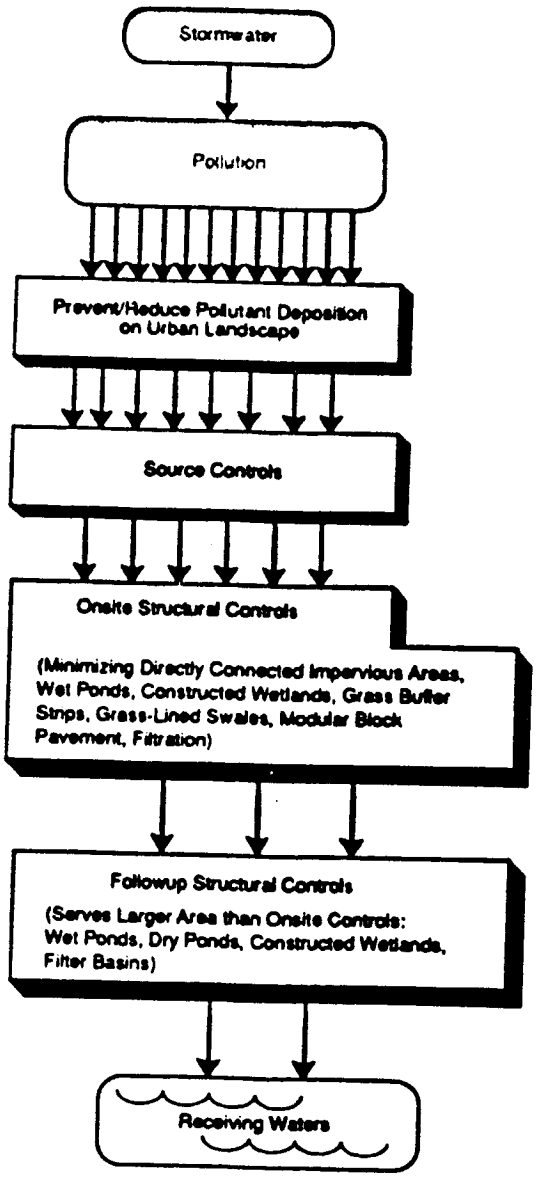

FIGURE 2-2. MULTI-LEVEL STORMWATER QUALITY MANAGEMENT STRATEGY

R0056767

VOL 12 2 3473

sediment can erode from a construction site and be transported to adjacent properties and to receiving waters. If measures are not taken to reduce erosion and to capture sediment in runoff from construction sties, damage can occur to offsite areas and to aquatic habitats in the receiving water system.

Methods are available to limit erosion and sediment losses from a construction site. One of the most effective is to prevent erosion from occurring. Oftentimes large areas are excavated or graded at one time in preparation for construction of site facilities and buildings. By limiting the amount of disturbance that occurs to the landscape at any given time, soil erosion is reduced. Prevention, along with the application of erosion control practices to all areas disturbed during construction, can significantly reduce soil erosion. Finally, the installation of sediment trapping devices at construction sites will ensure that soil erosion and sediment transport offsite is controlled to the maximum extent practicable.

There are many structural and nonstructural options available in the design of an erosion and sediment control plan. It is recommended, however, that the erosion and sediment control plan be developed consistent with the postdevelopment stormwater management goals of the site. Opportunities often exist for converting temporary sediment control structures into permanent structural stormwater BMPs at the end of the construction phase. These options should be explored by the designer of an erosion control plan, final site BMPs, and their eventual owners.

Regardless of the specific details used in an erosion control plan, the goal is to implement erosion and sediment control as a standard practice at all construction sites, and to incorporate it as an integral part of any stormwater quality management strategy. To facilitate sound erosion and sediment control practices during construction, technical criteria were developed, along with a model ordinance for their implementation by local municipalities. These criteria and the model ordinance are contained in the *Erosion Control* chapter of Volume 3 of this Urban Storm Drainage Criteria Manual (USDCM).

VOL 12 2 3475

3. USE OF STRUCTURAL BMPs

3.1 Primary Structural BMPs

The structural BMPs listed below were selected after an exhaustive screening of known structural BMPs with representatives of a number of cities and counties in the Denver metropolitan area. Final selection by this group was based on the review of documentation on potential effectiveness in a semiarid climate, local applicability, maintenance considerations and cost. The following BMPs were the ones selected for initial use in the Denver metropolitan area:

- Minimizing directly-connected impervious areas
- Grass buffer strips (irrigated)
- Grass-lined swales
- Extended-detention basins (dry)
- Retention ponds (wet)
- Constructed wetlands
- Modular block porous pavement

Several of the other BMPs that were investigated showed promise, but need further studies to determine their pollutant removal effectiveness in a semiarid climate and to develop cost-effective design criteria to insure that they are properly designed, constructed, and maintained. As additional BMPs are field tested, and as supporting information becomes available, they may be added to this manual. Additional structural BMPs that were also considered, but not included in the September 1992 edition, were sand filters, infiltration basins, and percolation trenches.

The experience in structural BMP design, construction, and maintenance, and the resulting cost per pound of pollutants removed, are limited. The seven structural BMPs presented in this manual are known to be effective in reducing the pollutant loads being transported to the receiving water system. Their true effectiveness, however, will depend on a number of variables, some of which have yet to be identified. As the performance of these and other BMPs are documented and assessed over the coming years, more cost-effective selection, design, and maintenance guidance will be possible.

R0056769

VOL 1 2 2 3 4 7 6

3.2 Objectives in the Use of Structural BMPs

The goal of this chapter is to provide planners, engineers, and developers with guidance on how to select structural BMPs for specific projects. Specific BMPs should be implemented with the following objectives in mind:

- An effective level of urban pollutant removal
- An appropriate BMP for the site, given the site's physical constraints
- A reasonably cost-effective BMP in comparison with other BMPs
- A reasonable (that is, not excessive) future maintenance burden
- Minimize, to the maximum extent practical, impacts on receiving waters
- Whenever possible, provision for multiuse benefits, such as parks, green spaces, and landscaping features

3.3 Structural BMP Effectiveness

When selecting the BMPs that are appropriate for a particular site, one needs to consider their pollution-removal efficiencies. Table 3-1 presents the ranges of the removal efficiencies reported in literature for a number of structural BMPs. Although combinations of nonstructural/structural BMPs can improve the overall water quality of the runoff, the effectiveness of several BMPs in their ability to reduce influent pollutant concentrations as a group are not directly additive.

Removal rates by an individual structural BMP are related to the influent stormwater characteristics and the initial concentrations of the constituents in stormwater. For instance, Figure 3-1 shows that in laboratory settling tube experiments with stormwater, the percentage of removed total suspended solids (TSS) increased as the influent concentration increased. Although not shown on Figure 3-1, removal of TSS reaches its lowest point when the initial concentration of TSS is about 10 parts per million (ppm) and it is virtually not possible to discharge water with lower TSS concentrations. At the

R0056770

VOL 1 2 2 3 4 7 7

same time, the greatest percent removal in the least amount of time is achieved when initial TSS concentrations are 100 milligrams per liter or more.

3.4 Pollutant Removal Mechanisms

Although runoff may contain many individual pollutants, pollutants are grouped into two general categories in this manual: particulate and soluble. Even though the exact boundary between the two does not need to be defined at this level of design, the boundary lies somewhere around the equivalent particle diameter of 0.4 micron (for example, very fine clays). In many cases, constituents (such as metals and oxygen demand compounds) become adsorbed or attached to particulate matter. Therefore, if the particulate matter is removed, so are the adsorbed or attached constituents.

One, or a combination of up to four basic pollutant removal or immobilization mechanisms, are used by the suggested BMPs to treat stormwater runoff for water quality enhancement. The following is a brief overview of each mechanism:

1. **Sedimentation**–Particulate matter is, in part, settled out of urban runoff. Smaller particles under 60 microns in size (fine silts and clays) (Stahre and Urbonas, 1990) can account for approximately 80 percent of the metals in stormwater attached or adsorbed along with other contaminants and can require long periods of time to settle out of suspension. Fortunately, extended detention allows smaller particles to agglomerate into larger ones (Randall et al, 1982), and for some of the dissolved and liquid state pollutants to adsorb to suspended particles, thus removing a larger proportion of them through sedimentation.

2. **Filtering**–Particulates are removed, in part, from water by filtration. Filtration removes particles by attachment to small-diameter collectors such as sand.

3. **Infiltration**–Pollutant loads in surface runoff are removed or reduced as surface runoff infiltrates or percolates into the ground. Particulates are removed at the ground surface by filtration, while soluble constituents can be adsorbed into the soil, at least in part, as the runoff percolates into the ground. Site-specific soil characteristics, such as permeability, cation exchange potential, and depth to groundwater or bedrock limit the number of sites where this mechanism can be used effectively.

R0056773

VOL 12 2 3480

4. **Biological Uptake**–Plants and microscopic animals require soluble constituents such as nutrients and minerals for growth. Soluble constituents are ingested or taken up from the water column and concentrated through bacterial action and phytoplankton growth. In some instances, plants could be harvested to remove the constituents permanently. In addition, certain biological activities can reduce toxicity of some pollutants and/or possible adverse effects on higher aquatic species. Unfortunately, not much is understood yet about how biological uptake or activity interacts with stormwater during the relatively brief periods it is in contact with the biological media in most BMPs, with the possible exception of retention ponds between storm events (Hartigan, 1989).

3.5 Structural BMP Selection and Use Guidance

Not all of the structural BMPs presented here are suitable for application at all locations and sites. Their applicability depends on the following:

- The permeability and types of soil underlying the BMP
- The size of the watershed area served and the generated runoff volume in relation to the size of the BMP
- The slopes and geometry of the site
- The amount of base flow (surface water or groundwater)
- The proximity to bedrock to the surface
- The proximity to the seasonal high groundwater table to the surface
- Land uses
- The ability to handle high sediment loads
- The presence or absence of turf irrigation

R0056774

Table 3-2 compares the benefits for the primary structural BMPs. The table can be used for general guidance on structural BMP selection. More specific guidance for selecting a particular BMP is presented in the *Structural BMPs* chapter of this volume. It is suggested that the designer complete Worksheet 3-1 before attempting to select the BMPs to use in final design.

4. USE OF NONSTRUCTURAL BMPs

4.1 Primary Nonstructural BMPs

A number of nonstructural BMPs for potential use in urban areas were identified. After evaluating these for effectiveness, feasibility of implementation, cost, and maintenance, a group of local government representatives recommended the following as the nonstructural BMPs for inclusion in this manual:

- Stormwater quality control planning for new developments and redevelopment
- Adoption of stormwater BMP criteria and standards, including standards for erosion and sediment control during construction
- Guidelines and educational programs covering the proper disposal of household waste, litter, pet waste, yard waste, and toxic waste
- Guidelines of pesticides, herbicides, and fertilizer application
- Suggestions on monitoring and elimination of illicit discharges, management of spills, and illegal connections to storm sewer systems
- Landscaping and vegetation practices

The first two items above address the practices and standards associated with new developments and areas undergoing redevelopment. The remainder are applicable to developed areas, whether new or old.

Other nonstructural BMPs were considered for inclusion in this manual, but were deemed at this time to be inappropriate to use, for local governments to require their use by others, or were judged to be ineffective in controlling sources of pollution. Additional nonstructural measures will be examined in the future, and if they prove to be promising in reducing the amount of pollutants being delivered by stormwater to the receiving water system, they will be included in future editions of this manual.

R0056778

VOL 1 2 2 3 4 8 5

4.2 Objectives in the use of Nonstructural BMPs

To be effective, nonstructural BMPs need to prevent or reduce the sources of stormwater pollution. They fall into the general categories of prevention and source controls as listed in Figure 2-2. Preventing and controlling the source of pollutants that come in contact with stormwater requires a change in the behavior of the urban population and in the waste disposal practices they employ.

The objectives for promoting the use of nonstructural BMPs are as follows:

- Improve the quality of receiving waters
- Consistency with stormwater quality objectives
- Consistency with structural BMPs
- Cost effectiveness
- Widespread applicability in all urban areas
- Widespread public acceptance

4.3 Nonstructural BMP Effectiveness

The effectiveness of nonstructural BMPs is very difficult, if not impossible, to assess in quantitative terms. Data is unavailable on the baseline amounts of chemical usage in residential and commercial areas, the amounts attributable to improper usage or disposal, the amounts that are washed off by stormwater from these sources, and the level of public participation that will result from implementation of nonstructural programs. As a result, the assessment of their effectiveness is only as accurate as the assumptions made by those making such assessments. It is anticipated that with time, sufficient research will take place to provide data and statistical correlations addressing these questions, which will provide guidance for more quantitative assessments.

The recommendations for the use of nonstructural practices included in this manual are based on the intuitive presumption that some level of water quality improvement will be realized if these practices are implemented. In addition, preventing or reducing the amount of pollutants on the urban landscape have to be more cost effective than attempting to remove these from stormwater using structural controls. It can also be argued that aggressive use of nonstructural measures will reduce concentrations and loads of various pollutants in stormwater being conveyed to downstream structural BMPs or to the receiving waters. This is especially the case in existing urban areas where structural

R0056779

VOL 1 2 2 3 4 8 6

controls cannot be easily built, or are extremely expensive to retrofit into the fully-developed urban landscape.

4.4 Pollutant Removal Mechanisms

Nonstructural BMPs can, to some degree, prevent the deposition of pollutants on the urban landscape or remove pollutants at their source. The source of pollutants for assimilation into stormwater is the land surface itself, especially the impervious surfaces in the urban area. Thus, it is hoped that when nonstructural measures are effectively implemented, they will reduce the amount of pollutants being deposited on land surfaces for eventual contact with stormwater and transport to the receiving water system.

4.5 Nonstructural BMP Selection and Use Guidelines

Most nonstructural BMPs are applicable for use in residential, commercial, and industrial areas. This can be said for newly developing areas, recently redeveloped areas, and old neighborhoods as well.

For newly developing and redeveloping areas, nonstructural BMPs include municipal programs to ensure that new urban development and redevelopment incorporates appropriate erosion and sediment control during construction and also construct structural BMPs as a part of the development. Such municipal programs include institutional mechanisms that require the proponents of a new development to prepare and submit stormwater quality control management plans in accordance with the municipality's stormwater BMP design criteria and standards, including the erosion control and stormwater management during construction. These programs need adequate staff and fiscal resources to review and approve development plans and to ensure that the approved stormwater quality provisions of these plans are properly implemented.

The remaining nonstructural BMPs described in this manual, namely those targeted at developed areas, rely primarily on public education and possible enforcement programs. In selecting the appropriate nonstructural pollutant reduction programs to adopt, each municipality needs to evaluate its current land-use condition and the potential for removal of pollutants offered by each of these practices. The specifics for selection and use of each nonstructural BMP effort are described in the *Nonstructural Best Management Practices* chapter of this manual.

R0056780

VOL 1 2 2 3 4 8 7

5. STORMWATER QUALITY HYDROLOGY

5.1 Overview

Urbanization affects stormwater runoff by increasing the following:

- The volumes and rates of surface runoff
- The concentrations and the types of pollutants found in stormwater
- The loads of pollutants carried and their transfer rates to receiving waters

Urbanization leads to a decrease in pervious land areas, an increase in impervious areas, and enhanced efficiency of surface runoff. The influx of commercial, residential, and industrial products into an urban area often brings new pollutants that result in concentrations of these pollutants in stormwater greater than before urbanization has occurred. Additional impervious areas can make pollutants more easy to wash off the surface and quicken their conveyance through the watershed. The cumulative effect is that urbanization results in much larger loads of all constituents being washed off than would otherwise occur from nonurbanized land (with the possible exception of nutrients found in runoff coming from irrigated agricultural land), and in the delivery of certain pollutants, such as petroleum-based products not normally found in nonurban and nonindustrial runoff.

The rate of runoff and the extent of pollutant loads depend on the hydrologic conditions that lead to stormwater runoff. Some investigators hypothesize that pollutant loads being delivered by the urban stormwater system are affected by the period between storms (storm separation). They suggest that this period provides time for pollutants in the atmosphere and from other sources to build up on impervious areas. However, the Denver Urban Runoff Evaluation Program studies (Mustard et al., 1985) conducted by the USGS did not support this hypothesis beyond a 2- to 5-day dry buildup period. This is not to say that the above-mentioned hypothesis is not true for other regions of United States.

5.2 Denver Area Precipitation Statistics

Studies of the precipitation records for 36 years from the Denver Stapleton Raingauge have revealed several pertinent hydrologic features. Analyses show that the average storm has an 11-hour duration and that the average time interval between storms (storm separation) is 11.5 days. However, the

R0056781

great majority of storms are less than 11 hours in duration. The limited number of extended rainfall periods within the data base tend to increase this average. Table 5-1 summarizes the relationship between total storm depth and the annual number of storms. As the table shows, about 46 of a total of 75 storm events that occur on an annual average basis, or 61 percent, have less than 0.1 inch of precipitation. These storms produce practically no runoff. The table also shows that about 22 of the 30 remaining runoff-producing events, or 75 percent, total between 0.1 inches and 0.5 inches of depth. If runoff can be controlled from most of the storms that range 0.1 inches to 0.5 inches in precipitation, the overall treatment of stormwater runoff in the Denver region should be very effective.

Table 5-1

Number of Rainfall Events in the Denver Area

Total Rainfall Depth (inches)	Average Annual Number of Storm Events
0.0 to 0.1	46.
0.1 to 0.5	22.
0.5 to 1.0	4.7
1.0 to 1.5	1.5
1.5 to 2.0	0.60
2.0 to 3.0	0.30
3.0 to 4.0	0.19
4.0 to 5.0	0.028
>5.0	0
Total	75.318

5.3 Diminishing Returns with Increasing Size of Design Storms

The above analysis and other studies indicate that small-sized, frequently occurring storm events account for the predominate number of events that result in stormwater runoff and the pollution of receiving waters. Consequently, these frequent storms also account for a significant portion of annual pollution loadings from an urban watershed. Capture and treatment of the stormwater from these small and frequently occurring storms is the recommended design approach for water quality enhancement, as opposed to flood control facility designs that focus on less frequent, larger events. Incorporating both sets of criteria into a single stormwater management facility is not only possible,

VOL 1 2
2 3 4 8 8
R0056782

VOL 1 2 2 3489

but is encouraged. Whenever practicable, combining several objectives, such as water quality enhancement and flood control, maximizes the cost-effectiveness of stormwater management facilities.

The analysis of precipitation data collected from 1948 through 1984 (36 years) at the Denver Stapleton Rain Gauge revealed a relationship between the percent imperviousness of a basin, and the capture volume needed to significantly reduce stormwater pollutants (Urbonas, Guo, and Tucker, 1990). As a result of these studies, water quality facilities are recommended to capture and treat the 80th percentile runoff event. Capturing and properly treating this volume was estimated to remove between 80 and 90 percent of the annual TSS load, while doubling the capture volume was estimated to increase the removal rate by only 1 to 2 percent.

While bigger may appear to be better in the case of stormwater quality, larger basins can provide less holding time for the predominant number of smaller storms. Larger basins can result in less net reduction of pollutants than is obtained when using the recommended 80th percentile capture volume obtained from Figure 5-1. Storms larger than the 80th percentile events still receive some treatment when their capacity is exceeded by larger storms, but at a somewhat lower efficiency. Thus, the law of diminishing returns for cost-effective pollutant removal takes effect, not only because of the large number of small storms found in the total population of storms, but because pollutant removal continues to occur in in-line capture basins when the runoff exceeds their design capacity.

5.4 Determining the Water Quality Capture Volume

5.4.1 Use of Directly Connected Impervious Area. The procedures described in the *Rainfall* and in the *Runoff* chapters of Volume 1 of the *USDCM* are intended for the design of drainages and flood facilities that prevent damage to property and help protect human life. These procedures show that the depth of rainfall produced from a design storm varies somewhat throughout the Denver region and that runoff is a function of total imperviousness. Water quality enhancement focuses more on the smaller events that deliver frequent flow pulses and pollutant loads to the receiving waters. The runoff volume for smaller events is especially sensitive to the impervious area that is hydraulically connected to the stormwater runoff system.

The impervious portion of a watershed determines the runoff volume that needs to be used for the design of water quality facilities, and the percentage of impervious surface therefore becomes important in the design of structural BMPs. The methodology for calculating basin imperviousness is presented in the *Runoff* chapter of Volume 1 of the *USDCM*. This procedure needs to be modified,

R0056783

VOL 1 2

however, when using the practice of *minimizing directly connected impervious areas* in combination with *extended detention basins, retention ponds, wetlands*, and other practices depended on a design capture volume. Whenever applicable, the needed modifications are described in the appropriate *Structural BMP* section.

5.4.2 Water Quality Capture Volume. Extended detention facilities (dry), retention ponds (wet), and wetland basins should be designed to capture and treat runoff equal to the 80th percentile event. This is achieved by draining the design capture volume over a specified time. Extended detention basins need to be designed to drain their design volume in approximately 40 hours. Retention ponds require only a 12-hour drain time because the sedimentation process is more efficient and some mixing and dilution between a permanent dry weather pool and storm runoff occurs. The wet pond also provides for treatment between storms, which provides long periods of time for fine particles to settle out and for biological activity to occur. Wetland basins should be designed to drain the design capture volume in no less than 24 hours, thereby providing for some biological uptake during the contact time with wetland media.

Infiltration-type structural BMPs such as porous pavement shall be designed to capture and treat the runoff from at least a 2-year storm. The use of a 2-year storm is also recommended for the design of slow-moving grass-lined swales and of wetland channels.

The following is a step-by-step procedure for determining the water quality capture volume needed to size extended detention basins, retention ponds, and wetland basins:

1. Determine basin imperviousness.

2. Select either a 12- or 40-hour brim-full volume drain time for the proposed facility. Use a 40-hour detention time for extended detention basins and a 12-hour detention time for retention ponds. For wetland basins, use the arithmetic average of the 12- and 40-hour drain time volumes.

3. Estimate the brim-full storage volume in watershed inches of runoff from Figure 5-1.

2 3490

R0056784

4. Determine the water quality capture volume (WQCV) in acre-feet as follows:

$$WQCV = \left(\frac{\text{Required Storage}}{12}\right)(\text{Area})$$

In which,

Required Storage = Required storage from Figure 5-1 in watershed inches

Area = The tributary drainage area upstream of the water quality enhancement facility in acres

1. INTRODUCTION

1.1 Overview

This chapter contains guidance for the design of structural BMPs. This guidance addresses the following items for each BMP:

- Description of the practice
- General application
- Advantages and disadvantages
- Site suitability
- Potential pollutant removal rates
- Design considerations and criteria
- Maintenance requirements
- Cost estimating guidelines

The following BMPs are covered in this chapter:

- Minimizing Directly Connected Impervious Areas
- Irrigated Grass Buffer Strips
- Grass-Lined Swales
- Extended-Detention Basins (dry basins)
- Retention Ponds (wet ponds)
- Constructed Wetlands
- Modular Block Porous Pavement

1.2 Advantages of Using Structural BMPs

Structural BMPs offer the following advantages in newly developing and redeveloping urban areas:

- Enhance stormwater runoff quality
- Can sometimes reduce runoff volumes through infiltration and interception

R0056792

VOL 12 2 3499

- Can reduce peak rates of runoff, especially for smaller storms, by capturing and slowly releasing urban runoff
- Can often be combined with drainage and flood control facilities at very little added cost over the cost of providing facilities for drainage and flood control alone
- Can be constructed first and then be used to control erosion and sedimentation during construction of the remainder of the site
- Can often be combined with other municipal uses such as active and passive recreation, open space, and wildlife habitat
- Can sometimes integrate BMPs into site landscaping to supplement irrigation of vegetation

1.3 Disadvantages of Structural BMPs

The following disadvantages can be associated with structural BMPs:

- Structural BMPs require land and can sometimes limit the density of a new development or redevelopment
- BMPs require ongoing maintenance and will need to be regularly inspected and regulated by each city and county to insure they are properly maintained and are performing as designed
- The use of structural BMPs requires a change in well-established traditional design practices, which will require training and a change in attitudes by municipal officials, planners, engineers, and developers
- BMPs require increased initial capital expenditures to incorporate into a development
- Standing water in BMPs can lead to nuisance problems, such as odors, breeding of mosquitos, and nesting areas for water fowl, as well as potential safety concerns

R0056793

- Disposal of deposited sediments will be needed. Unless the sediments are known to be badly contaminated and require disposal to appropriate types of landfills, they probably could be disposed of as land applications at less formal sites.

- When used for erosion and sedimentation control during construction, BMPs will need to be cleaned out and restored to their original design configuration after construction is completed.

2. MINIMIZING DIRECTLY CONNECTED IMPERVIOUS AREAS

2.1 Description

Minimizing directly connected impervious areas (DCIAs) is a structural BMP strategy that requires a basic change in drainage design philosophy. This change in drainage strategy directs stormwater runoff to landscaped areas, grass buffer strips, and grass-lined swales to slow down the rate of runoff, reduce runoff volumes, attenuate peak flows, and encourage filtering and infiltration of stormwater. Traditional land development practices that do not focus on water quality enhancement promote runoff from rooftops, parking lots, driveways, and roads to quickly flow to a curb and gutter and to a formalized stormwater conveyance system. This practice concentrates runoff quickly, which results in a fast responding system and relatively large peak runoff rates. Minimizing DCIAs can reduce the size of onsite and regional water quality enhancement facilities and the size of downstream conveyance systems. When integrated into new landscaping plans, minimizing DCIAs can divert some of the rainwater to irrigate vegetation by using the runoff from impervious areas.

2.2 Levels of Minimized DCIA Application

Minimizing DCIAs is an onsite stormwater management technique to help improve water quality and to reduce the pollutant load being flushed downstream. It can be made an integral part of drainage planning for any development. Roof collection systems can direct flow to landscaped areas, infiltration areas, grassed buffer strips, and to grass swales. Instead of using solid curbing, slotted curbing could be used along with stabilized grass shoulders and swales. Residential driveway runoff can be redirected from flowing directly into the street. Large parking lots can reduce DCIAs by using modular block porous pavement in less used portions of the lot to encourage local infiltration or storage.

Minimizing DCIAs can be implemented in varying degrees. Three general levels associated with minimizing DCIAs have been identified for the purpose of this manual and are described below:

- Level 1. The primary intent is to direct the runoff generated by impervious surfaces to flow over grass-covered areas, and to provide sufficient travel time so as to encourage the removal of suspended solids before runoff leaves the site, enters a curb and gutter, or enters another stormwater collection system. Thus, at Level 1, *all* impervious

R0056795

surfaces are made to drain over grass buffer strips before reaching a stormwater conveyance system.

- Level 2. As an adjunct to Level 1, this level replaces street curb and gutter systems with low-velocity grass-lined swales and pervious street shoulders. Conveyance systems and storm sewer inlets will still be needed to collect runoff at downstream intersections and crossings where stormwater flow rates exceed the capacity of the swales. Small culverts will be needed at street crossings and at individual driveways until inlets are provided to convey the flow to a storm sewer.

- Level 3. In addition to Levels 1 and 2, this level oversizes swales and configures driveway and street crossing culverts to use the grass-lined swales as elongated detention basins having at least the water quality capture volume, but preferably to have additional volume sufficient to also detain the 2-, 5-, 10-, or 100-year runoff. This further slows runoff and provides an added opportunity for infiltration.

By minimizing the DCIAs, runoff volumes from the site should decrease. This decrease translates into reduced demands on downstream stormwater capture basins and stormwater conveyance facilities, at least for storms with return periods of 2 years or less. Initial studies by the Urban Drainage and Flood Control District resulted in the development of Figure 2-1, which relates the total imperviousness in a tributary watershed to the "effective" imperviousness when the DCIAs are minimized within a development to the greatest extent possible, namely Level 3. Figure 2-1 may be used when performing hydrologic calculations and when estimating the required capture volume using Figure 5-1 of the *Stormwater Quality Management* chapter of this volume.

The use of Figure 2-1 is limited to the 2-year and lesser storm events. It should not be used for estimating runoff for larger events. Also, if less than Level 3 of minimizing DCIAs is being used, the *net reduction in imperviousness* shall be reduced using the multiplier provided in Table 2-1.

Note: Use this figure in conjunction with Figure 5-1 of the *Stormwater Quality Management Chapter.*

FIGURE 2-1. IMPERVIOUSNESS TO USE WITH WATER QUALITY CAPTURE VOLUME CHART

R0056797

VOL 1 2 2 3504

Table 2-1

Multiplier to Apply Against *Net Reduction in Imperviousness* for Levels 1 and 2

Level of Minimized DCIA Practice	Factor by which the *Net Reduction in Imperviousness* Needs to be Multiplied
Level 1	0.25
Level 2	0.50

As an example, if a single-family residential site with a total imperviousness of 40 percent is minimizing DCIA, the effective imperviousness is 24 percent and the *net reduction in imperviousness* for Level 3 is 40% - 24% = 16%. For Level 1 practice, this then becomes 0.25 x 16 = 4%, and for Level 2 practice, this becomes 0.5 x 16 = 8%. Thus, the final effective imperviousness of the development for use in the design of downstream followup structural BMPs and storm drainage systems conveying up to the 2-year floods become as follows:

Practice Level	Effective Imperviousness
Level 1	36% (i.e., 40% - 4%)
Level 2	32% (i.e., 40% - 8%)
Level 3	24% (i.e., directly from Figure 2-1)

As the storm size increases, the effects of reducing DCIAs diminishes, and in Denver's semi-arid climate, probably disappears around the 10-year storm. Thus, some credit for minimizing DCIAs can be taken for up to a 5-year storm. To do so for a 5-year storm, calculate the peak flow using the effective imperviousness obtained from the above described procedure and do so again using total imperviousness of the watershed. For the design of a 5-year system, use the average of the two peak flows.

R0056798

VOL 1 2 2 3505

2.3 Advantages/Disadvantages

2.3.1 General. A primary advantage of minimizing DCIA is that it decreases runoff peaks, volumes, and pollutant loads at their source. It has a low capital cost. Its use has the potential for decreasing the size of downstream conveyances and treatment facilities through volume reductions and attenuation of flow rates.

The primary disadvantage of minimizing DCIAs is the potential increase in site open space requirements over the traditional development systems and the introduction of a nonconventional development design strategy. Infiltration of water near building foundations and parking lots is a concern that also needs to be considered for certain types of soils and sites.

This practice will likely result in increased maintenance along the swales, which may be offset somewhat by the reduced capital cost of downstream drainage system and its maintenance.

2.3.2 Physical Site Suitability. Site slopes should be capable of directing stormwater runoff by gravity in a sheet flow away from buildings, roads, and parking lots toward grass-covered areas. The runoff then needs to flow as a sheet over these grassed areas before it reaches swales, storage, stormwater collection, and stormwater conveyance systems. As a result, in areas of high permeability soils (Hydrologic Soil Class A and B soils), the ground can provide for infiltration of significant portions of surface runoff.

Steep sites with average terrain slopes exceeding 3 to 4 percent may not lend themselves well to implementing this BMP. Some of the difficulties can be dealt with by using terracing and retaining walls, which can increase costs, however, most sites with general terrain slopes flatter than 3 to 4 percent should be suitable for this BMP; the flatter the better.

2.3.3 Pollutant Removal. The amount of pollutant removed by the use of this BMP is not measurable. It is related, however, to the degree that this practice is employed. Projects with less impervious areas have the greatest potential for reducing pollutant loads. Combining this BMP with a number of other structural BMPs can result in the greatest potential for minimizing pollutant loads. Implementation of this BMP can also help reduce the erosion potential in downstream channels.

R0056799

VOL 1 2 2 3506

2.4 Planning Considerations and Design Criteria

As discussed above, minimizing DCIA is a design strategy. Figure 2-2 compares traditional site and street drainage design and the strategy of minimizing DCIA. Traditional designs often convey water offsite as quickly as possible and by the shortest route. Minimizing DCIA slows down the rate of runoff leaving the site by directing flow onto grass-covered surfaces before runoff leaves the site.

Specific design guidance for grass filter strips and grass-lined swales that are an integral part of minimizing DCIA are presented in Sections 3 and 4 of this chapter. The following are some of the specific site layout and landscaping considerations that need to be used when minimizing DCIA:

- Design the site drainage flow path to maximize flow over vegetated areas before leaving a site and entering the street gutter or other collection system. Occasional check dams, berms, terracing, and maximized infiltrating areas can enhance water quality leaving a site.

- Minimize ground slopes to limit erosion and slow down the flow, especially around areas with exposed soil such as flower beds or gardens. Stepped terraces with small retaining walls can help to achieve this. Limit ground slopes in accordance with the values tabulated in Table 2-2.

- Select vegetation that will not only survive but also enhance water quality. Dense grasses and other beneficial vegetation will typically require irrigation in semi-arid regions.

R0056800

VOL 12 2 3507

Table 2-2

Maximum Allowable Slopes for Grassed Area When Using Minimized DCIA Site Design

Type of Cover	Maximum Allowable Slope
Irrigated Grass Cover:	
General Site Lot Areas	10H:1V (10%)
Sheet Flow over Swale Sideslope	4H:1V
Nonirrigated Grass Cover:	
General Site Lot Areas	20H:1V (5%)
Sheet Flow over Swale Sideslope	Not Permitted as Part of BMP
Dense Flower Beds	Zero Slope
Sparsely Covered Flower Beds	Not Permitted as Part of BMP

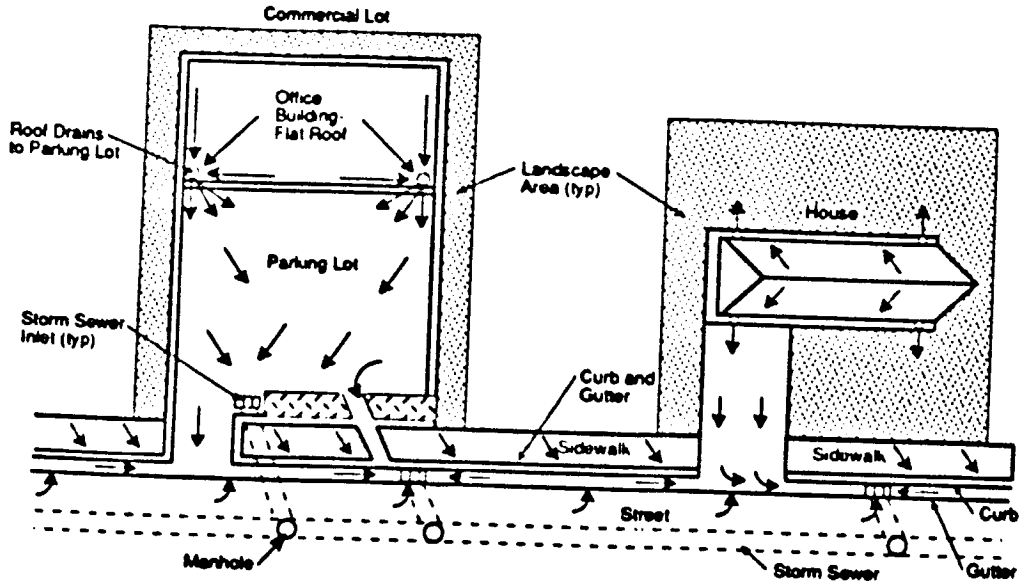
2.5 Maintenance Considerations

Requirements associated with this BMP include maintaining grass and other vegetation, picking up debris, and conducting ongoing inspections to observe possible unintended site erosion and changes in drainage patterns. Sediment buildup in grass swales and grass buffers receiving deicing materials from roads and parking lots will eventually require removal and replacement of damaged grass cover. Refer to Sections 3 and 4 in this chapter on grass-filter strips and grass lined swales for additional guidance and criteria on maintenance needs and practices.

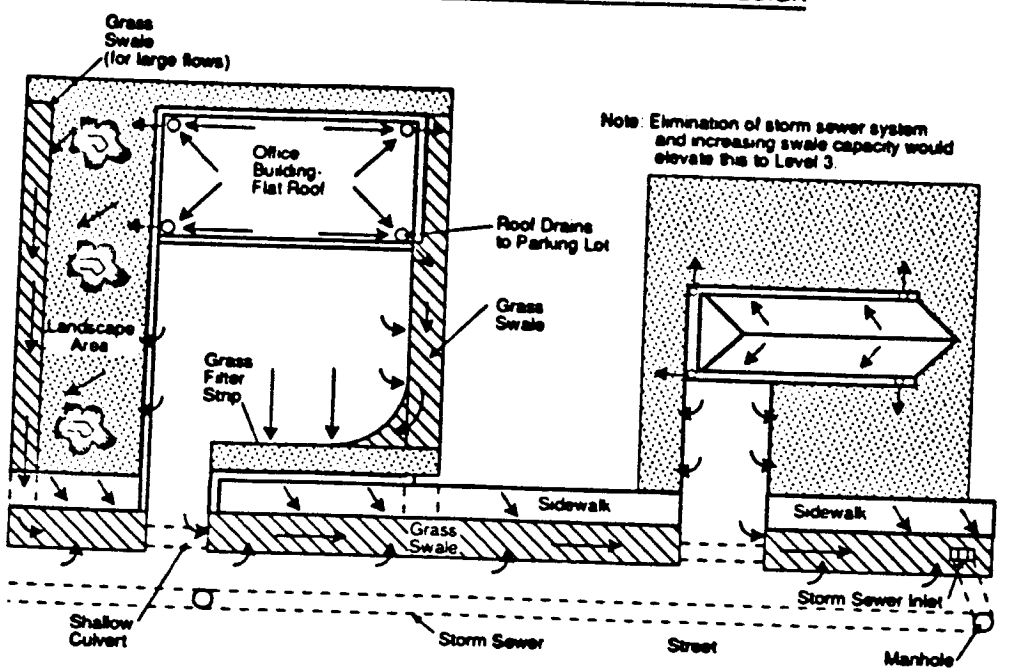
2.6 Cost-Estimating Guidelines for Minimizing DCIAs

The actual costs for minimizing DCIA are difficult to estimate since they depend on the level of action selected for this BMP and how the action may affect the actual cost of site development. A procedure for evaluating costs would be to compare costs of a development area designed using traditional site

R0056801



TRADITIONAL SITE & STREET DRAINAGE DESIGN



MINIMIZING DIRECTLY CONNECTED IMPERVIOUS AREAS (LEVEL 2 PRACTICES SHOWN)

FIGURE 2-2. EXAMPLES OF MINIMIZING DIRECTLY CONNECTED IMPERVIOUS AREAS

VOL 1 2

2 3 5 0 8

R0056802

drainage to with the one designed to minimize DCIA. Differences in development costs will be related to the following:

- Increased open-space land requirements and right-of-ways, which could possibly be somewhat offset if the additional open space is accepted in part, or in total, by the city or county as part of the open space requirements of the site.

- Decreased peak runoff flow rates and volumes for downstream conveyance and stormwater best management facilities (that is, regional or other onsite BMPs). The cost of installing curbs and gutters is eliminated by this BMP, and the reduced cost of a smaller storm sewer system, smaller follow-up detention/retention BMPs, and narrower residential street pavement can help to either offset the cost of lost right-of-way or may even reduce the total cost of developing a site.

R0056803

VOL 12 2 3510

3. IRRIGATED GRASS BUFFER STRIPS

3.1 Description

Grass buffer strips are uniformly graded and densely vegetated areas of irrigated turf grass. They require sheet flow to promote filtration, infiltration and settling to reduce runoff pollutants. Grass buffer strips differ from grass-lined swales as they are designed to accommodate overland sheet flow rather than concentrated or channelized flow. They can be used to remove larger sediment from sheet flow runoff flowing off impervious areas.

Whenever concentrated runoff occurs, it should be evenly distributed across the width of the buffer strip via a porous pavement strip or another type of structure to achieve sheet-flow conditions. Grass buffers can also be combined with riparian zones in treating sheet flows and in stabilizing channel banks adjacent to major drainageways and receiving waters. Buffer strips can be interspersed with shrubs and trees that can take up nutrients and provide shading. In a semiarid climate, irrigation is required to maintain a healthy and dense grass on the grass buffer strip to withstand runoff from impervious areas.

3.2 General Application

Grass buffer strips can be used in residential and commercial areas and are located adjacent to impervious areas of the site. When used, they should be incorporated into site drainage, street drainage, and master drainage planning. Because their effectiveness depends on having an evenly distributed sheet flow over their surface, the size of the contributing area, and the associated volume of runoff have to be limited. Flow can be directly accepted from an impervious area such as from a parking lot and building roofs, provided the flow is distributed uniformly over the strip with a level spreader device. Grass buffer strips provide only marginal pollutant removal and require that followup structural BMPs be provided. They do, however, help to reduce some of the runoff volume from very small storms.

R0056804

VOL 1 2 2 3 5 1 1

3.3 Advantages/Disadvantages

3.3.1 General. The grass and other vegetation provide aesthetically pleasing green space, which can be incorporated into a development landscaping plan. In addition, their use adds little cost to a development that has to provide open space, and their maintenance should be no different than routine maintenance of the site's landscaping. Eventually, the grass strip next to the spreader will have accumulated sufficient sediment to block runoff. At that point in time, a portion of the strip will need to be removed and replaced.

The grass and optional trees can provide wildlife habitat and help reduce runoff through runoff infiltration. If infiltration occurs to any extent, it can reduce the size of downstream facilities. Even though, in some cases, gravel underdrains can be used to provide infiltration, they are being recommended only as an optional feature at this time until more is learned on how such an arrangement operates and how long it will function.

When buffer strips are used over unstable slopes, soils, or vegetation, they can lead to the formation of rills and gullies that disrupt sheet flow. The resultant short-circuiting will invalidate the intended water quality benefits. Grass buffer strip areas should be protected from excessive pedestrian or vehicular traffic that can damage the grass cover and affect even sheet-flow distribution. A mixture of grass and trees may offer benefits for increased slope stability.

3.3.2 Physical Site Suitability. The site, after final grading, should have a uniform slope and be capable of maintaining an even sheet flow throughout. Typical slopes of the site before final grading can range from 2 to 10 percent. (For more guidance, see Table 2-2.) The allowable tributary area depends on the width, length, and the soils that lay under the buffer strip. Hydrologic Soil Groups A and B provide the best infiltration capacity, while Soil Groups C and D provide best site stability. The swelling potential of underlying soils should also be taken into account in how the soils may affect adjacent structures and pavement when water is delivered to the grassed areas.

3.3.3 Pollutant Removal. Pollutant removal depends on many factors such as soil permeability, site slope, the flow path length along the buffer strip, the characteristics of drainage area, runoff volumes and velocities, and the type of vegetation. The general pollutant removal of both particulate and soluble pollutants is projected to be low to moderate. Grass buffer strips rely primarily upon the 781 settling and interception of solids, and to only a minor degree, on biological uptake and runoff infiltration.

R0056805

VOL 1 2 2 3512

3.4 Planning Considerations and Design Criteria

Grass buffer strip design is based primarily on maintaining sheet-flow conditions across a uniformly graded, irrigated, dense grass cover strip. Figure 3-1 shows potential grass filter strip configurations. Design guidance is presented in Table 3-1. General sizing requirements are used to determine the design width and length of the continuous grass buffer strip.

3.5 Maintenance Considerations

Grass buffer strips require general maintenance of the turf grass cover and repair of any rill or gully development. Table 3-2 presents a summary of specific maintenance requirements and a suggested frequency of action.

R0056806

VOL 12 2 3 5 1 3

Table 3-1

Grass Buffer Strip Design Considerations and Criteria

Criteria	Design Considerations
Design Length	General guidance suggests applying a hydraulic load no greater than 0.05 cfs/linear foot of buffer strip during a 2-year storm to maintain a sheet flow of less than 1 inch throughout dense grass that is at least 2 inches high.
Design Width	The design width (W_o) (the distance along the sheet flow direction) shall be the greater of the following: $W_o \geq 8$ feet $W_o \geq 0.2\ L_t$ Where: L_t = The length of flow path of the sheet flow over the upstream impervious surface.
Geometry	A rectangular shape strip is preferred and should be free of gullies or rills that concentrate the overland flow.
Flow Distribution	Runoff must be evenly distributed onto the grass strip. Slotted curbing or other spreader devices can be used to apply flows. Concentrated flow needs to use a level spreader to evenly distribute flow onto the strip.
Site Slopes	Slopes can vary and should be selected in accordance with Table 2-1 found in Section 2.0.
Vegetation	Dense turf is needed to promote sedimentation and entrapment and to protect against erosion. Irrigated turf grass should be maintained to a blade height of 2 to 4 inches. The strip typically needs to be irrigated during dry weather. Although trees and other vegetation can increase infiltration, they can cause uneven sheet flow across the strip.
Outflow Collection	Most of the runoff during significant events will not be infiltrated and will require a collection and conveyance system. A grass-lined swale can be used for this purpose and can provide another BMP level. The buffer strip can also drain to a storm sewer or to a street gutter.

R0056807

Table 3-2

Irrigated Grass Buffer Strip Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Lawn mowing	Maintain a dense grass cover at a recommended length of 2 to 4 inches. Collect and dispose of cuttings offsite or use a mulching mower.	Routine–As needed or recommended by inspection.
Lawn care	Use the minimum amount of biodegradable, nontoxic fertilizers and herbicides needed to maintain dense grass cover, free of weeds. Reseed and patch damaged areas.	Routine–As needed.
Irrigation	Adjust the timing sequence and water cover to maintain the required minimum soil moisture for dense grass growth. Do not overwater.	As needed.
Litter removal	Remove litter and debris to prevent gully development, enhance aesthetics, and prevent floatables from being washed offsite.	Routine–As needed by inspection.
Inspections	Inspect irrigation, turf grass density, flow distributuon, gully development, and traces of pedestrian or vehicular traffic and request repairs as needed.	Annually and after each major storm (that is, larger than 0.75 inches in precipitation).
Turf replacement	To lower the turf below the surface of the adjacent pavement, use a level flow spreader, so that sheet flow is not blocked and will not cause water to back up onto the upstream pavement.	As needed when water padding becomes too high or too frequent a problem. The need for turf replacement will be higher if the pavement is sanded in winter to improve tire traction on ice. Otherwise, expect replacement once every 5 to 15 years.

4. GRASS-LINED SWALES

4.1 Description

Grass-lined swales are densely vegetated drainageways with low-pitched sideslopes that collect and slowly convey runoff. Design of their longitudinal slope and cross-section size forces the flow to be slow and shallow, thereby facilitating sedimentation while limiting erosion. Berms or check dams should be installed perpendicular to the flow as needed to slow it down and to encourage settling and infiltration.

4.2 General Application

Swales can be located to collect overland flows from areas such as parking lots, buildings, residential yards, roadways and grass buffer strips. They can be made a part of the plans to minimize a directly connected impervious area. Grass-lined swales can be used as an alternative to curb-and-gutter systems. Swales are set below adjacent ground level, and runoff enters the swales over grassy banks. The potential exists for wetland vegetation to become established if the swale experiences standing water or if there is a base flow. A site with a base flow should be managed as either a swale with an unlined trickle channel, or as a wetland bottom channel, the latter providing an additional BMP to stormwater runoff.

In most applications, a followup BMP will be needed to enhance water quality to the maximum extent practicable. However, if a swale is designed to act as an extended detention basin for adjacent runoff, followup BMPs may not be needed, *provided the runoff from adjacent public streets is also intercepted by the swale.*

4.3 Advantages/Disadvantages

4.3.1 General. A grass-lined swale, which can be more aesthetically pleasing than concrete or rock-lined drainage systems, is generally less expensive to construct. Although limited by the infiltration capacity of local soils, this BMP can also provide some reduction in runoff volumes from small storms. Dense grasses can reduce flow velocities and protect against erosion during larger storm events. Swales in residential and commercial settings can also be used to limit the extent of directly connected impervious areas.

R0056810

VOL 1 2 2 3 5 1 1 7

The disadvantages of using grass swales include the possibility of soggy and wet areas in front yards, the potential for mosquito breeding areas, and the potential need for more right-of-way than is needed for a storm sewer.

4.3.2 Physical Site Suitability. Grass swales are practical only at sites with general ground slopes of less than 3 to 4 percent and are definitely not practical for sites steeper than 6 percent. The longitudinal slopes of a swale should be kept to less than 1.0 percent, which often necessitates the use of grade control checks or drop structures. Where the general terrain slope exceeds 3 percent, a grass swale is often practical only on the upslope side of the adjacent street.

When soils with high permeability (for example, Class A or B) are available, the swale can be used to infiltrate a portion of the runoff into the ground, but such soils are not required for effective application of this BMP.

4.3.3 Pollutant Removal. Removal rates reported in literature vary and fall into the low to medium range. Under good soil conditions and low flow velocities, moderate removal of suspended solids and associated other constituents can be expected. If soil conditions permit, infiltration can remove low to moderate loads of soluble pollutants when flow velocities are very low. As a result, small frequent storms can benefit the most. See Table 3-1 in the *Stormwater Quality Management* chapter for known ranges in pollutant removal rates by this BMP.

4.4 Planning Considerations and Design Criteria

Figure 4-1 shows trapezoidal and triangular grass-lined swale configurations; Table 4-1 discusses the design criteria. Swales should be sized to maintain a low velocity during small storms and to collect and convey larger runoff events – all for the projected fully developed land use conditions. If the design flows are not based on fully developed land conditions, the swales will be undersized and will not provide the intended pollutant removal or flow attenuation.

A hearty turf grass must be used so that it will foster dense vegetation, because many storm events occur in early spring when the grass may still be dormant and prone to erosion. Irrigation, fertilization, and erosion protection of newly planted grass or sod are also necessary. Permanent irrigation in some cases may also be necessary. Using swales can possibly replace both curb-and-gutter systems and storm sewer systems in the upper portions of each watershed when properly designed to meet local criteria for the "initial storm" (for example, a 2- or a 5-year storm). However, if one or both sides

R0056811

of the swale are to be used as grass buffers also, their design has to follow the requirements of Section 3, *Irrigated Grass Buffer Strips*.

4.5 Maintenance Considerations

Table 4-2 summarizes maintenance needs and related issues and shows the recommended frequency of various maintenance activities.

Healthy grass can generally be maintained without using fertilizers because runoff from lawns and other areas contains the needed nutrients. Occasionally inspecting the grass over the first few years will help to determine if any problems are developing and to plan for long-term restorative maintenance needs.

R0056812

VOL 12 2 3518

Table 4-1

Grass-Lined Swale Design Considerations and Criteria

Criteria	Design Considerations
Velocity	Maintaining low velocities in a swale during small, frequent storms encourages sedimentation and infiltration. Design the swale for a velocity of 2 fps or less during the 2-year event. Use a Mannings roughness coefficient of n=0.035 and set the longitudinal channel slope and channel cross-section dimensions to limit the flow velocity.
Swale Geometry	A shallow trapezoidal or triangular channel cross-section is preferred. A maximum depth of 3 feet is recommended during a 2-year storm. Swale side slopes should be no steeper than 4:1 and preferably 5:1 or flatter.
Longitudinal Slope	Providing a mild slope helps maintain the flow velocities recommended above. Typically, longitudinal slopes will be between 0.2 percent and 0.5 percent, but shall not exceed 1.0 percent. Sites with greater slopes should use grade control checks or small drop structures to maintain the required longitudinal slope.
Grade Checks	Slow velocities down through the use of grade control checks in a swale to promote sedimentation and infiltration. Provide them as needed to maintain the longitudinal slope and to limit maximum flow velocity.
Vegetation	Dense turf grass cover is recommended to promote sedimentation, filtration, and nutrient uptake, to limit erosion, and to help maintain low flow velocities.
Street and Driveway Crossings	Small culverts at each street crossing and driveway crossings may be used to provide onsite stormwater capture and to use the swale, if adequate volume is available, as an extended detention basin.
Drainage and Flood Control	Check the water surface during larger storms such as the 5-year through the 100-year floods to ensure that drainage from such events is being handled without flooding critical areas or residential, commercial, and industrial structures.

R0056813

VOL 12 2 3519

Table 4-2

Grass-Lined Swale Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Lawn mowing and lawn care	Maintain irrigated grass at 2 to 4 inches tall and nonirrigated native grass at 6 to 8 inches tall. Collect cuttings and dispose of them offsite or use a mulching mower.	Routine–As needed.
Debris and litter removal	Keep the area clean for aesthetic reasons, which also reduces floatables being flushed downstream.	Routine–As needed by inspection, but no less than two times per year.
Sediment removal	Remove accumulated sediment near culverts and in channels to maintain flow capacity. Replace the grass areas damaged in the process.	Routine–As needed by inspection. Estimate the need to remove sediment from 3 to 10 percent of total length per year, as determined by annual inspection.
Grass reseeding and mulching	Maintain a healthy dense grass in channel and side slope.	Nonroutine–As needed by annual inspection.
Inspections	Check the grass for uniformity of cover, sediment accumulation in the swale, and near culverts.	Routine–Annual inspection is suggested.

5. EXTENDED DETENTION BASINS (DRY)

5.1 Description

Extended detention basins are designed to totally empty out sometime after stormwater runoff ends. They are adaptations of the detention basins used for flood control. The primary difference is in the outlet design. The extended basin uses a much smaller outlet that extends the emptying time of the more frequently occurring runoff events to facilitate pollutant removal. A drain time of the brim-full capture volume of 40 hours is recommended to remove a significant portion of fine particulate pollutants found in urban stormwater runoff. Soluble pollutant removal can be somewhat enhanced by providing a small wetland marsh or ponding area in the basin's bottom to promote biological uptake. The basins are considered to be "dry" because they are designed not to have a significant permanent pool of water.

5.2 General Application

Extended detention basins can be used to enhance stormwater runoff quality and reduce peak stormwater runoff rates. If these basins are constructed early in the development cycle, they can also be used to trap sediment from construction activities within the tributary drainage area. The accumulated sediment will need to be removed, however, before the basin is placed into final long-term use. Also, extended detention basins can sometimes be retrofit into existing flood control detention basins.

Extended detention basins can be used to improve the quality of urban runoff from roads, parking lots, residential neighborhoods, commercial areas, and industrial areas and are generally used as regional or followup treatment BMPs. They can also be used as an onsite BMP. Extended detention basins work well in conjunction with other BMPs, such as upstream onsite source controls and downstream filter basins or wetland channels. If desired, a flood routing detention volume can be provided above the water quality capture volume (WQCV) of the basin.

R0056816

VOL 1 2 2 3 5 2 3

5.3 Advantages/Disadvantages

5.3.1 General. Extended detention basins can also be designed to provide multiuse benefits by reducing peak runoff flow rates and by improving water quality while incorporating recreation and open space opportunities. They can be effective in removing particulate matter and associated heavy metals and other pollutants. As with other BMPs, safety issues need to be addressed through proper design.

5.3.2 Physical Site Suitability. Normally, the land required for an extended detention basin is approximately 0.5 to 2.0 percent of the total tributary development area. Although the soil types beneath the pond seldom prevent the use of this BMP, they should be considered during design. Any exfiltration capacity should be considered a short-term characteristic because exfiltration will decrease over time as the soil is clogged with fine sediment and as the groundwater beneath the basin develops a mound that can eventually surfaces into the basin.

High groundwater should not preclude the use of this BMP or its performance. Groundwater, however, should to be considered during design and construction, and the outlet design must account for any base flows that result from groundwater surfacing or that arrive from upstream. In high groundwater areas, consider the use of retention ponds to avoid many of the problems associated when a basin bottom is located below the seasonal high water table.

Construction costs may be high if bedrock excavation of the pond is required. Soil maps should be consulted, and soil borings should be conducted to establish geotechnical parameters.

5.3.3 Pollutant Removal. The performance range of an extended detention pond was presented in Table 3-2 in the *Stormwater Quality Management* chapter of this volume. Removal of suspended solids and metals can be moderate to high, and removal of nutrients is low to moderate. When a small shallow wetland is included as part of the basin's bottom or the basin is followed by BMPs more efficient at removing soluble pollutants, such as constructed wetlands or wetland channels, the removal of nutrients can be improved.

The major factor controlling the degree of pollutant removal is the emptying time provided by the outlet. The rate and degree of removal will also depend on influent particle sizes. Metals, oil and grease, and some nutrients have a close affinity for suspended sediment and will be removed partially through sedimentation.

R0056817

5.3.4 Aesthetics and Multiple Uses. Since an extended detention basin is designed to drain very slowly, its bottom and lower portions will be inundated frequently and for extended periods of time. Grasses in this frequently inundated zone will tend to die off, with only the species that can survive the specific environment at each site eventually prevailing. In addition, the bottom will be the depository of all the sediment that settles out in the basin. As a result, the bottom can be muddy and can have an undesirable appearance. To reduce this problem and to improve the basin's availability for other uses (such as passive recreation), it is suggested that the designer provides a lower-stage basin as suggested in Table 5-1 under Two Stage Design. As an alternative, a retention pond could be used, in which the settling occurs primarily within the permanent pool.

5.4 Planning Considerations and Design Criteria

Extended detention basins rely on an outlet designed to extend the emptying time of the basin's capture volume. Figure 5-1 shows a representative layout of an extended detention basin; Figure 5-2 shows some of the basin outlet details. Table 5-1 summarizes extended detention design criteria. Although flood control storage can be provided by a storage volume above the water quality storage, how to accomplish this is not included in this discussion. Whether or not flood storage is incorporated, embankments should be protected from catastrophic failure when runoff exceeds the design event. The State Engineer's regulatory requirements for larger embankments and storage volumes must be followed whenever regulatory height and/or volume thresholds are exceeded. Below those thresholds, the engineer should design the embankment-spillway-outlet system so that catastrophic failure will not occur.

For a perforated pipe outlet configuration, similar to the one shown in Figure 5-2, the number of perforations per row can be determined with the aid of Figure 5-3. The relationship in Figure 5-3 equates the WQCV, which needs to be emptied over 40 hours, to the total area of perforations required per row in the riser. The chart is based on the rows being equally spaced vertically at 4-inch centers. This total area of perforation per row is then used to determine, with the aid of Figure 5-2, the number of uniformly sized holes per row. Multiple perforated pipes or a perforated plate located at the front of an outlet can be used instead of a single riser. Other types of outlets may also be used, provided they control the release of the WQCV in a manner consistent with the *Emptying Time* requirements of Table 5-1.

2
3524
R0056818

VOL 1 2 2 3525

5.5 Maintenance Considerations

Dry extended detention basins have low to moderate maintenance requirements. Routine and nonroutine maintenance is necessary to assure performance, enhance aesthetics, and protect structural integrity. The dry basins can result in nuisance complaints if not properly designed or maintained. Bio-degradable pesticides may be required to limit insect problems. Frequent debris removal and grass-mowing can reduce aesthetic complaints. If a shallow wetland or marshy area is included, mosquito breeding and nuisance odors could occur if the water becomes stagnant. Access to critical elements of the pond (inlet, outlet, spillway, and sediment collection areas) must be provided. The basic elements of the maintenance requirements are presented in Table 5-2.

R0056819

Table 5-1

Extended Detention Basin Design Considerations and Criteria

Criteria	Design Considerations
Basin Volume (WQCV)	Provide a storage volume for 120 percent of the WQCV above the lowest outlet in the basin. The WQCV should be determined following the procedure described in *Stormwater Quality Management* chapter of this manual using a 40-hour drain time. The additional 20 percent of storage volume provides for sediment accumulation and the resultant loss in storage volume.
Emptying Time	A 40-hour emptying time should be used for the WQCV, with no more than 50 percent of the WQCV being released in 12 hours.
Flood Control Storage	Combining the water quality facility with a flood control facility is recommended. The 10-year, 100-year, or other floods may be detained above the WQCV.
Basin Geometry	Shape the pond with a gradual expansion from the inlet and a gradual contraction toward the outlet, thereby limiting short circuiting. The basin length to width ratio should be no less than 2, with a ratio of 4 recommended where feasible.
Two-Stage Design	A two-stage design with a lower frequency pool that fills often with frequently occurring runoff minimizes standing water and sediment deposition in the remainder of the basin. The top stage should be 2 to 5 feet deep with its bottom sloped at 2 percent toward the low flow channel. The bottom stage should be 1.5 to 3 feet deeper than the top stage and store 10 to 25 percent of the WQCV.
Low-Flow Channel	Conveys low flows from the forebay to the bottom stage. Erosion protection should be provided where the low-flow channel enters bottom stage.
Basin Side Slopes	Slopes should be stable and gentle enough to limit rill erosion and facilitate maintenance access and needs. Side slopes should be no steeper than 4:1, preferably flatter.
Inlet	Dissipate flow energy at pond's inflow point(s) to limit erosion and promote particle sedimentation. Inlets should be designed in accordance with UDFCD drop structure criteria or as another type of an energy dissipating structure.
Forebay Design	Provide the opportunity for larger particles to settle out in an area that has a solid surface bottom to facilitate mechanical sediment removal. A rock or an earthen berm should be constructed with a minimum top width of 4 feet and side slopes no steeper than 4:1. The forebay volume of the permanent pool should be 5 to 10 percent of the WQCV. A trapezoidal outlet throughout the berm should be offset from the inflow streamline to prevent short circuiting, and the bottom width should be no wider than the low flow channel width.

Note: WQCV = water quality capture volume. Refer to Section 5 of the *Stormwater Quality Management* chapter of this volume.

VOL 1 2 2 3526

R0056820

Table 5-1 (Continued)

Extended Detention Basin Design Considerations and Criteria

Outlet Design	Use a water quality outlet that is capable of slowly releasing the WQCV over a 40-hour period. A perforated riser can be used in conjunction with a weir box opening above it to control larger storm outflows. A cutoff collar should be considered for the outlet pipe to control seepage. A sample outlet is illustrated in Figure 5-2, however, any other outlet that can meet the *Emptying Time* requirements stipulated above should be acceptable.
Trash Rack	If the outlet is not protected by a gravel rack, similar to one shown on Figure 5-2, provide a trash rack of sufficient size to prevent clogging of the primary water quality outlet while not interfering significantly with its hydraulic capacity. As a minimum, use Figure 5-4 as a guidance to size all trash racks.
Dam Embankment	The embankment should be designed not to fail during a 100-year and larger storm. Embankment slopes should be no steeper than 3:1, preferably 4:1, and flatter, and planted with turf forming grasses. Poorly compacted native soils should be excavated and replaced. Embankment soils should be compacted to at least 95 percent of their maximum density according to ASTM D 698-70 (Modified Proctor). Spillway structures and overflows should be designed in accordance with local drainage criteria and should consider UDFCD drop-structure design guidelines.
Vegetation	Bottom vegetation provides erosion control and sediment entrapment. Pond bottom, berms, and side sloping areas may be planted with native grasses or with irrigated turf, depending on the local setting.
Maintenance Access	Access to the forebay and outlet area shall be provided to maintenance vehicles. Maximum grades should be 6 percent, and a solid driving surface of gravel, rock, concrete, or gravel-stabilized turf should be provided.
Multiple Uses	Whenever desirable and feasible, incorporate the water quality within a larger flood control basin. Also, whenever possible try to provide for other urban uses such as active or passive recreation, and wildlife habitat. If multiple uses are being contemplated, consider first the issues discussed in Section 5.3.4 and use the multiple-stage detention basin to limit inundation of passive recreational areas to one or two occurrences a year. Generally, the area within the WQCV is not well suited for active recreation facilities such as ballparks, playing fields, and picnic areas, which are best located above this pool level.

2 3 5 2 7

R0056821

VOL 1 2 2 3528

Table 5-2

Extended Detention Basin Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Lawn mowing and lawn care	Occasional mowing to limit unwanted vegetation. Maintain irrigated turf grass as 2 to 4 inches tall and nonirrigated native turf grasses at 4 to 6 inches.	Routine - Depending on aesthetic requirements.
Debris and litter removal	Remove debris and litter from the entire pond to minimize outlet clogging and improve aesthetics.	Routine - Including just before annual storm seasons (that is, April and May) and following significant rainfall events.
Erosion and sediment control	Repair and revegetate eroded areas in the basin and channels.	Nonroutine - Periodic and repair as necessary based on inspection.
Structural	Repair pond inlets, outlets, forebays, low flow channel liners, and energy dissipators whenever damage is discovered.	Nonroutine - Repair as needed based on regular inspections.
Inspections	Inspect basins to insure that the basin continues to function as initially intended. Examine the outlet for clogging, erosion, slumping, excessive sedimentation levels, overgrowth, embankment and spillway integrity, and damage to any structural element.	Routine - Annual inspection of hydraulic and structural facilities. Also check for obvious problems during routine maintenance visits, especially for plugging of outlets.
Nuisance control	Address odor, insects, and overgrowth issues associated with stagnant or standing water in the bottom zone.	Nonroutine - Handle as necessary per inspection or local complaints.

R0056822

Table 5-2 (Continued)

Extended Detention Basin Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Sediment removal	Remove accumulated sediment from the forebay and the bottom of the basin.	Nonroutine–Performed when sediment accumulation occupies 20 percent of the WQCV. This may vary considerably, but expect to do this every 5 to 15 years, as necessary per inspection. The forebay will require more frequent cleanout than other areas of the dry pond.

6. RETENTION PONDS (PONDS WITH A PERMANENT POOL)

6.1 Description

A retention pond has a permanent pool of water that is replaced with stormwater, in part or in total, during storm runoff events. Temporary detention is provided above this permanent pool to allow more sedimentation. Retention ponds are similar to extended detention basins because they are designed to capture in total and detain a volume of runoff from frequently occurring storms. However, detention ponds differ from extended detention basins because the influent water mixes with the permanent pool water as it rises above the permanent pool. The captured volume above the permanent pool is then released over 12 hours.

Retention ponds require a dry-weather base flow to maintain the permanent pool. They can be very effective in removing pollutants, and, under the proper conditions, can satisfy multiple objectives.

6.2 General Application

Retention ponds can be used to improve the quality of urban runoff from roads, parking lots, residential neighborhoods, commercial areas, and industrial sites and are generally used as regional or followup treatment because of the base-flow requirements. They can be used as an onsite BMP if the owner provides sufficient water to keep the pond full between storms. Retention ponds work well in conjunction with other BMPs, such as upstream onsite source controls and downstream filter basins or wetland channels. The required design volume of a retention pond includes the volume needed for a permanent pool plus a water quality capture volume (WQCV) above the permanent pool. If desired, a flood routing detention volume can be provided above the WQCV.

If retention ponds are constructed in the early phase of development, they can be used to trap sediment from construction activities within the tributary drainage area.

R0056828

VOL 1 2 2 3 5 3 3 5

6.3 Advantages/Disadvantages

6.3.1 General. Retention ponds can be cost-effective for larger tributary watersheds. They can be used in providing the following:

- Achieving moderate to high removal rates of many urban pollutants
- Creating wildlife habitat
- Providing recreation, aesthetics, and open space areas
- Incorporation into a larger flood control basin

The primary disadvantages include safety concerns, more difficult sediment removal than for extended detention basins when needed, floating litter, scum and algal blooms, nuisance odors, and possible mosquito problems. Aquatic plant growth can be a factor in clogging outlet works. The permanent pool can attract water fowl, which can add to the nutrient load entering and leaving the pond.

6.3.2 Physical Site Suitability. Although site suitability concerns are similar to those stated for an extended detention basin, a retention pond has one primary difference–it requires sufficient continuous base flow to maintain the pool. A complete water budget under the projected urbanized watershed conditions should be performed to assure that the base flow will exceed evaporation, evapotranspiration, and seepage losses.

Land requirements are typically 0.5 to 2 percent of the tributary watershed's area. High exfiltration rates can initially make it difficult to maintain a permanent pool in a new pond, but the bottom can eventually seal with fine sediment and become relatively impermeable over time. It is best, however, to seal the bottom and the sides of a permanent pool if the pool is located on permeable soils and to leave the areas above the permanent pool unsealed.

6.3.3 Pollutant Removal. Retention ponds achieve moderate to high removal rates for particulate matter through sedimentation during and shortly after the runoff event. During a storm event, a portion or all of the permanent pool water is displaced and the pool becomes a mixture of the former pool water and new runoff. The period between storms allows biological uptake of soluble nutrients and metals from the water column in the permanent pool while also providing time for quiescent settling of fine sediment particles that remain in the pool after a storm. Some of the sediment can resuspend and soluble compounds can remobilize if a large storm event causes intense mixing or when unfavorable chemical conditions exist in the pool (such as low dissolved oxygen [DO] or pH). Also,

R0056829

VOL 1 2 2 3536

algal growth and other biological activity can produce suspended solids and increased concentrations of certain forms of phosphates and nitrogen compounds in base flow discharges from the pond.

Without a sufficient continuous base flow, a wet pond can, through evaporation, concentrate levels of salts and algae between storm events. Besides contributing to nuisance problems, the water quality of the pool is very important. A storm event will displace any concentrated pond water, and in some instances, can result in a discharge of water with pollutant concentrations exceeding the inflow – exactly the opposite of the intent for providing this BMP.

6.3.4 Aesthetics and Multiple Uses. Retention ponds can offer improved aesthetics and multiple-uses beyond those typically found at extended detention basins. The bulk of the capture volume occurs as a surcharge above the permanent pool, with some of it occurring above the dry-weather bank areas. As a result, most of the sediment deposits are left behind within the permanent pool zone, where they are not seen by the public. Also, the permanent pool offers some aquatic habitat and is a habitat for water fowl. However, water fowl can be a nuisance because of the fecal matter they deposit on the banks and in the pool.

6.4 Planning Considerations and Design Criteria

There are two primary differences in design between a retention pond and an extended detention basin:

- The first is that the retention pond requires a base flow to maintain and to flush a permanent pool.
- The second major difference is the emptying time; retention ponds are designed to empty the water quality capture volume over a 12-hour period, instead of the longer 40 hours needed for an extended detention basin. The reason for this is that the sediment removal process is more efficient when the outflow occurs above the bottom of the basin. Sediments become trapped below the outlet and sedimentation continues in the pool after the captured surcharge volume is emptied.

Figure 6-1 shows a representative layout for a retention pond; Figure 6-2 shows the configuration for one type of outlet. Table 6-1 presents design criteria for retention ponds. Although flood storage has not been addressed in these recommendations for the same reasons mentioned under extended

R0056830

detention basins, it can be easily provided for above the WQCV. Embankment design and safety design considerations for a retention pond are identical to those discussed for an extended detention basin, except more attention should be given to cutoff collars on the outlet pipe to safeguard against piping along the outlet.

For the perforated pipe outlet configuration shown in Figure 6-2, the number of columns of holes per row can be determined with the aid of Figure 6-3. The relationship in Figure 6-3 equates the WQCV that should be drained over 12 hours to the total area of the holes installed per row in the perforated riser. This relationship is based on the rows being equally spaced vertically at 4 inches on center. The total area of holes obtained from Figure 6-3 is then used to determine, with the aid of Figure 6-2, the number of holes per row that will need to be drilled in the perforated riser. Multiple perforated pipes or perforated steel plate in an outlet may be used instead. Other types of outlets may also be used, provided they control the release of the WQCV in a manner consistent with the *Emptying Time* requirements of Table 6-1.

6.5 Maintenance Requirements

The amount of construction activity within a basin, the erosion control measures implemented, and the size of the basin will influence the frequency of sediment removal from the pond. With aggressive erosion control is practiced in the tributary watershed, it is estimated that accumulated sediment will need to be removed at 5- to 20-year intervals. Table 6-2 summarizes the required maintenance activities and their frequency for retention ponds.

VOL 1 2 2 3 5 3 7

R0056831

Table 6-1

Retention Pond Basin Design Considerations and Criteria

Criteria	Design Considerations and Design Criteria
Capture Volume	Provide storage for the WQCV above the permanent pool level. The WQCV should be calculated following the procedure described in Volume 3 of this Manual using a 12-hour drain time.
Emptying Time	A 12-hour emptying time should be used for the WQCV.
Permanent Pool	The permanent pool provides stormwater quality enhancement between storms through biological uptake and continuing sedimentation. The volume of the permanent pool should be 1.0 to 1.5 times the WQCV and shall have two depth zones: (1) a littoral zone 6 to 18 inches deep that accounts for 25 to 50 percent of the permanent pool surface area for aquatic plant growth along the perimeter of the permanent pool, and (2) a deeper zone of 4 to 8 feet average depth in the remaining pond area to promote sedimentation and nutrient uptake by phytoplankton, with a maximum depth in the pond of no more than 12 feet.
Base Flow	A net influx of water must be available through a perennial base flow and must exceed the losses. The following equation and parameters can be used to estimate the net quantity of baseflow available at a site: $$Q_{Net} = Q_{Inflow} - Q_{Evap} - Q_{Seepage} - Q_{ET}$$ Where: Q_{Net} = Net quantity of base flow (acre-ft/year) Q_{Inflow} = Estimated base flow (acre-ft/year) (Estimate by seasonal measurements and/or comparison to similar watersheds) Q_{Evap} = Loss because of evaporation less the precipitation (acre-ft/year) (Computed for average water surface) $Q_{Seepage}$ = Loss (or gain) because of seepage to groundwater (ac-ft/year) Q_{ET} = Loss because of plant evapotranspiration (additional loss through plant area above water surface not including the water surface)
Basin Geometry	Shape the pond with a gradual expansion from the inlet and a gradual contraction toward the outlet, thereby limiting short circuiting. The basin length to width ratio should be no less than 2:1, with 4:1 being preferred. Combining the water quality facility with a flood control facility is recommended. The 10-year, 100-year, or other flood may be detained above the WQCV.
Basin Side Slopes	Side slopes should be stable and sufficiently gentle to limit rill erosion and to facilitate maintenance. Side slopes above the permanent pool should be no steeper than 4:1, preferably 5:1 or flatter. The littoral zone should be very flat (that is, 20:1 or flatter) with the depth ranging from 6 inches near the shore and extending to no more than 18 inches at the furthest point from the shore. The side slope below the littoral zone shall be 3:1 or flatter.

Note: WQCV=water quality capture volume. See Section 5 of the *Stormwater Quality Management* chapter to this volume.

R0056832

VOL 12 2 3538

Table 6-1 (Continued)

Retention Pond Basin Design Considerations and Criteria

Criteria	Design Considerations and Design Criteria
Inlet	Dissipate flow energy at the inlet to limit erosion and to diffuse the inflow plume where it enters the pond. Inlets should be designed in accordance with USDCM drop-structure and energy-dissipating structure criteria in Volume 2.
Forebay Design	To provide an opportunity for larger particles to settle out, install an area that has a solid driving surface bottom to facilitate sediment removal. A protected earthen berm should be part of the littoral bench to create the forebay and have a minimum top width of 8 feet and side slopes no steeper than 4:1. The forebay volume of the permanent pool should be 5 to 10 percent of the WQCV.
Outlet Design	Use a water quality outlet that is capable of slowly releasing the WQCV over a 12-hour period. A perforated riser can be used with a weir box located at a higher elevation to control the permanent pool level and provide for storm outflows, respectively. Cutoff collars should be used along the outlet pipe to prevent piping. Other types of outlets may be used, provided they achieve a reasonably uniform outflow rate.
Trash Rack	The outlet shall be protected against clogging by a stiff steel coarse screen that also acts as a surface skimmer. The skimmer screen openings shall be smaller than the perforations in the riser and shall extend to the top of the WQCV and no less than 2 feet below the permanent water surface.
Dam Embankment	See Table 5-1 for discussion. Use Figure 5-4 to size trash racks.
Vegetation	The embankment should be designed not to fail during a 100-year and larger storms. Embankment slopes should be no steeper than 3:1, preferably 4:1 and flatter, covered with turf-forming grasses to limit erosion. Poorly compacted native soils should be removed and replaced. Embankment soils should be compacted to 95 percent of their maximum density according to ASTM D 698-70 (modified proctor).
Maintenance Access	Vegetation provides erosion control and enhances site stability. Berms and side-sloping areas should be planted with native turf-forming grasses or irrigated turf, depending on the local setting. The shallow littoral bench should be first covered with organic topsoil and then vegetated with aquatic species.
Multiple Uses	Access to the forebay and outlet area must be provided to maintenance vehicles. Maximum grades should be 8 percent, and a solid driving surface of gravel, rock, concrete, or gravel stabilized turf should be provided.
	Whenever desirable and feasible, incorporate the water quality pond within a larger flood control basin. Also, whenever possible try to provide for other urban uses such as active or passive recreation, and wildlife habitat. If multiple uses are being contemplated, consider first the issues discussed in Section 6.3.4. Try to locate recreational areas to limit the frequency of inundation to one or two occurrences a year. Generally, the area within the WQCV is not well suited for active recreation facilities such as ballparks, playing fields, and picnic areas. These should be located above this pool level.

R0056833

Table 6-2

Retention Pond Basin Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Lawn mowing and lawn care	Mow occasionally to limit unwanted vegetation. Maintain irrigated turf grass 2 to 4 inches tall and nonirrigated native turf grasses at 4 to 6 inches.	Routine - Depending on aesthetic requirements.
Debris and litter removal	Remove debris and litter from the entire pond to minimize outlet clogging and aesthetics. Include the removal of floatable material from the pond's surface.	Routine—Including just before annual storm seasons (that is, April and May) and following significant rainfall events.
Erosion and sediment control	Regrade and revegetate eroded and slumped areas above the pond and along channels. Repair damaged inlet and outlet energy dissipators.	Nonroutine—Periodic and repair as necessary based on inspection.
Inspections	Inspect the retention pond for functioning as initially intended. Pay attention to outlet clogging. Also note erosion, slumping, sedimentation levels, overgrowth, embankment and spillway integrity, and damage to structural elements of the facility.	Routine—Annual inspection of hydraulic and structural facilities. Biannual performance and maintenance inspections.
Nuisance control	Address odor issues, insects, and overgrowth with appropriate measures.	Nonroutine–As necessary per inspection or local complaints.
Structural repairs	Repair such items as inlet/outlet works and energy dissipator liners. Stabilize banks and berms. Repair damage caused by larger storm events.	Nonroutine–As necessary per inspection.
Sediment removal	Empty the pond, divert the base flow, and dry out bottom sediments in fall and winter months to allow access with backhoe.	Nonroutine–As indicated per inspections and sediment accumulation.
Aquatic Growth Harvesting	Remove aquatic plants such as cattails or reeds, which also permanently removes nutrients. Use an aquatic harvester and dispose of the material offsite.	Nonroutine–Perform every 3 to 10 years or as needed to control their accumulation.

7. CONSTRUCTED WETLANDS

7.1 Description

Two types of constructed wetlands are described in this section - very shallow retention ponds and wetland-bottomed channels. Both configurations require a perennial base flow to permit the growth of rushes, willows, cattails, and reeds to slow down runoff and allow time for settling and biological uptake.

Constructed wetlands differ from "natural" wetlands as they are artificial and are built to enhance stormwater quality. Sometimes small wetlands that exist along ephemeral drainageways on Colorado's high plains could be enlarged and incorporated into the constructed wetland system. Such action, however, requires the approval of federal and state regulators.

Regulations intended to protect natural wetlands recognize a separate classification of wetlands constructed for a water quality treatment. Such wetlands generally are not allowed to be used to mitigate the loss of natural wetlands but are allowed to be disturbed by maintenance activities. Therefore, the legal and regulatory status of maintaining a wetland constructed for the primary purpose of water quality enhancement is separate from the disturbance of a natural wetland.

7.2 General Application

Wetland basins can be used as a followup BMP in a watershed, or as an onsite facility if the owner provides sufficient water to sustain the wetland. Flood control storage can be provided above the wetland basin's water quality capture volume (WQCV) pool to act as a multiuse facility.

Wetland bottom channels can be used in the following two ways:

- First, a wetland can be established in a man-made channel and can act as a conveyance system and water quality enhancement facility. This design can be used along wide and gently sloping channels.

- The second use of a wetland bottom channel, and perhaps the most effective, is to locate the channel downstream of a stormwater detention facility (water quality and/or

R0056840

VOL 12 2 3547

flood control) where a large portion of the sediment load can be removed. The wetland channel then receives stormwater and base flows as they drain from the detention facility, provides water quality enhancement, and at the same time conveys it downstream. This application of a wetland channel is recommended upstream of receiving waters and within lesser (ephemeral) receiving waters, thereby delivering better quality water to the more significant receiving water system.

For either application, wetlands require a net influx of water to maintain their vegetation and microorganisms. A complete water budget analysis is necessary to ensure the adequacy of the base flow.

7.3 Advantages/Disadvantages

7.3.1 General. Constructed wetlands offer several potential advantages, such as natural aesthetic qualities, wildlife habitat, erosion control, and pollutant removal. Constructed wetlands provide an effective followup treatment to onsite and source control BMPs that rely upon settling of larger sediment particles. In other words, they offer yet another effective BMP for larger tributary basins.

The primary drawback to wetlands is the need for a continuous base flow to ensure their presence. In addition, salts and scum can accumulate and unless properly designed and built, can be flushed out during larger storms.

Other disadvantages include the need for regular maintenance to provide nutrient removal. Regular harvesting and removal of aquatic plants, cattails, and willows is required if the removal of nutrients in significant amounts has to be assured. Even with that, recent data puts into question the net effectiveness of wetlands in removing nitrogen compounds and some form of phosphates. Periodic sediment removal is also necessary to maintain the proper distribution of growth zones and of water movement within the wetland.

7.3.2 Physical Site Suitability. A perennial base flow is needed to sustain a wetland, and should be determined using a water budget analysis. Loamy soils are needed in wetland bottom to permit plants to take root. Infiltration through a wetland bottom cannot be relied upon because the bottom is either covered by soils of low permeability or because the groundwater is higher than the wetland's bottom. Both wetland ponds and channels require a near-zero longitudinal slope. A single wetland

R0056841

basin can be developed using an embankment, while a multistage wetland or a wetland channel needs drop structures to create and maintain a flat grade.

7.3.3 Pollutant Removal. Removal efficiencies of constructed wetlands vary significantly. Primary variables influencing removal efficiencies include design, influent concentrations, hydrology, soils, climate, and maintenance. With periodic sediment removal and plant harvesting, expected removal efficiencies for sediments, organic matter, and metals can be moderate to high; for phosphorous, low to moderate; and for nitrogen, zero to low. Pollutants are removed primarily through sedimentation and entrapment, with some of the removal occurring through biological uptake by vegetation and microorganisms. Without a continuous dry-weather base flow, salts and algae can concentrate in the water column and can be released into the receiving water in higher levels at the beginning of a storm event as they are washed out.

Harvesting aquatic plants and periodic removal of sediment also removes nutrients and pollutants associated with the sediment. Researchers still do not agree that routine aquatic plant harvesting affects pollutant removals. Until research documents these effects, periodic harvesting for the general upkeep of wetland, and not routine harvesting of aquatic plants, is recommended.

7.4 Planning Considerations and Design Criteria

Wetlands can be constructed either as a wetland basin (see Figure 7-1), or set into a drainageway to form a wetland bottom channel (see Figure 7-2). Table 7-1 presents the design criteria for a wetland pond, and Table 7-2 pertains to a wetland bottom channel. The criteria for a wetland bottom channel presented here differs somewhat from the criteria presented in Volume 2 of the *USDCM* under the *Major Drainage* chapter. This is because of the water quality focus of this BMP. An analysis of the water budget should show a net inflow of water after accounting for all the projected losses (such as evaporation, evapotranspiration, and seepage). An insufficient base flow could cause the wetland to become saline or to die because of lack of water.

7.5 Maintenance Considerations. To achieve and maintain a healthy wetland for water quality enhancement, the proper depth and the spatial distribution of growth zones must be maintained. Table 7-3 summarizes suggested activities and their frequencies to maintain an operational wetland.

VOL 12 2 3548
R0056842

Table 7-1

Wetland Pond Design Considerations and Criteria

Criteria	Design Considerations
Capture Volume and Depth	Provide the full WQCV above the permanent pool level. The WQCV should be calculated following the procedure in this manual by averaging the volume obtained using the 12- and 40-hour drain times. The depth of this WQCV shall not exceed 2.0 feet.
Emptying Duration	A 24-hour emptying time should be used for the WQCV above a wetland pond.
Flood Control Storage	Although a wetland pond can be used as a flood storage facility in addition to being a water quality enhancement facility, an alternate to this approach is to use a flood control detention facility upstream of the wetland. This separation can reduce resuspension of pollutants within the wetland and extend the life of a wetland by settling large amounts of sediment in the upstream detention basin.
Basin Geometry	Shape the pond with a gradual expansion from the inlet and a gradual contraction to the outlet, thereby limiting short circuiting. The basin length to width ratio should be 2:1 to 4:1 with 3:1 recommended.
Water Budget	A net influx of water must be available through a perennial base flow and must exceed all of the losses. The following equation and parameters can be used to estimate the net quantity of base flow available at a site:

$$Q_{net} = Q_{inflow} - Q_{Evap} - Q_{Seepage} - Q_{E.T.}$$

Where:

Q_{net} = Net quantity of base flow (acre-ft/year)

Q_{inflow} = Estimated base flow (acre-ft/year) (Estimate by seasonal measurements and/or comparison to similar watersheds)

Q_{Evap} = Loss attributed to evaporation less the precipitation (acre-ft/year) (Computed for average water surface)

$Q_{Seepage}$ = Loss (or gain) attributed to seepage to groundwater (ac-ft/year)

$Q_{E.T.}$ = Loss attributed to plant evapotranspiration (computed for average plant area above water surface, not including the water surface)

Note: WQCV = water quality capture volume. See Section 5 of the *Stormwater Quality Management* chapter to this volume.

VOL 1 2 2 3549
R0056843

Table 7-1 (Continued)

Wetland Pond Design Considerations and Criteria

Criteria	Design Considerations
Wetland Depths and Volume	The volume of the water in the wetland pool shall be no less than three-fourths of WQCV. Also, the proper distribution of wetland habitat is required to establish a diverse ecology. General area requirements and the water depths of the permanent pool are presented below:

Components	Percent of Permanent Pool Area	Water Depth
Forebay outlet and free water surface areas	30% to 50%	2 to 4 feet deep
Wetland zones with emergent vegetation	50% to 70%	6 to 12 inches deep[a]

[a]One-third to one-half of this zone should be 6 inches deep.

Basin Side Slopes	Slopes should be stable and gentle enough to limit rill erosion and facilitate maintenance access and needs. Side slopes should be no steeper than 4:1, preferably 5:0 or flatter.
Inlet/Outlet Protection	Dissipate flow energy entering the basin to limit sediment resuspension. Inlets should correspond to UDFCD drop-structure and energy-dissipating structure criteria. Outlets should be placed in a offbay that is at least 3 feet deep. The outlet should be protected from clogging by a skimmer shield that starts approximately one-half of the depth below the permanent water surface and extends above the maximum capture volume depth. Skimmers can be fabricated from a stiff steel screen material that has smaller openings than the outlet orifice or perforations.
Forebay Design	Provide the opportunity for larger particles to settle out in an area that has a solid driving surface bottom for vehicles to facilitate sediment removal. The forebay volume of the permanent pool should be 5 to 10 percent of the WQCV.
Outlet Design	Use a water quality outlet that is capable of slowly releasing the WQCV in no less than a 24-hour period. A perforated riser can be used with a weir box to control the permanent pool level and storm outflows. A cutoff collar should be used on the outlet culvert. See the inlet/outlet protection discussion above for a need to install a skimmer.

R0056844

VOL 1 2 2 3550

Table 7-1 (Continued)

Wetland Pond Design Considerations and Criteria

Criteria	Design Considerations
Trash Rack	See Table 5-1 for discussion. Use Figure 5-4 for design.
Vegetation	Cattails, sedges, reeds, and wetland grasses should be planted in the wetland bottom. Berms and side-sloping areas should be planted with native or irrigated turf-forming grasses. Initial establishment of the wetlands requires control of the water depth. After planting wetland species, the permanent pool should be lowered 3 to 4 inches to allow growth and to help establish the plants, after which the pool can be raised to its final operating level.
Maintenance Access	Access to the forebay and the outlet area shall be provided for vehicles for maintenance and vegetation harvesting. Maximum grades should be 8 percent, and a solid driving surface needs to be provided.

VOL 1 2 2 3551
R0056845

Table 7-2

Wetland Channel Design Considerations and Criteria

Criteria	Design Considerations
Longitudinal Slope and Channel Capacity	Design the channel to have a longitudinal slope that provides for a maximum 2-year flow velocity of 2.5 feet per second or less using channel Mannings n-value of 0.03 and a flow depth of 3 to 5 feet. Assume a Mannings n-value of 0.08 to calculate its final (or mature) capacity during a 2-year flood at the same depth and slope used when initially designing the channel with n=0.03. In setting the channel's longitudinal slope, use the peak runoff rate from the tributary watershed *without* reducing it for any upstream ponding or flood routing effects.
Channel Geometry	The channel should have a bottom width-to-depth ratio greater than 8:1 during the 2-year event. Drop structures should be used to maintain the design slope whenever it exceeds the slope of the terrain. Limit side slopes to 4:1 or flatter.
Drop Structures	Drop structures should be designed to satisfy the drop structure criteria of the *Major Drainage* chapter in Volume 2 of the *USDCM*.
Vegetation	Vegetation provides solids entrapment and biological nutrient uptake. Cover the channel bottom with loamy soils upon which cattails, sedges, and reeds should be established. Side slopes should be planted with native or irrigated turf grasses.
Maintenance Access	Access to the channel length should be provided for maintenance. Maximum grades for maintenance vehicles should be 8 percent and provide a solid driving surface.

VOL 1 2 2 3552
R0056846

Table 7-3

Constructed Wetlands Maintenance Considerations

Required Action	Maintenance Objective	Frequency of Action
Lawn mowing and lawn care	Mow occasionally to limit unwanted vegetation. Maintain irrigated turf grass at 2 to 4 inches tall and nonirrigated native turf grasses at 4 to 6 inches.	Routine–Depending on aesthetic requirements.
Debris and litter removal	Remove debris and litter from entire pond to minimize outlet clogging and aesthetics. Include removal of floatable material from the pond's surface. Also remove debris and litter from the channel.	Routine–Including just before annual storm seasons (that is, in April and May) and following significant rainfall events.
Sediment removal	Remove accumulated sediment and muck. Maintain growth zone depths and spatial distribution.	Nonroutine–Every 5 to 15 years as needed by inspection.
Aquatic plant harvesting	Cut and remove plants growing in wetland (such as cattails and reeds) to remove nutrients permanently with manual work or specialized machinery.	Nonroutine until further evidence indicates such action would provide significant nutrient removal. In the meantime, perform this task once every 5 years or less frequently as needed to clean the wetland zone out.
Inspections	Observe inlet and outlet works for operability. Verify the structural integrity of all structural elements, slopes, and embankments.	Routine–At least once a year, preferably once during one rainfall event resulting in runoff.

8. MODULAR BLOCK POROUS PAVEMENT

8.1 Description

Modular block porous pavement consists of perforated concrete slab units underlain with gravel. The surface perforations are filled with coarse sand, or sandy turf. This BMP is intended to be used in low traffic areas to accommodate vehicles while facilitating stormwater infiltration near its source. Modular block porous pavement has been in use since the mid-1970s. Although it lacks field data that quantify its long-term performance as an infiltration device, the episodal record indicates it is reliable and has experienced few problems. Modular-block porous pavement should be placed in a poured-in-place concrete grid that restricts horizontal movement of infiltrated water through the underlying gravels.

8.2 General Application

Modular block porous pavement is best used in low traffic zones. Where underlying soils permit infiltration and the high seasonal groundwater and impermeable soil layers are at least 4 feet below the surface of the gravel bedding infiltration of stormwater is possible. Otherwise, porous pavement can be installed with underdrain pipes and outlets that control the release rate of the water stored in the rock media. Although this BMP is commonly used for less frequently occupied zones of parking lots, the following are other applications:

- Low traffic airport zones
- Crossover/emergency stopping/parking lanes on divided highways
- Residential street parking lanes
- Driveways
- Maintenance roads and trails

Although grass can be used in the modular block voids, it requires irrigation and lawn care in a semi-arid climate. Even though stormwater infiltration is often the goal when underlying soils and geology permit, it is not necessary for the use of this BMP.

R0056850

VOL 12 2 3557

8.3 Advantages/Disadvantages

8.3.1 General. Aside from the potential for high particulate pollutant removal, modular block porus pavement can reduce the flooding potential by infiltrating or slowing down runoff. Modular block patterns, colors, and materials can serve functional and aesthetic purposes to provide variety in a sometimes uniform site.

The primary disadvantages for use of modular block are its cost and the lack of specific performance data in semi-arid areas that are subject to severe freeze-thaw cycles; however, episodal descriptions indicate this type of pavement, when properly installed, functions well in under freeze-thaw cycles. Other disadvantages could be associated with snow removal, uneven driving surfaces, and potential traps for the high heels of women's shoes. Also, the cost of restorative maintenance can be very high when the system seals with sediment and no longer functions as permeable pavement.

8.3.2 Physical Site Suitability. If infiltration is the goal, the soils underlying the modular blocks should have good infiltrating capacities when saturated. As a minimum, underlying soils need to be equivalent to SCS Hydrologic Group B or better. Also, the bottom of the gravel layer of the pavement section needs to be at least 4 feet above seasonal high groundwater table and the top of any impermeable soil level.

8.3.3 Pollutant Removal. Specific field data on pollutant removal rates are not available for modular block porous pavement. When the pavement is designed to infiltrate runoff into the ground, removal rates are projected to be high for both suspended sediment and associated constituents, such as metals, oil, and grease are moderate to high for soluble constituents. Runoff filtration through the sand, gravel, or sandy sod turf of the modular block voids and entrapment are the primary removal mechanisms of pollutants along with the filtration, adsorption, and ion exchange that occur as stormwater travels through the underlying soils before the stormwater reaches groundwater. When this BMP is designed with underdrains, the removal rates for suspended constituents are still projected to be high, but the removal rates for dissolved constituents are expected to be only low to moderate.

R0056851

VOL 1 2

2 3558

8.4 Planning Considerations and Design Criteria

Although modular block porous pavement is untested as a stormwater BMP in the Denver area, initial (or interim) design guidance is presented in Table 8-1, while Figure 8-1 shows two commonly used modular block units and a cross-section of modular block installation and its subgrades. Schematic representations of various uses are shown in Figure 8-2. Specific manufacturers make precast units or molds, and their specifications can be used in addition to the criteria listed in Table 8-1. Upon installation, every effort should be made to assure even flow distribution over the entire porous surface.

For the purpose of sizing downstream drainage systems and followup BMPs, assume that the permeable pavement areas are 30 percent impervious when infiltration into subsoil is possible and is provided for, and assume that the permeable pavement areas are 60 percent impervious if infiltration is not possible at the site and the pavement has a subdrain outlet.

8.5 Maintenance Considerations

Modular block porous pavement requires little routine maintenance. On the other hand, when the top filter layers seal or the rock media fills with fine sediment, expensive nonroutine maintenance may be necessary. Table 8-2 presents suggested maintenance guidance and frequency.

R0056854

VOL 1 2 2 3 5 6 1

Table 8-1

Modular Block Porous Pavement Design Considerations and Criteria

Criteria	Design Considerations
Rock Media Pore Volume	The facility should provide, as a minimum, sufficient pore volume in the large gravel layer to store 85 to 90 percent of the runoff volume from a 2-year storm (assume 85 to 90 percent of the runoff from 1.15 inches of rainfall for a 100 percent impervious basin tributary to porous pavement). Assume that 30 percent of the rock layer is open pore space. Available pore storage volume can be increased by installing perforated concrete or clay tile in the coarse gravel layer. Limit impervious tributary area to less than two times the pervious pavement area.
Design Selection	1. Soil infiltration can be considered for Hydrologic Soil Classes A and B soils provided the seasonal groundwater table or any impervious layer is at least 4 feet below the top of the subgrade. Reduce the available infiltration rate by a safety factor of 2 to assure sufficient drainage. 2. Use a perforated collection pipe in each cell for poorly infiltrating soils or to augment poor infiltration conditions.
Inlay Material	The modular block should be filled with coarse sand or sandy sod (sod will require irrigation) to form a smooth firm driving surface.
Base Coarses	The filter coarse layers should be a minimum of 4 inches, clean, well-graded, crushed stone (1/8 to 3/4 inch in size). (Do not use geotextile filter fabric in this location). The stone reservoir layer shall be at least 12 inches deep of clean crushed 1.5- to 3-inch-size stone. If offsite drainage from adjacent impervious surfaces occurs, increase this rock layer thickness to provide needed *Rock Media Pore Volume* as required above in this table.
Modular Block Units	The manufacturer's installation requirements for stormwater quality enhancement shall be followed with the exception that *Rock Media Pore Volume Inlay Material*, and *Base Course* dimension, and requirements in this section shall be adhered with.
Concrete Cells	Provide vertical, poured-in-place concrete walls to separate porous cells and to cut off horizontal flow of water. Space the walls so that the distance along the subgrade slope L_{max} does not exceed: $$L_{max} = \frac{0.54}{S_o} \text{ ft}$$
Subbase	Native soil subbase shall be brought to grade by excavation only if infiltration is to be used. In such cases, excavate by using light equipment, and do not roll or compact the exposed subbase to protect the native soil's infiltrating capacity. No such restrictions apply when infiltration into the underlying soils is not the goal or when site conditions do not permit infiltration into the ground. Install a geotextile filter fabric on top of the subbase if the installation is being designed to infiltrate stormwater into underlaying soils. Otherwise install impermeable membrane. Place the base coarse on top of the fabric or the membrane.

R0056855

Table 8-2

Modular Block Porous Pavement Maintenance Considerations

Requires Action	Maintenance Objective	Frequency of Action
Debris and litter removal	Accumulated material should be removed as a source control measure.	Nonroutine–As needed.
Sod maintenance	Lawn care, the irrigation system, and inlay depths should be inspected and maintained as needed.	Routine–As dictated by inspection.
Inspection	Inspect representative areas of surface filter sand, fine gravel, and sandy turf.	Routine and during a storm event to ensure that water is not running off these surfaces.
Replacement of Surface Filter Layer	Remove individual blocks, remove, dispose, and replace surface filter media.	Nonroutine–when it becomes evident that runoff doese not rapidly infiltrate into the surface.

1. INTRODUCTION TO NONSTRUCTURAL BMPs

1.1 Overview

This section contains guidance on the evaluation, selection and use of nonstructural Best Management Practices (BMPs). Each BMP is described and discussed as to its general application in an urban area. The following nonstructural BMPs are considered to be appropriate and effective in stormwater quality enhancement and are described in following sections of this chapter:

- Stormwater quality control planning
- Adoption of criteria and standards (including erosion control during construction)
- Disposal of household waste and toxics
- Use of pesticides, herbicides, and fertilizer
- Illicit discharge controls
- Landscaping and vegetation practices

1.2 Advantages of Nonstructural BMPs

Pollution of stormwater originates from many sources in urban areas. Structural controls reduce the amounts of pollutants that migrate off the urban landscape by reducing runoff and by providing facilities to remove pollutants from stormwater. Nonstructural BMPs prevent or limit the entry of pollutants into stormwater at their source. Prevention is desirable and can be cost effective because it avoids pollution in the first place and thereby reduces the amounts that need to be removed by subsequent treatment. In urbanized portions of the municipality, it may be one of the few affordable methods for stormwater quality enhancement.

The advantages of nonstructural BMPs, among others, are:

- The quality of stormwater runoff is improved

R0056864

- The volume of sediment, debris and other pollutants deposited in receiving waterbodies is reduced
- Operation and maintenance of structural controls is reduced
- Attendent benefits to air quality, ground water quality, and solid waste control
- Enhanced open space and wildlife habitat
- Heightened public awareness of water-quality problems and involvement in solutions
- Increased public awareness of stormwater quality issues
- Most require only a modification of existing practices, are simple to understand, and make good sense
- Implementation can occur rapidly
- Do not require major capital construction financing

1.3 Disadvantages of Nonstructural BMPs

The effectiveness of most nonstructural BMPs depends on the public's attitude, its willingness to accept information, and its willingness to put BMPs into practice. Low participation will result in little or no measurable benefit. A high percentage of participation has the potential for noticeable changes in water quality.

Disadvantages to the use of nonstructural BMPs include:

- Public information is expensive to develop and distribute, and must be updated and redistributed on an ongoing basis
- Effectiveness of good housekeeping measures is determined primarily by voluntary participation on the part of community residents
- Initial public/private expenditures are needed to remove impediments to participation and encourage development of information and infrastructure improvements such as recycling centers and household toxics collection programs

VOL 12 2 3511
R0056865

- Effectiveness of vegetative practices is determined by how successfully permanent ground cover is established
- Requires a dedicated workforce and funds to maintain viable programs and to continue citizen participation
- Effects on stormwater quality are virtually impossible to quantify and to measure accurately without long-term data. On the other hand, the amounts of materials collected and recycled are quantifiable and could serve as an indirect measure of overall success

VOL 1 2 2 3 5 7 3

2. STORMWATER QUALITY CONTROL PLANNING

2.1 Description

Stormwater management planning is an established practice with a long history of use by municipalities in Colorado. Its primary focus prior to the end of the 1980s was the prevention and mitigation of flood damages and loss of life. Emphasis in planning was on storm runoff events with return periods of 2- through 100-years with very little attention paid to stormwater quality enhancement.

As a result of the 1987 Clean Water Act (CWA) requirements, stormwater quality planning is a required practice. These requirements extend to planning for water quality enhancement whenever conducting flood control and floodplain management planning activities.

Planning for stormwater quality can take several forms such as planning for an individual site, a new subdivision, overall planning for an urban watershed or a portion thereof, or overall planning for an entire municipality. As the planning area expands, less specific detail can be addressed and the plans become more conceptual in scope. A well developed citywide or watershed conceptual plan is useful because it provides guidance on how to deal with stormwater runoff and its quality as changes occur in land use. On the other hand, site-specific plans can clearly describe the types of BMPs to use, the phasing for their installation, and the type of long-term maintenance that will be required to keep them operational.

This nonstructural BMP identifies the stormwater planning needs for individual developments and the general nature of the review and approval process of local governments. Municipalities should consider development and adoption of a stormwater quality planning process. It is recommended that the proponent of any new development or redevelopment contact the local government of jurisdiction to determine the exact steps to be taken to obtain final approval of their site plans. The process begins with the preparation and submittal of a stormwater management plan by the proponent to the local government as a part of local zoning, subdivision, or other applicable development review process.

Section 2.2 contains example stormwater management planning requirements that a municipality may employ. It should not be viewed as the only process to follow by every local jurisdiction. It is

R0056867

VOL 12 2 3574

provided, however, as an example and a checklist of some of the many features individual local governments could use in establishing municipal stormwater site-planning requirements.

2.2 General Applicability

As a first step in managing stormwater quality from new development, local governments are encouraged to require all new development and significant redevelopment to prepare and obtain approval of a drainage report for the site that contains a *Stormwater Quality Control Plan*.

For clarification, the local jurisdiction must define what constitutes "new development" and "significant redevelopment." Clearly there is also a need for exemptions for very small sites and infill such as individual lots that are part of existing subdivisions.

The requirement for the preparation of and compliance with a *Stormwater Quality Control Plan* is a nonstructural BMP. The implementation of this BMP is in the form of adoption or promulgation of ordinances, resolutions, or executive orders granting authority to municipal staff to review such plans and to either approve or present recommendations for approvals to elected officials. In addition, implementation of this BMP requires the commitment of staff and fiscal resources of the municipality to follow through with the review, approval, and enforcement of the site-specific plans. Regulations must also be adopted that specify the content of stormwater quality information required for inclusion in the drainage report.

2.2.1 Plan Requirements. A *Stormwater Quality Control Plan* is developed as part of the overall drainage plan. The primary stormwater quality design elements to be addressed in the drainage report are as follows:

- Description of water-quality objectives contained in master plans adopted for the basin or subbasin
- Description of the stormwater quality management planning concept for the specific site and how this is designed to meet basin objectives
- Map showing locations of drainage features
- Drawings of drainage features including structural BMPs in the drainage facility design

R0056868

VOL 1 2 2 3515

- Hydrologic and hydraulic calculations to document adequate sizing and stability of drainage features
- Description of maintenance access and responsibilities

Appendix A is provided as an example of drainage plan submittal requirements that cities and counties in the Denver metropolitan area may consider for adoption. These requirements include both stormwater quality and quantity considerations in the definition of drainage criteria. Appendix A can be used as a model and checklist for local governments in developing their own submittal requirements.

2.2.2 Plan Review Procedures. A drainage report is prepared as part of the overall development review process. The report is prepared as a three-step process:

1. Preliminary drainage report
2. Final drainage report
3. Construction drawings

At the initial stage of planning, a preliminary report is prepared that identifies the general project location, the location relative to major basins and subbasins, and a conceptual design for drainage facilities. After review and comment by the municipality, a final drainage report is prepared that includes details of the drainage facility design. After approval of the final report, construction drawings are prepared that describe the configuration of the site, design of drainage features, and details of structures as appropriate.

2.2.3 Exemptions and Variances. Exemptions and variances may be considered appropriate under certain circumstances. The following examples are noted for consideration by municipalities in making a determination on possible exemptions. For areas of new development, the only criteria may be to establish a minimum area exempt from the requirement to prepare a drainage report. This determination must be made by each individual municipality. For areas being redeveloped, the following criteria can be considered as to what constitutes "significant redevelopment" for the purposes of defining exemptions:

- Minimum Area. A minimum area of 2 lots or 1 acre, whichever is smaller

R0056869

VOL 12 2 3576

- Change in Zoning. A change in zoning of a parcel of land
- Change in Use. A change in use within a major zoning classification
- Change in Plan. A change in the development plan from that originally approved
- Demolition. The total demolition of a site prior to planned redevelopment, or partial demolition dependent on a minimum size of the area being demolished, such as 1 acre
- Asphalt Removal. Removal of greater than 1 acre of asphalt from an existing site is considered significant redevelopment

Variances may also be included as a provision in the municipal drainage planning submittal requirements. This provision would allow a variance from specific information required in the submittal of a drainage plan where this information is unavailable or reasons for its exclusion are justified. If a variance provision is included, each municipality should consider the terms presented by the proponent for requesting a variance on a case-by-case basis.

2.3 Advantages and Disadvantages

New development can incorporate elements of drainage design that reduce impacts on stormwater quality. The requirement to prepare a drainage report that addresses stormwater quality is a method to include structural BMPs in any new development within the municipality. This ensures that all proposed land development includes BMPs that are consistent with technical criteria and the stormwater permit issued by the State of Colorado to the municipality.

2.3.1 Advantages. The primary advantages of stormwater quality management planning are:

- Provides a clear written statement of municipal drainage planning submittal requirements
- Provides guidance on municipal procedures for review of development and redevelopment proposals
- Provides for consistency in achieving municipal stormwater quality goals and objectives

R0056870

- Can serve as a basis for compliance with a municipal stormwater discharge permit issued by the State of Colorado

2.3.2 Disadvantages. The major disadvantages of stormwater quality control planning include:

- Requires commitment of additional administrative and fiscal resources to develop regulations addressing stormwater quality aspects of drainage planning on the part of municipal government
- Can expand the time and expense required on the part of a developer and municipality to implement new development and redevelopment

2.4 Implementation

Implementation of this nonstructural BMP is accomplished as follows:

- Provide staff and fiscal resources to implement review of drainage plans
- Develop review procedures, guidance documents, and coordination mechanisms among various municipal departments
- Adopt drainage planning submittal requirements
- To support full implementation of stormwater quality management planning, a municipality should also consider *Adoption of Criteria and Standards* as described in Section 3 of this chapter

R0056871

VOL 12 2 3 5 7 7

VOL 12 2 3578

3. ADOPTION OF CRITERIA AND STANDARDS

3.1 Description

The adoption by a municipality of criteria and standards for the selection, planning, and design of stormwater quality facilities can be considered a nonstructural Best Management Practice (BMP). Criteria and standards establish the requirements for the design, construction, operation and maintenance of structural stormwater quality BMP facilities that the municipality considers to be the minimum it will accept. Their formal adoption or promulgation must occur before these minimum standards have a legal basis within the community. Since the criteria set forth the minimum standard, their use should not preclude innovation, or the use of detail other than presented in the criteria as long as the basic technology and sound engineering practice are not violated and the goals are being met.

When combined with the municipality's legislative authority and its comprehensive planning process, the adoption of criteria and standards supports the review and approval of zoning, plat-filing, and construction actions for land development and redevelopment. This also ensures that the structural BMPs being used are based on sound technical and engineering design principles that should provide the intended stormwater quality enhancement.

3.2 General Application

Once adopted, a set of technical criteria and engineering design standards for structural BMPs serve to identify structural BMPs that are considered useful for pollutant removal or reduction. The land developer is responsibile for preparing a stormwater management plan as a part of the overall site development plan as described in Section 2. The adopted criteria then provide general guidelines on BMP selection, direction on their intended purpose and function, applicability in various settings, design details and guidance, operation and maintenance needs, pollutant load reduction potential, and initial guidance for estimating their cost. These criteria and standards can also ensure that BMPs are applied uniformly within the municipality.

The success of BMPs for stormwater management is dependent not only on their original design. Subsequent construction, operation, and maintenance are key to their implementation. If structural

R0056872

VOL 1 2

controls are not operated or maintained properly, then the adopted criteria and the designs are ineffectual and their use will have a greatly diminished impact on improving stormwater quality.

3.3 Advantages and Disadvantages

Adoption of technical criteria and standards for BMPs has many advantages and some disadvantages in pursuing runoff quality enhancement by a city or county. Each municipality must evaluate these and the specific criteria and standards prior to adoption.

3.3.1 Advantages. The primary advantages of adopting local stormwater quality criteria and standards are:

- Provides a clear written minimum design standard for a municipality
- Identify structural BMPs suitable for use under local conditions
- Provides a written standard for review and approval of development and redevelopment proposals and designs
- Provides a primary reference source for information
- Provides a basis for considering alternative proposals and designs by the municipality
- Provides for consistency in achieving municipal stormwater quality goals and objectives
- Serves as a basis for compliance with a municipal stormwater discharge permit issued by the State of Colorado
- Serves as a basis for presumptive effectiveness in compliance, thereby reducing or eliminating the need for end-of-pipe compliance monitoring
- Reduces the time and expense needed to implement new development and redevelopment

3.3.2 Disadvantages. The often-stated disadvantages of adopting municipal standards and criteria are:

2 3 5 7 9

R0056873

VOL 1 2 2 3580

- Requires commitment of administrative and fiscal resources for plan review, field inspection, and eventual acceptance of completed facilities on the part of municipal government
- Expands the time and expense on the part of developers and the municipality to implement new development or redevelopment
- Requires periodic updating
- Can stifle innovation or use of designs that differ significantly in detail from the standards if municipal staff are inflexible

3.4 Implementation

The implementation of this nonstructural BMP consists of the following:

- Research known BMPs and identify those considered appropriate for use under local conditions
- Develop clear technical criteria and design standards for the selected BMPs
- Publish and adopt criteria and standards as the minimum standards of the municipality
- Provide staff and fiscal resources to implement the adopted criteria through review, construction, and final acceptance of facilities

Model criteria for structural and nonstructural BMPs were developed by UDFCD in cooperation with many municipalities in the Denver metropolitan area. These are described in detail in the *Structural Best Management Practices* chapter in Volume 3 of this Manual. These model criteria will be updated in the future as more information becomes available on effective stormwater quality BMPs. As a result, the adoption of these or other local criteria should provide for eventual changes as technology or legislation change over time.

R0056874

VOL 1 2 2 3581

4. DISPOSAL OF HOUSEHOLD WASTE AND TOXICS

4.1 Description

Improperly disposed waste materials are a source of stormwater pollution. This is especially true when wastes are placed on impervious surfaces directly connected to the storm drainage system, such as streets, alleys, parking lots and sidewalks.

The development of public education programs and dissemination of information that promotes proper disposal of household waste, litter, pet waste, yard waste, used oil, and toxic waste is a nonstructural Best Management Practice (BMP) that can be employed by the state, municipalities, civic groups and industry. The passage of municipal ordinances prohibiting improper disposal of these materials, and their enforcement, is another step in this management practice; however, an on-going education program; along with facilities for such disposal, has been judged to be most effective at this time.

4.2 General Application

Waste materials deposited on the urban landscape, especially the impervious surfaces, can be washed off by stormwater runoff and delivered to the receiving water system. Thus, all measures that help to minimize the presence of these materials on the urban landscape can improve water quality. Proper disposal of household waste and toxics can reduce the deposition of solids, organics, nutrients, oxygen-demanding substances, solvents, caustics, paints, automotive fluids, toxic substances and fecal material on the land and reduce their presence in the stormwater reaching receiving waters.

Public education can be used to raise the level of understanding in the general public on how improper disposal of wastes can degrade stormwater quality, and how proper disposal can help to protect the quality of receiving waters. Several categories of waste materials were identified where public education can be effective in reducing the amounts of pollutants entering municipal stormwater runoff. Each of these are discussed below.

4.2.1 Household Waste. Household waste includes materials discarded on the land surface or into the stormwater system from residential and commercial areas. Wastes from commercial businesses are generated by stores, restaurants, hotels, offices, and other nonmanufacturing activities. Commercial waste is considered to be similar to residential waste and is addressed collectively

R0056875

VOL 1 2 2 3582

under this definition. Toxic wastes from residential and commercial areas are considered a subcategory of household waste.

Refuse is solid waste that is contained, whereas litter is uncontained. Refuse is controlled through existing programs of solid waste collection and disposal. The goal of household waste disposal is to contain all refuse, reduce litter, and encourage proper waste disposal through public education.

4.2.2 Litter. Most litter is biodegradable and can create an oxygen demand in water as it decomposes. Research by Keep America Beautiful, Inc. (1990) has shown that people litter where litter has already accumulated. Also according to Keep America Beautiful, Inc. (1987), pedestrians and motorists account for less than 25% of litter, the other sources being household waste, commercial and industrial waste, haulage vehicles, loading docks, and construction sites. Reduction of litter through proper disposal can reduce its accumulation on the urban landscape and its eventual entry into the stormwater system.

4.2.3 Pet Waste. Pet waste deposited on impervious surfaces can be transported by the stormwater drainage system to receiving waters. Fecal matter contains pathogenic bacteria and also creates an oxygen demand in water.

The majority of improperly disposed pet waste occurs in public areas, such as streets and parks. Pet waste ordinances are common in municipalities, however, these are difficult to enforce especially with limited municipal resources. Public education can help bring this problem to the public's attention, and can thereby reduce deposition of pet waste on urban surfaces.

4.2.4 Yard Waste. Yard waste is also a category of household waste. It is distinguished from other categories of household waste in that it can be disposed of by composting. Composting is the aerobic decomposition of plant and other organic materials.

Yard waste accounts for 18% of the municipal waste stream on a weight basis (Keep America Beautiful, 1987). Fallen tree leaves, grass clippings and garden detritus can become water pollutants when they are disposed of in alleys, driveways, parking lots, streets, street gutters and drainage channels. Public education efforts on the benefits of composting and on proper disposal of yard waste can help to reduce the volume of yard waste entering the stormwater system and receiving waters.

R0056876

VOL 12 2 3 5 8 3

4.2.5 Used Oil and Automotive Fluids. Used oil and automotive fluids including antifreeze, brake fluid, transmission fluid, grease, other lubricants, and petroleum-based cleaning solvents are wastes generated during automobile maintenance by residential households and commercial businesses. These can enter the storm drainage system if poured directly into storm inlets or disposed on concrete or asphalt exposed to precipitation.

Improper disposal of used oil and automotive fluids cause receiving waters to become contaminated with hydrocarbons and residual metals that can be toxic to stream organisms. Used oil and other petroleum products can be recycled. A number of different recycling centers presently exist in the metropolitan area. Public education on the location of these centers, the benefits of recycling, prevention of fluid leaks, and the importance of proper disposal for improving stormwater quality, can reduce the amounts of oil and used automotive fluids reaching receiving waters.

4.2.6 Toxic Wastes. Toxic wastes are generated by residential households and commercial businesses. These primarily consist of certain types of used and unused consumer products. Included among these are paint, solvents, putties, cleaners, waxes, polishes, oil products, aerosols, acids, caustics, pesticides, herbicides, and certain medicines or cosmetics. These products and their containers should always be disposed of properly. Some of these unused toxic materials can also be recycled.

Improper disposal of toxic substances cause stormwater to become contaminated by these wastes. This occurs when toxic substances are dumped into street gutters or storm inlets. This also happens when stormwater comes in contact with toxic substances or where they have been improperly disposed on land surfaces.

There is no need for improper disposal of toxic substances since, according to legislation passed by the U.S Congress (1976), small amounts of toxic materials can legally be disposed of in landfills. Educational efforts to heighten public awareness of the environmental damage due to improper disposal, and to encourage proper disposal and recycling can reduce the amounts of these pollutants entering stormwater, provided the public as a whole actively participates.

4.3 Advantages and Disadvantages

It is unknown at present the extent of runoff contamination due to improper disposal of various household waste materials. The amount of water quality improvement that can result from public

R0056877

VOL 1 2 2 3584

education on proper disposal methods and opportunities for recycling have yet to be quantified. Intuitively, there should be some benefit if the amount of these wastes is reduced.

4.3.1 Advantages. Major advantages of public education on proper disposal of household waste and toxics can include:

- Reduction in the quantities of solids, metals, floatable materials, oxygen-consuming materials, nutrients, fecal matter, oil and toxic substances transported by stormwater to receiving waters
- Improved aesthetics of parks and public areas
- Appropriate disposal of more wastes at landfills
- Reduced littering on the urban landscape
- Increased recycling and resource recovery
- Heightened awareness and public understanding of how each person can pollute receiving waters and how each person can help to prevent their pollution

4.3.2 Disadvantages. Some disadvantages associated with the use of this BMP include:

- Its success and effectiveness depends on voluntary efforts
- Places an increased demand on recycling facilities and products
- Extremely difficult to quantify pollutant load reduction
- Requires an on-going effort to continuously provide public education through distribution of educational materials
- May require ordinances and enforcement actions in some cases to address the more difficult and persistent activities generating pollutants

4.4 Implementation

The implementation of a public education and information program can include one or more of the following:

R0056878

VOL 1 2

- Development, publication and distribution of brochures
- Utility bill inserts, flyers and handbills
- Newspaper articles and/or advertisements
- Development and distribution of educational videos
- Public workshops, including field demonstrations
- Developing school curricula
- Developing and installing posters and signs

The following are examples that may be considered for use:

- Signs, including graphics, on dumpsters and other locations encouraging proper waste disposal
- Brochures and utility bill inserts on separation of wastes and recycling
- Advertising the locations of existing toxic disposal sites and waste recycling centers
- Advertising the locations of existing automobile used oil disposal sites
- Establishing and maintaining household toxics disposal sites
- Annual or curbside collection of household toxics
- Signs in parks and along streets on pet waste control and ordinances
- Pet waste disposal bags in public parks
- Voluntary neighborhood clean-up efforts
- Waste containers in problem litter areas
- Requiring waste-haulage truck covers
- Seasonal collection programs for tree branches and leaves

2 3 5 8 5

R0056879

VOL 12 2 3586

- On-going collection program, or disposal sites, for grass clippings and other yard waste
- Distribution programs to recycle compost as mulch
- Advertisements or notices of private locations accepting yard waste for composting
- Information on backyard or neighborhood composting and proper disposal of yard waste

All of these examples are not likely to be used by a municipality at any given time. Local conditions, public attitudes, and fiscal constraints will determine what combination is most appropriate and effective for use in each municipality.

R0056880

VOL 1 2 2 3587

5. USE OF PESTICIDES, HERBICIDES AND FERTILIZER

5.1 Description

Pesticides, herbicides, and fertilizers are used to maintain landscaping in residential and commercial areas. These substances are toxic and can contaminate surface runoff if not properly used. This nonstructural BMP consists of the development and dissemination of public information that encourages proper use and application of pesticides, herbicides, and fertilizers.

5.2 General Application

Pesticides, herbicides, and fertilizers are chemicals used in landscape maintenance. Pesticides are used for insect control, herbicides are used for weed control, and fertilizers are used to promote growth of grasses, flowers, trees, shrubs, and other vegetation. While pesticides and herbicides are toxic to aquatic life at low concentrations, fertilizers can be toxic at high concentrations. Fertilizers, however, are more commonly a problem because of their nutrient-enrichment effect on receiving waterbodies. An oversupply of phosphorus and nitrogen will promote algal growth that can lead to a depletion of dissolved oxygen needed for fish and other aquatic organisms. These chemicals are applied on urban landscape areas and, when improperly applied or used, can be transported to receiving waters in surface runoff.

The rate and timing of application of pesticides, herbicides, and fertilizer are important to minimize transport by surface runoff, as well as to optimize their intended purpose in landscape maintenance. Overapplication and overspraying of pesticides, herbicides, and fertilizers onto impervious areas, such as streets and sidewalks, need to be avoided as well as excessive or too frequent use of these chemicals. Use of these chemicals in accordance with manufacturer's recommendations can prevent most of the surface water contamination being attributed to their use.

Public education can be an effective method. Raising the general level of understanding of how individual action in the use of these chemicals can contaminate surface runoff and the receiving waterbodies can make each citizen aware of the problem. Whether this awareness will translate into an improved use of these products will then depend on individual attitudes. Thus, dissemination of information to the public on the impacts of improper use and how to use landscape maintenance chemicals is the basis for this nonstructural BMP.

R0056881

VOL 1 2 2 3 5 8 8

5.3 Advantages and Disadvantages

Although it is possible to quantify the amounts of pesticides, herbicides, and fertilizers used in residential and commercial areas within a given market zone, it is not known what amounts are improperly used. There should be some amount of overall benefit, however, if educational efforts result in a general increase in the number of people properly using and applying these chemicals in urban areas.

5.3.1 Advantages. Major advantages of the use of this BMP include:

- Can reduce the source of pesticides and herbicides eventually entering receiving waters
- Can help reduce the level of phosphorus and nitrogen in receiving waters, thereby positively affecting the problem of nuisance growth of algae, and eutrophication of small lakes and tributary streams
- Encourage the use of less toxic or substitute methods of pest and weed control that, if followed, further reduce the supply of pesticides and herbicides for contact with surface runoff
- Heighten the awareness and public understanding of how individual actions can add to or reduce stormwater pollution

5.3.2 Disadvantages. Some disadvantages associated with the use of this BMP include:

- Difficult to reach and influence all commercial and residential users of these chemicals
- Difficult to present technical information in simplified form to all users
- Extremely difficult to quantify extent of how implementation of this BMP translates into water quality effects in receiving waters
- Requires on-going educational activities an the distribution of information

R0056882

VOL 1 2 2 3589

5.4 Implementation

The development of an ongoing educational program is the basis of this nonstructural BMP. The audience to be targeted is residential homeowners and small businesses.

As a first step, technical information on pesticides, herbicides and fertilizers and their proper use must be developed. The following sources can be consulted:

- Existing state regulations on pesticide application, certification, and weed control,
- Federal legislation, regulations and technical reports,
- Chemical manufacturer's technical manuals, product labels and use directions, storage and proper disposal guidelines, and material safety data sheets,
- Sprayer manufacturer's calibration guides,
- Sorbent manufacturer's spill management guides,
- University and County Agricultural Extension Service horticultural guides,
- Rocky Mountain Poison Center safety guidelines, and
- Other studies and available information.

Methods available for public education on the use of pesticides, herbicides and fertilizers are very similar to those described in Section 4.4 of this chapter and the reader is referred to that section for details.

R0056883

VOL 12 2 3590

6. ILLICIT DISCHARGE CONTROLS

6.1 Description

Activities that reduce the entry of pollutants into the municipal storm sewer system during dry-weather periods can enhance the quality of receiving waters. These include controls on illegal dumping of toxic substances and petroleum products, responses to contain accidental spills, measures to locate and disconnect illicit connections of wastewater sewers from storm sewers, and measures to prevent additional illicit wastewater sewer connections in the future. To their credit, many municipalities already have programs in place to address all of these concerns. Measures that limit these types of illicit discharges to the storm drainage system are considered nonstructural best management practices (BMPs).

6.2 Illegal Dumping

Illegal dumping can occur at various times and places whenever toxic substances or other pollutants are dumped into or disposed of directly into storm inlets, other storm drainage facilities, or onto the urban landscape. Prohibitions against such activity have been enacted by many municipalities, however, enforcement is difficult because of the often clandestine nature of illegal dumping and the large areas over which such activities can take place.

Nonstructural BMPs that can be considered for implementation by local municipalities are based on efforts to increase surveillance of illegal dumping. These include developing educational materials for the public about these illegal practices and the hazards they create to the public health and the environment, encouraging increased public reporting, possibly establishing a "hotline" telephone number for citizens to call to report dumping incidents, or making illegal dumping a part of the 911 reporting network. Strong enforcement action against violations, accompanied by publicity, could discourage such activities by others.

6.3 Accidental Spill Response

The storage, transport and disposal of hazardous and toxic substances is a regulated activity under state and federal laws. Response procedures for management of accidental spills of pollutants are practiced presently by many municipalities. As a result, many local police and fire departments are

R0056884

VOL 1 2 2 3591

equipped to respond to such spills. Nevertheless, most spills have the potential to contaminate receiving waters via transport by the storm sewer system.

Additional measures that might be considered by local governments include mapping of storm sewer systems to identify the locations of stormwater inlets for each sewer line. Such maps can then be used by the emergency response crews to help identify which inlets, areas, or sewers to protect or block off in the event of a spill. Once a spill occurs, it should be monitored to determine when the area of the spill has been adequately cleaned up. All of these measures, as well as on-going practices, need periodic updating and refresher training to be current. Training, updating of procedures, field exercises and proper equipment are all part of a spill response program.

6.4 Illicit Connections

Illicit connections of wastewater sewers to the storm runoff system in new developments can be prevented by an aggressive and competent inspection program by municipal or utility personnel. Illicit connections can exist, however, in older developments. Some municipalities have taken steps in the past to identify these and have disconnected those that were found. A well-organized program to find illicit wastewater connections also requires accurate mapping of the sanitary and storm sewer systems and a thorough understanding of these systems.

To isolate likely sources, personnel first need to look for visual signs of illicit connections at storm sewer outfalls, relying on sight and smell. If the initial screening indicates a possible illicit connection, random dry-weather sampling and testing for indicator constituents can help to further identify if there may be illicit connections in the system. These then need to be investigated further with a well-planned "seek and destroy" effort that is designed to address the specific nature of the storm drainage and wastewater systems. Occasional random dry-weather screening can also be conducted, especially in areas where the greatest potential exists for illicit connections. These tests may identify illicit connections that discharge occasionally and in a random manner, a typical scenario for individual wastewater discharges. Excavation of sewer lines at the point of connection, and reconnection of the wastewater line to the appropriate system is the final step to correct the problem.

R0056885

VOL 1 2

6.5 Advantages and Disadvantages

The question whether actions to reduce illegal dumping, contamination from accidental spills and illicit discharges have advantages or disadvantages is immaterial. This is evidenced by the fact that many municipalities have one or more programs in place. Pollutants entering the storm sewer systems by illegal dumping, spills, and illicit connections can contribute public health problems that deserve on-going attention. Thus, mitigation efforts can provide benefits to water quality in the receiving system while protecting public health and welfare. However, there are costs associated with these activities.

6.6 Implementation

The following actions, if not already in place, can be considered for use by local jurisdictions:

- Enactment of ordinances prohibiting illegal dumping and illicit connections
- Developing a public education program advising the residents of potential problems that can result from illegal dumping, illicit connections and accidental spills. Section 4 of this chapter describes elements of a public education program
- Install a "hotline" telephone number, or make 911 a part of this program to handle calls from citizens reporting illegal dumping or accidental spills
- Review and update training procedures, equipment and material inventories, and administrative procedures for spill containment and management
- Conduct random field screening of stormwater outfalls to find illicit wastewater connections to storm drainage systems. All illicit connections that are discovered should be eliminated
- Train field inspectors and develop field inspection procedures that prevent new illicit connections of wastewater lines to storm sewers

VOL 1 2 2 3593

7. LANDSCAPING AND VEGETATIVE PRACTICES

7.1 Description

Establishment and maintenance of landscaping and vegetation in existing urban areas can assist in reducing stormwater runoff rates and volumes, sediment loads, and pollutants associated with sediment from entering streams and lakes. In any urban area, many areas of land exist that are devoid of vegetation for long periods of time. Efforts to revegetate these areas and those experiencing soil disturbance activities, or otherwise provide stabilization from erosion during storm runoff, will improve the quality of stormwater runoff entering receiving waters. This nonstructural Best Management Practice (BMP) encourages the establishment and maintenance of urban landscaping and vegetation through the development of public education programs, dissemination of information, and the adoption of erosion control ordinances.

7.2 General Application

A vegetative cover on soil will reduce the volume of runoff, reduce soil erosion, and encourage deposition of sediments, as stormwater flows through the vegetated area. Vegetation acts to reduce raindrop impact on soil, slows runoff rates, and encourages infiltration of precipitation into the soil. Additional pollutants, such as metals, nutrients, and bacteria that are attached to sediment will also be removed. The overall volume of runoff from a vegetated area is less than from an area of bare soil. Although bare soil will also allow some infiltration, its surface has a tendency to seal and erode. The eroded soils are a source of sediment transported to streams and lakes.

Soil erosion and transport from urban areas, except during construction activities, produces only a fraction of total sediment arriving at streams and lakes as wash load. Agricultural activities by far exceed the quantities from urban areas. Nevertheless, it is a problem that can be addressed in urban areas through education and can thus be reduced.

A number of areas within an existing urbanized portion of a city or a county can remain non-vegetated for prolonged periods of time. These can occur on vacant lots, edges of roadways and other transportation corridors, utility corridors, equipment storage areas, overflow parking areas, and other parcels of land. Also, areas that are undergoing, or have recently experienced construction, grading, or other soil disturbance activity are of particular concern.

R0056887

VOL 1 2 2 3594

Most homeowners and commercial businesses attempt to landscape areas within a short period of time after building on their property. However, some areas may be neglected and remain bare of vegetation for long periods of time. Areas may also exist where no attempt was made initially to establish a permanent cover of vegetation.

The need for erosion control and its technology for all new construction activities are described in the *Erosion Control* chapter of this Manual. It is a need that also has to be addressed through state regulations, municipal ordinances, and their enforcement. Section 2 of this chapter describes the local government review and approval process for stormwater quality planning for new development, while the *Erosion Control* chapter contains technical guidance and a model erosion control ordinance.

Development of guidelines and educational materials on landscaping and vegetation for existing urban areas are recommended under this nonstructural BMP. In addition, fugitive dust and bare-ground revegetation ordinances are recommended for local consideration. The dissemination of educational materials to the public can be accomplished by a number of methods, as described in Section 4. This BMP, however, is targeted primarily at existing urbanized portions of metropolitan areas.

7.3 Advantages and Disadvantages

7.3.1 Advantages. The primary advantages to the use of landscaping and vegetation include:

- Reduction of sediment in stormwater runoff
- Potential for improvement in receiving water quality during storm events
- Potential for reduced deposition of sediment in receiving waters, drainageways, and detention facilities
- Reduced maintenance of storm sewers and facilities
- Potential for improved aquatic habitat
- Improved aesthetics of vacant lands

R0056888

VOL 1 2 2 3595

- Potential for reduced wind erosion and windblown dust
- Possible to document area of revegetated lands

7.3.2 Disadvantages. The major disadvantages to the use of this BMP include:

- Cost to revegetate bare soil areas
- Cost of landscape maintenance
- Limited voluntary effort on the part of homeowners and businesses
- Extremely difficult to document water-quality improvement
- Enforcement actions are costly and politically unpopular

7.4 Implementation

The development and dissemination of public education materials are very similar to those described in Section 4.4. The reader is referred to this section for further guidance. The specifics of this activity, namely the need to establish permanent vegetative cover on vacant lands and lands undergoing construction, can be incorporated into a separate set of brochures, booklets, and guidelines. Some methods in particular that might be effective and could be pursued for this BMP include:

- Booklets describing revegetation methods
- Brochures showing "before and after" photographs of successful revegetation or landscaping efforts
- Demonstration areas and field workshops
- Earth Day activities or similar public involvement campaigns

Each local jurisdiction needs to determine which of these, or combination thereof, is most effective for use in their community. At the same time, the city or county may want to adopt and enforce ordinances requiring owners of bare, or poorly vegetated, vacant land to establish a permanent vegetative cover. Reasons that can be used to justify such ordinances are fugitive dust concerns

R0056889

regarding air quality, and effects of sediment on the municipal stormwater system and state receiving waters. Such ordinances can include provisions for timely compliance on the part of a landowner, with a requirement that noncompliance be subject to action by the municipality to revegetate the area with charges assessed to the landowner.

APPENDIX A

Example Drainage Planning Submittals

(Model Local Criteria Section)

The following is an example of criteria for submittal of information required on storm drainage planning and design during the zoning and subdivision platting process for an individual site of proposed development or significant redevelopment. These submittal requirements present only those specific to stormwater drainage facilities. In addition to these, the proponent of a land-use change typically has to also provide information addressing water and sanitary sewer service, streets, other utilities, site planning, grading, emergency access, traffic, building construction, and many others needed to integrate the new development, or a redevelopment, into the municipality.

In the example presented in this appendix, various sections refer to CRITERIA. This term is used as a generic reference to only the storm drainage design and technical criteria of the municipality, of which this sample section is only one part. At the same time, all references to MANUAL in this example refer to the *Urban Storm Drainage Criteria Manual*, Volumes 1, 2 and 3.

R0056892

VOL 1 2

2 3599

R0056893

EXAMPLE SITE DEVELOPMENT
STORM DRAINAGE DESIGN AND TECHNICAL CRITERIA

CITY (COUNTY) OF _____

CHAPTER (x) DRAINAGE PLANNING SUBMITTAL REQUIREMENTS

x.1 REVIEW PROCESS

All subdivisions, resubdivisions, Planned Unit Developments or any other development or redevelopment done within the jurisdiction of these CRITERIA shall be required to submit drainage reports, plans, construction drawings, specifications and as-constructed information in conformance to the requirement of these CRITERIA.

x.1.1 Subdivision Process

The general requirements for the subdivision of land in the City (County) of _____, and conditions requiring subdivision, are set forth in (reference subdivision rules, or land development code, ordinance, resolution, etc.). Readers are referred to the (reference subdivision rules) for standards and procedures for the review and approval of subdivision plats.

x.1.2 Permit Process

Any structure, or other development or redevelopment, which requires a building permit under the City (County) of _____ and (name of rules) may also require a (name of other permit) to be issued by the Department of (department name). These permits will only be issued upon conformance to requirements contained in these and other applicable CRITERIA as evidenced by approval of the Final Drainage Report.

x.2 DRAINAGE REPORT

(____) copies of the drainage report, prepared and signed by a Professional Engineer registered in the State of Colorado, shall be submitted to the (Department Name) for review. Reports shall be cleanly and clearly reproduced and legible throughout. Blurred or unreadable portions of the report will be deemed unacceptable and will require resubmittal. Incomplete or absent information may require resubmittal of the report.

A pre-submittal conference is suggested in cases involving large development or redevelopment or where special conditions or problems have become apparent during the development review process.

x.2.1 Preliminary Drainage Report

At the time of land zoning, rezoning, or proposal for development or redevelopment, a preliminary drainage report is required in advance of the final drainage report.

VOL 1 2 2 3600
R0056894

VOL 1 2 2 3601

x.2.2 Preliminary Drainage Report Contents

The purpose of a preliminary report is to define on a conceptual level the nature of the proposed development or project and to describe all existing conditions and propose facilities needed to conform to the requirements of these CRITERIA. Each preliminary drainage report shall provide the following:

I. GENERAL LOCATION AND DESCRIPTION

A. Location

1. City, County, State Highway and local streets within and adjacent to the site, or the area to be served by the drainage improvements.
2. Township, range, section, 1/4 section, (subdivision, lot and block).
3. Major drainageways and facilities.
4. Names of surrounding developments.
5. Name of receiving water(s) and I.D. number(s).

B. Description of Property

1. Existing ground cover (type and vegetation).
2. Area in acres.
3. Existing major irrigation facilities such as ditches and canals.
4. Proposed land use and ground cover.

II. DRAINAGE BASINS AND SUB-BASINS

A. Major Basin Description

1. Reference to major drainageway planning studies such as flood hazard delineation report, major drainageway planning reports, and flood insurance rate maps.
2. Major basin drainage characteristics, and existing and planned land uses within the basin, as defined by the (department name).
3. Identification of all nearby irrigation facilities that will influence or be influenced by the local drainage.

R0056895

B. Sub-Basin Description

1. Describe historic drainage patterns of the property.

2. Describe offsite drainage flow patterns and impact on development under existing and fully developed basin conditions.

III. DRAINAGE FACILITY DESIGN

A. General Concept

1. Discuss proposed drainage concept and how it fits existing drainage patterns.

2. Discuss how offsite runoff will be considered and how expected impacts will be addressed.

3. Discuss anticipated and proposed drainage patterns.

4. Discuss stormwater quantity and quality management concept and how it will be employed.

5. Describe the content of tables, charts, figures, plates, drawings and design calculations presented in the report.

6. Discuss maintenance and maintenance access.

B. Specific Details (Optional Information)

1. Discussions of drainage problems, including stormwater quality, and solutions at specific design points.

2. Discussion of detention storage and outlet design.

3. Discussion of impacts of concentrating flow on downstream properties.

IV. REFERENCES

Reference all criteria, master plans, and technical information used in support of concept.

x.2.3 Preliminary Report Drawing Contents

(a) General Location Map: All drawings shall be 22" x 34" in size. A map shall be provided in sufficient detail to identify drainage flows entering and leaving the development and general drainage patterns. The general location map should be at a scale of 1" = 500' to 1" = 4000' and show the path of all drainage from the upper end of any offsite basins to the defined major drainageways. The map shall identify all major facilities (i.e., irrigation ditches, existing detention facilities, stormwater quality facilities, culverts, storm sewers) downstream of the property along the flow path to the nearest major drainageway. Basins, along with basin identification numbers, and divides are to be identified and topographic contours are to be included. An annotated copy of the enlarged USGS maps maintained by the Urban Drainage and Flood Control District can be used as a base map.

VOL 1 2 2 3602
R0056896

VOL 1 2 2 3603

(b) Floodplain Information: A copy of any published floodplain maps (i.e., flood hazard area delineation, flood insurance rate maps) showing the location of the property shall be included with the report as outlined in Section x.2.2. All major drainageways shall have the defined floodplain shown on the report drawings.

(c) Drainage Plan: Map(s) of the proposed development at a scale of 1" = 20' to 1" = 200' on a 22" x 34" drawing shall be included. The plan shall show the following:

1. Existing topographic contours at 2-feet (or less) intervals. In mountainous areas, the maximum interval may be extended to 5 feet. The contours shall extend a minimum of 100-feet beyond the property lines.
2. All existing drainage facilities within map limits.
3. Flooding limits based on available information.
4. Conceptual major drainage facilities including proposed stormwater quality BMPs, detention basins, storm sewers, swales, riprap, and outlet structures in the detail consistent with the proposed development plan.
5. Major drainage basin boundaries and sub-boundaries.
6. Any offsite feature including drainage that influences the development.
7. Proposed drainage patterns and, if available, proposed contours.
8. Legend to define map symbols.
9. Project name, address, engineering firm and seal, and date in Title block in lower right corner.
10. North arrow, scale and available bench mark information and location for each benchmark.

x.3 FINAL DRAINAGE REPORT

The final drainage report serves to define and expand the concepts shown in the preliminary report or is sufficient of itself to assure conformance to these CRITERIA. The final report may be submitted at any point during the permitting and platting process, but must be reviewed and approved prior to issuance of any permit.

(_____) copies of the report shall be submitted to the _____ Department. Reports shall be typed and bound on 8-1/2" x 11" paper with pages numbered consecutively. Drawings, figures, tables, etc., shall be bound with the report or contained in an attached pocket. The report shall include a cover letter presenting the design for review prepared or supervised by a Professional Engineer licensed in the State of Colorado. The report shall contain a certification that reads as follows:

"This report for the drainage design of (Name of Development) was prepared by me (or under my direct supervision) in accordance with the provisions of City (County) of _____ Storm Drainage Design and Technical Criteria, and was designed to comply with the provisions thereof.

R0056897

I understand that the City (County) of _____ does not and will not assume liability for drainage facilities design.*

_____
Registered Professional Engineer
State of Colorado
No. _____
(Affix Seal)

x.3.1 Final Drainage Report Contents

The report shall be in accordance with the following outline and contains the following applicable information:

I. GENERAL LOCATION AND DESCRIPTION

A. Location

1. Township, range, section, 1/4 section.
2. Local streets within and adjacent to the subdivision.
3. Major drainageways, facilities, and easements within and adjacent to the site.
4. Names of surrounding developments.
5. Name of receiving water(s) and number(s).

B. Description of Property

1. Area in acres.
2. Existing ground cover (type of trees, shrubs, vegetation, general soil conditions, topography, and slope).
3. Major drainageways.
4. General project description.
5. Irrigation facilities.
6. Proposed land use and ground cover.

VOL 1 2 2 3604
R0056898

VOL 1 2 2 3605

II. DRAINAGE BASINS AND SUB-BASINS

A. Major Basin Description

1. Reference to major drainageway planning studies such as flood hazard delineation reports, major drainageway planning reports, and flood insurance rate maps.

2. Major basin drainage characteristics, existing and planned land uses.

3. Identification of all irrigation facilities within the basin that will influence or be influenced by proposed site drainage.

B. Sub-Basin Description

1. Discussion of historic drainage patterns of the property.

2. Discussion of offsite drainage flow patterns and impact on development under existing and fully developed basin conditions, as defined by the (department name).

III. DRAINAGE DESIGN CRITERIA

A. Regulations: Discussion of the use of optional provisions and any deviation from the CRITERIA and justification for such actions.

B. Development Criteria Reference and Constraints

1. Discussion of previous drainage studies (i.e., project master plans) for the site that influence or are influenced by the drainage design and how implementation of the plan will affect drainage and stormwater quality for the site.

2. Discussion of the effects of adjacent drainage studies.

3. Discussion of the drainage impact of site constraints such as streets, utilities, transitways, existing structures, and development or site plan.

C. Hydrologic Criteria

1. Identify design storm rainfall and its return period(s).

2. Identify runoff calculation method(s).

3. Identify detention discharge and storage calculation method(s).

4. Discussion and justification of other criteria or calculation methods used that are not presented in or referenced by the CRITERIA.

R0056899

D. Hydraulic Criteria

1. Identify various capacity references.

2. Discussion of other drainage facility design criteria used that are not presented in these CRITERIA.

E. Stormwater Quality Criteria

1. Identify BMPs to be used for stormwater quality control.

2. Identify, as appropriate, water-quality capture volume and drain time for extended-detention basins, retention ponds and constructed wetland basins.

3. Identify, as appropriate, runoff volume and flow rates for design of water-quality swales, wetland channels and porous pavement.

4. Discussion of other drainage facility design criteria used that are not presented in these CRITERIA or the MANUAL.

F. Waivers from Criteria

1. Identify provisions by section number for which a waiver is requested.

2. Provide justification for each waiver requested.

IV. DRAINAGE FACILITY DESIGN

A. General Concept

1. Discussion of proposed concept and typical drainage patterns.

2. Discussion of compliance with offsite runoff considerations.

3. Discussion of anticipated and proposed drainage patterns.

4. Discussion of proposed stormwater quality management strategy.

5. Discussion of the content of tables, charts, figures, plates, or drawings presented in the report.

B. Specific Details

1. Discussion of drainage problems encountered and solutions at specific design points.

2. Discussion of detention storage and outlet design.

3. Discussion of stormwater quality BMPs to be used.

4. Discussion of maintenance access and aspects of the design.

VOL 1 2
2
3
6
0
0
6
R0056900

VOL 1 2 2 3607

5. Discussion of easements and tracts for drainage purposes, including the conditions and limitations for use.

V. CONCLUSIONS

A. Discussion of Compliance with Standards by Proposed Drainage Facility Plan.

1. "CRITERIA"

2. "Major Drainageway Planning Studies"

3. "MANUAL"

B. Discussion of Final Drainage Concept

1. Effectiveness of drainage design to control damage from storm runoff.

2. Effectiveness of design to remove pollutants from storm runoff.

3. Influence of proposed development on the Major Drainageway Planning Studies recommendation(s).

VI. REFERENCES

Reference all criteria and technical information used.

VII. APPENDICES

A. Hydrologic Computations*

1. Land use assumptions regarding adjacent properties.

2. Initial and major storm runoff at specific design points.

3. Historic and fully-developed runoff computations at specific design points.

4. Hydrographs at critical design points.

5. Time of concentration and runoff coefficients for each basin.

6. Stormwater quality BMP sizing calculations including runoff adjustments for minimizing directly-connected impervious areas.

B. Hydraulic Computations*

1. Culvert capacities.

2. Storm sewer capacity, including energy grade line (EGL) and hydraulic grade line (HGL) elevations.

3. Gutter capacity as compared to allowable capacity.

R0056901

VOL 1 2 2 3608

4. Storm inlet capacity including inlet control rating at connection to storm sewer.

5. Open channel design.

6. Check and/or channel drop design.

7. Detention area/volume capacity and outlet capacity calculations for flood detention and water quality basins; depths of detention basins.

8. Wetland area and area/depth distribution for constructed wetland basins.

9. Infiltration rates and volumes for porous pavement or release rates where underdrains or infiltration is not possible.

10. Flow rates, velocities, longitudinal slopes and cross-sections for wetland channels and water quality swales.

11. Downstream/outfall system capacity to the Major Drainageway System.

- Include any input and output listings for any computer models used.

x.3.2 Final Report Drawing Contents

(a) General Location Map: All drawings shall be 22" x 34" in size. A map shall be provided in sufficient detail to identify drainage flows entering and leaving the development and general drainage patterns. The location map should be at a scale of 1" = 500' to 1" = 4000' and show the path of all drainage from the upper end of any offsite basins to the defined major drainageways. The map shall identify any major construction (i.e., development, irrigation ditches, existing detention facilities, culverts, storm sewers) along the entire path of drainage. Basins, along with basin identification numbers, and divides are to be identified and topographic contours are to be included.

(b) Floodplain Information: A copy of applicable published floodplain maps showing the location of the property shall be included with the report. All major drainageways shall have the floodplain defined and shown on the report drawings in accordance with the provisions of this and other sections of these CRITERIA.

(c) Drainage Plan: Map(s) of the proposed development at a scale of 1" = 20' to 1" = 200' on a 22" x 34" drawing shall be included. The plan shall show the following:

1. Existing and proposed contours at 2-feet (or less) intervals. In areas of little relief, 1-foot contours shall be shown. In mountainous areas, the maximum interval may be extended to 5 feet The contours shall extend a minimum of 100-feet beyond the property lines.

2. Property lines, existing easements, and easements proposed for dedication, with purposes noted.

3. Streets, indicating ROW width, flowline width, curb or roadside swale type, sidewalk, and approximate slopes.

R0056902

4. Existing drainage facilities and structures, including irrigation ditches, roadside ditches, crosspans, drainageways, gutter flow directions, and culverts. Also show pertinent information such as material, size, shape, slope, and locations.

5. Overall tributary drainage basin area boundary, basin identification number, if appropriate, and drainage sub-area boundaries.

6. Proposed type of street flow (i.e., vertical or combination curb and gutter), roadside ditch or swale, gutter, slope and flow directions, and cross pans.

7. Proposed storm sewers and open drainageways, including inlets, manholes, culverts, and other appurtenances, including riprap or other erosion protection.

8. Proposed structural water-quality BMPs, their location, sizing, and design information.

9. Proposed outfall point for runoff from the developed area and, if required, facilities to convey flows to the final outfall point without damage to downstream properties.

10. Routing and accumulation of flows at various critical points for the initial and water-quality storm runoff events.

11. Routing and accumulation of flows at various critical points for the major storm runoff events.

12. Volumes and release rates for detention storage and water-quality capture volume for facilities and information on outlet works.

13. Location and water surface profiles or elevations of all previously defined floodplains affecting the property. If floodplains have not been previously published, they shall be defined and shown on the drainage plan.

14. Location, and measured or estimated elevations, of all existing and proposed utilities affected by or affecting the drainage design.

15. Routing of upstream offsite drainage flow through the development.

16. Location of any improvements included in the appropriate or accepted outfall system plan, major drainage plan, and/or storm drainage plan.

17. Definition of flow path leaving the development through the downstream properties ending at a major drainageway or receiving water.

18. Legend to define map symbols as accepted or recognized by these CRITERIA.

19. Title block in lower right hand corner.

VOL 12 2 3609

R0056903

VOL 1 2 2 3 6 1 0

x.4 CONSTRUCTION PLANS

For on-site drainage improvements, the final construction plans (22" x 34") shall be submitted after approval of the Final Drainage Report. (____) sets of plans shall be submitted for approval. Upon approval, four sets, stamped and signed, will be returned to the design engineer for use by the contractor, owner and design engineer. However, before any construction work begins, appropriate bonds, letters-of-credit, or other surety as required by these CRITERIA should be issued to the City (County) of _____. The construction plans as a minimum and as appropriate will include:

1. Plan and profile of proposed pipe installations, inlets and manholes with pertinent elevations, dimensions, type and horizontal control shown.
2. Property and right-of-way lines, existing and proposed structures, fences and other land features.
3. Plan and profile of existing and proposed channels, ditches, swales, and on-site water-quality BMPs with construction details, cross-sections and erosion controls.
4. Detention and water quality (if separate) facility grading, trickle channels (if any), outlet and inlet locations, cross-sections or contours sufficient to verify volumes, etc..
5. Details of inlet and outlet control devices and of all structural components being constructed.
6. Maintenance access.
7. General overlot grading and the erosion and sediment control plan prepared in accordance with applicable provisions of these CRITERIA and the MANUAL.
8. Areas of modular block porous pavement, if any, and installation details.
9. Landscaping and revegetation plans and details.
10. Proposed finish floor elevations of structures.
11. Relation of site to current and, if appropriate, modified floodplain boundaries.
12. A statement agreeing to maintain and operate all privately-owned facilities (if any) in a working manner and/or in accordance with the requirements of the Colorado Water Quality Control Division specified in the stormwater discharge permit issued to the City (County) of _____:
13. Signature and seal of a professional engineer preparing these plans.

Approval by the City (County) of _____ does not constitute an approval or the issuance of permits by the State of Colorado, which approval and/or permits shall be obtained prior to initiating any construction activities on the site

R0056904

VOL 1 2 2 3 6 1 1

x 4.1 As-Built Drawings and Certification

Upon completion of construction, the professional engineer that prepared the design plans (or one that assumes the responsibility for the inspection if the design engineer is no longer available) shall provide the City (County) of _____ with a signed and sealed Certification of Inspection verifying that all work was performed in accordance with the approved plans and in compliance with all applicable criteria of the City (County) of _____. Special circumstances may require that as-built reproducible drawings of the drainage improvements also be provided. Certification of Inspection and as-built drawings (if required) will be required prior to the issuance of a final sewer connection permit or the issuance of a Certificate of Occupancy.

x.5 PUBLIC DRAINAGE IMPROVEMENTS

If the project requires that drainage improvements be constructed that will be turned over and owned and maintained by the City (County) of _____, the following process must also be followed:

1. Two sets of plans (22" x 34") submitted for initial review.
2. An application to design, plan, construct, re-construct or remodel a public improvement must be filed with the (department name).
3. A bond or letter of credit guaranteeing payment and performance must be executed prior to commencing with work on the project.
4. Upon completion of the project, a set of reproducible as-constructed plans, certified by a licensed engineer, must be submitted before the bond or other guarantee is released.
5. After approval of the initial review set, (specify number of copies) sets of plans must be supplied which will be distributed by the City (County) for review by all departments and utility companies. After comments are received and addressed, (specify number of copies) final sets will be stamped as approved and returned to the design engineer for use by the contractor and owner.

The information required for the plans shall be in accordance with sound engineering principles, the technical provisions of the MANUAL (as modified by these CRITERIA where appropriate), these CRITERIA, and other applicable City (County) of _____ ordinances, regulations, criteria or design guidelines. The plans may also be subject to review by outside agencies such as the Urban Drainage and Flood Control District, Federal Emergency Management Agency, U.S. Army Corps of Engineers, Environmental Protection Agency, Colorado Water Quality Control Division, or other agencies as required. The plans shall be signed and sealed by a Professional Engineer registered in the State of Colorado.

1. INTRODUCTION

This section of Volume 3 of the *Urban Storm Drainage Criteria Manual* (*Manual*) provides a set of criteria and technical guidance for erosion and sediment control at construction sites. In addition, it describes suggested plan submittal requirements, planning considerations, general exemptions, and variances that cities and counties may wish to follow. The practices contained in this document should be viewed as suggested minimum requirements. A model erosion control ordinance is included in Appendix A. An example erosion and sediment control plan is included in Appendix B.

1.1 General

These criteria were developed to help mitigate the increased soil erosion and subsequent deposition of sediment off-site during the period of construction from start of earth disturbance until final landscaping and stormwater quality measures are effectively in place.

An *Erosion and Sediment Control Plan* must be developed and submitted to the local jurisdiction to obtain a construction or site grading permit. Site planning and drainage planning should, whenever possible, occur concurrently with site grading and erosion control planning. When site grading precedes final development, an erosion and sediment control plan for site grading must be submitted. This plan may have to be modified at the time a final site development plan is prepared. This modified plan must be submitted for review and approval prior to final development.

Implementation and maintenance of erosion control measures are ultimately the responsibility of the property owner. Because site conditions will affect the suitability and effectiveness of erosion control measures, a plan specific to each site is required. In addition, should the approved plan not function as intended, and it is determined by the city or county that additional measures are needed, the owner will have to provide additional measures needed to reduce soil erosion and sediment discharged from the construction site.

Nothing in these criteria limit the right of individual cities and counties to impose additional or more stringent standards.

1.2 Performance Objectives

The objectives for erosion control during construction include the following:

R0056911

VOL 12 2 3618

1. Conduct all land disturbing activities in a manner that effectively reduces accelerated soil erosion and reduces sediment movement and deposition off-site.

2. Schedule construction activities to minimize the total amount of soil exposed at any given time to reduce the period of accelerated soil erosion.

3. Establish temporary or permanent cover on areas that have been disturbed as soon as possible after final grading is completed.

4. Design and construct all temporary or permanent facilities for the conveyance of water around, through, or from the disturbed area to limit the flow of water to non-erosive velocities.

5. Remove sediment caused by accelerated soil erosion from surface runoff water before it leaves the site.

6. Stabilize the areas of land disturbance with permanent vegetative cover or stormwater quality control measures.

1.3 Erosion and Sediment Control Plan

An *Erosion and Sediment Control Plan* consisting of a written narrative report and a site plan map must be submitted to the appropriate local government for review and approval. Figures 1-1A and 1-1B provide standard symbols that can be used on such plans. An example plan is given in Appendix B.

1.3.1 Narrative Report. The narrative report must contain, or refer to, the drainage report and should contain the following:

1. Name, address, and telephone number of the applicant. The name, address, and telephone number of the professional engineer preparing the *Erosion and Sediment Control Plan* should also be included if different from the applicant.

2. Project description - A brief description of the nature and purpose of the land disturbing activity, the total area of the site, the area of disturbance involved, and project location

R0056912

VOL 1 2 2 3619

including township, range, section, and quarter-section, or the latitude and longitude, of the approximate center of the project.

3. Existing site conditions - A description of the existing topography, vegetation, and drainage; and a description of any wetlands on the site.

4. Adjacent areas - A description of neighboring areas such as streams, lakes, residential areas, roads, etc., which might be affected by the land disturbance.

5. Soils - A brief description of the soils on the site including information on soil type and names, mapping unit, erodibility, permeability, hydrologic soil group, depth, texture, and soil structure. (This information may be obtained from the soil report for the site, or, if available, from soils reports from adjacent sites if acceptable to the local jurisdiction).

6. Areas and Volumes - An estimate of the quantity (in cubic yards) of excavation and fill involved, and the surface area (in acres) of the proposed disturbance.

7. Erosion and sediment control measures - A description of the methods described in this chapter of the *Manual* which will be used to control erosion and sediment on the site.

8. Timing schedule indicating the anticipated starting and completion time periods of the site grading and/or construction sequence, including the installation and removal time periods of erosion and sediment control measures, and the time of exposure of each area prior to the completion of temporary erosion and sediment control measures.

9. Permanent stabilization - A brief description, including specifications, of how the site will be stabilized after construction is completed.

10. Stormwater management considerations - Explain how stormwater runoff from and through the site will be handled during construction. Provide a brief description of the post-construction stormwater quality control measures to be included as a part of the site development.

11. Maintenance - A schedule of regular inspections during construction and repair of erosion and sediment control structures should be described. A description of routine sediment basin maintenance should also be included.

R0056913

VOL 1 2 2 3620

12. The estimated total cost (installation and maintenance) of the required temporary soil erosion and sediment control measures to assist the city or county determine surety or bonding requirements for the proposed plan.

13. Calculations - Any calculations made for the design of such items as sediment basins, diversions, waterways; and calculations for runoff and stormwater detention basin design (if applicable).

14. Other information or data as may be reasonably required by the local jurisdiction.

15. A surety, bond, letter-of-credit, escrow account or other financial arrangement acceptable to the local jurisdiction submitted in an amount sufficient to install and maintain for a period of one year the temporary and permanent erosion and sediment control measures described in the plan.

16. The following note - "This *Erosion and Sediment Control Plan* has been placed in the (insert name of local jurisdiction) file for this project. The plan appears to fulfill the Urban Drainage and Flood Control District's technical criteria and the criteria for erosion control and requirements of (insert name of local jurisdiction). I understand that additional erosion control measures may be needed if unforeseen erosion problems occur or if the submitted plan does not function as intended. The requirements of this plan shall run with the land and be the obligation of the land owner until such time as the plan is properly completed, modified or voided.".

17. Signature page for owner/developer acknowledging the review and acceptance of responsibility, and a statement by the Professional Engineer acknowledging responsibility for the preparation of the *Erosion and Sediment Control Plan*.

1.3.2 Site Plan. The site plan must show:

1. A general location map at a scale of 1-inch to 1000-feet to 1-inch to 8000-feet indicating the general vicinity of the site location.

2. The property lines for the site on which the work will be performed.

R0056914

VOL 1 2 2 3 6 2 1

3. The *Erosion and Sediment Control Plan* at a scale of 1-inch to 20-feet up to 1-inch to 200-feet. The plan may be placed on the site drainage plan if it can be clearly presented. The plan must include:

   a. Existing topography at one- or two-foot contour intervals. The map should extend a minimum of 100-feet beyond the property line.

   b. Proposed topography at one- or two-foot contour intervals. The map should show elevations, dimensions, location, extent, and the slope of all proposed grading, including building site and driveway grades, if known.

   c. Location of any existing structures or hydrologic features on the site.

   d. Location of all structures or natural features on the land adjacent to the site and within a minimum of 100 feet of the site boundary line. The map must show the location of the street gutter, storm sewer, channel, or other waters receiving storm runoff from the site.

   e. Location of all proposed structures and development on the site, if known.

   f. Limits of clearing and grading - Areas which are to be cleared and graded.

   g. Location of soil stockpiles - Areas designated for topsoil and subsoil storage.

   h. Location of storage areas - Areas designated for equipment, fuel, lubricants, chemical and waste storage.

   i. Location of temporary roads designated for use during the construction period.

   j. Plans of all drainage features, paved areas, retaining walls, cribbing, planting, temporary or permanent soil erosion control measures, or other features to be constructed in connection with, or as a part of, the proposed work together with a map showing the drainage area of land tributary to the site and estimated 2-year runoff of the area served by all drains. All erosion control measures should be depicted using the standard map symbols given in Figures 1-1A and 1-1B.

R0056915

VOL 12 2 3622

k. Detail drawings - Design drawings of sediment controls, temporary diversions, and any practices used that are not referenced in these criteria.

l. Other information or data as may be reasonably required by the local jurisdiction.

m. The following note: "This *Erosion and Sediment Control Plan* has been placed in the (insert name of local jurisdiction) file for this project and appears to fulfill applicable erosion control criteria. I understand that additional erosion control measures may be required of the owner and his or her agents due to unforeseen erosion problems or if the submitted plan does not function as intended. The requirements of this plan shall run with the land and be the obligation of the land owner until such time as the plan is properly completed, modified or voided".

n. Signature block for owner (or agent) acknowledging the review and acceptance of responsibility, and a signed and stamped statement by the Professional Engineer acknowledging responsibility for the preparation of the *Erosion and Sediment Control Plan*.

1.3.3 Approval of Erosion and Sediment Control Plan. An *Erosion and Sediment Control Plan* must be approved prior to issuance of an Overlot Grading or Site Disturbance Permit by the city or county. The final *Erosion and Sediment Control Plan* must be consistent with a Drainage Report considered acceptable to the approving jurisdiction. Approval of the *Erosion and Sediment Control Plan* does not imply acceptance or approval of Drainage Plans, Utility Plans, Street or Road Plans, Design of Retaining Walls, or any other aspect of site development.

1.3.4 Exemptions and Variances. A provision for exemptions and variances may be provided by a city or county. These are generally processed according to the applicable subdivision regulations and reviewed on a case-by-case basis.

1. Exemptions from the erosion control planning process will be considered for any of the following; however, exempting the owner from preparing an erosion control plan and applying for a grading permit does not exempt the owner from controlling erosion of soil at each construction site through the use of the techniques described in this Manual:

R0056916

VOL 12 2 3623

a. Agricultural use of land.

b. Grading or an excavation below finished grade for basements, footings, retaining walls, or other structures on plots zoned R1 - R3 of less than five (5) acres in size unless required otherwise.

c. A sidewalk or driveway authorized by a valid permit.

d. Land-disturbing activities involving less than five (5) acres of disturbed area. Individual lots involving less than five (5) acres of disturbed area in a larger subdivision project shall not be considered separate development projects, but rather as a part of the subdivision development as a whole. It will be the responsibility of the homeowner or homebuilder to conform to all requirements of the locally-approved *Erosion and Sediment Control Plan* for the subdivision. As part of any Building Permit for which a specific erosion control plan is not required, the following statement must be included: "We have reviewed the *Erosion and Sediment Control Plan* for (subdivision name) and agree to conform to all requirements contained therein and all erosion control requirements of the (insert name of local jurisdiction). We further agree to construct and maintain all erosion and sediment control measures required on the individual lot(s) subject to this Building Permit and/or in accordance with the provisions of the Erosion Control section of the *Manual* of the Urban Drainage and Flood Control District."

e. Underground utility construction including the installation, maintenance, and repair of all utilities under hard-surfaced roads, streets, or sidewalks provided such land-disturbing activity is confined to the area which is hard-surfaced and provided that runoff and erosion from soil stockpiles are confined and will not enter the drainage system.

f. Gravel, sand, dirt or topsoil removal as authorized pursuant to approval of the Colorado Mined Land Reclamation Board, provided said approval includes an erosion and sediment control plan that meets the minimums specified.

g. Projects having a period of exposure (from time of land disturbance until permanent erosion control measures are installed) of less than 14 days.

R0056917

VOL 1 2 2 3624

h. Where the owner certifies in writing to local jurisdiction and the local jurisdiction agrees in writing that the planned work and the final structures or topographical changes will not result in or contribute to soil erosion or sedimentation and will not interfere with any existing drainage course in such a manner as to cause damage to any adjacent property or result in the deposition of debris or sediment on any public way, will not present any hazard to any persons or property, and will have no detrimental influence upon the public welfare or upon the total development of the watershed.

2. Variances - Cities and counties may consider waiving or modifying any of the criteria which are deemed inappropriate or too restrictive for site conditions by granting a variance. Variances may be granted at the time of plan submission or request for plan revision. Variances must be requested in accordance with the subdivision regulations and must define:

   a. The criteria from which the applicant seeks a variance.

   b. The justification for not complying with the criteria.

   c. Alternate criteria or standard measures to be used in lieu of these criteria. The criteria and practices specified within this section of the *Manual* relate to the application of specific erosion and sediment control practices. Other practices or modifications to specified practices may be used if approved by the local jurisdiction prior to installation. Such practices must be thoroughly described and detailed to the satisfaction of the local city or county reviewing and approving the erosion control plan.

To expedite the review and decisions on variance requests, it is suggested that a variance request be included with, or submitted prior to, the initial *Erosion and Sediment Control Plan* submittal.

2. EROSION CONTROL PLANNING

2.1 Erosion and Sedimentation

2.1.1 Erosion. Soil erosion is the process by which the land surface is worn away by the action of wind, water, ice, and gravity. This section of the manual addresses erosion caused by wind and water. Erosion is a natural process and has occurred since the earth was formed. The shape of the land as we know it was created, in large part, by erosional processes. The natural rate of erosion is increased greatly by many urban activities--especially construction activities. Any activity that disturbs the natural soil and vegetation has the potential to increase erosion because bare, loose soil is easily moved by wind or water.

Wind erosion is caused when winds of sufficient velocity create movement of soil particles. The potential for wind erosion is dependent upon soil cover, soil particle size, wind velocity, duration of wind, and unsheltered distance. Within the Denver metropolitan area winds often exceed 60 miles per hour (mph), and occasionally exceed 100 mph. Wind erosion can begin at a wind velocity as low as 10 mph, and can even result from turbulence created by passing vehicles.

Water erosion has five primary mechanisms: raindrop erosion, sheet erosion, rill erosion, gully erosion, and channel erosion. Raindrops detach soil particles and splash them into the air. These detached particles are then vulnerable to stormwater runoff or snowmelt. Shallow surface flows rarely move as a uniform sheet for more than several feet before concentrating in surface irregularities, known as rills. As the flow changes from a shallow sheet to a deeper rill flow, the velocity and turbulence of the flow increase. The energy of the concentrated flow is able to detach and transport soil particles. This action begins to cut into the soil mantle and form tiny to large channels. Rills are small, but well-defined channels which are only a few inches deep. Gullies occur as the flows in rills come together into larger and larger channels. The major difference between rill and gully erosion is size. Rills caused by erosion can be smoothed out by standard surface treatments such as harrowing. Gully erosion on the other hand cannot be repaired with standard farming equipment and requires heavy equipment to regrade and stabilize the gullies.

2.1.2 Sedimentation. During a rainstorm, runoff normally builds up rapidly to a peak and then diminishes. Because the amount of sediment a watercourse can carry is dependent upon the velocity and volume of runoff, sediment is deposited as runoff decreases. The deposited sediments

R0056921

VOL 1 2 2 3628

may be resuspended when future runoff events occur. In this way, sediments are moved progressively downstream in the waterway system.

Windblown silt and sand particles are deposited whenever the force of the wind lessens. Much of the wind-eroded material is deposited behind fences, in landscaped areas or downwind of buildings or other obstructions to the wind. (Dust will form "drifts" just like snow.) Materials transported by bouncing or creeping along the surface are often trapped in surface irregularities near the point of initial movement.

2.1.3 Factors Influencing Erosion. Factors affecting the erosion potential of any site include soil type, geology, vegetative cover, topography, climate, and land use. Physical properties of soils such as particle size, cohesiveness, and density affect its erodibility. Loose silt and sand-sized particles are more susceptible to erosion than "sticky" clay soils. Rocky soils are also less susceptible to wind erosion, but are often found on steep slopes that are subject to water erosion. Most of the soil types found locally are calcareous in nature and are susceptible to either wind or water erosion, or both.

When surface cover and soil structure are disturbed, the soil's erodibility potential increases. Construction activities disrupt the soil structure and it's vegetative cover. Examples are excavation and grading for construction of homes, roads, utilities, commercial and industrial areas. In some parts of the Denver metropolitan area, overgrazing by livestock also contributes to increased erosion.

Vegetation plays an extremely important role in controlling erosion. Roots bind particles together and the leaves or blades of grass reduce raindrop impact forces on the soil. Grass, forest floor litter and other ground cover traps rain which allows infiltration and reduces runoff velocity. Vegetation reduces wind velocity at the ground surface, and provides a rougher surface which will trap particles moving along the ground. Once vegetation is removed, erosion can proceed unchecked.

2.1.4 Principles of Erosion and Sediment Control. The objective of erosion control is to limit the amount and rate of erosion occurring on disturbed areas. The objective of sediment control is to capture the soil that has been eroded before it leaves the construction site. Despite the use of both erosion control and sediment control measures, it is recognized that some amount of sediment will remain in runoff leaving the construction site.

R0056922

VOL 1 2 2 3629

An erosion and sediment control plan is comprised of three major elements:

1. The erosion control measures that will be used to limit erosion of soil from disturbed areas at a construction site;

2. The sediment control measures that will be used to limit transport of sediment to off-site properties and downstream receiving waters; and,

3. The drainageway protection measures that will be used to protect streams and other drainageways located on the construction site from erosion and sediment damages.

Erosion controls are surface treatments that stabilize soil exposed by excavation or grading. Erosion control measures, or Best Management Practices (BMPs) are variously referred to as source controls, vegetative controls or non-structural controls.

Sediment controls capture soil that has been eroded. Soil particles suspended in runoff can be filtered through a porous media or deposited by slowing the flow and allowing the natural process of sedimentation to occur. Sediment controls (or BMPs) are facilities built to perform this function, and are also referred to as structural controls.

Drainageway control measures (or BMPs) protect channels or storm sewers during site construction. This can be accomplished by limiting equipment travel across a stream, constructing a temporary channel crossing, or diverting a stream into a temporary channel while work is done on the permanent channel. Where storm sewers are used, sediment can be filtered prior to entry of runoff into the storm drainage system.

Non-sediment impacts to water quality can be managed by controls (or BMPs) on equipment, material storage, or use of chemicals at construction sites. These additional practices are included for discussion in the *Manual* because they occur commonly at construction sites.

2.2 Summary of Criteria

The list below is a summary of erosion and sediment control activities as described in this manual:

R0056923

VOL 1 2 2 3630

Erosion Control. Permanent or temporary soil surface stabilization must be applied to disturbed areas and soil stockpiles as soon as possible but no later than 14 days after final grade is reached on any portion of the site. Soil surface stabilization should also be applied within 14 days to disturbed areas that may not be at final grade but will remain dormant (undisturbed) for longer than an additional 30 days. (Section 3.0).

Surface Roughening. Surface roughening should be performed after final grading to create depressions two to four inches deep and four to six inches apart. (Section 3.1).

Mulching. All disturbed areas must be properly mulched, or seeded and mulched, within 14 days after final grade is reached on any portion of the site not otherwise permanently stabilized. (Section 3.2).

Revegetation. A viable vegetative cover should be established within one year on all disturbed areas and soil stockpiles not otherwise permanently stabilized. Vegetation is not considered established until a ground cover is achieved which, in the opinion of the city or county of jurisdiction, is sufficiently mature to control soil erosion and can survive severe weather conditions. (Section 3.3).

Temporary Revegetation. Temporary revegetation is required on all disturbed areas having a period of exposure prior to final stabilization of one year to two years. All temporary seeding shall be properly mulched. (Section 3.3.2).

Permanent Revegetation. Permanent revegetation is required on all disturbed areas having a period of exposure greater than two years, or for an indeterminate length of time. A perennial grass mix should be planted and mulched. (Section 3.3.3).

Roads and Soil Stockpiles. Road cuts, road fills, and parking lot areas should be covered as early as possible with the appropriate aggregate base course where this is specified as part of the pavement. This practice is not needed when final construction of roads will take place within 30 days of reaching final subgrade level.

All non-paved portions of roads should be seeded and mulched as soon as possible after final grading has occurred, but in no case later than 14 days after grading has been completed.

Soil stockpiles expected to be in place longer than 60 days should be seeded with a temporary grass cover and mulched within 14 days after completion of stockpile construction.

R0056924

VOL 1 2 2 3631

If stockpiles are located within 100 feet of a drainageway, additional sediment controls, such as a diversion dike or silt fence, should be provided. (Section 3.4).

Sediment Control. Properties and roadways adjacent to a construction site should be protected from eroded sediment being transported to them. (Section 4.0).

Vehicle Tracking. Whenever construction vehicles enter onto paved roads, provisions must be made to prevent the transport of sediment (mud and dirt) by vehicles tracking onto the paved surface. Whenever sediment is transported onto a public road, regardless of the size of the site, the roads shall be cleaned at the end of each day. (Section 4.1).

Slope Diversion Dikes. Temporary diversion dikes shall be provided as required by the provisions of Section 4.2. Diversion dikes located above disturbed areas may be discharged to a permanent or temporary channel. Diversion dikes located midslope on a disturbed area must discharge to temporary slope drain. Diversion dikes located at the base of a disturbed area must discharge to a sediment trap or basin. (Sections 4.2.1 and 4.3).

Roads and Roadside Swales. For road areas that are not paved within 30 days of final grading, and have not received early application of roadbase, rough-cut street controls should be provided. (Section 4.2.2).

Sediment Entrapment Facilities. Sediment entrapment facilities include straw bale barriers, silt fences, sod filter strips, sediment traps and sediment basins. The criteria for selection and use of sediment entrapment facilities are given in Table 4-1 and design criteria are described in Section 4.3.

All runoff leaving a disturbed area shall pass through at least one sediment entrapment facility before it exits the site. (Section 4.3).

Working Within or Crossing a Waterway. Construction vehicles shall be kept out of waterways to the maximum extent practicable. Where an actively-flowing watercourse must be crossed regularly by construction vehicles, a temporary stream crossing or channel diversion must be provided. (Sections 5.1 and 5.2).

Outlet Protection. The outlets of temporary slope drains, culverts, sediment traps, and sediment basins must be protected from erosion and scour. (Section 5.3).

R0056925

VOL 1 2 2 3 6 3 2

Inlet Protection. All storm sewer inlets made operable during construction must have sediment entrapment facilities installed to prevent sediment-laden runoff from entering the inlet. (Section 5.4).

Chemicals, Oils and Material Storage. Areas used for storage of chemicals, petroleum-based products and waste materials, including solid and liquid waste, shall be designed to prevent discharge of these materials in the runoff from a construction site. (Section 6).

Underground Utility Construction. Construction of underground utility lines that are not exempted is subject to the provisions of Section 7. (Section 1.3.4 for exemptions and Section 7).

Disposition of Temporary Measures. All temporary erosion and sediment control measures shall be removed within 30 days after final stabilization is achieved, or after the temporary measures are no longer needed, whichever occurs earliest, or as authorized by the city or county of local jurisdiction. (Section 8).

Maintenance. All temporary and permanent erosion and sediment control practices shall be maintained and repaired by the owner during the construction phase as needed to assure continued performance of their intended function. All facilities must be inspected and replaced if necessary, following each precipitation or snowmelt event that results in runoff. (Section 9).

2.3 Planning Process

Erosion control planning should occur early in the site development process. The planning process can be divided into five separate steps:

1. Gather information on topography, soils, drainage, vegetation and other predominant site features.
2. Analyze the information in order to anticipate erosion and sedimentation problems.
3. Devise a plan which schedules construction activities and minimizes the amount of erosion created by development.
4. Develop an *Erosion and Sediment Control Plan* which specifies effective erosion and sediment control measures.

R0056926

VOL 1 2 2 3633

5. Follow the *Erosion and Sediment Control Plan* and revise it when necessary.

2.3.1 Site Assessment. Topography is the primary factor to be considered in developing an *Erosion and Sediment Control Plan*. Soils, vegetation, and hydrologic features must also be considered.

Final grading will determine slope gradient and slope length of the disturbed area. Small areas, or subbasins, will be created that have relatively uniform characteristics of slope and slope length. After grading is completed, areas that remain exposed to precipitation and runoff will require erosion control, and the overall size of subbasin areas will determine what sediment controls are appropriate for each area.

Soil conditions should be assessed as to their potential for erosion and suitability for revegetation. A detailed analysis of soil-erosion potential is not necessary because all soils will be subject to erosion and can be generalized as equivalent for the design of control measures recommended in the *Manual*.

Most vegetation will be removed from a construction site during clearing and grading operations. An assessment of existing vegetation on the site is of limited use when post-development landscaping and irrigation are planned, but can be useful in selecting grasses when non-irrigated revegetation is planned. Analysis of soil is useful to determine fertilizer requirements for vegetation establishment.

Analysis of waterbodies and other hydrologic features of a site is important in the design of sediment controls. The drainage basins upslope and within the site should be assessed. The configuration of hillslope areas and drainageways, in the context of planned roads and buildings, will determine what erosion and sediment controls will be needed. The location of permanent drainage channels and other elements of the drainage system should be defined as a part of the plan.

2.3.2 Selection of Controls. The following guidelines are recommended in developing the erosion and sediment control plan:

1. Determine the limits of clearing and grading. If the entire site will not undergo excavation and grading, the boundaries of cut-and-fill operations should be defined. Buffer strips of natural vegetation may be utilized as a control measure.

R0056927

VCL 12 2 3634

2. Define the layout of buildings and roads. This will have been decided previously as a part of the general development plan. If building layout is not final, the road areas stabilized with pavement and the drainage features related to roads should be defined as they relate to the plan.

3. Determine permanent drainage features. The location of permanent channels, storm sewers, roadside swales, and stormwater quality controls such as ponds, wetlands, grassed-lined swales, buffer strips, and areas of porous pavement, if known, should be defined.

4. Determine extent of temporary channel diversions. If permanent channel improvements are a part of the plan, the route, sizing, and lining needed for temporary channel diversions should be determined. Location and type of temporary channel crossings can be assessed.

5. Determine the boundaries of watersheds. The size of drainage basins will determine the types of sediment controls to be used. Areas located off the site that contribute overland flow runoff must be assessed. Measures to limit the size of upland overland flow areas, such as diversion dikes, may be initially considered at this stage.

6. Select sediment controls. Areas greater than five acres will require that sediment basins be installed. Division of large drainage basins into subareas each served by a sediment basin can also be considered.

   Areas smaller than five acres can utilize other sediment controls. Limitations on the size of areas served by individual controls are defined in these criteria. (Section 4.3).

7. Determine staging of construction. The schedule of construction will determine what areas must be disturbed at various stages throughout the development plan. The opportunity for staging cut-and-fill operations to minimize the period of exposure of soils can be assessed. The sequence for installing sediment controls and erosion controls can also be determined at this time.

8. Identify locations of topsoil stockpiles. Areas for storing topsoil should be determined.

R0056928

VOL 1 2

9. Identify location of temporary construction roads, vehicle tracking controls, and material storage areas. These three elements can be determined in the context of previously defined aspects of the plan.

10. Select Erosion Controls. All areas of exposed soil will require a control measure be defined dependent on the duration of exposure. These can be selected based on the schedule of construction.

An example erosion and sediment control plan for a small commercial development has been included as Appendix B. Figure 2-1 shows an oblique view of an example highway construction project and the sediment controls used. Figure 2-2 illustrates how these measures are described on a site plan map.

2.4 Consistency with Other Plans

2.4.1 Drainage Plans. The *Erosion and Sediment Control Plan* should be prepared consistent with the final drainage plan for a development. All of the hydrologic features of the drainage plan must be incorporated into the site at the time of development. Permanent drainage features will be built during the construction phase. Temporary sediment controls can be located and designed to take advantage of the final drainage design features. All temporary controls should be staged and removed at the appropriate time relative to the construction of permanent drainage features.

2 3635

2.4.2 Stormwater Quality Plans. New developments will incorporate elements of stormwater quality control into their design. The erosion and sediment control plan must be prepared consistent with these structural and nonstructural controls. Many of the temporary controls used for sediment control can be modified into permanent structural controls. Where possible, permanent stormwater quality controls can be constructed at the initial stages of construction, or modified at the end of construction.

Where local regulations have not been developed, stormwater quality plans should be developed consistent with the guidelines in the *Stormwater Quality* section of Volume 3 of the *Manual*.

2.4.3 Air Quality Plans. All of the erosion and sediment control measures specified in this section will perform as well to control wind erosion. The surface stabilization measures identified for control of precipitation-induced erosion act also to prevent soils from becoming windborne.

R0056929

Although these guidelines were developed to control erosion by rainfall and snowmelt, they are consistent with design principles for wind erosion and will be effective for this purpose.

The Air Pollution Control Division, Colorado Department of Health, has passed air quality regulations consistent with federal legislation. Regulation No. 3 requires submittal of an Air Pollutant Emission Notice (APEN) for sources of fugitive dust from construction sites, as well as other sources. Regulation No. 1 defines particulate emission control regulations for haul roads and roadways. Additional controls, such as road watering, may be necessary to fully comply with these regulations at a construction site.

In certain counties in Colorado, the local health department administers these regulations. This agency, or CDH, should be contacted about APENs and other air quality requirements.

3. EROSION CONTROL

The planning for the installation of permanent or temporary soil erosion controls needs to begin in advance of all major soil distrubance activities on the construction site. After construction begins, soil surface stabilization shall be applied within 14 days to all disturbed areas that may not be at final grade but will remain dormant (undisturbed) for periods longer than an additional 30 calendar days.

Soil surface stabilization protects soil from the erosive forces of raindrop impact, flowing water, and wind. Erosion control practices include surface roughening, mulching, establishment of vegetative cover, and the early application of gravel base on areas to be paved. Stabilization measures to be used should be appropriate for the time of year, site conditions and estimated duration of use. The maximum time limits of land exposure for selection of erosion controls are summarized in Table 3-1.

Table 3-1

Maximum Time Limits of Land Exposure
for Selection of Erosion Controls

Erosion Control Method	Maximum Allowable Period of Exposure (months)
Surface Roughening	1
Mulching	12
Temporary Revegetation	12-24
Permanent Revegetation	24 or more
Soil Stockpile Revegetation	2
Early Application of Road Base	1

3.1 Surface Roughening

Surface roughening provides temporary stabilization of disturbed areas from wind and water erosion. It is particularly useful where temporary revegetation cannot be immediately established due to seasonal planting limitations.

The soil surface is considered roughened if depressions are created two to four inches deep and are spaced approximately four to six inches apart. If slopes are sufficiently rough after final grading, no further treatment is required. The surface of exposed soil can be roughened by a number of

R0056932

techniques and equipment. A chisel or ripping implement can be used in most soil conditions. Roughening cannot be performed in very sandy or rocky soil.

Surface roughening, also referred to as scarification, should be performed after final grading. Fill slopes can be constructed with a roughened surface. Cut slopes that have been smooth graded can be roughened as a subsequent operation. Roughening of ridges and depressions should follow along the contours of the slope. On slopes steeper than 2:1, the tracks left by a dozer working perpendicular to the contour can leave acceptable horizontal depressions. A diagram illustrating surface roughening is shown on Figure 3-1.

Care should be taken not to drive vehicles or equipment over areas that have been scarified. Tire tracks will smooth the roughened surface and encourage runoff to collect into channels. As surface roughening is only a temporary control, additional treatments may be necessary to maintain the soil surface in a roughened condition.

3.2 Mulching

All disturbed areas must be mulched, or seeded and mulched, within 14 days after final grade is reached on any portion of the site not otherwise permanently stabilized. Areas that will remain in an interim condition for more than one year should also be seeded (See Section 3.3.2). An example of mulching is shown on Figure 3-2.

To protect newly seeded areas and to provide temporary cover on other disturbed areas which will not require temporary revegetation, or which cannot be seeded due to seeding date limitations, a mulch should be applied consisting of:

1. Clean, weed- and seed-free, long-stemmed grass hay (preferred) or cereal grain straw. Hay is preferred as it is less susceptible to removal by wind. Mulch should be applied evenly at a rate of two tons per acre. At least 50 percent of the mulch, by weight, should be ten inches or more in length.

   Mulch must be anchored. This can be accomplished mechanically by crimping or with the aid of tackifiers or nets. Anchoring with a crimping implement is preferred, and is the recommended method for all areas equal to or flatter than 3:1. Mechanical crimpers must be capable of tucking the long mulch fibers into the soil four inches deep

R0056933

VOL 1 2 2 3640

VOL 1 2 2 3641

without cutting them. An agricultural disk, while not an ideal substitute, may work if the disk blades are dull or blunted and set vertically. However, the frame may have to be weighted to afford proper soil penetration.

On small areas sheltered from the wind and from heavy runoff, spraying a tackifier on the mulch is satisfactory for holding it in place. For steep slopes and other special situations, blankets, anchored with staples, may be required instead of mulch.

2. Hydraulic mulching shall be limited to those situations where it is too difficult to apply and anchor a mulch of long-stemmed grass hay or cereal straw; namely, slopes steeper than 3:1 or where access is limited. Wood cellulose fibers must be mixed with water and a tackifying agent and applied at a rate of 1500 pounds per acre with a hydraulic mulcher.

3. Mats, blankets, and nets are available to help stabilize steep slopes and drainage channels. Depending on the product, these may be used alone or in conjunction with grass or straw mulch. Normally, use of these products will be restricted to relatively small areas. Mats made of jute, coconut fiber, or various geosynthetic fibers can be used instead of mulch. Blankets are straw mulch that have been woven and oftentime include a synthetic layer or net. Plastic netting can be used to anchor mulch. Two diagrams showing installation and orientation of these materials are provided as Figures 3-3 and 3-4.

4. Some synthetic tackifiers or binders may be used to anchor mulch. Caution should be used to prevent the introduction of any potentially harmful material into the environment. Manufacturer's recommendations should be followed at all times.

5. Rock can also be used as a mulch. It provides protection of exposed soils to wind and water erosion and allows infiltration of precipitation. Rock of aggregate base-coarse size can be spread on disturbed areas for temporary or permanent stabilization. Rock must be removed from those areas planned for vegetation establishment.

R0056934

VOL 1 2 2 3642

3.3 Revegetation

A viable vegetative cover should be established within one year on all disturbed areas and soil stockpiles not otherwise permanently stabilized. Vegetation is not considered established until a ground cover is achieved which, in the opinion of the city or county of jurisdiction, is sufficiently mature to control soil erosion and can survive severe weather conditions.

3.3.1 Seedbed Preparation. Areas to be revegetated should have soil conditions capable of supporting vegetation. Overlot grading will oftentimes bring to the surface subsoils that have low nutrient value, little organic matter content, few soil microorganisms, and conditions less conducive to infiltration of precipitation. Under certain conditions, soil amendments and treatments may be necessary to provide an adequate growth medium to sustain vegetation.

Whenever possible, topsoil should be salvaged for respreading on areas to be revegetated. The depth of soil stripping is determined by the depth of available topsoil. Areas near drainageways may have a considerable depth of topsoil, whereas lesser amounts may be available on the crowns of hills and flat slopes. Topsoil can be viewed as a resource to be utilized for vegetation establishment, primarily due to its water-holding capacity.

The rooting zone of most semi-arid grasslands evident in the Denver metropolitan area is 6 - 18 inches. At a minimum, the upper six (6) inches of topsoil can be stripped and stockpiled, and respread to a thicker depth on surfaces not planned for buildings or impervious areas. If the surface is compacted, ripping of subsoils prior to topsoiling is recommended. Scarification will assist in placement of a stable topsoil layer on steeper slopes, and allow percolation and root penetration to greater depth.

Where topsoil is not available or utilized, subsoils can be treated to provide a plant-growth medium. Fertilizer can be added to improve nutrient levels necessary for plant growth. Other treatments, such as liming, can be used to adjust soil conditions as necessary with amendments. Soil testing is recommended to determine appropriate amendments required.

A suitable seedbed will enhance the success of revegetation efforts. The surface should be rough and the seedbed should be firm, but neither too loose or compacted. The upper layer of soil should be in a condition suitable for seeding at the proper depth and conducive to plant growth.

R0056935

VOL 1 2 2 3643

3.3.2 Temporary Revegetation. Temporary revegetation is required on all disturbed areas having a period of exposure prior to final stabilization of one year or longer. All temporary seeding shall be protected with mulch.

To provide temporary vegetative cover on disturbed areas which will not be paved, built upon, or fully landscaped within 12 months but will be completed within 24 months, plant an appropriate annual grass and mulch the planted areas. The annual grasses generally suitable for the Denver metropolitan area are listed in Table 3-2. These are to be considered only as a general recommendation whenever specific design guidance for a particular site is not available.

3.3.3 Permanent Revegetation. To provide vegetative cover on disturbed areas not paved or built upon for a period of 2 years or longer, or for an indeterminate length of time, a perennial grass mix should be planted. Each site will have different characteristics, and a landscape professional should be contacted to determine the most suitable seed mix for a specific site. In lieu of a specific mix and for planning purposes, one of the perennial grass mixes listed in Table 3-3 can be used. The pure live seed (PLS) rates of application recommended in these tables are considered to be absolute minimum rates for seed applied using proper drill-seeding equipment. All permanent seeding shall be protected with mulch. See Table 3-4 for appropriate seeding dates.

If desired for wildlife habitat or landscape diversity, shrubs such as rubber rabbitbrush (*Chrysothamnus nauseosus*), fourwing saltbush (*Atriplex canescens*) and skunkbrush sumac (*Rhus trilobata*) could be added to the upland seedmixes at .25, .5 and 1 pounds per acre, respectively. In riparian zones, planting root stock of such species as American plum (*Prunus americana*), woods rose (*Rosa Woodsii*), plains cottonwood (*Populus sargentii*), and willow (*Populus spp.*) may be considered. On non-topsoiled upland sites, a legume such as Ladak alfalfa at 1 lb. PLS per acre can be included as a source of nitrogen for perennial grasses.

3.4 Roads and Soil Stockpiles

Road cuts, road fills, and parking lot areas should be covered with the appropriate aggregate base course on the surfaces to be paved in lieu of mulching. Early application of road base is suitable where a layer of course aggregate is specified for final road or parking lot construction. This practice may not be desirable in all instances, and is not needed when final pavement construction will take place within 30 days of grading to final contours. All non-paved portions of road cut, fill,

R0056936

and parking lot areas should be seeded and mulched as soon as possible after final grading has occurred, but in no case later than 14 days after grading has been completed.

Soils stockpiled for more than 60 days should be seeded with a temporary or permanent grass cover within 14 days after completion of stockpile construction. Mulching is recommended to ensure vegetation establishment. If stockpiles are located within close proximity to a drainageway (i.e., 100 feet), additional sediment control measures, such as a temporary diversion dike or silt fence, should be provided (see Section 4).

Annual ryegrass	Cool	20
Cereal rye	Cool	30
Winter wheat/barley	Cool	30
Spring wheat/barley	Cool	30
Millet	Warm	20

a Successful seeding of annual grass resulting in adequate plant growth, will usually produce enough dead-plant material residue to provide protection from wind and water erosion for an additional year. This assumes that the cover is not disturbed or mowed closer than 8 inches.

Hydraulic seeding may be substituted for drilling only where slopes are steeper than 3:1 or where access limitations exist. When hydraulic seeding is used, hydraulic mulching should be done as a separate operation to prevent the seeds from being encapsulated in the mulch.

b See Table 3-4 for seeding dates.

c Seeding rates should be increased by 50 percent if seeding is done by hydraulic seeding or using a Brillion Drill; or doubled if seed is broadcast.

Table 3-3 (continued)

FOOTNOTES:

a All of the above seeding mixes and rates are based on drill seeding followed by crimped hay or straw mulch. These rates should be doubled if seed is broadcast and should be increased by 50 percent if the seeding is done using a Brillion Drill or is applied through hydraulic seeding. Hydraulic seeding may be substituted for drilling only where slopes are steeper than 3:1. If hydraulic seeding is used, hydraulic mulching should be done as a separate operation.

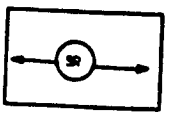
b See Table 3-4 for seeding dates.

c Crested wheatgrass should not be used on slopes steeper than 6H to 1V.

d If site is to be irrigated, the transition turf seed rates should be doubled.

e Could substitute 0.5 lbs PLS of Blue grama for the 2.0 lbs PLS of Vaughn sideoats grama.

R0056942



SR

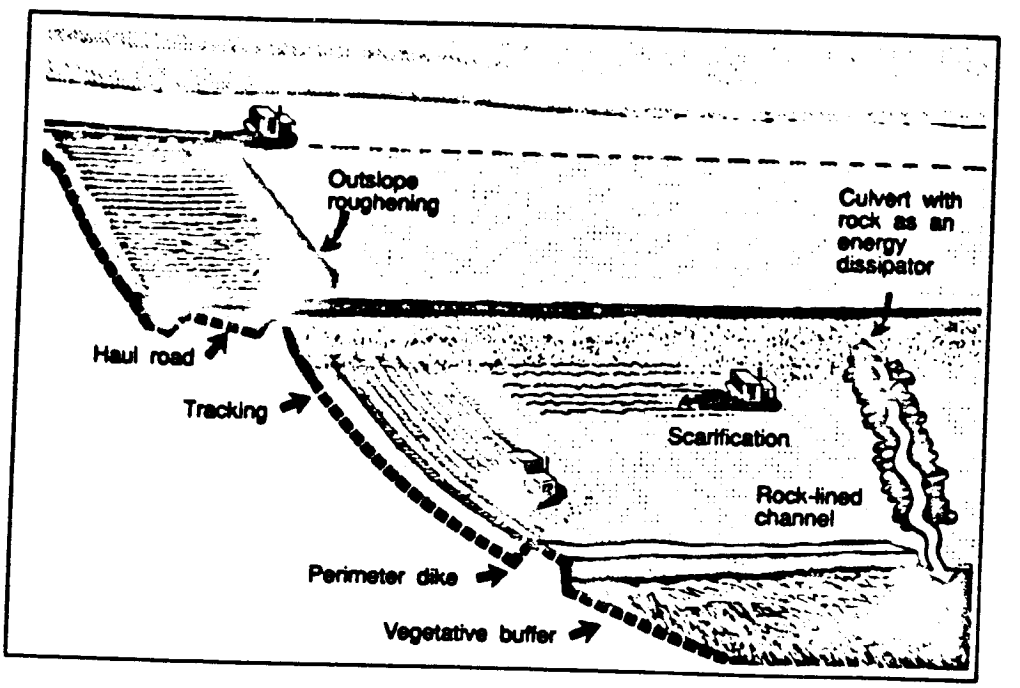
SURFACE ROUGHENING

Definition

Provide a rough soil surface with horizontal depressions created by operating a tillage or other suitable implement on the contour, or by leaving slopes in a roughened condition by not fine-grading them.

Purposes

1. To aid in seed bed preparation and establishment of vegetative cover.
2. To reduce runoff velocity and increase infiltration.
3. To reduce runoff and wind erosion and provide for sediment trapping.



From: Environmental Protection Agency, 1976

Figure 3-1 Surface Roughening

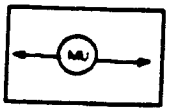
2 3651

R0056943



MU

MULCHING

Definition

Application of plant residues or other suitable materials to the soil surface.

Purposes

1. To prevent erosion by protecting the soil surface from raindrop impact and reducing the velocity of overland flow.
2. To foster the growth of vegetation by increasing available moisture and providing insulation against extreme heat and cold.

4. SEDIMENT CONTROL

The installation of sediment entrapment and control facilities has to begin before major land distrubance activities begin on a construction site.

Sediment control will be site specific and jcan include vehicle tracking controls; sod buffer strips around the lower perimeter of the land disturbance; sediment barriers, filters, dikes, traps or sediment basins; or a combination of any or all of these measures.

Sediment controls must be constructed before land disturbance takes place. Earthen structures such as dams, dikes, and diversions should be mulched within 14 days of installation. Earthen structures that are expected to remain in place for more than one year must be seeded and mulched.

Dams must address stable embankment design and water rights considerations. Consult with the State Engineer's Office on these requirements prior to constructing any dam.

4.1 Vehicle Tracking

Wherever construction vehicles enter onto paved public roads, provisions must be made to prevent the transport of sediment (mud and dirt) by runoff or by vehicles tracking onto the paved surface. For sites greater than two (2) acres, a stabilized vehicle tracking control must be constructed (see Figure 4-1A). Whenever deemed necessary by the city or county of jurisdiction, wash racks shall be installed to remove mud and dirt from the vehicle and its tires before it enters onto public roads (see Figure 4-1B).

Whenever sediment is transported onto a public road, regardless of the size of the site, the road shall be cleaned at the end of each day. Sediment shall be removed from roads by shoveling or sweeping and be transported to a controlled sediment disposal area. Street washing shall not be allowed until after sediment is removed in this manner. Storm sewer inlet protective measures should be in place at the time of street washing.

R0056947

VOL 1 2 2 3656

4.2 Slope-Length and Runoff Considerations

Cut-and-fill slopes must be designed and constructed to minimize erosion. This requires consideration of the length and steepness of the slope, the soil type, upslope drainage area, groundwater conditions and other applicable factors. Slopes which are found to be eroding excessively will require additional slope stabilization until the problem is corrected. The following guidelines should assist site planners and plan reviewers in developing an adequate design:

1. Rough soil surfaces are preferred over smooth surfaces on slopes (Section 3.1).

2. Temporary diversion dikes (Section 4.2.1) can be constructed at the top of long or steep slopes, or hillslopes that have an upslope tributary drainage area over five acres. Diversion dikes or terraces (Section 4.2.3) may also be used to reduce slope length within the disturbed area.

   Temporary diversion dikes shall be provided whenever:

   $$S^2L > 2.5$$

   where: S = slope of the upstream tributary area (in feet/foot); and,
   L = length of the upstream slope (in feet).

3. Concentrated stormwater should not be allowed to flow down cut or fill slopes unless contained within an adequately-sized temporary channel diversion, a permanent channel, or temporary slope drain (Section 4.2.4).

4. Wherever a slope face crosses a water seepage plane which endangers the stability of the slope, adequate drainage should be provided.

5. Provide sediment traps, basins or barriers (silt fences or straw bale dikes) below slopes to reduce offsite sediment transport or to reduce slope lengths (Section 4.3).

4.2.1 Slope Diversion Dikes. A temporary diversion dike is a horizontal ridge of soil placed perpendicular to the slope and angled slightly to provide drainage along the contour. Temporary diversion dikes can be constructed by excavation of a V-shaped trench or ditch and placement of the fill on the downslope side of the cut. A design of a temporary diversion dike is shown on Figure 4-2.

R0056948

VOL 1 2 2 3657

There are two types of temporary slope diversion dike:

1. A diversion dike located at the top of a slope to divert upland runoff away from the disturbed area. The discharge from undisturbed or previously-developed upland areas collected by these diversion dikes may be directed to a permanent channel or temporary channel diversion (Section 5.2).

2. A diversion dike located at the base or midslope of a disturbed area to divert sediment-laden water to a sediment trap or basin. The discharge from these diversion dikes may be directed to a temporary slope drain or sediment basin.

4.2.2 Roads and Roadside Swales. The drainage system provided for roads will define to some extent the length and area of individual slope segments within the disturbed area. A number of smaller hillslope segments will be created by construction of roads. These areas will require erosion control as described in Section 3.4, and sediment controls dependent on the size of upslope tributary area (Section 4.3).

For road areas that are not paved within 30 days of final grading, and have not received early application of roadbase (Section 3.4), rough-cut street controls should be used. These are runoff barriers that are constructed at intervals down the road. The barrier projects perpendicular to the longitudinal slope from the outer edge of the roadside swale to the crown of the road. The barriers are positioned alternately from the right and left side of the road to allow construction traffic to pass in the lane not barred. The design and spacing of temporary rough-cut road controls are shown on Figure 4-3.

4.2.3 Terracing. Sediment can be controlled on slopes that are particularly steep by the use of terracing. During grading, relatively flat sections, or terraces, are created and separated at intervals by steep slope segments. The steep slope segments are prone to erosion, however, and must be stabilized in some manner. Retaining walls, gabions, cribbing, deadman anchors, rock-filled slope mattresses and other types of soil retention systems are available for use. These should be specified in the plan and installed according to manufacturer's instructions.

4.2.4 Slope Drains. There are certain instances when runoff must be directed down a slope within the disturbed area. A temporary slope drain can be used to protect these hillslope areas from scour and additional erosion. A number of alternative designs and materials can be used for a slope drain. These are illustrated in Figures 4-4A and 4-4B.

R0056949

VOL 12 2 3658

The sizing of temporary slope drains must be defined but do not need rigorous hydraulic analysis. Criteria for sizing are given in the design criteria. The discharge from all slope drains must be directed to a stabilized outlet (Section 5.3).

4.3 Sediment Entrapment Facilities

Sediment entrapment facilities are necessary to reduce sediment discharges to downstream properties and receiving waters. Sediment entrapment facilities include straw bale barriers, silt fences, sod filter strips, sediment traps and sediment basins. The type of sediment entrapment facility to be used depends on the tributary area, basin slope and slope length of the upstream area. Table 4-1 summarizes the recommended maximum tributary areas, slope lengths and slopes for five types of sediment entrapment facilities.

All runoff leaving a disturbed area shall pass through a sediment entrapment facility before it exits the site and flows downstream.

Table 4-1

Sediment Entrapment Facility Limitations

Sediment Control Facility	Allowable Maximum Limit		
	Tributary Drainage Area (ac)	Tributary Slope Length (ft)	Tributary Slope Gradient
Sod Filter Strips	n/a	50	6:1 (17%)
Straw Bale Barrier or Silt Fence	0.5 per 100 lineal ft	150	2:1 (50%)
Sediment Trap	5.0	n/a	n/a
Sediment Basin	n/a	n/a	n/a

For small sites a sod filter strip may be adequate provided the limits for tributary slope are not exceeded and the flow is not concentrated. Straw bale barriers or silt fences may be used for somewhat larger areas depending on the upslope drainage area. When the tributary area is less than five acres but greater than that allowed for straw bale barriers or silt fences, runoff shall be collected in diversion swales and routed through temporary sediment traps.

R0056950

VOL 1 2 2 3659

4.3.1 Straw Bale Barriers. Straw bales can be placed at the base of a hillslope to act as a sediment barrier. These are not recommended for use within a swale or channel. Straw bales are temporary in nature and may only perform for a period of weeks or months. Proper installation and maintenance is necessary to ensure their performance. Guidance on design and installation of straw bales is given on Figures 4-5A and 4-5B.

4.3.2 Silt Fence. A silt fence is made of a woven synthetic material and acts to filter runoff. Silt fence can be placed as a temporary barrier at the base of a disturbed area but is not recommended for use in a channel or swale. The material is durable and will last for more than one season if properly installed and maintained. Silt fence design criteria, construction techniques, and example applications are shown on Figures 4-6A and 4-6B.

4.3.3 Filter Strips. Vegetated filter strips act to cause deposition of sediment within the area of vegetation. Buffer strips of natural vegetation can be left at the time of site grading, or can be created by using sod. A dense ground cover is necessary or runoff will channelize within the area. A minimum width of 20 feet is recommended.

4.3.4 Sediment Traps. A sediment trap is a temporary structure that is designed to fill with sediment. A sediment trap can be constructed by either excavating below grade or building an embankment across a swale. Excavated traps are less prone to failure than embankments. No pipe is used at the outlet, as in a sediment basin, and an open-channel spillway must be included in the design. A minimum of 900 cubic feet of storage volume must be provided for each tributary acre. A generalized design for a sediment trap is provided on Figure 4-7.

4.3.5 Sediment Basins. Areas draining more than five acres must be routed through a sediment basin. A temporary sediment basin is shown in Figure 4-8 and is similar to a permanent retention pond shown in Figure 6-1 in the *Structural BMPs* chapter.

If the site is to include a stormwater quality or flood detention basin, the permanent detention facility may be used as the temporary sediment basin, provided the outlets are modified upon completion for this purpose (Figure 6-2 in the *Structural BMPs* chapter). Such permanent detention facilities shall be restored to design grades, volumes, and configurations after site development is completed and the project is finalized.

Temporary sediment basins shall be designed to provide a minimum 900 cubic feet of sediment storage volume per tributary acre, and a minimum of 900 cubic feet of runoff storage volume per tributary acre

R0056951

VOL 12 2 3660

(i.e., a total of 1800 cubic feet per acre). The outlet from a sediment basin should be designed to empty the runoff storage volume in no less than 12 hours. The basin's length shall be no less than twice the basin's width. The inflow structures at the entrance of the basin should be designed to dissipate inflow energy and to spread the flow so as to achieve uniform flow throughout the basin's width.

4.3.6 Example Design: Sediment Basin

Given: Tributary Area = 10 acres

Required: Minimum Sediment Storage Volume = 10 acres x 900 cubic feet per acre
= 9000 cubic feet

The dimensions of the sediment storage area will be determined by site conditions. In this example, if a depth of 3 feet is selected, a 75 feet long by 40 feet wide area will provide the required 9000 cubic feet of sediment storage volume.

Required: Minimum Runoff Storage Volume = 10 acres x 900 cubic feet per acre
= 9000 cubic feet
= 0.207 acre-feet

The runoff storage volume is designed to be located vertically above the sediment storage volume. In this example, try a 4-inch diameter riser with the design pond maximum water surface elevation being two-feet above the sediment storage level. From Figure 6-3 of the *Structural BMPs* chapter, using a surcharge depth of 2.0 feet and a runoff storage volume of 0.207 acre-feet, it is determined that 1.60 square inches of outlet area is required for each row of outlet holes in the riser. From Figure 6-2 of the *Structural BMPs* chapter, it is determined that either eight 1/2-inch diameter holes or two 1-inch holes per row have a total area of 1.57 square inches and that these rows are spaced vertically four inches apart. Selecting 1/2-inch holes, this means that the riser will have six rows with eight 1/2-inch holes per row over a two-foot height. The uppermost row will be four inches below the top of the riser and the lowest row will be two feet below the top of the riser. The lowest row corresponds in elevation to the top of the sediment storage level.

See Figure 4-9 for guidance on the locations of baffles to make length-to-width ratio 2:1 or greater. See Figure 6-1 in the *Stormwater BMPs* chapter for guidance on embankment and emergency spillway design.

TEMPORARY DIVERSION DIKE

Definition

A temporary ridge of compacted soil located at the top, midslope, or base of a disturbed area.

Purposes

1. To divert storm runoff from higher drainage areas away from unprotected slopes to a permanent channel or temporary channel diversion.
2. To divert sediment-laden runoff from the midslope of a disturbed area to a temporary slope drain.
3. To divert sediment-laden runoff from the base of a disturbed area to a sediment trapping facility.

ROUGH-CUT STREET CONTROL

Definition

A temporary sediment barrier placed on alternate sides of a rough cut street.

Purposes

To divert sediment-laden runoff from rough-cut streets and slow the velocity of storm runoff.

Note: 1. Alternate materials such as straw bale barriers or silt fences may be used where large flows are not expected.

2. Requirements for and spacing of velocity reducers for streets with grades of less than 4% shall be as shown on the erosion control plan.

5. DRAINAGEWAY PROTECTION

At times construction activities must occur adjacent to or within a drainageway. Whenever this occurs, bottom sediments will be disturbed and transported downstream. The goal of these criteria is to minimize the movement of sediments resulting from construction activities that take place within any drainageway. Temporary facilities can be installed to divert flowing water around such sediment-generating construction activities within drainageways.

Some construction activities within a waterway are short lived, namely a few hours in duration, and are minor in nature. These are typically associated with maintenance of utilities and stream crossings and minor repairs to outfalls and eroded banks. In these cases, construction of temporary diversion facilities may cause more soil disturbance than the maintenance activity itself. If it can be reasonably determined that any channel work is maintenance related, is of very short duration, and will result in only a small disturbance of bottom sediment, it is reasonable to exempt these from the requirement to construct temporary diversion facilities.

5.1 Working Within or Crossing a Waterway

Whenever work occurs within a waterway, the following should be considered as appropriate:

1. Construction vehicles should be kept out of a waterway to the maximum extent practicable. Where in-channel work is necessary, steps, such as temporary channel diversions, must be taken to stabilize the work area during construction to control erosion. The channel (including bed and banks) must be restabilized immediately after in-channel work is completed.

2. Where an actively-flowing watercourse must be crossed regularly by construction vehicles, a temporary crossing should be provided. Two primary methods are available: (1) a culverted crossing; and, (2) a stream ford.

   A culverted crossing should be designed to pass the 2-year design flow. A typical temporary stream crossing is shown on Figure 5-1. For additional discussion on design of box culverts and pipes, see Sections 3 and 4, *Major Drainage*, of this *Manual*.

   A ford should be lined with a minimum six-inch thick layer of 1-1/2 inch diameter rock. A typical stream ford is shown on Figure 5-2.

R0056967

VOL 12

2

3676

statistical foundation for Figure 5-3. The designer of a temporary diversion facility and the construction contractor must recognize that the design flows taken from Figure 5-3 are for sediment control and not job-site protection from large runoff events, since these flow values are not representative of major or minor floods. However, all temporary channel diversions shall be sized to convey no less than the flows provided by Figure 5-3. Since each construction project is unique, it is recommended that the contractor consider the use of larger temporary water diversion facilities to protect the job site from higher runoff.

While Figure 5-3 suggests minimum design flows for April through September, the chances of high runoff decrease substantially during the months of October through Merch. During these months, much of the precipitation is snow that produces snowmelt runoff rates that are low when compared to runoff from rainstorms. As a result, it is suggested that temporary channel diversion structures for projects scheduled to be performed and completed during October through March be designed to carry no less than one-half of the flow values taken from Figure 5-3.

5.2.2 Stability Considerations. Temporary channels are not likely to be in service long enough to establish adequate vegetative lining. Temporary channel diversions must be designed to be stable for the design flow with the channel shear stress less than the critical tractive shear stress for the channel lining material. Unlined channels should not be used unless it can be demonstrated that an unlined channel will not erode during the design flow. Table 5-1 gives allowable channel lining materials for a range of slope and flow depth. Table 5-2 gives Mannings 'n' values for lining materials. Design procedures for temporary channels are described in detail in the Hydraulic Engineering Circular No. 15 published by the Federal Highway Administration. The methods presented in this section are greatly simplified and are based on information developed using only the most commonly used erosion control materials.

5.2.3 Example: Temporary Diversion Design. A simplified method for designing a non-erosive channel is given as follows:

Step One:

Using the tributary area A (in acres) determine peak flow according to Figure 5-3.

R0056968

VOL 12 2 3 6 7 7

A permit is required for placement of fill in a waterway under Section 404 of the Clean Water Act. The U.S. Army Corps of Engineers has issued nationwide general permit Number 14 for Minor Road Crossing Fills. This is defined as placement of less than 200 cubic yards of fill material below the plane of ordinary high water. The local office of the Corps should be contacted about the requirements for obtaining a 404 permit. The city or county of jurisdiction should also be consulted and can provide assistance. A further discussion on the need for 404 permits is included in Section 2.1, *Major Drainage*, of this *Manual*.

3. Whenever feasible, use a temporary water diversion (Section 5.2) to bypass the work areas when work takes place within a channel itself.

4. Whenever possible, construction in a waterway should be sequenced to begin at the most downstream point and work progressively upstream installing required channel and grade control facilities.

5. Complete work in small segments, exposing as little of the channel at a time as possible.

6. Where possible, perform all in-channel work between September 15 and April 15.

5.2 Temporary Channel Diversions

Limiting construction activities within actively-flowing water will significantly reduce sediment movement downstream from these activities. This can be done by using a temporary diversion facility that carries water around construction activities taking place within a waterway.

Permanent drainage channels should be constructed at the earliest possible stage of development. Temporary channel diversions should not remain in place for more than two years prior to removal or replacement by permanent facilities.

5.2.1 Temporary Diversion Sizing. Figure 5-3 must be used to determine the minimum design discharge to size temporary diversions. The two curves in Figure 5-3 were developed using monthly peak flow data for the months of April through September collected at 17 watersheds within the Urban Drainage and Flood Control District. Data for these watersheds were collected over periods that ranged from six years to eleven years and, as a result, provide reasonable

R0056969

VOL 12 2 3678

statistical foundation for Figure 5-3. The designer of a temporary diversion facility and the construction contractor must recognize that the design flows taken from Figure 5-3 are for sediment control and not job-site protection from large runoff events, since these flow values are not representative of major or minor floods. However, all temporary channel diversions shall be sized to convey no less than the flows provided by Figure 5-3. Since each construction project is unique, it is recommended that the contractor consider the use of larger temporary water diversion facilities to protect the job site from higher runoff.

While Figure 5-3 suggests minimum design flows for April through September, the chances of high runoff decrease substantially during the months of October through March. During these months, much of the precipitation is snow that produces snowmelt runoff rates that are low when compared to runoff from rainstorms. As a result, it is suggested that temporary channel diversion structures for projects scheduled to be performed and completed during October through March be designed to carry no less than one-half of the flow values taken from Figure 5-3.

5.2.2 Stability Considerations. Temporary channels are not likely to be in service long enough to establish adequate vegetative lining. Temporary channel diversions must be designed to be stable for the design flow with the channel shear stress less than the critical tractive shear stress for the channel lining material. Unlined channels should not be used unless it can be demonstrated that an unlined channel will not erode during the design flow. Table 5-1 gives allowable channel lining materials for a range of slope and flow depth. Table 5-2 gives Mannings 'n' values for lining materials. Design procedures for temporary channels are described in detail in the Hydraulic Engineering Circular No. 15 published by the Federal Highway Administration. The methods presented in this section are greatly simplified and are based on information developed using only the most commonly used erosion control materials.

5.2.3 Example: Temporary Diversion Design. A simplified method for designing a non-erosive channel is given as follows:

Step One:

Using the tributary area A (in acres) determine peak flow according to Figure 5-3.

R0056970

VOL 1 2 2 3679

Step Two:

Determine depth of flow, one foot maximum for flows less than 20 cfs and three feet maximum for flows less than 100 cfs. (Flows in excess of 100 cfs should be designed in accordance with the *Major Drainage* Section of the *Manual*).

Step Three:

Determine channel slope based on existing and proposed site conditions.

Step Four:

Select lining material from Table 5-1.

Step Five:

Determine the channel geometry and check the capacity using Manning's Equation and the "n" value given in Table 5-2. The steepest side slope allowable for a temporary channel is two horizontal to one vertical (i.e., 2:1). It is suggested that the design for temporary bypass channels include an additional 0.5 feet of freeboard.

5.3 Outlet Protection

To protect adjacent downstream properties from erosion due to concentrated flows, a stable outlet or channel is necessary. If there is no stable outlet, one may have to be constructed. In lieu of constructing a temporary or permanent outlet to the storm drainageway system, temporary total retention of the runoff from a 24-hour, 100-year storm may be provided. Written approval by the local city or county must be obtained for total retention of stormwater.

The outlets of slope drains, culverts, sediment traps, and sediment basins must be protected from erosion and scour. Outlet protection should be provided where the velocity of flow will exceed the maximum permissible velocity of the material where discharge occurs. This may require the use of a riprap apron at the outlet location. Design guidance on outlet protection is provided on Figure 5-4.

Check dams can be used in ditches or swales and downstream of the outlets of temporary slope drains, culverts, sediment traps, and sediment basins. Check dams reduce the velocity of

R0056971

VOL 12 2 3 6 8 0

concentrated flows and trap sediment eroded from the upstream ditch or swale. They are not a primary sediment trapping facility and are a temporary flow-control structure.

Check dams may be used under the following conditions:

- In temporary or permanent swales that need protection during the establishment of grasses
- In permanent swales that need protection prior to installation of a non-erodible lining
- In temporary ditches or swales that need protection where construction of a non-erodible lining is not practicable.

Check dams should be constructed of four- to six-inch angular rock to a maximum height of two-feet. The center of the top of the dam should be six-inches lower than the sides to concentrate the flow to the channel center. Where multiple check dams are used, the top of the lower dam should be at the same topographical elevation as the toe of the upper dam. Cross-sections of a loose-rock check dam and the spacing between a series of check dams are illustrated on Figure 5-5.

Sediment that collects behind a check dam shall be removed when the sediment reaches the spillway level. Check dams constructed in permanent swales should be removed when perennial grasses have become established, or immediately prior to installation of a non-erodible lining. All of the rock and accumulated sediment should be removed, and the area seeded and mulched, or otherwise stabilized.

5.4 Inlet Protection

All storm sewer inlets which are made operable during construction must be protected to prevent sediment-laden runoff from entering the conveyance system without first being filtered or otherwise treated to remove sediment. A number of alternate inlet protection designs are available for use as shown on Figures 5-8 through 5-12.

Inlets may be temporarily blocked to prevent sediment-laden runoff from entering storm sewers. Inlet protection measures may be removed after upstream disturbed areas are stabilized.

R0056972

Table 5-2
Temporary Channel Design Criteria

Manning's "n" Values for Channel Linings		
Lining Material	Flow Depth 0 ft to 1.0 ft	Flow Depth 1.0 ft to 3.0 ft
Plastic Membrane	0.011	0.010
Jute Netting	0.028	n/a
Straw or Curled Wood Mats	0.035	0.025
Riprap, Type VL	0.070	0.035
Riprap, Type L	0.073	0.037
Riprap, Type M	0.075	0.040

NOTES:

Determine flow rates with FIGURE 5-1.

Maximum Depth is 1 foot for flows less than 20 cfs.

Maximum Depth is 3 feet for flows equal to or greater than 20 cfs but less than 100 cfs (flows than 100 cfs should be designed in accordance with the Major Drainage Section of the USDCM).

Determine the channel bottom width by using Manning's Equation and the "n" value given above.

See Table 5-1 in the Major Drainage Section of the USDCM for riprap gradation

Unless structurally reinforced, side slopes shall be two horizontal to one vertical (2:1) or flatter.

Erosion protection should extend to 0.5 feet above the design depth.

TEMPORARY STREAM CROSSING

Definition

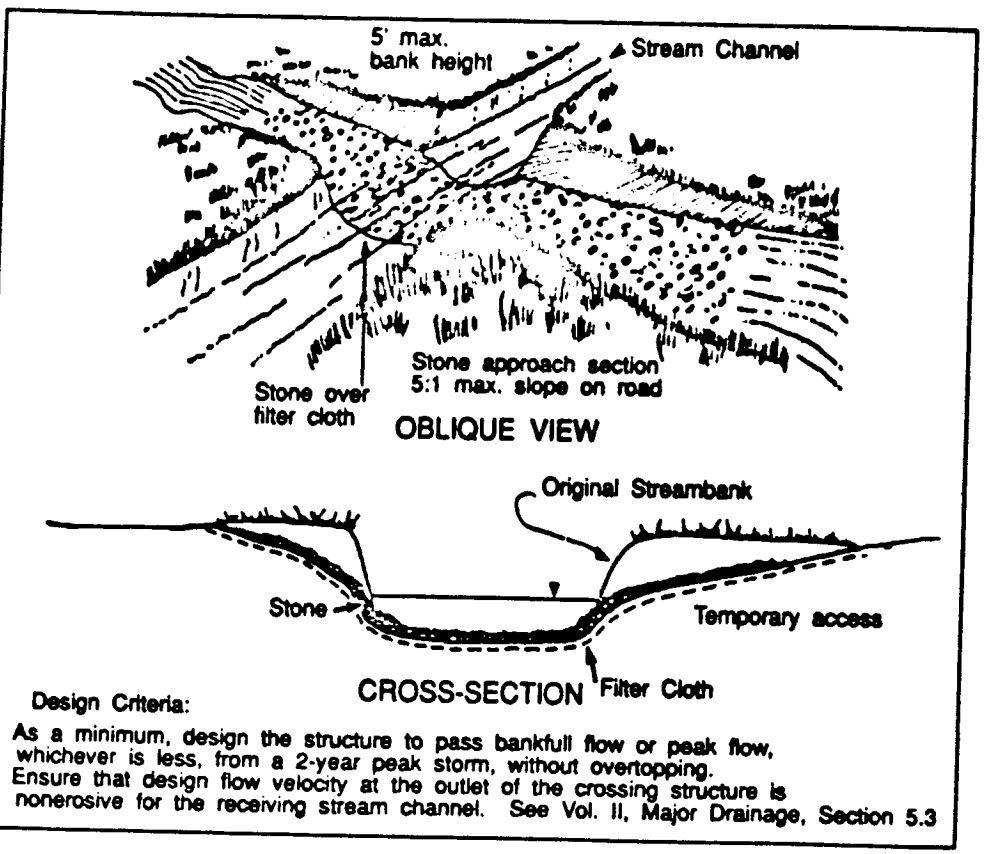
A temporary at-grade stream crossing installed across a normally dry watercourse for use by construction traffic.

Purposes

To stabilize stream crossings and reduce erosion created by construction traffic.



Design Criteria:

- As a minimum, design the structure to pass bankfull flow or peak flow, whichever is less, from a 2-year peak storm, without overtopping.
- Ensure that design flow velocity at the outlet of the crossing structure is nonerosive for the receiving stream channel. See Vol. II, Major Drainage, Section 5.3

VOL 1 2 2 3695

6. MATERIAL STORAGE

Materials are sometimes used at a construction site that present a potential for contamination of stormwater runoff. These include fuel, oil, lubricants, paints, solvents, concrete-curing compounds and other liquid chemicals such as fertilizers, herbicides and pesticides. Practices that can be used to prevent or minimize toxic materials in runoff from a construction site are described in this section.

6.1 Chemical and Petroleum Products Storage

Areas at the construction site that are used for storage of toxic materials and petroleum products should be designed with an enclosure, container, or dike located around the perimeter of the storage area to prevent discharge of these materials in runoff from the construction site. These barriers will also function to contain spilled materials from contact with surface runoff.

Measures to prevent spills or leaks of fuel, gear oil, lubricants, antifreeze, and other fluids from construction vehicles and heavy equipment should be considered to protect groundwater and runoff quality. All equipment maintenance should be performed in a designated area and measures, such as drip pans, used to contain petroleum products. Spills of construction-related materials, such as paints, solvents, or other fluids and chemicals, should be cleaned up immediately and disposed of properly.

6.2 Waste Storage

Areas used for collection and temporary storage of solid or liquid waste should be designed to prevent discharge of these materials in runoff from the construction site. Collection sites should be located away from the storm drainage system. Consideration should be given to covering waste storage areas, fencing these areas, if necessary, to contain windblown materials, and construction of a perimeter dike to exclude runoff. These measures may not be necessary if all waste is placed immediately in covered waste containers at the site and is otherwise controlled in an effective manner. All waste should be disposed at an approved landfill.

R0056987

8. DISPOSITION OF TEMPORARY MEASURES

All temporary erosion and sediment control measures shall be removed and disposed within 30 days after final site stabilization is achieved, or after the temporary measures are no longer needed, whichever occurs earliest, or as authorized by the city or county of local jurisdiction. For example, a site containing only one building will have temporary erosion control measures removed after building construction is complete and final landscaping is in place. Temporary erosion control measures may be removed from a commercial construction site or residential subdivision only after streets are paved and all areas have achieved final stabilization. Trapped sediment and disturbed soil areas resulting from the disposal of temporary measures must be returned to final plan grades and permanently stabilized to prevent further soil erosion.

The Professional Engineer preparing the erosion and sediment control plan shall submit, as part of the narrative report, a schedule of removal dates for temporary control measures. The schedule should be consistent with key construction items such as street paving, final stabilization of disturbed areas, or installation of structural stormwater controls.

VOL 1 2 2 3696
R0056988

VOL 12 2 3697

7. UNDERGROUND UTILITY CONSTRUCTION

The construction of underground utility lines that are not exempted (see Section 1.3.4) shall be subject to the following criteria:

1. No more than 200 feet of trench are to be opened at one time (local criteria may be more restrictive).

2. Where consistent with safety and space considerations, excavated material is to be placed on the uphill side of trenches.

3. Trench dewatering devices must discharge in a manner that will not adversely affect flowing streams, wetlands, drainage systems, or off-site property. Site dewatering permit requirements should be discussed with the Colorado Department of Health.

4. Provide storm sewer inlet protection (Section 5.4) whenever soil erosion from the excavated material has the potential for entering the storm drainage system.

R0056989

8. DISPOSITION OF TEMPORARY MEASURES

All temporary erosion and sediment control measures shall be removed and disposed within 30 days after final site stabilization is achieved, or after the temporary measures are no longer needed, whichever occurs earliest, or as authorized by the city or county of local jurisdiction. For example, a site containing only one building will have temporary erosion control measures removed after building construction is complete and final landscaping is in place. Temporary erosion control measures may be removed from a commercial construction site or residential subdivision only after streets are paved and all areas have achieved final stabilization. Trapped sediment and disturbed soil areas resulting from the disposal of temporary measures must be returned to final plan grades and permanently stabilized to prevent further soil erosion.

The Professional Engineer preparing the erosion and sediment control plan shall submit, as part of the narrative report, a schedule of removal dates for temporary control measures. The schedule should be consistent with key construction items such as street paving, final stabilization of disturbed areas, or installation of structural stormwater controls.

VOL 1 2 2 3698
R0056990

9. MAINTENANCE

All temporary and permanent erosion and sediment control practices shall be maintained and repaired by the owner during the construction phase as needed to assure continued performance of their intended function. Straw bale barriers or silt fences may require periodic replacement and all sediment accumulated behind them must be removed and disposed of properly. Sediment traps and basins will require periodic sediment removal when the design storage level is one-half full. All facilities must be inspected by the owner or owner's representative following each heavy precipitation or snowmelt event that results in runoff.

The Professional Engineer preparing the erosion and sediment control plan shall submit, as part of the narrative report, a schedule of planned maintenance activities for temporary and permanent erosion and sediment control measures. The schedule should be consistent with the level of maintenance required for the control measures proposed in the plan.

APPENDIX A

MODEL ORDINANCE FOR EROSION AND SEDIMENTATION CONTROL
(Revised August 28, 1991)

AN ORDINANCE TO AMEND THE CODE OF THE CITY (COUNTY) OF _____ BY ADDING A NEW CHAPTER RELATING TO EROSION AND SEDIMENT CONTROL, AND ADOPTING BY REFERENCE THE PUBLISHED CRITERIA FOR "EROSION AND SEDIMENT CONTROL FOR CONSTRUCTION ACTIVITIES" OF THE URBAN DRAINAGE AND FLOOD CONTROL DISTRICT, BY ADDING A NEW CHAPTER, WHICH NEW CHAPTER SHALL BE DESIGNATED AS CHAPTER ____ OF TITLE _____ OF SAID CODE.

THE CITY (COUNTY) OF _____, ORDAINS:

Title _____ of the Code of the City (County) of _____, is amended by adding a new Chapter _____ - Grading and Soil Erosion Control, which shall read as follows:

CHAPTER NO.

GRADING AND SOIL EROSION CONTROL

Section 1. Legislative Findings. The City Council (Board of County Commissioners) hereby finds that excessive quantities of soil are eroding from certain areas that are undergoing development for non-agricultural uses such as housing and commercial developments, industrial areas, recreational facilities, and roads. This erosion makes necessary costly repairs to gullies, washed out fills, roads and embankments. The resulting sediment clogs storm sewers and road ditches, and leaves deposits of silt in streams, lakes and reservoirs and is considered a significant water pollutant.

Section 2. Purposes. The purpose of this Ordinance (Resolution) is to prevent soil erosion and sedimentation from leaving construction sites that occur from non-agricultural development and construction activities within the City (County) by requiring proper provisions for water disposal and the protection of soil surfaces during and after construction, in order to promote the safety, public health, convenience and general welfare of the community (County).

Any person who undertakes or is responsible for an undertaking which involves earth disturbance is ultimately responsible to see that soil erosion and sedimentation as well as changed water flow characteristics resulting therefrom are controlled to the extent necessary to avoid damage to property and to avoid pollution of receiving waters. Nothing in this Ordinance (Resolution) shall be taken or construed as lessening or modifying the ultimate responsibility of such persons. Nor do the permit requirements of this Ordinance (Resolution) imply the assumption of any liability therefor on the part of the City (County). The standards, criteria and requirements of this Ordinance (Resolution) are to be seen as minimum standards which are not necessarily adequate to meet the highly variable conditions which must be covered by effective control measures. Compliance with the requirements of this Ordinance (Resolution) may not, therefore, of itself discharge such person's responsibility to provide effective control measures.

Section 3. Definitions. The following definitions shall apply in the interpretation and enforcement of this Chapter.

2 3 7 0 0 0

R0056992

VOL 12 2 3701

(1) "Accelerated soil erosion" - The increased migration and movement of soils on all land surfaces that occur as a result of man's activities.

(2) "Inspector" - The chief of the _____ Department (insert department title) of the City (County) or his duly authorized representative.

(3) "Certificate of completion" - A signed written statement by a licensed professional engineer working for the applicant stating that all construction, all earth disturbance work, and all permanent soil erosion control measures were inspected by the engineer and were installed in strict compliance with the approved plans and specifications.

(4) "City (County) Engineer" - The City (County) Engineer of the City (County) or his duly authorized representative.

(5) "Earth disturbance" - A man-made change in the natural cover or topography of land, including all grading, cut and fill, building, paving and other activities, which may result in or contribute to soil erosion or sedimentation of the waters of the State.

(6) "Erosion" - The process by which the ground surface is worn away by action of wind, water, gravity, or a combination thereof.

(7) "Excavation" - Any act by which soil or rock is cut into, dug, quarried, uncovered, removed, displaced, relocated, or stockpiled, and also included shall be the conditions resulting therefrom.

(8) "Filling" - Any act by which soil, rock or other construction materials are placed, stockpiled, dumped, or a combination thereof onto the surface of the earth that may exposed to rain or wind.

(9) "Flood plain" - An area adjacent to a watercourse, which area is subject to flooding as the result of the occurrence of the 100-year flood and which area thus is so adverse to past, current, or foreseeable construction or land use as to constitute a significant hazard to public health and safety or property.

(10) "Grading" - Any stripping, excavating, filling, stockpiling, or any combination thereof, and also included shall be the land in its excavated or filled condition.

(11) "Grading permit" - A permit issued to authorize work to be performed under this Ordinance.

(12) "Land use" - A use of land which may result in an earth disturbance, including, but not limited to, subdivision, residential, commercial, industrial, recreational, or other development, private and public highway, road and street construction, drainage construction, logging operations, agricultural practices, and mining.

(13) "Limits of allowable erosion" - The natural or historic rate of soil loss.

(14) "Permanent soil erosion control measures" - Those control measures which are installed or constructed to control soil erosion and which are maintained after completion of all grading and earth disturbance activities.

R0056993

VOL 12 2 3702

(15) "Person" - A natural person, firm, corporation, partnership, or association.

(16) "Slope" - Slope of land measured in horizontal distance necessary for the land to fall or rise one foot, expressed by horizontal distance in feet to one vertical foot.

(17) "Stripping" - Any activity which removes or significantly disturbs the vegetative surface cover including clearing and grubbing operations.

(18) "Temporary soil erosion control measures" - Interim control measures which are installed or constructed and maintained whenever grading or other earth disturbance is to occur for the purpose of control soil erosion until permanent soil erosion control is effected.

Section 4. Compliance with Chapter Required for Site Plan or Plat Approval. No site plan, plot plan, or plat shall be approved under Chapters _____ and _____ of this Code unless said site plan, plot plan, or plat shall include soil erosion and sediment control measures consistent with the requirements of this Chapter and related land development regulations.

Section 5. Compliance with Chapter Required for Occupancy. No certificate of occupancy for any building shall be issued under Chapter _____ of this Code unless the applicant for said Certificate of Occupancy submits a Certificate of Completion to the City (County) and said Certificate of Completion is approved by the City (County) Engineer.

Section 6. Adoption by reference of Erosion and Sediment Control Criteria. There is hereby adopted by reference, as a part of this ordinance (resolution), as if fully set forth herein, that certain code consisting of the published criteria of The Urban Drainage and Flood Control District, adopted by said District on _____ 1991, effective on the _____ day of _____, 1991, known as "Erosion and Sediment Control for Construction Activities," published on _____, 1991, which shall be known and referred to in this ordinance (resolution) by that name. The Inspector and the City (County) Engineer shall be guided by and shall apply the criteria contained in said code in the administration of this ordinance (resolution).

Section 7. Permits and Fees.

(1) Permit requirement. Except as exempted by sections of this ordinance (resolution), no person shall do any grading, stripping, excavating, or filling, or undertake any earth disturbance, unless a valid grading permit is issued by the City (County). Issuance by City (County) does not exempt the parties from obtaining any permits required by State of Colorado or the Federal Government.

(2) Permit application. A separate application shall be required for each grading permit, along with plans, specifications, and timing schedules for all earth disturbance. The plans shall be prepared under the supervision of a professional engineer licensed in the State of Colorado experienced in soil erosion and sedimentation control methods and techniques.

(3) Application data required. The plans and specifications shall include an Erosion and Sedimentation Control Plan and a Site Plan, which shall include and contain all of the requirements of Section 1.4 of the "Erosion and Sediment Control for Construction Activities".

R0056994

VOL 12 2 3703

(4) Fees. At the time of filing an application for a grading permit, a non-refundable filing fee of _____ Dollars $_____ shall be paid to the City (County) Treasurer. An additional non-refundable fee of _____ Dollars per acre of site area involved will be charged for plan review and site inspections (with a minimum fee of _____ Dollars $_____ for such review and inspection).

Section 8. Bond Requirement. A grading permit shall not be issued unless the permittee shall first post with the City (County) Engineer a bond executed by the landowner and a corporate surety with authority to do business in this State as a surety, or at the option of the City (County) Engineer, secured by a letter of credit drawn upon a bank doing business in Colorado, or having a Colorado correspondent bank at which such letter of credit may be collected.

The bond and letter of credit, whichever is used, shall be in a form approved by the City (County) Attorney, payable to the City (County), and in the amount of the estimated total cost of all temporary or permanent soil erosion control measures. The total cost shall be estimated by the City (County) Engineer or Building Inspector. The bond, and letter of credit, whichever is used, shall include penalty provisions for failure to complete the work on schedule as specified on the grading permit. In lieu of a surety bond or letter of credit, the applicant may file with the City (County) a cash bond or other instrument of credit which gives the City (County) at least equal security protection, approved by the City (County) Attorney in the amount equal to that which would be provided for in the surety bond or letter of credit.

Every bond and letter of credit or other instrument of credit shall include and every cash deposit shall be made on the conditions that the permittee shall comply with all of the provisions of this ordinance (resolution) and all of the terms and conditions of the grading permit, and shall complete all of the work contemplated under the grading permit within the time limit specified in the grading permit, or if no time limit is specified, within 180 days after the date of issuance of the grading permit.

A bond and surety thereon, or letter of credit, whichever is used, will be released to applicant four hundred ten (410) days after the Certificate of Completion has been approved by the City (County) Engineer, provided the City (County) Engineer, after field inspection, is satisfied the work completed under the grading permit is functioning as represented by applicant, or in the event defects are identified by the City (County) Engineer the applicant satisfactorily corrects all the defects identified in writing by the City (County) Engineer and said corrections are accepted in writing by the City (County) Engineer.

Section 9. Extension of Time. If the permittee is unable to complete the work within the specified time, at least ten (10) days prior to the expiration of the permit, a written request to the City (County) Engineer for an extension of time shall be submitted setting forth the reasons for the requested extension. In the event such an extension is warranted, the City (County) Engineer may grant additional time for the completion of the work, but no such extension shall release the owner or surety on the bond or the issuer of the letter of credit, or the person furnishing the instrument of credit or cash bond.

Section 10. Failure to Complete the Work. In the event of failure to complete the work or failure to comply with all the requirements, conditions, and terms of permit, the City (County) Engineer may order such work as is necessary to eliminate any danger to persons or property and to leave the site in a safe condition and he may authorize completion of all necessary temporary or

R0056995

VOL 1 2 2 3704

permanent soil erosion control measures. The permittee and the surety executing the bond or the issuer of the letter of credit, or person issuing the instrument of credit or making the cash deposit shall continue to be firmly bound under a continuing obligation for the payment of all necessary costs and expenses that may be incurred or expended by the City (County) in causing any and all such work to be done. In the case of a cash deposit, any unused portion thereof shall be refunded to the permittee.

Section 11. Denial of Permit. Grading permits shall not be issued where:

(1) The proposed work would cause hazards to the public safety and welfare; or

(2) The work as proposed by the applicant will damage any public or private property or interfere with any existing drainage course in such a manner as to cause damage to any adjacent property or result in the deposition of debris or sediment on any public way or into any waterway or create an unreasonable hazard to persons or property; or

(3) The land area for which grading is proposed is subject to geological hazard to the extent that no reasonable amount of corrective work can eliminate or sufficiently reduce settlement, slope instability, or any other such hazard to persons or property; or

(4) The land area on which the grading is proposed may lie within the designated flood plain of any stream or watercourse (not specifically designated by the City (County) as an area subject to flood hazard), unless a hydrologic report, prepared by a professional engineer, is submitted to certify that the proposed grading will have, in his professional opinion, no detrimental influence on the public welfare or upon the total development of the watershed and is also consistent with flood plain ordinances and Federal Emergency Management Agency regulations.

Section 12. Modifications of Approved Plans. All proposed modifications of the approved grading plan must be submitted along with all supporting materials, to the City (County) Engineer. No work in connection with the proposed modifications shall be permitted without prior approval of the City (County) Engineer, approval for which may be issued if the applicant can demonstrate that the modifications will provide soil erosion controls equivalent to, or better that the originally approved soil disturbance plans.

Section 13. Responsibility of Permittee. During grading operations the permittee shall be responsible for:

(1) The prevention of damage to any public utilities or services within the limits or grading and along any routes of travel of the equipment;

(2) The prevention of damage to adjacent property (No person shall grade on land so close to the property line as to endanger any adjoining public street, sidewalk, alley, or any public or private property without supporting and protecting such property from settling, cracking, or other damage which might result).

(3) Carrying out the proposed work in accordance with the approved plans and in compliance with all the requirements of the permit and this ordinance (resolution);

(4) The prompt removal of all soil, miscellaneous debris, materials applied, dumped, or otherwise deposited on public streets, highways, sidewalks, or other public

R0056996

VOL 12 2 3705

thoroughfares or any other non-authorized offsite location, during transit to and from the construction site, or otherwise, where such spillage constitutes a public nuisance, trespass or hazard in the determination of the City (County) Engineer or a Court of competent jurisdiction.

Section 14. General Requirements.

(1) All temporary erosion control facilities and all permanent facilities intended to control erosion of any earth disturbance operation shall be installed before any earth disturbance operations take place.

(2) Any earth disturbances shall be conducted in such a manner so as to effectively reduce accelerated soil erosion and resulting sedimentation, and should not exceed the erosion expected to occur for the site in is totally undeveloped state.

(3) All persons engaged in earth disturbances shall design, implement, and maintain acceptable soil erosion and sedimentation control measures, in conformance with the erosion control technical standards adopted by the City.

(4) All earth disturbances shall be designed, constructed and completed in such a manner so that the exposed area of any disturbed land shall be limited to the shortest possible period of time.

(5) Sediment cause by accelerated soil erosion shall be removed from runoff water before it leaves the site of the earth disturbance.

(6) Any temporary or permanent facility designed and constructed for the conveyance of water around, through, or from the earth disturbance area shall be designed to limit the water flow to a non-erosive velocity.

(7) Temporary soil erosion control facilities shall be removed and earth disturbance areas graded and stabilized with permanent soil erosion control measures pursuant to standards and specifications prescribed in accordance with the provisions of the "Erosion and Sediment Control for Construction Activities" and in accordance with the permanent erosion control features shown on the soil stabilization plan approved by the City (County).

(8) Permanent soil erosion control measures for all slopes, channels, ditches, or any disturbed land area shall be completed within fourteen (14) calendar days after final grading or the final earth disturbance has been completed. When it is not possible to permanently stabilize a disturbed area after an earth disturbance has been completed or where significant earth disturbance activity ceases, temporary soil erosion control measures shall be implemented within fourteen (14) calendar days. All temporary soil erosion control measures shall be maintained until permanent soil erosion measures are implemented.

Section 15. Maintenance Requirements. Persons carrying out soil erosion and sediment control measures under this Chapter, and all subsequent owners of property concerning which such measures have been taken, shall maintain all permanent erosion control measures, retaining wall, structures, plantings, and other protective devices. Should the applicant or any of the subsequent property owners fail to adequately maintain the permanent erosion control facilities, retaining walls,

R0056997

VOL 12 2 3706

structures, plantings, and other protective devices, the City (County) reserves the authority, after properly notifying the owner of needed maintenance and the owner failing to respond to the City's (County's) demand for such maintenance to enter affected property, provide needed maintenance and to charge the owner for the work performed by the City (County) or its contractors.

Section 16. Minimum Design Standards for Erosion and Sediment Control. All erosion control plans and specifications including extensions of previously approved plans shall include provisions for erosion and sediment control in accordance with the "Erosion and Sediment Control for Construction Activities". Erosion control plans are required on sites which are:

(1) Five (5) acres in size or larger, and all sites smaller than five (5) acres if they are a part of a total development or subdivision that is larger than five (5) acres in size; or

(2) Any development containing 15 dwelling units; or

(3) Where physical features have a cumulative effect and will create erosion problems such as:

a. Steep slopes - 8-feet (horizontal) to 1-foot (vertical) or steeper, and

b. Significantly erodible soils - "K" in the universal soil loss equation is greater than or equal to 0.25;

Section 17. Variances and Exceptions.

(1) No permits shall be required for the following:

(a) Agricultural use of land zoned agricultural.

(b) Grading or an excavation below finished grade for basements, footings, retaining walls, or other structures on plots zoned R1 - R3 of less than five (5) acres in size unless required otherwise under Section 16 above.

(c) A sidewalk or driveway authorized by a valid permit under Chapters _____ of _____.

(d) Gravel, sand, dirt or topsoil removal as authorized pursuant to approval of the Colorado Mined Land Reclamation Board, provided said approval includes an erosion plan that meets the minimums specified by this ordinance.

(e) Sites smaller than five (5) acres which are not a part of a larger development and which constitute an infill of an established older development within the City.

(f) Where the City (County) Engineer certifies in writing that the planned work and the final structures or topographical changes will not result in or contribute to soil erosion or sedimentation and will not interfere with any existing drainage course in such a manner as to cause damage to any adjacent property or result in the deposition of debris or sediment on any public way, will not present any hazard to any persons or property and will have no detrimental influence upon the public welfare or upon the total development of the watershed.

R0056998

VOL 12 2 3707

(g) Even though no permits are required under subsections (1)(a), (b), (c), (d), and (e) of this section, those operations and construction activities which are exempted from obtaining permits must comply with the rules and regulations concerning grading and erosion specified in this Chapter, and shall provide appropriate controls to retain soil erosion on the construction site.

(2) Where it is alleged that there is error or misinterpretation in any order, requirements, decisions, grant or refusal made by the City (County) Engineer, the (chose as appropriate: Deputy City Manager, Manager of Public Works, Public Works Director, County Manager, Chairman of the Board of County Commissioners) may appoint a technical hearing board that shall have the power to hear specific applications and all complaints regarding the decisions of the City (County) Engineer and to determine if the decisions of the City (County) Engineer were based on a misinterpretation of the requirements of this Chapter and referenced criteria. Whenever it is determined that an interpretation error was made, the case will be returned to City (County) Engineer, along with the board's recommendations on how the Engineer's decision could be modified to made consistent with the provisions of this Chapter.

• *In absence of this, or another similar appeals process, resort directly to court would be the only remedy, which may not be desired as a matter of policy. If such policy is desired, however, it is suggested it be spelled out by substituting for (2) above, the following, or a similar subsection:*

(2) Review of any order, requirement, decision, grant or refusal made by the City (County) Engineer, and claimed to be illegal, shall be by the District Court pursuant to the Colorado Rules of Civil Procedure.

Section 18. Inspection. The requirements of this Chapter shall be enforced by the City (County) Engineer. The City (County) Engineer shall inspect the work and shall require the owner to obtain services to provide adequate on-site inspection and/or compaction testing by a soil engineer, approved by the City (County) Engineer, unless he determines that such inspection requirements may be waived due to the non-hazardous nature of the grading.

Upon satisfactory execution of all approved grading plans and other requirements, the City (County) Engineer shall issue a certification of completion. If the City (County) Engineer finds any existing conditions not as stated in any application, grading permit or approved plan, he may refuse to approve further work until a revised grading plan which will conform to the existing condition has been prepared and approved.

If the City (County) Engineer finds that eroded soils are leaving the construction site, the City (County) Engineer may direct the owner(s) or his agents or his contractor on the site by written order to install any and all erosion controls that are deemed necessary to prevent said soil erosion from migrating off site. It shall be the duty of the owner(s) and his agent(s) and contractor(s) immediately to take all necessary steps to comply with such order and otherwise to take all necessary steps to prevent such migration off premises or entering receiving waters. Delivery of such a written order by the City (County) Engineer to the owner's agent or contractor shall be deemend to be notice thereof to and binding upon the owner.

R0056999

Section 19. Enforcement. Notwithstanding the existence or pursuit of any other remedy, the City (County) may maintain an action in its own name in any court of competent jurisdiction for an injunction or other process against any person to restrain or prevent violations of this ordinance (resolution).

The City (County) Engineer, or his duly authorized agents, may enter at all reasonable times in, or upon, any private or public property for the purpose of inspecting and investigating conditions and practices which may be a violation of this ordinance (resolution).

Project Description

The Project consists of the development of a 6.2 acre parcel with two office buildings. The project is located in the SW quarter of Section #, Township, Range of the 6th principal meridian located in County, Colorado. The project involves grading of 5.2 acres of the parcel, constructing two office buildings, two parking lots, an access road, a box culvert over Dry Creek and associated site utilities.

Existing Site Conditions

Most of the existing site is vegetated with native grass. The plant density is estimated to be 50% coverage of the ground surface. Cottonwood trees and other riparian vegetation are found adjacent to Dry Creek. The site drains to Dry Creek except the southeast portion which drains offsite to the southeast. About 0.2 acres of wetlands are found next to Dry Creek. The riparian and wetland vegetation will not be disturbed by the site development. The existing slopes on the site range from 2% to 19% adjacent to the Creek.

R0057003

VOL 1 2

Adjacent Areas

Surrounding development consists of office and commercial development. The site is bounded by Broadway and Monroe Streets. Dry Creek bisects the site. The proposed improvements to Dry Creek are limited to a box culvert and preservation of the 100-year floodplain (Refer to the Drainage Report for the Site).

Soils

Existing site soils consists of Ascalon sandy loam and Nunn sandy clay loam on the uplands and alluvial soils next to Dry Creek. Ascalon sandy loam is well drained with moderate permeability (Hydrologic soil group B) and has a slight erosion hazard. Nunn sandy clay loam is well drained with moderately slow permeability (Hydrologic soil group C) and presents a moderate erosion hazard. The alluvial soils adjacent to the Creek will not be disturbed.

II. Erosion and Sediment Control Plan

Volumes and Areas Impacted

The site will be graded with topsoil stripped and stockpiled. The total quantity of cut and fill is 3,500 cubic yards. The cut and fill is balanced, that is, no fill will be imported to the site. The access road, building site and parking areas will be graded, then covered with granular base course. Other graded areas will be mulched until permanent landscaping is installed.

Erosion and Sediment Control Measures

The erosion control measures for the site are shown on the "Sample Erosion and Sedimentation Control Plan." (Note: Proposed contours are not shown on this example plan for clarity; however, proposed contours are required to be shown on the site plan.) Offsite drainage from the north is diverted to the east along Broadway Avenue. Offsite drainage from the west is diverted to the south along Monroe Road. The area southeast of the proposed parking lot for Building "B" drains offsite. This area will remain undisturbed and will be protected with a silt fence. A stabilized construction entrance will be provided at the access point off Monroe Road. Diversion channels will be constructed near Dry Creek to collect runoff from the building areas and route flows to sediment traps. Each sediment trap collects runoff from 2.0 acres and will be excavated below grade. The sediment traps will be about 30 feet square and about two feet deep (show details) below the outlet. Sediment traps will have a surcharge volume of 1,800 cubic feet above the outlet. Straw

R0057004

VOL 1 2

bale barriers will be anchored next to the creek for the areas where runoff is not intercepted by the diversion channels.

Schedule

The construction schedule is as follows:

Install Construction Entrance, Sediment traps and Straw Bale Barriers:	September 15 - September 30
Site Grading:	September 30 - October 15
Install Base Course and Mulch All Exposed Soil Areas:	October 15 - October 20
Utility and Building Construction:	October 20 - April 1
Paving and Landscaping:	April 1 - April 15
Removal of Erosion Control Measures:	April 15 - April 20

The schedule will minimize the exposure of unprotected areas to less than 30 days. The perimeter controls will be installed prior to site grading.

Permanent Stabilization Measures

Permanent landscaping will include bluegrass sod, zeriscape plantings and trees and shrubs. The two sediment traps will be converted to the site detention ponds after sod is installed (Refer to the site Drainage Report for the detention requirements). The box culvert will be constructed early in the construction period to provide access across the creek during construction.

Stormwater Management Considerations

Stormwater will sheet flow from the building areas towards the creek, then be intercepted and routed to sediment traps during construction. All areas that will not be intercepted by the diversions will be protected with straw bale barriers. Post-development stormwater quality control will be provided by the vegetated filter strip adjacent to Dry Creek.

VOL 1 2 2 3 7 1 4

Construction Materials and Equipment

The contractor shall store all construction materials and equipment and shall provide maintenance and fueling of equipment in confined areas on site from which runoff will be contained and filtered.

Maintenance

The erosion control measures will be inspected weekly during construction. Sediment traps will be cleaned of excessive sediment if necessary. Erosion control blankets in the diversion channels will be checked after runoff events. Straw bale barriers will be checked for undermining and bypass and repaired or expanded as needed. Mulching of bare soils will be checked regularly and areas where it was lost or damage will be remulched within seven working days when needed.

Cost Estimate

The estimated cost of the erosion control measures is $7,320. A total of 780 linear feet of silt fences and straw bale barriers will be constructed at an estimated cost of $4.00 per foot. The two sediment traps involve excavation at a cost of $250 each. The diversion channels will be lined with a coconut fiber blanket at an estimated cost for grading and the blanket of $7.50 per linear foot for the 400 linear feet to be installed. The construction entrance will require 10 cubic yards of material at $10 per cubic yard. Site mulching and it maintenance prior to final revegetation is estimated to cost $500,000.

Calculations

Calculations for the diversion channels and sediment traps are provided herein. Details for the erosion control measures can be found in Figures 3-2, 3-3, 3-4, 4-1, 4-2, 4-5, 4-6 and 4-7 of the *Erosion Control Chapter* of Volume 3 of the *Urban Storm Drainage Criteria Manual*. (The figures are not included with this example to save space but shall be included with the erosion and sediment control plans submitted to the local jurisdiction.)

R0057006

VOL 1 2 2 3 7 1 5

Slope Diversion Channel Sizing:

$Q = C I A$

$C = 0.2$ (From Table 3-1, USDCM, Runoff)

(Weighted average of undeveloped and parking areas.)

$I_{2\text{-}yr} = 2.6$"/hour (From Fig. 5-1, USDCM, Rainfall)

$A = 2.0$ acres each

$Q = 0.2 \times 2.6 \times 2.0 = 1.04$ cfs

Try a triangular channel with depth of 0.5 ft and four to one sideslopes. (Actual depth will be 1.0 ft. allowing 0.5 ft. as freeboard.)

Proposed Slope = 0.75%

$A = 1$ ft^2, $P = 4.47$ ft. $R = 0.224$ ft.

Use a fiber blanket for erosion control.

$n = 0.035$

from Manning's Equation:

$V = 1.486/0.035 \times (.0075)^{1/2} = 1.35$ feet per second

$Q = A V = 1.35$ cfs

(more than 1.04 so this channel section is acceptable)

Check Erosion potential:

$t = g d s$ (Shear Stress Formula)

$t = 62.4 \times 0.5 \times 0.0075 = 0.23$ lb/ft^2

from HEC-15, $t_{allowable} = 0.65$ lb/ft^2

t_{actual} is less than $t_{allowable}$ so the diversions should be stable.

Sediment Traps

Tributary Area = 2.0 acres

Required Volume = 900 ft^3/acre x 2.0 acres = 1,800 ft^3

Use a 30 ft. x 30 ft. x 2.0 ft. deep sediment trap

VOL 12 2 3711

APPENDIX C

GLOSSARY OF TERMS

Erodibility - The susceptibility of a particular soil type to erosion by water or wind.

Erosion - The wearing away of the land surface by water, wind, ice or other geological agents, including the detachment and movement of soil or rock fragments by water, wind, ice, or gravity.

Erosion Control Measures - Practices that slow or stop erosion.

Final Stabilization - Completion of all land disturbing activities, removal of all temporary sediment controls, establishment of vegetative cover on exposed soil areas, and installation of permanent roads and structural stormwater quality best management practices.

Land Disturbing Activity - Grading, cut, fill, stockpiling of dirt, removal of vegetation, or any other alteration or disturbance of the ambient land surface.

Mapping Unit - Soil name and symbol given in the Soil Conservation Service Soil Survey for each soil type. Most areas of the Denver metropolitan area are included in a soil survey. In older urban portions of the City and County of Denver, soils analysis will be needed to determine soil types.

Permanent - Installation of land-surface cover, or erosion and sediment control measures, that will remain in place for a long period of time.

Sedimentation - The process of solid materials, both inorganic (mineral) and organic, coming to rest on the earth's surface either above or below sea level.

Sediment - Particulate solid material, either inorganic or organic, that will settle or be deposited in a liquid under the force of gravity.

Sediment Barrier - Straw bale barrier (dike) or a silt fence.

Sediment Basin - A depression, either excavated or formed by a dam, that holds water and debris and facilitates sedimentation of soil particles. Normally used for drainage areas equal to and greater than 5.0 acres.

R0057009

Sediment Trap - A small depression that holds water and debris and facilitates sedimentation. Normally used for drainage areas less than 5.0 acres.

Temporary - Installation of erosion or sediment control measures, either structural or nonstructural, that are planned to be removed or inactivated after a period of time.

Viable Vegetative Cover - A measure of performance for establishment of appropriate vegetative cover (or density) on sites planned for revegetation for the period of duration of successful growth as approved by the city and county of jurisdiction.

BIBLIOGRAPHY

The bibliography that follows contains more than 120 listings of papers, proceedings, reports and books, all of which relate to stormwater, stormwater quality and erosion control engineering and management. The text of Volume 3 of the *Urban Storm Drainage Criteria Manual* (*Manual*) specifically refers to some of these listings, while others are included to provide the reader with literature sources in these areas of technology. Although many of the listings in this bibliography were not specifically cited in the text, all of this literature was reviewed and considered by the Urban Drainage and Flood Control District, its advisors and consultants in the selection of practices included in Volume 3 of this *Manual* and in the development of the technical criteria for these practices.

Stormwater Compliance: Municipal Techniques and Strategies

8:00 Final Registration

8:30 **What the Regulations Say . . . and the Missing Pieces**
Similarities, differences and overlap between municipal stormwater regulations and the non-point source program.

9:00 **Pieces of the Puzzle**
- EPA regulatory requirements for a storm water plan;
- Identifying and addressing the primary areas of concern: municipal separate storm sewers; industrial facilities operated by the municipality; industrial operations and land disturbances within a municipality.

9:30 **The Impact of Industry and Land Development on Municipal Storm Water Compliance**
A critical first step is understanding the regulatory requirements affecting industrial operations and land development, and the responses of the municipality.

Challenges from industrial operations:
- identifying illicit discharges;
- obtaining access to storm water monitoring data;
- identifying industrial facilities which are out of compliance;
- program enforcement at the municipal level.

Challenges from land development:
- erosion control;
- program enforcement at the municipal level.

10:15 **Break**

10:30 **Best Management Practices (BMP) for Achieving Program Objectives**
Practical best management practices which have been designed to reduce loads on storm water discharges; examples will be selected based on most common applications, cost effectiveness, and the ability to achieve desired results.

11:30 **Evaluation and Development of a Municipal Storm Water Management Program: A Case Study (Local Speaker)**
- Typical challenges when conducting storm water monitoring;
- Ordinances to address industrial and construction activities;
- Activities within cities that have been identified as primary pollutant sources;
- Challenges to identifying illicit discharges;
- Time, staff and cost requirements for program development and implementation;
- Relying on outside assistance.

12:00 **Lunch**

1:00 **Legal Issues**
A city or local attorney will provide an overview of the potential pitfalls for municipalities concerning stormwater regulatory compliance.

1:30 **Implementing the Storm Water Management Plan**
- City ordinances which address storm water management; what are other cities doing and why?
- Fees, permits, inspections and enforcement;
- Monitoring out-fall locations: number, frequency and staffing levels;
- Testing parameters: cost, common mistakes, results of first round of testing, program modifications.
- Illicit discharges: where to focus and how to perform tests;
- Identifying activities and discharges that have a negative impact on storm water discharge quality;
- Reducing receipt of pollutants from municipal landfills, hazardous waste treatment, disposal and recovery facilities, construction runoff.
- Common reporting and recordkeeping mistakes.
- Periodic re-evaluation and update to meet changing needs and methodologies.

3:15 **Break**

3:30 **Current and Future Priorities for EPA's Clean Water Program**
To be presented by an EPA representative.

4:30 **Questions and Answers**
State regulatory agency representatives have been invited to participate in roundtable discussions with municipalities in their respective states.

What the Regulations Say . . . and the Pieces of the Puzzle

R0057030

VOL 12 2 3139

Putting the Puzzle Together

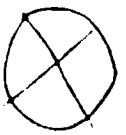
What are the primary components of the program?

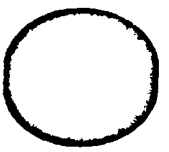
Key Components of the Regulations

- Municipal Separate Sewers.
- Municipal activities such as maintenance areas, landfills, airports, and salt piles.
- Land disturbances greater than 5 acres.
- Industrial operations that have manufacturing SIC codes.

R0057031

How and why do these regulations fit together?





If you are responsible for the discharge, you should look closely at the waters that enter your system.

What responsibilities does industry have to the municipality?

VOL 12 2 3740

R0057032

AS SPECIFIED IN
40 CFR 122.26 (a)(4)

By May 18, 1991, or 180 days prior to commencing such discharge, industry must submit:

- The name of the facility;
- a contact person and phone number;
- the location of the discharge;
- a description, including Standard Industry Code, which best reflects the principal products and services provided by each facility; and
- any existing NPDES permit number.

Why was this requirement put into place?

40 CFR 122.26 (a)(4)

Provides a legal means for collecting important information about industrial facilities and identifying pollution sources.

VOL 12 2 3741

R0057033

WHO IS RESPONSIBLE?

The operator of the municipal separate storm water system is ultimately responsible for storm water discharges.

What role is the Municipality being forced to assume?

REGULATORY ENFORCEMENT

for industrial and land disturbance activities.

VOL 12 2 3142

R0057034

How can we spread load the enforcement burden?

Consider a watershed management approach rather than a program that relies on political boundaries and subdivisions.

R0057035

3744

STORM WATER COMPLIANCE: MUNICIPAL TECHNIQUES AND STRATEGIES

SECTION I WHAT THE REGULATIONS SAY AND THE MISSING PIECES

First point to realize is that municipal storm water management is a long-term and never ending project.

The primary objective of the application process was to collect information and to establish a foundation for the development of long term program strategy which will lead to the improvement of surface water discharges from the municipal separate storm sewer system.

The municipal storm water management program, if properly implemented, will evolve with time and address new, best available technologies, new pollutant sources, and changing land uses. Regardless of how effective the program is today, it is imperative that it be under constant review and revision.

SECTION II PIECES OF THE PUZZLE

What are the primary components of the program?

According to the current National Pollutant Discharge Elimination System (NPDES) Storm Water Regulations, their are two primary types of municipalities involved in the NPDES program:

1) municipalities, greater than 250,000 persons
2) municipalities, greater than 100,000 persons

Within each of these municipalities, there exist several key areas which ultimately impact the compliance effort:

a) municipal separate sewers
b) municipal activities such as maintenance areas, landfills, airports, and salt piles.
c) land disturbances greater than 5 acres
d) industrial operations which have manufacturing SIC Codes

How do they fit together?

Since municipalities are responsible for all discharges from the separate storm sewer system, each one indirectly becomes responsible for all waters received from land disturbance activities, industrial operations, and other activities occurring within the city limits.

What responsibilities does industry have to the municipality?

As specified in 40 CFR 122.26 (a)(4)

...an operator of a storm water discharge associated with industrial activity which discharges through a large or medium municipal separate storm sewer system shall submit, to the operator of

R0057036

the municipal separate storm sewer system receiving the discharge no later than May 15, 1991, or 180 days prior to commencing such discharge:

- the name of the facility;
- a contact person and phone number;
- the location of the discharge;
- a description, including Standard Industry Code, which best reflects the principal products and services provided by each facility; and
- any existing NPDES permit number.

Who is ultimately responsible for storm water discharges?

The operator of the municipal storm water system.

What role is the municipality being forced to assume?

The writing is on the wall. Congress has passed on an unfunded mandate that has forced municipal government into the role of enforcement of the NPDES Storm Water Regulations.

Political vs. Watershed Boundaries of Responsibility

The most effective programs that have been developed to this point have relied on a shared program development that includes all municipal governments within a common watershed. Political boundaries do not provide an effective means for addressing storm water management issues.

LIST
OF
SIC CODES

WHAT ARE THE PROGRAM DEADLINES FOR INDUSTRY?

Programs administered by the US EPA require that:

1) By October 1, 1992 most industries were required to submit a permit application for permit coverage under the NPDES Storm Water Program.

WHAT ARE THE PROGRAM DEADLINES FOR INDUSTRY? (continued)

Programs administered by the US EPA require that:

2) By April 1, 1993 most industries throughout the country (some states had different deadlines and approaches) were required to develop a formal Storm Water Pollution Prevention Plan.

Individual state managed programs may vary.

R0057041

WHAT IS REQUIRED OF
INDUSTRY THAT MAY BE HELPFUL
TO MUNICIPALITIES?

STORM WATER
MONITORING

According to the EPA's
General Permit
monitoring requirements for
industry

VOL 12 2 3750

R0057042

INDUSTRY MUST INVENTORY ALL SIGNIFICANT MATERIALS EXPOSED TO STORM EVENT ACTIVITY

INDUSTRY MUST IDENTIFY SPILLS AND LEAKS THAT OCCURRED DURING THE PAST 3 YEARS

INDUSTRY MUST CONDUCT AN ASSESSMENT FOR ILLICIT DISCHARGES

The industrial facility provide a certification that includes the following information:

- Identification of potential non-storm water discharges.
- The evaluation criteria or test method used.
- The date of testing and/or evaluation.
- The on-site drainage points that were directly observed during the test and/or evaluation.

VOL 12 2 3751

R0057043

INDUSTRY MUST IDENTIFY ALL POLLUTANT SOURCES

Each plan should provide a description of potential sources which may be reasonably expected to add significant amounts of pollutants to storm water discharges or which may result in the discharge of pollutants during dry weather from separate storm sewers draining the facility. Each plan shall identify all activities and significant materials which may potentially be significant pollutant sources.

INDUSTRY MUST IMPLEMENT

SPECIFIC BEST MANAGEMENT PRACTICES THAT WILL AID IN THE REDUCTION OF POLLUTANTS IN STORM WATER DISCHARGES.

INDUSTRY MUST PROVIDE EMPLOYEE TRAINING

The training program must inform personnel at all levels of responsibility of the components and goals of the facilities Storm Water Pollution Prevention Plan. Topics will include:

- Spill prevention and response;
- Good housekeeping; and
- Material management practices.

VOL 12 2 3752

R0057044

TRAINING REQUIREMENTS FOR SECTION 313 FACILITIES

- Preventive measures, including spill prevention and response and preventative maintenance;
- Pollution control laws and regulations;
- The facility's Storm Water Pollution Prevention Plan; and
- Features and operations of the facility which are designed to minimize discharges of Section 313 water priority chemicals, particularly spill prevention procedures.

A FACILITIES SWPPP MUST BE CONSISTENT WITH OTHER ENVIRONMENTAL MANAGEMENT PLANS

Other programs include:

- Preparedness Prevention and Contingency Plan (40 CFR 264 and 265)
- Spill Control and Countermeasure Plans (40 CFR 112)
- Facility Response Plans (OPA-90)
- NPDES Toxic Organic Management Plan (40 CFR 413, 433, 469)
- OSHA Emergency Action Plan (29 CFR 1910)

WHAT KIND OF LAND DISTURBANCES REQUIRE PERMITTING?

Land disturbances of greater than 5 acres.

VOL 12 2 3753

R0057045

› Relatively speaking, municipalities seem to have a greater understanding of the potential impact from land disturbance activities, mainly because of citizen complaints with mud in streets and the siltation of lakes and storm sewers.

CHALLENGES FOR LOCAL GOVERNMENTS DEALING WITH LAND DEVELOPERS

Challenges for Local Governments Dealing with Land Developers

› Many citizen complaints are the result of erosion from properties smaller than 5 acres. What can be done about the development of smaller lots?

› How big of a problem is erosion, for land disturbances?

VOL 12 2 3754

R0057046

Challenges for Local Governments Dealing with Land Developers (continued)

- Besides erosion, what other areas of concern should be considered?
- How do you hold the developer responsible for large residential development areas, once the developer has sold many of the lots to builders?

Challenges for Local Governments Dealing with Land Developers (continued)

- Is the State or EPA actively enforcing the regulatory requirements placed on those responsible for the land disturbances?

VOL 12 2 3155

R0057047

SECTION III THE IMPACT OF INDUSTRY AND LAND DEVELOPMENT ON MUNICIPAL STORM WATER COMPLIANCE

A municipality's ability to comply with storm water permit provisions will be directly impacted by storm water discharges received from industrial facilities and land disturbance activities.

The provisions of the permits issued to industrial operators and land developers should be clearly understood and integrated into the Municipal Storm Water Management Program.

The compliance actions taken by private industry and land developers should be considered a viable portion of the overall municipal compliance effort.

NPDES Storm Water Regulatory Requirements for Industry

WHO IS INVOLVED?

Industries listed in one of eleven Standard Industry Code (SIC) categories, identified in attachment A which is reprinted from the Federal Register, September 9, 1992.

WHAT ARE THE OBLIGATIONS OF AN INDUSTRY TO THE OPERATOR OF A MUNICIPAL STORM WATER SYSTEM?

In accordance with the 40 CFR Section 122.26(a)(4), an operator of a storm water discharge associated with industrial activity which discharges through a large or medium municipal separate storm sewer system shall submit, to the operator of the municipal separate storm sewer system receiving the discharge no later than May 15, 1991, or 180 days prior to commencing such discharge: the name of the facility; a contract person and phone number; the location of the discharge; a description, including SIC which best reflects the principal products or services provided by each facility; and any existing NPDES permit number.

WHAT WERE THE PROGRAM DEADLINES FOR INDUSTRY?

Programs administered by the US Environmental Protection Agency (EPA) required that:

1) By October 1, 1992, most industries were required to submit an application for permit coverage under the NPDES Storm Water Program.

2) By April 1, 1993, most industries throughout the country (some states had different deadlines and approaches) were required to develop a formal storm water pollution prevention plan.

Individual state managed programs may vary.

WHAT IS SPECIFICALLY REQUIRED?

As stated in the EPA General Permit:

A storm water pollution prevention plan (SWPPP) shall be developed for each facility covered by this permit. Storm water pollution prevention plans shall be prepared in accordance with good

VOL 12 2 3756

R0057048

engineering practices. The plan shall identify potential sources of pollution which may reasonably be expected to affect the quality of storm water discharges associated with industrial activity from the facility. In addition, the plan shall describe and ensure the implementation of practices which are to be used to reduce the pollutants in storm water discharges associated with industrial activity at the facility and to assure compliance with the terms and conditions of this permit. Facilities must implement the provisions of the storm water pollution prevention plan required under this part as a condition of this permit.

WHO IS RESPONSIBLE FOR DEVELOPING AND IMPLEMENTING AN INDUSTRIAL FACILITIES SWPP PLAN?

The facility is responsible for developing a storm water pollution prevention plan that addresses all of the regulatory requirements provided in their NPDES Storm Water Permit.

Once the program is developed the facility should establish a storm water pollution prevention team. The people designated for the team should be made responsible for developing the SWPPP and assisting the facility in this implementation, maintenance, and revision of the plan.

Effective organization of the pollution prevention team is important in order for it to be able to accomplish the task of developing and implementing a comprehensive storm water pollution prevention plan. The plan should clearly identify the responsibilities of each team member.

A FACILITIES SWPPP MUST BE CONSISTENT WITH OTHER ENVIRONMENTAL MANAGEMENT PLANS (PART IV.D.6)

The SWPPP must be consistent with other plans. SWPPPs may reflect requirements for spill prevention control and countermeasure (SPCC) plans developed for the facility under Section 311 of the Clean Water Act or best management practices (BMP)programs otherwise required by an NPDES permit for the facility as long as such requirement is incorporated into the SWPPP.

Other programs include:

* Preparedness Prevention and Contingency Plan (40 CFR 264 and 265)
* Spill Control and Countermeasure Plans (40 CFR 112)
* Facility Response Plans (OPA-90)
* NPDES Toxic Organic Management Plan (40 CFR 413, 433, 469)
* OSHA Emergency Action Plan (29 CFR 1910)

ENFORCEMENT OF SPILL PREVENTION CONTROL AND COUNTERMEASURE (SPCC) PLAN REGULATIONS

Part 112 of the 40 CFR details the current requirements for SPCC Planning. The basic requirement for determining if a facility requires a SPCC plan is based upon the volume of petroleum product stored at a facility. Two thresholds have been established: (1) any single container with capacity equal to or greater than 660 gallons, and (2) the combined total storage of equal to or greater than 1320 gallons.

Currently the EPA is developing new regulations for SPCC planning.

VOL 12 2 3 7 1 5 7

R0057049

FACILITY RESPONSE PLAN REQUIREMENTS

In addition to Phase I modifications for SPCC, the EPA is developing the draft regulations for facility response plans. In accordance with the Oil Pollution Act of 1990, these plans are required by February 18, 1993. However, without final regulations to use as a guide for plan development, it seems impractical to expend a lot of effort attempting to comply with the deadline.

SARA TITLE III, SECTION 313 FACILITIES, A POTENTIAL HOT SPOT IN THE MUNICIPAL STORM WATER SYSTEM

Special consideration must be given to those facilities that report SARA Title III, Section 313 chemicals on Form R. If these materials have potential for being exposed to storm water runoff, they pose a significant threat to receiving waters. For this reason, the EPA has established special monitoring requirements which must be conducted twice each calendar year.

INDUSTRY MUST HAVE A MATERIAL INVENTORY OF ALL SIGNIFICANT MATERIALS EXPOSED TO STORM EVENT ACTIVITY.

An inventory of all hazardous substances utilized and/or generated at the facility should be kept with the plan. More significant to the SWPPP than the material inventory is the identification of those materials which are exposed to storm water.

IDENTIFICATION OF SPILLS AND LEAKS

It is only necessary to describe those spills which occurred during the three year period preceding the effective date of the permit.

NON-STORM WATER DISCHARGE ASSESSMENT AND CERTIFICATION

The SWPPP shall include a certification that the discharge has been tested or evaluated for the presence of non-storm water (illicit) discharges. The certification shall include the identification of potentially significant sources of non-storm water at the site, a description of the results of any test and/or evaluation for the presence of non-storm water discharges, the evaluation criteria or testing methods used, the date of any testing and/or evaluation, and on-site points that were directly observed during the test.

Methods for identifying illicit discharges include:

* visual inspections conducted during dry weather conditions.
* review of sewer maps.
* dye testing.

The certification shall include the following information:

* identification of potential non-storm water discharges.
* the evaluation criteria or test method used.
* the date of testing and/or evaluation.
* the onsite drainage points that were directly observed during the test and/or evaluation.

VOL 12 2 3158

R0057050

POLLUTANT SOURCE IDENTIFICATION

Each plan should provide a description of potential sources which may be reasonably expected to add significant amounts of pollutants to storm water discharges or which may result in the discharge of pollutants during dry weather from separate storm sewers draining the facility. Each plan shall identify all activities and significant materials which may potentially be significant pollutant sources.

This section is designed to help you target the most important pollutant sources for corrective and/or preventive action, thus using a "risk-based" approach to environmental protection.

A successful approach to developing this portion of the plan could break the site description into the following categories:

LAND DEVELOPMENT

The EPA and many state agencies have developed NPDES Storm Water Permits for land disturbances of greater than five acres. The primary focus of the permit is to control erosion during construction.

Many municipalities have adopted strict ordinances and design standards that address land development concerns. Strict enforcement of these ordinances is necessary if they are to be effective.

COMMON QUESTIONS AND CHALLENGES FOR LOCAL GOVERNMENTS DEALING WITH LAND DEVELOPERS

- Many citizen complaints are the result of erosion from properties smaller than five acres. What can be done about the development of smaller lots?
- Is erosion a significant problem of land disturbances?
- Besides erosion, what other areas of concern should be considered?
- How do you hold the developer responsible for large residential development areas once the developer has sold many of the lot to builders?
- Is the state or EPA actively enforcing the regulatory requirements placed on those responsible for the land disturbances?
- What have other municipalities done to address this problem?

Best Management Practices

2 37160

R0057052

Notes

VOL 12 2 3761

R0057053

VOL 12 2 3762

WHAT WERE THE REQUIREMENTS FOR BEST MANAGEMENT PRACTICES IN PART II OF THE MUNICIPAL STORM WATER APPLICATION?

Part II of the Storm Water Permit Application

Required municipalities:

1) A description of structural and source control measures to reduce pollutants from runoff from commercial and residential areas.

2) A description of maintenance activities and a maintenance schedule.

Part II of the Storm Water Permit Application (continued)

3) A description of the planning procedures including a comprehensive master plan to develop, implement and enforce controls to reduce the discharge of pollutants from municipal separate storm sewers which receive discharges from areas of new development and significant redevelopment.

R0057054

Part II of the Storm Water Permit Application (continued)

4) Describe a program to implement and maintain structural and non-structural best management practices to reduce pollutants in storm water runoff from construction sites to municipal storm sewer system.

WHAT DO THE REGULATIONS SAY?

The final regulations indicate that the management programs shall be based on structural and source controls, or non-structural controls.

Management Program

Should include:

1) Maintenance activities for existing and future structural controls;

2) Institutional and structural controls which can be incorporated into permits for new developments;

VOL 12 2 3763

R0057055

Management Program

Should include:

3) Institutional and structural controls to reduce pollutant loads from streets;

4) Evaluation procedures to modify operations or structures of existing and future flood control projects to reduce pollutant loadings;

Management Program

Should include:

5) Programs to reduce pollutants from herbicides, pesticides, or fertilizers;

6) Monitoring programs for municipally-owned waste facilities; and

7) Programs to detect and eliminate illicit discharges.

BEFORE YOU INVEST ADDITIONAL MONEY AND RESOURCES, TAKE A SECOND LOOK AT YOUR PROGRAM AND ASK SOME QUESTIONS.

VOL 12 2 3764

R0057056

QUESTION:
What is it that you want to achieve?

A good objective would be to maintain and/or improve the quality of storm water discharges from the municipal separate storm water system.

QUESTION:
Do we fully understand the problem?

It is strongly recommended that the problem is understood before large amounts of money are spent on the solutions. This can be done by evaluating the results of the monitoring program.

QUESTION:
What are the primary concerns?
(worst areas of pollution)

- Illicit discharges
- Specific industrial facilities
- Household hazardous waste

VOL 12 2 3765

R0057057

QUESTIONS:

What kind of funding is available?

What kind of resources do you have to work with?

- Manpower (city employees and/or volunteers)

QUESTION:

What types of programs does the city already have that can be slightly modified to help us achieve our overall objectives?

- Street sweeping
- Household hazardous waste collection program
- Used oil recycling program

QUESTION:

What are others doing in the community, that can be dovetailed into the municipal program?

- Private citizen;
- Private industry; and
- Civic groups.

VOL 12 2 3766

R0057058

QUESTIONS:

What other government agencies have a shared interest in this type of program?

- United States Geologic Service
- Soil Conservation Service

What are other local governments doing?

CATEGORIZATION OF BEST MANAGEMENT PRACTICES

Categorization

- INSTITUTIONAL SOURCE CONTROLS
- NON-STRUCTURAL SOURCE CONTROLS

Intended to eliminate pollutants at the source and prevent storm water pollution

VOL 12 2 3767

R0057059

EXAMPLES OF INSTITUTIONAL SOURCE CONTROLS

- Public education (billing inserts, news releases, radio public service announcements, school programs and pamphlets;
- Litter control;
- Recycling programs;
- "No Littering" and "Pooper Scooper" Ordinance;

EXAMPLES OF INSTITUTIONAL SOURCE CONTROLS (continued)

- Develop and enact Spill Response Plan to prevent hazardous chemicals from entering the storm drain;
- Require that spills are cleaned up from vehicle accidents;
- Clean-up vacant lots;

EXAMPLES OF INSTITUTIONAL SOURCE CONTROLS (continued)

- Prohibit illegal and illicit connections and dumping into storm drain systems;
- Identify, locate, and prohibit illegal or illicit discharge to storm drain system;

VOL 12 2 3168

R0057060

EXAMPLES OF INSTITUTIONAL SOURCE CONTROLS (continued)

- Require proper storage, use and disposal of fertilizers, pesticides, solvents, paints and varnishes, and other household chemicals (oil, grease, and antifreeze, etc.); and
- Restrict paving and use of non-porous cover materials in recharge areas.

VOL 12 2 3769

R0057061

EXAMPLES OF NON-STRUCTURAL SOURCE CONTROLS

- Street sweeping & sidewalk cleaning
- Clean and maintain storm drain channels annually
- Clean and inspect storm inlets and catch basins annually
- Clean and inspect debris basins annually
- Inspect and maintain sewer system

MINOR AND MODERATE STRUCTURAL CONTROLS

The moderate cost categories are designed to remove pollutants from local storm water flows, and thereby minimize the amount of storm water which must be treated.

EXAMPLES OF MINOR STRUCTURAL SOURCE CONTROLS

- Storm drain inlet protection to prevent debris from entering storm drain;
- Outlet protection to prevent erosion at the outlet of pipes or paved channels;
- Slope stabilization and erosion control measures;

VOL 12 2 3710

R0057062

EXAMPLES OF MINOR STRUCTURAL SOURCE CONTROLS (continued)

- Interceptor swale to shorten length of exposed slopes;
- Improve and maintain natural channels;
- Diversion channels;
- Grass-lined channels;
- Riprap and gabions;
- Vegetative control;
- Filter strips; and
- Fence open channels.

EXAMPLES OF MINOR STRUCTURAL DISCHARGE ELIMINATION METHODS

- French drains and subsurface drains;
- Infiltration trench and dry wells;
- Porous pavement ; and
- Retention basins.

MODERATE STRUCTURAL CONTROLS FOR FLOATABLES AND OILS REMOVAL

Moderate structural controls provide for pollutant removal from stormwater which flows from local areas, such as parking lots.

VOL 12 2 3711

R0057063

EXAMPLES OF MODERATE STRUCTURAL CONTROLS

FOR THE REMOVAL OF FLOATABLES AND OILS:

- Clarifiers and oil/water separators on parking structures;
- Oil and grit separators; and
- Sediment/grease traps.

MAJOR STRUCTURAL CONTROLS

The most expensive controls (Major Structural Controls) are designed to physically, chemically, or biologically treat large storm water flows after pollutants have entered the main stream channels.

EXAMPLES OF MAJOR STRUCTURAL CONTROLS

FOR SOLIDS REMOVAL:

- Detention basins;
- Bar screens; and
- Wetlands.

VOL 12 2 3772

R0057064

EXAMPLES OF MAJOR STRUCTURAL CONTROLS

FOR MICROORGANISMS REMOVAL:

- Conversion of wastewater treatment plants to wet weather facilities;
- Swirl concentrators and chlorination/dechlorination;
- Primary clarifiers; and
- Filters.

EXAMPLES OF MAJOR STRUCTURAL CONTROLS

FOR METALS REMOVAL:

- Primary clarifiers and lime precipitation; and
- Detention basins and wetland treatment.

WHAT INNOVATIVE BEST MANAGEMENT PRACTICES ARE OTHER MUNICIPALITIES PLANNING TO USE?

VOL 12 2 3773

R0057065

DEVELOP A BMP CREDITING SYSTEM

As an incentive for developers of new areas to build and maintain approved structural BMP's, the City of Charlotte is planning to develop a crediting mechanism for the reduction of pollutants from non-single-family-residential sites.

DEVELOP PRIVATE BMP INSPECTION AND ENFORCEMENT

This program element will enable the City to both inspect and bring enforcement action against any BMP and other privately owned and operated storm water structure which is not built or maintained in accordance with city standards.

DEVELOP PRIVATE BMP INSPECTION AND ENFORCEMENT (continued)

IT INCLUDES:

- Setting design and maintenance standards;
- Monitoring;
- Hiring and training inspectors;
- Modifying ordinances for enforcement capability; and
- Developing the appropriate forms, procedures and policies to implement ordinances.

VOL 12 2 3774

R0057066

DEVELOP A BMP PILOT PROGRAM

Charlotte will institute a pilot program to design, construct and evaluate the effectiveness of both structural and non-structural BMP's targeted toward the commercial and residential land use types.

FOR INDUSTRIAL CONCERNS:

- Industrial Facilities Database Development
- Develop Inspection Procedures
- Industrial Monitoring Program

FOR CONSTRUCTION CONCERNS:

- Establish Design Criteria for Developers
- Require Self-Inspections
- Conduct Yearly Education Seminars for Construction Site Operators

VOL 12 2 3775

R0057067

STORM WATER INLET STENCILING

With the support of civic action groups, the City of Independence, Missouri has begun stenciling storm water inlets with information that encourages the general public not to dump oils and other household waste.

DEICING SALTS

Since deicing salts are the main source of pollutants in runoff of urban snow melt, explore ways to minimize the salt content, such as reducing the amount of liquid calcium chloride used, or reducing the content and rates of sand/salt mix, or use alternative deicing materials.

In my opinion the top 5 best management practices that exist are:

1) The establishment of adequate legal authority and effective ordinances;
2) Public education;
3) Illicit discharge evaluation and termination;
4) Monitoring of industrial compliance with state or EPA requirements; and
5) Future land use planning.

VOL 12 2 3776

R0057068

SECTION IV BEST MANAGEMENT PRACTICES

As is now commonly known among municipal staff involved in the permit application process, Part II of the Storm Water Permit Application required municipalities to:

1) describe structural and source control measures to reduce pollutants from runoff from commercial and residential areas.

2) describe maintenance activities and a maintenance schedule.

3) describe the planning procedures including a comprehensive master plan to develop, implement and enforce controls to reduce the discharge of pollutants from municipal separate storm sewers which receive discharges from areas of new development and significant redevelopment.

4) describe a program to implement and maintain structural and non-structural best management practices to reduce pollutants in storm water runoff from construction sites to municipal storm sewer system.

WHAT DO THE REGULATIONS SAY?

The final regulations for the stormwater NPDES permit application, as listed in 40 CFR 122.26 (d)(2)(iv), indicate that the management programs shall be based on structural and source controls, or non-structural controls.

The regulations indicate that the management program should include:

1) maintenance activities for existing and future structural controls;

2) institutional and structural controls which can be incorporated into permits for new developments;

3) institutional and structural controls to reduce pollutant loads from streets;

4) evaluation procedures to modify operations or structures of existing and future flood control projects to reduce pollutant loadings;

5) programs to reduce pollutants from herbicides, pesticides, or fertilizers;

6) monitoring programs for municipally-owned waste facilities; and

7) programs to detect and eliminate illicit discharges.

GETTING STARTED

When a municipality first begins to look at BMPs that they will want to utilize, it is critical that first questions are answered.

1) What is it that we want to achieve?

VOL 12 2 3777

R0057069

A good objective would be to maintain and/or improve the quality of storm water discharges from the municipal separate storm water system.

2) Do we fully understand the problem?

It is strongly recommended that the problem is understood before large amounts of money are spent on the solutions. This can be done by evaluating the results of the monitoring program.

3) What are the primary concerns (worst sources of pollution)?

- illicit discharges
- specific industrial facilities

4) What kind of funding is available?

Currently, in many communities there is not a fund for financing storm water management and pollution control. However, some communities have adopted users' fees that pay for the operation of a storm water utility. This can be a politically difficult situation which many people may view as an additional tax.

- Does the city operate a storm water utility? If not, would such a program provide a future benefit?

5) What kind of resources do I have to work with?

- manpower (city employees)
- manpower (volunteers)

6) What types of programs does the city already have that can be slightly modified to help us achieve our overall objectives?

- street sweeping
- household hazardous waste collection program
- used oil recycling program

7) What are others doing in the community, that can be dovetailed into the municipal program?

- private citizen groups organized to pick up trash in parks and along roads.
- private industry incorporating BMPs to address their storm water requirements.
- League of Women Voters
- 4H Group
- local scouts
- high school organizations

VOL 12 2 3778

R0057070

8) What other government agencies have a shared interest in this type of program?

- United States Geologic Service
- Soil Conservation Service

9) Does the city need to bring in outside consultants and contractors to help develop programs and construct structural control systems?

10) What are other local cities doing?

BUILDING ON CURRENT MANAGEMENT PRACTICES

1) Enforce the requirements of the regulations currently addressing industrial operations and land disturbance activities (e.g. request results of illicit discharge investigations, copies of SWPPPs, and monitoring data).

2) Enforcement of current city ordinances that serve as a best management practice (e.g. erosion control, anti-littering).

3) Manage street sweeping program in a manner that targets the greatest impact for removing pollution from the streets.

BEST MANAGEMENT PRACTICES CATEGORIZATION

One of the key concerns of municipalities when evaluating BMPs is the cost for implementation.

Many types of best management practices exist that have the ability to reduce pollutant loads in discharged storm water.The following is a list of a wide array of options.

- institutional source controls
- non-structural source controls
- minor structural source controls
- minor structural discharge elimination methods
- moderate structural controls for floatables and oils removal
- major structural controls for solids removal
- major structural controls for microorganism removal
- major structural controls for metals removal

Institutional Source Controls: Implementation of institutional source controls prevents pollutants from entering the stormwater flows. It cana be done through the adoption and enforcement of local ordinances, the expansion of existing recycling programs, and implementation of public education programs. Many of these programs, such as recycling programs, may need to be implemented to comply with other regulations. Therefore, the costs can be applied to two or more programs. This type of cost allocation may improve the feasibility of the program.

Types of practices:

- public education (billing inserts, news releases, radio public service announcements, school programs and pamphlets;
- litter control;
- recycling programs;

VOL 12 2 3719

R0057071

- "no littering" ordinance;
- "pooper scooper" ordinance;
- develop and enact a spill response plan to prevent hazardous chemicals from entering the storm drain;
- require that spills are cleaned up from vehicle accidents;
- clean-up vacant lots;
- prohibit illegal and illicit connections and dumping into storm drain systems;
- identify, locate, and prohibit illegal or illicit discharge to storm drain system;
- require proper storage, use and disposal of fertilizers, pesticides, solvents, paints, and varnishes, and other household chemicals (oil, grease, and antifreeze, etc.); and
- restrict paving and use of non-porous cover materials in recharge areas.

Non-Structural Source Controls: These controls also prevent pollutants from entering the stormwater flows through the expansion of clean-up programs, such as street sweeping, sidewalk sweeping, cleaning of storm drains, and enforcement actions against illicit dischargers. These controls could be implemented without construction of new facilities.

- street sweeping;
- sidewalk cleaning;
- clean and maintain storm drain channels annually;
- clean and inspect storm inlets and catch basins annually;
- clean and inspect debris basins annually;
- storm drains cleaned and maintained every 3 to 6 years;
- storm system pump stations cleaned and maintained annually; and
- inspect and maintain sewer system.

Minor Structural Source Controls: These controls provide for a reduction in sediment loads and associated pollutants that enter the receiving waters. The controls include improved diversion channels, grass swales and grass lined channels, improved natural channel banks, and planting of vegetation on exposed soils. These minor structural source controls could be included as part of development projects or when other improvements are being completed.

- storm drain inlet protection to prevent debris from entering storm drain;
- outlet protection to prevent erosion at the outlet of pipes or paved channels;
- slope stabilization and erosion control measures;
- interceptor swale to shorten length of exposed slopes;
- improve and maintain natural channels;
- diversion channels;
- grass-lined channels;
- riprap;
- gabions;
- vegetative control;
- filterstrips; and
- fence open channels.

Minor Structural Discharge Elimination Methods: These methods will eliminate storm water discharges, and thereby reduce the levels of pollutants discharged to the receiving waters. The controls, including recharge areas and porous pavement, have been installed by many communities throughout the United States as part of flood controls projects or water augmentation projects. However, to provide water quality improvements, many facilities would require increased maintenance to prevent pollutants from being discharged.

VOL 12 2 3718 0

R0057072

- french drains and subsurface drains;
- infiltration trench and dry wells;
- porous pavement; and
- retention Basins.

Moderate Structural Controls for Floatables and Oils Removal: Moderate structural controls provide for pollutant removal from stormwater which flows from local areas, such as parking lots. The controls, such as parking lot oil and grease separators, generally are constructed close to the pollutant source. They treat a small volume of stormwater with a concentrated pollutant level. These controls have been constructed in manufacturing sections of many metropolitan areas. However, increased maintenance may be required to ensure continued performance. To improve water quality further, these facilities could be constructed throughout all light industrial and commercial areas of the communities.

- clarifiers and oil/water separators on parking structures;
- oil and grit separators; and
- sediment/grease traps.

Major Structural Controls for Solids Removal: Major structural controls,. such as detention basins or wetlands, remove solids, oils, and greases of large stormwater flows prior to discharge into receiving waters. These controls would require construction of major facilities. These controls also may remove nutrients associated with solids, such as animal droppings or litter. Operation and maintenance costs for these facilities are higher than for theminor or moderate structural controls. These facilities generally are designed to be operated passively, and therefore do not require expensive instrumentation equipment.

- detention basins;
- bar screens; and
- wetlands.

Major Structural Controls for Microorganisms Removal: These controls provide for removal of microorganisms in large stormwater flows prior to discharge into receiving waters. Implementation would require construction of major sedimentation facilities and disinfection facilities.

- Conversion of wastewater treatment plants to wet weather facilities;
- Swirl concentrators and chlorination/dechlorination;
- Primary clarifiers; and
- Filters.

Major Structural Controls for Metals Removal: These controls remove metals in large stormwater flows prior to discharge into receiving waters. These controls would require construction of sedimentation facilities followed by either wetlands or lime precipitation. Operation and maintenance costs for these facilities are high.

- primary clarifiers and lime precipitation; and
- detention basins and wetland treatment.

The categories with the least expensive controls (institutional and non-structural source controls)

VOL 12 2 3718 1

R0057073

will eliminate pollutants at the source and prevent stormwater pollution. The moderate cost categories (minor and moderate structural controls) are designed to remove pollutants from local stormwater flows, and thereby minimize the amount of stormwater which must be treated. These controls are constructed close to the pollutant source to reduce or prevent pollutants from entering larger stream channels. The most expensive controls (major structuralcontrols are designed to physically, chemically, or biological treat large stormwater flows after pollutants have entered the main stream channels.

WHAT INNOVATIVE BEST MANAGEMENT PRACTICES ARE OTHER MUNICIPALITIES PLANNING TO USE?

This information has been taken from Part II of the applications from various cities, throughout the United States:

Develop a BMP Crediting system. As an incentive for developers of new areas to build and maintain approved structural BMPs the City of Charlotte is planning to develop a crediting mechanism for the reduction of pollutants from non-single-family-residential sites.

Develop private BMP inspection and enforcement. This program element will enable the city to both inspect and bring enforcement action against any BMP and other privately owned and operated storm water structure which is not built or maintained in accordance with City of Charlotte standards. It includes:

- setting design and maintenance standards;
- monitoring;
- hiring and training inspectors;
- modifying ordinances for enforcement capability; and
- developing the appropriate forms, procedures and policies to implement ordinances.

Develop a BMP Pilot Program. Charlotte will institute a pilot program to design, construct and evaluate the effectiveness of both structural and non-structural BMPs targeted toward the commercial and residential land use types.

Industrial Facilities Database Development. A database of industrial and related facilities that are or will be subject to regulatory inspections and/or monitoring programs.

Develop Inspections Procedures. The industrial and related facilities inspection procedures must be developed. The procedures will include: review of on-site SWPPPs, materials management plans, and/or spill response plans, depending on the facility; review and inspection procedures to determine the status of plan implementation; and, inspection of locations for compliance monitoring (if any) and potential illegal connections to the storm drainage system.

Industrial Monitoring Program. A random monitoring program designed to monitor compliance with the state's storm water permitting program for industrial activities. The results of the random monitoring program will be entered into the GIS-based database of the City of Charlotte's storm water program.

Self-Inspections for Construction Activities. The city will place a self-inspection requirement on all new construction in accordance with the general permit. Records of the inspections must be maintained by the operator and shall be available to city inspectors upon request.

VOL 12 2 3782

R0057074

Yearly Education Seminars for Construction Site Operators. A seminar once every two years will be held to educate all construction site operators and plan preparers on the available (and accepted) technologies for erosion and sedimentation controls.

Storm Water Inlet Stenciling. With the support of civic action groups, the City of Independence has begun stenciling storm water inlets with information that encourages the general public not to dump oils and other household waste.

Deicing Salts. Since deicing salts are the main source of pollutants in runoff of urban snow melt, the city, during the life of the Permit, will explore or study ways to minimize the alt content, such as reducing the amount of liquid calcium chloride used, or reducing the content and rates of sand/salt mix, or use alternative deicing materials.

PRIORITY BEST MANAGEMENT PRACTICES

Establishment of adequate legal authority and effective ordinances
Education
Illicit Discharge Evaluation and Termination
Monitoring of Industrial Compliance with state or EPA requirements
Future land use planning

POOL RESOURCES

AND

WORK TOGETHER

THE FIRST PRIORITY IS

EDUCATION

TOPICS FOR PUBLIC AND CITY EMPLOYEE TRAINING

- Household hazardous waste disposal
- Used oil recycling
- Septic tank maintenance
- Hazardous material/waste management

VOL 12 2 3791

R0057083

TOPICS FOR PUBLIC AND CITY EMPLOYEE TRAINING (continued)

- Proper use of pesticides, herbicides and fertilizers
- Erosion and sediment control
- Illicit discharge evaluation
- Spill response and prevention
- Inspection techniques for city staff

COMMON METHODS FOR REACHING THE PUBLIC

1) Fact sheets,
2) Pamphlets,
3) Radio/television,
4) Newspaper/magazines,
5) Displays models/posters and
6) Group presentation/one-on-one/community events.

EXAMPLES OF SPECIFIC TRAINING RESOURCES

VOL 12 2 3792

R0057084

THE STORM WATER POLLUTION PREVENTION COMMITTEE

Suggested participants:

- Business owners
- Members of professional, civic and environmental organizations
- Representatives of home owners associations
- City staff
- Elected officials

POTENTIAL BENEFITS OF THE POLLUTION PREVENTION COMMITTEE

- General awareness and understanding should be developed;
- A sense of ownership should develop;
- New ideas may be brought to the table; and
- A resource of volunteers may come forward to help put the plan to work.

WHAT PERMIT CONDITIONS ARE PERMIT WRITERS PLANNING TO REQUIRE?

The Model Municipal Permit developed by EPA Region VI

VOL 12 2 3193

R0057085

POLLUTION PREVENTION REQUIREMENTS

Shall consider water quality impacts of new and significant redevelopment in their comprehensive master planning process.

POLLUTION PREVENTION REQUIREMENTS (continued)

Shall utilize a comprehensive master planning process to develop, implement, and enforce controls to reduce the discharge of pollutants from areas of new development and significant redevelopment after construction is completed.

HOW IS THIS APPROACHED?

Need to work with the Planning Commission and the City Council. Identify those sensitive areas that should be protected during future development.

Do an overlay on the City's long term master plan.

VOL 12 2 3794

R0057086

POLLUTION PREVENTION REQUIREMENTS (continued)

Shall insure the establishment or availability of a program to collect used motor vehicle fluids (including oil and antifreeze) for recycle or reuse.

POLLUTION PREVENTION REQUIREMENTS (continued)

Shall insure the establishment or availability of a program to collect household hazardous waste materials (including paint, pesticides, herbicides, and other hazardous wastes) for recycle, reuse, or safe disposal.

POLLUTION PREVENTION REQUIREMENTS (continued)

Shall implement controls to reduce the discharge of pollutants related to application of pesticides, herbicides, and fertilizers applied by municipal employees or contractors to public right of ways, parks, and other municipal facilities.

VOL 12 2 3195

R0057087

POLLUTION PREVENTION REQUIREMENTS (continued)

Shall implement an ongoing program to detect and remove (or require the discharger to the MS4 to remove or obtain a separate NPDES permit for) illicit discharges and improper disposal into the storm sewer.

WHAT IS AN ILLICIT DISCHARGE?

Residential and Commercial Sources of Illicit Discharges

Sanitary waste water :

- Improper sewerage connections or leakage
- Effluent from improperly operating or improperly designed septic tanks

VOL 12 2 3796

R0057088

Residential and Commercial Sources of Illicit Discharges (continued)

- Household chemicals
- Laundry waste water
- Car wash waste waters
- Radiator flushing waste waters
- Engine de-greasing wastes
- Improper oil disposal
- Leaking underground storage tank

Industrial Sources of Illicit Discharges

- Leaking tanks and pipes
- Floor drains within industrial facilities
- Wash waters
- Boiler blow down water
- Cooling water discharge
- Miscellaneous process waters

SCREENING PROCEDURES

Screening methodology may be developed and/or modified based on experience gained during actual field screening activities and need not conform to the protocol of 40 CFR 122.26(d)(1)(iv)(D).

VOL 12 2 3797

R0057089

POLLOW-UP ON DRY WEATHER SCREENING RESULTS

Shall implement a program to locate and eliminate suspected sources of illicit connections and improper disposal identified during dry weather screening activities.

Follow-up Activities

May be prioritized on the basis of :

1) Magnitude and nature of the suspected discharge;
2) Sensitivity of the receiving water; and
3) Other relevant factors.

Follow-up with INDUSTRY

Have they done their investigations?

VOL 12 2 3198

R0057090

UNITED STATES GEOLOGIC SERVICE (USGS)

They have a shared interest in gathering information about the quality of urban storm water discharges.

UNITED STATES GEOLOGIC SERVICE (USGS)

What can they do to help?

- Conduct dry and wet weather monitoring
- Map storm sewer system
- Identify illicit discharges
- Conduct analytical testing in the field and the lab

If you plan to use city staff for evaluating illicit discharges,

TRAIN YOUR PERSONNEL !

Make sure they know what they are looking for !

VOL 12 2 3799

R0057091

SECTION IV IMPLEMENTING THE STORM WATER MANAGEMENT PLAN

HOW DO YOU GO FROM A PLANNED PROGRAM TO A PROGRAM THAT IS FULLY IMPLEMENTED?

The answer is simply, one step at a time.

THE FIRST STEP IS EDUCATION

TOPICS FOR PUBLIC AND MUNICIPAL EMPLOYEE TRAINING AND EDUCATION

Effective and specific training on issues that impact storm water quality will go a long way toward the success of the storm water management program. The collective involvement of multiple cities will reduce the cost for each that participates and will enhance the overall effectiveness in the field. The following is a short list of possible topic areas:

- household hazardous waste disposal;
- used oil recycling;
- septic tank maintenance
- hazardous material/waste management
- proper use of pesticides, herbicides and fertilizers
- erosion control
- illicit discharge evaluation
- spill response and prevention
- inspection techniques for city staff

The effectiveness of the city's storm water management staff will hinge on the ability to educate the public.

The development and implementation of an education and information program is critical to having a successful urban non-point pollution project. The reason is twofold. First, public awareness of urban nonpoint pollution is low. The public is inundated daily with a barrage of potential risks by the press ranging from the threat of war, crime and violence, etc.

Second, the education and informational program is important to having a successful project because most of the urban non-point pollution can be directly attributed to people. It is the actions of people at both home and work that affect the type and amount of non-point pollution from their community. A 1989 study by the Michigan Department of Natural Resources found that more oil is illegally released annually into the environment in Michigan than was released in the Exxon Valdez accident.

The first step in developing a successful urban non-point education and information program is to define your target audience. The one rule that must always be remembered is to provide understandable and useful information. The better you understand your target audience (education, background and industry type) the more effective will be your education program.

The second step in developing a successful urban education program is to define the types of media available for use in your programs. Among the common methods are: (1) fact sheets, (2) pamphlets, (3) radio/television, (4) newspaper/magazines, (5) displays models/posters and (6) group presentation/one-on-one/community events.

VOL 12 2 3800

R0057092

In Ann Arbor, Michigan, the Huron River Pollution Abatement Project (HRPAP) education program was designed after reviewing the pilot program and analyzing the community. It was noted during this phase that the community was mainly urban, well educated and generally supportive of environmental issues; it had many industrial shops versus one main plant; and it had numerous organized and influential civic and professional groups.

Based on this analysis, the education and information program was developed with three main components. They were business and industry, community and civic groups, component, and the schools.

THE STORM WATER POLLUTION PREVENTION COMMITTEE

In order to effectively implement the Storm Water Management Plan it is important to solicit the dedicated cooperation of those within your community.

It is suggested that persons from various sectors of the population be invited to attend. The following is a partial list of suggested participants:

- business owners
- members of professional, civic and environmental organizations
- representatives of home owners associations
- municipal staff
- elected and appointed officials.

The development of the storm water pollution prevention committee will potentially provide several important accomplishments:

- general awareness and understanding should be developed;
- a sense of ownership should develop;
- new ideas may be brought to the table; and
- and volunteers may come forward to help put the plan to work.

VOL 12 2 3801

R0057093

VOL 12

2

Pollution Prevention Requirements

7

3802

R0057094

Notes

VOL 12 2 3803

R0057095

POLLUTION PREVENTION REQUIREMENTS (continued)

Shall implement a program to prevent, contain, and respond to spills that may discharge into the MS4. The spill response program may include a combination of spill response actions by the municipal government or private entity, and legal requirements for private entities within the co-permittee's municipal jurisdiction.

R0057096

VOL 12 2 3804

Talk with Spill Response Personnel

Include a representative in the Storm Water Pollution Prevention Committee.

Work with the Spill Response team to evaluate potential impacts that Standard Operating Procedures may have on receiving streams.

Is private industry holding up their end of the bargain?

Do they have Spill Prevention, Control and Countermeasure Plans?

Are they developing Facility Response Plans, as required by the EPA, DOT, and U.S. Coast Guard?

Random inspections and swift enforcement will go a long way to improve the level of compliance by industry.

VOL 12 2 3805

R0057097

CONSTRUCTION SITE RUNOFF

Shall implement a program to reduce the discharge of pollutants from construction sites, including:

- Requirements for the use and maintenance of appropriate structural and nonstructural best management practices to reduce pollutants discharged to the MS4 during the time construction is under way;

CONSTRUCTION SITE RUNOFF (continued)

Including:

- Procedures for site planning which incorporates considerations for potential short and long term water quality impacts, and minimizes these impacts;

CONSTRUCTION SITE RUNOFF (continued)

Including:

- Prioritized inspection of construction sites and enforcement of control measures;
- Appropriate education and training measures for construction site operations; and

VOL 12 2 3806

R0057098

CONSTRUCTION SITE RUNOFF (continued)

Including:

- Notification of all construction permit applicants of their potential responsibilities under the NPDES permitting program for construction site runoff.

NOTE: Notification can be accomplished through the building permit approval or platting processes.

Storm Water Management Plan REVIEW AND MODIFICATION Requirements

ANNUAL REVIEW

Shall participate in an annual review of the current SWMP in conjunction with preparation of the annual report required under Part II. G. This annual review shall include:

- A review of the status of program implementation and compliance (or non-compliance) with all schedules of compliance contained in the permit;

VOL 12 2 3807

R0057099

ANNUAL REVIEW
(continued)

This annual review shall include:

- An assessment of the effectiveness of controls established by the SWMP;
- A review of monitoring data and any trends in estimated cumulative annual pollutant loadings; and

ANNUAL REVIEW
(continued)

This annual review shall include:

- An assessment of any SWMP modifications needed to comply with the CWA § 402(p)(3)(iii) requirement to reduce the discharge of pollutants to the maximum extent practicable (MEP).

PROGRAM MODIFICATION

The approved SWMP program shall not be modified by the permittee without the prior approval of the EPA, unless in accordance with the items that follow :

VOL 12 2 3808

R0057100

PROGRAM MODIFICATION (continued)

- Modifications adding (but not subtracting or replacing) components, controls, or requirements to the approved SWMP may be made by the permittee at any time upon written notification to the permitting authority.

PROGRAM MODIFICATION (continued)

- Modifications replacing a failing BMP identified in the SWMP with an alternate BMP may be requested in conjunction with the annual report.

ANNUAL REPORT

An annual system-wide report shall be submitted by no later than the anniversary of the date the permit is issued.

The report shall include the following separate sections, with an overview for the entire MS4 and subsections for each co-permittee:

VOL 12 2 3809

R0057101

ANNUAL REPORT (continued)

- The status of implementing the components of the storm water management programs that are established as permit conditions (status of compliance with any schedules established under this permit shall be included in this section);

ANNUAL REPORT (continued)

- Proposed changes to the storm water management programs that are established as permit conditions, including an update on areas added to the MS4 due to annexation or other legal means;

ANNUAL REPORT (continued)

- Revisions, if necessary, to the assessments of controls and the fiscal analysis reported in the permit application under 40 CFR 122.26(d)(2)(iv) and (d)(2)(v);

VOL 12 2 3810

R0057102

ANNUAL REPORT (continued)

- A summary of the data, including monitoring data, that is accumulated throughout the reporting year ;
- Annual expenditures and budget for the year following each annual report ;

ANNUAL REPORT (continued)

- A summary describing the number and nature of enforcement actions, inspections, and public education programs; and
- Identification of water quality improvements or degradation.

RECORD KEEPING

The permittee shall retain records of all:

- Monitoring information including all calibration and maintenance records and all original strip chart recordings for continuous monitoring;
- Copies of the reports required by this permit; and

VOL 12 2 3811

R0057103

RECORD KEEPING
(continued)

- Records of all data used to complete the application for this permit

The records must be maintained for a period of at least 3 years from the date of the sample, measurement, report or application.

RECORD KEEPING
(continued)

Records of monitoring information shall include:

- The date, exact place, and time of sampling or measurements;
- The initials or name(s) of the individual(s) who performed the sampling or measurements;

RECORD KEEPING
(continued)

- The date(s) analyses were performed;
- The time(s) analyses were initiated;
- The initials or name(s) of the individual(s) who performed the analyses;

VOL 12 2 3812

R0057104

RECORD KEEPING
(continued)

- References and written procedures, when available, for the analytical techniques or methods used; and
- The results of such analyses, including the bench sheets, instrument read outs, computer disks or tapes, etc., used to determine these results.

Penalties for Violations of Permit Conditions

Criminal

1. Negligent Violations : Subject to a fine of not less than $2,500 nor more than $25,000 per day of violation, or by imprisonment for not more than 1 year, or both.

Penalties for Violations of Permit Conditions
(continued)

2. Knowing Violations: Subject to a fine of not less than $5,000 nor more than $50,000 per day of violation, or by imprisonment for not more than 3 years, or both.

VOL 12 2 3813

R0057105

Penalties for Violations of Permit Conditions (continued)

3. Knowing Endangerment: Subject to a fine of not more than $250,000, or by imprisonment for not more than 15 years, or both.
4. False Statement: Shall upon conviction, be punished by a fine of not more than $10,000 or by imprisonment for not more than 2 years, or by both.

VOL 12 2 3814

R0057106

WHAT PERMIT CONDITIONS ARE PERMIT WRITERS PLANNING TO REQUIRE?

A well developed Part II application may very well be approved in its entirety. However, Region VI of the EPA has developed a model permit for municipalities that has several key requirements. You may find that these stipulations are added to your permit conditions if they were not included in the Part II you submitted.

I. POLLUTION PREVENTION REQUIREMENTS

The co-permittees shall develop and implement the following pollution prevention measures (PPMs):

A. Each co-permittee with jurisdiction over land use shall include requirements to consider water quality impacts of new and significant re-development in their comprehensive master planning process. The goal of such requirements shall be limiting, to the maximum extent practicable (MEP), the discharge of pollutants to pre-development levels.

B. The co-permittees shall insure the establishment or availability of a program to collect used motor vehicle fluids (including oil and antifreeze) for recycle or reuse. Such program shall be readily available to all private residents. This program shall be publicized and promoted on a regular basis .

C. The permittee shall insure the establishment or availability of a program to collect household hazardous waste materials (including paint, pesticides, herbicides, and other hazardous wastes) for recycle, reuse, or safe disposal. Such program shall be readily available to all private residents and include information on locations accepting such wastes on a continuous basis. This program shall be publicized and promoted on a regular basis (including mailouts to individual residences).

D. The co-permittees shall insure the establishment of a program, including structural controls where necessary, to reduce the discharge of floatable (including solid wastes) to the maximum extent practicable.

E. *Structural Controls:* Each co-permittee shall operate and maintain any storm water structural controls over which they have jurisdiction, in a manner so as to reduce the discharge of pollutants (including floatable) to the MEP.

F. *Areas of New Development:* Each co-permittee shall utilize a comprehensive master planning process to develop, implement, and enforce controls to reduce, to the MEP, the discharge of pollutants from areas of new development and significant redevelopment after construction is completed.

G. *Roadways:* Each co-permittee shall operate and maintain public streets, roads, and highways under its jurisdiction in a manner so as to reduce, to the MEP, discharge of pollutants (including those related to deicing or sanding activities).

H. *Flood Control Projects:* Each co-permittee shall insure any flood control projects it

VOL 12 2 3815

R0057107

undertakes assess, and minimize to the MEP, the impacts on water quality of receiving waters. Each co-permittee shall also evaluate the feasibility of retro-fitting existing structural flood control devices to provide additional pollutant removal from storm water.

I. *Pesticide, Herbicide, and Fertilizer Application:* Each co-permittee shall implement controls to reduce, to the MEP, the discharge of pollutants related to application of pesticides, herbicides, and fertilizers applied by municipal employees or contractors to public right of ways, parks, and other municipal facilities. Co-permittees with jurisdiction over lands not directly owned by that entity (ex. incorporated city) shall implement controls to reduce, to the MEP, discharge of pollutants related to application and distribution of pesticides, herbicides, and fertilizers by commercial and wholesale distributors and applicators .

J. *Illicit Discharges and Improper Disposal:* Each co-permittee shall implement an ongoing program to detect and remove (or require the discharger to the municipal separate storm sewer system (MS4) to remove or obtain a separate NPDES permit for) illicit discharges and improper disposal into the storm sewer.

1. Each co-permittee shall prohibit the discharge or disposal of all used motor vehicle fluids and household chemical wastes into separate storm sewers.

2. Each co-permittee shall require the elimination of illicit connections as expeditiously as possible and the immediate cessation of improper disposal practices upon identification of responsible parties. Where elimination an illicit connection within seven (7) days is not possible, the municipality shall require an expeditious schedule for removal of the discharge. In the interim, the co-permittee shall require the operator of the illicit connection to take all reasonable and prudent measures to minimize the discharge of pollutants to the MS4. Elimination schedules should not exceed ninety (90) days, except for capital intensive projects which should not exceed one (1) year.

K. *Spill Prevention and Response:* Each co-permittee shall implement a program to prevent, contain, and respond to spills that may discharge into the MS4. The spill response program may include a combination of spill response actions by the co-permittee (and/or another municipal or private entity), and legal requirements for private entities within the co-permittee's municipal jurisdiction.

L. *Industrial & High Risk Runoff:* Each co-permittee shall implement a program to identify, monitor, and control pollutants in storm water discharges to the MS4 from municipal landfills; hazardous waste treatment, storage and disposal facilities that are subject to EPCRA Title III, Section 313; and any other industrial or commercial discharge the co-permittee determines are contributing a substantial pollutant loading to the MS4. The program shall include:

1. priorities and procedures for inspections and establishing and implementing control measures for such discharges;

2. a monitoring (or self-monitoring) program for facilities identified under this section, including the collection of quantitative data on the following constituents:

VOL 12 2 3816

R0057108

a. any pollutants limited in an existing NPDES permit for an identified facility;
b. oil and grease;
c. chemical oxygen demand (COD);
d. pH;
e. biochemical oxygen demand, five-day (BOD_5);
f. total suspended solids (TSS);
g. total phosphorous;
h. total Kjeldahl nitrogen (TKN);
i. nitrate plus nitrite nitrogen; and
j. any information on discharges required under 40 CFR 122.21(g)(7)(iii) and (iv).

Note: Data collected by the industrial facility to satisfy the monitoring requirements of an NPDES or state discharge permit may be used to satisfy this requirement. Municipalities may require the industrial facility to conduct self-monitoring to satisfy this requirement.

M. *Construction Site Runoff:* Each co-permittee shall implement a program to reduce, to the MEP, the discharge of pollutants from constructions sites, including:

1. requirements for the use and maintenance of appropriate structural and nonstructural best management practices to reduce pollutants discharged to the MS4 during the time construction is underway;

2. procedures for site planning which incorporates considerations for potential short and long term water quality impacts and minimizes, to the MEP, these impacts;

3. prioritized inspection of construction sites and enforcement of control measures;

4. appropriate education and training measures for construction site operators; and

5. notification of all construction permit applicants of their potential responsibilities under the NPDES permitting program for construction site runoff.

Note: Notification can be accomplished through the building permit approval or platting processes.

N. *Public Education:* Each co-permittee shall implement a public education program including:

1. a program to promote, publicize, and facilitate public reporting of the presence of illicit discharges or improper disposal of materials into the MS4;

VOL 12 2 3817

R0057109

2. a program to promote, publicize, and facilitate the proper management and disposal of used oil and household hazardous wastes,

3. a program to promote, publicize, and facilitate the proper use, application, and disposal of pesticides, herbicides, and fertilizers by commercial and private applicators and distributors.

II. SWMP REVIEW AND MODIFICATION

A. *Program Review:* Each co-permittee shall participate in an annual review of the current SWMP in conjunction with preparation of the annual report required under Part II.G. This annual review shall include:

1. A review of the status of program implementation and compliance (or non-compliance) with all schedules of compliance contained in this permit;

2. An assessment of the effectiveness of controls established by the SWMP;

3. A review of monitoring data and any trends in estimated cumulative annual pollutant loadings; and

4. An assessment of any SWMP modifications needed to comply with the Clean Water Act (CWA) § 402(p)(3)(B)(iii) requirement to reduce the discharge of pollutants to the maximum extent practicable (MEP).

Note: Information collected can be used in the annual report required by Part V.C.

B. *Program Modification:* The approved SWMP program shall not be modified by the permittee without the prior approval of the EPA, unless in accordance with items a. through c. below:

1. Modifications adding (but not subtracting or replacing) components, controls, or requirements to the approved SWMP may be made by the permittee at any time upon written notification to the permitting authority.

2. Modifications replacing a failing BMP identified in the SWMP with an alternate BMP may be requested in conjunction with the annual report required by Part II.I. below. Such requests must be made in writing, provide an analysis of why the BMP is failing or ineffective (including cost prohibitive), expectations on the effectiveness of the replacement BMP, and why the replacement BMP is expected to provide at least the same level of performance as originally expected of the BMP to be replaced.

3. Modifications made under this paragraph shall not become enforceable permit conditions until such time as the modifications are approved by EPA.

C. *Modifications Required by the Permitting Authority:* The permitting authority may require any or all co-permittees to modify the SWMP as needed to:

VOL 12 2 3818

R0057110

1. Address contributions by the MS4 discharges to impacts on receiving water quality;

2. Include more stringent requirements necessary to comply with new state or federal statutory or regulatory requirements; or

3. Include such other conditions deemed necessary by the Director to comply with the goals and requirements of the Clean Water Act.

Modifications requested by the Director shall be made in writing, set forth the time schedule for the co-permittee(s) to develop the modification(s), and offer the co-permittee(s) the opportunity to propose alternative program modifications to meet the objective of the requested modification.

III. ANNUAL REPORT

Each co-permittee shall contribute to the preparation of an annual system-wide report to be submitted by no later than the anniversary of the date this permit is issued. The report shall include the following separate sections, with an overview for the entire MS4 and subsections for each co-permittee:

A. The status of implementing the components of the storm water management programs that are established as permit conditions (status of compliance with any schedules established under this permit shall be included in this section);

B. Proposed changes to the storm water management programs that are established as permit conditions, including an update on areas added to the MS4 due to annexation or other legal means;

C. Revisions, if necessary, to the assessments of controls and the fiscal analysis reported in the permit application under 40 CFR 122.26(d)(2)(iv) and (d)(2)(v);

D. A summary of the data, including monitoring data, that is accumulated throughout the reporting year;

E. Annual expenditures and budget for the year following each annual report;

F. A summary describing the number and nature of enforcement actions, inspections, and public education programs; and

G. Identification of water quality improvements or degradation.

VOL 12 2 3819

R0057111

IV. IMPLEMENTATION OF POLLUTION PREVENTION MEASURES

An example of permit requirements:

POLLUTION PREVENTION MEASURE	ACTIVITY	DATE DUE
Part II A.1 - New & Re-Development	Implement construction-phase storm water runoff control program	January 1, 1994
	Modify comprehensive land use planning process to require controls for storm water quality.	January 1, 1995
	Implement requirements for post-construction storm water quality controls for new and significant re-development.	July 1, 1996
Part II A 2 - Vehicle Fluids	Implement public education program.	January 1, 1994
	Develop collection/recycling program.	January 1, 1994
	Implement collection/recycling program.	July 1, 1994
Part II A 3 - Household Hazardous Waste	Implement public education program.	January 1, 1994
	Develop collection/recycling/safe disposal program	July 1, 1994
	Implement collection/recycling/safe disposal program	January 1, 1995
Part II A 4 - Floatable	Implement public education program.	January 1, 1994
	Implement litter control program.	January 1, 1994
	Install two floatable monitoring locations (See Part V A.2)	January 1, 1994
	Complete study for targeting of structural controls.	January 1, 1995
	Complete installation of structural controls on 50 % of targeted storm sewer-sheds.	January 1, 1995
	Complete installation of structural controls on 100% of targeted storm sewer-sheds.	January 1, 1996

Part II.B.7 - Illicit Discharges and Improper Disposal	Implement public education program.	January 1, 1994
	Complete screening of the MS4.	January 1, 1997
	Complete follow up investigations based on screening results.	January 1, 1999

VOL 12 2 3820

R0057112

V. MONITORING AND REPORTING REQUIREMENTS

A. Storm Event Monitoring. The co-permittees shall implement a wet-weather monitoring program for the MS4 to provide data necessary to assess the effectiveness and adequacy of control measures implemented under the SWMP; estimate annual cumulative pollutant loadings from the MS4; estimate event mean concentrations and seasonal pollutants in discharges from major outfalls; identify and prioritize portions of the MS4 requiring additional controls, and identify water quality improvements or degradation.

B. *Representative Monitoring:* The co-permittees shall monitor representative outfalls and/or in stream monitoring locations to characterize the quality of storm water discharges from the MS4.

1. Monitoring Requirements: (See Table V.A.1.a)

2. Outfall Descriptions

3. Alternate representative outfalls may be substituted for just cause during the term of the permit. Alternate wet weather monitoring locations may not be used until approved by the Director. Four samples shall be collected during the first year of monitoring at substitute outfalls.

NOTE: Details of wet weather screen would be contained in the SWMP. Region 6 anticipates use of a combination of in-system and in-stream sampling locations where appropriate, and a combination of inexpensive field kit sampling and non-sampling techniques to accomplish the wet weather screening. The goal of this portion of the permit is to actively look for areas of the system with poorer quality discharges during storm events.

C. *Wet Weather Screening Program:* The co-permittees shall implement a program to screen all major storm sewer-sheds for the presence of excessive pollutants in discharges from the MS4. The wet weather screening program:

D. Shall screen the entire MS4 at least once during the permit term.

1. Shall specify the sampling and non-sampling techniques, parameters, collection techniques, and analytical methods to be used for initial screening purposes. For screening samples only, sample collection and analysis need not conform to the requirements of 40 CFR Part 136 and are not subject to the requirements of Paragraphs 3, 4, and 5 below..

2. Shall establish two monitoring locations for removal of floatable material in discharges from the MS4. The amount of material collected shall be estimated in cubic yards. Floatable material shall be measured periodically as necessary for maintenance of the removal device.

3. Shall submit, along with the annual report required by Part II.I, the following information:
   a. Percent of MS4 screened during the year and the cumulative percent of system screened;

VOL 12 2 3821

R0057113

b. An estimate of the amount of floatable material collected (cubic yards);

c. A summary of results and actions taken or proposed based on the results of the wet weather screening program.

E. *Storm Event Data:* Quantitative data shall be collected to estimate pollutant loadings and event mean concentrations for each parameter sampled. In addition to the parameters listed above, the permittee shall maintain records of the date and duration (in hours) of the storm event(s) sampled; rainfall measurements or estimates (in inches) of the storm event which generated the sampled runoff; the duration between the storm event sampled and the end of the previous measurable (greater than 0.1 inch rainfall) storm event; and an estimate of the total volume (in gallons) of the discharge sampled.

F. *Sample Type, Collection, and Analysis:*

1. For discharges from holding ponds or other impoundments with a retention period greater than 24 hours, (estimated by dividing the volume of the detention pond by the estimated volume of water discharged during the 24 hours previous to the time that the sample is collected) a minimum of one grab sample may be taken.

2. Grab samples taken during the first two hours of discharge shall be used for the analysis (if required) of pH, temperature, cyanide, oil & grease, fecal coliform, fecal streptococcus, total phenols,residual chlorine, and (at the co-permittee's option) volatile organics. For all other parameters, data shall be reported for flow weighted composite samples of the entire event or, at a minimum, the first three hours of discharge.

Note: adding volatile organics to the "grab" list avoids the problems associated with composite collection for these parameters.

3. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. Composite samples may be taken with a continuous sampler or as a combination of a minimum of three sample aliquots taken in each hour of discharge for the entire discharge or for the first three hours of the discharge, with each aliquot being separated by a minimum period of fifteen minutes.

4. Analysis and collection of samples shall be done in accordance the methods specified at 40 CFR Part 136. Where an approved Part 136 method does not exist, any available method may be used.

G. *Sampling Waiver.* When a discharger is unable to collect samples due to adverse climatic conditions, the discharger must submit in lieu of sampling data a

VOL 12 2 3822

R0057114

description of why samples could not be collected, including available documentation of the event. Adverse climatic conditions which may prohibit the collection of samples includes weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.). Dischargers are precluded from exercising this waiver more than once during a two year period.

VI. DRY WEATHER MONITORING.

A. *Dry Weather Screening Program:* Each co-permittee shall continue ongoing efforts to detect the presence of illicit connections and improper discharges to the MS4. All portions (but not necessarily all outfalls) of the MS4 must be screened at least once during the permit term, in accordance with the schedule set forth in PART III.A.2.

B. *Screening Procedures:* Screening methodology may be developed and/or modified based on experience gained during actual field screening activities and need not conform to the protocol at 40 CFR 122.26(d)(1)(iv)(D).

C. *Follow-up on Dry Weather Screening Results:* Each co-permittee shall implement a program to locate and eliminate suspected sources of illicit connections and improper disposal identified during dry weather screening activities. Follow-up activities may be prioritized on the basis of:

1. magnitude and nature of the suspected discharge;
2. sensitivity of the receiving water; and
3. other relevant factors.

VII. MONITORING AND RECORDS.

A. Samples and measurements taken for the purpose of monitoring shall be representative of the monitored activity.

B. The permittee shall retain records of all monitoring information including all calibration and maintenance records and all original strip chart recordings for continuous monitoring instrumentation, copies of the reports required by this permit, and records of all data used to complete the application for this permit, for a period of at least 3 years from the date of the sample, measurement, report or application. This period may be extended by request of the Director at any time.

C. Records of monitoring information shall include:

1. The date, exact place, and time of sampling or measurements;
2. The initials or name(s) of the individual(s) who performed the sampling or measurements;
3. The date(s) analyses were performed;
4. The time(s) analyses were initiated;

VOL 12 2 3823

R0057115

5. The initials or name(s) of the individual(s) who performed the analyses;

6. References and written procedures, when available, for the analytical techniques or methods used; and

7. The results of such analyses, including the bench sheets, instrument readouts, computer disks or tapes, etc., used to determine these results.

VIII. Penalties for Violations of Permit Conditions.

A. Criminal

1. Negligent Violations The CWA provides that any person who negligently violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than $2,500 nor more than $25,000 per day of violation, or by imprisonment for not more than 1 year, or both.

2. Knowing Violations The CWA provides that any person who knowingly violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than $5,000 nor more than $50,000 per day of violation, or by imprisonment for not more than 3 years, or both.

3. Knowing Endangerment The CWA provides that any person who knowingly violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act and who knows at that time that he is placing another person in imminent danger of death or serious bodily injury is subject to a fine of not more than $250,000, or by imprisonment for not more than 15 year, or both.

4. False Statement The CWA provides that any person who knowingly makes any false material statement, representation, or certification in any application, record, report, plan, or other document filed or required to be maintained under the Act or who knowingly falsifies, tampers with, or renders inaccurate, any monitoring device or method required to be maintained under the Act, shall upon conviction, be punished by a fine of not more than $10,000 or by imprisonment for not more than 2 years, or by both. If a conviction is for a violation committed after a first conviction of such person under this paragraph, punishment shall be by a fine of not more than $20,000 per day of violation, or by imprisonment of not more than 4 years, or by both. (See Section 309(c)(4) of the Clean Water Act).

B. Civil Penalties - The CWA provides that any person who violates a permit condition implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a civil penalty not to exceed $25,000 per day for each violation.

C. Administrative Penalties - The CWA provides that any person who violates a permit condition implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to an administrative penalty, as follows:

VOL 12 2 3824

R0057116

1. Class I penalty Not to exceed $10,000 per violation nor shall the maximum amount exceed $25,000.

2. Class II penalty Not to exceed $10,000 per day for each day during which the violation continues nor shall the maximum amount exceed $125,000.

D. Penalties for Falsification of Reports

Section 309(c)(4) of the Clean Water Act provides that any person who knowingly makes any false material statement, representation, or certification in any record or other document submitted or required to be maintained under this permit, including reports of compliance or noncompliance shall, upon conviction, be punished by a fine of not more than $10,000, or by imprisonment for not more than 2 years, or by both.

VOL 12 2 3825

R0057117

storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, finished product, by-product or waste product. The term excludes areas located on plant lands separate from the plant's industrial activities, such as office buildings and accompanying parking lots as long as the drainage from the excluded areas is not mixed with storm water drained from the above described areas. Industrial facilities (including industrial facilities that are Federally, State or municipally owned or operated that meet the description of the facilities listed in this paragraph (i)–(xi) of this definition) include those facilities designated under 122.26(a)(1)(v). The following categories of facilities are considered to be engaging in "industrial activity" for purposes of this subsection:

(i) Facilities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutant effluent standards under 40 CFR subchapter N (except facilities with toxic pollutant effluent standards which are exempted under category (xi) of this definition);

(ii) Facilities classified as Standard Industrial Classifications 24 (except 2434), 26 (except 265 and 267), 28 (except 283), 29, 311, 32 (except 323), 33, 3441, 373;

(iii) Facilities classified as Standard Industrial Classifications 10 through 14 (mineral industry) including active or inactive mining operations (except for areas of coal mining operations no longer meeting the definition of a reclamation area under 40 CFR 434.11(l) because the performance bond issued to the facility by the appropriate SMCRA authority has been released, or except for areas of non-coal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990) and oil and gas exploration, production, processing, or treatment operations, or transmission facilities that discharge storm water contaminated by contact with or that has come into contact with, any overburden, raw material, intermediate products, finished products, byproducts or waste products located on the site of such operations; inactive mining operations are mining sites that are not being actively mined, but which have an identifiable owner/operator;

(iv) Hazardous waste treatment, storage, or disposal facilities, including those that are operating under interim status or a permit under Subtitle C of RCRA;

(v) Landfills, land application sites, and open dumps that have received any industrial wastes (waste that is received from any of the facilities described under this subsection) including those that are subject to regulation under Subtitle D of RCRA;

(vi) Facilities involved in the recycling of materials, including metal scrapyards, battery reclaimers, salvage yards, and automobile junkyards, including but limited to those classified as Standard Industrial Classification 5015 and 5093;

(vii) Steam electric power generating facilities, including coal handling sites;

(viii) Transportation facilities classified as Standard Industrial Classifications 40, 41, 42 (except 4221–25), 43, 44, 45 and 5171 which have vehicle maintenance shops, equipment cleaning operations, or airport deicing operations. Only those portions of the facility that are either involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication), equipment cleaning operations, airport deicing operations, or which are otherwise identified under paragraphs (i)-(vii) or (ix)-(xi) of this subsection are associated with industrial activity;

(ix) Treatment works treating domestic sewage or any other sewage sludge or wastewater treatment device or system, used in the storage treatment, recycling, and reclamation of municipal or domestic sewage, including land dedicated to the disposal of sewage sludge that are located within the confines of the facility, with a design flow of 1.0 mgd or more, or required to have an approved pretreatment program under 40 CFR 403. Not included are farm lands, domestic gardens or lands used for sludge management where sludge is beneficially reused and which are not physically located in the confines of the facility, or areas that are in compliance with 40 CFR 503;

(x) Construction activity including clearing, grading and excavation activities except: operations that result in the disturbance of less than five acres of total land area which are not part of a larger common plan of development or sale;

(xi) Facilities under Standard Industrial Classifications 20, 21, 22, 23, 2434, 25, 265, 267, 27, 283, 285, 30, 31 (except 311), 323, 34 (except 3441), 35, 36, 37 (except 373), 38, 39, 4221–25, (and which are not otherwise included within categories (i)–(x)).[8]

[8] On June 4, 1992, the United States Court of Appeals for the Ninth Circuit remanded the exclusion for manufacturing facilities in category (xi) which do not have materials or activities exposed to storm water to the EPA for further rulemaking (Nos. 90-70671 and 91-70200).

Time-weighted composite means a composite sample consisting of a mixture of equal volume aliquots collected at a constant time interval.

Upset means an exceptional incident in which there is unintentional and temporary noncompliance with the numeric effluent limitations of part V of this permit because of factors beyond the reasonable control of the permittee. An upset does not include noncompliance to the extent caused by operational error, improperly designed treatment facilities, inadequate treatment facilities, lack of preventive maintenance, or careless or improper operation.

Waste pile means any noncontainerized accumulation of solid, nonflowing waste that is used for treatment or storage.

Waters of the United States means:

(a) All waters which are currently used, were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of the tide;

(b) All interstate waters, including interstate "wetlands";

(c) All other waters such as interstate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds the use, degradation, or destruction of which would affect or could affect interstate or foreign commerce including any such waters:

(1) Which are or could be used by interstate or foreign travelers for recreational or other purposes;

(2) From which fish or shellfish are or could be taken and sold in interstate or foreign commerce; or

(3) Which are used or could be used for industrial purposes by industries in interstate commerce;

(d) All impoundments of waters otherwise defined as waters of the United States under this definition;

(e) Tributaries of waters identified in paragraphs (a) through (d) of this definition;

(f) The territorial sea; and

(g) Wetlands adjacent to waters (other than waters that are themselves wetlands) identified in paragraphs (a) through (f) of this definition.

Waste treatment systems, including treatment ponds or lagoons designed to meet the requirements of CWA are not waters of the United States.

Part XI. State Specific Conditions

The provisions of this part provide modifications or additions to the applicable conditions of parts I through

VOL 12 2 3826

R0057118

that I am no longer the operator of the industrial activity. I understand that by submitting this notice of termination, that I am no longer authorized to discharge storm water associated with industrial activity under this general permit, and that discharging pollutants in storm water associated with industrial activity to waters of the United States is unlawful under the Clean Water Act where the discharge is not authorized by a NPDES permit. I also understand that the submittal of this notice of termination does not release an operator from liability for any violations of this permit or the Clean Water Act."

B. Addresses

All Notices of Termination are to be sent, using the form provided by the Director (or a photocopy thereof),[4] to the Director of the NPDES program in care of the following address: Storm Water Notice of Termination, PO Box 1185, Newington, VA 22122.

Part X. Definitions

Best Management Practices ("BMPs") means schedules of activities, prohibitions of practices, maintenance procedures, and other management practices to prevent or reduce the pollution of waters of the United States. BMPs also include treatment requirements, operating procedures, and practices to control facility site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.

Bypass means the intentional diversion of waste streams from any portion of a treatment facility.

Coal pile runoff means the rainfall runoff from or through any coal storage pile.

CWA means Clean Water Act (formerly referred to as the Federal Water Pollution Control Act or Federal Water Pollution Control Act Amendments of 1972).

Director means the Regional Administrator or an authorized representative.

Flow-weighted composite sample means a composite sample consisting of a mixture of aliquots collected at a constant time interval, where the volume of each aliquot is proportional to the flow rate of the discharge.

Landfill means an area of land or an excavation in which wastes are placed for permanent disposal, and which is not a land application unit, surface impoundment, injection well, or waste pile.

Land application unit means an area where wastes are applied onto or incorporated into the soil surface (excluding manure spreading operations) for treatment or disposal.

Large and medium municipal separate storm sewer system means all municipal separate storm sewers that are either: (i) located in an incorporated place (city) with a population of 100,000 or more as determined by the latest Decennial Census by the Bureau of Census (these cities are listed in Appendices F and G of 40 CFR Part 122); or (ii) located in the counties with unincorporated urbanized populations of 100,000 or more, except municipal separate storm sewers that are located in the incorporated places, townships or towns within such counties (these counties are listed in Appendices H and I of 40 CFR Part 122); or (iii) owned or operated by a municipality other than those described in paragraph (i) or (ii) and that are designated by the Director as part of the large or medium municipal separate storm sewer system.

NOI means notice of intent to be covered by this permit (see Part II of this permit.)

NOT means notice of termination (see Part II of this permit.)

Point source means any discernible, confined, and discrete conveyance, including but not limited to, any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, landfill leachate collection system, vessel or other floating craft from which pollutants are or may be discharges. This term does not include return flows from irrigated agriculture or agricultural storm water runoff.

Section 313 water priority chemical means a chemical or chemical categories which: 1) Are listed at 40 CFR 372.65 pursuant to Section 313 of the Emergency Planning and Community Right-to-Know Act (EPCRA) (also known as Title III of the Superfund Amendments and Reauthorization Act (SARA) of 1986); 2) are present at or above threshold levels at a facility subject to EPCRA Section 313 reporting requirements; and 3) that meet at least one of the following criteria: (i) Are listed in Appendix D of 40 CFR 122 on either Table II (organic priority pollutants), Table III (certain metals, cyanides, and phenols) or Table V (certain toxic pollutants and hazardous substances); (ii) are listed as a hazardous substance pursuant to section 311(b)(2)(A) of the CWA at 40 CFR 116.4; or (iii) are pollutants for which EPA has published acute or chronic water quality criteria. See Addendum B of this permit.

Significant materials includes, but is not limited to: raw materials; fuels; materials such as solvents, detergents, and plastic pellets; finished materials such as metallic products; raw materials used in food processing or production; hazardous substances designated under section 101(14) of CERCLA; any chemical the facility is required to report pursuant to EPCRA Section 313; fertilizers; pesticides; and waste products such as ashes, slag and sludge that have the potential to be released with storm water discharges.

Significant spills includes, but is not limited to: releases of oil or hazardous substances in excess of reportable quantities under section 311 of the Clean Water Act (see 40 CFR 110.10 and CFR 117.21) or section 102 of CERCLA (see 40 CFR 302.4).

Storm water means storm water runoff, snow melt runoff, and surface runoff and drainage.

Storm water associated with industrial activity means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant. The term does not include discharges from facilities or activities excluded from the NPDES program. For the categories of industries identified in paragraphs (i) through (x) of this definition, the term includes, but is not limited to, storm water discharges from industrial plant yards; immediate access roads and rail lines used or traveled by carriers of raw materials, manufactured products, waste material, or by-products used or created by the facility; material handling sites; refuse sites; sites used for the application or disposal of process waste waters (as defined at 40 CFR 401); sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage, or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials, and intermediate and finished products; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water. For the categories of industries identified in paragraph (xi) of this definition, the term includes only storm water discharges from all areas (except access roads and rail lines) listed in the previous sentence where material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, or industrial machinery are exposed to storm water. For the purposes of this paragraph, material handling activities include the:

[4] A copy of the approved NOT form is provided in Appendix D of this notice.

VOL 12 2 3827

R0057119

Table V.A.1.a. - Representative Monitoring Requirements

PARAMETER	MONITORING FREQUENCY				
	YEAR 1	YEAR 2	YEAR 3	YEAR 4	YEAR 5
Biochemical Oxygen Demand (BOD_5) (mg/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Chemical Oxygen Demand (COD) (mg/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Total Suspended Solids (TSS) (mg/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Total Dissolved Solids (TDS) (mg/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Total Nitrogen (mg/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Total Kjeldahl Nitrogen (TKN) (mg/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Total Phosphorus (mg/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Dissolved Phosphorus (mg/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Oil & Grease (mg/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Total Cadmium (ug/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Total Copper (ug/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Total Lead (ug/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Total Zinc (ug/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Ph (S.U.)	Two/year	Two/year	Two/year	Six/year	Two/year
Hardness (as $CaCO_3$) (mg/l)	Two/year	Two/year	Two/year	Six/year	Two/year
Temperature (°C)	Two/year	Two/year	Two/year	Six/year	Two/year
Other Water Quality Parameters[1]	One/year	One/year	One/year	Six/year	One/year

[1] Other Water Quality Parameters to be monitored include any parameter for which the State has established numeric water quality criteria applicable to the receiving waters of the MS4 and which was detected in the wet weather monitoring required by the permit application.

3. Shall establish two monitoring locations for removal of floatable material in discharges from the MS4. The amount of material collected shall be estimated in cubic yards. Floatable material shall be measured periodically as necessary for maintenance of the removal device.

Storm Water Publications

Stormwater: Issues and Answers (APWA) 1989. 16 pp.

Members $20 per order; Non-Members $30 per order; (Sold in groups of 10)

Why does every community need a drainage management plan? What are the options? Whose responsibility is it? And how will you pay for it? Here are the answers. This insightful booklet is designed to provide elected and appointed officials, as well as concerned citizens, with a better understanding of the issues involved in managing urban stormwater drainage. Public officials will find it to be an indispensable resource when developing their own management plans.

Water Quality: Urban Runoff Solutions. Spec Report 31. (APWA) 1991. 32 pp. ISBN 0-917084-18-7

Members $25; Non-Members $35

The title says it all: this practical information-packed manual offers solutions to challenging stormwater problems. Get the inside story on pre-tested programs, an learn how they can fit into your own comprehensive plan for stormwater management. This practical report will clue you into best management practices, as well as correct ways to conduct a fiscal analysis and coordinate an effective stormwater program.

A Study of Nationwide Costs to Implement Municipal Stormwater Best Management Practices. Final Report. (Water Resources Committee, APWA, Southern California Chapter) 1992. 105 pp. ISBN)-017084-10-5

Members $15; Non-Members $20 This comprehensive study was conducted to determine the order-of-magnitude of costs that municipalities would incur under several different stormwater management program scenarios. Over 100 agencies were contacted to obtain information on current programs and projected costs for developing and maintaining best management programs. An invaluable planning tool, this report examines regulatory history, the existing permit process, monitoring costs, the cost of controls, and costs to implement best management practices.

NEW NEW NEW NEW NEW NEW

Available late 1993

Operations and Maintenance: Stormwater Practices (APWA) 1993. 100 pp.

This thorough resource explores all aspects of maintenance and operations of urban storm water facilities, including preventive maintenance functions, organization of operations and maintenance departments, facility inventory, financing operations and maintenance, and management of contract services. Review storm water problems and priorities and learn how to avoid the costly consequences of ill-managed facilities. Learn methods that have worked for other agencies, and select the best approaches for you.

INFORMATION SERVICES

Information Services provides comprehensive information on a wide variety of topics. Recently the department acquired stormwater best management practices documents from several agencies. There are two ways you can obtain information:

APWA Infolink Entitles public agency or private company subscribers to receive unlimited access to all of APWA's library reference facilities, an annual subscription to a newsletter and discounts for Information Service's special publications. Also available are library reference professionals who have access to over 100 computerized bibliographic databases and thousands of periodicals.

Infodoc Services will provide, free of charge, detailed and informative search results from our database. Non-Infolink subscribers are charged a per page fee for copying and one handling fee when they ask to receive copies of reports or reference materials cited.

For more information about the new publication and other APWA information services, please fax your request to (816) 472-1610, attention: Information Services or mail it to Information Services, American Public Works Association, 106 West 11th Street, Kansas City, Missouri 64105. Questions? Call (816) 472-6100.

RE: APWA Education Foundation Programs

Welcome to the program, **Stormwater Management: Municipal Techniques and Strategies.**

It is very important to us that you find the information useful and the day worthwhile. Please fill out the evaluation form to help us continually improve the program.

On the next page is a list of the seminars and workshops which are currently available. Other seminars are under development. Also available are packaged programs which provide an instructor's guide and student manuals. If you wish to receive brochure(s) for one or more of the listed programs, please return a copy of that page to us.

The APWA Education Foundation is also able to present these programs at your site. By working cooperatively, we can provide education and training for your staff members at a reasonable fee. Additional benefits are that you save time away from the job for travel as well as travel costs.

If you have questions or comments, please call me at (816) 472-6100, extension 534.

Urban Stormwater: An Overview for Municipalities

GAIL BOYD
Vice President
and
NANCY GARDINER
Assistant Project Scientist,
Water Pollution Control Group,
Woodward-Clyde,
Oakland, California

Editor's Note: This is the first of three articles PUBLIC WORKS will present over the next several months to help our readers understand and deal with a recently-issued set of federal water quality regulations (i.e., EPA's new NPDES stormwater requirements) in a practical manner. This article covers the following:

- A description of the major processes that typically contribute to or result in stormwater quality problems.
- A description of typical urban stormwater characteristics.
- A historical review of the regulatory efforts to control urban stormwater quality problems.
- An overview of the NPDES regulations that apply to most large- and medium-size U.S. cities (and many smaller communities as well.).

Future PUBLIC WORKS issues will present articles on the following topics:

- Descriptions of strategies that municipal stormwater dischargers may wish to consider when planning their efforts to develop the information required for NPDES permit applications.
- Descriptions of strategies for evaluating and selecting among candidate stormwater controls (i.e., best management practices [BMPs] and associated implementation programs).
- Discussions of some technical and institutional issues that public works engineers and planners have found especially challenging in their efforts to develop and implement practical stormwater quality control programs.

In addition, a Woodward-Clyde team is presently writing a full-length book on municipal and industrial stormwater pollution and control strategies.

DURING the past 20 years, the findings from several major research and demonstration programs have shown that urban stormwater typically contains pollutants that limit its subsequent use as a resource and or may lead to impacts when it is discharged to receiving waters. The control of stormwater-related pollution is a new field of endeavor for many public works engineers and planners, and it is sure to present challenges as well as opportunities.

The increased recognition of the pollution potential of urban stormwater has led to several important regulatory developments, including the following:

- EPA has developed regulations that require municipalities and industries to apply for and obtain stormwater discharge permits under amended provisions of the National Pollutant Discharge Elimination System (NPDES). These regulations were circulated in draft form for public review (via the *Federal Register*, December 7, 1988), have evolved through a process of revision and refinement for nearly two years, and were recently released in final form. Municipalities (and or flood control or drainage agencies) in most sizeable urban areas are required to compile certain existing information and to conduct prescribed field studies. In effect, municipal dischargers will be required to file permit applications in which they describe themselves (and any co-applicants), describe their stormwater conveyance systems, and characterize their systems' flows and discharges during dry weather and wet weather. The applicants will also be required to describe their present efforts and facilities for controlling stormwater quality, and to supplement their present capabilities by obtaining adequate regulatory authority and implementing appropriate BMPs to the "maximum extent practicable."
- Several EPA regional offices and state-level water quality control agencies have also initiated focused programs (under other provisions of federal and or state water quality laws) that have required certain designated municipal and industrial stormwater dischargers to define and describe their stormwater conveyance systems, conduct studies to characterize wet-weather and dry-weather discharges from stormwater systems, and develop and implement practical programs for controlling stormwater quality.

Although these other programs derive from different legal institutional origins and impose somewhat different requirements, they are important in that they collectively will encompass many U.S. communities (well beyond just the cities that are over 100,000 population). In fact, the combined effect of the final NPDES regulations and these other programs (i.e., under Sections 304(l), 319, and 402(p)(2)(E) of the Federal Clean Water Act and state and local initiatives) is that many public works engineers and planners will be faced with the need to characterize and control stormwater-related water quality problems. The list of such communities will go well beyond those inferred by the original definitions provided in the draft NPDES stormwater regulations (i.e., December 7, 1988).

Many municipal officials and public works professionals have anticipated federal and or state stormwater regulations of some type for several years and have tracked their evolution with interest. Nonetheless, the specific requirements of the final NPDES stormwater regulations and other state and or local stormwater regulatory programs will still present challenges because of the breadth and degree of detailed investigation and planning they entail. Perhaps even more significant in the long term are the commitments municipalities will be required to make regarding their implementation and continuing support of various BMPs, some of which may be somewhat foreign to their routine public works programs.

This article provides a general background description of the major processes that lead to stormwater-related water quality problems. It continues with a discussion of how the resultant problems can be considered and prioritized in planning and decision-making context. It concludes with an overview of the historical development of the new NPDES regulations and a brief summary of what they require. Subsequent PUBLIC WORKS articles will describe the regulations in greater detail.

Major Stormwater Processes

When it rains in an urban area, the rain collects pollutants from many sources, and the runoff carries these pollutants and eroded sediments through stormwater conveyance sys-

Table 2 – Information Required for Part 2 of the NPDES Permit Application

(i) **Adequate Legal Authority:**
Demonstration that the Applicant will be able to exercise adequate legal authority to control discharges to the municipal separate storm sewer system

(ii) **Source Identification:**
Description of any major outfalls not fully described in the Part 1 application

(iii) **Characterization Data:**
Sampling and analysis of selected major outfalls (to identify and characterize illicit connections and illegal dumping)
Sampling and analysis of 5 to 10 representative outfalls to characterize overall system
Extrapolation of measured data to estimate annual pollutant load for overall system
Plans for continuing monitoring program to develop loading data and event mean concentrations

(iv) **Proposed Management Program:**
Description of proposed structural and non-structural control measures
Description of proposed program for detecting and eliminating illicit connections and illegal dumping
Description of proposed program to monitor industrial runoff
Description of proposed program to implement and maintain structural and non-structural BMPs

(v) **Assessment of Controls:**
Estimate of the anticipated overall effectiveness of the proposed control measures (reductions in loadings)

(vi) **Fiscal Analysis:**
Estimate of the capital, operating, and maintenance costs of the proposed characterization and control programs (fiscal year by fiscal year projections)

(vii) **Roles/Responsibilities:**
Description of the roles and responsibilities of the various entities that may have joined together to submit an NPDES application

eration of local conditions, processes, and public sentiments; and/or were established to guard against chronic (rather than short-term) effects of pollutants. This latter point is important, because stormwater-borne pollutants usually cause only short-term exceedances of criteria in most flowing receiving waters.

The new NPDES stormwater regulations require municipal dischargers to collect and report a broad variety of information on their respective agencies, systems, and discharges. However, they do not specifically require municipal permit applicants to define or evaluate local water quality "problems," or to establish their respective share of the responsibility for causing or rectifying "problems." This lack of specificity in the regulations will be welcomed by some dischargers, but it may cause others difficulties because experience has repeatedly shown the need for some evaluation of this type before a public agency can implement strategic control plans or commit to a large-scale control program (such as using BMPs, as called for by the new regulations).

History of Water Quality Regulations

In 1972, Congress passed significant amendments to the Federal Water Pollution Control Act (commonly referred to as the Clean Water Act or CWA). These amendments were provisions that were specifically focused on controlling point sources of pollutants that were being discharged to navigable waters of the U.S. The newly formed EPA then implemented the NPDES permit program, which provides administrative and legal mechanisms for issuing conditional discharge permits and enforcing their respective stipulations.

The NPDES program has focused almost entirely on the goal of reducing pollutants from municipal sanitary sewage and industrial process wastewater, because these point sources were identified as being responsible for poor, often drastically degraded, water quality conditions.

As noted previously, many engineers, the public, and most environmental lawmakers were inclined to deal with stormwater runoff as though it were a lesser priority, even though it was known to contain significant quantities of pollutants in most locations. However, during the past 20 years or so, attitudes have changed considerably, for example:

We now understand the need to control the concentrations of certain toxic pollutants to very low levels (in the interest of protecting human health and sensitive aquatic life).

We now recognize that rainfall picks up a multitude of pollutants as a result of falling on and draining off of urban surfaces, and that the runoff also transports pollutants that are dumped or improperly discharged into stormwater systems.

We now know that stormwater-borne pollutants can (and do) cause problems for water supply, recreation, and other beneficial uses, because they threaten human health and interfere with aquatic ecosystems.

We now see the need to shift priorities somewhat and begin to employ control strategies that apply to both traditional point sources (i.e., municipal and industrial wastewater) and to stormwater-borne pollutants.

The history of federal rulemaking regarding stormwater discharges has been long and complex. Although EPA has had sustained interest and involvement in exploring the technical issues surrounding urban stormwater problems and control strategies, it has experienced difficulties in establishing a nationwide regulatory program. As summarized in the preamble of the new NPDES stormwater program (published in the December 7, 1988 *Federal Register*), EPA has long been both stimulated and frustrated by the efforts of several environmental activist groups. Nonetheless, it has managed to issue a set of final regulations. On February 4, 1987, Congress passed the Water Quality Act of 1987 (WQA), which (among many other things) amended the CWA by adding a new subsection "p" to existing Section 402 of the CWA. The amendments call for a phased approach to control pollutants that are mobilized by and carried by stormwater discharges. Section 402(p) established phased permit application requirements, permit issuance deadlines, and permit compliance conditions for different categories of stormwater discharges.

Overview of Regulations for Municipalities

Section 402(p) of the CWA required EPA to establish regulations governing stormwater discharge permit application requirements under the NPDES program. It is interesting to note that for the purposes of most technical assessments, stormwater from urban and industrial areas traditionally have been thought of as being diffuse sources or "nonpoint" sources of pollution. However, from the legal standpoint, most municipal stormwater is now considered by EPA to be a "point" source, because it is discharged through conveyance facilities (such as separate

Section 402(p) established phased permit application requirements, permit issuance deadlines, and permit compliance conditions for different categories of stormwater discharges.

Overview of Regulations for Municipalities

Section 402(p) of the CWA required EPA to establish regulations governing stormwater discharge permit application requirements under the NPDES program. It is interesting to note that for the purposes of most technical assessments, stormwater from urban and industrial areas traditionally have been thought of as being diffuse sources or "nonpoint" sources of pollution. However, from the legal standpoint, most municipal stormwater is now considered by EPA to be a "point" source, because it is discharged through conveyance facilities (such as separate

VOL 12 2 3844

R0057136

the new NPDES Stormwater Permit program.

Pollutants in Stormwater

The principal types of pollutants found in stormwater and their resultant potential adverse effects on receiving waters are typically as follows:

- Sediment. Suspended sediment in itself is often not considered to be a pollutant, but it can lead to numerous adverse effects on aquatic ecosystems. Biological impacts of high sediment levels include reduced light penetration, interference with sight feeding and photosynthesis, and clogging of gills and filter systems in aquatic organisms. General aquatic habitat can be degraded if streambed accumulations of sediment bury benthic organisms and or interfere with egg deposition and hatching. Sediments in runoff from developed areas can also serve as "carriers" of pollutants, because pesticides, heavy metals, and other toxic chemicals tend to bind to clay and organic particles.
- Oxygen demanding substances. Decomposition of oxidizable organic matter (typically measured as BOD, COD, or TOC) depletes dissolved oxygen levels in receiving waters, especially in slower moving streams, estuaries, and lakes. However, urban runoff is generally not a primary cause of problems associated with depressed dissolved oxygen levels.
- Nutrients. The levels of phosphorus and nitrogen in runoff can lead to accelerated eutrophication in downstream receiving waters. Phosphorus is generally the controlling nutrient in freshwater systems. Surface algal scums, algal blooms, water discoloration, unpleasant tastes and odors, depressed oxygen levels (as the bloom decomposes), and release of toxins are among the problems encountered.
- Toxic substances. Heavy metals are observed in stormwater more frequently and at more significant levels than organic toxic compounds. Both are concerns, however, because of their potential toxic effects on aquatic life and their potential to contaminate drinking water supplies. The heavy metals having the highest concentrations in urban runoff are typically copper, lead, and zinc, with cadmium a distant fourth. Organic compounds most commonly found in urban stormwater are those associated with herbicides, pesticides, and wood preservatives.
- Oil and grease. Oil and grease have both esthetic and ecosystem implications. The category includes a wide variety of hydrocarbon compounds, some of which (e.g., polynuclear aromatic hydrocarbons, PAHs) are known to accumulate in sediments and to be toxic to aquatic life at low concentrations. Hydrocarbons often show up as a film or sheen on the water's surface, but other forms (especially weathered crankcase oil) tend to be present in solution or in emulsion and may produce no sheen.
- Bacteria. Fecal coliform levels in urban runoff can usually be expected to exceed public health standards for water contact recreation and shellfish harvesting, and they frequently impair these uses.

Assessment of Stormwater Problems

Because every pollution control strategy must begin with an assessment of the problems themselves, it is important to formally define what constitutes a problem. In the area of stormwater quality planning, this task can be challenging, because (ideally) it involves structuring the problem well enough to adequately identify sources, define appropriate clean-up goals, select effective control strategies, and quantify the costs and associated benefits. As noted, the problems associated with urban stormwater runoff vary considerably in type, severity, and duration; and these in turn vary from location-to-location and from time-to-time at any given location. Because of this inherent variability, it is often difficult to classify and prioritize problems.

Stormwater-borne pollutants can be defined as causing a "problem" if they result in any of the following impacts:

- Interference with the desired *beneficial uses* of the receiving waters (i.e., at the point of discharge and or within the zone of influence of the discharge). Examples include impacts on water quality that interfere with water supplies and or restrict recreational uses.
- A significant adverse impact on *aquatic ecosystems* resulting from degradation of water quality and/or changes in essential habitat characteristics. Examples include direct effects on biota due to water quality and/or indirect physical effects on habitat (e.g., sediment deposition).
- A significant increase in the frequency, duration, and or degree of exceedances of applicable *water quality standards or criteria*.

This approach of using three different definitions of a "problem" may be especially useful in cases where prescribed water quality standards or criteria are over-protective or under-protective for a specific location. It should be noted that over-protective criteria are not uncommon, especially in cases where the official criteria were established several years ago; were established without taking adequate consid-

Table 1—Information Required for Part 1 of the NPDES Permit Application

(i) **General Information:**
- Name
- Address
- Telephone number
- Ownership status
- Institutional status

(ii) **Legal Authority:**
- Description of existing legal authority to control discharges to the municipal system
- Description of additional authority required to control discharges
- Schedule and commitment to seek additional authority

(iii) **Source Identification:**
- Description of historic use of controls to limit discharges
- Maps of municipal system and surrounding locale
- Location of "outfalls" to "waters of the U.S."
- Description of corresponding watersheds for each major outfall (e.g., land uses, industrial activities, NPDES permittees, waste facilities, existing NPS controls)

(iv) **Discharge Characterization:**
- Precipitation data
- Existing data on stormwater from municipal outfalls (quality and quantity)
- Descriptions of receiving waters (condition and regulatory status)
- Field screening analysis for illicit connections and/or illegal dumping (visual observations plus non-standard methods of chemical analysis)
- Description of proposed characterization plan (workplan to guide Part 2 studies)

(v) **Management Programs:**
- Description of existing control measures (structural and non-structural)
- Description of existing program for identifying illicit connections

VOL 12 2 3845

R0057137

tems and into the local receiving waters. There, the pollutants and sediments can degrade water quality and or impact aquatic ecosystems. The specific pollutants involved, the washoff and transport mechanisms, and the extent and importance of the resultant impacts vary considerably from city-to-city, from location-to-location within a given city, and from time-to-time at any given location—depending upon numerous physical, chemical, and biological factors. The major processes and pertinent factors are summarized here.

The major processes that collectively can lead to stormwater-related impacts at a given location include the following:

♦Atmospheric scrubbing. Airborne particles (e.g., dust, soot, aerosols) can be scrubbed out of the atmosphere by falling rain. Therefore, rain itself contains more than clean water.

♦Surface washoff. Rainfall washes pollutants off of virtually all urban surfaces (e.g., roadways, parking lots, buildings, storage and equipment areas, landscaped areas, construction sites, vacant lots, parklands, open space).

♦Other sources. Pollutants from illicit sewer connections and illegal dumping have been found to be important additional sources in most urban areas.

♦Erosion and scour. Rainfall and runoff erode pollutants, soil, and finely-divided minerals from exposed land surfaces and scour them from stream banks and streambeds.

♦Transport. Depending upon their physical and chemical form, pollutants may float, dissolve, or become suspended and move with the main volume of runoff.

♦Deposition. Pollutants are carried with the storm runoff until they are deposited by adhering to surrounding surfaces, settling out, and or interacting with one another or with other processes that remove them from the runoff. During periods of intense runoff, some of these previously-deposited pollutants can be re-mobilized and transported to other locations.

Some major factors that influence the above processes (and, hence the extent and severity of any stormwater-related impacts at a given location) include the following:

♦Meteorological conditions. These include storm intensity, storm volume and duration, the time period between storm events (during which some pollutants can accumulate in parts of the watershed, and soils can dry out), and local air quality.

♦Watershed characteristics. The most important physical characteristics of the watershed usually include topography, soil types, vegetative cover, amount of impermeable areas (e.g., pavement, buildings), land uses (and the associated activities), and the effects of various stormwater management facilities and practices.

♦Conveyance system characteristics. Important factors governing runoff quantities and characteristics in natural stream channels and improved or man-made channels are the channels' hydraulic capacities at key locations, their corresponding slopes, the stability of their banks (regarding erosion), the physical and chemical properties of bottom sediments, and the amounts and types of vegetation that are present.

♦Available pollutants. The types of pollutants commonly found in urban runoff include sediments, oxygen demanding substances, nutrients, toxic substances (e.g., heavy metals and complex organic compounds), oil and grease, and bacteria.

♦Receiving water characteristics. The impacts of stormwater runoff on receiving waters depend on the type of water body (e.g., wetlands, creeks, rivers, lakes, estuaries, ocean), local hydrographic and hydrodynamic conditions, cumulative pollutant loadings (i.e., pollutant contributions from other sources), and the beneficial uses and types of aquatic ecosystems that the water body is expected to support.

Sources of Pollutants

The principal sources of pollutants that are discharged from municipal separate stormwater conveyance systems generally include the following:

Atmospheric deposition. A significant source of pollutants in urban areas, and some industrial sites, is atmospheric deposition in the form of both wetfall and dryfall. Some atmospheric pollutants attach to and remain on urban surfaces, but a significant fraction may wash off during storm events. Areas with poor control of general or fugitive air emissions can contribute significant loads to runoff from this source.

Erosion. Soil erosion can be an important source of pollutants in runoff. Erosion can result from stream bank erosion produced by high runoff flow rates, and from the disturbance of land surfaces during construction or renovation. For example, site clearing and grading operations during construction can expose large areas of erodable surface soils. Unless adequate erosion controls are implemented and maintained, large quantities of sediment can be delivered to storm sewers, drainage channels, streams, and receiving waters. Such soil-derived sediment typically carries attached nutrients, organic matter, and often other adsorbed pollutants.

Construction materials. Materials used in the construction and maintenance of buildings and infrastructure are major sources of pollutants. Various heavy metals, for example, are common materials in many structures (e.g., flashing and shingles, gutters and downspouts, copper and galvanized piping, metal plating, paints, wood preservatives). Over time, these surfaces corrode, flake, dissolve, decay, or are subject to leaching, thereby allowing various potentially-harmful heavy metals to be carried away in urban runoff. The process can be exacerbated by the acidity of the rainfall.

Manufactured products. Manufactured products used in developed areas and exposed to the elements are major sources of pollutants in urban runoff. Some examples include heavy metals and synthetic organic compounds present in the following types of products: fertilizers, insecticides, algicides, and fungicides; automobile brake linings, clutch facings, and tire compounds; lubricants, hydraulic fluids, combustion products, and automotive coolants; and solvents, detergents, and other cleaning compounds.

Plants and animals. Other sources of pollutants that accumulate and subsequently wash off of urban surfaces include plant debris and animal excrement (which are normally recycled in natural systems). Trees and shrubs deposit pollen, fruit, bark, twigs, and leaves which enter into stormwater runoff. During the growing season, nutrients leach from tree leaves and stems during storms and are quickly conveyed to the storm sewers, drainage channels, or streams, if the ground is saturated or if the tree's drip lines extend over impervious areas.

Accidental spills and unintended discharges. Another source of pollutants in stormwater systems is accidental spills. This could include virtually any pollutant, depending upon the nature of the spill. Leaking underground storage tanks, faulty septic systems, leachate from sanitary landfills, and improperly managed hazardous waste treatment, storage, and disposal sites can also contribute to pollutants in storm sewers.

Although the above focuses on urban runoff related pollutant sources, there are two other very important sources of pollutants that are carried through urban stormwater conveyance systems. They are designated by EPA as "illicit connections" and "illegal dumping." Illicit connections include both deliberate and inadvertent discharges of sanitary sewage or industrial process or wash waters to storm drains. Illegal dumping refers to the dumping of solid or liquid wastes (e.g., the illegal dumping of spent motor oil and antifreeze is very common in most urban areas). These pollutant sources have been identified as a widespread and serious problem, and the detection and elimination of such discharges are major focuses of

VOL 12 2 3846

R0057138

storm sewers or flood control channels) which, at their respective points of discharge to receiving waters, are regarded as point sources under the CWA.

The new regulations regard urban stormwater as a point source to be controlled using the provisions of NPDES. The newly-established NPDES permit application requirements pertain to the following: stormwater discharges associated with industrial activity, discharges from large municipal separate stormwater systems (i.e., systems serving a population of 250,000 or more); and discharges from medium municipal separate stormwater systems (i.e., systems serving a population of 100,000 or more, but less than 250,000).

The general philosophy guiding the municipal stormwater regulations is that control strategies and programs should be site-specific, rather than generalized in their approach. Furthermore, the philosophy appears to stress and encourage the applicants' introspection and self-initiation, rather than their compliance with a rigid set of water quality criteria or the implementation of some externally prescribed set of controls. In effect, the regulations pose a series of questions that municipal applicants are to answer in a stepwise manner, over the course of the application process. Responses to these questions will draw upon both existing factual information and the results of studies that are to be performed in the applicants' study area. Stated very simply, these questions deal with the following kinds of information:

- Who are you?
- What is your storm drainage system like?
- What pollutants get into your system?
- Where do these pollutants come from, where do they go, and what is the condition status of the receiving waters?
- What do you presently do to minimize pollution problems?
- What else do you need to do?
- What additional authority do you need to obtain to take effective action?

The NPDES stormwater regulations specify a series of pointed requirements grouped within two separate parts of the permit application. Large municipalities are to submit Part 1 of the application within one year of the publication of the final regulations, and Part 2 within two years of publication. Medium municipalities are to submit both parts at a later time.

Tables 1 and 2 provide a more accurate summary of the information required by Part 1 and Part 2 of the NPDES stormwater permit application process, respectively. Subsequent issues of PUBLIC WORKS will provide additional information on the requirements and practical strategies for obtaining the required information. □□□

VOL 12 2 3841 L

R0057139

VOL 12 2 3848 F

R0057140

Historically, pollution from separate storm sewers has received little attention by the general public on a national scale. Indeed, a handful of comprehensive stormwater management programs has been implemented in recent years. But a lack of widespread attention has existed to date primarily because water quality problems associated with stormwater discharges have not been readily apparent to the general public, and are usually less dramatic than more visibly detrimental effects such as flooding. In addition, efforts to improve water quality under the National Pollutant Discharge Elimination System (NPDES) program have traditionally focused on reducing pollutants in discharges from municipal wastewater treatment plants and industrial process wastewater.

However, pollution from separate stormwater discharges has negatively affected U.S. waters in a variety of ways, including increased sediment loads, nutrient enrichment, decreased dissolved oxygen concentrations, bacterial contamination, discharges of high levels of metals and organics, thermal effects, and aesthetic impacts such as trash and other debris in the receiving water. Also important is the effect of increased volumes of stormwater runoff that is generated during storms. Large intermittent volumes of runoff can reduce the diversity of aquatic organisms by changing the hydraulics and chemistry in receiving waters.

As a first step to address stormwater problems, 173 cities, 47 counties, and an estimated 100,000 industries will be required to submit NPDES permit applications during the next 2 to 3 years for their stormwater discharges. The purpose of the regulations is to begin the process of reducing nonpoint-source (NPS) pollutants associated with urban stormwater.

The clock started ticking for cities and industries when the NPDES permit application regulations for stormwater discharges were published in the November 16, 1990, *Federal Register*. The deadlines for municipalities and industries are different (see Table). These dates are later than the statutory deadlines established by Congress in the Water Quality Act (WQA) of 1987—a reauthorization of the Clean Water Act (CWA). EPA has indicated that, while the CWA deadlines remain enforceable, the deadlines established in the final rule are necessary for the development of enforceable and sound stormwater permits. EPA's advice regarding deadlines was published in the November 16, 1990, *Federal Register* as part of the preamble to the final rule: "Dischargers concerned with complying with the statutory deadline should submit a permit application as required under this rulemaking as expeditiously as possible."

The final regulations are far-reaching in that they significantly affect U.S. cities serving millions of people. The requirements for obtaining permits, especially for municipalities, are not trivial. Some cities have anticipated the new regulations and have already begun the permit application process. Many cities and counties have not adequately prepared themselves, financially or technically, to prepare the stormwater permit applications. Indeed, many cities are facing reduced revenues as the economy slips into a recession.

URBAN RUNOFF PROGRAM

An important element in the development of the stormwater regulations was the Nationwide Urban Runoff Program (NURP). This program was conducted between 1978 and 1983 and received funding and guidance from EPA. Twenty-eight cities across the U.S. generated data used to characterize stormwater discharges from residential, commercial, and light industrial areas. NURP data indicated that annual suspended solids loads from separate storm sewers sampled during the study were about an order of magnitude greater than effluent from secondary wastewater treatment plants. Chemical oxygen demand was comparable in magnitude to that found in effluent from secondary wastewater treatment plants. Data collected in NURP showed that fecal coliform counts in urban runoff were in the tens to hundreds of thousands per mL of

An infiltration system, previous page, under sod near the White House in Washington, D.C., reduces the volume of stormwater runoff. [illegible]

VOL 12 2 3849

R0057141

jurisdiction that they are covered by the permit. In addition, the permit authority could require some group members in its jurisdiction to submit individual applications. It may be appropriate for a potential group member to contact the respective permit authority before becoming part of a group application. As of mid-January 1991, Missouri indicated that it will not accept group permit applications because the Missouri Clean Water Law makes group applications illegal.

An advantage of using the group application approach over the baseline general permit is that the group would be able to negotiate the terms of its model permit with EPA. The baseline general permit is not negotiable.

The third option for industrial dischargers is to apply for the baseline general permit, also known as the notification of intent to be covered by the baseline general permit (NOI). The baseline general permit would include permit conditions for many types of industries. This permit application approach is potentially the easiest for an industrial stormwater discharger to use. The general permit application is expected to require only basic information about a discharger and does not require any sampling. The problem with this approach is that the application requirements, which are actually part of the baseline general permit itself, have not been finalized yet. While it would be desirable to see the baseline general permit conditions before applying for the permit, timing is a problem.

As of mid-January 1991, the proposed baseline general permit was still being reviewed by the Office of Management and Budget (OMB). After this review is complete, the proposed baseline general permit will be published in the *Federal Register*. EPA will take comments on the proposed general permit and then develop the final draft general permit, which will probably require OMB review again. If industries choose the baseline general permit option, they are banking on the final baseline general permit being available before November 18, 1991. If the baseline general permit is not available by November 18, 1991, a discharger who intended to use this application method could conceivably be in noncompliance after that date.

As of mid-January 1991, only 17 states had general permit issuing authority: Arkansas, Colorado, Illinois, Kentucky, Minnesota, Missouri, Montana, New Jersey, North Dakota, Oregon, Rhode Island, Utah, Washington, West Virginia, and Wisconsin. An industrial discharger that is considering applying for the general permit should contact its permit authority to find out whether the permit authority has or intends to get general permit authority.

COOPERATION PAYS OFF

The new regulations contain methods for characterizing a separate stormwater system and developing a stormwater management plan. Fifteen jurisdictions in the south San Francisco Bay area have had experience in developing and implementing a successful stormwater management plan.

Numerous field studies have shown that there are a variety of water-quality problems in various parts of the San Francisco Bay Estuary system, including the Lower South Bay. In these areas, elevated concentrations of several classes of water pollutants cause a variety of adverse effects on beneficial uses. The water-quality issues that have triggered the most concern are those related to toxic pollutants and their acute and chronic effects on aquatic ecosystems. The substances of particular concern in this area include heavy metals, pesticides and herbicides, and oil and grease. Coliform bacteria and sediments are also often cited as being related to water-quality and ecosystems issues in the receiving waters.

Thirteen cities, a county, and a water district in Santa Clara Valley, Calif., joined together to respond to NPS requirements promulgated as a result of the San Francisco Regional Water Quality Control Board's 1986 basin plan. The Santa Clara Valley stormwater management program was initiated by these jurisdictions to provide a sound technical basis for developing effective plans for reducing water-quality problems attributed to NPS runoff. An *ad hoc* NPS task force was formed to guide their collective efforts to develop an action plan that included conducting the required NPS studies and developing a strategy for selecting and implementing effective control measures.

As a result of numerous strategy meetings, members of the participating jurisdictions made the following decisions regarding implementation of the stormwater management program.

Cooperative approach. Members agreed to work together and function as a unified entity to effectively address the present and emerging NPS regulations and policies. The water district agreed to be the lead agency for the unified entity. All participants agreed to provide support in the form of personnel time, in-kind services, and actual funding. The task force serves as a steering committee for the control programs affecting all the jurisdictions.

Budgeting. Participants dedicated short- and long-term funding for the stormwater program.

Permit process. The participants agreed to act as co-applicants to obtain a NPDES permit for stormwater discharges.

More than 120 separate NPS control measures were considered during development of the stormwater management program. Of these, 68 control measures were judged to be most appropriate for Santa Clara Valley and were included in the final stormwater management plan. A monitoring program was also developed to help characterize NPS water quality and loads, to evaluate the effectiveness of the control measures, and to improve understanding of the cause and effect relationships affecting runoff water quality and loads.

The control strategy developed by the unified entity included permit application development, liaison with the regulatory agencies leading to the permit issuance, and compliance with the stipulations of the permit to be carried out over the 5-year term of the permit in accordance with an agreed-upon implementation schedule. The areawide stormwater management program is currently being implemented.

CLOSING REMARKS

The momentum for the promulgation of new federal stormwater regulations has been growing over the last 2 decades, and now we have reached the "end of the beginning" of federal regulations that address water quantity and water-quality aspects of stormwater discharges. It's the end of a long process to finalize a set of comprehensive requirements for some stormwater dischargers. But, there are still a lot of questions to be answered through guidance materials and creative problem-solving, and many issues are yet to be addressed in future stormwater regulations.

Although the 1990 stormwater regulations will be challenging to implement, the rewards will ultimately benefit the public. ■

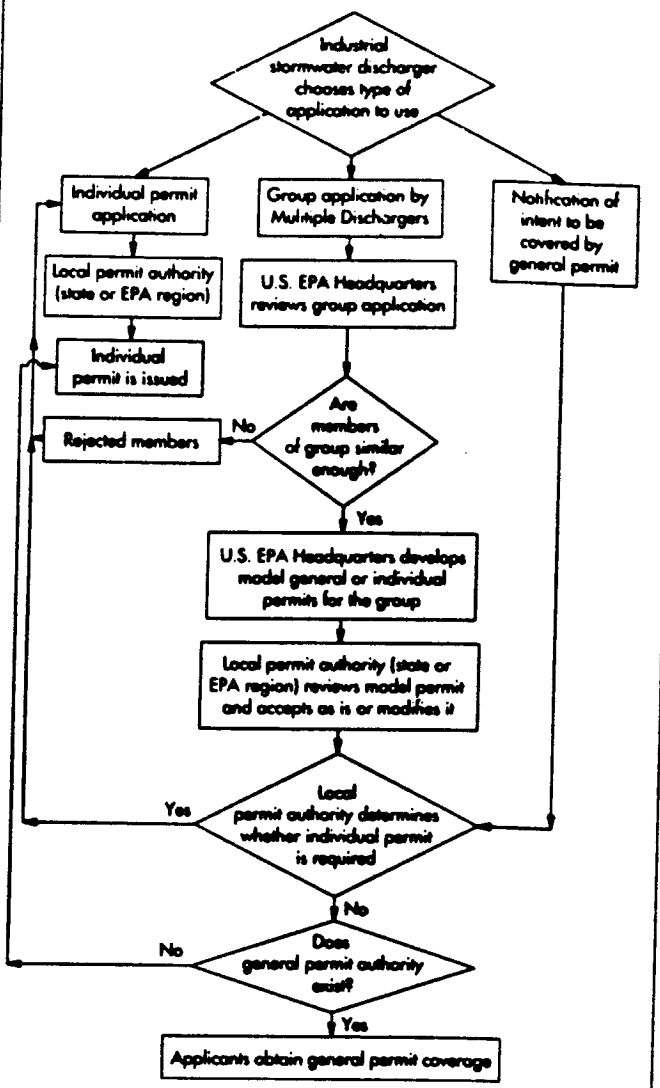
Figure 1—Obtaining an Industrial Storm Permit



runoff during warm-weather conditions. At selected NURP sites, stormwater discharges were analyzed for 120 priority pollutants. Results indicated that 77 priority pollutants were present, with 24 priority pollutants detected in at least 10% of the discharges sampled.

Although NURP resulted in a large database on the characterization of stormwater discharges across the nation, other studies, before and after NURP, have also made significant contributions, especially in local areas.

BRIEF HISTORY

In 1972, the CWA was passed, which prohibited the discharges of any pollution to navigable waters from a point source unless the discharge was authorized by a NPDES permit. Some exceptions applied. In 1973, EPA promulgated regulations exempting stormwater dischargers from permit requirements unless their discharges were identified as significant contributors to pollution. After court action, EPA issued a new rule in 1976 that provided for general permits for separate storm sewers in urban areas. No permit applications would be required in these cases, only notification of intent to be covered by the general permit. After additional court action, the stormwater rule was revised in 1979 and 1980 to require individual permit applications from all stormwater dischargers.

Between 1980 and 1987, several more rounds of proposed regulations and court actions ensued until Congress passed the WQA. This law is the basis for the current regulations. On December 7, 1988, EPA issued the proposed rule, and after reviewing more than 3000 pages of comments, the rule was revised and the final version was signed on October 31, 1990 (see Box).

MUNICIPAL VS. INDUSTRIAL

To satisfy the intent of the WQA, the new NPDES permit application regulations for stormwater discharges specify two types of stormwater permits: municipal and industrial. EPA defines a municipal separate storm sewer as municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains that discharge into U.S. waters. Industrial stormwater discharges include any conveyance that collects and conveys stormwater and that is directly related to manufacturing, processing, or raw materials storage areas at an industrial plant.

Industries affected include many industrial categories called standard industrial classifications. Along with industries, most municipalities will be required to obtain industrial permits, because several types of facilities typically owned and operated by municipalities are involved in industrial activities and, therefore, will be subject to this regulation. These facilities include, but are not limited to, wastewater treatment plants serving more than .04 m^3/s (1 mgd), certain kinds of recycling centers, certain transportation facilities, landfills that accept or have accepted industrial waste, and construction sites with an area of disturbance greater than 2 ha (5 ac). Because industrial facilities have no lower size limit, all municipalities that have these kinds of operations will be required to submit industrial permit applications, regardless of their population. It is likely that if municipalities have these kinds of operations and are also classified as medium or large, two different permits may be required because there are different philosophies regarding the types of stormwater controls municipalities and industries will be required to implement.

VOL 12 2 3851
R0057143

Municipal separate storm sewer systems will have to reduce the discharge of pollutants to the maximum extent practicable (MEP). A MEP program would use management practices, control techniques and system, design and engineering methods, and other appropriate provisions to accomplish this goal. EPA has indicated that, given the material management problems associated with end-of-pipe controls, management programs that are directed at pollution sources are more practical than end-of-pipe controls. Municipal systems must also prohibit non-stormwater discharges into storm sewers and, where necessary, have water-quality-based controls.

On the other hand, industrial dischargers must implement best available technology (BAT) and best conventional pollutant control technology (BCT) to control their stormwater discharges. BAT treatment requires maximum economically achievable pollution reduction, and primarily applies to priority pollutants—metals and organics. BCT is similar to BAT, but is applied primarily to conventional pollutants such as biochemical oxygen demand, total suspended solids, pH, and fecal coliform. Industrial discharges must also have water-quality-based controls where necessary.

All industrial dischargers must now obtain their own permits rather than be included as part of a municipal permit. This is a major change in the final regulations from the proposed version. However, because stormwater from industrial facilities may be a major pollutant contributor to municipal separate storm sewer systems, municipalities must develop controls for industrial stormwater discharges in their stormwater management program.

All industrial dischargers covered by these regulations must notify the operator of the municipal separate sewer system receiving the discharge no later than May 15, 1991. The municipality is required to list the industrial dischargers to its system in its own permit application. EPA anticipates that the municipal stormwater management plans will include controls on industrial stormwater discharges to the municipal system, but that as with all NPDES permits, responsibility and liability is determined by the discharger's compliance with the terms of the permit. A municipality's responsibility for industrial stormwater discharged through their system is governed by the terms of the permit issued. Alas, municipalities have not been completely absolved of their responsibility for industrial stormwater discharges.

NPDES Permit Application Deadlines for Discharges

	Part 1 Application	Application Part 2 Review	Application
Municipal			
Large municipalities	November 18, 1991	90 days	November 16 1992
Medium municipalities	May 18, 1992	90 days	May 17, 1993
Industrial			
Individual	One-part application—due November 18, 1991		
Group	March 18, 1991	60 days	12 months after Part 1 application is approved
General permit, notification of intent to be covered	The general permit, when issued, will establish a date when a discharger must submit a notice of intent to be covered by the general permit.		

Documents Expected from EPA

- Municipal and industrial permit application guidance is expected to be released in February 1991.
- At press time, the implementation rule, which is to include a proposed baseline general permit and other materials related to permit applications, was still under review by the Office of Management and Budget. The implementation rule will be published in the *Federal Register*.
- Implementation guidance, or permit writer's guidance, is not expected before the end of 1991.

EPA is planning to issue a guidance document addressing municipal permit applications that may address this issue further.

MUNICIPAL APPLICATIONS

There are two types of municipal permit applications covered by the new regulations: one is for large municipalities with a population greater than or equal to 250,000, and another is for medium municipalities with a population between 100,000 and 250,000. The only difference in applications for these two categories is the deadline for submittal; medium municipalities are allowed 6 months longer than large municipalities to complete Part 1 of the application. Forty-seven counties that have urban characteristics are included on the list of jurisdictions that must submit municipal applications.

A permit authority—an EPA region or a NPDES authorized state—can designate additional municipal separate storm sewer systems to submit permit applications. This decision would be based on such criteria as the interrelationship with other systems currently required to submit permit applications, or whether a system is part of a larger, regional stormwater management authority.

If the 1990 Census reveals that additional municipalities have a population greater than or equal to 100,000, these cities will be required to submit permit applications for their stormwater discharges. Notification will appear in the *Federal Register*. These cities will have 1.5 years to complete the Part 1 application and another year to complete the Part 2 application. Their clock starts ticking after notification in the *Federal Register*. Cities with a population of less than 100,000 when results from the 1990 Census are finalized can petition their permit authority to be removed from the rule.

Part 1. Part 1 of the stormwater permit application includes a description of legal authority to address separate storm sewer systems, an inventory of outfalls and details about drainage areas, a field screening program to detect illicit discharges, a plan for a representative sampling program to be implemented in Part 2 of the application, and a description of existing stormwater controls.

For the field screening program, two options are available for determining where to look for illicit dischargers. One method is to select major outfalls

VOL 12 2 3852

R0057144

Changes From the December 7, 1988 Proposed Rule

Significant items that have changed from the proposed version are as follows:

- The definition of a municipality was changed to include additional jurisdictions such as counties. In addition, the EPA Regional Director may at any time add other municipalities to the list that require stormwater discharge permits, such as smaller municipalities that discharge their stormwater to a larger system.
- No field screening is required in the Part 2 permit application for municipalities.
- Industrial dischargers are to obtain separate permits, even if they discharge into a municipal separate stormwater system.
- The number of standard industry codes (SICs) requiring permits was reduced to try to focus attention on sources that have more potential for contributing to water-quality degradation.
- Increased flexibility was incorporated into the monitoring programs, such as the number of sites that need to be monitored.
- Construction activities requiring permits are now for projects greater than 2 ha (5 ac) instead of projects greater than 0.4 ha (1 ac).
- Oil and gas activities were clarified.
- Deadlines for permit application submittal were changed.

for screening. The other is to place a 0.25-mi square grid over a map of the area in question and select the most downstream location in each box. If flow is detected during dry weather at a screening location, sampling is required. Colorimetric analysis methods may be used. The maximum number of locations to be screened is 250 for medium municipalities and 500 for large municipalities.

Part 2. Part 2 of the stormwater permit application includes a list of industrial dischargers to the municipal separate storm sewer system, even though they will have separate NPDES permits; quantitative data from the representative sampling program developed in Part 1; and a stormwater management plan to be implemented during the term of the permit. An assessment of effectiveness of the stormwater management plan and a fiscal analysis of necessary capital and operations and maintenance expenditures are also included in Part 2.

EPA has indicated that it will not develop application forms for municipal permit applications. However, this does not preclude permit authorities from developing forms.

If a municipality has combined sewer overflows, it can petition the permit authority (the NPDES authorized state or EPA region) to effectively reduce its population proportional to the length of combined sewers as a fraction of the total of combined sewers plus separate sewers (see final rule for procedure). A change in population could affect how or whether a municipality is regulated.

INDUSTRIAL APPLICATIONS

Industries that are required to obtain permits include manufacturing facilities where stormwater comes into contact with raw materials or wastes, construction sites disturbing greater than 5 ac of land, landfills that accept industrial waste, junkyards, wood treaters, power plants, mining operations, some oil and gas operations, airports, and certain other transportation facilities. Industries that discharge stormwater to combined sewers are excluded from the rule. As shown in the Figure, industries can apply for stormwater discharge permits in one of three ways: an individual permit application, a group permit application, and notification of intent to be covered by a general permit (hereinafter called a general permit application).

The one-part individual permit application is the most straightforward option. An applicant would conduct the necessary sampling, collect the required information, and fill out the necessary forms. After permit authority review of the application, permit conditions would be negotiated and a permit would be issued. Significant items required in an individual permit application include a site map, estimate of impervious area and total area drained by each outfall, narrative description for current and historical (3 years) significant materials usage, description of existing structural and nonstructural controls, certification that outfalls have been tested or evaluated for non-stormwater discharges, information on significant leaks or spills of toxic or hazardous materials in the last 3 years, and comprehensive sample data for one storm.

A group permit application is more complex administratively than an individual application, but it may be less costly because of reduced sampling requirements. To implement a group application, industrial stormwater dischargers with sufficiently similar process characteristics would form a group and appoint an administrator. The administrator would collect basic information from members of the group and prepare the Part 1 permit application. The Part 1 application would identify each member, summarize the industrial activities of each member, significant materials stored outside and materials management practices of each member. In addition, 10% of the members for a group with more than 10 members would be required to conduct a sampling program, to be implemented during Part 2 of the application, equal to that required for an individual permit application. A group must have at least four members to submit a group permit application. For groups between four and ten members, 50% of the members must conduct sampling programs during the Part 2 application.

The Part 1 group application is to be submitted directly to EPA headquarters by March 18, 1991, for review. EPA would send copies of the Part 1 permit application to the respective EPA region or state permit authorities and has 60 days to review the Part 1 application. During this review, some members may be rejected from the group if EPA determines that they are not similar enough to the majority of the group members. If this happens, rejected members then have 12 months to submit an individual application. If certain members who were designated to do sampling during Part 2 are rejected during Part 1, or if they have to withdraw from the group for some other reason, this could create a problem for the group. Therefore, it may be in the group's interest to identify more than 10% of the members to do sampling in case these types of problems are encountered.

After the group members designated to sample finish their data collection and the Part 2 application is complete and submitted to EPA headquarters, EPA would develop a model general and/or individual permit for the group, as appropriate. This model permit would then be forwarded to the appropriate permit authorities. The state or EPA region would use the model permit as is or modify it before notifying the group members in their

The New Federal Stormwater Regulations

GAIL B. BOYD
Vice President,
Woodward-Clyde,
Oakland, California

Editor's Note: This is the third in a series of PUBLIC WORKS articles on EPA's new National Pollutant Discharge Elimination System (NPDES) permitting requirements for municipal separate storm sewer systems. The first article (December 1990) described the physical processes that combine to cause stormwater related pollution problems, and it presented an overview of EPA's emerging regulatory program for controlling stormwater quality problems on a nationwide basis. The second article (January 1991) article described EPA's new regulations that apply to municipal stormwater conveyance systems, and suggested a step-wise approach that municipal NPDES permit applicants can use to structure their efforts to develop the information and plans required to apply for and comply with stormwater discharge permits. This third article discusses the final version of the new federal NPDES stormwater regulations and the challenges that municipalities will face as they develop stormwater management programs and control measures.

EPA will soon provide guidance documents that will explain the new federal stormwater regulations' requirements and will suggest methods for developing the information required from permit applicants. The purpose of this article is to provide municipal permit applicants with some insights that will help put EPA's guidance in perspective for a given community.

The articles in the December and January issues of PUBLIC WORKS discussed various aspects of municipal stormwater pollution assessment and control in the context of both technical/environmental problems and EPA's new nationwide initiative to require permits for discharges from stormwater conveyance systems. At the time those articles were written, the new regulations had not been finalized or signed into effect. Now that they have been, it is possible to discuss the following topics in more detail:

- What cities and counties will be affected?
- What do the new regulations intend to accomplish?
- When are the affected municipalities required to act?
- How do the final regulations differ from the draft that was published in December 1988?
- How are the results of the required studies to be used by the applicants and the regulatory agencies?

Who will be affected? The 1987 revisions of the Federal Clean Water Act required EPA to develop and implement regulations that apply to both "municipal" and "industrial" dischargers of stormwater. The regulations for municipal and industrial dischargers differ from one another in several significant ways, although both make use of EPA's NPDES, which has been used primarily for permitting wastewater and treatment plant dischargers. Here, we will deal only with municipal stormwater systems. However, it is important to note that EPA uses the term "municipal" in ways that differ from common usage, so it is necessary to make direct reference to the regulations (*Federal Register*, November 16, 1990, pages 47990 through 48091) to determine whether and/or how a given city, county, or other type of urbanized area is likely to be included. This article focuses on municipally owned and operated stormwater conveyance systems that meet EPA's definition of "separate storm sewer systems." Combined sewer systems (i.e., those that are intended to convey both stormwater and municipal sewage) are dealt with by other regulations and programs.

The new regulations will apply first to "large" and "medium" municipal systems, where the population served by the system is used to classify dischargers and to define both the corresponding regulatory requirements and the schedule for filing permit applications and implementing compliance programs. In general, large municipal separate storm sewer systems are those serving populations of 250,000 of more, whereas medium systems serve populations of 100,000 or more but less than 250,000. Again, the definitions in the regulations are complex and must be consulted directly. This will be especially important for smaller communities that might become recruited to participate as co-applicants by neighboring medium or large cities, and for smaller cities that discharge stormwater into receiving water bodies that are known to be suffering water pollution problems. Communities that have medium or large municipalities as neighbors or that share the use of regional-scale drainage systems should review the regulations carefully to develop an understanding of the pros and cons of joining as co-applicants. EPA regional offices and most state-level water pollution control agencies have developed their view of which cities, counties, and other urban areas are affected and how they plan to deal with them. It is incumbent upon the potential applicants to be strategic here, as well.

What do the regulations intend to accomplish? EPA's published notices in the December 7, 1988, and November 16, 1990, editions of the *Federal Register* provided valuable insights regarding their intentions in establishing programs for assessing and controlling water quality effects of municipal stormwater system discharges. At the risk of introducing some unintended bias through the process of abbreviating and simplifying EPA's lengthy commentaries, it would appear that the following are three important intentions:

- Applicants are intended to develop an elementary understanding of their respective stormwater conveyance systems and the associated water pollution problems.
- Applicants are intended to develop some of the basic information they need to begin what, for most communities, will be a long-term process of planning and implementing various types of control measures to reduce pollutant discharges.
- Applicants are intended to begin the process of working with regulatory agencies to monitor and control pollutants carried by stormwater conveyance systems.

Review of EPA's published commentary and the language of the regulations themselves indicate that the agency recognizes that, in most communities, the first steps toward implementing effective stormwater controls on a large scale will require a considerable degree

VOL 12 2 3855
R0057147

of introspection—i.e., getting to know the local system at several levels (e.g., legal, institutional, physical, environmental). These new regulations require many municipalities to begin that process.

Introspective Questions

Again, at the risk of introducing some bias through the process of abbreviation and simplification, the new regulations can be viewed as requiring applicants to respond to the following introspective questions:

- Who are you? This will involve developing a clear, concise description of the applicant agency and its relevant legal institutional characteristics. This will be fairly straight-forward for single-city applicants, but it could be challenging in cases where there are many co-applicants and where there are complex physical and/or legal/institutional relationships among neighboring cities, counties, flood control agencies, and/or special districts. In many cases, neighboring agencies will want to pull together and function as co-applicants. There are some distinct advantages to doing so, but there may be some important disadvantages as well. This is certainly an area where it will pay to be thoughtful and strategic, especially in the light of scheduling constraints. Municipalities that have joined together as co-applicants have found the process of developing prudent inter-agency agreements to be challenging indeed.
- What is your storm drainage system like? This will involve defining and mapping watersheds and corresponding major storm drainage facilities. This is usually fairly straight-forward, but it could be challenging in areas that have little topographic relief, in systems that serve numerous communities, and in very old parts of some cities (e.g., where existing maps are inadequate or virtually non-existent). In typical cities, it will be necessary to field check maps to verify their credibility.
- What pollutants get into your system? Where do they come from? Where do they go? Such questions are easy to address in general terms but will generally be difficult to answer in specific terms. In fact, the corresponding answers are central to EPA's overall program, so simplistic, generic responses will not suffice. The regulations (and EPA's forthcoming guidance manuals) provide suggestions on how to survey municipal stormwater conveyance systems and their respective watersheds to identify and characterize potential sources of pollutants (including certain land uses and activities, illicit connections of wastewater sewers, and illegal dumping of contaminants).
- What do you presently do to minimize stormwater related pollution problems? Here, applicants are given the opportunity to take credit for various facilities, programs, and activities that help control potential water quality problems associated with stormwater discharges. Most cities have a variety of facilities, programs, and or activities that provide some degree of stormwater quality control, despite the fact that they were intended for some other purpose. Examples might include various public programs regarding hazardous materials disposal, recycling and litter control programs, street cleaning programs, erosion control and grading ordinances and inspection programs, storm sewer inspection and maintenance programs, and catch basin cleaning programs. Also, the detention, retention, and or infiltration facilities that are provided in some drainage systems to alter runoff hydrographs (for flood control and or stream channel protection) can often provide water quality benefits, as well (or might be easily modified to do so).
- What else do you need to do? This is perhaps the most challenging question of all. On the one hand, applicants have the freedom to suggest control strategies that they believe will be well suited to local conditions and needs. On the other hand, the scale of the studies required by the regulations will generally not be adequate to provide enough information or stimulate the insights that are needed to develop and evaluate good control strategies. Some cities and counties have responded pro-actively by beginning with the question: "What do I have to know to come up with practical, effective, and well-balanced strategies for stormwater pollution control?" They have then conducted studies designed to answer that basic question. Another basic un-asked question is "How much control is enough?" Neither the Clean Water Act nor the new stormwater regulations provide much guidance to applicants or to regulators. Yet this is the crucial question for people who are charged with managing limited public works budgets. We anticipate that the next several years will see much debate over that question.
- What additional authority do you need to obtain? This will involve determining the applicant's present level of authority and developing a strategy for supplementing any pertinent shortcomings. Upon surveying their local charters and ordinances, some cities and counties have found that they have all the authority they need. For example, some have dredged up long- forgotten codes that were originally intended to protect urban drainage courses from impacts by horses, or creeks from impacts by livestock and farming practices. On the other hand, some cities and counties have been surprised to discover that they do not have the ability to control improper discharges or dumping into their stormwater conveyance systems.
- What is the schedule? "Large" municipalities (as defined by the regulations) are required to act first. They have one year (from November 16, 1990, the official date of publication in the *Federal Register*) to prepare and submit their Part 1 permit applications and a second year to prepare and submit their Part 2 applications. "Medium" municipalities are on a parallel track, but the corresponding due dates for Part 1 and Part 2 submittals are delayed by six months. Figure 1 summarizes the respective schedules.

The final regulations reflect a few specific changes in the information required for Parts 1 and 2 of the permit applications, as outlined in Tables 1 and 2 of the first article of this series, which ran in the December 1990 PUBLIC WORKS. Information Required for Part 1, as listed in Table 1, is amended as follows:

Under (iii) **Source Identification**, "Description of corresponding watersheds for each major outfall" is changed to read "Description of watersheds."

Added to the information required is:

(vi) **Fiscal Resources:** Description of financial resources available for completing Part 2 of permit application. Description of overall financial resources for existing stormwater programs (e.g., budget, assets, indebtedness, funding sources).

Information for Part 2, as listed in Table 2, is amended as follows:

Under (iii) **Characteristics Data**, "Sampling and analysis of 5 to 10 representative outfalls to characterize overall system" is changed to read "Sampling and analysis to characterize overall system."

Not Enough Time?

The regulations indicate that the NPDES administering agency (which will be an officially-designated state water pollution control agency in most cases, or the Regional office of EPA in other cases) will have a period of 90 days to review the Part 1 application and to approve or deny the applicants' proposed sampling plan. Because this sampling plan is intended to guide the Part 2 activities, it would appear that the agency's review period could effectively detract from the applicants' performance schedule. This could be problematic for applicants that are pressed for time (e.g., those that begin their Part 1 programs late, those that have complex institutional arrangements and or numerous co-applicants, those that have especially complex systems, those that have systems that are not well understood and or well documented at present, those that are located in areas with challenging meteorological/

VOL 12 2 3856

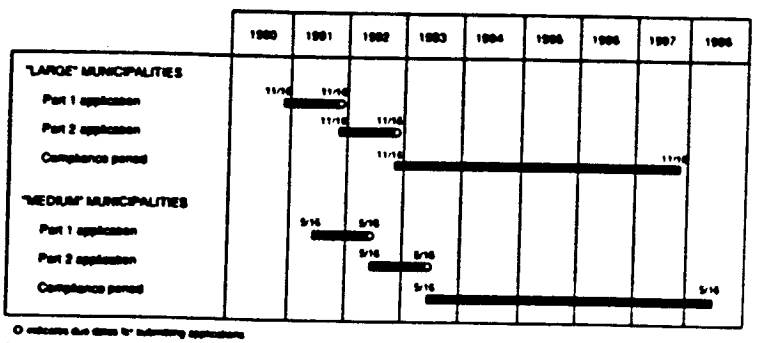
R0057148

hydrological conditions, and those that are using relatively inexperienced personnel to obtain the required technical, institutional, and legal information). Such applicants will need as much time as possible to do the work called for in Part 1 and to prepare a good sampling plan to guide Part 2 activities. Most applicants will also need a full year to conduct the field work, data analyses, and planning efforts required for the Part 2 application. Therefore, the loss of up to 90 days anywhere in the schedule could pose a significant problem for many municipal applicants. Given the fact that most state water pollution control agencies and EPA Regional offices are not well prepared to respond to this new regulatory program, it is difficult to imagine how applicants will be able to stay on schedule and obtain the necessary degree of regulatory oversight and guidance.

How do the final regulations differ from the 1988 draft? When EPA published its draft stormwater NPDES regulations (*Federal Register*, December 7, 1988), it provided a great deal of historic, technical, philosophical, and legal/institutional background information. It also solicited review and comments on numerous major and minor points, in the interest of developing final regulations that would be clear, concise, reasonable, practical, and as free as possible from inconsistencies and ambiguities. During the official 90-day review period, EPA received about 3,200 pages of comments from municipal and industrial dischargers, technical and professional organizations, industrial associations, environmental groups, and other special interest groups. Most of these were critical, but some provided good suggestions for modifications. As a result of these official comments and continuing commentary from interested parties, EPA worked to respond to comments and to revise and improve the regulations leading toward the final version that was published in the November 16, 1990, edition of the *Federal Register*.

People familiar with the 1988 draft regulations will see that most of the changes are in the preamble materials and that there are some important procedural changes in the sections pertaining to industrial stormwater dischargers. The requirements that apply to operators of municipal separate storm sewer systems were revised in several important ways, but still less than many people had expected. Some useful clarification was provided in several important areas, but the general content and even the schedules of the two-part application process were changed very little. Perhaps the most important changes in the municipal regulations were the following:

- The definitions of "municipalities" that are required to apply were expanded to include 47 designated counties that have major urban populations and certain other communities that are logical extensions of the designated municipalities. This change is, of course, very important to communities that had thought they would not be involved.
- The final regulations require less data on land uses and population (e.g., the data can be compiled for the municipality as a whole, not for each respective watershed).
- The final regulations provide a "cap" on the maximum number of sampling locations for the field screening analyses (500 locations for large municipalities, 250 for medium).
- An alternative (optional) scheme for defining sampling locations was provided for use by applicants in conducting the field screening analyses called for in Part 1. The originally-defined scheme required applicants to study "major outfalls," but the technical complexities of identifying sampling locations could have posed a challenge to applicants and regulators alike. The newly-described optional scheme might be viewed as being rather arbitrary in some ways, but it is likely to lead to better investigative results in many systems, especially those where the original definitions of major outfalls would have led to inappropriate selections of sampling locations.
- Applicants are now required (in Part 1) to describe the financial resources that are currently available to conduct the work called for by the Part 2 application. Applicants are also required to describe their budget for existing stormwater programs, including financial resources, sources of stormwater funds, and overall assets and indebtedness.
- Some of the field studies that had been required in Part 2 were moved to the permit compliance period (for example, the requirement for a second-phase screening for illicit connections was deferred). Other requirements for Part 2 field studies were also changed somewhat (e.g., first flush samples will not be required at most sampling stations, the number of locations and storm events to be sampled was increased).
- The relationship between the municipal applicants and the industrial facilities that discharge stormwater into their respective municipal separate storm sewer systems was revised significantly. Now industries will be required to obtain permits directly from EPA or state water pollution control agencies, but not from the municipalities. However, such industries will be required to notify municipalities of their discharges and designated activities.
- The industrial inventory that had been required in the Part 1 application was moved to Part 2, thus giving applicants more time to compile the lists.



■ **FIGURE 1. Permit application and compliance schedule.**

How will applicants and regulators use the results of the required studies to select and implement water quality control measures? This is perhaps one of the most challenging aspects of the municipal stormwater programs that will derive from this new regulatory initiative. In an ideal case, the applicant would do the following:

- Follow EPA's requirements and collect the information called for by the regulations.
- Collect whatever additional information is needed to develop an understanding of water pollution problems, pollutant sources and other causative factors, and relevant legal/political/institutional information that would help define local opportunities.
- Evaluate and select among a variety of control measures that appear to be relevant to the identified causes, problems, and practical constraints in the specific area.
- Develop strategic plans that define which measures will be implemented, when and where they will be imple-

VOL 12 2 3857

R0057149

mented (perhaps in a phased manner), and who will be the responsible parties.

The above-listed planning steps are idealized. Most municipalities will need to perform them, but will also have to deal with other issues that are not required by the regulations and are not explicitly dealt with in EPA's guidance documents. The following are examples of issues that most municipal applicants will have to deal with in their efforts to develop practical management plans for improving stormwater quality:

- Applicants will have to make some partly-technical, partly-subjective decisions about the focus, scale, and timing of the management plan they will offer to implement. Existing information and new information developed through field studies will help define pollutant sources, quantities, and impacts, but there is no prescribed process for determining "how much is enough" in terms of controls. At present, EPA has no target values to guide municipal applicants (i.e., there are no discharge standards, there are no specified control technologies). Applicants are merely told to implement "Best Management Practices" (which are not clearly defined) and to employ them to the "Maximum Extent Practicable" (which is also not clearly defined). Applicants will have to decide which pollutant control measures and which sources are the most likely to be practical and cost-effective, and what level of intensity of control (which translates to budget) is appropriate. This will require subjective judgment, because it implies striking a balance between controlling program costs and satisfying the expectations of regulatory personnel and interested environmental groups.
- Applicants will have to develop strategic ways to monitor their proposed control programs to be sure that they are being properly implemented/operated/maintained and to be sure that they will get credit for complying with NPDES permit stipulations. This matter of what to monitor, how to obtain relevant information, and how to use that information to demonstrate regulatory compliance will be a challenge. Most stormwater controls (i.e., Best Management Practices) do not lend themselves to being monitored in simple "before and after" terms, except perhaps at great expense. Therefore, applicants will want to be strategic in collecting indirect evidence of their control efforts.
- What control measures are available? Experience has shown that most municipalities could significantly reduce stormwater borne pollutant loads by implementing a variety of non-structural control measures, and supplementing these with structural controls only in specific locations where local conditions present special opportunities. In most cases these non-structural controls should be carried out by the general public, commercial institutional/industrial interests, and public agencies working together in a well-guided program. Controls can be categorized in different ways; it is useful to categorize them in terms of how they work, but also in terms of how they are to be implemented.

Important Categories

If one were to categorize controls in terms of how they work, two important categories would be:

- Source controls. These work in a pre-emptive way. Pollutants are prevented from getting into the stormwater in the first place. Examples would include educational programs that tell people not to dispose of spent oil and antifreeze via the storm sewer inlet, and programs to clean pollutants out of catch basins before they can be carried away by storm runoff.
- Treatment-based controls. These work after-the-fact. They involve treating stormwater to remove pollutants that have already contaminated the runoff. They are inherently expensive, but they are more predictable in their overall performance, because they do not rely as much on human behavior.

EPA has repeatedly expressed the view that it will look favorably upon stormwater management programs that aggressively implement source controls, and it does not expect municipalities to implement treatment-based controls as a first step in pursuing improved stormwater quality.

If one were to categorize controls in terms of how they are to be implemented, three important categories would be:

- Education. This involves telling people what to do and what not to do to prevent stormwater pollution. The effectiveness of such controls depends heavily upon identifying the right "audience," convincing them of the need to change their behavior, and explaining what they are to do (and not do). Some educational programs can be very general and can cover a broad spectrum of people and deal with a broad spectrum of recommended practices. It will usually be necessary to supplement the general program(s) with additional educational efforts that target specific audiences and provide very specific recommendations. Experience has shown the need to use all types of media (e.g., brochures, posters, lectures, TV, radio, events).
- Regulatory controls. This generally involves passing new or more specific municipal regulations, conducting inspections/surveillance to identify cases of non-compliance, and enforcing applicable regulations. Some such controls would focus on existing problems (e.g., illicit connections with wastewater sewers, illegal dumping); some would be preventive (e.g., controls on new construction).
- Public agency activities. This category would include activities by public works programs (e.g., catch basin cleaning, storm sewer cleaning, litter control, street sweeping), planning and building departments (e.g., erosion and grading controls, land use and zoning controls, environmental impact studies), park departments (e.g., leaf and debris disposal, application of pesticides and fertilizers), and general services agencies (e.g., vehicle repair, building maintenance, management of wastes from all types of maintenance activities).

At the present state of the art, it will be very difficult for applicants to select among the many specific controls that might be useful in their area. This is partly because of the previously mentioned problem of not being told "how much is enough," and partly because there are so few sources of information concerning the unit costs of such controls and their corresponding effectiveness in solving pollution problems. □□□

SCOPE OF RECOMMENDATIONS 59
STRATEGIES CONSIDERED AND IN NEED OF FURTHER ANALYSIS .. 60
OVERALL RECOMMENDATIONS 61
Recommendation 1: Integrate impervious surface reduction into policies and regulations. 62
Recommendation 2: Establish growth management policies that encourage infill of urban areas and reduce urban sprawl 67
Recommendation 3: Provide a public transit system and other alternative modes of transportation that reduce the need for streets and parking. 71
RECOMMENDATIONS FOR VEHICLE-ORIENTED PAVEMENT 74
Recommendation 4: Develop standards for narrower residential streets with reduced, but adequate, parking opportunities ... 74
Recommendation 5: Use pavers and other pervious surfaces for low use areas such as overflow parking and emergency access roads 77
Recommendation 6: Narrow alley width, use alternative surfaces for alleys, and/or design alleys to drain to vegetated strips or central drains 82
Recommendation 7: Encourage cooperative parking such as joint (combined), shared, and coordinated parking 84
Recommendation 8: Encourage underground or under-the-building parking and the construction of multi-storied parking structures 87
Recommendation 9: Develop flexible parking regulations related to parking region-wide that limit the amount of impervious surface, while still providing for parking needs 90

VOL 12 2 3863

EXECUTIVE SUMMARY

WHAT ARE IMPERVIOUS SURFACES?

Impervious surfaces are surfaces which cannot be effectively (easily) penetrated by water. Examples include pavement, buildings, and compacted soils.

WHY STUDY IMPERVIOUS SURFACES?

As part of our development pattern in the Northwest, we replace natural land covers with new surfaces such as buildings, streets, parking lots, driveways, and sidewalks. These new surfaces are impervious to our rains. They block the rain (stormwater) from soaking into the ground and increase the amount of water running off into streams, lakes, and the marine waters of Puget Sound (Figure 1, page 2).

A growing body of scientific evidence indicates that there is a direct link between impervious surface coverage and degradation of streams (Schueler, 1994). Even relatively low levels of impervious surface coverage (10 to 15 percent of the total land area) in a watershed (drainage basin) can make it difficult to maintain stream quality. Greater impervious surface coverage (15 to 20 percent of total land area in a watershed) has been linked to dramatic changes in the shape of streams, water quality, water temperature, and the health of insects, amphibians, and fish that live in these streams. Based on zoning and population estimates, the total amount of impervious surface coverage in three of our local drainage basins (Figure 2, page 3) is expected to increase from an estimated 14 percent to 29 percent of the total land area, with corresponding impacts to our local water resources.

Keeping the rain (stormwater) on the surface instead of letting it soak into the ground depletes the groundwater supplies upon which Olympia and other Thurston County communities (Figure 2, page 3) depend for drinking water. When less water soaks into the ground, groundwater levels drop, less groundwater is available to supplement summer flows in streams, and stream levels may fall below the minimum needed to support fish or recreation and other uses. In order to minimize the consequences of impervious surfaces, we build expensive stormwater runoff storage and treatment systems. Most current development practices and local policies and regulations aim to deal with and reduce the impacts of impervious surfaces, but fail to address the source of the problem.

As the Northwest's population grows, impervious surfaces also will increase. It's important to act now to identify feasible and practical ways to reduce impervious surfaces. Acting now can reduce the long-term development and environmental costs of growth and help keep our water resources healthy for the future.

ELEMENTS OF THE STUDY

The Impervious Surface Reduction Study (ISRS) was conducted to identify possible strategies for impervious surface reduction in Olympia, the surrounding North Thurston County Urban Growth Management Area (North Thurston UGMA) (Figure 2, page 3), and other locations. This report summarizes the results of the study and offers recommendations based on study results. The study consisted of three basic tasks: project management, involvement and education, and technical and policy analysis.

Project Management

The City of Olympia's Public Works Department, Water Resources Program, provided project leadership with support and participation from the cities of Lacey and Tumwater, and Thurston County. Funding for the study was provided by the Washington Department of Ecology through a Centennial Clean Water Fund grant and Olympia residents through their Storm and Surface Water Utility.

Involvement and Education

The study was guided by both steering and citizen advisory committees. These committees were comprised of neighborhood, development, and business representatives, and natural resource management experts from both the public and private sectors of the Olympia area community (Project Team, page i). Other avenues for involving and educating the local community and interested parties included a needs assessment; community forums, displays, conferences, and presentations; distribution of fact sheets, buttons, reports, and research summaries; and media coverage. Approximately 50 people were directly involved in the research and development of the study's recommendations. Approximately 1,600 people from all over the United States were informed about the study and invited to participate or receive more information.

Technical and Policy Analysis

In order to better understand the problems with impervious surfaces and the costs, benefits, and incentives associated with possible reduction strategies, various technical and policy issues were analyzed. The analysis consisted of several tasks including: literature and policy review, demonstration projects, basin and site coverage assessment, parking analysis, and other research (Chapter 2, page 31).

VOL 12 2 3873
R0057165

STUDY RESULTS

Summary of Results

Changes in attitudes, policies, and regulations were perhaps the greatest results of the study. Early on, the project team realized that impervious surface reduction was not an explicit goal of Olympia's policies and regulations, nor was it an explicit goal for many other local governments. Although there was some recognition that impervious surface reduction would occur as a result of growth management and regional transportation planning, it became apparent that changing attitudes, policies, and regulations could be a significant first step in reducing impervious surfaces.

Increased Awareness of Impervious Surfaces

Through public involvement and education, technical assistance, and sharing of the study's results, it is expected that the local community's awareness of the problems and solutions associated with impervious surfaces has increased. Local, regional, and national media coverage has brought the study to the attention of local jurisdictions in other Washington communities, as well as in other states. Ten presentations to local groups and two community forums were conducted to share the study's findings with members of the local community. In addition, eight briefings were given to other departments or groups within Olympia's city government to explore and coordinate policy changes resulting from the study.

Policies Changed

Staff participated in the revision of the city's parking, street, and development standards and shared early results of the study with other local jurisdictions. By taking advantage of these implementation opportunities before the study was complete, many lessons were learned about balancing impervious surface reduction with other public goals. The public goals considered during development of the recommendations are listed under the incentives and barriers sections of Chapter 3, Recommendations for Olympia, North Thurston County Urban Growth Management Area, and Other Locations (page 59).

Opportunities for Reduction Identified

In order to identify what types of land use and impervious surfaces provided the greatest potential for reduction, the basin and site coverage assessment was conducted. The assessment demonstrated that vehicle-oriented pavement, including streets, driveways, and parking lots, offer the greatest opportunity for reduction. It also demonstrated that commercial/industrial and high density residential land uses in the Olympia area contain the most vehicle-oriented impervious surfaces.

VOL 12 2 3874

R0057166

EXECUTIVE SUMMARY

To further determine practical ways to reduce vehicle-oriented impervious surfaces, a parking analysis was conducted. Informational interviews and field visits expanded our understanding about how to reduce the overall area dedicated to parking, without compromising the viability of local businesses or increasing development costs. In recognition of the coverage assessment and parking analysis findings, several of the study recommendations address streets and parking. (Recommendations for Reduction, page 7).

Data Gaps Identified

In the Thurston County area, we currently have limited knowledge about our impervious surface coverage, aquifer recharge areas, and groundwater system. This lack of data limited the scope of the study and the ability to provide location-specific recommendations. The study brought to light additional reasons for making better use of development tracking systems and for funding and conducting groundwater and other research.

Recommendations to Achieve a 20 Percent Reduction in Future Impervious Surfaces

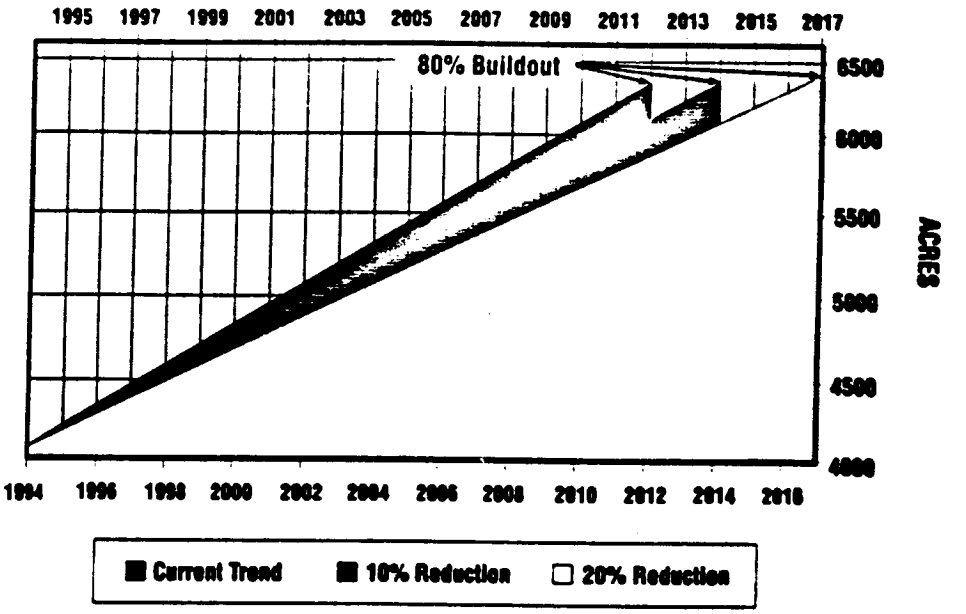
A 20 percent reduction in impervious surfaces associated with new development is expected in Olympia and the North Thurston UGMA if the study's recommendations are implemented by the cities of Olympia, Lacey, and Tumwater, and Thurston County. However, each community needs to determine for themselves the recommendations and specific strategies that work for them, given their specific mix of public goals and community character. Other jurisdictions are highly encouraged to involve citizens, businesses, and members of the development community in reducing impervious surfaces. A 20 percent reduction is a feasible and practical goal for Olympia and will not require exceptional changes in the Olympia community.

It is important to remember that a 20 percent reduction does not solve the long-term problems with impervious surfaces. This study's recommendations only address future development, and do not address existing impervious surfaces or problems. A 20 percent reduction in the total amount of effective impervious surface coverage that is expected in the Percival, Woodard/Woodland, and Chambers/Ward/Hewitt drainage basins at 80 percent buildout (Figure 3, page 7), could result in approximately 600 fewer acres of impervious surface coverage by the year 2012. Strategies such as narrower streets and creating smaller building footprints are expected to reduce the per capita amount of impervious surfaces for the region.

VOL 12 2 3875

R0057167

Figure 3: Current and Potential Future Trends in Acres of Impervious Surfaces in the Percival Creek, Woodard/Woodland, and Chamber/Ward/Hewitt Drainage Basins



Need for Cumulative Impact Assessment Realized

Many of the problems with impervious surfaces are not linked to water resources. For example, asphalt absorbs and releases heat from the sun differently from vegetation. Replacing existing vegetation with pavement can significantly alter local temperatures. These changes in local temperatures can negatively affect the health of remaining vegetation and contribute to an overall warming trend. It is suggested that future research of impervious surfaces be in the form of a cumulative impact assessment. This would provide an opportunity to consider all the costs and benefits of impervious surface reduction, rather than just those related to water resources.

Recommendations for Reduction

It was recognized early on that recommendations suitable for Olympia may not work for other communities, and that ideas not suitable for Olympia may work elsewhere. As one reviews the recommendations, keep in mind that this report summarizes a study, not a planning process. The information and recommendations contained in this report are provided as guidance to Olympia and other communities, and will not necessarily be adopted by the City Council. For specific information on actions that

VOL 12 2 3876

R0057168

Olympia has or will be taking to reduce impervious surfaces, the reader should refer to the detailed Implementation Actions sections under each recommendation in Chapter 3 (page 59) and Chapter 4, Implementation Strategy (page 125).

This study signifies a new emphasis on impervious surface reduction for the Olympia community, and has left as many unanswered questions as it has answered. More research could be conducted to better define hydrological relationships, costs and incentives, and water quality impacts (Chapter 3, Strategies Considered and In Need of Further Analysis, page 60). It is important to keep in mind that impervious surface reduction is still an experiment—one that needs to begin so that we can discover real-world solutions.

Overall Recommendations

The project team developed three overall recommendations. Recommendation 1 recognizes that changing attitudes, policies, and regulations are a significant first step in impervious surface reduction. Recommendations 2 and 3 are reminders that growth management and transportation planning can be used to reduce impervious surfaces. The project team included these recommendations to encourage Olympia and other jurisdictions to consider policies and regulations, growth management, and transportation planning as tools for impervious surface reduction.

Recommendation 1.
Integrate impervious surface reduction into policies and regulations.

Recommendation 2.
Establish growth management policies that encourage infill of urban areas and reduce urban sprawl.

Recommendation 3.
Provide a public transit system and other alternative modes of transportation that reduce the need for streets and parking.

Recommendations for Vehicle-Oriented Pavement

Seven of the 19 recommendations address vehicle-oriented pavement such as streets and parking areas. According to the basin and site coverage assessment (Chapter 2, page 34), streets and parking areas make up a significant portion of Olympia's impervious surfaces. Reducing vehicle-oriented pavement can result in impervious surface reduction, but needs to be done in cooperation with the local business and development community in order to identify cost-effective strategies.

Recommendation 4.
Develop standards for narrower residential streets with reduced, but adequate, parking opportunities.

VOL 12 2 3877
R0057169

Recommendation 5.
Use pavers and other pervious surfaces for low use areas such as overflow parking and emergency access roads.

Recommendation 6.
Narrow alley widths, use alternative surfaces for alleys, and/or design alleys to drain to vegetated strips or central drains.

Recommendation 7.
Encourage cooperative parking such as joint (combined), shared, and coordinated parking.

Recommendation 8.
Encourage underground or under-the-building parking and the construction of multi-storied parking structures.

Recommendation 9.
Develop flexible parking regulations related to parking region-wide that limit the amount of impervious surface, while still providing for parking needs.

Recommendation 10.
Gently slope sidewalks away from streets and other impervious surfaces towards vegetated strips or gravel catchments.

Recommendations for Construction Practices and Landscaped Areas

Naturally occurring, undisturbed areas typically infiltrate 60 percent of rain, depending on soil type (Figure 1, page 2). Clearing and grading a site typically removes existing vegetation and compacts the soils, greatly reducing the infiltration capacity of the site.

For the purpose of this study, the project team considered compacted soils an impervious surface. The team recommends reducing soil compaction and the clearing of vegetated areas to retain the inherent infiltration capacity of undisturbed areas.

Recommendation 11.
Limit soil compaction on newly developed residential and commercial sites, especially those sites with sensitive features. Reduce soil compaction and restore infiltration capacity on already cleared sites whenever practical.

Recommendation 12.
Limit land clearing on newly developed residential and commercial sites, especially those sites with sensitive features.

VOL 12 2 3878

R0057170

Recommendation 13.
Encourage measures such as homeowner association covenants, plat map conditions, and/or conservation easements that protect existing vegetation and undisturbed areas.

Recommendations for Design and Placement of Buildings

In recognition that our current development pattern plays a large role in how much impervious surface we create, the project team recommends two key strategies for reducing building-related impervious surfaces: clustering and taller buildings.

Recommendation 14.
Encourage cluster development that minimizes impervious surfaces.

Recommendation 15.
Encourage the building and use of taller structures to reduce the size of building footprints.

Recommendations for Community Involvement and Education

Involvement and education of the community is a high priority for Olympia. The city and project team recognized that community participation in the study was essential to accomplishing implementation of the study's recommendations, and was necessary to ensure that policy and regulatory changes reflected the community's values, needs, and interests. Community members helped identify incentives and brought a real-world perspective to reduction strategies.

Recommendation 16.
Develop and distribute printed materials that complement the study's recommendations.

Recommendation 17.
Develop and provide training and technical assistance to the region's development and business community.

Recommendations for Study Evaluation

Evaluation is an essential step for learning from past experiences and recognizing successes. For the project team, this study raised as many questions as it answered. It also identified the need for better information concerning impervious surfaces and local groundwater hydrology. The following recommendations, if implemented, would not only continue the research efforts begun with this study but would help us measure success and identify areas for improvement. These recommendations would provide information and data for evaluating the overall success of the study,

VOL 12 2 3879

R0057171

as well as the specific policy and regulatory changes made as a result of study recommendations.

Recommendation 18.
Monitor the increase in impervious surfaces in Percival, Woodard/Woodland, and Chambers/Ward/Hewitt drainage basins to determine effective impervious surface coverage trends.

Recommendation 19.
Assess the results of the study's recommendations in Olympia, North Thurston UGMA, and other locations.

CHAPTER 1
INTRODUCTION

STUDY OVERVIEW

As urban areas develop, more and more land is covered with impervious surfaces such as buildings, streets, driveways, and parking lots. Historically, these impervious surfaces have created several well-documented water resources problems. These are illustrated on Figure 1 (page 2) and are summarized below.

The 84-square-mile North Thurston County Urban Growth Management Area (North Thurston UGMA) (Figure 2, page 3) is already experiencing water quality and stream habitat degradation. The entire area depends on groundwater for its drinking water which is vulnerable to contamination from the surface. In addition, the Squaxin Island Tribe and others are concerned that loss of groundwater recharge is affecting fish habitat by reducing summer stream flows.

Impervious surfaces and inadequate stormwater management have been linked to an increase in excessively high stream flows during winter and harmful low flows during summer (Booth and Reinelt, 1994; Booth, 1990; Hammer, 1972). Local drainage basins (watersheds) such as Woodard Creek and Percival Creek (Figure 2, page 3) currently exhibit instream habitat losses as a result of relatively high density development and impervious surface coverage of 17 percent and 25 percent, respectively. The habitat offered by other basins such as Woodland Creek and Chambers/Ward/Hewitt (Figure 2, page 3), which have 12 percent impervious surface coverage in each, reflect the relatively low density residential and commercial development in these basins. While many human actions affect and degrade local instream habitat conditions, the affects of excess stormwater runoff is pronounced. Future growth will require efforts beyond current stormwater management practices if we wish to preserve our local urban creeks.

Over the next 20 years, the population of the North Thurston UGMA is projected to increase by 66 percent to a total of 184,000 people (Thurston Regional Planning Council, 1993a). If that growth occurs and is accommodated with the current pattern of urban sprawl, the total amount of impervious surface in the Percival, Woodard/Woodland, and Chambers/Ward/Hewitt basins could increase from an estimated 14 to 29 percent of the land area, with corresponding increases in stormwater runoff and water quantity and quality problems. At 80 percent of buildout (full development) in these basins, it is estimated that the total amount of impervious surface would displace enough water to flood Olympia two-feet deep. At 80 percent of buildout, it is also estimated there would be 6,200 acre feet of stormwater added to the runoff we currently manage. This new stormwater would be enough to create a 62-acre lake that is 100 feet deep, and would need to be

VOL 12 2 3802
R0057174

managed to ensure recharge of our groundwater supplies and long-term preservation of water resources.

To address these challenges, the Impervious Surface Reduction Study (ISRS) was conducted by the City of Olympia in cooperation with the neighboring governments of Lacey, Tumwater, and Thurston County as part of an overall stormwater management strategy. Funding for the study was provided by the Washington Department of Ecology through a Centennial Clean Water Fund grant and Olympia residents through their Storm and Surface Water Utility. The study was initiated in March 1993, and was originally scheduled to be completed December 1994. In order to accommodate construction of demonstration projects, the grant deadline has been extended to June 1996. At this time, all study tasks except for the demonstration projects are complete. A separate technical report summarizing the results of the demonstration project will be completed May 1996.

GOALS AND OBJECTIVES

Goals

The goal of the study was to *identify and gain community support for future impervious surface reduction techniques that result in increased stormwater treatment and groundwater recharge in the Thurston County region, without causing appreciable increases in development costs.*

Another goal established for the study was a 20 percent reduction in impervious surfaces throughout the North Thurston UGMA stemming from implementation of the recommendations. Based on study results, it seems that a 20 percent reduction could be achieved.

Objectives

Objectives of the study were to:

1. Inform the public of the need for alternatives to impervious surfaces and foster support for necessary policy and development changes.

2. Develop standards to encourage reduction in impervious surfaces in future construction, and develop and initiate policies to support these standards.

3. Provide technical assistance to members of the development community interested in incorporating alternative techniques into proposed site and building plans.

VOL 12
2
3883
R0057175

4. Work with other local governments and members of the development community to apply alternative development practices at one or more highly visible sites.

5. Present information to the development and business community, professional organizations, government entities, and other interested parties concerning results of the study.

STUDY APPROACH

In September 1991, the study goal and tasks were conceptualized during an early scoping meeting for a Centennial Clean Water Fund grant application (Figure 4, page 16). The meeting was attended by staff from Olympia, Lacey, Thurston County, and the Squaxin Island Tribe. Olympia convened an additional meeting of local jurisdictions once the grant application was selected for funding. In August 1992, about 25 private and public sector representatives participated in a brainstorming session that identified constraints and opportunities, and provided additional feedback on the study's approach.

It was decided early on that Olympia's Water Resources Program would be the agency responsible for administering the study, and that Lacey, Tumwater, and Thurston County would be involved as advisors to ensure that the study contributed to regional impervious surface reduction. It was also asked by Olympia City Council that the study be used as a model to test Olympia's sustainability criteria. These guiding parameters of the study are discussed in more detail below.

Regional Perspective

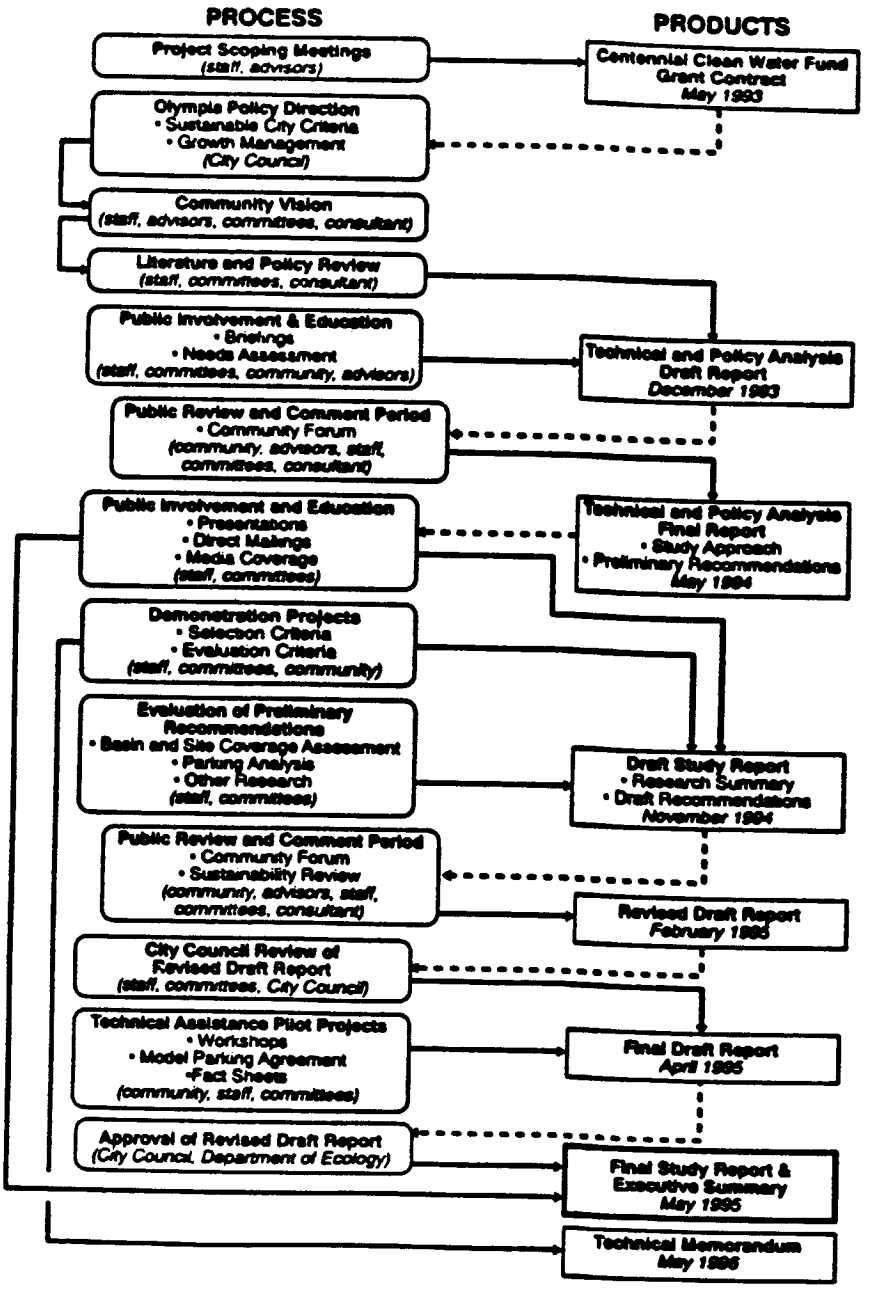
Washington's Growth Management Act of 1990 and 1991 (Revised Code of Washington 36.70A) requires Thurston County and cities within the county to plan cooperatively to accommodate the additional people expected to live here by 2015. The four local governments in north Thurston County are currently updating their comprehensive plans to meet Growth Management Act (GMA) requirements and coordinating their efforts based on county-wide growth management policies. A major result of growth management would be a shift in the development pattern in north Thurston County from one of low density suburban sprawl to a denser urban pattern, as illustrated in Figure 5, page 17.

The new development pattern would reduce the per person amount of impervious surfaces for the Olympia, Lacey, Tumwater, and Thurston County area because there would be:

VOL 12 2 3884

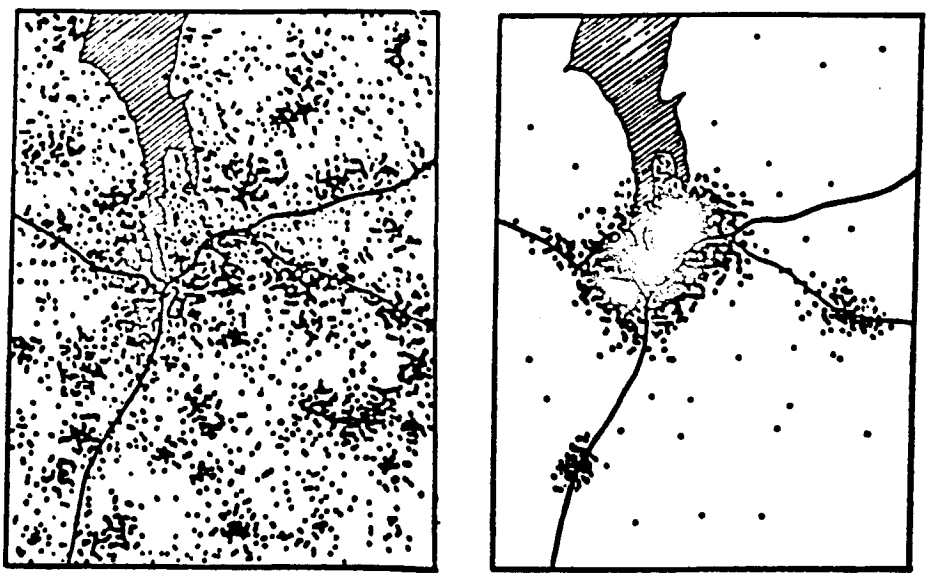
R0057176

Figure 4: Impervious Surface Reduction Study Flow Diagram



VOL 12 2 3885
R0057177

Figure 5: Current and Future Development Patterns



Source: R/UDAT, 1990.

Current pattern.

- Low density sprawl
- Separate zones
- Strip commercial
- Underdeveloped downtowns
- Fewer connected roads

Future pattern if the growth management strategy is implemented.

- High density in urban areas
- Mixed use zones
- Vital city centers
- Low density rural and resources lands
- More connected roads

- Less impervious surface in outlying rural and low density areas due to the concentration of development in urban areas.
- More efficient use of impervious surface in the urban areas (more total impervious surface in Olympia, Lacey, and Tumwater due to higher densities, but less impervious surface per person or unit of development for the whole county).

VOL 12 2 3886

R0057178

However, the high population growth for the area is expected to result in an ever increasing total amount of impervious surface. This is expected to jeopardize availability of clean groundwater, instream flows, and drinking water supplies for future generations.

Policy Focus and Early Implementation

From the beginning of the study, it was clear that water resources problems associated with impervious surfaces could not be addressed without considering policy issues such as urban sprawl and transportation management. Therefore, the study initially took a broad look at water resources concerns and proposed preliminary recommendations for reducing impervious surfaces that mirrored the regional growth management planning efforts of the four local governments.

It also became clear that a policy approach would be complementary to other research efforts in the Puget Sound region. During the study, project staff met twice with staff from a Centennial Clean Water Fund grant project administered by the University of Washington's Center for Urban Water Resources Management and King County's Department of Public Works. The meetings' purpose was to coordinate efforts and reduce duplication. As a result of the meetings, Olympia choose to take more of a policy focus that could complement the construction practices focus of the Seattle-based project. Results of the Center's research of onsite infiltration capacity, including mulching techniques and pavers, will be available in 1995 and will be reviewed by Olympia staff for local applicability.

Staff and some Ad Hoc Citizen Advisory Committee members (Project Team, page i) also participated in the revision of Olympia's street, parking, and development standards being conducted concurrently with the study. The revisions were driven by the need to have local policies and regulations comply with the Growth Management Act and Olympia's comprehensive plan. The revisions posed an opportunity to incorporate key recommendations of this study into existing policies. This early implementation of the study's findings provided an arena for considering impervious surface reduction along with other issues, and provided an opportunity to immediately implement reduction strategies.

Olympia's Sustainable City Philosophy

In March 1992, the Olympia City Council formally decided to evaluate its actions based on two sustainability criteria:

- Criteria 1: *Future generations*

  City actions will meet present needs without jeopardizing future generations.

VOL 12 2 3887
R0057179

- Criteria 2: *Interrelationships*

  City actions will take into account the environmental, economic, social, and political requirements for their success and the impact on the natural environment and human activities.

These criteria are intended to help guide Olympia towards actions that will help create a sustainable community, one that "persists over generations and is far-seeing enough, flexible enough, and wise enough to maintain its natural, economic, social, and political support systems" (City of Olympia, 1993d).

The Impervious Surface Reduction Study was used as a model to see how these criteria could be applied to a complex issue. A sustainability analysis of the study was conducted in two parts. Part one was an initial analysis at the beginning of the study and part two was a more in-depth analysis affiliated with the January 1995 Community Forum. The basic steps for both parts of the analysis were:

Step 1. Define the problem.

Step 2. Define the proposed solution.

Step 3. Envision a future if the solution is successfully implemented (related to Criteria 1).

Step 4. Assess interrelated future impacts of the proposed solution (related to Criteria 1 and 2).

Step 5. Assess what would be required for the proposed solution to be successful (related to Criteria 2).

Part One: Initial Analysis

Early in the study, members of the project team conducted an initial analysis. The members went through all five steps of the analysis with the following results:

Step 1.

The problem was generally defined as water quality and flooding impacts of increased stormwater runoff from impervious surfaces.

Step 2.

The solution was generally defined as reducing impervious surfaces associated with new development.

VOL 12 2 3888

R0057180

Step 3.

The vision for the future was defined very broadly and reflected a wide range of transportation, housing, land use, economic, and social issues. The vision included higher densities, clustered housing, taller buildings, neighborhoods with services within walking distances, more transportation options, fewer cars, smaller parking lots, multi-storied and unpaved parking, narrower sidewalks, alternative surfaces, and more green spaces.

This broad vision was the basis of the study's preliminary recommendations which overlapped with several growth management planning strategies. During additional committee meetings, the focus of the preliminary recommendations was narrowed to address a few general growth management strategies, streets and parking, construction practices and landscaped areas, design and placement of buildings, community involvement and education, and study evaluation.

Steps 4 and 5.

Discussion of future impacts and requirements for success was constrained by time, the committee members' confusion over sustainability concepts, and the general difficulty of analyzing a topic connected to such a wide range of issues.

The initial analysis was complemented by a technical and policy analysis (Chapter 2, page 31) conducted by staff and the policy consultant (Project Team, page i). The analysis yielded a number of examples of innovative land use and regulatory practices in other communities, as well as the results of other impervious surface research.

Part Two: Community Forum Roundtable Exercise

Part two of the sustainability analysis included a roundtable exercise. The exercise involved the five attendees of a Community Forum, and was facilitated by the policy consultant. The roundtable exercise consisted of a brief presentation on sustainability concepts and Olympia's two criteria, followed by a group discussion that reviewed the main goal of the study—a 20 percent reduction in new impervious surfaces. Objectives of the exercise included:

- Expand citizen understanding of key sustainability concepts.
- Receive input from citizens for use in this final study report.
- Test one method for conducting sustainability analyses.

VOL 12 2 3889

R0057181

The roundtable exercise was designed to assess future impacts of and requirements for a 20 percent reduction in impervious surfaces associated with new development. The exercise consisted of figuratively placing the 20 percent goal at the center of a table and the Community Forum participants considering two questions. The questions were:

1. What changes will be needed in natural, social, economic, and political systems to achieve a 20 percent reduction in new impervious surfaces by the year 2012?

2. What will be the impacts on natural, social, economic, and political systems if a 20 percent reduction is achieved by the year 2012?

After a group discussion, the participants wrote responses to the questions on a handout illustrating key natural and human systems (Figure 6, page 22). Following a break, the participants shared their responses to the sustainability presentation and exercise. As a follow up to the Community Forum, the policy consultant summarized the participants' responses and performed a more in-depth analysis.

Results of the Sustainability Analysis

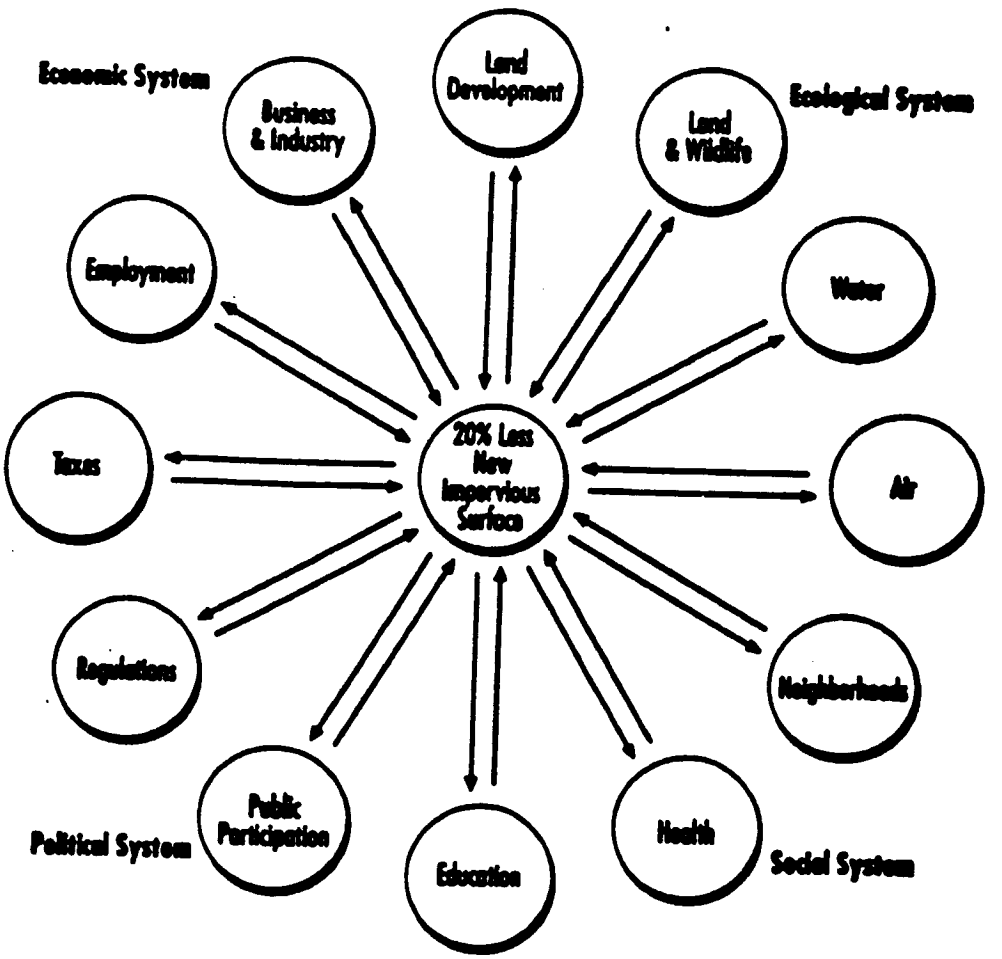
Table 1 (page 23) summarizes a variety of impacts and requirements that were identified for the success of a 20 percent reduction in impervious surfaces. Feedback from Community Forum participants indicated that the concepts of sustainability were relatively clear and that looking at something from a new perspective was useful. Feedback also indicated that the roundtable exercise was good, but the link between the exercise and impervious surface reduction was unclear.

To contribute significantly to Olympia becoming a sustainable community, there would need to be a greater effort to reduce impervious surfaces than is laid out in this report, and the effort would need to be maintained over several generations. Such an effort would require greater agreement among sectors of the community about strategies. New information and technology would be needed to enhance groundwater infiltration and minimize impacts on water resources. Such information and technology would need to be complemented by economic incentives and relatively stable climatic conditions (e.g., rainfall).

VOL 12 2 3890

R0057182

Figure 6: Sustainability Interrelationships—
Natural and Human Systems



VOL 12 2 3891
R0057183

Table 1: Sustainability Interrelationships—Impacts and Requirements for Success

IMPACTS	REQUIREMENTS FOR SUCCESS	
NATURAL ECOSYSTEM **Land/Wildlife** **Water** **Air**	• More runoff and related impacts. • Urban watersheds highly managed to collect, treat, reuse, or infiltrate runoff. • Rural watersheds protected (short term). • Density may create opportunities for neighborhood-scale technology (e.g., solar cars/solar heating that improve air quality).	• Climate relatively stable (e.g., increase in rainfall could counteract effect of reduced impervious surface.)
ECONOMIC SYSTEM **Land Development** **Business/Industry** **Employment**	• More efficient use of land. • Reduced development costs due to reduced parking requirements. • More ground space for commercial use from less surface parking. • Cooperation on shared parking could lead to further cooperation. • New businesses—development and sale of alternative products and services. • New employment resulting from labor-intensive high maintenance technology and value-added manufacturing.	• Changes in development technology become common practice. • New technology to replace natural recharge, manage, and treat surface runoff and create new transportation and construction methods. • Prices for alternative products and services become competitive. • Availability of workers skilled in new technology and willing to work at maintenance jobs.
SOCIAL SYSTEM **Housing** **Health** **Education**	• People living closer together, potential for more neighborhood vitality or more crime, violence, and stress. • Schools and jobs closer to home, more time for family and community. • More attractive public urban spaces. • More playground space due to multi-story school buildings. • Improved general health due to better air quality. • Improved health among people working outdoors in maintenance jobs.	• People adapt to living in more compact neighborhoods. • People preferences shift to "small is beautiful," values on neighborhood interaction. • More public awareness of water resources and impacts of development. • More development community awareness of benefits of alternative land use/construction practices.
POLITICAL SYSTEM **Public Participation** **Taxes** **Regulations**	• More awareness/concern from community leaders and more public participation and responsibility. • Potentially less need for regulation based on public participation and consensus. • More careful review of development permits. • Better feedback from monitoring used to adjust policy. • Revenue impacts unclear.	• High level of consensus to sustain implementation over time. • More neighborhood involvement in decision making. • Regulations create incentives for denser development (e.g., parking, higher buildings). • Taxes create incentives for denser development (e.g., two-tier tax system for land and buildings, taxes on gas and parking).

R0057184

INVOLVEMENT AND EDUCATION

Broad-based involvement and education of the local and regional community was important to meeting the study's goals. Education was an important avenue for citizens and local jurisdictions to become well-informed of the problems addressed by the study. In addition, the education process was used as a two-way street, providing an opportunity to discover community concerns and generate innovative, workable solutions.

Strategy for Involving and Educating Audiences

Olympia used a multi-faceted strategy for gaining broad-based support for the study's impervious surface reduction recommendations. The strategy was initially summarized in a public involvement and education plan (Appendix A, page 159). The plan contains goals, objectives, activities, and evaluation measures, and was implemented consistent with the grant agreement for the study. The strategy focused on a variety of audiences and included many opportunities for citizens and neighboring local governments to influence the direction and outcome of the study.

Audiences included the local development community (developers, contractors, landscapers, architects, realtors, etc.); individual homeowners and neighborhood associations; small business owners and retail and commercial businesses; and city and county governments, including their planning, public works, and parks department staff, management, and elected officials. Completed involvement and education activities are summarized below.

Committees

Public and private sector representatives were involved in defining the study from its inception (Project Team, page i). Community, business, and local government representatives assisted in the study through two committees.

Steering Committee

Since long-term success depends on cooperation and coordination among the four local governments in the North Thurston UGMA, Olympia managed the study with the assistance of a Steering Committee comprised of planning, community development, and public works staff from Olympia, Lacey, Tumwater, and Thurston County. The Steering Committee met four times, helped refine the scope of the study, and provided technical review of reports and other products. The committee also shared the results of the study with their management and elected officials and participated in technical assistance activities.

VOL 12
2
3893
R0057185

Ad Hoc Citizen Advisory Committee

A six-member committee of community representatives met 14 times during the course of the study. The committee advised staff by reviewing drafts, discussing ideas, and assessing the environmental, economic, social, and political implications of various recommendations. Committee members included a consulting engineer, architect, commercial realtor, soils scientist, private utility manager, and neighborhood association representative. The committee's second meeting (July 1993) consisted of a visioning exercise with the Steering Committee members based on Olympia's sustainability criteria (Figure 4, page 16). The Ad Hoc Citizen Advisory Committee subsequently met to review comments on the draft report and provide input to this final report.

Needs Assessment

An informal needs assessment (Appendix B, page 165) was conducted over a three-month period (January through May 1994) to identify communication tools and incentives appropriate for reducing impervious surfaces. A secondary purpose was to inform members of the community about the study. The assessment results were incorporated into the Public Involvement and Education Plan (Appendix A, page 159).

Of the approximately 125 assessment forms distributed to local business and development community representatives, and planning and public works staff, 41 (33 percent) were returned. Survey responses indicate that, with the exception of tours and field trips, technical assistance and education tools developed for the public sector may not be suitable for the private sector. However, newspapers are a good media format for reaching both sectors.

The survey results also indicate that the public sector is more willing to participate in demonstration projects than the private sector. Responses indicate that the private and public sectors agree on the incentives for participating in demonstration projects: training, streamlined permit process, and reduced development costs.

Community Forums

Two community forums were held to discuss the study's recommendations (Figure 4, page 16). A meeting with the attendees of the early scoping meetings and additional members of the community was convened to discuss the Technical and Policy Analysis Report (City of Olympia, 1994b) in January 1994. Another meeting was held in January 1995 to present the draft study report, provide an opportunity to discuss the draft recommendations, and involve the public in a sustainability review. The comments from the community forums were incorporated into this final study report.

VOL 12 2 3894

R0057186

Technical Assistance

To encourage further understanding and actual reduction of impervious surfaces, technical assistance was offered to the local and regional community. Information and training on how to identify and take advantage of impervious surface reduction opportunities was provided to citizens, policymakers, developers, business owners, builders, and others. Technical assistance consisted of two workshops, an alternative surfaces fact sheet (Appendix C, page 169), and a model legal agreement for shared parking (Appendix D, page 179). In January 1995, information on alternative surfaces and impervious surface reduction techniques was presented to the local chapter of the Ecobuilders Guild. In March 1995, an Exploring and Understanding Soils Workshop was offered to builders, contractors, excavators, and interested citizens. Both workshops were successful in expanding understanding about impervious surface reduction techniques (Study Results, page 5, and Appendix E, page 181).

The alternative surfaces fact sheet was distributed to 30 soils workshop attendees. An additional 600 copies are scheduled to be printed and distributed during 1995. A model legal agreement for shared parking (Appendix D, page 179) is distributed through the Olympia permit counter and was distributed to local governments throughout Washington, via the Association of Washington Counties' and Association of Washington Cities' mailing lists.

Sharing the Results

Information was shared with citizens, professional groups, and various jurisdictions within Thurston County, Washington State, and across the United States to encourage application of the studies results. A shared parking fact sheet was developed and over 500 were distributed to local jurisdictions throughout the United States. Nineteen articles about the study were published, including two in national publications and three professional papers. Twelve news releases, one radio announcement, two professional papers, and two ads were also completed.

Printed materials distributed or scheduled to be distributed include approximately 1,575 reports, 1,000 buttons, and 2,000 copies of three different fact sheets (Appendix C, page 169). Printed materials were disseminated at two national conferences, at 23 presentations and briefings, and in response to requests. The project mailing list contains 431 names and addresses, including 183 local, 139 within Washington State, 104 out-of-state, and five names and addresses outside the United States.

An informational display board with illustrations of alternatives and a flip book with photos of example designs were used at the two national conferences and several of the presentations.

VOL 12 2 3895

R0057187

STUDY EVALUATION

An evaluation of the study and whether or not it met its goals and objectives was conducted by project staff March and April 1995. Evaluation of the public involvement and education plan (Appendix A, page 159) was an important part of the overall evaluation because it provided data on the amount and distribution of printed materials, numbers of people informed about the study, and knowledge gained from technical assistance workshops. However, actual behavior changes resulting from printed materials, presentations, or other methods were not measured. Without measuring behavioral change, crediting the study with actual impervious surface reduction is difficult. Staff assume that some reduction will occur given the policies that have been changed as a result of the study, and because citizens, businesses, development community members, and several jurisdictions nationwide have learned more about impervious surface reduction strategies.

Public Involvement and Education Plan Results

The Public Involvement and Education Plan (Appendix A, page 159) contains nine evaluation measures. According to evaluation results, four of the measures were clearly met, three were partially met, one is no longer applicable, and one is difficult to evaluate because it is based on future actions. The evaluation measures and results are listed below.

1. At least 1,000 people were informed of the study through briefings, presentations, etc.

This objective was met. Approximately 2,190 people attended briefings, presentations, and technical assistance workshops, or received printed materials. If 25 percent of these people were at one or more presentations or received printed materials and attended a presentation, then approximately 1,650 different people were informed of the study.

2. Demonstration projects included private-public partnerships.

This objective was partially met. Although the project team was not successful at constructing a demonstration project on private property, Olympia School District No. 111 is participating in a demonstration project. The school district is a separate entity from the city and, thus, a special letter of agreement was required for construction of the project. The Olympia High School project was brought to the team's attention by a citizen and utilized private contractors for soils analysis and sod replacement.

3. At least five site plans submitted to Olympia during 1995 integrated techniques recommended by the study.

VOL 12 2 3896

R0057188

This objective is no longer applicable for two reasons. First, when written, this objective assumed the study would be completed in 1994 rather than 1995. Second, because many of the policy changes that occurred as a result of the study have yet to be adopted, it is too early to see study results reflected in site plans. This evaluation measure has been folded into Olympia's implementation actions for Recommendation 19 (page 121).

4. At least 20 people were involved in training.

This objective was met. Forty-six people attended the two training workshops.

5. Results of workshop evaluations indicated that the training workshops were useful.

Written evaluations were distributed at both training workshops (Appendix E, Workshop Evaluations, page 181). Participants' responses to both workshops were favorable. Eight of the nine respondents to the Ecobuilders Guild evaluation indicated that "they would reduce impervious surfaces associated with their next construction project." The twelve respondents to the Soils Workshop evaluation rated the overall quality of the workshop a 4.42 out of 5.00 possible points. Nine of the respondents from that workshop indicated they "certainly did" learn new facts or new ideas that would be helpful on their job.

6. At least 75 percent of the study's recommendations were adopted by Olympia and 50 percent by other local governments.

This objective will be partially met if draft policies are adopted as proposed. It is expected that at least nine recommendations will be wholly or partially incorporated into Olympia's policies. Three of the study's recommendations were incorporated into city policy prior to the study, and are included as guidance for other local jurisdictions outside the North Thurston UGMA. Four additional recommendations may be implemented depending on funding. If funding is provided for these four recommendations and policies are adopted as proposed, Olympia will implement all or part of 81 percent of the study's recommendations not already implemented.

Only a few of the recommendations are proposed for adoption by Lacey, Tumwater, and Thurston County. As with Olympia, some recommendations had already been wholly or partially incorporated into policy prior to the study, while other recommendations have been incorporated into proposed street standards and other policies. Staff estimate that approximately 10 to 20 percent of the recommendations will be adopted by other local governments in the North Thurston UGMA.

VOL 12 2 3897

R0057189

7. At least 10 jurisdictions requested study results.

It is difficult to determine the exact number of requests from jurisdictions because phone calls and personal contacts were not always documented. However, those that requested materials were added to the project mailing list. As of March 15, 1995, the mailing list contained 165 names of representatives from various jurisdictions, including five tribal representatives, 18 representatives from federal agencies, 47 from state agencies or universities, 44 from county agencies, and 51 from city agencies or ports. Project staff continue to get requests for information. These requests are expected to continue throughout 1995.

8. At least one letter of support for the study was received from a leading business organization.

Staff did not request a letter of support from local business organizations. Informal verbal support of the study was given by the Olympia/Thurston County Chamber of Commerce.

9. The Ad Hoc Citizen Advisory Committee and Steering Committee members generally support the study's recommendations.

The Ad Hoc Committee members have indicated that they support most or all of the study's results and recommendations. Committee members worked well together, sharing ideas and wrestling with challenging issues. The committee came to general consensus concerning many elements of the study's approach and recommendations. Steering Committee support also was achieved, although to a lesser degree. More frequent meetings or direct contact with Steering Committee members could have resulted in greater support for and implementation of the study's recommendations.

Overall Study Evaluation Results

Evaluation measures were not established for the overall study. However, results of an evaluation of the study's goals and objectives (Goals and Objectives, page 14) are summarized below.

The study's two goals were generally met.

Goal 1: The Ad Hoc Citizen Advisory and Steering Committees generally support the impervious surface reduction techniques recommended by the study. Many of the recommendations are proposed as part of new street, parking, and development standards. Results of the cost analysis indicate savings associated with some recommendations. However, there will be some costs incurred for alternative surfaces, taller buildings, and other recommendations depending on individual site factors.

VOL 12
2
3898
R0057190

Goal 2: Based on the basin and site coverage assessment and expected results from the proposed street, parking, and development standards, an estimated 20 percent reduction in future impervious surfaces is likely to occur. This reduction will be complemented by additional reduction from infill and other growth management strategies currently being implemented.

The study's five objectives (Goals and Objectives, page 14) were clearly met.

Objective 1: Over 1,600 people were informed of the need for alternatives to impervious surfaces and encouraged to support impervious surface reduction in their local community. Nineteen articles, 12 news releases, one radio announcement, two professional papers, and two ads were used to inform the public about study results or invite participation. In addition, approximately 1,000 buttons were distributed with a "Save It–Don't Pave It" message, 2,000 fact sheets were distributed, and 23 presentations or briefings were provided to the local and regional community.

Objective 2: Street, parking, and development standards were modified to encourage impervious surface reduction in future construction.

Objective 3: Although not as extensive as initially proposed in the Public Involvement and Education Plan (Appendix A, page 159), technical assistance was provided to the development community during the study and will be continued to some degree into the future.

Objective 4: Two demonstration projects are underway. Both are at highly visible sites (Olympia City Hall and Olympia High School) and utilize alternative development practices.

Objective 5: Many of the presentations and briefings noted under Objective 1 were designed specifically to share results. As of March 15, 1995, approximately 875 copies of the Technical and Policy Analysis Report and Impervious Surface Reduction Study Draft Report had been distributed. Approximately 200 copies of this final report and 1,500 copies of a separate Executive Summary will be distributed nationwide.

VOL 12 2 3899

R0057191

CHAPTER 2
TECHNICAL AND POLICY ANALYSIS

Research of technical and policy issues was important to understanding the problems caused by impervious surfaces and developing feasible and practical recommendations. The technical and policy analysis element of the study included five main tasks:

1. Literature and Policy Review
2. Demonstration Projects
3. Basin and Site Coverage Assessment
4. Parking Analysis
5. Other Research

LITERATURE AND POLICY REVIEW

The literature and policy review was conducted early in the technical and policy analysis (Figure 4, page 16) and helped define the study approach (Chapter 1, page 15). The review included the following activities.

- A survey of the literature and interviews with knowledgeable people to determine quantifiable relationships between impervious surface and the quality and quantity of stormwater runoff.
- Development of recommendations for reducing impervious surfaces based on 1) Olympia City Council policy direction; 2) initial visioning (brainstorming) and lengthy discussions by the Steering and Ad Hoc Citizen Advisory Committees; 3) a review of literature on sustainable communities and alternative development techniques; 4) input from a forum of select community leaders; and 5) public review and comment.
- Analysis of stormwater runoff quantity, water quality, groundwater recharge, and stream flow information.

The literature and policy review culminated in the publication of the Technical and Policy Analysis Report (City of Olympia, 1994b). For the sake of continuity, some of the early analysis has been incorporated into Chapter 3 (page 59) of this report.

DEMONSTRATION PROJECTS

A key task of the technical and policy analysis was to demonstrate the feasibility and practicality of the recommendations at one or more new development sites. Numerous proposed developments in the Olympia area were investigated in light of

VOL 12 2 3900

R0057192

the goals of the study. These proposed developments were evaluated for suitability as demonstration projects by staff and the Ad Hoc Citizen Advisory Committee using the following nine selection criteria:

1. Project provides an opportunity for techniques that are not readily familiar to the development community, and at a size that demonstrates their applicability to the local community.

2. Project has high visibility and accessibility to the development and business community.

3. Project provides useful information for an urbanized, intensely used setting.

4. Project provides an opportunity to use techniques that meet stormwater detention and treatment goals.

5. Project provides an opportunity to demonstrate cost-effective techniques.

6. Project provides an opportunity for a public/private partnership.

7. Project provides an opportunity to demonstrate several recommendations.

8. Project provides an opportunity to monitor it long-term.

9. Project costs are no more than $50,000.

Recommendations considered the most practical for demonstration included Recommendation 4 (narrow residential streets); Recommendation 5 (use pavers or alternative surfaces); Recommendation 11 (limit soil compaction); and Recommendation 12 (limit land clearing).

Both commercial and residential, private and public sites were considered for demonstration of the recommendations. Considerable effort was spent investigating potential projects. Barriers associated with identifying a viable demonstration construction project included:

- Many of the recommendations focus on changes in current policies or regulations. A variance would have been required for almost every potential project in order to legally construct an alternative or innovative design that is not currently allowed. Most projects did not come to the attention of staff or the committee until it was too late in the design phase and would have required a construction delay for the developer or builder.

VOL 12 2 3901

R0057193

- Because there were only a few techniques identified for demonstration through the study, many of the potential projects offered limited opportunities. Pavers and alternative surfaces were the most obvious items suitable for demonstration, but they are suitable for low-use areas which contradicts with high-visibility and other selection criteria.

- Many of the potential projects offered only minor improvements in the infiltration or treatment of stormwater due to site specific limitations (e.g., soils) and were therefore not pursued.

- Potential projects tended to lack long-term viability of the demonstration techniques and/or an opportunity for long-term monitoring of the project.

The above barriers delayed starting the projects until early 1995. Since that time, two projects have been pursued: a sidewalk renovation project at Olympia City Hall and a soil restoration project at Olympia High School.

The Olympia City Hall sidewalk renovation project will consist of using pavers for bike rack facilities and for replacing segments of existing sidewalk. Approximately three different types of pavers will be used and displayed with information about costs, installation methods, and expected benefits.

The Olympia High School soil restoration project will consist of reducing the soil compaction along one side of a dirt and gravel parking lot in order to increase infiltration of surface water runoff. Runoff is currently flowing from the parking lot into an adjacent soccer field, limiting use of the field. A trench approximately three to six feet wide, four feet deep, and 100 feet long will be dug. Rock and other materials will replace the soil removed from the trench. The soils will be reinforced with a layer of plastic cellular confinement material (e.g., Geoweb) just below the surface. The added rock and materials, and the cellular confinement layer are expected to help protect the deeper soil from compaction and increase infiltration capacity.

The following six criteria will be used to evaluate the demonstration projects:

1. The new techniques can be implemented without causing appreciable increases in development costs.

2. The amount of impervious surface is less with new techniques than with standard development practices.

3. The new techniques are acceptable to users and provide a safety, aesthetic, or other advantage compared to standard development practices.

VOL 12 2 3902

R0057194

4. The new techniques are acceptable to contractors and builders and are easier to construct than standard development practices.

5. The new techniques increase the ease of maintenance and reduce maintenance costs compared to standard development practices.

6. The new techniques increase stormwater treatment and infiltration and reduce flooding compared to standard development practices.

The study grant was recently extended to June 1996 to accommodate completion of the demonstration projects. Because the demonstration projects are not complete in time for this report, a separate technical report that summarizes lessons learned and monitoring results will be submitted to the Washington Department of Ecology in April 1996. Readers interested in information about the demonstration projects are encouraged to contact the study coordinator.

BASIN AND SITE COVERAGE ASSESSMENT

Project staff conducted a basin and site coverage assessment to better understand the level of impervious surface reduction that could be expected in the North Thurston UGMA from key study recommendations. The assessment consisted of a site-specific analysis and a two-part analysis of impervious surface coverage at predicted buildout conditions in the Percival, Woodard/Woodland, and Chambers/Ward/Hewitt drainage basins (Figure 2, page 3). The three drainage basins total 37,000 acres and were selected for the assessment because:

- Land use and impervious surface coverage information was readily available and fairly current;
- They represent an area that overlaps with the North Thurston UGMA and is equivalent in size to almost 69 percent of the North Thurston UGMA (Figure 2, page 3); and
- It is expected that the three basins will experience less development and lower growth rates than the North Thurston UGMA as a whole, and thus, the analysis results are a conservative estimate of reduction we can expect from the study's recommendations in the UGMA.

Information for the assessment was obtained from engineering plans for 11 Olympia-area developments and Hydrological Simulation Program - Fortran (HSPF) models created for the three basins. The engineering plans provided information on typical coverage for high-density residential (three to seven units/acre), multifamily (seven to 30 units/acre), and commercial/industrial land uses. The HSPF models are predictive hydrologic computer models for surface water that provided information on existing and potential future land use. The models also provided information on

VOL 12
2
3903
R0057195

the effectiveness of various impervious surface types (i.e., streets, sidewalks) at producing runoff from a site. The engineering plan and HSPF information was evaluated to answer the following questions:

- How much impervious surface is associated with typical developments in the North Thurston UGMA?
- What is the amount of impervious surface we can expect at buildout in the three basins given current development regulations and patterns, as a representation of North Thurston UGMA development trends?
- What reductions in impervious surfaces can be expected with implementation of key study recommendations?

Site-specific Analysis

The quantity of streets, sidewalks, parking/driveways, roofs, lawn/landscaping, and open space associated with recent Olympia area developments was calculated from the engineering plans. Numerous developments exhibiting typical, but varied, site opportunities and constraints were used. The following developments were chosen for the analysis:

- Residential development:

Springfield	16 units; 6 units/acre
Mapleview II	49 units; 4 units/acre
North Pointe	38 units; 6 units/acre
Bigelow Park	71 units; 4 units/acre

- Multifamily development: Homeport, Fern Ridge, Cambridge II, Creekwood
- Commercial development: Safeway, Home Depot, Eastside Office Building

The approximate composition of site coverage for the 11 developments is shown in Table 2 (page 36). The average coverages are also presented graphically in Figure 7 (page 36).

VOL 12 2 3904

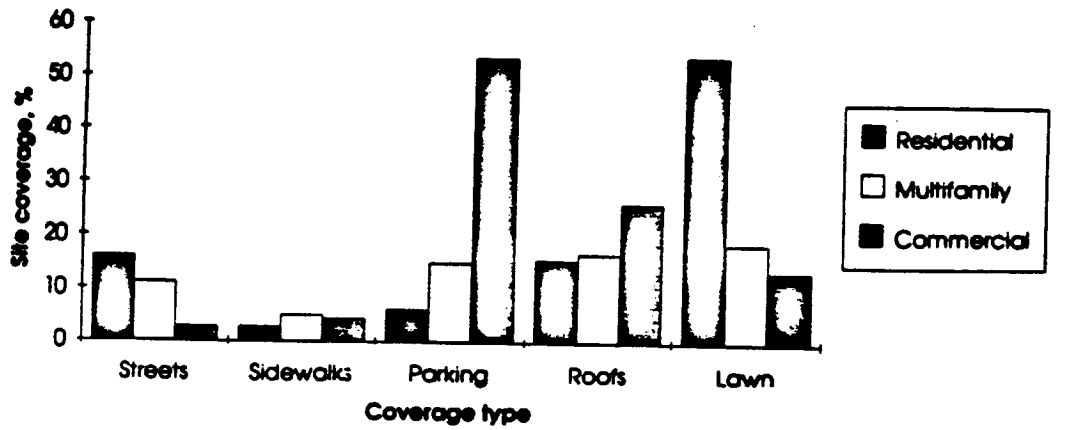
R0057196

Table 2: Site Coverage for Three Land Uses

Surface Coverage Type	Approximate Site Coverage, % Residential Average	Range	Multifamily Average	Range	Commercial Average	Range
Streets	16	11-22	11	7-17	3	2-4
Sidewalks	3	2-4	5	2-11	4	2-9
Parking/driveways	6	4-9	15	10-20	53	39-64
Roofs	15	10-18	17	15-17	26	25-27
Lawns/landscaping	54	44-65	19	14-22	13	4-26
Open space		n/a[1]	34	25-40	n/a[1]	
Total impervious surface	40		48		86	

(1) Open space typically represents a small portion of residential and commercial developments.

Figure 7: Site Coverage for Three Land Uses



VOL 12
2
3905
R0057197

The total impervious surface for each land use category is generally in agreement with accepted Puget Sound values used in the HSPF program (Aqua Terra, 1994). Table 3 compares the estimated HSPF coverage values with the coverage of Olympia area developments.

Table 3: Comparison of HSPF and Olympia Area Development Coverage Values

Land Use	Impervious Surface, % HSPF Model	Olympia Developments
Low-density residential (<1 unit/acre)	10	n/a[1]
High-density residential (3-7 units/acre)	40	40
Multifamily (7-30 units/acre)	60	48
Commercial/industrial	90	86

(1) Low density residential developments were not evaluated.

Impervious surfaces can also be evaluated with respect to their effectiveness at producing runoff. For example, a residential roof may be similar in size to a commercial roof, but given the presence of permeable landscaping around the typical residential roof and the presence of impervious surface around the commercial roof, the commercial roof is more effective at producing runoff (produces more runoff) than the residential roof. This evaluation approach can be helpful in defining stormwater problems and opportunities. Commonly accepted HSPF relationships between impervious surface and effective impervious surface (Aqua Terra, 1994) in the Puget Sound area are presented in Table 4.

Table 4: Comparison of Total Impervious Surface and Effective Impervious Surface for Several Land Uses

Land Use	Total, %	Effective, %
Low-density residential (<1 unit/acre)	10	4
High-density residential (3-7 units/acre)	40	26
Multifamily (7-30 units/acre)	60	48
Commercial/industrial	90	86

VOL 12
2
3906
R0057198

Table 5 indicates that a given unit of impervious surface will produce appreciably more runoff in a commercial setting than in a low-density residential setting. However, these assumed values do not, as stand-alone numbers, reflect the importance of soil type and slope on the effectiveness of the surface. Impervious surfaces discharging to highly pervious soil are ineffective. This evaluation does not address the effect of soil type on effectiveness, and, therefore, provides generalized rather than site-specific results.

Table 5: Estimated Impervious Surface Effectiveness for Residential Development

Surface Coverage Type	Surface Type, %	Effective Fraction	Effective Surface, %
Streets	16	.8	12.8
Sidewalks	3	.7	2.1
Parking/driveways	6	.6	3.6
Roofs	15	.35	5.3
Lawns/landscaping	54	.05	2.7
Total			26.5

Effective impervious surface estimates have also been developed for low-density residential, multifamily, and commercial/industrial land use. Multifamily and commercial/industrial impervious surfaces were assumed to be entirely effective. Lawns and landscaping for all development land uses were assigned an effective fraction of 0.05. Table 6 presents the estimates; Figure 8 (page 39) illustrates the estimates.

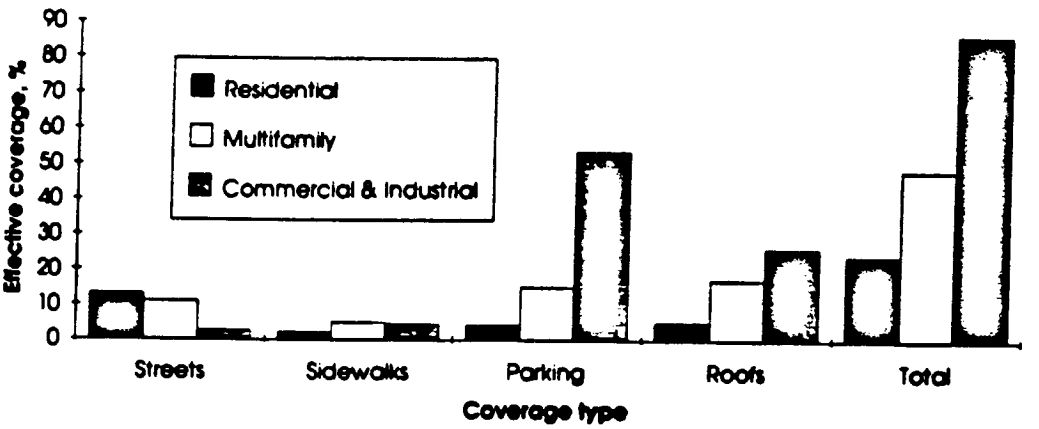
Table 6: Estimated Effective Impervious Surface Coverage for Residential, Multifamily, and Commercial Development

	Effective Impervious Surface, %			
Land Cover	Low-Density Residential	High-Density Residential	Multifamily	Commercial
Streets	3.5	13	11	3
Sidewalks	0	2	5	4
Parking/driveways	0.5	4	15	53
Roofs	0	5	17	26
Lawns/landscaping	0	2	1	1
Total	4	26	49	87

VOL 12 2 3907

R0057199

Figure 8: Estimated Effective Impervious Surface Coverage for Residential, Multifamily, and Commercial Development



The estimated effective impervious surface values for the four land uses closely approximate values used in HSPF modeling (Table 4, page 37).

The results of the site-specific analysis include:

- Streets are the primary producers of stormwater runoff in residential areas.
- Sidewalks and lawns/landscaping contribute minimally to effective impervious surface.
- Parking lots are highly effective impervious surface.
- Streets, parking lots, and roofs generate similar quantities of runoff in multifamily developments.

Analysis of Potential Impervious Surfaces in Three Olympia Area Drainage Basins

Like most areas adjacent to the urban core of Olympia, Lacey, and Tumwater, the three representative drainage basins can expect considerable development growth in the near future. The extent of the basins' growth potential has been thoroughly evaluated through basin plans developed by the local governments and is presented below in Table 7 and Figure 9.

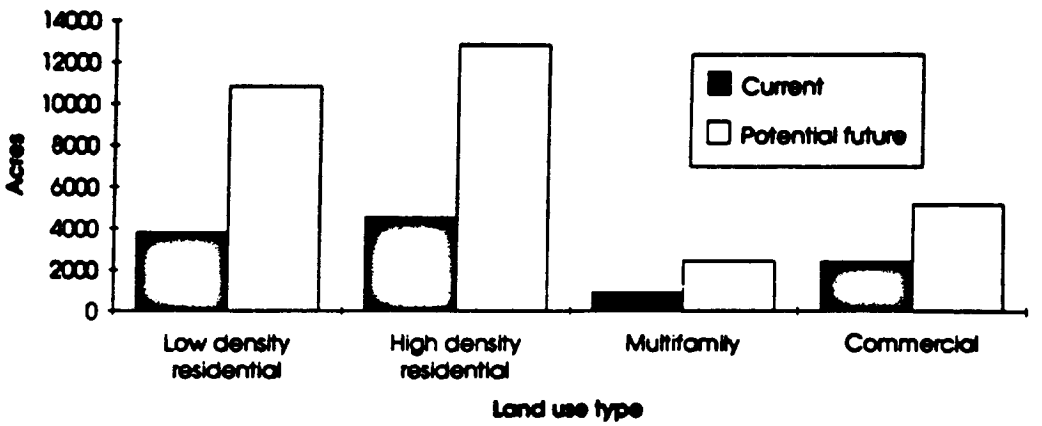
VOL 12 2 3908

R0057200

Table 7: Current and Potential Future Land Use in Three Olympia Area Drainage Basins

Land Use Category	Land Use, Acres Current	Potential Future
Undeveloped	24,663	791
Sparse residential	3,805	12,592
Suburban residential	3,448	12,492
Medium residential	1,559	2,409
High residential	869	2,807
Light commercial	1,527	2,963
High commercial	868	2,854

Figure 9: Current and Potential Future Land Use in Three Olympia Area Drainage Basins



VOL 12
2
3909
R0057201

The HSPF model requires consolidation of the seven land uses shown in Table 7 (page 40) into the categories of undeveloped, low- and high-density residential, multifamily, and commercial/industrial land uses. Successful computer modeling and calibration is feasible with the broad level of detail provided by the consolidated land uses. The categories of low-density residential, high-density residential, multifamily, and commercial/industrial are the same categories used on the previous evaluation of total and effective impervious surfaces. The consolidated land uses are presented in Table 8. Additionally, potential future development acreage (expected buildout) in Table 9 has been reduced by 20 percent compared to zoning allowances because sites in the Olympia area typically develop at lower densities than are allowed by zoning.

Table 8: Consolidation of Current and Potential Future Land Use in Three Olympia Area Drainage Basins at 80 Percent Buildout

Land Use, Acres

Land Use	Current	Potential future
Low-density residential (<1 unit/acre)	3,805	10,835
High-density residential (3-7 units/acre)	4,507	12,838
Multifamily (7-30 units/acre)	869	2,419
Commercial/industrial	2,395	5,133

Table 9: Potential Future Increases in Total and Effective Impervious Surfaces in Three Olympia Area Drainage Basins

Impervious Surface Increases, Acres

Land Use	Total	Effective
Low-density residential (<1 unit/acre)	703	281
High-density residential (3-7 units/acre)	3,332	2,166
Multifamily (7-30 units/acre)	915	732
Commercial/industrial	2,464	2,354

VOL 12
2
3910
R0057202

Given these values for current and potential future land use in the drainage basins (Table 8, page 41), and total and effective impervious surfaces associated with different development types (Table 4, page 37, and Table 6, page 38), we can expect the following increases in impervious surfaces for full development conditions (20 percent less than buildout) in the basins.

Tables 10 and 11 show total and effective surfaces in the basins under full development conditions. The information is also presented graphically on Figures 10 (page 43) and Figure 11 (page 43). Due to its relatively minor contribution to runoff, lawns and landscaped areas have been omitted from these analyses.

Table 10: Total Impervious Surfaces for Future Potential Development in Three Olympia Area Drainage Basins

Reduction Analysis

Based on the previous analysis, six potential strategies for impervious surface reduction were evaluated. The six strategies included:

1. Reduce residential sidewalks by 50 percent by installing sidewalks on only one side of the street.
2. Reduce residential sidewalks from five feet to four feet in width.
3. Reduce local access street widths from 32 feet to lesser widths.
4. Reduce commercial parking by five, ten, or 20 percent.
5. Reduce multifamily parking by five, ten, or 20 percent.
6. Reduce commercial, industrial, and multifamily roof areas by 10 or 20 percent.

For each strategy, two questions were asked:

- What percent of total and effective impervious surface would be reduced for a given development site?
- What percent of total and effective impervious surface would be reduced in the three drainage basins at 80 percent buildout?

The results of the reduction analysis calculations are summarized in Table 12 (page 45). Results of the reduction analysis include:

- Reducing sidewalks offers minor, possibly insignificant, reductions in total and effective impervious surfaces.
- Major reductions in residential street widths are needed before significant reductions in impervious surfaces can be expected.
- Reducing commercial, industrial, and multifamily parking could readily reduce impervious surfaces.
- Roof reductions imply constructing taller buildings with associated reductions in impervious surfaces.

VOL 12 2 3 9 1 3

R0057205

Table 12: Basin and Site Coverage Assessment Reduction Analysis Results

Potential Strategy	Impervious Surface Reduction Percentages			
	Site-Specific		Basin-Wide	
	Total	Effective	Total	Effective
1. Reduce residential sidewalks by 50 percent by installing the walks on one side of the street only.	1.33	1.00	1.59	0.83
2. Reduce residential sidewalks from 5 feet width to 4 feet width.	0.53	0.40	0.64	0.33
3. a. Reduce local access street widths from 32 feet to 27 feet.	2.50	2.00	2.98	3.12
b. Reduce local access street widths from 32 feet to 25 feet.	3.50	2.80	4.17	4.37
c. Reduce local access street widths from 32 feet to 20 feet.	6.00	4.80	7.15	7.49
4. a. Reduce commercial parking by 5 percent.	2.67	2.67	1.04	1.37
b. Reduce commercial parking by 10 percent.	5.33	5.33	2.09	2.74
c. Reduce commercial parking by 20 percent.	10.67	10.67	4.18	5.47
5. a. Reduce multifamily parking by 5 percent.	0.74	0.74	0.16	0.21
b. Reduce multifamily parking by 10 percent.	1.48	1.48	0.32	0.42
c. Reduce multifamily parking by 20 percent.	2.95	2.95	0.64	0.84
6. a. Reduce commercial, industrial, and multifamily roof areas by 10 percent.	4.25	4.25	1.38	0.94

R0057206

VOL 12 2 39-4

Assumptions of the Basin and Site Coverage Assessment

Results of the basin and site coverage assessment should be considered in light of several important assumptions.

- The street width reduction calculation assumed that all streets in residential areas were minor local access roads and would, therefore, be considered for width reduction. Since all residential streets are not local access roads, this assumption leads to an overestimate of impervious surface reduction.
- The analysis assumes that the area surplused by the parking reduction or other strategies would be landscaped rather than covered by impervious surfaces (i.e., building).
- The estimate of the effective fraction of impervious surfaces was based entirely upon best judgement. The subsequent analysis of impervious reduction strategies for residential sites is directly affected by these estimates.
- The effect of soil type on the effectiveness of impervious surfaces has not been addressed. Sites with highly permeable soils may have no effective impervious surfaces even though site coverage is high.
- Impervious surfaces associated with multifamily land use are assumed to be entirely (100 percent) effective at producing runoff.
- Full development conditions were assumed to be 20 percent less than allowed by zoning. This assumption has been commonly used in computer modeling of urban hydrology. It acknowledges that full development at zoning levels is unlikely, especially for residential development.

Even with these assumptions, the methodology used in this assessment provides a justifiable basis for investigating the performance of various impervious surface reduction strategies. Strategies investigated offer basin-wide impervious surface reductions ranging from 0.16 to 10.67 percent (Table 12, page 45). Once implemented, the performance of the new strategies could be easily quantified.

PARKING ANALYSIS

Special Parking Capacity Study

In order to better understand the parking situation in Olympia, a special parking capacity study was conducted. The purpose of the Special Parking Capacity Study was to assist Olympia's Community Planning and Development Department in revising the parking ordinance and to determine if proposed changes in Olympia's parking ratios (standards) would reduce impervious surfaces. The draft ordinance

VOL 12 2 391 5

R0057207

VOL 12 2 3916

(City of Olympia, 1994g), if adopted by the Olympia City Council, would replace the current "minimum" parking ratios with "median" parking ratios.

Methodology

Determining parking ratios for various land uses is not an exact science. The method most often used is to modify ratios from other local governments. Another method is to use the Institute of Transportation Engineers handbook (ITE, 1992). The handbook provides parking ratios that are based on national surveys of select land uses.

These two common methods normally establish the minimum parking ratios necessary to provide sufficient onsite parking, to prevent traffic congestion and overflow into residential neighborhoods. However, they do not provide parking ratios that avoid excess parking or allow for specific needs of individual communities.

Direct observation of parking stall occupancy during peak operating hours, though labor intensive, is an effective approach for determining if there is insufficient or excess parking in a community. This method is most helpful when trying to establish parking medians and was the one selected for the Impervious Surface Reduction Study's Special Parking Capacity Study.

Three tasks comprised the Special Parking Capacity Study:

1. Informational survey
2. Field survey
3. Reduction analysis

These tasks are described in detail below.

Informational Survey:

The first task was to administer an informational survey through phone and personal interviews (Appendix F, Parking and Informational Survey, page 187). Conducted from August 1 to August 14, 1994, this survey was administered to owners or managers of 31 selected sites in the North Thurston UGMA.

The sites were chosen by Olympia's Community Planning and Development Department, which identified them as representative of 15 different land uses that would be most affected by adoption of the proposed parking revisions. Six sites were located in the cities of Lacey and Tumwater. The remaining sites were located in Olympia. No sites in downtown Olympia were chosen. A committee convened in 1994 will be developing and reviewing a separate Downtown Olympia Parking Management Strategy.

R0057208

Several respondents indicated that summertime was not the peak season for their respective activities. Caution was used when drawing conclusions about peak occupancy rates for churches, retail stores, schools, and movie theaters since the counts were not made during their self-defined peak season. Due to the limited scope of this survey, further surveys using larger samples throughout the year are recommended.

Field Survey:

The second task was a field survey of 15 land uses conducted from August 1 through August 9, 1994 (Appendix G, Parking Field Survey Data Results, page 189). All existing parking spaces were counted at each site, for each land use. Occupied spaces were counted four times for each site, with the exception of the general office site which was counted only once. Counts were taken during peak hours, twice on weekdays, and twice on weekends.

Peak hours were determined by consulting the Transportation - Traffic Engineering Handbook (ITE, 1992), consultation with planning staff, and field observations. Peak hours for each land use and the number of occupied spaces during peak hours are listed in Appendix G (page 189).

Reduction Analysis:

The third task was to analyze what effect the proposed parking ordinance would have on impervious surfaces. To determine if median parking ratios would reduce impervious surfaces in Olympia, information from 11 of the field survey sites was combined with information taken from plans for four additional sites. The number of parking stalls for the 15 sites was determined (Table 13, page 49). Then, the number of parking stalls that would exist if they were constructed under the median parking ratios of the draft ordinance was calculated (Table 14, page 50).

Parking Capacity Study Results

Results of the surveys and reduction analysis overlap and are divided into three general categories: excess parking, parking deficiencies, and parking reductions.

VOL 12 2 3911

R0057209

Table 13: Selected Sites for Comparison of Existing, Proposed, and Actual Amount of Parking Stalls

Development Name/Type	Number of Existing Stalls	Number of Stalls Required Under Existing Minimum Regulations	Number of Stalls Required Under Proposed Median Regulations
Home Depot/Commercial Retail	544	324	520
Safeway/Commercial Retail	323	308	248
Top Foods/Commercial Retail	526	148	259
Costco/Commercial Retail	616	588	468
Best/Commercial Retail	211[1]	217	209
Windermere Offices/General	21	15	20
Eastside Office/General	29	23	18
McDonald's Downtown/Restaurants	44[2]	73	44
McDonald's West Side/Restaurants	83	76	46
Brewery City/Restaurants	37	37	37
Lacey Cinema Theaters/ Entertainment	425[1]	497	442
Pac West Health Club/Entertainment	117	—[3]	260
Kolb Storage/Warehouse	9	7	10
Homeport/Multifamily	180	96	134
Cambridge Court/Multifamily	316	240	238

(1) Shared parking arrangements skew the totals.
(2) The downtown McDonald's site was allowed to have 29 fewer parking stalls than the minimum required because of its downtown location.
(3) There are no existing regulations specific to health clubs.

VOL 12 2 3918
R0057210

Table 14: Comparison of Existing Stalls to Required Stalls Under Existing Regulations and Proposed Regulations

Type of Land Use/ Development	Number of Existing Stalls per Site Calculated From Site Visit or Plans	Number of Stalls Required Under Existing Minimum Regulations	Number of Stalls Required Under Proposed Median Regulations
Commercial Retail	2,220	1,585	1,704
General Office	50	38	38
Restaurants	164	186	127
Entertainment—Theaters/Health Clubs (1)	—	—	—
Storage Warehouse	9	7	10
Multifamily	496	336	372
Total Development	2,939	2,152	2,251

(1) Theaters are not included in the comparison because shared parking arrangements skew the number of existing stalls. Health clubs are not included because there are no existing regulations specific to health clubs.

Excess Parking:

- The majority of respondents (71 percent) indicated that the amount of available onsite parking was adequate (Appendix G, page 189).
- Despite parking capacity numbers that indicated as much as 60 and 70 percent vacancy rates, no respondent defined excess parking as a problem (Appendix G, page 189).
- Eighteen of the 31 representative sites had less than 75 percent occupancy rates during their busiest peak hour surveyed (Appendix G, page 189).
- Respondents from sites with more traditional daytime uses, such as a medical clinic, retail store, and service station, indicated that parking was inadequate even though occupancy ranged from 46 to 67 percent (Appendix G, page 189).

VOL 12 2 3919
R0057211

- The majority of sites have more parking than the minimum parking ratios require. There are a total of 809 more parking stalls at 12 of the survey sites than required (Table 15, page 52).

- The multifamily and large retail sites have the greatest percentage of parking in excess of the existing minimum parking ratios (Table 15, page 52).

Parking Deficiencies:

- Definitions of inadequate parking varied among respondents. Inadequate parking seems to be occurring at developments serving seniors, including both senior housing and institutional care facilities. Interview results indicate that there are more senior drivers now than in previous years, and that seniors receive more visitors and care providers in these facilities now than in the past (Appendix G, page 189).

- Seven representative sites exceeded 75 percent parking occupancy rates during their busiest peak hour surveyed (Appendix G, page 189).

- Churches, theaters, health clubs, and motels all had above 75 percent peak occupancy, yet reported that parking was adequate for their needs the majority of the time. Each of these land uses have evening peak hours (Appendix G, page 189).

- Prior to August 1994, health clubs were not included as a land use under Olympia's parking ordinance. The health club that was surveyed had an 87 percent occupancy rate at peak hours with six cars choosing to park on the street (Appendix G, page 189).

- Parking for storage warehouses would increase by 11 percent under the proposed median parking ratios (Table 16, page 53).

Parking Reductions:

- If the proposed median parking ratios had been applied instead of the existing minimum parking ratios, there would be fewer parking stalls and less impervious surface at 10 of the 15 sites used in the analysis (Table 13, page 49).

- Four of the six land use categories analyzed would have fewer parking stalls and less impervious surface associated with them if the proposed median parking ratios had been applied instead of the existing minimum parking ratios (Table 14, page 50).

VOL 12 2 3920

R0057212

Table 15: Difference in the Number and Percent of Parking Stalls Built Compared to Existing Minimum Requirements

Type of Land Use/Development	Number of Existing Stalls in Excess of Minimum Required	Percent of Existing Stalls in Excess of Minimum Required	Total Number of Stalls Fewer Than Minimum Required	Total Percent of Stalls Fewer Than Minimum Required
Commercial Retail	635	40%	—	—
General Office	12	32%	—	—
Restaurants (1)	—	—	29	16%
Entertainment—Theaters/Health Clubs (2)	—	—	—	—
Storage Warehouse	2	29%	—	—
Multifamily	160	48%	—	—
Total Development	809	38%	29	1%

(1) The downtown McDonald's site (Table 13, page 49) was allowed to have 29 fewer parking stalls than the minimum required because of its downtown location.

(2) Theaters are not included in the comparison because shared parking arrangements skew the number of existing stalls. Health clubs are not included because there are no existing regulations specific to health clubs.

- If the proposed median parking ratios had been applied instead of the existing minimum parking ratios, the parking for the multifamily, general office, commercial retail, and restaurant sites would have been reduced by 23 to 25 percent (Table 16, page 53).

Parking Capacity Study Conclusions

The results of the parking analysis indicate that most land uses have more parking than currently required. This finding confirms what planners have known for some time—that current parking ratios are artificially low and do not accurately reflect the parking needs of various land uses. The results also indicate that the majority of sites have excess parking stalls under the minimum parking ratios. However, due to the limitations of this analysis, further studies of median parking ratios are recommended. Future studies should include a greater number of observations conducted throughout the year.

VOL 12 2 3921

R0057213

VOL 12 2 3922

Table 16: Change in Number and Percent of Parking Stalls Built Under Proposed Regulations Versus Existing Stalls

Type of Land Use/ Development	Number of Stalls Reduced	Percent of Reduction	Number of Stalls Increased	Percent of Increase
Commercial Retail	516	23%	—	—
General Office	12	24%	—	—
Restaurants	37	23%	—	—
Entertainment— Theaters/Health Clubs [1]	—	—	—	—
Storage Warehouse	—	—	1	11%
Multifamily	124	25%	—	—
Total Development	689	23%	1	<1%

(1) Theaters are not included in the comparison because shared parking arrangements skew the number of existing stalls. Health clubs are not included because there are no existing regulations specific to health clubs.

Using minimum parking ratios has encouraged planners and developers to think of parking as negative only when there is not enough. This "bigger is better" view of parking lots has created excess impervious surface, particularly at large commercial retail and multifamily sites. This preliminary parking analysis indicates that using median parking ratios is an effective strategy for reducing impervious surfaces while providing parking ratios which are neither too high nor too low. Further studies are recommended for continued analysis of median parking ratios.

Cooperative Parking Survey

Smaller and fewer parking lots can result when separate land uses share parking. The Cooperative Parking Survey of Local Jurisdictions was used to assess existing local cooperative parking policies or regulations, and to identify incentives that may increase the use of shared parking.

R0057214

The informal survey was administered through phone interviews of five selected jurisdictions during the month of August 1994. The survey tool used can be found in Appendix H, Cooperative Parking Survey, page 205. The jurisdictions surveyed included the Cities of Olympia, Tumwater, Lacey, and Bellevue, and Thurston County. Respondents were planners in Community Development Departments. Responses to Questions 1 through 7 are summarized in the Results Summary (Appendix H, page 205). Responses to Question 7 were used to generate a list for a separate Cooperative Parking Participant Survey (City of Olympia, in preparation).

Results

Results of the Cooperative Parking Survey can be divided into two categories: incentives and barriers. Incentives for participating in cooperative parking that were mentioned by the respondents included:

- Reduced construction, landscaping, and maintenance costs.
- Decreases in required parking, ranging from five to 25 percent, if developers agree to share parking.
- An increased ability for developers to complete projects that would otherwise have been denied due to parking deficits.

Barriers to cooperative parking that were mentioned by the respondents included:

- Inflexible regulations and rigid regulatory language that limit locations appropriate for some cooperative parking and require a shared property line.
- Developer's perceptions that large parking lots are a necessity, particularly for large retail and commercial uses.
- The lack of model cooperative parking agreements. Local governments require legal agreements between some cooperative parking partners, but do not provide prototypes as part of technical assistance.
- Local governments do not document the benefits from cooperative parking or maintain records of cooperative parking arrangements.
- Though regulatory language allows cooperative parking, it is not highly promoted.
- Participation or exploration of cooperative parking options is not required as an option to building excess parking.

VOL 12 2 3923

R0057215

Cooperative Parking Survey Conclusions

Smaller and fewer parking lots can result from cooperative parking regulations. Developers and local governments can reduce parking by joining, sharing, or coordinating parking facilities. Parking ordinances that contain cooperative parking policies are an excellent avenue for jurisdictions to promote the reduction of impervious surfaces. Parking ordinances that require the exploration of cooperative parking, such as shared parking, can prove an effective educational tool, moving public thinking towards reducing impervious surfaces.

Language used for cooperative parking varies from local government to local government. Developing common language for the various types of cooperative parking arrangements may facilitate a clearer understanding of parking options for developers. Some suggested language and accompanying parking reductions are as follows:

- Shared parking reduces parking for land uses with noncompeting hours of operation. Suggested parking reductions are 100 percent reduction of the smaller parking requirement for complimentary daytime and nighttime land uses, and 50 percent of the smaller parking requirement for land uses with some overlap of hours.

- Joint parking reduces the total parking required for multi-tenant retail and commercial facilities. The possibility of captured trips and increased overflow parking allows for overall reductions for each land use at these sites. Suggested parking reductions are 10 percent for developments with two buildings, and 25 percent for developments with three or more buildings.

- Coordinated parking reduces total parking by using large retail or commercial overflow parking for safe, convenient park-and-ride or trail head locations.

OTHER RESEARCH

In addition to the literature and policy review, demonstration projects, basin and site coverage assessment, and parking analysis, staff also researched other issues related to the recommendations.

Cost Analysis

The study goal includes a commitment to determine strategies that don't increase development costs (Chapter 1, page 14). In order to compare recommended strategies with current practices, staff researched costs for many of the recommendations. The resulting information is summarized in Chapter 3 in the incentives and barriers sections for each recommendation.

VOL 12 2 3924

R0057216

A formal cost/benefit analysis was not conducted due to the breadth of the recommendations and complexity of the issue. Although a formal cost/benefit analysis was not conducted, the information contained in this report does provide some useful guidance. However, the cost calculations reflect a large measure of best professional judgment and are based on numerous assumptions. In a real-world development, soils and other site characteristics would greatly influence actual costs. Any conclusions or application of the costs to other locations or uses should be done with caution.

Paver Places and Faces Survey

During the study, several citizens, members of the development community, and others noted their support for using pavers as a solution to the infiltration blockage caused by impervious surfaces. However, there is widespread misunderstanding about the limited usefulness of pavers. Pavers have limited usefulness for three main reasons. First, the use of pavers should be restricted to low use areas because of the need to infiltrate only clean water and avoid groundwater contamination. Second, pavers are two to four times as costly as asphalt, making widespread use of pavers an expensive alternative. Third, most pavers do not meet Americans with Disabilities Act (ADA) standards and pose a liability problem for local governments and businesses.

Appropriate applications for pavers include emergency or stormwater facility access roads, overflow parking areas, and non-handicapped parking stalls. Residential driveways, walkways, patios, and other areas are some of the most appropriate locations for pavers. Residential areas generally do not receive extensive use or pollutants. Residential applications do not need to meet ADA standards.

In order to better understand how well pavers have worked in residential settings, staff conducted an informal survey of homeowners. Residential applications of pavers were identified during staff field activities. Six homeowners were sent letters requesting they contact the study coordinator for a phone interview. The three homeowners that responded were asked six questions concerning how long the pavers had been installed; ease of installation, costs, and source of materials; use of the area; maintenance required or problems encountered; the motivation for putting in pavers; and willingness to recommend pavers to others. The results include:

- The period of time that the pavers had been installed range from one month to 10 years.
- All three homeowners said the pavers were easy to install and required no professional assistance. All three installed them on a sand base and purchased the pavers from Mutual Materials Company, Tumwater. Exact costs were unavailable but were estimated at $600 to $3,000, depending on size and type of paver used.

VOL 12 2 3925
R0057217

- All three homeowners are using the pavers for parking. One homeowner used them to replace a center area of his driveway, where a tree was removed. The area is now used for washing cars and parking. The two other homeowners use the pavers for overflow parking of boats and extra cars.

- All three homeowners had not experienced significant maintenance problems.

- The main motivation for installing the pavers for all three homeowners was aesthetics. All three had seen pavers in other locations (Tumwater Falls Park, South Puget Sound Community College, Thurston County Courthouse) and liked the look of them. Two homeowners also installed the pavers to increase infiltration due to poor soils or topography of their yard.

- All three homeowners would recommend pavers to others. One homeowner has integrated pavers into his new house plan.

VOL 12 2 3926

R0057218

CHAPTER 3
RECOMMENDATIONS FOR OLYMPIA, NORTH THURSTON COUNTY URBAN GROWTH MANAGEMENT AREA, AND OTHER LOCATIONS

This chapter summarizes study results and presents 19 recommendations. The recommendations are grouped into six categories:

- Overall Recommendations
- Vehicle-Oriented Pavement
- Construction Practices and Landscaped Areas
- Design and Placement of Buildings
- Community Involvement and Education
- Study Evaluation

The information contained in this chapter is derived from the technical and policy analysis described in previous chapters, interviews with representatives of local governments, input from the Ad Hoc Citizen Advisory and Steering Committees, and input received through community forums and other public involvement and education activities. Each recommendation is presented, followed by discussion of technical and policy issues, incentives and barriers to implementation, policy trends, specific actions for implementation, and implementation costs for Olympia.

SCOPE OF RECOMMENDATIONS

It was recognized early on by the project team that recommendations designed for Olympia may not work for all of the North Thurston County Urban Growth Management Area (North Thurston UGMA) or other locations because of the specific mix of public goals in Olympia. It also was recognized that recommendations not suitable for Olympia may work elsewhere. Consequently, efforts have been made to document the process and results so others may learn from Olympia's successes and challenges, and to provide useful policies and techniques that can be readily applied in Olympia, the North Thurston UGMA, or other locations throughout the state and nation.

As you review the recommendations, please keep in mind that this report summarizes a study, not a planning process. The recommendations and information contained in this report are provided as guidance to Olympia and other communities and will not necessarily be adopted by the City Council. Integration of most recommendations into policies or regulations will occur or have occurred through separate processes—such as revision of the parking, street, and development standards. These processes will provide or have provided opportunities for the public to weigh impervious surface reduction with other public goals, and ensure

VOL 12 2 3927
R0057219

that recommendations are applied in a reasonable and practical manner. Other local governments that implement some or all of the recommendations are highly encouraged to solicit early and abundant involvement from the community.

This report signifies a beginning for reducing impervious surfaces in Olympia, and leaves as many unanswered questions as it has answered. More research could be done to better define hydrological relationships, costs, and incentives. When applying the recommendations to Olympia, North Thurston UGMA, or other locations, it is important to keep in mind that impervious surface reduction is still an experiment—one that needs to begin so that we can find real-world solutions. Evaluation is an essential step to understanding the success and limitations of the study (Recommendations for Study Evaluation, page 119). Communities working to reduce impervious surfaces are encouraged to contribute to a study evaluation by contacting the study coordinator and sharing their experience.

STRATEGIES CONSIDERED AND IN NEED OF FURTHER ANALYSIS

The Ad Hoc Citizen Advisory Committee and project staff spent several meetings exploring possible impervious surface reduction strategies. Many of these strategies are summarized in the Technical and Policy Analysis Report (City of Olympia, 1994b), which contains 11 more recommendations then this report. Many of the preliminary recommendations were dropped due to conflicts with other public goals or because of overlap with other planning processes. The substantial changes made to the recommendations during the course of the study reflect the lessons learned by the committee and project staff concerning community goals.

Many strategies contained in the initial recommendations and resulting from recent committee discussions may have value for other locations, depending on site-specific public goals, soils, precipitation, and population or community structure. However, these strategies are not recommended at this time because they require further discussion and research. To assist other local governments in applying the study's findings, these strategies are briefly described below. More detail is available from the study coordinator.

- In recognition that impervious surface reduction strategies are new and will need refinement, develop performance-based standards for sidewalks, parking, and landscaping to encourage innovation and provide flexibility in meeting impervious surface reduction goals.

- Provide public support and sponsorship of private developments meeting impervious surface reduction goals such as higher-density development, reduction in vehicle-oriented pavement, use of pervious surfaces, and less land clearing and soil compaction. Use tax increment financing, redevelopment loans, density credits and other public funding mechanisms, and encourage

VOL 12 2 3928

R0057220

private funding of such developments. Meet with the development and business community to identify practical incentives.

- Use zero or narrower setbacks, consolidate landscaped areas and perimeter plantings into one large area, count undisturbed areas and native vegetation towards landscaping requirements, and/or give density credits for pocket parks to encourage large blocks of undisturbed areas that infiltrate runoff. Convert parking lots into parks and restore infiltration capacity (where possible).

- Identify opportunities for retrofitting existing paved areas. Some suggestions include placing vegetated islands designed to treat stormwater in cul-de-sacs and intersections where safety will not be jeopardized; reducing the size of parking areas, using pervious surfaces, or building taller buildings when redeveloping a site; and reducing street widths by replacing existing pavement with street trees.

OVERALL RECOMMENDATIONS

Several of the recommendations reflect the growth management planning being done in the North Thurston UGMA. Growth management strategies are being applied or considered to varying degrees by Olympia, Lacey, Tumwater, and Thurston County through their comprehensive plans (Thurston County, 1988; City of Tumwater, 1993; City of Lacey, 1994c; City of Olympia, 1994d) and the Regional Transportation Plan (Thurston Regional Planning Council, 1993b). During the study, several growth management strategies were evaluated to determine their effectiveness in reducing impervious surfaces and to ensure that study recommendations are consistent with the local policy direction.

In the early stages of the study, the project team developed preliminary recommendations that overlapped the growth management planning occurring in the North Thurston UGMA. Several of the preliminary recommendations restated transportation and land use planning decisions being made in larger public forums, rather than providing new or specific direction to reducing impervious surfaces. To reduce duplication of planning efforts, many of the preliminary recommendations were grouped into the following three, overall recommendations.

VOL 12 2 3929

R0057221

Recommendation 1.
Integrate impervious surface reduction into policies and regulations.

Discussion

Local stormwater management practices are designed to manage stormwater runoff and remove pollutants but don't directly address a significant source of runoff—impervious surfaces. A whole host of development, transportation, urban design, and other policies and regulations affect the land use pattern in our communities, and the resulting amount of impervious surfaces. General review of local policies and regulations, and conversations with other jurisdictions revealed that it is unusual to find impervious surface reduction mentioned or considered in local government policies or regulations.

Although most city and county staff contacted during the study seemed aware of the water resources problems related to impervious surfaces, reduction of impervious surfaces generally has not been implemented through formal policies and regulations, or considered an explicit public goal by local governments. Integrating impervious surface reduction into several policies and regulations ensures that it will be put before the public for comparison with other public goals, and with other strategies for achieving water resource protection and enhancement.

Incentives and Barriers

Most policies and regulations address a single issue, such as parking, streets, or clearing and grading practices. Even though this may be practical for other reasons, this poses a barrier to implementing impervious surface reduction strategies. Because the problems with impervious surfaces are not related to just one issue, it is important to make lots of small changes to several policies and regulations in order to achieve a measurable reduction. The common practice of revising only a few policies or regulations a year requires several years to accomplish a significant level of implementation and results, and vigilance on the part of staff and concerned citizens to keep the issue "on the table."

Inadequate involvement of the business and development community in decisions that directly affect them is a barrier to successful policies and regulations. Having the development and business community involved in land use decisions that reduce impervious surfaces is important. What may intuitively sound feasible and rational on paper may not always work in the real world given financing and construction constraints. The development and business community can help identify incentives and barriers to specific strategies.

VOL 12 2 3930

R0057222

Policy Trends

Local comprehensive drainage basin plans contain a recommendation to revise development standards to minimize impervious surfaces by such measures as requiring narrower streets, increasing the use of porous pavements, reducing parking requirements, and revising landscaping requirements. The plans recommend adoption of common standards by the four local governments in Thurston County (City of Olympia, 1993b).

Olympia

The Olympia City Council has pledged to evaluate all city policy decisions based on the city's Sustainable City Criteria (see Olympia's Sustainable City Philosophy, page 18). The criteria ask that policies and regulations not jeopardize future generations, and take into account environmental, economic, and social implications. Applying the criteria results in taking a long-term view of decisions and using an integrated or holistic approach to community planning. Having impervious surface reduction as a stated goal or objective of policies and regulations reminds decision-makers, staff, and the public of one way to achieve sustainability.

During the study, project staff have participated in the revision of parking, street, and development standards as a means to implement early findings of the study. Many of the recommendations contained in this report have already been incorporated into versi[illegible] Olympia's parking, street, and development standards (City of Olympia, 1994e; 1994g; 1994h). These regulations will be or have been presented for public review and comment in separate forums.

Olympia's Community Planning and Development Department (CPDD) is considering conducting a consolidated annual review of proposed revisions to city policies and regulations. A consolidated review would be more cost effective and time efficient and allow an opportunity to resolve inconsistencies. An annual review would give Water Resources Program staff and citizens an opportunity to identify economic incentives and additional areas where impervious surface reduction could be integrated.

Lacey

Current comprehensive plan policies do not explicitly refer to impervious surface reduction as a goal (Carr, pers. comm.).

VOL 12 2 3931

R0057223

Tumwater

The transportation element of the comprehensive plan includes policies to reduce the amount of impervious surface to the extent practicable, and to use alternative surfaces and natural design methods to reduce total surface runoff, slow concentrations, and capture pollution (Bauer, pers. comm.).

Thurston County

Adopted city/county joint comprehensive plans will apply city policies on parking and development to appropriate locations within the unincorporated portion of the North Thurston UGMA (Dosherry, pers. comm.). The current comprehensive plan, adopted in 1988, and proposed revisions now being considered do not explicitly refer to impervious surface reduction. However, the natural environment chapter includes a policy that existing and new development should minimize increases in total runoff quality and maximize infiltration. A proposed revision would discourage increases in peak stormwater runoff and alteration of natural drainage systems to prevent flooding and water quality degradation (Morrison, pers. comm.).

Implementation Actions

Olympia

Many policies and regulations are being revised to bring them into compliance with Olympia's comprehensive plan (Chapter 1, Policy Focus and Early Implementation, page 18). The commercial, multifamily, and residential development standards; landscaping ordinance; parking ordinance; and street standards are currently being revised. Such revisions have provided or will provide a cost effective opportunity to integrate impervious surface reduction.

Several changes to the parking ordinance's goals statement, ratios (standards), shared parking section, and variance requirements are being proposed as a direct result of this study. Proposed changes to the draft street standards include narrower residential streets and alleys (Table 17, page 65). If these regulations are adopted as proposed, Olympia should experience an almost immediate reduction in future impervious surfaces from what is expected under the current trend (Figure 3, page 7).

North Thurston UGMA and Other Locations

Lacey, Tumwater, Thurston County, and many other Washington local governments are currently required by state law to bring their policies and regulations into compliance with their new comprehensive plans. This presents an opportunity for many communities in the state to implement impervious surface reduction in the near future.

Because every community adopts policies and regulations as a way to define its character and land use, every community could consider impervious surface reduction regardless of its size or growth management framework. Public hearings and meetings, document review and comment periods, and other community involvement and education activities are readily-available opportunities for involving the public in impervious surface reduction issues. Even if a community is not currently creating or revising regulations, it may want to conduct a one-time review of all policies and regulations to see how local laws or practices could be changed to encourage impervious surface reduction. Important to successful impervious surface reduction is the early participation and collaboration of all segments of the community in identifying strategies and avenues for implementation.

Implementation Costs for Olympia

No additional costs.

Recommendation 2.
Establish growth management policies that encourage infill of urban areas and reduce urban sprawl.

Discussion

The recommendations in this report are designed to raise awareness and complement the growth management policies being developed and implemented for Olympia and the rest of the North Thurston UGMA. The local growth management strategies encourage, among other things, infill of urban areas and use of congestion reduction programs, public transit, and other alternative modes of transportation. Infill reduces the amount of impervious surfaces per capita (person) and complements the goal and objectives of this study.

The basic premise of infill is that higher densities in urban areas allow rural areas to remain in low density or resource-based land uses, requiring fewer roads and other impervious surfaces region-wide. Successful implementation of this recommendation would increase total impervious surface in the region, but at a slower rate than with

VOL 12 2 3935
R0057227

the current development trend (Figure 3, page 7). In rural areas, impervious surfaces would increase less than the current trend because the current low density land uses would not be replaced with suburban or commercial development. In urban areas, more impervious surfaces such as buildings would occur to accommodate higher commercial and residential densities. However, there would be less impervious surface per capita (person) or per development unit.

This recommendation includes developing vacant residential or commercial lots in the urban growth management area and redeveloping underused areas to a higher density. Possibilities include redevelopment of lots with deteriorating structures to higher density, and building in parking areas or vacant lots.

Water quality and quantity impacts depend on several factors, including soil type, previous site disturbance, population, and traffic levels. Building on a vacant lot that has been largely undisturbed usually results in more runoff from the site, requiring installation of a stormwater management system. Redeveloping a previously developed lot usually does not appreciably change the amount of runoff unless the amount of impervious surface is increased.

Incentives and Barriers

Reducing the costs of public services is a community-wide incentive for infill. Infill results in reduced impervious surfaces and less low-density residential sprawl into previously rural areas. The costs of sprawl have been documented in certain studies (American Farmland Trust, 1986). These studies have concluded that the public economic and environmental costs are higher for low-density development than for high-density development.

The costs of public services required to serve low-density residential areas usually exceeds the tax revenues generated by them. For example, a study in Loudoun County, Virginia concluded that the net public cost to the county would be approximately 40 percent more for low-density residential (1 unit per 5 acres) than for high-density residential (4.4 units per acre). The higher public cost for low-density residential development primarily results from inefficient use of schools and transportation services, and higher liabilities for roads and future water and sewer services. Annual road maintenance costs were estimated to be four times greater for low-density residential than for high-density residential (American Farmland Trust, 1986).

Higher densities are a key to infill and reducing urban sprawl. However, infill may change the existing character of neighborhoods or other areas. Such change is a barrier to public acceptance of increasing densities. Undeveloped lots in urban areas are often the most expensive to develop, creating a barrier to infill. Developers may avoid infill projects because they anticipate neighborhood resistance or because lots located elsewhere are less expensive to develop.

VOL 12 2 3936

R0057228

When encouraging infill, it is important to have coordination among neighboring cities and counties. Such coordination reduces the chances that one community will concentrate its urban growth next to another community's rural area, and create a patchwork land use pattern. The long history of independent legal authority of local governments may be a barrier to region-wide growth management planning that result in impervious surface reduction. Incentives for coordination include saving money by providing joint public services such as arterial streets and regional stormwater, sewer, and water systems; and providing consistent regulations for the development and business community.

Policy Trends

Olympia

The existing Planned Residential Development ordinance is intended to promote infill and more economic, efficient use of urban land by allowing more site coverage than would normally be allowed by the zoning code (City of Olympia, 1991). The ordinance is being revised to encourage both infill and mixed use development, and it is intended to be easier to implement (City of Olympia, 1994j).

Consistent with the Growth Management Act requirements and urban design strategy recommendations, the recently adopted comprehensive plan (City of Olympia, 1994c) encourages infill development and redevelopment that is compatible with the surrounding area. Policies for maximum and minimum densities and allowing accessory units, zero lot line development, and small conventional lots support this goal.

Plan policies also support infill strategies such as mixed uses and cluster housing. Plan policies allow increased building heights, reduced parking, and increased site coverage, especially in downtown Olympia and along high density corridors. Olympia is currently updating its zoning code and other regulations to implement these policies.

The current zoning code (City of Olympia, 1991) disallows accessory dwelling units in single family zones. Minimum lot sizes and setback requirements also restrict the possibility of infill. For example, the zoning code allows only 35 to 50 percent site coverage in residential zones.

VOL 12 2 3931

R0057229

Lacey

The housing element of the comprehensive plan (City of Lacey, 1994c) allows accessory units in all residential areas and higher density in exchange for providing affordable housing. The transportation element of the comprehensive plan encourages development of parking that can be redeveloped later to a more intense use.

Tumwater

The comprehensive plan (City of Tumwater, 1993) proposes to prohibit development at less than the minimum net densities for a given area in order to promote cost-efficient services, affordable housing, and alternative transportation. The plan also recommends allowing accessory units in all residential zones.

Thurston County

City polices allowing accessory units, small lot sizes, and minimum densities in residential districts are also proposed for the unincorporated portion of the North Thurston UGMA as part of the city/county joint plans (Dosherry, pers. comm.).

Implementation Actions

Olympia

Complete growth management planning process and implementation. Adopt the Draft Unified Development Code (City of Olympia, 1995) as proposed.

North Thurston UGMA and Other Locations

Complete growth management planning process and implementation. If a growth management framework is not in place, consider conducting a comprehensive land use planning process that designates areas for infill and urban growth concentration, and increases densities and building heights where possible as a way to reduce sprawl. Consider relaxing setback standards and modifying other policies or regulations to encourage infill.

Implementation Costs for Olympia

No additional costs.

VOL 12 2 3938

R0057230

Recommendation 3.
Provide a public transit system and other alternative modes of transportation that reduce the need for streets and parking.

Discussion

The basin and site coverage assessment (Chapter 2, page 34) identified streets and parking as key contributors of impervious surfaces. Providing public transit and other alternative modes of transportation, promoting parking management, and using other strategies can reduce our reliance on cars and the need for more vehicle-oriented impervious surfaces in the future.

Reducing the current growth trend of vehicle-oriented impervious surfaces (Figure 3, page 7) depends upon having facilities that support public transit and alternative transportation such as buses, carpools, and bikes. Facilities such as park and ride lots, bike lanes, sidewalks, bus stops, and trails will contribute to the total amount of impervious surface. However, pollution from these facilities is expected to be less than from streets and parking areas because of the low or non-existent use by cars.

Incentives and Barriers

There are numerous incentives and barriers to providing, maintaining, and using a public transit system and alternative transportation. Increased use of public transit would reduce the number of single-occupant vehicles and auto-related contaminants in stormwater and maximize use of existing streets. Achieving reduced auto dependence will take a full range of actions including land use changes, incentives, and disincentives. Specific actions include infill of city centers and high density corridors, carpool and vanpool programs, and parking management. The Regional Transportation Plan (Thurston Regional Planning Council, 1993b) for the North Thurston UGMA presents detailed discussion on incentives and barriers.

Providing positive incentives is essential to encouraging the use of public transit and alternative transportation. Also essential is providing alternatives that are convenient, safe, and practical that will provide adequate access by customers to businesses. Ensuring the viability of businesses, especially in city centers like downtown Olympia, is crucial to community support and use of transportation alternatives.

VOL 12
2
3939
R0057231

Policy Trends

The Regional Transportation Plan (Thurston Regional Planning Council, 1993b) recommends emphasizing the needs of pedestrians, transit riders, cyclists, and carpoolers in urban core areas and high density areas.

Olympia

Comprehensive plan (City of Olympia, 1994c) policies encourage development of transit and bicycle/pedestrian facilities on arterials and off-street bicycle/pedestrian trails. The land use and transportation elements of the comprehensive plan emphasize land use patterns, densities, site designs, and facilities that encourage public transit and alternative transportation.

Several draft policies or regulations encourage alternative transportation. The draft parking ordinance (City of Olympia, 1994g) includes incentives to encourage use of mass transit, bicycles, pedestrian, and carpool facilities. Draft street standards require bicycle facilities (Class II or Class III) on all major collectors and arterials (City of Olympia, 1994d). The draft zoning ordinance (City of Olympia, 1994f, 1994g, 1994i) encourages alternative transportation.

A Transportation Demand Management (TDM) Ad Hoc Committee was convened in 1994 to guide the application of TDM measures to the 4th/5th Avenue Corridor. The committee will complete the following tasks:

1. Develop a TDM strategy for the corridor;

2. Develop and review the Downtown Olympia Parking Management Strategy Update Study; and

3. Coordinate and participate in efforts by Intercity Transit, the Olympia Bicycle/Pedestrian Advisory Committee, Washington State Department of General Administration, and Energy Outreach Center to implement commute trip reduction and TDM measures. The TDM measures applied to the 4th/5th Avenue Corridor will serve as a model for further TDM efforts the city may undertake in the future (Stimson, pers. comm.).

Lacey

Existing zoning for the Lacey Central Business District requires pedestrian and transit facilities and site designs that cluster buildings to reduce walking distance between each building. The recently adopted comprehensive plan requires and encourages alternative transportation (Carr, pers. comm.).

VOL 12 2 3940

R0057232

Tumwater

The transportation element of the comprehensive plan emphasizes a mixed transportation system, including roadways, transit, bicycle, and pedestrian facilities, as well as policies promoting TDM and non-motorized transportation. A system of bicycle lanes is included in the draft transportation element, and an urban trails system is included in the parks and recreation element of the comprehensive plan (Bauer, pers. comm.).

Thurston County

Adopted city/county joint comprehensive plans will apply city policies on alternative transportation to the unincorporated portion of the North Thurston UGMA (Dosheery, pers. comm.).

Implementation Actions

Olympia

Implement the Regional Transportation Plan and complete the TDM Ad Hoc Committee's tasks (Downtown Parking Management Strategy).

North Thurston UGMA and Other Locations

Implement the Regional Transportation Plan. If no regional plan is in place, consider working with the local and neighboring communities in the planning and implementation of regional public transit and facilities for alternative transportation.

Implementation Costs for Olympia

No additional costs.

The following seven recommendations address vehicle-oriented pavement such as streets and parking areas. According to the basin and site coverage assessment (Chapter 2, page 31), streets and parking areas make up a significant portion of Olympia's impervious surfaces. Reducing vehicle-oriented pavement can result in impervious surface reduction, but needs to be done in cooperation with the local business and development community in order to identify cost-effective strategies.

VOL 12 2 3941

R0057233

RECOMMENDATIONS FOR VEHICLE-ORIENTED PAVEMENT

According to the basin and site coverage assessement (Chapter 2, page 31), streets and parking areas make up a significant portion of Olympia's impervious surfaces. Reducing vehicle-oriented parvement can result in impervious surface reduction.

Recommendation 4.
Develop standards for narrower residential streets with reduced, but adequate, parking opportunities.

Discussion

Since residential streets make up a large portion of impervious surfaces in north Thurston County, narrowing residential streets could appreciably reduce stormwater runoff and increase infiltration.

Reducing the widths of new residential streets from 32 feet to 25 feet could result in approximately a 4.4 percent reduction in effective impervious surfaces for the North Thurston UGMA at 80 percent of buildout (Table 12, page 45). Reducing widths from 32 feet to 20 feet could result in a 7.5 percent reduction. However, significant increases in water quality are not expected from reducing the amount of vehicle-oriented impervious surfaces unless there also is a reduction in the source of pollution: cars and other vehicles.

Residential streets should be wide enough to allow access by emergency response vehicles, city maintenance and garbage trucks, and transit buses and vans. Several options exist to accommodate narrower streets and the need for adequate access. For example, installing sprinkler systems in buildings and spacing hydrants closer together could compensate for narrower streets. However, fire suppression systems and other options are more expensive than current requirements. Having an interconnected grid system of streets (interconnected streets), minimizing cul-de-sacs and dead end streets, and shortening the length of city blocks allows easier access by emergency response vehicles.

Incentives and Barriers

The incentives for narrowing streets include reduced vehicle speeds, construction costs, stormwater runoff, and need for public right-of-way. However, narrowing arterials or high use streets such as those in downtown Olympia can decrease safety and contribute to congestion if narrowed too much. Such congestion can become inconvenient and act as barrier to business. Consequently, this recommendation to narrow streets is limited to residential streets only.

VOL 12 2 3942
R0057234

Residents like narrower streets because they slow traffic, as long as there is adequate parking for visitors. Grid patterned streets can be designed with jogs, islands, or other devices to slow drivers and enhance safety on residential streets.

Narrowing residential streets could result in a cost savings to developers, builders, and local governments. The cost of asphalt paving is typically $1.00 per square foot. Given a residential lot with 75 feet of street frontage, the cost savings from narrowing the asphalt street would be $7.00 per linear foot if the residential street is narrowed from 32 feet to 25 feet in width. The total cost savings would be $525 per residential lot. For a 40 unit subdivision, the cost savings would be approximately $21,000. In addition, narrowing the street would provide 21,000 square feet of land for other purposes.

Policy Trends

Olympia

Current comprehensive plan policies aim to ensure that local streets are as narrow as practical for providing adequate emergency access, minimizing stormwater runoff, and other purposes. The plan encourages a "dense pattern of interconnected streets," and limiting cul-de-sacs and dead-ends. The interconnected streets policy promotes a modified grid that includes curved streets and some dead ends and cul-de-sacs where topography precludes connections. This new policy will likely increase the total amount of vehicle-oriented impervious surface, but will result in fewer arterial streets being widened (City of Olympia, 1994c).

Standards for all street classifications are currently being evaluated (Table 17, page 65). The city is proposing to base street widths on projected function, need, or volume in the next 20 years, rather than solely on street classification (e.g., arterial, local access). This strategy will provide more options to build narrower streets where appropriate.

The city is proposing to narrow local access streets to 20 or 25 feet, depending on block length, and narrowing neighborhood collector streets from 32 to 27 feet. The city also is proposing narrowing arterial lane widths from a typical 12 feet to the acceptable federal standard of 11 feet. This narrowing will occur where the lane is not immediately adjacent to a curb, and where there is a bike facility (Class II or Class III) or parking lane. High-use streets do not accommodate on-street parking safely, and require wider lanes for safe travel and emergency access (City of Olympia, 1994d).

VOL 12 2 3943

R0057235

Lacey

Current policy allows private streets to be 24 feet wide in **Planned Residential Developments (PRDs)**. The land use element of the comprehensive plan recommends a grid system for planning areas that are relatively undeveloped (Carr, pers. comm.). Most of these planning areas are outside the current city limits. The housing element of the comprehensive plan recommends interconnected residential streets no more than 24 to 32 feet wide with planter strips and sidewalks. The transportation element includes several major arterial widening projects and new arterials that include bike lanes (City of Lacey, 1994b).

Tumwater

The comprehensive plan housing element calls for a review of the city development standards to identify requirements such as residential street widths which may unnecessarily increase the cost of housing (Bauer, pers. comm.). The Capitol Campus Plan for the future town center builds on the existing Tumwater grid of interconnected streets (Washington Department of General Administration, 1992).

Thurston County

Adopted city/county joint plans will apply the street design strategies in the city comprehensive plans to the unincorporated portion of the North Thurston UGMA (Dosheery, pers. comm.).

Implementation Actions

Olympia

Adopt the street standards as proposed (City of Olympia, 1994g).

North Thurston UGMA and Other Locations

Because Lacey, Tumwater, and Thurston County will be revising their streets standards in the near future to comply with their comprehensive plans, they will have an opportunity to narrow residential and other streets where practical. Several other cities and counties planning under Washington's Growth Management Act also have an immediate opportunity to narrow residential and other streets where practical. Before narrowing streets, it is recommended that discussions be held with the local fire department to ensure adequate access for fire fighting equipment, and with the local businesses to ensure that narrower commercial streets do not act as a deterrent for customers.

VOL 12 2 3 9 4 4

R0057236

Implementation Costs for Olympia

No additional costs.

Recommendation 5.
Use pavers and other pervious surfaces for low use areas such as overflow parking and emergency access roads.

Discussion

Porous pavement, pavers, and alternative surfaces such as bark and gravel can be used for recreational bike and jogging trails, walkways, alleys, overflow parking, emergency access roads, and other low-use areas to increase infiltration and decrease stormwater runoff.

The most common form of pervious surface for roadway use is a coarse asphalt (porous pavement) which has more open pore space than typical asphalt. Porous pavement has been used in numerous research and investigative settings over the past 15 years. By diverting rainfall through a porous pavement into an underground rock reservoir, the need for traditional stormwater conveyance and treatment may be reduced or eliminated, depending on site-specific factors. Potentially, porous pavement could provide stormwater quality control, flow moderation, and groundwater recharge, and could reduce the need for stormwater facilities. When performing properly, porous pavement is comparable in cost and effectiveness to traditional paving techniques and associated stormwater management systems (Schueler et al., 1992).

Porous pavement has been used successfully in some large, commercial parking lots in the eastern United States (Cahill Associates, 1995). However, problems can arise if porous pavement is not designed, constructed, or maintained properly (Field et al., 1982; Gogorth et al., 1983; Schueler, 1987). According to one source, if moisture is allowed to intrude the aggregate base and subgrade, the ability of porous pavement to bear weight is weakened. The pavement will fail unless it is thick enough to compensate for the weak base. Thickening the pavement can be very expensive. Placing an impermeable membrane between the porous pavement and base and redirecting water out and away from the pavement can help keep moisture from intruding into the aggregate base and subgrade (Asphalt Institute, 1994). However, this potentially negates the purpose of using porous pavement in some situations.

The following constraints should be kept in mind when using porous pavement:

- High susceptibility to siltation and subsequent clogging.

VOL 12 2 3945
R0057237

- Need to infiltrate clean water and reduce risk of groundwater contamination.
- Feasible only where soil is permeable, water table is deep, slopes are gentle, and traffic levels are very low.
- Need to provide a high level of care in design, construction, and maintenance to ensure proper performance.

Using porous pavement is supportable only after site-specific feasibility studies are conducted and regular inspections can ensure very high levels of workmanship (Schueler, 1987). Although not appropriate for widespread use, porous pavement may be suitable for the following applications (Washington Department of Ecology, 1991):

- Parking areas, especially fringe and overflow areas.
- Emergency lanes and vehicle cross-overs on divided highways.
- Low-traffic volume roads such as maintenance and emergency access roads.

Various types of pavers in numerous shapes and sizes also can be used for infiltrating stormwater while providing a rigid surface. Many of these are aesthetically pleasing alternatives to concrete, but typically cost two to four times as much as conventional pavement (Washington Department of Ecology, 1991). Grass can often be grown within the pavers. Several different types of pavers are available:

- Lattice pavers are generally flat with a grid-like appearance. Grass is commonly encouraged to grow within the grids, although some pavers are designed for gravel and thus avoid the historic maintenance and siltation problems of grass-filled pavers.
- Modular unit pavers such as solid bricks and cast concrete can accommodate infiltration if installed in a loose configuration.
- Subsurface plastic rings are capable of supporting substantial weight while allowing full grass coverage.

Many of the same concerns and limitations described for porous pavement apply to use of pavers. Appropriate sites for pavers include:

- On-street parking in residential neighborhoods.
- Parking pads in camping areas for recreational vehicles.
- Private roads, easement service roads, and fire lanes.

VOL 12
2
3946
R0057238

- Industrial storage yards and loading zones.
- Residential and light commercial driveways.
- Bike paths, walkways, patios, and swimming pool aprons.

Alternative surfaces such as gravel, bark, and rock provide some infiltration compared to asphalt and concrete. The amount of infiltration depends on the type of underlying soils, the amount of soil compaction, and the thickness of the materials. Initial installation of most alternative surfaces are less expensive than asphalt or concrete. Like porous pavement and pavers, use of alternative surfaces should be restricted to reduce possible risk of groundwater contamination and only if a high level of maintenance can be guaranteed.

Incentives and Barriers

The Drainage Design and Erosion Control Manual for Olympia (City of Olympia, 1994a) currently provides some cost incentives for using pavers. The runoff volume stored in paver interstices (openings) can be deducted from stormwater storage and other management requirements if the interstices are 0.75 inches or more deep. This can result in smaller stormwater facilities.

If a typical two-acre commercial development used pavers for fringe and overflow parking amounting to 20 percent of the total parking area, the stormwater detention pond (facility) could be reduced by approximately seven percent or 850 square feet of land area. This could potentially provide space for additional density or leasable commercial space and be an incentive in some cases. Though a savings in stormwater detention may be gained by using pavers, a preliminary cost analysis indicates that the additional cost incurred for pavers exceeds the savings.

Results of a small, informal survey (Chapter 2, Paver Places and Faces Survey, page 56) indicate that increased aesthetics and infiltration are key incentives for using pavers in residential uses. Because homeowners may utilize pavers that are slightly flawed (factory seconds) and not suitable for commercial or industrial use, the costs for small residential applications of pavers may be less than for other applications.

The greatest barrier to using porous pavement or pavers is the initial installation costs. Pavers cost two to four times as much as asphalt, averaging $2.00 to $4.00 per square foot compared to $1.00 per square foot for asphalt. A parking area with 20 percent of the area in $4.00 per square foot pavers would be approximately 60 percent more expensive to install than a traditional asphalt parking area.

If 10 years of replacement and maintenance costs are figured into the equation, pavers are less costly but still more expensive than asphalt. For example, the cost of installation ($1,979) and 10 years of replacement and maintenance costs ($2,164) of 10

VOL 12 2 3947
R0057239

typical asphalt parking stalls is estimated to be $414 per stall over a 10-year period. The cost of installation ($6,173) and replacement and maintenance costs ($1,000) for 10 paver parking stalls is estimated to be $717 per stall over a 10-year period (Lonsbery, pers. comm.). The main reason that paver parking areas are expensive is the high price of pavers themselves. Over time, if the market demand for pavers increases, the pavers may become more feasible for widespread application.

Any porous pavement, pavers, or alternative surface used in public areas need to meet Americans with Disabilities Act (ADA) requirements, industry standards, and local government safety policies. ADA requires surfaces to be stable, firm, and slip resistant, which poses a barrier to using pavers and other pervious surfaces. When using pavers, it is important to remember that the ADA requires depths no greater than one-half inch. Paving of handicapped parking stalls and the route between the parking stalls and building entrance is mandatory, precluding use of pavers or pervious surfaces in these areas (Allen and Moffett, 1992; Washington State, 1992).

Policy Trends

Olympia

The Drainage Design and Erosion Control Manual (City of Olympia, 1994a) supports and encourages the use of "lattice blocks, geotextiles, or other such semi-pervious pavements" for offstreet areas of pavement. The manual states that pavers can improve runoff quality, reduce drainage system investment, reduce stormwater utility rates, and improve aesthetics. The city will deduct the storage provided by the pavers from storage requirements for the development and count grass areas as pervious, given certain constraints and the completion of a maintenance plan. Current development policy indicates a preference for pervious surfaces on the required 15-foot maintenance access roads for stormwater facilities (City of Olympia, 1994a).

The revised draft zoning ordinance provides incentives for commercial projects that include porous pavement in parking lots (City of Olympia, 1994f). The revised draft parking ordinance would allow porous surfaces for reserve parking or other approved uses, and offers an incentive to use porous surfaces if increased parking is requested (City of Olympia, 1994g).

Lacey

The Drainage Design and Erosion Control Manual for Lacey is very similar to Olympia's drainage design manual, and the policies concerning pavers for offstreet parking areas are the same (City of Lacey, 1994a). Olympia, Lacey, Tumwater, and Thurston County worked together to develop regional consistency in their manuals.

VOL 12 2 3948

R0057240

The Development Guidelines and Public Works Standards require permanent all-weather surfaces for parking areas. Gravel surfaces are not acceptable or approved. Combination grass/paving systems are allowed following approval of a paving plan and description of how the system will be irrigated and maintained (Carr, pers. comm.).

Tumwater

The transportation element of the comprehensive plan includes a policy to use alternative surface materials where practical.

Drainage Design and Erosion Control Manual requirements are similar to those described above for Olympia. In calculating impervious surface as the basis for stormwater utility rates for a recent school development project, grasscrete was counted as a "disturbed pervious surface" rather than an impervious surface (Webb, pers. comm.). The parking ordinance allows use of turfstone as well as asphalt or concrete for parking areas and fire lanes (Booth, pers. comm.).

Thurston County

Following adoption of the Drainage Design and Erosion Control Manual (Thurston County, 1991a), county road standards were revised to allow parking areas to be surfaced with lattice blocks as well as asphalt or concrete. The county engineer may require a surface of grass reinforced with geotextiles in parking areas that are used lightly enough to allow the survival of such a surface. Proposed revisions to the Thurston County Comprehensive Plan include a policy requiring use of pervious pavement devices such as lattice blocks "to the extent practical" to reduce runoff from lightly-used off-street parking and other areas of commercial and industrial sites (Swanson, pers. comm.).

Current zoning regulations require parking areas within urban growth areas to be surfaced with asphaltic concrete or concrete. This does not apply to single-family detached homes or to duplexes with attached garages. Porous pavement or gravel is currently allowed for parking areas in rural areas only (outside urban growth areas).

Implementation Actions

Olympia

Develop and distribute a model maintenance plan for sites using pervious surfaces. Print and distribute the alternative surfaces fact sheet.

VOL 12 2 3949

R0057241

North Thurston UGMA and Other Locations

Consider developing a model maintenance agreement. Consider replicating Olympia's agreement for sites using pervious surfaces. Consider revising policies and regulations to encourage installation of pervious surfaces in low use areas where groundwater contamination can be avoided. Work with other local jurisdictions to sponsor workshops and training for public works personnel, development and building community representatives, businesses, and homeowners on porous pavement, pavers, and alternative surfaces.

Implementation Costs for Olympia

Development and initial distribution of the model maintenance plan and distribution of the alternative surfaces fact sheet will be completed as part of the study's technical assistance. After June 1996, additional printing and distribution of the fact sheet on an as-needed basis would cost $100 a year and could be included in the Water Resources Program budget.

Recommendation 6.
Narrow alley widths, use alternative surfaces for alleys, and/or design alleys to drain to vegetated strips or central drains.

Discussion

Olympia's street standards are currently being revised (Table 17, page 65). The revisions will include a design standard for alleys. The design standard recommends an alley width of 12 feet and two 30 or 36-inch concrete ribs (strips) bounded by gravel or grass. With the proposed changes, approximately 500 to 600 square feet of concrete would be created for every 100-foot length of alley. Gravel surfaces and the soils underneath them can become highly compacted from cars and other vehicular traffic depending on soil type, traffic volumes, and initial construction practices. If gravel surfaces are used and assumed 100 percent impervious, there is no real benefit from leaving alleys unpaved.

Incentives and Barriers

Several barriers to the use of mixed surface alleys exist. These include:

- Traffic levels may exceed the survival capacity of grass. The result could be muddy alleys that could contribute sediment to stormwater runoff. Gravel may be a better alternative to grass if clean gravel is used and sized to resist compaction.

VOL 12 2 3950

R0057242

- Constructing and maintaining two surfaces could be difficult. The edges of the concrete ribs would be exposed to wear and could tend to break down faster than a larger, continuous surface. Continuous gravel would probably be easier and less expensive to maintain in the long run.

- A paved alley could be crowned and sloped to swales for infiltration of runoff.

Reducing alley widths too much can limit the turning radius for residents who access their homes and garages from alleys, and be a barrier to practical use. Too narrow of alleys also could pose problems for garbage haulers and other large utility vehicles that require access.

Policy Trends

Olympia

See discussion above for information on current and pending street standards for alleys. The comprehensive plan encourages the use of alleys for access to residences (City of Olympia, 1994c).

Lacey

Alleys are now allowed only in Planned Residential Developments (PRDs). Under the newly adopted comprehensive plan, alleys will be allowed in the new village center overlay areas. St[illegible]tandards may be revised this year to implement comprehensive plan policies supporting streets no wider than 20 to 32 feet (Carr, pers. comm.).

Tumwater

The draft Development Guide Manual (City of Tumwater, undated) includes standards for alley construction. Alleys must be paved and 16 feet wide (Bauer, pers. comm.).

Thurston County

The county is in the process of updating its road standards. Currently, alleys are treated as roads; there are no separate standards for alleys (Payton, pers. comm.). Adopted city/county joint comprehensive plans will apply city policies on parking and development to appropriate locations within the unincorporated portion of the North Thurston UGMA (Dosheery, pers. comm.).

VOL 12 2 3951
R0057243

Implementation Actions

Olympia

Adopt the street standards as proposed (City of Olympia, 1994g).

North Thurston UGMA and Other Locations

Consider narrowing alley widths and allowing use of pervious surfaces. Revise street standards to encourage drainage of alleys into vegetated strips or central drains.

Implementation Costs for Olympia

No additional costs.

Recommendation 7.
Encourage cooperative parking such as joint (combined), shared, and coordinated parking.

Discussion

Cooperative parking can help provide more parking capacity with less impervious surface. The three types of cooperative parking are shared, joint, or coordinated parking. Shared parking reduces the parking area for land uses with noncompeting hours of operation, such as a church and a school or office. Joint parking reduces the total parking area required for multi-tenant retail and commercial facilities, especially those with little overlap of hours such as a movie theater and paint store.

Coordinated parking reduces the total parking area by using churches, large retail, and commercial overflow parking areas for commuter park-and-ride locations. For example, the infrequently used parking areas at Olympia area malls or large retail outlets could be used by commuters or by visitors to the state capitol during the week, and used by shoppers in the evenings or on the weekends. Churches also have infrequently used parking areas that could be used for joint and shared parking or other parking needs.

Incentives and Barriers

An incentive for large commercial or retail stores to include park-and-rides in their parking lots is the increased sales they may receive because commuters are encouraged to shop at the stores. These captured morning and evening trips are an incentive for both joint and coordinated parking facilities.

VOL 12 2 3952
R0057244

Shared parking tends to work best for long-term tenants with consistent parking needs. Where needs for parking fluctuate over time, shared parking agreements may limit flexibility in use of the property and act as a barrier.

In order to achieve reductions and still provide adequate parking for businesses and their customers, legal agreements between neighboring or cooperating businesses would be needed to ensure long-term availability of parking, avoid disagreements over maintenance, and provide leasing options to realtors and building owners. In order to avoid future problems with new tenants or property owners, legal agreements need to clarify issues such as leasing arrangements or be based on a fee-simple exchange. The agreements also need to be nonrevocable to ensure that parking capacity stays with the building.

Local governments can create an alternative to nonrevocable agreements for cooperative parking by establishing an in-lieu-of-parking fees program. Under the program, developers would have the option to contribute to a fund for the development, maintenance, and operation of off-street parking areas rather that constructing their own parking areas. Such a program can be an incentive for participating in cooperative parking.

Because shared parking and coordinated parking are not that prevalent, examples of legal agreements are not abundant and presents a barrier to implementation. Local governments could encourage cooperative parking by providing example agreements and facilitating arrangements.

Local government policies tend to limit the proximity of shared parking partners. Most policies require close proximity which becomes a barrier to possible partnerships. There could be an increase in shared parking opportunities if farther proximity was allowed. Shuttle buses could provide a link between users and the parking area.

Policy Trends

Olympia

The comprehensive plan includes policies that allow and encourage shared parking (City of Olympia, 1994c). The revised draft zoning ordinance includes incentives for shared parking in some commercial and residential zones (City of Olympia, 1994g, 1994i).

The draft parking ordinance encourages cooperative parking whenever developments with complementary hours are proposed; developments with some overlap of hours are proposed; developments with multiple retail or commercial facilities are proposed; and whenever more than five percent additional parking above the standard is requested by the developer or builder

VOL 12 2 3953

R0057245

(City of Olympia, 1994g). The Site Plan Review Committee (SPRC) reserves the right to require a developer to explore joint (combined) and shared parking opportunities (Davis, pers. comm.).

Lacey

Current policy allows a reduction in on-site parking requirements for properties that share parking. Legal agreements are required to ensure continued shared use when ownership changes. Several churches share parking with nearby schools or businesses (Carr, pers. comm.).

Tumwater

No parking reductions are currently allowed for shared parking (Bauer, pers. comm.). The Capitol Campus Plan includes construction of shared, multi-storied parking structures in the town center to reduce the need for surface parking areas and on-street parking (Washington Department of General Administration, 1992).

Thurston County

Under current policy, use of joint parking facilities is encouraged. Adopted city/county joint comprehensive plans will apply city policies on parking to appropriate locations within the unincorporated portion of the North Thurston UGMA (Dosheery, pers. comm.).

Implementation Actions

Olympia

Adopt the parking ordinance as proposed in the Draft Unified Development Code (City of Olympia, 1995). Print and distribute the model legal agreement for shared parking (Appendix D, page 179).

North Thurston UGMA and Other Locations

Consider modifying parking ordinances to encourage cooperative parking. Develop and distribute a model legal agreement for shared parking to those submitting development plans.

VOL 12 2 3954

R0057246

Implementation Costs for Olympia

No additional costs for revising the parking ordinance. Copies of the model legal agreement will be printed and distributed as part of this study's technical assistance. It is recommended that the Community Planning and Development Department (CPDD) will need to provide copies once the study is completed in 1996.

Recommendation 8.
Encourage underground or under-the-building parking and the construction of multi-storied parking structures.

Discussion

Stormwater quantity is directly related to the quantity of impervious surface exposed to rain and would therefore be reduced by placing parking underground or within buildings, or by building multi-storied parking structures.

Incentives and Barriers

Consolidating parking into one, tall building or incorporating it into a building results in less of the site dedicated to parking (Recommendation 15, page 110, for related discussion on taller buildings). Such consolidation or incorporation could be an incentive for developers and builders if the area once dedicated to parking could be used for additional leasable space or residences. Policies and regulations could be modified to allow increased densities or building coverage and provide incentives. Increased densities would contribute to a per capita reduction in impervious surfaces for the region (Recommendation 2, page 67).

In-lieu-of-parking fees could be used as an incentive for multi-storied parking structures. Part or all of parking requirements prescribed by local regulations could be waived upon the applicant's request in lieu of paying a fee into a parking improvement fund. The fund could be established and used for construction of public parking facilities, such as a multi-storied parking structure.

Concerns about vandalism and personal safety may affect public support of parking structures and is a barrier to construction. The Olympia Police Department recommends that parking structures be constructed with adequate **defensible space** that area around an individual that allows for a feeling of safety.

The high water table in downtown Olympia and Lacey, and other locations, is a barrier to underground or tall parking structures. Constructing underground parking

VOL 12 2 3955
R0057247

or tall buildings on the fill material that exists under much of downtown Olympia would be difficult and costly.

A group of public and private partners, including the City of Olympia, completed a feasibility study in 1993 for a mixed use parking and transit facility, including a multi-storied parking structure alternative for downtown Olympia. The study evaluated a variety of public, public/private, and private development options and concluded that current parking demand is not sufficient to financially support a parking garage. Lease rates for the two Olympia options were estimated at $126.68 per month and $135.22 per month per stall, both well above current market rates. However, state government employment may increase and eventually create more parking demand (City of Olympia, 1993c).

Policy Trends

Olympia

The comprehensive plan supports development of multi-storied parking structures in commercial areas to enable redevelopment of surface parking into more intensive use (City of Olympia, 1994c). The commercial and residential development standards are currently being revised to bring them into compliance with the comprehensive plan. Under the draft standards, additional building height may be added when parking is incorporated into buildings located in certain zones. The draft standards also allow a 45 percent increase from the 40 percent impervious surface coverage base for under-the-building parking in the Arterial Commercial zone (Harrison Avenue and Division Street area). Impervious surface coverage in the rest of the zones is based on a maximum. In General Commercial zones, an additional story may be added if at least 50 percent of the parking is under the building (City of Olympia, 1994h; 1994i; McCormick, pers. comm.). In the draft language for the Urban Village and Community Oriented Shopping Center zone, an additional story may be added if at least 50 percent of the parking is under the building. Seventy percent site coverage by a building is allowed in this zone if parking is not put under the building (McCormick, pers. comm.).

A TDM Ad Hoc Committee was formed in 1994 to, among other things, update the Downtown Olympia Parking Management Strategy. The update will provide an opportunity to revisit the feasibility of multi-storied parking structures (Stimson, pers. comm.).

Lacey

Current downtown zoning regulations allow parking garages in the Downtown Central Business District. Understructure parking or parking garages would be encouraged, but no such proposals have been made. The

VOL 12 2 3956

R0057248

only understructure garage approved in Lacey is a townhouse project in the Lakepointe subdivision (Carr, pers. comm.).

Tumwater

The Capitol Campus Plan includes construction of shared, multi-level parking structures in the town center to reduce the need for surface lots and on-street parking (Washington Department of General Administration, 1992).

Thurston County

Adopted city/county joint comprehensive plans will apply city policies on parking and development to appropriate locations within the unincorporated portion of the North Thurston UGMA (Dosherry, pers. comm.).

Implementation Actions

Olympia

Adopt the commercial and residential development standards as proposed in the Draft Unified Development Code (City of Olympia, 1995).

Update the Downtown Parking Management Strategy in 1995. Consider strategies such as in-lieu-of-parking fees that could help fund multi-storied parking structures. Continue to involve the Olympia Downtown Association in developing strategies.

North Thurston UGMA and Other Locations

Consider revising commercial, multifamily, and other development standards to allow taller buildings and greater densities if parking is incorporated into buildings. Explore with local development and business representatives potential public/private partnerships and policy changes that will result in less surface parking and impervious surface reduction.

Implementation Costs for Olympia

No additional costs.

VOL 12 2 3957

R0057249

Recommendation 9.
Develop flexible parking regulations related to parking region-wide that limit the amount of impervious surface, while still providing for parking needs.

Discussion

According to the parking analysis and basin and site coverage assessment (Chapter 2, page 34), parking areas comprise a significant amount of the existing impervious surfaces in Olympia area watersheds.

The results of the parking analysis (Chapter 2, page 46) suggest that the amount of impervious surface used for parking could be reduced by encouraging cooperative use of parking areas (Recommendation 7, page 84); use of an average of several peak days instead of just one or two; use of diagonal parking, single lanes between stalls, and smaller parking stalls; and/or construction of underground, under-the-building parking, or multi-storied parking structures (Recommendation 8, page 87).

Parking policies are local governments' key method for determining the size and amount of parking, and the resulting amount of parking-related impervious surfaces. Parking policies have traditionally adopted the "bigger is better" view of parking. Regulations need to provide enough parking to sustain businesses while avoiding traffic congestion or overflow into residential neighborhoods, but have resulted in too much parking in some cases.

Typically, parking policies are based on artificially low "minimum" parking ratios that do not accurately reflect true parking needs. Based on a limited review of Olympia area developments, developments average 38 percent more parking than the minimum ratios require in the Olympia area (Chapter 2, Parking Analysis, page 46). Median parking ratios or minimums combined with maximums provide a limit to the amount of impervious area dedicated to parking.

If medians or maximums are used, some flexibility in the standards would have to be provided to allow for exceptional cases. Median ratios combined with the option to build five percent more or less than the ratio would provide flexibility for developers to tailor parking to individual site or business conditions in most cases.

Parking policies also generally allow parking areas to be constructed using peak-day projections. The day and amount of highest parking demand, such as Christmas Eve or the day after Thanksgiving, is determined and the parking area is designed to accommodate this single-day demand. Using a peak-day projection results in under-utilized parking areas for most of the year, although much of a business' gross income is generated during the holiday or other peak seasons.

VOL 12 2 3958
R0057250

Ratios that limit the amount of parking-related impervious surface work best if combined with technical assistance, Transportation Demand Management (TDM), and other strategies that assist the development and business community in meeting impervious surface reduction goals without jeopardizing the local economy.

An example strategy is the leasing of on-street parking. On-street parking is sometimes leased to businesses as an alternative to building new parking areas, or to provide parking in city centers where space for new parking areas is limited.

The size of parking stalls varies, but typical dimensions are 9.0 feet by 18.5 feet. During a two-year rain event (2.8 inches in 24 hours), approximately 38 cubic feet of runoff is generated by a typical parking stall. Reducing a commercial parking lot of 526 stalls (Top Foods, Table 13, page 49) by 20 percent, or 105 stalls, could reduce runoff from a typical two-year event by almost 4,000 cubic feet. Reducing the parking area of any commercial site by 20 percent could reduce the total effective impervious surface coverage of the site by an estimated 11 percent (Table 12, page 45).

The quantity of pollutants in parking lot runoff is a function of vehicular traffic, vehicular condition (i.e., well or poorly maintained vehicles), and atmospheric deposition. However, reducing the amount of parking-related impervious surface may reduce the volume of polluted runoff, and the size and costs of stormwater facilities needed to store and treat the runoff, depending on site-specific factors.

Incentives and Barriers

Construction cost savings are one incentive for smaller parking areas. Smaller parking areas can reduce development costs, but not substantially. Asphalt typically costs $1.00 per square foot to install. If a 1,000 square foot parking lot was reduced by 20 percent, the cost savings would be approximately $200. Some additional cost savings would occur over time because of reduced fees for parking lot maintenance, which averages $216 per asphalt stall for a 10-year period (Lonsbery, pers. comm.). A greater incentive may be the decreased percentage of the site dedicated to parking. The area once dedicated to parking could be used for additional leasable space or residences if parking and development standards allow increased densities or building coverage as an incentive. Increased densities would contribute to a per capita reduction in impervious surfaces for the region (Recommendation 2, page 67).

Although smaller parking areas reduce development costs, too little parking may be a barrier to successful businesses and cause spillover into adjacent neighborhoods.

Lot designs that reduce the size of parking areas without compromising the number of stalls include diagonal parking with one-way aisles, and narrower stalls. Both can significantly increase the capacity of parking areas and reduce costs. However, a barrier to narrower stalls is the possible increase in accidents, dented doors, and

VOL 12 2 3959
R0057251

number of inefficiently parked vehicles that may occur. Narrower than recommended stalls occasionally reduce the availability of parking due to overlapping of vehicles into two stalls.

Policy Trends

Olympia

The current zoning code (City of Olympia, 1991) specifies offstreet minimum or absolute parking requirements for various uses, and disallows joint use of parking facilities unless used at different times of the day or week. By contrast, the draft revised parking ordinance is designed to avoid excess parking by establishing median parking requirements for various uses. Increases or decreases from the median would be allowed by administrative variance if certain criteria are met. Criteria are designed as incentives to support alternative transportation, and encourage shared parking and designs that reduce impervious surface (City of Olympia, 1994g).

If an improved public transit system is provided, it is expected that parking requirements in the downtown and high-density corridors could be reduced to the minimum needed to accommodate average demand. In neighborhood and urban villages, parking requirements would be reduced by 10 to 15 percent (City of Olympia, 1994).

The recently-adopted comprehensive plan reflects a shift in parking policy in order to encourage travel by bus, carpool, bicycle, and foot. While the previous comprehensive plan encouraged "ample," or "adequate, convenient parking," the new plan policy supports parking requirements designed to meet actual demand (City of Olympia, 1994c).

The current proposed revisions to the parking ordinance will not apply to downtown Olympia. The new downtown zoning ordinance (City of Olympia, 1993f) does not include revisions in parking standards. A TDM Ad Hoc Committee was formed in 1994 to, among other things, conduct a needs assessment and update the Downtown Olympia Parking Management Strategy. Revisions in downtown Olympia parking policies will be deferred until completion of the needs assessment and update in 1995 (Stimson, pers. comm.).

Lacey

Under the downtown element of the comprehensive plan adopted in 1989 (City of Lacey, 1989), maximum parking standards took effect in 1994. Maximums will be reduced in three year intervals. For example, a 1,200-

VOL 12 2 3960

R0057252

square-foot retail business would be allowed a maximum of seven parking stalls in 1994-1997, six in 1998-2001, and five in 2002 and beyond.

Tumwater

Under current policy, parking requirements are determined case-by-case based on a needs assessment that takes into account the number of customers, length of stay, peak use, and number of employees. The housing element of the new comprehensive plan calls for reduced parking requirements for residential development. The transportation element promotes several TDM techniques that could reduce parking-related impervious surfaces (Bauer, pers. comm.).

Thurston County

Adopted city/county joint comprehensive plans will apply city policies on parking and development to appropriate locations within the unincorporated portion of the North Thurston UGMA (Dosherry, pers. comm.).

Implementation Actions

Olympia

Adopt the parking ordinance as proposed (City of Olympia, 1994g).

North Thurston UGMA and Other Locations

Explore using median parking ratios that reflect true parking needs. Provide density credits such as increased densities or building coverage instead of parking-related impervious surfaces where appropriate. Assist developers whenever possible in the exploration of TDM options and meeting parking needs while reducing impervious surfaces. Consider leasing onstreet parking to businesses.

Implementation Costs for Olympia

No additional costs.

Recommendation 10.
Gently slope sidewalks away from streets and other impervious surfaces towards vegetated strips or gravel catchments.

VOL 12 2 3961
R0057253

Discussion

As a result of the basin and site coverage assessment (Chapter 2, page 34), it is clear that sidewalks are not a significant source of effective impervious surface in the Olympia area when compared with streets and parking areas. Sidewalks generate less contaminants than streets and parking areas because sidewalks do not accommodate vehicular traffic.

In residential developments, yards typically border one side of the sidewalk. Lawns and other vegetated areas can be expected to provide some treatment and infiltration if sidewalk runoff is directed into these areas. However, sidewalks can contribute to stormwater runoff problems when they are sloped to streets, parking areas, or other impervious surfaces.

To avoid stormwater runoff problems associated with sidewalks, various strategies can be used and include:

- Install sidewalks at a two percent slope. Add vegetative strips adjacent to sidewalks designed to detain and infiltrate runoff.
- Install sidewalks at a two percent slope and install washed rock percolation strips adjacent to the sidewalk. Design the strips to provide 50 to 75 cubic feet of storage for every 500 square feet of sidewalk.
- Provide drywells at certain intervals of the sidewalk. Slope the sidewalk one percent towards the drywells.

Incentives and Barriers

Sidewalk slopes, widths, and surfaces must comply with the ADA, industry standards, and safety policies of local governments. The ADA requires surfaces to be stable, firm, and slip resistant. Vertical changes in grades can be no more than one-half inch (Allen and Moffett, 1992; Washington State, 1992).

Policy Trends

Olympia

Comprehensive plan policies encourage development of pedestrian facilities on arterials and off-street pedestrian trails, and require sidewalks on both sides of the street. The plan calls for landscaping and trees to create pedestrian-friendly streets and allow infiltration (City of Olympia, 1994c). The zoning code's design review provisions and design guidelines encourage pedestrian walkways and amenities (City of Olympia, 1991). The new downtown zoning

VOL 12 2 3962

R0057254

ordinance includes a pedestrian overlay district that requires a variety of design features and facilities for pedestrians (City of Olympia, 1993f).

Olympia's proposed street standards require sidewalks on both sides of the street (Table 16, page 53). New transportation and development policies will result in higher density commercial and residential development and narrower local access streets that make sidewalks essential. The requirement for two-sided sidewalks is strongly supported by most of Olympia's neighborhood associations and the City Council. The proposed street standards widen sidewalks for some streets and incorporate planting strips or street trees between curbs and sidewalks on certain streets (City of Olympia, 1994d).

Lacey

Existing zoning for the Lacey Central Business District requires pedestrian facilities such as designated pedestrian lanes within parking areas; planter strips between the sidewalk and street; and site designs which cluster buildings to reduce walking distance between each building and transit facilities (Carr, pers. comm.).

Sidewalks are currently required on both sides of all public streets. Required sidewalk widths are five feet for neighborhood collectors and local streets. For boulevards, major and minor arterials, and commercial collectors, required sidewalk widths are six feet except in pedestrian corridors (eight feet) and neighborhoods with zero setbacks (10 feet) (Carr, pers. comm.).

Tumwater

The adopted comprehensive plan emphasizes pedestrian-oriented development in the Capitol Campus, mixed-use, and high-density corridor areas. The transportation element of the comprehensive plan emphasizes pedestrian facilities and policies promoting TDM and non-motorized transportation. Under current regulations, sidewalks are required on both sides of the street. Sidewalk width standards vary from four to six feet (Bauer, pers. comm.).

Thurston County

Adopted city/county joint plans will apply city policies on alternative transportation to the unincorporated portion of the North Thurston UGMA. The city/county plan with Tumwater does not specifically mention sidewalk standards (Dosheery, pers. comm.).

The county currently requires four foot sidewalks on one side of local Section C roads and on both sides of local collectors. No sidewalks are required on local Sections D and E roads. Sidewalks are required on both

VOL 12 2 3963
R0057255

sides of arterials; four to five feet wide for residential areas and six feet wide for commercial areas. Projects in the county are currently required to meet all city standards (including sidewalks) if they receive city water and sewer services (Payton, pers. comm.).

Implementation Actions

Olympia

Adopt the street standards as proposed (City of Olympia, 1994g).

North Thurston UGMA and Other Locations

Encourage developers and builders to reduce runoff by sloping sidewalks towards vegetated areas designed to infiltrate runoff. Explore new designs and ideas with the development and business community.

Implementation Costs for Olympia

No additional costs.

RECOMMENDATIONS FOR CONSTRUCTION PRACTICES AND LANDSCAPED AREAS

Naturally occurring, undisturbed areas typically infiltrate 60 percent of rain, depending on soil type. Clearing and grading a site typically removes existing vegetation and compacts the soils, greatly reducing the infiltration capacity of the site. For the purpose of this study, the project team considered compacted soils are an impervious surface. The following three recommendations address reducing soil compaction and the clearing of vegetated areas to retain the inherent infiltration capacity of undisturbed areas.

Recommendation 11.
Limit soil compaction on newly developed residential and commercial sites, especially those sites with sensitive features. Reduce soil compaction and restore infiltration capacity on already cleared sites whenever practical.

Discussion

In naturally occurring undisturbed soil and vegetated conditions, many local soils do not produce runoff even during severe storms. A lesser number of local soils will infiltrate the vast majority of rainfall regardless of the degree of soil compaction and the type or condition of the vegetation.

VOL 12 2 3964

R0057256

Certain construction practices can increase the amount of stormwater runoff generated by a site. The amount and quality of runoff is affected by the extent of soil compaction created by clearing of a site, heavy equipment traffic, and other factors.

This recommendation aims to preserve wherever possible the infiltration and pollutant removal capacity provided by soil under natural conditions. The majority of disturbed, compacted, and subsequently landscaped soils in north Thurston County are contributors to stormwater runoff. Current stormwater management policies require calculations for the conveyance and storage of runoff from both impervious and landscaped areas of the site. Given that many residential developments have extensive landscaped areas, the calculated stormwater contribution from landscaped areas can approach or exceed the contribution from impervious surfaces.

The practice of removing, storing, and replacing the original topsoil found at a building site greatly modifies or destroys the naturally occurring soil structure, increases compaction, and decreases infiltration capacity. Mixing (discing or rototilling) mulch into the sub-soil before replacing the topsoil can dramatically increase infiltration capacity (Jensen, pers. comm.). Adequate mixing of organic mulches is essential. Simply turning organic mulches into the soil can create a barrier to infiltration (Gillian, pers. comm.).

Various research indicates that most precipitation can be directed into the soil and subsequently to groundwater by mixing compacted soils with mulches. Research also indicates that adding gravel and sand mulches has the potential to increase aquifer recharge from its present range of 0 to 30 percent, up to 60 to 90 percent of precipitation in most areas of the United States (Kemper et al., 1994).

Wheeled vehicles such as trucks and backhoes compact forest soils. Depending on soil type, soil density can be reduced as deep as two to three feet. This can create a barrier to infiltration and create runoff problems. Construction practices for reducing soil compaction of forest soils includes lower tire pressures (using floating tires on vehicles), concentrating traffic patterns, and roping off areas where traffic and storage can occur. Skilled operators are more aware of soil compaction than in the past, which may increase the acceptance of new practices (Harrison, pers. comm.).

On small urban sites, avoiding soil compaction may be difficult because the whole site may need to be cleared and used for maneuvering heavy equipment. In this case, infiltration can be achieved through use of organic mulches and drywells in certain cases.

Incentives and Barriers

The economic feasibility of using mulches to restore infiltration capacity depends on the cost of the mulch and time and equipment for mixing. Olympia and other local

VOL 12 2 3965

R0057257

governments currently provide the mulch created from trimming street trees to developers and builders for erosion control purposes. This practice of providing free mulch is an incentive for developers and builders to restore infiltration capacity. Many developers or builders also chip existing trees and use the mulch for erosion control on site and for mixing into the soil.

Policy Trends

Olympia

The Uniform Building Code (UBC) currently does not require restoring disturbed soils to their predisturbance condition (Washington State, 1992). However, several existing ordinances include provisions that have the effect of limiting soil compaction. One purpose of the Tree Protection and Replacement Ordinance (City of Olympia, 1993g) is to minimize adverse effects of land disturbance on surface drainage and other factors. The ordinance requires protection of the root zone around trees during clearing and grading.

Olympia's Drainage Design and Erosion Control Manual describes a number of standard erosion control methods that prevent or mitigate soil compaction. These include net or mat blankets, mulch, seeding, topsoil, and sod. Mulch is described as providing immediate protection to exposed soils during construction delays or over winter, and is required on slopes greater than two to one. Recommendations for application rates vary depending on the material used (City of Olympia, 1994a).

The Drainage Design and Erosion Control Manual also specifies practices to avoid soil compaction during construction of stormwater infiltration facilities. Project plans and specifications must describe construction procedures, barricades, and other practices that prevent heavy equipment from crossing over the area that is going to be used for the infiltration facility.

The Drainage Design and Erosion Control Manual requires that for additions or remodels of an existing development, the entire site must be brought up to current drainage standards if (a) the project would result in the addition of new impervious surface of 25 percent or more of the existing impervious surface, and the new impervious surface is at least 5,000 square feet, or (b) the construction cost of the project is 25 percent or more of the assessed value excluding land value, providing that the construction cost of the project is at least $250,000. The cumulative square footage and cost of all additions or remodels during the past five years (through 1996) shall apply to this retrofit "trigger" requirement.

The draft Landscaping and Screening Ordinance (City of Olympia, 1994i) includes a provision to increase landscaping in parking lots when a

VOL 12 2 3966

R0057258

redevelopment project is more than 50 percent of the assessed value of the property. In such cases, the ordinance would require an eventual 40 percent tree canopy and an increase in pervious surface. The ordinance is designed to discourage large parking lots by a formula that increases the *percentage* of landscaping as the size of the parking area increases.

Lacey

Lacey's requirements on soil compaction during construction of drainage facilities are similar to those described above for Olympia. The tree ordinance regulates when and how clearing can occur. Grading is regulated by the Uniform Building Code (Carr, pers. comm.).

The landscape ordinance requires landscaping of all disturbed areas in development projects. Natural vegetation can count towards required landscaping it if is retained and undisturbed. In naturally vegetated areas, all cleanup must be by hand to prevent compaction by equipment. No irrigation is required for natural vegetation, which acts as an incentive to retain existing vegetation. Under current regulations for major redevelopment projects, parking lot landscaping must be increased if the project exceeds 25 percent of the assessed value of the existing improvements (Carr, pers. comm.).

Tumwater

Tumwater's requirements on soil compaction during construction of drainage facilities are similar to those described above for Olympia (Webb, pers. comm.). The city's new tree protection ordinance requires fencing around the drip line of trees to protect them during construction. The sensitive areas ordinance restricts development on or near steep slopes (Booth, per. comm.).

Thurston County

The drainage provisions described above for Olympia also apply in unincorporated Thurston County. The County currently has no land clearing ordinance. Grading is regulated through the Uniform Building Code and permits are required if the duff (leaves, twigs) layer of soil is disturbed. Fill permits are required for fill of more than 50 cubic yards (Swanson, pers. comm.).

VOL 12 2 3967

R0057259

Implementation Actions

Olympia

Promote sources of mulch for construction practices through technical assistance materials and activities. Offer a soils workshop to the development community every other year. Require the identification or categorization of the degree of soil compactability at a site as part of the currently required soils report.

North Thurston UGMA and Other Locations

Continue to implement on-site chipping and mulching, and provide technical assistance and/or free mulch to encourage "retrofitting" soil compacted during construction. Encourage less soil compaction by providing free mulch and technical assistance, and modifying existing policies and regulations.

Implementation Costs for Olympia

Minimal staff time will be needed to coordinate implementation. Organizing a soils workshop would cost approximately $750 per workshop and could be included in the Water Resources Program budget. Promoting sources of mulch and construction practices could be integrated into current activities and would cost approximately $50 a year.

Recommendation 12.
Limit land clearing on newly developed residential and commercial sites, especially those sites with sensitive features.

Discussion

Clearing and grading practices greatly affect the infiltration capacity of a site. Clearing eliminates valuable vegetation and compacts soils, especially under wet soil conditions or during the rainy season (Recommendation 11, page 96). The less disturbance of existing vegetation, the less stormwater runoff generated and the greater the treatment of pollutants. However, many small sites that are good candidates for infill are too small to maneuver large equipment, and require clearing the whole site.

Increasing urban densities in the North Thurston UGMA may require sacrificing small undisturbed areas in order to preserve larger tracts in the outlying, rural areas. However, many of the undisturbed areas in cities and towns are wetlands and stream corridors.

VOL 12 2 3968

R0057260

Incentives and Barriers

Costco's Tumwater outlet is one local example of preserving an undisturbed area. Costco reserved a large block of evergreen trees in the middle of the parking area at the request of Tumwater's Planning Department. The incentives for reserving the block of trees included the following:

- The large trees offset the large size of the building, creating a more aesthetically pleasing appearance to the local community.
- The trees were a compromise with the local community, and created a more positive response towards Costco from the store's future customers.
- The trees provide a location for the hot dog stand and picnic area that is pleasant for the customers.
- The large trees provide an amenity that would take 50 to 75 years to attain.

Setting aside the trees has caused some minor problems with vehicle traffic flow. However, the architect that designed the store feels the benefits far outweigh the problems, even though the adjustments to accommodate the trees cost $10,000. Costs for accommodating the trees included handclearing underneath the trees, limbing, and curbing the area. Other communities are requesting similar large blocks of undisturbed areas as part of Costco's store design (Smith, pers. comm.).

Commercial developers usually try to keep costs down by utilizing all of a site for parking and other needs. This makes it difficult for them to aside blocks of undisturbed areas. The current practice of appraising property based on its development value rather than open space or natural area value is an economic disincentive and barrier to limiting land clearing. Open space tax incentives encourage preservation in the short term, but apply only to parcels larger than five acres.

Trees and shrubs can provide places for thieves or assailants to hide, and create a barrier to pedestrian safety. Adequate lighting can increase safety in areas of trees and shrubs in public or private parking areas and walkways.

Policy Trends

Local comprehensive drainage basin plans contain a recommendation to establish uniform standards for land clearing and grading within the North Thurston UGMA. Preservation of soil infiltration capacities is considered one of the primary benefits of such standards (City of Olympia, 1993b).

VOL 12 2 3969

R0057261

Olympia

Comprehensive plan policies call for preservation of existing vegetation, retaining natural open space and wildlife habitat in urban villages, preserving trees on hillsides near multifamily developments, and incorporating water bodies in landscaping (City of Olympia, 1994c).

Olympia currently has no open space requirement except for planned residential developments, no payment of open space impact fees, and no policy on acquisition of open space other than parks. The new downtown zoning ordinance requires multifamily zoned sites to include 15 percent landscaping and/or outdoor recreation area that is not covered by impervious surface. This area could be existing vegetation or undisturbed area (City of Olympia, 1993f). The revised residential zoning ordinance includes development standards that require open space (City of Olympia, 1994h).

Land clearing is regulated by a Land Clearing Ordinance which requires a permit prior to clearing, and a Tree Protection and Replacement Ordinance intended to protect and preserve trees and woodlands (City of Olympia, 1984a, 1993g). The later ordinance establishes minimum tree density for different zones to be accommodated by existing or newly planted trees. It also requires submission of a tree plan showing trees to be preserved and planted. A new Landscaping and Screening Ordinance, that complements the Tree Protection and Replacement Ordinance, is proposed for adoption by City Council. It would require retaining all unused portions of a lot in native or undisturbed vegetation (City of Olympia, 1992). The interim Critical Areas Ordinance restricts development in or near designated critical areas such as wetlands and steep slopes, (City of Olympia, 1994i).

Lacey

The comprehensive plan includes policies aimed at protecting open space. Development proposals are reviewed to determine the best location for open space. In order to create larger consolidated park areas, open space is required to be located such that, when surrounding properties develop, the open space can be contiguous (Carr, pers. comm.).

The tree ordinance regulates when and how clearing can occur. No clearcutting is allowed. The landscaping ordinance allows high quality existing trees and other native vegetation to be retained and counted as landscaping if left undisturbed and undamaged during construction. No irrigation is required for natural vegetation, which is an incentive for retaining existing vegetation (Carr, pers. comm.).

VOL 12 2 3910

R0057262

In new residential developments, native vegetation must be retained until preliminary plat approval is received. Lots may only be cleared once a building permit application for that lot has been received by the city. The developer or builder may then clear for the driveway, building footprint, and a 10-foot perimeter around the house. Any further clearing requires additional city review (Carr, pers. comm.).

Tumwater

The adopted comprehensive plan includes a system of open space and an open space preservation program including parks, critical areas, urban trails, and shorelines. Commercial landscaping standards are currently being developed (Bauer, pers. comm.).

Tumwater's new tree protection ordinance allows no more than 30 percent of the trees on a site to be removed during a five-year period unless a development project is proposed. If there is a proposed project, tree removal is limited to 20 percent or 12 trees per acre, whichever is greater. Tumwater will be considering a landscaping ordinance in 1995 (Booth, pers. comm.).

Tumwater's recently adopted land clearing ordinance restricts land clearing until a building permit application for that lot has been received by the city, similar to Lacey's policy (Booth, pers. comm.).

Thurston County

Existing county regulations require protection of wetlands, stream corridors, and important wildlife habitat areas. The Thurston County Comprehensive Plan refers to joint city/county comprehensive plans for policies that apply within the unincorporated portion of the North Thurston UGMA (Dosheery, pers. comm.).

Implementation Actions

Olympia

Adopt the landscaping requirements and policies as proposed in the Draft Unified Development Code (City of Olympia, 1995). Revise the clearing and grading ordinance (City of Olympia, 1984a) to require phased clearing similar to Lacey's and Tumwater's current policies.

North Thurston UGMA and Other Locations

Continue use of buffers to protect sensitive features and incremental clearing to reduce soil compaction. Encourage less land clearing through technical assistance,

VOL 12 2 3971 1

R0057263

policies, and regulations. Work with the development community to identify incentives for reducing land clearing. If a clearing and grading ordinance is not in place, consider replicating Lacey's policy as guidance for the development community.

Implementation Costs for Olympia

Community Planning and Development Department and Water Resources Program staff time are already scheduled to revise the clearing and grading ordinance.

Recommendation 13.
Encourage measures such as homeowner association covenants, plat map conditions, and/or conservation easements that protect existing vegetation and undisturbed areas.

Discussion

Protection of an undisturbed area that has been set aside by a developer or builder is not guaranteed. Such protection often becomes the responsibility of a home or business owner, or homeowners association. Protection of undisturbed areas could be accomplished through homeowner association covenants, plat map conditions, conservation easements, or other measures.

Homeowner association covenants are agreements that are tied to the land title and are enforceable by homeowner associations, but are not enforceable by local governments. Homeowner association covenants generally address such issues as fence heights, display of campaign signs, parking, landscaping, building design, and care and maintenance of commonly-owned areas. Covenants present an opportunity for homeowners to agree to protect undisturbed areas and enforce protection among it's members.

Plat maps are official documents approved by city councils or county commissioners that prescribe the subdivision of a specific piece of land. The plat map is filed and recorded with the auditor and usually contains wording that designates the location and dimensions of sensitive areas, stormwater facilities, dedicated open space, or other features. Wording could also be added to plat maps that "condition" the use or activities for these features, including limiting the removal of existing vegetation in undisturbed areas (Boettcher, pers. comm.).

Conservation easements are voluntary written agreements between landowners and non-profit land trusts that protect special features of private property, such as wildlife habitat, agricultural land, wetlands, and forests. The agreement is tailored to the landowner and to meet special preservation needs of the land. Restrictions set

VOL 12
2
3972
R0057264

forth in the agreement run with the property title. The land trust does not usually assume ownership, but does assume the long-term responsibility for stewardship and enforcement of the easement (Capitol Land Trust, undated).

Incentives and Barriers

Providing funding to homeowner associations could be an incentive for long-term protection. In Olympia, homeowner associations are eligible for funding from the city's Neighborhood Matching Grant Program. Grants are available for commonly held land such as open space areas. Projects such as tree planting and education programs are eligible for up to 50 percent of costs (City of Olympia, undated).

Incentives for using conservation easements include federal income, estate, and/or property tax reductions. For example, Thurston County allows a 90 percent reduction in property taxes if a conservation easement is associated with a piece of property. Another incentive is that the conservation easement runs with the title, which provides permanent (in perpetuity) preservation of the land even beyond the life of the land trust (Wells, S., pers. comm.).

Barriers that limit the enforceability of homeowner association covenants include the costs of litigation and the uncomfortableness of confronting neighbors not in compliance. Even if protection measures are added to the covenant when the homeowner association is first established, there is no assurance of long-term protection because covenants can be changed with the member's approval and are not enforceable by local governments.

In comparison to homeowner association covenants, plat map conditions may have fewer barriers to being effective measures for protection because they are enforceable by local governments. However, if plat map conditions that protect undisturbed areas are not added to the original plat map, it may be difficult to change at a later time because such changes require approval of all the property owners in a subdivision. The cost of changing the plat maps in Olympia is approximately $1,500 per request at the present time (Boettcher, pers. comm.).

When undisturbed areas are set aside, informing homeowners and others about property lines and designations is needed. Without such knowledge, encroachment by homeowners, dumping of yard waste, and other problems arise and create a barrier for maintaining undisturbed areas.

Policy Trends

Olympia

For urban villages, the new comprehensive plan requires a legally binding site plan which is to include provisions for environmental protection and

VOL 12 2 3973

R0057265

maintenance of parks and open space (City of Olympia, 1994c). The subdivision ordinance requires final plat maps to designate areas reserved for public use. For plats having commonly-owned tracts, plats must contain a restriction stating that such tracts are owned and maintained for the benefit of all lot owners (City of Olympia, 1984b).

Lacey

As a condition of plat approval, the city requires protection of land that is to be retained as forested open space. These conditions may be recorded on the plat map, making them enforceable by the city. The city requires homeowner associations to adopt covenants covering maintenance of common parcels and facilities; however, these are not enforceable by the city (Carr, pers. comm.).

Tumwater

If land is reserved as open space, a homeowner association is required as a condition of plat approval to accept responsibility for maintaining that open space (Booth, pers. comm.).

Thurston County

For subdivisions in excess of ten gross acres, ten percent of the site must be devoted to open space. Conditions of approval require the open space to be owned and maintained by the lot owners in common or by a homeowners association and is so noted on the final recorded map. As a condition of plat approval, the county requires homeowner associations to accept responsibility for maintaining open space, including the maintenance of stormwater facilities (Knostman, pers. comm.).

Implementation Actions

Olympia

Continue support of the Capitol Land Trust's work on conservation easements. Consider reducing plat map revision fees for homeowner associations or community groups. Develop and distribute model language for homeowner association covenants geared toward preserving existing vegetation and undisturbed areas.

North Thurston UGMA and Other Locations

Identify opportunities for educating homeowners, developers, and builders for retaining existing vegetation and undisturbed areas beyond current levels as time and budget allow. Review property tax policies and modify if necessary to allow a reduction in property tax for dedicated open space areas. Review other policies to

VOL 12 2 3974
R0057266

identify practical incentives for promoting homeowner association covenants, plat map conditions, and conservation easements.

Implementation Costs for Olympia

Annual support of the Capitol Land Trust is currently $50. Approximately $750 of city attorney, Community Planning and Development Department, and Water Resources Program staff time would be needed to develop the model language for covenants. The $100 fee for the initial development, printing, and distribution of the model language could be covered under the study grant if completed before June 1996. It is recommended that subsequent printing and distribution be the responsibility of the Community Planning and Development Department, as part of general services provided through the permit review process. Cost of subsequent printing and distribution would be approximately $50 a year.

RECOMMENDATIONS FOR DESIGN AND PLACEMENT OF BUILDINGS

Our current development pattern plays a large role in how much impervious surface we create. The following recommendations address two key strategies for reducing building-related impervious surfaces: clustering and taller buildings.

Recommendation 14.
Encourage cluster development that minimizes impervious surfaces.

Discussion

The basic principle of cluster development is to group, or "cluster" development onto one part of a site. Although the developed area is more compact, gross density of the site remains the same.

Cluster development can be utilized in a rural setting to provide resource protection, such as farms and timberlands, and in urban areas for the protection of environmentally sensitive areas. Cluster development also can be used to provide subdivisions such features as recreation areas, trails, or other amenities. Clustering also can be used to provide greater development potential on a site while protecting a resource, providing open space, or to save infrastructure costs (City of Lacey, 1994b).

By retaining a large undisturbed area, clustering can substantially reduce the amount of runoff from the site. This technique may be especially appropriate as a way to

VOL 12 2 3975
R0057267

reduce the amount of land clearing and soil compaction (Recommendation 11, page 96 and Recommendation 12, page 100).

Incentives and Barriers

One incentive for clustering is the reduction in development costs and site disturbance that can be achieved. Fewer roads and shorter driveways can be used, and less area needs to be disturbed to put in utilities. Another incentive for clustering is the potential for neighborhood enhancement by setting aside open space for trails, recreation areas, or other amenities.

One barrier to clustering is the close proximity of homes that may result. Some people may not find having close neighbors an amenity, reducing the marketability of clustered housing.

Policy Trends

The Growth Management Act encourages local governments to provide for cluster housing and other innovative techniques in their comprehensive plans. The North Thurston Ground Water Management Plan (Thurston County, 1992b) encourages cluster development, particularly in wellhead protection areas and aquifer recharge areas.

Olympia

The new comprehensive plan allows clustering as an option in all zones. It requires clustering in unsewered portions of the urban growth area to leave room for future infill at urban densities and to protect ground and surface water, environmentally sensitive areas, and significant wildlife habitat (City of Olympia, 1994c). Current regulations relevant to clustering are the Critical Areas Ordinance and Planned Residential Development Ordinance. The Critical Areas Ordinance allows reduced lot sizes or clustering, encourages planned residential developments, and requires calculation of density to be based on net acreage (City of Olympia, 1992). The Planned Residential Development Ordinance contains procedures and requirements for clustering on parcels four acres and larger (City of Olympia, 1991).

Lacey

The current municipal code allows clustering in single- and multi-family Planned Residential Developments, leaving consolidated open space for recreation. Clustering is also required to a certain extent through the open space requirements for conventional subdivisions. The new comprehensive plan's land use element encourages clustering to retain open space, and to

VOL 12 2 3976

R0057268

ensure that land in the long-term urban growth area is available for future development at urban densities (Carr, pers. comm.).

Tumwater

The current municipal code establishes an overlay zoning district in certain environmentally sensitive areas in which Planned Unit Developments (PUDs) are required. PUDs allow more design flexibility than conventional development and therefore make clustering possible. Previous policies required clustering within the overlay zoning district and did not allow clustering in other zones. The new comprehensive plan for the city limits encourages clustering in all residential zones to protect sensitive areas while accommodating residential development. These same policies have been proposed in the draft city/county joint plan for Tumwater's growth area, along with a policy that would make clustering mandatory in the long-term growth area to ensure potential for future infill at urban densities (Bauer, pers. comm.).

Thurston County

In planning under the Growth Management Act, Thurston County has adopted policies for clustering in the rural/resource area, long-term growth area, and unincorporated short-term growth area. In areas designated for long-term rural residential and resource use, clustering is intended to permanently preserve farm and forestry resource lands (Dosheery, pers. comm.).

New zoning classifications also encourage clustering through density bonuses in the Rural Residential/Resource Zone (one unit/five acres) and Rural Residential Zone (one unit/two acres). Clustering is allowed in the long-term Agriculture and Forestry Zones but with no density bonuses. In areas designated for long-term future growth, clustering in the new Urban Resource Zone (one unit/five acres) is intended to facilitate redevelopment at urban densities when urban services (sewer and water) are extended in the future. In areas designated for short-term growth, clustering is intended primarily to protect sensitive areas (Dosheery, pers. comm.).

Clustering also is allowed to provide for future infill in areas not now served by sewers. Within the unincorporated short-term urban growth areas, clustered single-family and multifamily subdivisions are allowed within Planned Residential Developments (PRDs). The PRD ordinance emphasizes maximum efficiency in the layout of streets and utilities and preservation of unique natural features of the site (Dosheery, pers. comm.).

VOL 12 2 3971

R0057269

Implementation Actions

Olympia

Complete current growth management planning activities that encourage clustering.

North Thurston UGMA and Other Locations

Complete current growth management planning activities that encourage clustering. If clustering isn't currently encouraged, consider providing density credits or other incentives for clustering.

Implementation Costs for Olympia

No additional costs.

Recommendation 15.
Encourage the building and use of taller structures to reduce the size of building footprints.

Discussion

Multi-story buildings have less impervious surface coverage per occupant unit than single story buildings. Reducing the "footprint" of a building while increasing its height allows a parcel to accommodate the same density use with less impervious surface, or accommodate greater densities with the same amount of impervious surface.

Taller buildings are considered appropriate primarily in urban centers where site coverage tends to be very high. Given the high pedestrian and vehicular traffic associated with high density developments, the area around the building is typically dominated by streets, sidewalks, and small landscaped areas. Effective stormwater management in these areas can be more challenging than on lots with less developed area.

Incentives and Barriers

One incentive for taller buildings is the panoramic view generally provided to occupants and the increase in value from such views. However, proposals to construct taller buildings often raise neighborhood concerns about view obstruction and unattractive architecture. Neighborhood involvement in the designing of taller buildings could help address such concerns.

VOL 12 2 3978

R0057270

Construction costs increase exponentially with a jump from two to five stories, partially because of the need for elevators in tall buildings. According to the ADA as outlined in the Washington State Building Code (Washington State, 1992), elevators are not required in facilities that are less than three stories or that have less than 3,000 square feet per story unless the building is a shopping center, professional office of a health care provider, or another type of facility as determined by the Attorney General. However, if an elevator is nonetheless planned, the elevator must meet ADA requirements.

Providing elevators and stairways (vertical circulation) uses up leasable space, reducing the viability of a project and the economic incentive for taller buildings. Typically, 90 percent of a commercial building should be leasable space (Wells, G., pers. comm.).

Taller buildings are currently economically infeasible in Olympia because of a combination of relatively low land values and higher construction costs per occupancy unit. Land values are low because of the current property tax structure, because market demand is relatively low, and because state government occupies so much office space at below-market lease rates.

Policy Trends

Olympia

The current zoning code restricts building height to two stories in most residential and neighborhood commercial zones, and five to six stories in commercial zones and downtown Olympia. The zoning code allows taller buildings in planned residential developments than in underlying zones. However, most development in Olympia is below these maximum allowed building heights. The zoning code also requires buildings to be "harmonious in scale" with existing nearby buildings, which discourages taller buildings (City of Olympia, 1991, 1993*f*).

Lacey

In Lacey's downtown area, maximum building height ranges from 60 to 250 feet, but most new development is much lower. In residential areas, maximum building heights are 35 feet in low and medium density zones, and 80 feet in high density zones. No changes are planned in these height limits. Lacey's design review ordinance requires buildings to be "harmonious in scale" with nearby buildings (Carr, pers. comm.).

VOL 12 2 3979
R0057271

Tumwater

Development codes will be updated in 1995 to reflect the new comprehensive plan. No existing policies encourage taller buildings at this time (Bauer, pers. comm.).

Thurston County

Adopted city/county joint plans will apply city policies regarding building height to the unincorporated portion of the North Thurston UGMA (Dosheery, pers. comm.).

Implementation Actions

Olympia

Adopt the development standards for residential and commercial zones as proposed in the Draft Unified Development Code (City of Olympia, 1995).

North Thurston UGMA and Other Locations

Consider allowing taller buildings under commercial and residential zone development codes. Consider involving the development and business community in the identification of incentives and policies for taller buildings.

Implementation Costs for Olympia

No additional costs.

RECOMMENDATIONS FOR COMMUNITY INVOLVEMENT AND EDUCATION

Improving public involvement and education opportunities for residents is an important part of local government strategies for managing water resources. Olympia, Lacey, Tumwater, and Thurston County coordinate public involvement and education efforts wherever possible. Programs are designed to raise citizens' awareness and knowledge of water quality and quantity issues, provide skills to take personal action, and provide citizens a way to influence decisions. Study accomplishments required changes in public policy, as well as cooperation and coordination among neighboring local governments and community members. To continue the implementation that has been started, involvement and education recommendations are proposed below.

VOL 12 2 3980

R0057272

Recommendation 16.
Develop and distribute printed materials that complement the study's recommendations.

Discussion

Studies can produce useful results but may never affect development practices or other activities because the information isn't shared with decisionmakers, citizens, and others who can apply it. Implementation can be limited due to lack of funds or staff to distribute results or provide supporting materials for carrying out recommendations.

To help avoid this problem with the Impervious Surface Reduction Study, the Department of Ecology and Olympia set aside approximately nine percent of the study's funds for dissemination of results. It is expected that inquiries for printed materials will continue after the grant has expired and will require additional funding and staffing.

Incentives and Barriers

An incentive for developing and distributing printed materials is the ability to complement local planning activities. The printed medium typically is used to communicate information to the development and business community during the site plan review and permit process. Providing impervious surface reduction information in printed form will make it easy for city planning staff to incorporate the study's findings into their general routine.

Another incentive is the ease with which you can provide new ideas to audiences with written materials that complement technical assistance, site plan review, and other "face-to-face" interactions.

Policy Trends

Local comprehensive drainage basin plans contain a recommendation to create a storm and surface water public information program to provide consistent, accurate information to the media and increased educational outreach to the public (City of Olympia, 1993a,b).

VOL 12 2 3981
R0057273

Olympia

The new comprehensive plan includes a chapter on public involvement, with the goal of establishing and maintaining city decision processes that include the informed, active participation of all those affected. The environmental chapter includes a goal of public education about environmental protection (City of Olympia, 1994c).

The city currently distributes general information to the public via a quarterly newsletter mailed to all residents. More detailed information is distributed through various departments. For example, the Department of Planning and Community Development distributes information on development regulations through the permit counter and at workshops on growth management planning. The Water Resources Program distributes information on storm and surface water management, groundwater management, and drinking water supply issues; and the Waste Management Program distributes information on recycling and waste reduction. This is done through direct mailings, utility inserts, community workshops, outreach and education programs, and on request.

Lacey

Lacey's new comprehensive plan (City of Lacey, 1994c) contains several goals and policies related to public involvement. These goals and policies are intended to incorporate a wide range of public participation techniques in order to encourage public input and to disseminate information on a range of land use issues.

The city currently distributes general information to the public through *Lacey Life*, a city newsletter published nine times a year. This publication is put out by the Department of Public Affairs and Community Relations which also distributes information on solid waste reduction and recycling, neighborhood associations, special events, and community issues. This is done through special presentations to neighborhood associations, live call-in shows with the city council, direct mailings, workshops, and utility inserts. The Water Resources Unit distributes information on storm and surface water management, groundwater management, and drinking water supply issues. The Department of Community Development distributes information on development regulations through the permit counter and at special workshops (Carr, pers. comm.).

Tumwater

Tumwater's Comprehensive Plan (City of Tumwater, 1993) emphasizes public participation throughout the plan. The city produces a monthly newsletter

VOL 12 2 3982

R0057274

that is mailed to all residents. This newsletter, the *Pioneer*, alerts people to public meetings and emerging projects and issues (Matlock, pers. comm.).

Thurston County

Thurston County's comprehensive plan identifies the need for public education activities to support policies on environmental quality and stormwater management (Thurston County, 1988). In 1992, the Board of County Commissioners adopted a set of policies and procedures for public participation aimed at consistent public notification and involvement in the development of plans and regulations. Procedures include publications and distribution of fact sheets about new plans and regulations (Thurston County, 1992a).

County agencies that currently distribute public information are: Development Services, which distributes printed materials about development standards and regulations through the Permit Assistance Center; Community and Environmental Programs, which prepares and distributes information and educational materials for most county resource management programs; and the Storm and Surface Water Management Program, which distributes the Drainage Manual and other printed materials on stormwater management techniques (Alexander, pers. comm.).

Implementation Actions

Olympia

Respond to requests for the final study report and executive summary. Print and distribute copies of the model legal agreement for shared parking, alternative surfaces fact sheet, and other training and technical assistance materials.

Use established avenues of distribution such as permit counters, site plan review, and informational displays. Work with Lacey, Tumwater, and Thurston County; local businesses; building, development, and business organizations; and neighborhood and homeowner associations to identify and utilize established avenues of distribution. Coordinate with other City of Olympia departments, other local jurisdictions, and existing involvement and education programs in the region.

North Thurston UGMA and Other Locations

Provide information to Olympia concerning needs for and distribution opportunities of printed materials. If interested, request written materials from Olympia for distribution or replication.

VOL 12 2 3983

R0057275

Implementation Costs for Olympia

The $150 annual cost of printing and distributing materials will be covered under the study grant until June 1996 After June 1996, minimal Water Resources Program funding and staff time would be needed to print and distribute materials.

Recommendation 17.
Develop and provide training and technical assistance to the region's development and business community.

Discussion

A key success of this study is the raised awareness among local governments and the development and business community. However, the task of sharing the study's findings, identifying incentives for action, and implementing changes in practices and designs is not complete. Without a clear understanding about the problems with impervious surfaces and possible solutions and incentives, actual reduction may not occur. Consequently, ongoing training and technical assistance are essential for implementing impervious surface reduction techniques "on the ground."

Incentives and Barriers

Some of the recommendations should result in cost savings to the development and business community. Learning about how to reduce construction costs and use sites more efficiently should be an incentive to participate in training and technical assistance.

Policies and regulations will be changed as a result of this study. Policies and regulations often change so frequently that business people feel they can't keep up. Training and technical assistance, if well-designed, can help the development and business community understand current policies and regulations, reducing frustration and increasing compliance. Reduced frustration and increased compliance are key incentives for sponsoring and participating in technical assistance and training. However, if the training and technical assistance are ineffective, they could increase frustration and act as a barrier to future government-sponsored educational processes designed for the development and business community.

Policy Trends

Local comprehensive drainage basin plans include a recommendation to provide education and training opportunities for business and industry, including workshops on new regulations, technical support on best management practices, and

VOL 12 2 3984
R0057276

coordination with business organizations. Another recommendation is to train local government staff to implement and enforce basin plan recommendations such as new drainage standards and land use regulations (City of Olympia, 1993b). Olympia, Lacey, Tumwater, and Thurston County staff are participating in training for regional drainage manual implementation.

Olympia

The new comprehensive plan includes a chapter on public involvement, with the goal of establishing and maintaining city decision processes that include the informed, active participation of all those affected. The environmental chapter includes a goal of public education about environmental protection (City of Olympia, 1994c).

The Water Resources Program works cooperatively with Lacey and Thurston County, Lacey Area and Olympia/Thurston Chambers of Commerce, and the Washington Department of Ecology to offer education and technical assistance to local businesses through the Operation: Water Works program. Workshops, onsite visits, and assistance with developing a pollution prevention plan are provided to businesses whose activities have the potential to pollute surface and groundwater (City of Olympia, 1993e).

Olympia's waste management section provides ongoing technical assistance to businesses including free waste audits, and advice and assistance on recycling and waste reduction. The City also works with businesses to help identify useful products made from recycled materials (Guttchen, pers. comm.).

Lacey

Lacey has jointly participated with Olympia, Tumwater, and Thurston County in staff training for regional drainage manual implementation. Staff will in turn provide guidance to the development community. The Water Resources Unit works cooperatively with others to implement the Operation: Water Works program (Carr, pers. comm.).

Tumwater

Tumwater has jointly participated with Olympia, Lacey, and Thurston County in staff training for regional drainage manual implementation. Staff will in turn provide guidance to the development community (Bauer, pers. comm.).

Thurston County

Thurston County participates in the Operation: Water Works Program, which provides business-specific training workshops for owners and managers on

VOL 12 2 3985

R0057277

best management practices. The County also provides informational materials and consultations to the development community through its "one-stop" permit counter. Technical assistance is also provided at pre-submission conferences and through code enforcement or site inspections (Alexander, pers. comm.).

Thurston County Health Department sponsors the Business Pollution Prevention Program. The program provides technical assistance designed to gain regulatory compliance from small quantity hazardous waste generators, and complements the technical assistance and regulatory compliance goals of the Thurston County Moderate Risk Waste Plan (Thurston County, 1991b). From winter 1993 to spring 1994, the program focused on printing, photography, and medical facilities as a pilot project for further technical assistance. The high rate of voluntary compliance and increased management of hazardous wastes resulting from the pilot project indicates that the program may be a good model for impervious surface technical assistance.

Implementation Actions

Olympia

Share information with Lacey, Tumwater, and Thurston County and encourage the replication of materials. Make materials available to others upon request. Offer a soils workshop to the development community every other year (Recommendation 11, page 96).

North Thurston UGMA and Other Locations

If appropriate, request copies of Olympia's training and technical assistance materials or develop ones for the local situation.

Implementation Costs for Olympia

The $150 annual cost of printing and distributing materials will be covered under the study grant until June 1996. After June 1996, minimal Water Resources Program funding and staff time would be needed to print and distribute materials. The cost for a soils workshop is included in Recommendation 11 (page 96).

VOL 12 2 3986

R0057278

RECOMMENDATIONS FOR STUDY EVALUATION

Evaluation is an essential step for learning from past experiences and recognizing successes. For the project team, this study raised as many questions as it answered. It also identified the need for better information concerning impervious surfaces and local groundwater hydrology. The following recommendations, if implemented, would not only continue the research efforts begun with this study but would help us measure success and identify areas for improvement. These recommendations would provide information and data for evaluating the overall success of the study, as well as the specific policy and regulatory changes made as a result of study recommendations.

Recommendation 18.
Monitor the increase in impervious surfaces in Percival, Woodard/Woodland, and Chambers/Ward/Hewitt drainage basins to determine effective impervious surface coverage trends.

Discussion

One outcome of the study has been the realization that we have limited impervious surface information for the Olympia area, and north Thurston County. The information that is available for Percival Creek, Woodard/Woodland Creeks, and Chambers/Hewitt/Ward basins (Chapter 2, Basin and Site Coverage Assessment, page 34) has been a foundation for this study. Many of the recommendations are based on growth and related impervious surface coverage projections. It would be useful to verify the accuracy of these projections and adjust policies and regulations accordingly.

Incentives and Barriers

Community Planning and Development Department currently uses a Howard Technology Enterprise System (HTE System) that tracks development information and could be modified to better track impervious surfaces. Impervious surface coverage information is acquired from permit applications, but is not kept up to date on the system because of a lack of staff time for data entry. This is a barrier to getting current and accurate data.

Policy Trends

Thurston Regional Planning Council maintains a Geographic Information System for the region. The GIS mapping and information services are available to other local jurisdictions.

VOL 12 2 3987

R0057279

Olympia

As mentioned above, the city currently has a tracking system in place that could be used for monitoring impervious surfaces. Monitoring is supported through informal policies of the Water Resources Program and Public Works Department.

Lacey

Lacey's Department of Community Development uses a permit tracking system to monitor and store development information. Information regarding impervious surfaces is contained within the system for some properties. If information regarding impervious surfaces were consistently entered, this system would be an excellent tool for monitoring impervious surfaces within the city.

Lacey's comprehensive plan contains numerous goals and policies related to water resources issues. These include a policy that strives to ensure coordination between the Puget Sound Water Quality Management Plan, North Thurston County Ground Water Management Plan, Henderson Inlet and Budd/Deschutes Watershed Action Plans, various basin plans, and other water resources plans.

Lacey also has a stormwater utility that charges commercial developments a stormwater fee based on percentage of impervious surface. This may be used to track the total amount of impervious surfaces. At this time, the utility information is stored in a different system than the above-mentioned permit tracking system (Carr, pers. comm.).

Tumwater

Tumwater is currently not equipped to track impervious surfaces associated with new development. This may be possible in the future as staffing and equipment are added (Matlock, pers. comm.).

Thurston County

Thurston County is currently not equipped to track impervious surfaces associated with new development. Similar to Olympia and Lacey, Thurston County has a stormwater utility for the northern, more urbanized part of the county. The utility charges a stormwater fee based on percentage of impervious surface (Knostman, pers. comm.).

VOL 12 2 3988

R0057280

Implementation Actions

Olympia

Consider providing a dedicated staff person for HTE System data entry. Every five years, generate a digitized land use map of the three drainage basins used in the basin and site coverage assessment. Calculate the increase in impervious surfaces and compare to Impervious Surface Reduction Study projections. Make corrections to policies and regulations as needed to achieve a 20 percent reduction in future impervious surfaces.

North Thurston UGMA and Other Locations

Consider monitoring impervious surfaces. Provide information to Olympia for calculating the increase in impervious surfaces, as staff time and budget allows.

Implementation Costs for Olympia

A few days of Water Resources Program and Transportation Division staff time and approximately $1,000 in map fees would be needed to analyze and produce the needed information. Staff time also would be needed to review the HTE system and information periodically. Total cost is estimated at $1,500.

Recommendation 19.
Assess the results of the study's recommendations in Olympia, North Thurston UGMA, and other locations.

Discussion

The study will be a success if it results in less impervious surface than expected under the current growth scenario (Figure 3, page 7). Evaluating results of the study's recommendations would provide important information for adjusting reduction strategies and techniques. The information could be used to adjust policies, regulations, technical assistance, and incentives to achieve a 20 percent reduction.

Incentives and Barriers

Effective study evaluation would require the cooperation of all four local governments. Impervious surface evaluation may not be as high a priority for Lacey, Tumwater, or Thurston County as for Olympia, and thus prove a barrier to completing a useful analysis.

VOL 12 2 3989
R0057281

Policy Trends

Olympia

Olympia's Water Resources Program is committed to integrating evaluation into existing and new programs. Annual evaluation of the Stream Team volunteer program is conducted, and periodic evaluation of Operation: Water Works and other programs also are conducted.

Lacey

In 1996, Lacey will participate with Olympia's Water Resources Program in evaluation of the Stream Team volunteer program. Periodic evaluation of policies and programs occurs as needed.

Tumwater

Tumwater conducts periodic policy and program evaluation as needed.

Thurston County

In 1996, Thurston County will participate with Olympia's Water Resources Program in evaluation of the Stream Team volunteer program. Periodic evaluation of policies and programs occurs as needed.

Implementation Actions

Olympia

Document changes in regulations and policies for Olympia, the North Thurston UGMA, and other locations that occurred as a result of the study. Conduct an analysis using developments that are constructed under the revised Olympia parking ordinance, to see if projections of the study's parking analysis (Chapter 2, Parking Analysis, page 46) were accurate. Adjust policies and regulations if a 20 percent reduction is not being achieved.

North Thurston UGMA and Other Locations

Cooperate with Olympia in conducting an evaluation, as staff time and budget allows. Consider tracking developments that incorporate reduction strategies. When policies and regulations come up for revision, consider modifying them as needed to increase incentives and achieve impervious surface reduction.

VOL 12 2 3990

R0057282

Implementation Costs for Olympia

Several days of staff time would be required to conduct the evaluation. Minimal printing and other costs would be incurred. The total cost is estimated to be $1,000. Documenting the changes in regulations and policies should be conducted in early 1996. The cost for this portion of the evaluation could be covered under the study grant.

VOL 12 2 3991
R0057283

CHAPTER 4
IMPLEMENTATION STRATEGY

Successful implementation of the study's recommendations relies on the commitment of the community and its decision-makers, and the existing policy framework of Olympia and other local governments. Some of the study's recommendations were partially or wholly incorporated into the local policy framework prior to the study and are included as guidance for others. Some have been incorporated into Olympia's Draft Unified Development Code (City of Olympia, 1995) and draft street standards that are being considered for adoption. The code includes the parking ordinance, landscaping ordinance, and development standards. If the Unified Development Code and draft street standards are adopted as proposed, many of the recommendations will be integrated into Olympia's existing policy framework during 1995. It is expected that Olympia will implement approximately 81 percent of the study's recommendations not already incorporated into city policy.

As with Olympia, some recommendations were partially or wholly incorporated into Lacey, Tumwater, and Thurston County policy prior to the study. Only a few additional recommendations are proposed for adoption. It is estimated that 10 to 20 percent of the recommendations will be adopted by neighboring local governments during 1995.

SCHEDULE

One challenge in developing an implementation schedule is that several recommendations are already implemented or will be in the near future. Another challenge is documenting implementation that has occurred or will occur in other locations, both within the North Thurston UGMA and across the nation. The many requests for information that originated outside the North Thurston UGMA indicates that some implementation is probably underway in other locations. Completing Olympia's implementation actions for Recommendation 19, Assessing Results (page 121), will provide a better indication of study implementation than what we can currently estimate. In response to these challenges, Table 18 (page 127) contains information pertaining only to Olympia.

RESOURCES NEEDED

Implementation in Olympia would require a minimum of staff time and materials because many of the recommendations would be implemented through existing programs and site plan review. Some staff time would be needed to participate in implementation. In particular, distribution of materials designed for the development community (Recommendation 16, page 113 and Recommendation 17, page 116) would primarily occur through the permit counter and site plan review activities

VOL 12 2 3992

R0057284

conducted by Community Planning and Development Department (CPDD) staff. Water Resources Program staff would develop the materials for CPDD staff to pass on to the development community and would be involved in site plan reviews from a stormwater management perspective. Water Resources Program staff also would be responsible for completing the study evaluation.

Completing the study evaluation would require some staff and material resources of Lacey, Tumwater, and Thurston County. Because the study is not being officially adopted by the other local governments, they are not legally bound to implement the study's recommendations. However, project staff expect that the cooperation offered by the other local governments during the study will continue into the future.

GLOSSARY

R0057306

accessory units
A second dwelling unit added to, created within, or separated from a single family dwelling with provision for cooking, eating, sanitation and sleeping. Commonly called "mother-in-law" units.

alternative surfaces
Surfaces other that conventional asphalt or concrete. Examples include bark and gravel.

alternative modes of transportation
Modes of transportation other than the single passenger automobile, such as transit, bicycling, carpooling, and walking.

amenity
Something that increases material or physical comfort.

Americans with Disabilities Act (ADA)
Federal legislation passed in 1990 to provide comprehensive protection of the civil rights of people with disabilities.

atmospheric deposition
Deposits on land and water from the atmosphere (air), often referring to pollutants.

arterial street
A street that provides a direct route for long-distance travel within the region and also to different parts of the city. Traffic on an arterial street is given preference at intersections, and some control of access may be used when arterials carry high volumes of traffic.

aquifer
The underground layer of rock or soil in which groundwater resides. Aquifers are replenished or recharged by surface water percolating through soil. Wells are drilled into aquifers to extract water for human use.

basin plans
A plan to identify and correct current and potential surface water problems within a creek system and surrounding drainage area including flooding, erosion, degraded water quality, and diminishing aquatic and wildlife habitat. Public involvement is one aspect of plan development and adoption.

best management practices
A method, activity, maintenance procedure, or other management practice for reducing the amount of pollution entering a water body.

VOL 12
2
4015
R0057307

buildout
Full development at the maximum densities allowed by zoning.

building footprint
Commonly used term to describe the ground area that a building covers.

calibration
To correlate readings from a system of measurement with a standard.

conservation easement
An agreement (grant of a property right) stating that land will remain in its natural condition precluding future or additional development.

Centennial Clean Water Fund
A common name for the Water Quality Account administered by the Washington Department of Ecology. In 1986, legislation was passed creating the Water Quality Account in the Washington State Treasury (RCW 70.146). The purpose of the account is to provide financing of water pollution control facilities and activities.

clearing and grading practices
Clearing practices refer to the destruction or removal of vegetation from a site by physical, mechanical, chemical, or other means. Grading practices refer to any excavating or filling of earth materials or natural covers.

cluster development
A development design technique which groups buildings on one part of a site so as to preserve another part of the site for common open space, recreation, or preservation of environmentally sensitive areas.

comprehensive land use plans (comprehensive plans)
A plan adopted by the local government to guide the physical growth and improvement of a city or county, including any future amendments and revisions.

cooperative parking
A term to describe various methods to increase the use of available parking areas including shared, joint, and coordinated parking.

coordinated parking
Use of large commercial or retail overflow parking areas for park-and-rides or other parking needs.

VOL 12
2
4016
R0057308

cumulative impact assessment
Cumulative impacts are the effects that accumulate over time and space from a series of similar or related individual actions, pollutants, or projects. Although each action may seem to have a minimal impact, the combined effect can be severe. A cumulative impact assessment studies and summarizes these impacts.

defensible space
The space around an individual that allows for a feeling of safety. The amount of necessary space to be considered defensible varies according to the situation. For instance, in a crowded elevator defensible space is less than in a parking lot.

density
The number of dwelling units per acre.

density credits
An increase in density provided to a developer or builder as a result of certain adjustments to the plan or layout of the development.

drainage basin (see watershed)
A land area bounded by high points, which drains all surface water into a single stream or other body of water.

drywell
A pit in the ground often filled with gravel into which stormwater is routed. The dry well holds the stormwater until it percolates into the ground.

effective impervious surface
The portion of impervious surface that generates stormwater runoff which must be managed or directed to a stormwater conveyance system, rather than infiltrating into the ground.

erosion
The wearing away of land surface by water, wind, ice or other chemical and mechanical forces, including human activities.

groundwater
Water stored underground that fills the spaces between soil particles or rock fractures. A zone underground with enough water to withdraw and use for drinking water or other purposes is called an aquifer.

VOL 12
2
4017
R0057309

Growth Management Act (GMA)
Washington state law enacted in 1990 that requires local governments in rapidly growing counties to plan for the projected population. Growth management planning typically addresses land use, transportation, housing, economic development, open space, recreation, and environmental issues.

habitat
The specific area or environment in which a particular plant or animal lives. A plant or animal's habitat must provide all of the basic requirements for life.

Hydrologic Simulation Program - Fortran (HSPF)
A specific computer program which simulates (models) land surface and in-stream hydrology on a continuous basis.

hydrology
The science of the behavior of water in the atmosphere (air), on the surface of the earth, and underground.

homeowner association covenants
A binding agreement or contract between a group of homeowners that typically contains criteria for behavior and home appearance in a subdivision.

impervious surface
Any surface which cannot be effectively (easily) penetrated by water. Examples include pavement, buildings, and compacted soils.

Impervious Surface Reduction Study (ISRS)
A study administered by the City of Olympia to recommend strategies for the reduction of impervious surfaces.

infill
Developing vacant parcels or redeveloping existing property to achieve higher density in urban areas as an alternative to development in outlying rural areas.

infiltration
The downward entry of water into the surface of the soil, as contrasted with percolation which is movement of water through soil layers.

infrastructure
The basic facilities needed for the functioning of a city or county, or other system. Examples include roads, schools, and hospitals.

in-lieu-of-parking fees
A mechanism to place money into a parking improvement fund administered by a city, county, or other governing body. Offered as an option to developers instead of furnishing required parking spaces.

VOL 12
2
4018
R0057310

interconnected streets
A street system that allows traffic to circulate between neighborhoods instead of a system of cul-de-sacs and dead end streets that results in disconnected residential areas. A grid pattern of blocks is a typical example.

interstices
Portions of generally impervious material that facilitate the movement of water into the soil.

joint parking
Mutual use of a parking area at multi-tenant retail and commercial facilities.

local access streets
Streets that provide passage between adjacent land uses and carry local traffic to collector streets.

local governments
The governing organizations of cities and counties.

local jurisdictions
The governing organizations with legal authority over specific territories, including but not limited to cities and counties. For example, the Port of Olympia or Thurston County Conservation District.

major collector streets
Streets that connect arterials to residential and commercial areas.

model agreements
Examples of written agreements that include sample language and content.

neighborhood collector streets
Streets which collect (or distribute) traffic within a neighborhood and provide connections to an arterial or major collector. They serve neighborhood traffic and also provide access to abutting land uses. Streets designed to be compatible with residential neighborhoods and neighborhood commercial centers.

needs assessment
A survey to determine the requirements or desires of a particular audience.

North Thurston County Urban Growth Management Area (North Thurston UGMA)
The area designated by Thurston County pursuant to RCW 36.7A.10. Includes land area sufficient to accommodate the urban growth projected to occur in the northern part of the county over the next 20 years.

VOL 12 2 4019
R0057311

offstreet parking
Any parking areas not on the street, including parking lots and parking garages.

open space
Any parcel or area of land or water essentially unimproved and set aside, dedicated, designated, or reserved for public or private use or enjoyment. These lands may include but are not limited to wetlands; wetland buffers; creek, stream or river corridors; forested areas; ravines, bluffs or other geologically hazardous areas; and undeveloped areas within existing parks or neighborhoods.

ordinance
A statute enacted by a government, such as the parking ordinance approved by Olympia's City Council and codified in the Unified Development Code.

organic mulches
A material derived from plant or animal matter used to enrich or amend a soil.

parking ratios
Parking required for a particular land use, stated as a ratio of "x" spaces per "y" units. Typical units are square footage, dwelling units, persons, and seats.

pavers
Concrete grid and modular pavement whose spaces are filled with pervious materials such as sod, sand, or gravel.

peak-day projections
Projections of parking demand during the day and time of highest use. Commonly used to determine the number of parking stalls needed for individual land uses.

performance-based standards
Technical standards for operation or appearance that are based on meeting objectives rather than specific sizes, widths, or other detailed requirements.

permeable
A type of soil or other material that allows passage of water or other liquid.

pervious
A soil or material that has the specific quality of allowing the passage of water or other liquid.

Planned Residential Developments (PRDs)
A type of development characterized by comprehensive planning for the project as a whole, clustering of structures to preserve usable open space and other natural features, and a mixture of housing types within the prescribed densities.

VOL 12 2 4020

R0057312

Planned Unit Developments (PUDs)
Similar to Planned Residential Developments except they can include a commercial land use component along with the residential land uses.

plat map
A map showing the division of a tract or parcel of land into lots, blocks, streets and alleys, or other divisions or dedications.

policies
A course of action adopted by local jurisdictions or organizations.

pollutants
A chemical or other additive that adversely alters the physical, chemical, or biological properties of the environment.

porous pavement
Asphalt or concrete paving material consisting of a coarse mixture cemented together with sufficient interconnected voids to provide a high rate of permeability.

recharge
Infiltration of surface water to groundwater.

regulations
A particular set of laws, rules, or procedures designed to govern a particular type of activity or solve a particular problem.

retrofitting
To provide or add new equipment, parts, or techniques unavailable at the time of original construction.

runoff (see stormwater runoff)

setback
A zone or distance between buildings and the lot line designated to protect areas or neighboring activities from negative impacts associated with development.

shared parking
Mutual use of a parking area by land uses with noncompeting hours of operation, such as a theater and office building.

siltation
The process by which a river, lake, or other body of water becomes clogged with excess soil or sediment.

VOL 12
2
4021
R0057313

sprawl
Haphazard, dispersed, or spread-out growth. Commonly refers to urban sprawl which is the spread of cities into rural areas.

standards
A regulation that contains specified amounts, widths, or sizes for streets, buildings, or other development.

stormwater conveyance
A system of gutters, pipes, or ditches used to carry stormwater from surrounding land areas to constructed or natural drainage systems.

stormwater facilities
Private or public infrastructures designed to collect, treat, and/or store rainfall and runoff.

stormwater runoff
Rain that flows off the surface of the land without entering the soil.

stormwater treatment
Mechanical, chemical, or biological removal of pollutants from stormwater runoff.

stormwater utility
A public service program to manage stormwater and collect fees to pay for such management.

surface water
Water on the surface of the land that has not infiltrated the soil including streams, lakes, rivers, and ponds.

sub-soil
Layers of soil beneath the surface layer (topsoil).

sustainability criteria
Criteria used to gauge the effectiveness of projects, plans, and new regulations in achieving a sustainable community. A sustainable community is one that persists over generations and is far-seeing enough, flexible enough, and wise enough to maintain its natural, economic, social, and political support systems.

swales
A shallow drainage ditch with relatively gentle side slopes, generally with flow depths less then one foot.

VOL 12 2 4022
R0057314

technical assistance
A combination of information, education and training activities that provide specific audiences with "face to face" learning and skill building opportunities. Often linked with a regulatory program as an incentive for compliance.

topsoil
The fertile layer of soil at the surface of the ground.

Uniform Building Code (UBC)
A Washington state code that regulates building practices.

variance
A license to engage in an act contrary to law.

watershed (see drainage basin)
The geographic region within which water drains into a particular river, stream or body of water. A watershed includes hill, lowlands, and the body of water into which the land drains. Watershed boundaries are defined by the ridges of separating watersheds.

water table
The upper surface of groundwater or the level below which the soil is saturated with water. The water table indicates the uppermost extent of groundwater.

wellhead protection areas
A protected surface and subsurface zone surrounding a well or wellfield supplying a public water system. Used as a planning tool to keep pollutants from reaching the well water.

wetlands
Habitats where the influence of surface or groundwater has resulted in development of plant or animal communities adapted to aquatic or intermittently wet conditions.

zero lot line
The location of a structure on a lot in such a way that one or more sides of the structure rests directly on the lot line.

zoning
A set of regulations and requirements governing the use, placement, spacing, and size of land and buildings in a specific area (zone).

APPENDICES

VOL 12 2 4024

R0057316

APPENDIX A
PUBLIC INVOLVEMENT AND EDUCATION PLAN

January 27, 1994

A. Goal

To identify and gain community and local government support for impervious surface reduction recommendations resulting from the study.

B. Objectives

1. Provide a broad array of forums for clarification and integration of the community's vision, interests, needs, concerns, and ideas.
2. Build on the existing cooperation and coordination among local jurisdictions.
3. Enhance private and public partnerships.
4. Involve all affected parties in such a way that technically and politically feasible recommendations are generated.

C. Recommended Activities

1. Needs Assessment

A needs assessment would be used to identify public involvement and education strategies suitable for reaching the goal. A secondary outcome of the needs assessment would be identification of barriers and incentives for implementation of the recommendations.

The assessment would consist of informal surveys of individuals, organizations, and local jurisdiction and agency representatives affected and involved in development activities and resource management. Examples of survey questions include:

a. Do you believe impervious surfaces pose a problem or problems? If so, what do you see as the problem or problems?

b. Do you see reducing impervious surfaces as beneficial?

c. How can reducing future amounts of impervious surface in developed areas benefit you?

VOL 12 2 4025

R0057317

d. What do you see as the barriers to reducing the amount of impervious surface?

e. What incentives would help overcome these barriers?

f. What would entice you to be involved in a model demonstration project that tests some new techniques and policies for reducing impervious surfaces?

g. How do you like to have information shared with you?

2. Community Strategies

a. Mailing and Contact Lists: As a basis for broad-based community involvement and education activities, mailing and contact lists of interested individuals and local, regional, and state-wide associations and groups representing the business and development community would be created. These lists would be used to schedule project briefings and presentations, send mailings, and build community interest and participation in the study. Sources include the Operation: Water Works landscaping and construction lists; referrals from permit counters in all four jurisdictions; business licenses; and others. The lists would be separated into primary and secondary levels of contact.

b. Visual Tools: Three or four visual tools would be developed to aid in the dissemination of information. Possible tools include slideshows, displays, schedule boards, three-D models and architectural renderings, photo albums, and a training video.

c. Briefings: Six to eight briefings would be provided to community and business groups, professional organizations, and local governments to introduce and spark interest in the study.

d. Multi-Media Presentations: More detailed presentations would be provided as a follow-up to the briefings or to reach additional audiences. These presentations also could serve as a forum for the needs assessment and for sharing community responses and opinions.

e. Workshops and Community Forums: At least two workshops or community forums would be convened to review the recommendations and the study's policy implications. These forums would target the business and development community and local jurisdictions to solicit reactions to the technical and economic feasibility of recommendations. The January 6 Community Forum is one of these meetings.

VOL 12 2 4026

R0057318

f. Tours and Open Houses: There currently exist examples of housing, landscaping, and commercial development where alternative strategies for reducing impervious surfaces have been used. In addition, the demonstration projects will provide an excellent opportunity for education (see No. 4 below). One or two tours or an open house co-sponsored by the development community for peers, elected officials, and planning and development staff from local jurisdictions would be organized. These events would encourage discussion concerning the benefits and constraints of alternative strategies, brainstorming innovative approaches, and viewing of the demonstration projects during construction.

g. Public Events and Conferences: Linkages with other jurisdictions and the business and development community would be expanded by participating in two or three public events and/or conferences. In particular, we would contact the Olympia Master Builders, the local Chambers of Commerce, and Thurston County concerning opportunities for linkages.

h. News Releases, Articles, and Interviews: Three or four news releases would be submitted to business publications and local papers. The purpose would be to inform affected parties and generate participation in the demonstration projects and study. Media coverage also would be used to acknowledge participation in demonstration projects and announce training on the new policies and techniques.

i. Recognition: Plaques or certificates would be presented to businesses participating in the demonstration projects. Signs also would be placed at the project site(s) to acknowledge participation. Over the long-term, notices to realtors also would be used to acknowledge homes or commercial construction projects that integrate the new policies and techniques.

3. Technical Assistance

a. Demonstration Project Training: One training workshop would be provided to those contractors, developers, and other private sector partners in the demonstration project(s) (see No. 4 below). This training would serve as a model for future training (see "c" below). Evaluations would be conducted to determine what worked and didn't work about this training.

b. Technical and Policy Assistance Materials: A packet of materials would be developed that explains the technical requirements of incorporating alternative strategies into proposed site and building plans, and the

VOL 12 2 4027

R0057319

policy changes that occurred and are recommended as a result of the study. Permit counter staff at the four local jurisdictions and key development community representatives would be invited to help develop training materials.

c. Training Workshops: Two training workshops would be offered to present the technical and policy assistance materials and encourage implementation of the study's final recommendations "on-the-ground." The development community would be invited to co-sponsor the training. A video or slideshow of the demonstration projects would be used to demonstrate the steps taken. Tours of the completed projects, a photobook of "desirable" architecture and landscaping, and 3-D renderings of alternative designs also could be included as part of the training. Training would emphasize the do-ability and cost-savings of the new policies and techniques.

4. Demonstration Projects

At least one demonstration project would be constructed that tests some of the alternative development techniques recommended in the study. In order to meet the time constraints of the Centennial grant, the project would most likely consist of an existing proposal that is modified to include some alternative techniques. Project staff are currently soliciting model project proposals and will be selecting one or more projects during January 1994, with the assistance of the Ad Hoc Citizen Advisory Committee and Steering Committees.

5. Dissemination of the Results

a. Professional Presentations and Papers: Information would be disseminated to other jurisdictions who may be interested in the study's results and replication of the project. Staff would present a paper at one regional conference. Staff also would look for opportunities to submit articles to professional journals and present at additional conferences, water resource forums, workshops, and meetings. The emphasis of the presentations and papers would be the integration of impervious surface reduction into a sustainability criteria framework, and tools and strategies for planners, architects, landscape architects, and developers.

b. Local, Regional, and National Publications: Professional organizations' publications would be used to invite study involvement and spread the word about the study's results. In printing of brochures, fact sheets, the final report, or other materials, we would print an additional 50 of each for distribution to other jurisdictions and advertise within at least two

VOL 12 2 4028

R0057320

professional publications the availability of the materials. Possible publications include Soundwaves and Puget Sound Notes.

D. **Public Involvement and Education Plan Evaluation**

Several forms of evaluation would be used, including written workshop evaluations, levels of participation and support for the project, implementation of the study's recommendations, and requests for information. In addition to evaluating completion of the activities listed under section "C" above, measures of evaluation could include:

a. at least 1,000 people informed of the study through briefings, presentations, etc.

b. demonstration project(s) that include private-public partnerships

c. at least five site plans integrating results of the study submitted to Olympia during 1995

d. at least 20 people involved in the training(s)

e. results of evaluation forms from training(s) indicate training was useful

f. at least 75 percent of the study's recommendations adopted by Olympia and 50 percent by the other local jurisdictions

g. at least 10 jurisdictions request study results

h. at least one letter of support for the study received from a leading business organization

i. support of the Ad Hoc Citizens Advisory Committee and Steering Committee members for the study's recommendations

E. **Schedule**

The schedule for implementation of the Public Involvement and Education Plan will change within the next few months to reflect Ad Hoc Citizens Advisory Committee and Steering Committee input, and results of the needs assessment. The tentative schedule as of December 1993 is:

VOL 12 2 4029

R0057321

November and December 1993:

- develop PIE plan proposal and submit to committees for review
- create mailing and contact lists
- prepare and begin briefings
- begin to develop project "identity" with graphics staff
- refine needs assessment strategy

January-March 1994:

- conduct needs assessment
- finalize PIE plan and submit to Ecology for approval
- identify recommendation implementation strategy with Ad Hoc Committee
- select demonstration project(s) and submit to Ecology for approval
- continue with briefings
- develop and conduct presentations
- solicit participation in demonstration project(s)
- develop training materials and provide training
- advertise study and encourage involvement (events, news releases, etc.)

April-June 1994:

- erect signs at demonstration project(s)
- conduct tours of demonstration project(s)
- continue to give presentations and solicit involvement
- identify possible publication and presentation opportunities

July-September 1994:

- revise recommendations based on demonstration project(s) and additional public input
- hold tours or open house of demonstration project(s)
- present at regional conferences and other forums

October-December 1994:

- prepare draft final report and solicit public review and comments
- evaluate PIE plan and demonstration project(s) for final report
- award plaques and certificates to demonstration project(s) participants
- present at regional conferences and other forums
- publish study results

January-March 1995:

- submit final report to Ecology for approval
- publicize and disseminate study results and information

APPENDIX B
NEEDS ASSESSMENT

July 1994

OVERVIEW

The purpose of the Impervious Surface Reduction Study (ISRS) needs assessment was to identify communication tools and incentives appropriate for reducing impervious surfaces. A secondary purpose was to inform members of both the public and private sectors of our community about the study. The assessment results have been incorporated into the ISRS public involvement and education strategy and will help guide technical assistance activities.

The informal assessment was conducted over a three-month period (January through May 1994). Forms were distributed at events to some members of the community and mailed to others. The form was slightly changed after it was initially distributed at the ISRS Community Forum in January 1994. The form was distributed at the following events:

- ISRS Community Forum (January 6)
- Olympia City Council meeting (March 22)
- Lacey Chamber of Commerce, Monthly Membership Meeting (April 6)
- American Society of Civil Engineers, Seattle Chapter Monthly meeting (April 21)
- Olympia Community Planning and Development staff meetings
- Various individual development and business community briefings
- ISRS Steering and Ad Hoc Citizen Advisory Committee meetings

RESULTS

Of the approximate 125 forms distributed, 41 (33 percent) were returned. Responses are summarized according to three groupings: (1) all respondents; (2) private sector respondents; and (3) public sector respondents. Responses by all the respondents to Questions 1 through 7 are summarized in Attachment A, Results Summary. Responses to Question 8 are summarized separately for the private and public sector and also are part of Attachment A. Private and public sector responses to Questions 3 through 7 are summarized in Attachment B, Tables 1 through 3.

Survey responses indicate that, with the exception of tours and field trips, technical assistance and education tools for the public sector may not be suitable for the private sector. However, newspapers are a good media format for reaching both

VOL 12 2 4031
R0057323

sectors. The survey results also indicate that the public sector is more willing to participate in demonstration projects than the private sector. Responses indicate that the private and public sectors agree on the incentives for participating in demonstration projects: training, streamlined permit process, and reduced development costs.

Questions 1 and 2: Characteristics of Respondents

Twenty-six (63 percent) of the 41 returned forms were from members of the private sector, and 15 (37 percent) were from the public sector. Nineteen occupations were represented. Each occupation category had at least one respondent. "Engineer" was the occupation best represented, with 12 (29 percent) respondents in this category.

Question 3: Technical Assistance and Public Education Tools

Table 1, Attachment B, summarizes the responses to Question 3. Tours and field trips were ranked high by all three groupings, while presentations and speakers were ranked low by all three groupings. The private and public sector respondents felt differently about some tools. The responses indicated that guidebooks, technical manuals, and one-on-one technical assistance are helpful tools for integrating ISRS recommendations into private sector activities, while demonstration projects and visual media are not very helpful. The responses also indicate that for the public sector, demonstration projects and visual media are helpful, while publications, seminars and training, guidebooks and technical manuals, and one-on-one technical assistance are not very helpful.

Question 4: Media Formats

Table 2, Attachment B, summarizes the responses to Question 4. There was more consistency among the private and public sector responses to Question 4 than to Question 3. Newsletters and newspaper articles were ranked "high" for reaching the respondents to the survey. Newspaper announcements were also ranked "high" by the private sector, but were ranked medium by the public sector. Television was ranked "low" by both sectors. Radio was ranked "medium" by all respondents and the private sector respondents, and ranked "low" by the public sector.

Questions 5a and 5b: Publications and Stations

The responses to Questions 5a and 5b were many and varied, indicating that there is no one newspaper, magazine, newsletter, television or radio station that will reach all respondents. However, most respondents did mention *The Olympian* newspaper. The most frequently given responses are listed in Attachment A.

VOL 12 2 4032

R0057324

Question 6: Presentation or Publication Opportunities

The varied responses to Question 6 are summarized in Attachment A.

Questions 7a and 7b: Participation in Demonstration Projects

The responses given by all respondents to Question 7a are summarized in Attachment A. Responses to Question 7b are grouped according to all respondents, private sector, and public sector and are summarized in Table 3, Attachment B.

Question 7a

Out of the 34 respondents who answered Question 7a, 6 (18 percent) indicated a definite interest in participating in demonstration projects. Another 19 (56 percent) indicated they may be interested in participating, and 9 (26 percent) indicated they definitely are not interested. Of the six positive responses, three were from the private sector and three from the public sector. Of the 19 "maybe" responses, 12 (63 percent) were from the private sector and seven (37 percent) from the public sector.

Question 7b

The private and public sector respondents ranked incentives for participating in demonstration projects the same. Highly ranked incentives include training in alternative techniques, streamlined permit process, and reduced development costs. Medium-ranked incentives include media coverage, signs, and sharing accomplishments with peers. Low-ranked incentives include plaques or awards, and letters of appreciation.

Question 8: General Ideas and Recommendations

The responses to Question 8 are summarized according to the private and public sectors in Attachment A.

R0057327

IMPERVIOUS SURFACE REDUCTION STUDY

City of Olympia Public Works Department • P.O. Box 1967 • Olympia, WA 98507-1967

FACT SHEET #1: STUDY OVERVIEW

Why Study Impervious Surfaces?

As the North Thurston urban region continues to grow, impervious surfaces such as streets and parking lots will also increase. With increasing amounts of impervious surfaces, we also increase flooding and erosion problems, decrease recharge of our groundwater and drinking water supplies, and degrade fish and wildlife habitat of our local streams and lakes. Local development practices aim to reduce these impacts, but fail to address a key source of the problem—impervious surfaces.

Goal Of The Study?

The goal of the Impervious Surface Reduction Study is:

"...to identify and gain community support for development techniques and policies that result in increased stormwater treatment and groundwater recharge without causing appreciable increases in development costs."

Benefits Of The Study?

Successful completion of the study will result in the following community benefits:

- Policy and regulatory changes that result in less impervious surfaces in the North Thurston Urban Growth Management Area.
- Construction of innovative projects that model the effectiveness of techniques and policies identified by the study.
- Technical information and training provided to the development community that makes incorporation of the new techniques and policies easier and more cost effective.

VOL 12 2 4036

R0057328

Project Schedule And Major Tasks?

The project began in Spring 1993 and will be completed Spring 1995. Major tasks include:

- Analysis of technical and policy issues related to impervious surfaces.
- Development of recommendations to reduce the amount of impervious surfaces.
- Construction of demonstration projects that test recommendations.
- Involvement and education of the local community.
- Sharing of the study's results.

Who Participates In The Study?

The study is being guided by both steering and citizen advisory committees. These committees are composed of neighborhood, development, and business representatives, and natural resource management experts from both the public and private sectors of the local community.

The City of Olympia's Public Works Department Water Resources Program provides project leadership with support and participation from Lacey, Tumwater, and Thurston County. Funding is provided by the Washington Department of Ecology through a Centennial Clean Water Fund Grant and by Olympia residents through their Storm and Surface Water Utility.

How Can You Get Involved?

You are invited to:

- Review and comment on products and reports of the study.
- Become a demonstration project partner.
- Participate in technical assistance and training.
- Call Cedar Wells (753-8454 or 753-8598, 24-hour line) for more information.

FACT SHEET #2: STRATEGIES FOR REDUCING PARKING

Why Reduce Parking?

Parking lots provide an important opportunity to reduce impervious surfaces—those hard surfaces that don't let water soak through to the ground. The more commercial and multifamily development you have in your watershed, the more important it is to reduce parking to achieve the goal of reducing impervious surfaces.

For example, parking lots cover approximately 53 percent of commercial sites and 15 percent of multifamily sites in the Olympia area. Reducing Olympia's commercial parking by 20 percent can reduce the impervious surface by almost 11 percent per site.

Shifts In Thinking

Parking policies have traditionally adopted the "bigger is better" view of parking lots. Regulations have focused on providing enough parking to avoid traffic congestion or overflow into residential neighborhoods, but have resulted in too much parking in some cases. Although smaller parking lots reduce development costs, developers need to provide adequate parking for customers and tenants. Parking lots can be reduced in creative ways that are good for both business and the environment.

Strategies For Local Jurisdictions To Reduce Parking

<u>Make reduction of impervious surfaces a goal of parking policies and regulations.</u>
Use site plan reviews and policy revisions as opportunities for addressing the problem of excess parking.

<u>Establish parking requirements that accurately reflect parking needs for various land uses.</u>
Typically, parking regulations are based on artificially low "minimum" parking ratios that do not accurately reflect parking needs. Developers have built up to 51 percent above these ratios in the Olympia area. Parking regulations should accurately reflect parking needs for various land uses and be based on a high average use—instead of single peak day projections.

VOL 12 2 4038

Strategies (continued) Suggested ways to accomplish this goal include:

- Establish "median" parking ratios that reflect parking needs.
- If "minimum" ratios are used, establish "maximum" ratios in conjunction with minimums.
- Encourage the use of transportation demand management techniques as an alternative to exceeding "median" or "maximum" ratios.

Establish cooperative parking regulations to reduce impervious surfaces.

Smaller and fewer parking lots can result from cooperative parking. Developers and local jurisdictions can reduce the size of parking lots through shared, joint, or coordinated parking.

- Shared parking reduces the parking area for land uses with noncompeting hours of operation. Suggested parking reductions are a 100 percent reduction of the smaller parking requirement for complimentary daytime and nighttime land uses, and 50 percent of the smaller parking requirement for land uses with some overlap of hours.
- Joint parking reduces the total parking area required for multi-tenant retail and commercial facilities. The possibility of captured trips and increased overflow parking allows for overall reductions for each land use at these facilities. Suggested parking reductions are 10 percent for developments with two buildings and 25 percent for developments with three or more buildings.
- Coordinated parking reduces the total parking area by using large retail or commercial overflow parking for safe, convenient Park and Ride locations.

Water Resources Program mission:
To provide regional leadership towards a sustainable community by ensuring the protection and enhancement of Olympia's water resources.

This study is funded by the Department of Ecology through a Centennial Clean Water Fund Grant and Olympia residents through their Storm and Surface Water Utility.

IMPERVIOUS SURFACE REDUCTION STUDY

City of Olympia Public Works Department • P.O. Box 1967 • Olympia, WA 98507-1967

FACT SHEET #3: GUIDANCE FOR USING ALTERNATIVE SURFACES

Impervious Surface Reduction Hits The Streets!

Olympia's Water Resources Program is conducting an Impervious Surface Reduction Study (ISRS) to identify alternatives to hard, water resistant surfaces such as asphalt, concrete, and compacted soils. Impervious surfaces block rain from recharging our groundwater and drinking water supplies, increase the potential for flooding and erosion, and contribute to the degradation of our local streams and lakes.

'Perkin' To The Ground...Helps Puget Sound!

As long as we depend on cars, we will need roads, streets, and driveways. Asphalt and concrete are the most common types of driving surfaces, but are very impervious (hard and water resistant). Alternative surfaces are more pervious than asphalt or concrete. Some let a little rain seep (infiltrate) into the ground, while others let 100 percent of the rain infiltrate. The more rain we infiltrate, the less runoff we create. The less runoff, the fewer pipes and storage systems we need to build in order to prevent flooding.

Types of Alternative Surfaces

Alternative surfaces include paving blocks, plastic matting, gravel, bark, and similar materials.

Paving Blocks: Interlocking, high-strength blocks made of cement or recycled plastic with open areas for grass or gravel are commonly referred to as paving blocks. These blocks are typically set on a compacted base of sand or a mix of sand and gravel. No mortar is required. Sand is vibrated into the space between the units causing them to interlock and form a tough, attractive surface that provides easy access to underground utilities. Their structural behavior and load spreading ability is similar to asphalt. These systems can be a solution for highly used lawn areas, overflow or low use parking areas, or emergency access roads. They support fairly heavy traffic and concentrated loads, reduce stormwater runoff, enhance groundwater recharge, and increase infiltration.

VOL 12 2 4040

R0057332

Types of Alternative Surfaces (Continued)

Plastic Matting: This type of system is usually a form of easily laid locking tiles made from recycled rubber tires and PVC, permitting thick grass to grow up through holes in the matting. It is often used to create safer, more natural playground, recreational, and sport surfaces, and can be an excellent application for pedestrian walkways. It typically infiltrates 100 percent and can be easily disassembled and relocated. Some plastic matting meets the Americans with Disabilities Act guidelines for wheelchairs.

Gravel, Bark, and Similar Materials: As long as these are placed over soil that is not already compacted, they will allow water to infiltrate back into the ground. Gravel, bark, and similar materials are practical for trails, bike paths, and walkways.

Where Can Alternative Surfaces Be Used?

Alternative Surfaces are appropriate for low traffic areas where there are few sources of pollutants, including:

- Fringe or overflow parking areas.
- Emergency parking and stopping lanes.
- Private roads, easement service roads, and fire lanes.
- Driveways in residential or light commercial zones.
- Bike paths, walkways, and patios.

Ways to Avoid Common Problems With Alternative Surfaces

There are some common problems that can arise if alternative surfaces are not installed and maintained properly. To avoid problems:

- Select the appropriate alternative surface to meet your objective (infiltration; reduce runoff, flooding, and erosion; aesthetics; soil stabilization; etc.).
- Locate paving blocks where they will not become clogged with dirt. If it is a new site, make sure the soil is stabilized before installing the blocks.

VOL 12 2 4041

R0057333

Ways to Avoid Common Problems With Alternative Surfaces (Continued)

- Use alternative surfaces where there are few pollutants and where the water table is well below the ground surface. This will keep our groundwater and drinking water free from pollutants.
- Use alternative surfaces on gentle slopes and where the soils is porous or loose enough to let water soak in.
- Avoid using alternative surfaces for high-traffic walkways and handicapped parking areas. Select paving blocks or plastic matting with small holes and locate them in "low traffic areas."

How Much Do Alternative Surfaces Cost?

Material and installation costs for paving blocks are typically more expensive than conventional asphalt or concrete. However, some manufacturers or vendors will sell discounted seconds that are suitable for home use. Plastic matting is typically more expensive than asphalt, concrete, and paving blocks. When comparing prices, one must consider the costs associated with man-made stormwater systems, which in some cases can be reduced if alternative surfaces are used.

Where Can I See Alternative Surfaces On-the-Ground?

Public Locations: Thurston County Courthouse, Tumwater Historical Park, Cambridge Court Apartments, and South Puget Sound Community College.

Private Locations: Many homeowners in Thurston County have installed alternative surfaces in their driveways. Of three local residents interviewed, all thought their alternative surfaces work great!

Where Can I Purchase Alternative Surfaces?

Most building supply and home improvement stores carry a variety of paving blocks. Gravel, bark, and similar materials can be purchased from local dealers. See the attached for some sources. Please note that the list does not represent all possible sources. Homeowners and builders are encouraged to explore additional sources of these materials.

Water Resources Program Mission:
To provide regional leadership towards a sustainable community by ensuring the protection and enhancement of Olympia's water resources.

APPENDIX D
MODEL LEGAL AGREEMENT FOR SHARED PARKING

NOTE: What follows is a shared parking easement which is offered as an example of an agreement which may be acceptable to the City of Olympia under the provisions of Section 18.38.180 - Shared Parking Facilities of the Olympia Municipal Code. This is not to say that other methods and approaches would not be acceptable to the City of Olympia, however, such agreements need to be reviewed by the City Attorney's office.

EASEMENT FOR SHARED PARKING

WHEREAS, the parties to this easement wish to take advantage of the shared parking provisions of Chapter 18.38 of the Olympia Municipal Code.

1. For consideration of Ten Dollars ($10.00) paid in hand, present and future benefits to be derived by Grantor and other good and valuable consideration, receipt of which is hereby acknowledged, Grantor, _____ (Name),
doing business as _____ (Name),
hereby conveys and warrants to Grantee, _____ (Name),
doing business as _____ (Name),
its successors, heirs and assigns, a nonexclusive, perpetual easement for motor vehicle parking on the following described real property:

[Legal Description of Servient Estate]

situated in the City of Olympia, Thurston County, Washington for the benefit of Grantee's property described as:

[Legal Description of Dominant Estate]

situated in the City of Olympia, Thurston County, Washington.

Such parking easement shall be applicable only to the following parking lot(s) located on the above-described servient estate. *[Include a map or sketch of the lots or parking facilities applicable to this easement, should more than one exist upon the subject property.]*

SUBJECT TO THE FOLLOWING:

VOL 12 2 4044
R0057336

APPENDIX D

1. This easement shall not be altered or terminated without the express written permission of the Director of Community Planning and Development of the City of Olympia or his/her designee.

2. Grantor covenants that there are ___(#)___ of motor vehicle parking spaces on the above-described property and that Grantor shall not decrease that number of parking spaces without the express written permission of the Director of Community Planning and Development of the City of Olympia or his/her designee.

3. Grantee shall post and maintain signage on the dominant and servient estates directing its customers and employees to parking.

4. Grantor may temporarily close the subject parking lot(s) for maintenance and repair. Cost of repair and maintenance shall be paid by _____ _____.

5. Neither Grantee nor Grantor shall change, alter or expand the use of their respective properties described above so as to require additional parking under the provision of the Olympia Municipal Code in excess of existing parking spaces without the express written permission of the Director of Community Planning and Development of the City of Olympia or his/her designee.

DATED this _____ day of _____, 199___.

APPENDIX E
WORKSHOP EVALUATIONS

ECOBUILDERS GUILD EVALUATION RESULTS
January 23, 1995

There were 11 surveys (44 percent) returned at the presentation, and of those 11, seven were incomplete.

1. The following technical assistance and public education tools were rated as **High** (3 points), **Medium** (2 points) or **Low** (1 point) in their potential for helping integrate impervious surface reduction or water conversation strategies into new construction.

   - **Presentations and speakers (7 High, 3 Medium = 27 points)**
   - **Publications (brochures/fact sheets) (5 High, 2 Medium = 19 points)**
   - **Workshops, forums, open houses (5 High, 1 Medium, 1 Low = 18 points)**
   - **Demonstration projects (5 High, 1 Medium, 1 Low = 18 points)**
   - **Visual Media (slideshows/videos) (3 High, 4 Medium, 1 Low = 18 points)**
   - **Seminars and training (3 High, 3 Medium = 15 points)**
   - **One-on-one technical assistance (3 High, 3 Medium = 15 points)**
   - **Guidebooks, technical manuals (3 High, 2 Medium, 1 Low = 14 points)**
   - **Tours and field trips (1 High, 3 Medium, 2 Low = 11 points)**

2. The following media formats were rated as **High** (3 points), **Medium** (2 points), or **Low** (1 points) according to their potential to reach the participants.

   - **Newspaper announcements (4 High, 3 Medium, 1 Low = 19 points)**
   - **Newsletter articles (4 High, 3 Medium, 1 Low = 19 points)**
   - **Newspaper articles (4 High, 3 Medium, 1 Low = 19 points)**
   - **Radio announcements (2 High, 6 Medium = 10 points)**
   - **Local public access (TCTV) (2 Medium, 6 Low = 10 points)**
   - **Network television channels (1 Medium, 7 Low = 9 points)**

3.a. Specific publications listed that would effectively reach participants are listed as follows.

   - Newspapers, magazines and newsletters:
     The Olympian (5)
     Green Pages (4)

VOL 12 2 4046

R0057338

EOC (4)
NW Ecobuilding Guild (2)
Cooper Point Journal
No Sweat News
Home Education Press
Co-Op
Energy Outreach Center
Washington Association of Realtors

3.b. Specific radio and TV stations that would effectively reach participants are listed as follows:

- Radio Stations:
  KAOS (6)
  KPLU (4)
  KMTT (2)
  KGY (2)
  KGBS
  KVOW
  KING

- TV Stations:
  KCTS channel 9

4.a. When asked if they would reduce the impervious surfaces associated with their next construction project as a result of this presentation, their answers were as follows.

- Yes (8)
- Not Sure (1)

Reasons given were as follows:

- Concerns for the earth
- Water resources concerns
- Groundwater/environmental protection
- Recharge the aquifer
- Control run off

4.b. When asked if they would modify the landscaping associated with their next construction project as a result of this presentation, their answers were as follows.

- Yes (3)

VOL 12 2 4047

R0057339

- Not Sure (3)

Reasons given were as follows:

- Protect and/or preserve water resources
- Protect and/or preserve groundwater
- Easy maintenance
- Conserve water
- Protect and/or preserve Mother Earth

5. When asked what changes, additions or improvements would be recommended for presentation, the following responses were recorded.

- Survey bad idea, too long.
- A video or a slide show of completed projects would be helpful.
- Excellent!
- No changes (2)

6. Sharing of general ideas they had concerning impervious surface reduction or landscaping for water conservation.

- It's all pretty new to me.
- Get this info to the real estate industry.
- More workshops and education!

VOL 12 2 4048

R0057340

APPENDIX E

EXPLORING AND UNDERSTANDING SOILS
WORKSHOP EVALUATION
March 11, 1995

1. **Did you learn any new facts or get any new ideas that will be helpful on your job?** Certainly did 9 Probably did 3 Maybe 0 Not at all 0

2. **What information or activities were the most useful?**

   (5) Soil terminology; water molecule movement characteristics; review of soil creation/setup; better understanding of soil formations; soil structure and physics

   (4) Hands on soil comparison examples; texturing; on hand soils

   (3) Discussion of what participants could do in field; discussion after lunch; "round robin" discussion of residential stormwater treatment

   (2) Good overall; all

   (1) Field trip
   (1) Learned a lot to look into and seek out more information than what I knew before
   (1) Slides were great and overheads were useful but out and out boring
   (1) Product demonstration was great and more of this would be useful
   (1) Sheet spreader

3. **Was there enough opportunity for questions and participation?**
   Too much 0 All that was needed 11 Should have been more 1

4. **How did you hear about the workshop?**
   Work 3 Direct mailing of flyer 7 Friend 2

5. **What suggestions do you have for future workshops (content, techniques, materials)?**

   (3) More discussion of solutions to dealing with different types of soils, i.e., what to do if you have X soil type on Y soil; since I'm new, I felt that some of the individuals in the room had input that would be useful to the city, contractors exploring new avenues to see if they work over time; expand time frame to slightly to allow more enforcement/private sector interaction

VOL 12 2 4049

R0057341

(1) More hands on equipment per person, and more in depth and guided soil [tax] program
(1) Wastewater treatment, native vegetation, and sources for landscaping, wildlife enhancement, and erosion control
(1) Lower calories of lunch
(1) Would like more decompaction information

Note: Six evaluations didn't contain a response to this question.

6. **Please evaluate the quality of the following based on your expectations, using a scale of 1 (poor quality) to 5 (excellent quality).**

Average Score		#Score and (Number of Responses)
4.25	Day and time of the workshop	#1 (0) #2 (0) #3 (3) #4 (3) #5 (6)
4.33	Workshop location	#1 (0) #2 (0) #3 (2) #4 (4) #5 (6)
4.25	Handouts and materials	#1 (0) #2 (0) #3 (1) #4 (7) #5 (4)
4.28	Field trip and presentation	#1 (0) #2 (1) #3 (0) #4 (2) #5 (4)
4.58	Classroom presentation	#1 (0) #2 (0) #3 (1) #4 (3) #5 (8)
4.83	Instructor(s)	#1 (0) #2 (0) #3 (0) #4 (2) #5 (10)
4.42	Overall quality of the workshop	#1 (0) #2 (0) #3 (0) #4 (7) #5 (5)

7. **Additional comments or suggestions?**

- As I mentioned, I really liked the informal discussion that developed about what some of the participants had done on their own projects in the field. Incorporating and expanding on this part may be a useful and interesting addition.
- Follow ups or further information dealing with soil in regards to construction and water (wells).
- Good lunch delivery company.
- Usually I fill a sheet with suggestions, but frankly, I can't think of any!
- Erosion control techniques could be expanded with more solicited input from contractors on their needs.
- Materials and content excellent. Facility, directions, and service very good.

Average Cars = 275

Site visits: Date-Time-Count
8/5-6:00 a.m.-275; 8/6-6:30 a.m.-264;
8/8-11:00 p.m.-283; 8/9-6:00 a.m.-279

Comment: 2 vacancies
Location: 3 years
Manager: 3 years

Responses to Survey Questions:

1. Adequate number of spots but located in places that the tenants won't use (around the clubhouse and office); so often forced to tow visitors and threaten tenants parking in fire lanes and nondesignated parking areas. Felt that this was a site plan problem that has developed into a concept of inadequate parking.

2. Adequate parking for employees.

3. No other parking in lot.

The Crowne Pointe Apartments
2800 Limited Lane, NW
Olympia

TS = 275 with 14 garages assumed full
Maximum Cars = 187 %TS = 68%
Average Cars = 180

Site visits: Date-Time-Count
8/5-6:00 a.m.-167; 8/6-6:00 a.m.-180;
8/8-10:30 p.m.-187; 8/9-5:30 a.m.-184

Location: 7 years
Manager: 3 years

VOL 12 2 4054

R0057346

Responses to Survey Questions:

1. Adequate spots, but inadequate site plan for actual use. Guests won't park in visitor spots located around the clubhouse when visiting apartments up the hill.

2. Adequate parking for employees.

3. Other than previously mentioned visitor problem, no others use the parking lot.

Seniors

Peak Hours: 8:00 a.m., 5:00 p.m. weekdays
10:00 a.m., 6:00 p.m. weekends

Casa Madrona
3948 Martin way E
Olympia

TS = 37
Maximum Cars = 29 %TS = 78%
Average Cars = 26

Site visits: Date-Time-Count
8/5-7:45 a.m.-26; 8/6-7:00 a.m.-24;
8/8-9:00 p.m.-29; 8/9-6:30 a.m.-26

Location: 20 years
Manager: 2 years

Responses to Survey Questions:

1. Barely adequate for tenants, currently more senior drivers than ever before, but the visitors that this population requires (visiting nurses, chore workers, relatives, etc.) have no parking provisions. They are parking regularly in fire lanes.

2. No onsite employees.

3. Service providers and family members, but no shared parking with other facilities.

Mobile Home/Trailer Parks

Peak Hours: 7:00 a.m., 7:00 p.m. weekdays
10:00 a.m., 9:00 p.m. weekends

8/5-10:00 a.m.-47; 8/6-12:00 p.m.-64;
8/8-4:00 p.m.-56; 8/8-7:30 p.m.-54

42,000 square feet
Location: 18 months
Manager: 18 months

Responses to Survey Questions:

1. Not enough parking on busy weekends in spring. Currently negotiating for additional parking.
2. Employees have to park on the street during the spring peak hours.
3. No one else uses the parking lot, and they are not interested in exploring shared parking arrangements for parking increase.

VOL 12 2 4056

R0057348

Furniture and Appliance Stores — Peak Hours: 10:00 a.m., 4:00 p.m. weekdays; 11:00 a.m.; 4:00 p.m. weekends

Desco Electronics Inc.
2306 Harrison Road, NW
Olympia (Westside)

TS = 15
Maximum Cars = 12 %TS = 80%
Average Cars = 10

Site visits: Date-Time-Count
8/5-1:00 p.m.-11; 8/5-4:00 p.m.-12;
8/6-10:30 a.m.-6; 8/6-3:00 p.m.-10

Location: 15 years
Owner: 15 years

Responses to Survey Questions:

1. Parking is adequate for customers.

2. Parking is a little inadequate for employees, they park in the nearby Westside Shopping Center. This is an informal arrangement between the shopping center and Desco.

3. No other people park in lot.

Hotels/Motels — Peak Hours: 12:00 p.m., 6:00 p.m. weekdays same for weekends

Westwater Inn
2300 Evergreen Park Drive
Olympia

TS = 380
Maximum Cars = 321+2 busses %TS = 85%
Average Cars = 285

Site visits: Date-Time-Count
8/6-10:30 p.m.-308; 8/8-9:00 p.m.-276;
8/6-7:00 a.m.-273 (dog show in lot)

Location: 27 years
Manager: 15 years

Responses to Survey Questions:

1. Adequate parking for hotel guests, but conflicts arise when there is a large banquet. Customers park in courthouse and nearby business parking lots and vice versa. Feels more parking and more enforcement is needed, though they have tried several solutions.

2. Adequate employee parking, but hard to enforce because the parking is so far away.

3. Courthouse customers and people visiting area businesses. There is no agreement that this can go on and is considered problematic.

VOL 12
2
4059
R0057351

Responses to Survey Questions:

1. Not enough parking. Customers complain during peak afternoon hours about lack of parking.

2. There are no designated employee parking spots, which could be part of the problem for customers.

3. Sporting events held in the school behind the building (Capital High School playing field) on weekends and evenings generate prohibited parking. There is no agreement about this parking.

Capital Medical Center
3900 Capital Mall Drive, SW
Olympia

TS = 335
Maximum Cars = 96 %TS = 29%
Average Cars = 78

Site visits: Date-Time-Count
8/6-3:00 p.m.-96; 8/8-6:45 p.m.-59

Location: 10 years
Engineer: 4 years

Responses to Survey Questions:

1. Adequate. There is extra parking most of the time.

2. Plenty of employee parking, though enforcement is an issue.

3. Unknown. Because of the amount of extra parking, it's hard to tell if neighboring businesses are using the parking lot.

Offices General

APPENDIX H
COOPERATIVE PARKING SURVEY

September 26, 1994

Date: _____
Name: _____
Affiliation: _____
Phone: _____
Address: _____

1. Do you have regulations or policies for shared parking? For how long? Could we have a copy?

2. Do you have a legal instrument for parties involved in shared parking?

   If yes, can you fax us a copy?

   If no, what do you recommend to shared parking participants? Are you aware of their formal arrangements? Informal?

3. Which land uses do you promote as good partners for successful shared parking?

4. Are developers and builders required to explore or participate in shared parking arrangements, or is it optional?

5. What do you see as the incentives for developers? Roadblocks?

6. Have you documented benefits from shared parking?

7. Do you have a list of shared parking participants that I could interview?

VOL 12 2 4070

R0057362

APPENDIX H

RESULTS SUMMARY

Date: August 12 through August 16, 1994
Name: All survey respondents were senior planners in their respective jurisdictions.
Location: Thurston County and the cities of Bellevue, Lacey, Olympia, and Tumwater were surveyed.
Note: The responses for all respondents are summarized below.

1. **Do you have regulations or policies for shared parking?**

   For how long? Could we have a copy?
   Five jurisdictions have shared parking regulations ranging in date from 1982 to 1989. Four jurisdictions provided copies of their regulations.

   If yes, are they promoted or successfully used in practice?
   Planners do not "promote" the practice in any of the surveyed jurisdictions. Interested developers self-identify their need for shared parking, and no follow-up on successful use has been pursued. Two jurisdictions felt that peak hours needed to be used as a focus of potential success, and used restaurants as an example of uses that could experience a reduction in parking.

2. **Do you have a legal instrument for parties involved in shared parking?**

   If yes, can you fax us a copy?
   None of the jurisdictions had a legal instrument.

   If no, what do you recommend to shared parking participants? Are you aware of their formal arrangements? Informal?
   Five jurisdictions recommended that interested developers have a lawyer draft a document.

3. **Which land uses do you promote as good partners for successful shared parking?**

   Three jurisdictions responded with "unknown" or "site specific." Other responses included mixed use retail, offices adjacent to retail traffic, and retail uses adjacent to restaurants.

VOL 12 2 4071
R0057363

4. **Are developers and builders required to explore or participate in shared parking arrangements, or is it optional?**

   Five jurisdictions had optional participation only. One jurisdiction specified optional participation through enabling regulatory language. Two jurisdictions mentioned the SEPA process as an additional opportunity for developers to explore shared parking.

5. **What do you see as the incentives for developers?**
   Five jurisdictions identified cost reductions as an incentive and two identified project completion as an incentive.

   Roadblocks?
   One jurisdiction identified rigid regulatory language and limiting regulations as a roadblock and one jurisdiction identified "perceived need for additional parking." Three jurisdictions could not identify any roadblocks.

6. **Have you documented benefits from shared parking?**
   None of the jurisdictions have documented benefits.

7. **Do you have a list of shared parking participants that I could interview?**
   The ones provided by the survey participants included:
   Martin Village-Lacey
   Nova School-Lacey
   Southgate Shopping Center-Tumwater
   Burger King and Bank-Tumwater
   K-Mart and Chehalis Western Trail-Thurston County
   Evergreen Christian Center and Furniture Store-Olympia

EXECUTIVE SUMMARY

WHY STUDY IMPERVIOUS SURFACES?

Impervious surfaces are surfaces which cannot be effectively (easily) penetrated by water. Examples include pavement, buildings, and compacted soils.

As part of the development pattern in the North Thurston County Urban Growth Management Area (North Thurston UGMA; *Figure 1, page 2*), we replace natural land covers with new surfaces such as buildings, streets, parking lots, driveways, and sidewalks. These new surfaces are impervious to our rains. They block the rain (stormwater) from soaking into the ground and increase the amount of stormwater running off into streams, lakes, wetlands, and the marine waters of Puget Sound (*Figure 2, page 3*).

Keeping the rain on the surface instead of letting it soak into the ground reduces the amount of groundwater upon which Olympia and other Thurston County communities (*Figure 1, page 2*) depend on for drinking water. When less stormwater soaks into the ground, groundwater levels drop, less groundwater is available to keep streams flowing in the summer, and streams may fall below the minimum levels needed to support fish, recreation, and other uses.

A growing body of scientific evidence indicates that there is a direct link between impervious surface coverage and degradation of streams. Even relatively low levels of impervious surface coverage (10 to 15 percent of the total land area) in a watershed or drainage basin can make it difficult to maintain stream quality. Greater impervious surface coverage (15 to 20 percent of total land area in a watershed) has been linked to dramatic changes in the shape of streams, water quality, water temperature, and the health of insects, amphibians, and fish that live in these streams (Schueler, 1994).

Over the next 20 years, the population of the North Thurston UGMA is projected to increase by 66 percent to a total of 184,000 people (Thurston Regional Planning Council, 1993). If that growth occurs and is accommodated with the current pattern of urban sprawl, the total amount of impervious surface in local watersheds (Percival, Woodard/Woodland, and Chambers/Ward/Hewitt drainage basins) could increase from an estimated 14 to 29 percent of the land area,

R0057374

with corresponding increases in stormwater runoff and water quantity and quality problems. Estimates indicate there would be 6,200 acre feet of stormwater runoff added to the amount Olympia currently manages. This new stormwater would be enough to create a 62-acre lake that is 100 feet deep, and would need to be managed to ensure recharge of local groundwater supplies and long-term preservation of local water resources.

Most local government policies and regulations require stormwater runoff storage and treatment systems and other development practices that reduce the impacts of impervious surfaces, but fail to directly address the source of the problem. To better address this issue, the Impervious Surface Reduction Study was conducted by the City of Olympia in cooperation with the neighboring cities of Lacey and Tumwater, and Thurston County as part of an overall stormwater management strategy for the North Thurston UGMA.

GOALS AND OBJECTIVES

"I firmly believe in the intent of the project—alternatives to reduce and mitigate for stormwater problems."
—Scott Merriman, Ad Hoc Citizen Advisory Committee member

Goals

The goal of the study was to *identify and gain community support for future impervious surface reduction techniques that result in increased stormwater treatment and groundwater recharge in the Thurston County region, without causing appreciable increases in development costs.*

Another goal established for the study was a 20 percent reduction in impervious surfaces throughout the North Thurston UGMA stemming from implementation of the recommendations. Based on study results, it appears that a 20 percent reduction could be achieved.

Objectives

Objectives of the study were to:

1. Inform the public of the need for alternatives to impervious surfaces and foster support for necessary policy and development changes.

VOL 12 2 4083

R0057375

2. Develop standards to encourage reduction in impervious surfaces associated with future construction, and develop and initiate policies to support these standards.

3. Provide technical assistance to members of the development community interested in incorporating alternative techniques into proposed site and building plans.

4. Work with other local governments and members of the development community to apply alternative development practices at one or more highly visible demonstration projects.

5. Share study results with the development and business community, professional organizations, government entities, and other interested parties.

A staff evaluation of whether the study's goals and objectives were achieved was conducted in 1995. The study's goals were generally achieved and the study's objectives were clearly achieved. See the Impervious Surface Reduction Study Final Report (City of Olympia, 1995) for details of the evaluation. Copies are available from the study coordinator (*Project Team, page i*).

STUDY APPROACH

"The timing is really good. We're working in conjunction with new comprehensive land use plans, water resource management plans, and critical areas ordinances."
—Tom Yates, Ad Hoc Citizen Advisory Committee member

Policy Focus and Early Implementation

From the beginning of the study, it was clear that water resources problems associated with impervious surfaces could not be addressed without considering policy issues such as urban sprawl and transportation management. Therefore, the study proposed policy changes as a way to reduce impervious surfaces. The study's policy focus also complemented other research in the Puget Sound region and local growth management planning.

Washington's Growth Management Act (GMA) of 1990 and 1991 requires Thurston County and the cities within the county to plan cooperatively to accommodate 20 years of population growth. As part of growth management planning, the local comprehensive plans,

VOL 12 2 4084
R0057376

ordinances, and development regulations were revised during the past few years, with some revisions still underway. A new development pattern consisting of less sprawl and denser urban development is expected as a result of these revisions.

The new development pattern should reduce the amount of impervious surface per person in Olympia, Lacey, Tumwater, and Thurston County because there should be:

- Less impervious surface in rural areas of Thurston County due to the concentration of development in the urban areas of north Thurston County.
- More efficient use of impervious surfaces in the urban areas due to higher concentrations of people using the roads, parking lots, and other impervious surfaces.

However, the high population growth expected for the southern Puget Sound region will result in an ever increasing amount of housing and other development and impervious surfaces. This is expected to threaten the future availability of clean groundwater, stream flows, and drinking water supplies.

"The study is a good opportunity to review and evaluate alternative development styles that will reduce runoff and improve groundwater recharge, while weighing barriers against the potential benefits."
—Dick Binn, Ad Hoc Citizen Advisory Committee member

Staff and some Ad Hoc Citizen Advisory Committee members (*Project Team, page i*) participated in the revision of Olympia's street, parking, and development regulations being done as part of growth management activities. The revisions provided an opportunity to have key study recommendations adopted into existing policy. The revisions also allowed consideration of impervious surface reduction along with other community goals, and provided an opportunity to immediately implement reduction strategies.

Olympia's Sustainable City Philosophy

In March 1992, the Olympia City Council formally decided to evaluate its actions based on two sustainability criteria:

VOL 12 2 4085

R0057377

- Criteria 1: *Future generations*

  City actions will meet present needs without jeopardizing future generations.

- Criteria 2: *Interrelationships*

  City actions will take into account the environmental, economic, social, and political requirements for their success and the impact on the natural environment and human activities.

These criteria are intended to help guide Olympia towards actions that will help create a sustainable community, one that "persists over generations and is far-seeing enough, flexible enough, and wise enough to maintain its natural, economic, social, and political support systems" (City of Olympia, 1993).

The study was used as a model to see how these criteria could be applied to a complex issue. A sustainability analysis of the study was conducted in two parts. Results of the analysis indicated that to contribute significantly to Olympia's sustainability, there would need to be a greater effort to reduce impervious surfaces than is recommended in this study, and the effort would need to be maintained over several generations. Such an effort would require greater agreement among sectors of the community about strategies. New technology would be needed to enhance groundwater infiltration and minimize impacts on water resources. Such information and technology would need to be complemented by economic incentives and relatively stable climatic conditions (e.g., rainfall in order to succeed).

Need for Cumulative Impact Assessment Realized

Many of the problems with impervious surfaces are not linked to water resources. For example, asphalt absorbs and releases heat from the sun differently from vegetation. Replacing existing vegetation with pavement can significantly alter local temperatures. These changes in local temperatures can negatively affect the health of remaining vegetation and contribute

VOL 12 2 4086

R0057378

to an overall warming trend. It is suggested that future research of impervious surfaces be in the form of a cumulative impact assessment. This would provide an opportunity to consider all the costs and benefits of impervious surface reduction, rather than just those related to water resources

ELEMENTS OF THE STUDY

The study consisted of several tasks: project management, technical and policy analysis, involvement and education, technical assistance, demonstration projects, and sharing of results.

Project Management

The City of Olympia's Public Works Department, Water Resources Program, provided project leadership with support and participation from the cities of Lacey and Tumwater, and Thurston County. Funding for the study was provided by the Washington Department of Ecology through a Centennial Clean Water Fund grant and Olympia residents through their Storm and Surface Water Utility. The study was initiated in March 1993 and was originally scheduled to be completed December 1994. In order to accommodate construction of demonstration projects, the grant deadline was extended to June 1996. As of December 1995, all study tasks except for three technical assistance tasks (research symposium, soils workshop for builders and developers, and model maintenance plan for alternative surfaces) and the demonstration projects were complete. A separate technical report summarizing the results of the technical assistance elements and the demonstration projects will be completed spring 1996.

Technical and Policy Analysis

"When we started the policy analysis, we realized we would need to look at a whole host of issues, from land use and transportation policies to urban design and development standards, since they all affect the amount of impervious surface."
—Dorothy Craig, Policy Consultant

Research of technical and policy issues was important to understanding the problems caused by impervious surfaces and developing feasible and practical recommendations. The technical and policy analysis task included five elements:

1. Literature and Policy Review
2. Basin and Site Coverage Assessment
3. Parking Analysis

VOL 12 2 4087

R0057379

4. Cost Analysis
5. Paver Survey

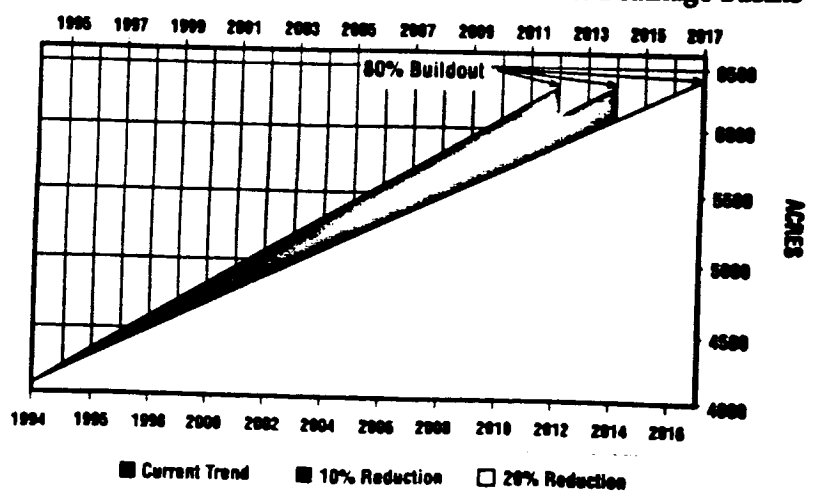
Literature and Policy Review

The literature and policy review was conducted early in the study and helped define the study approach. The literature and policy review culminated in the publication of the Technical and Policy Analysis Report (City of Olympia, 1994). For the sake of continuity, some of the early analysis has been incorporated into this Executive Summary and the final report (City of Olympia, 1995).

Basin and Site Coverage Assessment

Project staff conducted a basin and site coverage assessment to better understand the level of impervious surface reduction that could be expected in the North Thurston UGMA from key study recommendations. The assessment consisted of a site-specific analysis and an analysis of impervious surface coverage at 80 percent of predicted buildout (*Figure 3, below*) in three local watersheds (Percival, Woodard/Woodland, and Chambers/Ward/Hewitt drainage basins).

Figure 3: Current and Potential Future Trends in Acres of Impervious Surfaces in the Percival Creek, Woodard/Woodland, and Chamber/Ward/Hewitt Drainage Basins



VOL 12 2 4088
R0057380

Information for the assessment was obtained from engineering plans for 11 Olympia-area developments and Hydrological Simulation Program - Fortran (HSPF) models created for the three watersheds. The engineering plans and HSPF information was used to answer the following questions:

- How much impervious surface is associated with typical developments in the North Thurston UGMA?
- What is the amount of impervious surface we can expect at 80 percent of buildout in the three watersheds given current development regulations and patterns?
- What reductions in impervious surfaces can be expected with implementation of key study recommendations?

Results of the assessment include:

- Reducing sidewalks offers minor, possibly insignificant, reductions in total and effective impervious surfaces.
- Major reductions in residential street widths are needed before significant reductions in impervious surfaces can be expected.
- Reducing commercial, industrial, and multifamily parking could readily reduce impervious surfaces.
- Roof reductions can be achieved by constructing taller buildings with associated reductions in building footprints.
- Key study recommendations could offer potential impervious surface reductions ranging from 0.16 to 10.67 percent (*Table 1, page 11*).

The methodology used in the basin and site coverage assessment was based on several assumptions that should be considered if used elsewhere (see the final report for details). The outcome is highly influenced by

VOL 12 2 4089

R0057381

Table 1: Basin and Site Coverage Assessment Reduction Analysis Results

Potential Strategy	Impervious Surface Reduction Percentages			
	Site-Specific		Area-Wide	
	Total	Effective	Total	Effective
1. Reduce residential sidewalks by 50 percent by installing the walks on one side of the street only.	1.33	1.00	1.59	0.83
2. Reduce residential sidewalks from 5 feet width to 4 feet width.	0.53	0.40	0.64	0.33
3. a. Reduce local access street widths from 32 feet to 27 feet.	2.50	2.00	2.98	3.12
b. Reduce local access street widths from 32 feet to 25 feet.	3.50	2.80	4.17	4.37
c. Reduce local access street widths from 32 feet to 20 feet.	6.00	4.80	7.15	7.49
4. a. Reduce commercial parking by 5 percent.	2.67	2.67	1.04	1.37
b. Reduce commercial parking by 10 percent.	5.33	5.33	2.09	2.74
c. Reduce commercial parking by 20 percent.	10.67	10.67	4.18	5.47
5. a. Reduce multifamily parking by 5 percent.	0.74	0.74	0.16	0.21
b. Reduce multifamily parking by 10 percent.	1.48	1.48	0.32	0.42
c. Reduce multifamily parking by 20 percent.	2.95	2.95	0.64	0.84
6. a. Reduce commercial, industrial, and multifamily roof areas by 10 percent.	4.25	4.25	1.38	0.94
b. Reduce commercial, industrial, and multifamily roof areas by 20 percent.	8.50	8.50	2.76	1.89

R0057382

local land use patterns and the amount of impervious surface coverage per site. If implemented in other areas, the performance of certain recommendations should be assessed to better understand how impervious surface reduction strategies work under specific soil and site conditions.

Parking Analysis

A parking analysis was conducted to assist Olympia's Community Planning and Development Department in revising the city's parking ordinance. The analysis helped determine if changing Olympia's minimum parking ratios at to median parking ratios would reduce the amount of impervious surfaces.

The analysis consisted of a Special Parking Capacity Study and a Cooperative Parking Survey of Local Jurisdictions. The Special Parking Capacity Study consisted of the following tasks:

1. Informational survey: Owners or managers of 31 selected sites in the North Thurston UGMA were surveyed about parking capacity at their site.

2. Field survey: The parking spaces at each of 15 sites representing a variety of land uses were counted. Counts were taken during peak hours of use, twice on weekdays and twice on weekends, during August 1994.

3. Reduction analysis: Information from 11 field survey sites was combined with information taken from plans for four additional sites. The number of parking stalls for the 15 sites was determined. Then, the number of parking stalls that would exist if they had been constructed under median parking ratios instead of minimum parking ratios was calculated.

Results of the Special Parking Capacity Study indicated that most sites had more parking than required under Olympia's minimum parking ratios. This finding confirmed what Olympia's planners had suspected for

VOL 12 2 4091

R0057383

some time—that the City's minimum parking ratios did not accurately reflect actual parking needs of various land uses. The results also indicated that the majority of sites had parking stalls that were being used inefficiently. However, there were some limitations to the parking analysis. Additional studies should be conducted and include field surveys throughout the year and a greater number of observations.

The Cooperative Parking Survey of Local Jurisdictions was used to assess existing local cooperative parking policies and regulations, and to identify incentives that may increase the use of shared parking. Planning staff at five local governments (the Cities of Olympia, Tumwater, Lacey, and Bellevue, and Thurston County) were interviewed over the phone. Results of the informal survey indicated that smaller and fewer parking lots can result from cooperative parking policies. Developers and local governments can reduce parking by joining, sharing, or coordinating parking facilities. Parking ordinances that contain cooperative parking policies are an excellent avenue for jurisdictions to promote the reduction of impervious surfaces. Incentives for developers and local governments to participate in cooperative parking include:

- Reduced construction, landscaping, and maintenance costs.
- Decreased required parking, ranging from five to 25 percent, if parking is shared.
- Increased ability to complete projects that would otherwise have been denied due to lack of space for parking.

Cost Analysis

The study goal includes a commitment to determine strategies that don't appreciably increase development costs. In order to compare recommended strategies with current practices, staff researched costs for some of the recommendations. The results are presented in detail in Chapter 3 of the final report (City of Olympia, 1995). In general, the cost analysis indicated that some

VOL 12 2 4092
R0057384

of the obvious and practical strategies to reduce impervious surfaces are more expensive than traditional building methods, while other strategies are less expensive. For example, pavers (*Recommendation 5, page 20*) are two to four times more expensive than asphalt to install due to the cost of materials. Over time, if market demand for pavers increases, these materials may become a more feasible alternative surface. On the other hand, narrowing residential streets by seven feet (*Recommendation 4, page 19*) is estimated to save $21,000 in road costs per average 40 unit subdivision.

A formal cost/benefit analysis was not conducted due to the challenges in determining the value of clean water, fisheries, and healthy streams to the local community. Although the cost analysis provided some useful guidance, in a real-world development, soils and other site characteristics would greatly influence actual costs and benefits.

Paver Survey

During the study, several people noted their support for pavers as an alternative to paved driveways and parking areas. In order to better understand how well pavers work in residential settings, staff searched the North Thurston UGMA for homeowners who had installed pavers or other alternative surfaces. Staff discovered that only a few homes in the North Thurston UGMA have alternative surfaces. An informal survey of three homeowners indicated:

- The main motivation for installing the pavers was aesthetics. All three had seen pavers in other locations and liked the look of them. Two homeowners installed the pavers to increase infiltration due to poor soils or topography of their yard.

- The pavers had been installed for parking. The period of time since the pavers had been installed ranged from one month to 10 years. All three homeowners found the pavers required little maintenance.

VOL 12 2 4093

R0057385

- All three homeowners said the pavers were easy to install and required no professional assistance. Exact costs were unavailable but were estimated at $600 to $3,000, depending on size and type of paver used.

- All three homeowners would recommend pavers to others. One homeowner has integrated pavers into his new house plan.

Involvement and Education

Approximately 50 people were directly involved in the research and development of the study's recommendations. Approximately 1,600 people from all over the United States were informed about the study and invited to participate or receive more information.

"We want to make the study useful on the ground, in the field, by builders and developers in an urbanizing watershed. We're insisting on using real-life situations and finding solutions that are cost-effective."

—Priscilla Terry, Ad Hoc Citizen Advisory Committee member

The study was guided by both steering and citizen advisory committees. These committees were comprised of neighborhood, development, and business representatives, and natural resource management experts from both the public and private sectors of the North Thurston UGMA (*Project Team, page i*). Additional methods for involving and educating the local community and interested parties included a **needs assessment**; two community forums; and other activities detailed in the following sections.

Technical Assistance

To encourage further understanding and actual reduction of impervious surfaces, technical assistance was offered to the local and regional community. As of December 1995, technical assistance consisted of two workshops for the building community; three fact sheets (study overview, strategies for reducing parking, and alternative surfaces); and a model legal agreement for shared parking. Evaluation of the two workshops indicated they were successful in expanding understanding about impervious surface reduction techniques.

Technical assistance that will be provided in early 1996 includes a research symposium; a soils workshop for the

VOL 12 2 4094

R0057386

local building community; and a model maintenance plan for using alternative surfaces.

Demonstration Projects

"Local development practices such as stormwater detention ponds and swales are designed to manage increased runoff and remove pollutants, but don't do anything to reduce the amount of runoff. With this study, we're trying to get at the source of the problem."

—Joanne Richter, Supervisor of Olympia's Water Resources Program

Three demonstration projects either have been constructed or are under construction. The purpose of the demonstration projects is to test the practicality and feasibility of study recommendations. Because of delays in finding suitable sites, the demonstration projects were not started until early 1995. Since that time, significant progress has been made on a sidewalk renovation project at Olympia City Hall; a soil restoration project at Olympia High School; and an alternative surfaces test site at the King County Maintenance Center in Renton, Washington.

The sidewalk renovation project used pavers for bike rack facilities and sidewalks. The soil restoration project reduced the soil compaction along one side of a high school dirt and gravel parking lot in order to increase infiltration of stormwater runoff. A trench of existing compacted soils was replaced with better draining soils and reinforced with a layer of plastic cellular confinement material (Geoweb) just below the surface. The cellular confinement layer is expected to help protect the deeper soil from compaction and increase infiltration capacity.

The alternative surfaces project at Renton is a cooperative project with the University of Washington's Center for Urban Water Resources Management and King County Public Works Department. The project consists of eight parking stalls of alternative surfaces. The surfaces will be monitored for up to two years for infiltration capacity, stormwater treatment, and maintenance requirements.

A separate technical report that summarizes lessons learned from the demonstration projects will be available in spring 1996. Readers interested in information about the demonstration projects are encouraged to contact the study coordinator.

VOL 12 2 4095

R0057387

Sharing of Results

"This study is generating interest from Alaska to Washington, DC. The problems related to impervious surfaces are universal, and we hope to generate universal solutions."
—Cedar Wells, Study Coordinator

Information was shared with citizens, professional groups, and various jurisdictions throughout the United States to encourage application of the study's results. As of December 1995, 20 articles about the study were published, including three in national publications. Ten news releases, one radio announcement, and two ads were also completed. In 1996, additional new releases and other media coverage will be used to announce the research symposium and soils workshop.

Printed materials already distributed or scheduled to be distributed include approximately 2,600 draft and final reports, 1,500 buttons, and 2,000 copies of three fact sheets. Printed materials were disseminated at two national conferences, at 23 presentations and briefings, and in response to many requests. An informational display board with illustrations of alternatives and a flip book with photos of example designs were used at the two national conferences and several of the presentations. As of December 1995, the project mailing list contained approximately 500 names and addresses, including over 100 from outside Washington state.

RECOMMENDATIONS

It was recognized early on that recommendations suitable for Olympia may not work for other communities, and that ideas not suitable for Olympia may work elsewhere. As one reviews the recommendations, keep in mind that this report summarizes a study, not a planning process. The information and recommendations contained in this report were provided as guidance to Olympia and other communities, and were not formally adopted by the Olympia City Council. However, revised policies and regulations that integrate many of the study's recommendations have been formally adopted or are being considered for adoption by Olympia, Lacey, Tumwater, and Thurston County. For specific information on actions that Olympia has or will be taking to reduce impervious surfaces, the reader should refer to the full final report (City of Olympia, 1995) or contact the study coordinator (*Project Team, page i*).

VOL 12 2 4096

R0057388

Overall Recommendations

The project team developed three overall recommendations. Recommendation 1 recognizes that changing attitudes, policies, and regulations are a significant first step in impervious surface reduction. Recommendations 2 and 3 are reminders that growth management and transportation planning can be used to reduce impervious surfaces. The project team included these recommendations to encourage Olympia and other jurisdictions to consider policies and regulations, growth management, and transportation planning as tools for impervious surface reduction.

Recommendation 1.

Integrate impervious surface reduction into policies and regulations.

A whole host of development, transportation, urban design, and other policies and regulations affect the land use pattern in our communities, and the resulting amount of impervious surfaces. General review of local policies and regulations, and conversations with other jurisdictions revealed that it is unusual to find impervious surface reduction mentioned or considered in local government policies or regulations. Integrating impervious surface reduction into key policies and regulations ensures that it will be put before the public for comparison with other public goals, and with other strategies for achieving water resource protection and enhancement.

Recommendation 2.

Establish growth management policies that encourage infill of urban areas and reduce urban sprawl.

Growth management strategies in the North Thurston UGMA encourage infill of urban areas and use of congestion reduction programs, public transit, and other alternative modes of transportation. The basic premise of infill is that higher densities in urban areas allow rural areas to remain in low density or resource-based land uses, requiring fewer roads and other impervious

VOL 12 2 4097

R0057389

surfaces region-wide. Infill reduces the amount of impervious surfaces per person and complements the goal and objectives of this study.

Recommendation 3.

Provide a public transit system and other alternative modes of transportation that reduce the need for streets and parking.

According to the basin and site coverage assessment, streets and parking areas make up a significant portion of Olympia's impervious surfaces. Providing public transit and other alternative modes of transportation and promoting parking management and other strategies can reduce our reliance on cars and the need for more vehicle-oriented impervious surfaces.

Recommendations for Vehicle-Oriented Pavement

Seven of the 19 recommendations address vehicle-oriented pavement such as streets and parking areas. Reducing vehicle-oriented pavement can result in impervious surface reduction, but needs to be done in cooperation with the local business and development community in order to identify cost-effective strategies.

Recommendation 4.

Develop standards for narrower residential streets with reduced, but adequate, parking opportunities.

Since residential streets make up a large portion of impervious surfaces in north Thurston County, narrowing residential streets could appreciably reduce stormwater runoff and increase infiltration.

Reducing the widths of new residential streets from 32 feet to 25 feet could result in approximately a 4.4 percent reduction in effective impervious surfaces for the North Thurston UGMA at 80 percent of buildout (*Table 1, page 11*). Reducing widths from 32 feet to 20 feet could result in a 7.5 percent reduction. However, significant increases in the quality of stormwater runoff are not expected from reducing the amount of vehicle-

VOL 12 2 4098

R0057390

oriented impervious surfaces unless there also is a reduction in the source of pollution—cars and other vehicles.

Recommendation 5.

Use pavers and other pervious surfaces for low use areas such as overflow parking and emergency access roads.

Porous pavement, pavers, and alternative surfaces such as bark and gravel can be used for recreational bike and jogging trails, walkways, alleys, overflow parking, emergency access roads, and other low-use areas to increase infiltration and decrease stormwater runoff.

Recommendation 6.

Narrow alley widths, use alternative surfaces for alleys, and/or design alleys to drain to vegetated strips or central drains.

Gravel surfaces and the soils underneath them can become highly compacted from cars and other vehicular traffic depending on soil type, traffic volumes, and initial construction practices. If gravel surfaces are compacted and essentially 100 percent impervious, there is no real benefit from leaving alleys unpaved. Narrowing paved alleys, using alternative surfaces that allow more infiltration, or draining alleys to vegetated strips or drains would reduce stormwater runoff and enhance stormwater treatment.

Recommendation 7.

Encourage cooperative parking such as joint (combined), shared, and coordinated parking.

Cooperative parking can help provide more parking capacity with less impervious surface. The three types of cooperative parking are shared, joint, or coordinated parking. Shared parking reduces the parking area for land uses with noncompeting hours of operation, such as a church and a school or office. Joint parking reduces the total parking area required for multi-tenant retail and commercial facilities, especially those with little overlap of hours such as a movie theater and paint

VOL 12 2 4099

R0057391

store. Coordinated parking reduces the total parking area by using churches, large retail, and commercial overflow parking areas for commuter park-and-ride locations.

Recommendation 8.

Encourage underground or under-the-building parking and the construction of multi-storied parking structures.

Stormwater quantity is directly related to the quantity of impervious surface exposed to rain and would therefore be reduced by placing parking underground or within buildings, or by building multi-storied parking structures. Consolidating parking into one, tall building or incorporating it into a building results in less of the site dedicated to parking. Such consolidation or incorporation could be an incentive for developers and builders if the area once dedicated to parking could be used for additional leasable space or residences.

Recommendation 9.

Develop flexible parking regulations related to parking region-wide that limit the amount of impervious surface, while still providing for parking needs.

Parking policies are local governments' foremost method for determining the size and amount of parking, and the resulting amount of parking-related impervious surfaces. The results of the parking analysis suggest that the amount of impervious surface used for parking could be reduced by encouraging cooperative use of parking areas; using an average of several peak days to determine the amount of parking needed instead of just one or two peak days; using diagonal parking, single lanes between stalls, and smaller parking stalls; and/or construction of underground, under-the-building parking, or multi-storied parking structures.

VOL 12 2 4100

R0057392

Recommendation 10.

Gently slope sidewalks away from streets and other impervious surfaces towards vegetated strips or gravel catchments.

As a result of the basin and site coverage assessment, it is clear that sidewalks are not a significant source of impervious surface in the Olympia area when compared with streets and parking areas. Sidewalks generate less contaminants than streets and parking areas because sidewalks do not carry cars and other vehicles. However, sidewalks can contribute to stormwater runoff problems when they are sloped to streets, parking areas, or other impervious surfaces. In residential developments, yards typically border one side of the sidewalk. Lawns and other vegetated areas could provide some treatment and infiltration if sidewalk runoff is directed into these areas.

Recommendations for Construction Practices and Landscaped Areas

Naturally occurring, undisturbed areas in western Washington typically infiltrate 60 percent of rain, depending on soil type (*Figure 2, page 3*). Clearing and grading a site typically removes existing vegetation and compacts the soils, greatly reducing the infiltration capacity of the site.

For the purpose of this study, the project team considered compacted soils an impervious surface. The team recommended reducing soil compaction and the clearing of vegetated areas to retain the inherent infiltration capacity of undisturbed areas.

Recommendation 11.

Limit soil compaction on newly developed residential and commercial sites, especially those sites with sensitive features. Reduce soil compaction and restore infiltration capacity on already cleared sites whenever practical.

VOL 12 2 4101

R0057393

Certain construction practices can increase the amount of stormwater runoff generated by a site. The amount and quality of runoff is affected by the extent of soil compaction created by clearing of a site, heavy equipment traffic, and other factors. This recommendation aims to preserve wherever possible the infiltration and pollutant removal capacity provided by soil under natural conditions.

Recommendation 12.

Limit land clearing on newly developed residential and commercial sites, especially those with sensitive features.

Clearing and grading practices greatly affect the infiltration capacity of a site. Clearing eliminates valuable vegetation and compacts soils, especially under wet soil conditions or during the rainy season. The less disturbance of existing vegetation, the less stormwater runoff generated and the greater the removal of pollutants from stormwater.

Recommendation 13.

Encourage measures such as homeowner association covenants, plat map conditions, and/or conservation easements that protect existing vegetation and undisturbed areas.

Protection of an undisturbed area that has been set aside by a developer or builder is not guaranteed. Such protection often becomes the responsibility of a home or business owner, or homeowners association. Protection of undisturbed areas could be accomplished through homeowner association covenants, plat map conditions, conservation easements, or other measures.

Recommendations for Design and Placement of Buildings

In recognition that our current development pattern plays a large role in how much impervious surface we create, the project team recommended two key

VOL 12 2 4102

R0057394

strategies for reducing building-related impervious surfaces—clustering and taller buildings.

Recommendation 14.

Encourage cluster development that minimizes impervious surfaces.

The basic principle of cluster development is to group, or "cluster" development onto one part of a site. Although the developed area is more compact, gross density of the site remains the same. Cluster development can be used to provide subdivisions with such features as recreation areas, trails, or other amenities. Clustering also can be used to provide greater development potential on a site while protecting a natural resource, providing open space, or to save road or utility installation costs. By retaining a large undisturbed area, clustering reduces soil compaction and the amount of stormwater runoff.

Recommendation 15.

Encourage the building and use of taller structures to reduce the size of building footprints.

Multi-story buildings have less impervious surface coverage per occupant unit than single story buildings. Reducing the "footprint" of a building while increasing its height allows a parcel to accommodate the same density use with less impervious surface, or accommodate greater densities with the same amount of impervious surface.

Recommendations for Community Involvement and Education

Involvement and education of the community is a high priority for Olympia. The city and project team recognized that community participation in the study was essential to accomplishing implementation of the study's recommendations, and was necessary to ensure that policy and regulatory changes reflected the community's values, needs, and interests. Community members helped identify incentives and brought a real-world perspective to reduction strategies.

VOL 12 2 4103

R0057395

Recommendation 16.

Develop and distribute printed materials that complement the study's recommendations.

The Department of Ecology and Olympia set aside approximately nine percent of the study's funds for dissemination of results. It is expected that inquiries for printed materials will continue after the grant has expired and will require additional funding and staffing.

Recommendation 17.

Develop and provide training and technical assistance to the region's development and business community.

A key success of this study is the raised awareness among local governments and the development and business community. However, the task of sharing the study's findings, identifying incentives for action, and implementing changes in practices and designs is not complete. Consequently, ongoing training and technical assistance will be provided to ensure implementation of impervious surface reduction techniques "on the ground."

Recommendations for Study Evaluation

Evaluation is an essential step for learning from past experiences and recognizing successes. The following recommended actions would provide information and data for evaluating the study's achievements or shortcomings and the policy changes made as result of the study.

Recommendation 18.

Monitor the increase in impervious surfaces in Percival, Woodard/Woodland, and Chambers/ Ward/Hewitt drainage basins to determine coverage trends.

One outcome of the study has been the realization that we have limited impervious surface information for the Olympia area and north Thurston County. Many of the recommendations are based on growth and related

VOL 12 2 4104

Recommendation 16.

Develop and distribute printed materials that complement the study's recommendations.

The Department of Ecology and Olympia set aside approximately nine percent of the study's funds for dissemination of results. It is expected that inquiries for printed materials will continue after the grant has expired and will require additional funding and staffing.

Recommendation 17.

Develop and provide training and technical assistance to the region's development and business community.

A key success of this study is the raised awareness among local governments and the development and business community. However, the task of sharing the study's findings, identifying incentives for action, and implementing changes in practices and designs is not complete. Consequently, ongoing training and technical assistance will be provided to ensure implementation of impervious surface reduction techniques "on the ground."

Recommendations for Study Evaluation

Evaluation is an essential step for learning from past experiences and recognizing successes. The following recommended actions would provide information and data for evaluating the study's achievements or shortcomings and the policy changes made as result of the study.

Recommendation 18.

Monitor the increase in impervious surfaces in Percival, Woodard/Woodland, and Chambers/ Ward/Hewitt drainage basins to determine coverage trends.

One outcome of the study has been the realization that we have limited impervious surface information for the Olympia area and north Thurston County. Many of the recommendations are based on growth and related

VOL 12 2 4105

R0057397

impervious surface coverage projections used in the Basin and Site Coverage Assessment. It would be useful to verify the accuracy of these projections as growth occurs, and adjust policies and regulations accordingly.

Recommendation 19.

Assess the results of the study's recommendations in Olympia, North Thurston UGMA, and other locations.

The study will be a success if it results in less impervious surface than was previously expected under current growth projections. Evaluating results of implementing the study's recommendations would provide important information. The information could be used to adjust policies, regulations, technical assistance, and incentives to achieve a 20 percent reduction.

CONCLUSION

This study signifies a new emphasis on impervious surface reduction for the Olympia community, and has left as many unanswered questions as it has answered. It is important to remember that a 20 percent reduction does not solve the long-term problems with impervious surfaces. This study's recommendations only address future development, and do not address existing impervious surfaces or problems. More research could be conducted to better define hydrological relationships, costs and incentives, and water quality impacts.

The Project Team invites anyone conducting research or implementing reduction strategies to contact the study coordinator and share information. Impervious surface reduction is still an experiment—one that needs to continue so that we can discover real-world solutions.

GLOSSARY

building footprint
Commonly used term to describe the ground area that a building covers.

buildout
Full development at the maximum densities allowed by zoning.

cooperative parking
A term used to describe various methods to increase the use of available parking areas including shared, joint, and coordinated parking.

cumulative impact assessment
Cumulative impacts are the effects that accumulate over time and space from a series of similar or related individual actions, pollutants, or projects. Although each action may seem to have a minimal impact, the combined effect can be severe. A cumulative impact assessment studies and summarizes these impacts.

drainage basin (see watershed)
A land area bounded by high points, which drains all surface water into a single stream or other body of water.

effective impervious surface
The portion of impervious surface that generates stormwater runoff which must be managed or directed to a stormwater conveyance system, rather than infiltrating into the ground.

groundwater
Water stored underground that fills the spaces between soil particles or rock fractures. A zone underground with enough water to withdraw and use for drinking water or other purposes is called an aquifer.

Hydrologic Simulation Program - Fortran (HSPF)
A specific computer program which simulates (models) land surface and instream hydrology on a continuous basis.

infill
Developing vacant parcels or redeveloping existing property to achieve higher density in urban areas as an alternative to development in outlying rural areas.

needs assessment
A survey to determine the requirements or desires of a particular audience.

VOL 12 2 4108

R0057400

North Thurston County Urban Growth Management Area (North Thurston UGMA)
The area designated by Thurston County pursuant to RCW 36.7A.10. Includes land area sufficient to accommodate the urban growth projected to occur in the northern part of the county over the next 20 years.

parking ratios
Parking required for a particular land use, stated as a ratio or "x" parking spaces per "y" units. Typical units are square footage, dwelling units, persons, and seats.

pavers
Concrete grid and modular pavement whose spaces are filled with pervious materials such as sod, sand, or gravel.

shared parking
Mutual use of a parking area by land uses with noncompeting hours of operation, such as a theater and office building.

stormwater
Rain that flows off the surface of the land without entering the soil.

sustainability criteria
Criteria used to gauge the effectiveness of projects, plans, and new regulations in achieving a sustainable community. A sustainable community is one that persists over generations and is far-seeing enough, flexible enough, and wise enough to maintain its natural, economic, social, and political support systems.

watershed (see drainage basin)
The geographic region within which water drains into a particular river, stream, or body of water. A watershed includes hills, lowlands, and the body of water into which the land drains.

Impervious cover is a powerful indicator of future stream quality

The Importance of Imperviousness

The emerging field of urban watershed protection often lacks a unifying theme to guide the efforts of its many participants—planners, engineers, landscape architects, scientists, and local officials. The lack of a common theme has often made it difficult to achieve a consistent result at either the individual development site or cumulatively, at the watershed scale.

In this article a unifying theme is proposed based on a physically defined unit—imperviousness. Imperviousness here is defined as the sum of roads, parking lots, sidewalks, rooftops, and other impermeable surfaces of the urban landscape. This variable can be easily measured at all scales of development, as the percentage of area that is not "green".

This research has yielded a surprisingly similar conclusion—stream degradation occurs at relatively low levels of imperviousness (10-20%).

Imperviousness is a very useful indicator with which to measure the impacts of land development on aquatic systems. Reviewed here is the scientific evidence that relates imperviousness to specific changes in the hydrology, habitat structure, water quality and biodiversity of aquatic systems. This research, conducted in many geographic areas, concentrating on many different variables, and employing widely different methods, has yielded a surprisingly similar conclusion—stream degradation occurs at relatively low levels of imperviousness (10-20%). Most importantly, imperviousness is one of the few variables that can be explicitly quantified, managed and controlled at each stage of land development. The remainder of this paper examines in detail the relationship between imperviousness and stream quality.

The Components of Imperviousness

Imperviousness represents the imprint of land development on the landscape. It is composed of two primary components—the *rooftops* under which we live, work and shop, and the *transport* system (roads, driveways, and parking lots) that we use to get from one roof to another. As it happens, the transport component now often exceeds the rooftop component in terms of total impervious area created. For example, transport-related imperviousness comprised 63% to 70% of total impervious cover at the site in 11 residential, multifamily and commercial areas where it had actually been measured.[6] This phenomenon is observed most often in suburban areas and reflects the recent ascendancy of the automobile in both our culture and landscape. The sharp increases in per capita vehicle ownership, trips taken, and miles travelled have forced local planners to increase the relative size of the transport component over the last two decades.

Traditional zoning has strongly emphasized and regulated the first component (rooftops) and largely neglected the transport component. While the rooftop component is largely fixed in density zoning, the transport component is not. As an example, nearly all zoning codes set the maximum density for an area, based on dwelling units (rooftops). Thus, in a given area, no more than one single family home can be located on each acre of land, and so forth.

Thus a wide range in impervious cover is often seen for the same zoning category. For example, impervious area associated with medium density single family homes can range from 25% to nearly 60%, depending on the layout of streets and parking. This suggests that significant opportunities exist to reduce the share of imperviousness from the transport component.

Imperviousness and runoff

The relationship between imperviousness and runoff may be widely understood, but it is not always fully appreciated. Figure 1 illustrates the increase in the site runoff coefficient as a result of site imperviousness, developed from over 40 runoff monitoring sites across the nation. The runoff coefficient ranges from zero to one and expresses the fraction of rainfall volume that is actually converted into storm runoff volume. As can be seen, the runoff coefficient closely tracks percent impervious cover, except at low levels where soils and slope factors also become important. In practical terms this means that the total runoff volume for a one-acre parking lot ($R_v = 0.95$) is about 16 times that produced by an undeveloped meadow ($R_v = 0.06$).

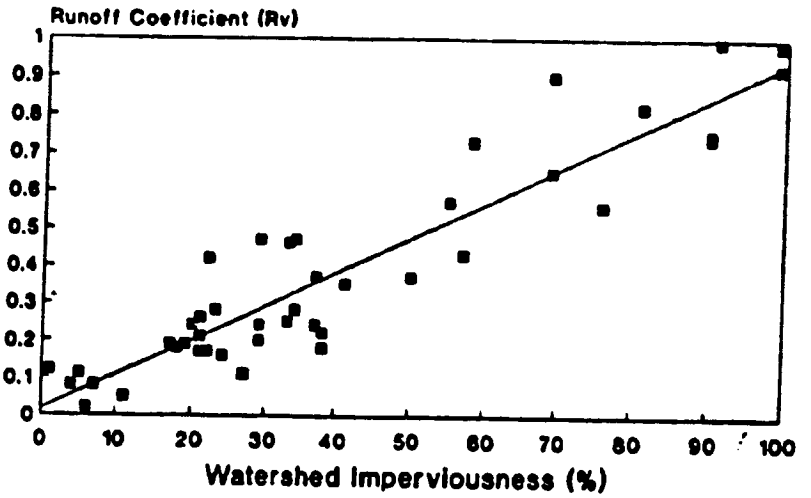
To put this in more understandable terms, consider the runoff from a one-inch rainstorm (see Table 1). The total runoff from a one-acre meadow would fill a standard size office to a depth of about two feet (218 cubic feet). By way of comparison, if that same acre was completely paved, a one-inch rainstorm would completely fill your office, as well as the *two* next to it. The peak discharge, velocity and time of concentration of stormwater runoff also exhibit a striking increase after a meadow is replaced by a parking lot (Table 1).

Because infiltration is reduced in impervious areas, one would expect groundwater recharge to be proportionately reduced. This, in turn, should translate into lower dry weather stream flows. Actual data, however, that demonstrate this effect is rare. Indeed, Evett et al.[8] could not find any statistical difference in low stream

VOL 12 2 4110 F

R0057402

Figure 1: Watershed imperviousness and the storm runoff coefficient



flow between urban and rural watersheds after analyzing 16 North Carolina watersheds. Simmons and Reynolds[26] did note that dry weather flows dropped 20 to 85% after development in several urban watersheds in Long Island, New York.

It should be noted that transport-related imperviousness often exerts a greater hydrological impact than the rooftop-related imperviousness. In residential areas, runoff from rooftops can be spread out over pervious areas, such as backyards, and rooftops are not always directly connected to the storm drain system. This may allow for additional infiltration of runoff. Roads and parking lots, on the other hand, are usually directly connected to the storm drain system.

Imperviousness and the Shape of Streams

Confronted by more severe and more frequent floods, stream channels must respond. They typically do so by increasing their cross-sectional area to accommodate the higher flows. This is done either through widening of the stream banks, downcutting of the stream bed, or frequently, both. This phase of channel instability, in turn, triggers a cycle of streambank erosion and habitat degradation.

The critical question is at what level of development does this cycle begin? Recent research models developed in the Pacific Northwest suggest that a threshold for urban stream stability exists at about 10% imperviousness[3,4] (Figure 2). Watershed development beyond this threshold consistently resulted in unstable and eroding channels. The rate and severity of channel instability appears to be a function of sub-bankfull floods, whose frequency can increase by a factor of 10 even at relatively low levels of imperviousness.[14,19,23]

A major expression of channel instability is the loss of instream habitat structures, such as the loss of pool and riffle sequences and overhead cover, a reduction in the wetted perimeter of the stream and the like. A number of methods have been developed to measure the structure and quality of instream habitat in recent

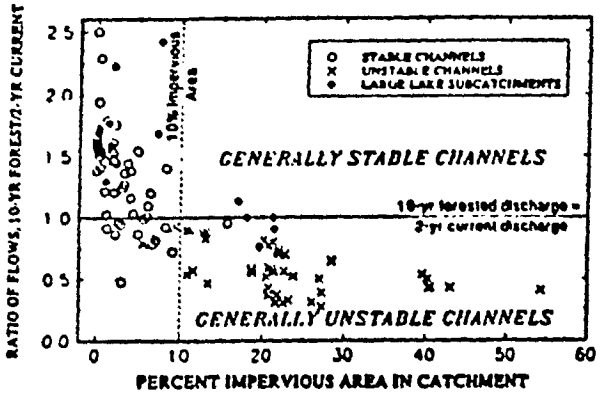
Table 1: Comparison of one acre of parking lot versus one acre of meadow in good condition

Runoff or Water Quality Parameter	Parking Lot	Meadow
Curve number (CN)	98	58
Runoff coefficient	0.95	0.06
Time of concentration (minutes)	4.8	14.4
Peak discharge rate (cfs), 2 yr., 24 hr. storm	4.3	0.4
Peak discharge rate (cfs), 100 yr. storm	12.6	3.1
Runoff volume from one-inch storm (cubic feet)	3450	218
Runoff velocity @ 2 yr. storm (feet/second)	8	1.8
Annual phosphorus load (lbs/ac./yr.).	2	0.50
Annual nitrogen load (lbs/ac./yr.).	15.4	2.0
Annual zinc load (lbs/ac./yr.)	0.30	ND

Key Assumptions:
Parking lot is 100% impervious with 3% slope, 200 feet flow length, Type 2 Storm, 2 yr. 24 hr. storm = 3.1 inches, 100 yr. storm = 8.9 inches, hydraulic radius = 0.3, concrete channel, and suburban Washington 'C' values.
Meadow is 1% impervious with 3% slope, 200 foot flow length, good vegetative condition, B soils, and earthen channel.

VOL 1 2 2 4 1 1 1 1
R0057403

Figure 2: Channel stability as a function of imperviousness
(Booth and Reinelt, 1993)



years.[6,11,21] Where these tools have been applied to urban streams, they have consistently demonstrated that a sharp threshold in habitat quality exists at approximately 10 to 15% imperviousness.[4,11,23] Beyond this threshold, urban stream habitat quality is consistently classified as poor.

Imperviousness and water quality

Impervious surfaces collect and accumulate pollutants deposited from the atmosphere, leaked from vehicles or derived from other sources. During storms, accumulated pollutants are quickly washed off and rapidly delivered to aquatic systems.

Habitat assessment tools have consistently demonstrated that a sharp threshold in habitat quality exists at approximately 10 to 15% imperviousness.

Monitoring and modeling studies have consistently indicated that urban pollutant loads are directly related to watershed imperviousness. Indeed, imperviousness is the key predictive variable in most simulation and empirical models used to estimate pollutant loads. For example, the Simple Method assumes that pollutant loads are a direct function of watershed imperviousness[21], as imperviousness is the key independent variable in the equation.

Threshold limits for maintaining background pollutant loads

Suppose that watershed runoff drains into a lake that is phosphorus-limited. Also assume that the present background load of phosphorus from a rural land use amounts to 0.5 lbs/ac/yr. The Simple Method predicts that the postdevelopment phosphorus load will exceed background loads once watershed imperviousness (I) exceeds 20 to 25% (Figure 3), thereby increasing the risk of nutrient overenrichment in the lake.

Urban phosphorus loads can be reduced when urban best management practices (BMPs) are installed, such as stormwater ponds, wetlands, filters or infiltration practices. Performance monitoring data indicates that BMPs can reduce phosphorus loads by as much as 40 to 60%, depending on the practice selected. The impact of this pollutant reduction on the postdevelopment phosphorus loading rate from the site is shown in Figure 3. The net effect is to raise the phosphorus threshold to about 35% – 60% imperviousness, depending on the performance of the BMP we install. Therefore, even when effective practices are widely applied, we eventually cross a threshold of imperviousness, beyond which we cannot maintain predevelopment water quality.

Imperviousness and stream warming

Impervious surfaces both absorb and reflect heat. During the summer months, impervious areas can have local air and ground temperatures that are 10 to 12 degrees warmer than the fields and forests that they replace. In addition, the trees that could have provided shade to offset the effects of solar radiation are absent.

Water temperature in headwater streams is strongly influenced by local air temperatures. Galli[9] reported that stream temperatures throughout the summer are increased in urban watersheds, and the degree of warming appears to be directly related to the imperviousness of the contributing watershed. He monitored five headwater streams in the Maryland Piedmont over a six-month period, the streams having differing levels of impervious cover (Figure 4). Each of the urban streams had mean temperatures that were consistently warmer than a forested reference stream, and the size of the increase (referred to as the delta-T) appeared to be a direct function of watershed imperviousness. Other factors, such as lack of riparian cover and ponds, were also demonstrated to amplify stream warming, but the primary contributing factor appeared to be watershed impervious cover.[9]

Imperviousness and stream biodiversity

The health of the aquatic ecosystem is a strong environmental indicator of watershed quality. A number of research studies have recently examined the links between imperviousness and the biological diversity in streams. Some of the key findings are summarized in Table 2.

Aquatic insects

The diversity, richness and composition of the benthic or streambed community has frequently been used to evaluate the quality of urban streams. Not only are aquatic insects a useful environmental indicator, but they also form the base of the stream food chain in most regions of the country.

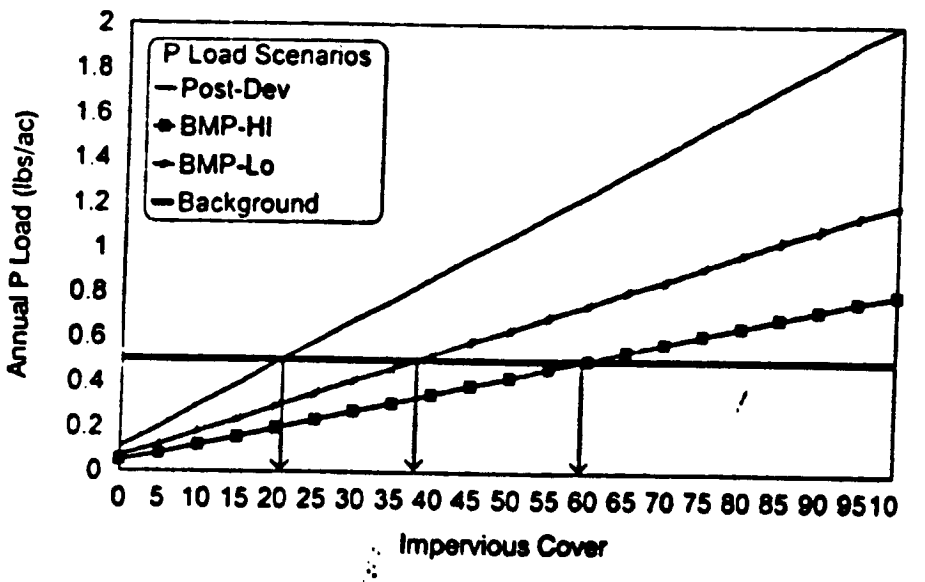

Figure 4: The effect of impervious cover on stream temperature *(Galli, 1991)*

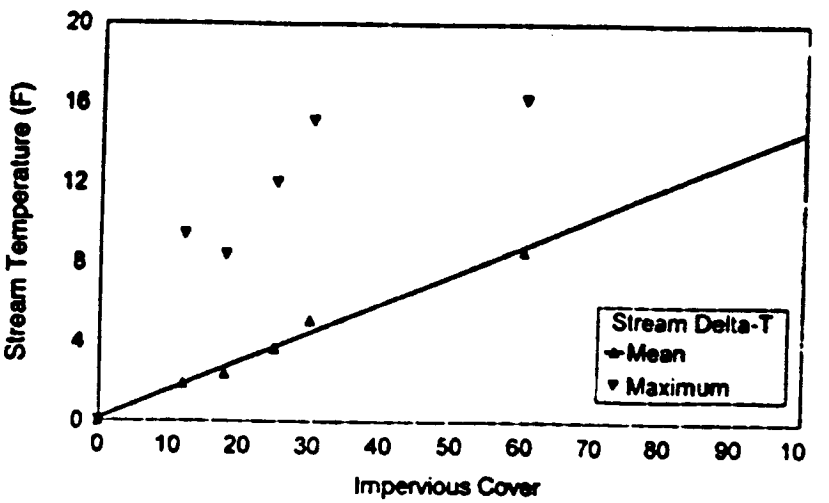
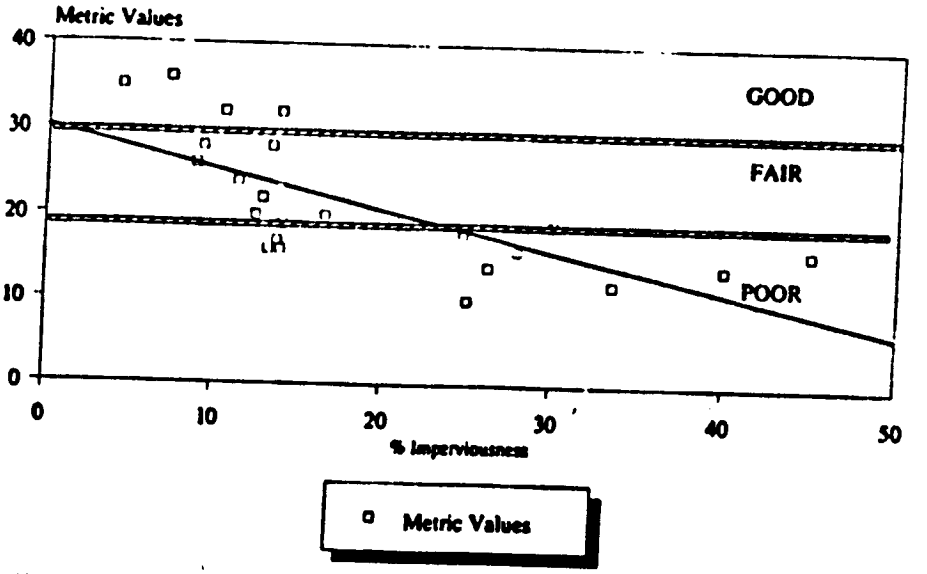


Delta-t is the difference in mean or max stream temperature from a developed stream, compared to an undisturbed stream.

VOL 12 2 4-1-13

R0057405

Figure 5: Impacts of imperviousness on macroinvertebrate communities in the headwater streams of the Anacostia River *(Schueler and Galli, 1992)*



Metric Values are based upon the sum of scores assigned for the following categories: EPTC balance, EPT Index, Average Generic Diversity, Chironomid Abundance, Taxonomic Richness (Family and Generic)

Klein[16] was one of the first to note that macroinvertebrate diversity drops sharply in urban streams in Maryland. Diversity consistently became poor when watershed imperviousness exceeded 10 to 15 percent. The same basic threshold has been reported by all other research studies that have looked at macroinvertebrate diversity in urban streams (Table 2).

It is clear that few, if any, urban streams can support diverse benthic communities at moderate to high levels of imperviousness (25% or more).

In each study, sensitive macroinvertebrates were replaced by ones that were more tolerant of pollution and hydrologic stress. Species such as stoneflies, mayflies, and caddisflies largely disappeared and were replaced by chironomids, tubificid worms, amphipods, and snails. Species that employ specialized feeding strategies—shredding leaf litter, grazing rock surfaces, filtering organic matter that flows by, and preying on other insects—were lost.

A typical example of the relationship between imperviousness and macroinvertebrate diversity is shown in Figure 5. The graph summarizes diversity trend for 23 sampling stations in headwater streams of the Anacostia watershed.[24] While good to fair diversity was noted in all headwater streams with less than 10% imperviousness, nearly all stations with 12% or more impervious cover recorded poor diversity. The same sharp drop in macroinvertebrate diversity at around 12 to 15% imperviousness was also observed in streams in the coastal plain and piedmont of Delaware.[25]

Other studies have utilized other indicators to measure the impacts of urbanization on stream insect communities. For example, Jones and Clark[15] monitored 22 stations in Northern Virginia and concluded that benthic insect diversity composition changed markedly after watershed population density exceeded four or more individuals per acre. The population density roughly translates to half-acre or one acre lot residential use, or perhaps 10 to 20 percent imperviousness.

Steedman[27] evaluated 208 Ontario stream sites, and concluded that benthic diversity shifted from fair to poor at about 35% urban land use. Since "urban land" includes both pervious and impervious areas, the actual threshold in the Ontario study may well be closer to 7 to 10% imperviousness.[4] Steedman also reported that urban streams with intact riparian forests had higher diversity than those that did not, for the same level of urbanization.

While the exact point at which stream insect diversity shifts from fair to poor is not known with absolute precision, it is clear that few, if any, urban streams can support diverse benthic communities at moderate to high levels of imperviousness (25% or more). Four different studies all failed to find stream insect communities with good or excellent diversity in any highly urban stream.[1,2,3,12]

VOL 1 2 2 4 1 1 4

R0057406

Table 2: Review of key findings of urban stream studies examining the relationship of urbanization on stream quality

Ref.	Year	Location	Biological Parameter	Key Finding
3	1991	Seattle	Fish habitat/ channel stability	Channel stability and fish habitat quality declined rapidly after 10% imperv.
11	1994	Maryland	Brown trout	Abundance and recruitment of brown trout declines sharply at 10-15% imperv.
1	1981	Atlanta	Aquatic insects	Negative relationship between number of insect species and urbanization in 21 streams
15	1987	Northern Virginia	Aquatic insects	Urban streams had sharply lower diversity of aquatic insects when human population density exceeded 4 persons/acre. (estimated 15-25% imperv. cover)
17	1990	New York	Fish spawning	Resident and anadromous fish eggs and larvae declined sharply in 16 tributary streams greater than 10% imperv.
25	1994	Delaware	Aquatic insects	Insect diversity at 19 stream sites dropped sharply at 8 to 15% imperv.
25	1994	Delaware	Habitat quality	Strong relationship between insect diversity and habitat quality; majority of 53 urban streams had poor habitat
24	1992	Maryland	Fish	Fish diversity declined sharply with increasing imperv., loss in diversity began at 10-12% imperv.
24	1992	Maryland	Aquatic insects	Insect diversity metrics in 24 subwatersheds shifted from good to poor over 15% imperv.
2	1994	Maryland	Fish/insects	Fish, insect and habitat scores were all ranked as poor in 5 subwatersheds that were greater than 30% imperv.
16	1979	Maryland	Aquatic insects/fish	Macroinvertebrate and fish diversity declines rapidly after 10% imperv.
18	1993	Seattle	Fish	Marked shift from less tolerant coho salmon to more tolerant cutthroat trout populations noted at 10-15% imperv. at 9 sites
27	1988	Ontario	Aquatic insects	Strong negative relationship between biotic integrity and increasing urban land use/ riparian condition at 209 stream sites. Degradation begins at about 10% imperv.
20	1986	Seattle	Aquatic insects	Macroinvertebrate community shifted to chironomid, oligochaetes and amphipod species tolerant of unstable conditions.
28	1983	Seattle	Salmon	Marked reduction in coho salmon populations noted at 10-15% imperv. at 9 sites
29	1993	Seattle	Wetland plants/ amphibians	Mean annual water fluctuation was inversely correlated to plant and amphibian density in urban wetlands. Sharp declines noted over 10% imperv.
12	1986	NewJersey	Aquatic insects	Drop in insect taxa from 13 to 4 noted in urban streams
30	1991	Ohio	Aquatic insects/ fish	100% of 40 urban sites sampled had fair to very poor index of biotic integrity scores

Fish Surveys

The abundance and diversity of the fish community can also serve as an excellent environmental indicator. Surprisingly, relatively few studies have examined the influence of imperviousness on fish communities in headwater streams. The results of one study is illustrated in Figure 6. Four similar subwatersheds in the Maryland Piedmont were sampled for the number of fish species present. As the level of watershed imperviousness increased, the number of fish species collected dropped. Two sensitive species (trout and sculpin) were lost as imperviousness increased from 10 to 12% and four more were lost when impervious cover increased to 25%. Significantly, only two species remained in the fish community at 55% imperviousness. Sensitive species, defined as those with a strong dependence on the substrate for feeding and/or spawning, showed a more precipitous decline. Klein[10] found a similar relationship between fish diversity and watershed imperviousness in several dozen headwater streams in the Maryland Piedmont.

Salmonid fish species (trout and salmon) and anadromous fish species appear to be most negatively impacted by imperviousness. Trout have stringent temperature and habitat requirements, and seldom are present in mid-Atlantic watersheds where imperviousness exceeds 15%.[11] Declines in trout spawning success are evident above 10% imperviousness.[11] In the Pacific Northwest, Luchetti and Feurstenburg[12] seldom found sensitive coho salmon in watersheds beyond 10 or 15% imperviousness. Booth and Reinelt[4] noted that most urban stream reaches had poor quality fish habitat when imperviousness exceeded 8 to 12%.

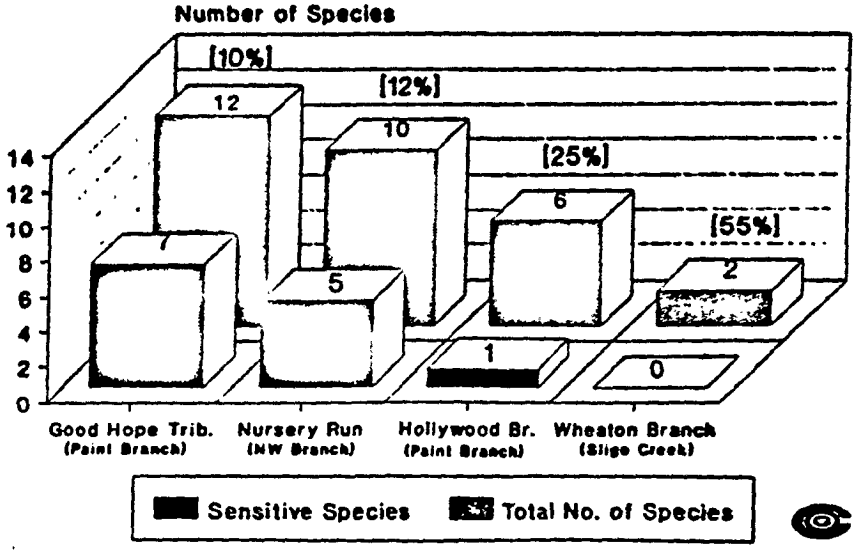
Fish species that migrate from the ocean to spawn in freshwater creeks are also very susceptible to impacts of urbanization such as fish barriers, pollution, flow changes, and other factors. For example, Limburg and Schmidt[13] discovered that the density of anadromous fish eggs and larvae declined sharply after a 10% imperviousness threshold was surpassed in 16 subwatersheds draining into the Hudson River.

The influence of imperviousness on other urban water resources

Several other studies point to the strong influence of imperviousness on other important aquatic systems such as shellfish beds and wetlands.

Even relatively low levels of urban development yield high levels of bacteria, derived from urban runoff or failing septic systems. These consistently high bacterial counts often result in the closure of shellfish beds in coastal waters and it is not surprising, that most closed shellfish beds are in close proximity to urban areas. Indeed, it may be difficult to prevent shellfish closure when more than one septic drain field is present per seven acres—a very low urban density.[7] Although it is widely believed that urban runoff accounts for

Figure 6: Fish diversity as a function of watershed imperviousness in four subwatersheds in the Maryland Piedmont *(Schueler and Galli, 1992)*



Numbers in brackets represent levels of watershed imperviousness.

Sources: 1) MdDNR, 1983 2) MdDNR, 1988 3) ICPRB, 1989

VOL 12 2 4 1 1 6
R0057408

many shellfish bed closures (now that most point sources have been controlled), no systematic attempt has yet been made to relate watershed imperviousness to the extent of shellfish bed closures.

Taylor[28] examined the effect of watershed development on 19 freshwater wetlands in King County, Washington, and concluded that the additional stormwater contributed to greater annual water level fluctuations (WLF). When the annual WLF exceeded about 8 inches, the richness of both the wetland plant and amphibian community dropped sharply. This increase in WLF began to occur consistently when upstream watersheds exceeded 10 to 15% imperviousness.

Implications at the Watershed Level

The many independent lines of research reviewed here converge toward a common conclusion— that it is extremely difficult to maintain predevelopment stream quality when watershed development exceeds 10 to 15% impervious cover. What implications might this apparent threshold have for watershed planning?

Should low density or high density development be encouraged?

At first glance, it would seem appropriate to limit watershed development to no more than 10% total impervious cover. While this approach may be wise for an individual "sensitive" watershed, it is probably not practical as a uniform standard. Only low density development would be feasible under a ten percent zoning scenario, perhaps one-acre lot residential zoning, with a few widely scattered commercial clusters. At the regional scale, development would thus be spread over a much wider geographic area than it would otherwise have been. At the same time, additional impervious area (in the form of roads) would be needed to link the community together.

Paradoxically, the best way to minimize the creation of additional impervious area at the regional scale is to concentrate it in high density clusters or centers. The corresponding impervious cover in these clusters is expected to be very high (25% to 100%), making it virtually impossible to maintain predevelopment stream quality. A watershed manager must then confront the fact that to save one stream's quality it may be necessary to degrade another.

A second troubling implication of the impervious/stream quality relationships involves the large expanses of urban areas that have already been densely developed. Will it be possible to fully restore stream quality in watersheds with high impervious cover? Some early watershed restoration work does suggests that biological diversity in urban streams can be partially restored, but only after extensive stormwater retrofit and habitat structures are installed. For example, fish and macroinvertebrate diversity has been partially restored in one tributary of Sligo Creek, Maryland.[11] In other urban watersheds, however, comprehensive watershed restoration may not be feasible, due to a lack of space, feasible sites, or funding.

Paradoxically, the best way to minimize the creation of additional impervious area at the regional scale is to concentrate it in high density clusters.

A proposed scheme for classifying urban stream quality potential

The thresholds provide a reasonable foundation for classifying the potential stream quality in a watershed based on the ultimate amount of impervious cover. One such scheme is outlined in Table 3. It divides urban streams into three management categories based on the general relationships between impervious cover and stream quality:

1. Stressed streams (1 to 10% impervious cover)
2. Impacted streams (11 to 25% impervious cover)
3. Degraded streams (26 to 100% impervious cover)

The resource objective and management strategies in each stream category differ to reflect the potential stream quality that can be achieved. The most protective category are "stressed streams" in which strict zoning, site impervious restrictions, stream buffers and BMPs are applied to maintain predevelopment stream quality. "Impacted streams" are above the threshold and can be expected to experience some degradation after development (i.e., less stable channels and some loss of diversity). The key resource objective for these streams is to mitigate these impacts to the greatest extent possible, using effective BMPs.

The last category, degraded streams, recognizes that predevelopment channel stability and biodiversity cannot be fully maintained, even when BMPs or retrofits are fully applied. The primary resource objective shifts to protect downstream water quality by removing urban pollutants. Efforts to protect or restore biological diversity in degraded streams are not abandoned; in some priority subwatersheds intensive stream restoration techniques are employed to attempt to partially restore some aspects of stream quality. In other subwatersheds, however, new development (and impervious cover) is encouraged to take place so as to protect stressed and impacted streams.

Watershed-based zoning

Watershed-based zoning is based on the premise that impervious cover is a superior measure to gauge the impacts of growth, compared to population density, dwelling units or other factors. The key steps in

VOL 12 2 4 1 1 7

R0057409

Table 3: A possible scheme for classifying and managing for headwater urban streams based on ultimate imperviousness

Urban Stream Classification	Stressed (0-10% Imperv.)	Impacted (11-25% Imperv.)	Degraded (26-100% Imperv.)
Channel stability	Stable	Unstable	Highly Unstable
Water quality	Good	Fair	Fair-Poor
Stream biodiversity	Good-Excellent	Fair-Good	Poor
Resource objective	Protect biodiversity and channel stability	Maintain critical elements of stream quality	Minimize downstream pollutant loads
Water quality objectives	Sediment and temperature	Nutrient and metal loads	Control bacteria
BMP Selection Factors	Secondary environmental impacts	Removal efficiency	Removal efficiency
Land Use Controls	Watershed-wide imp. cover limits (ICLs), site ICLs	Site imp. cover limits (ICLs)	Additional infill and redevelopment encouraged
Monitoring and enforcement	GIS monitoring of imp. cover, biomonitoring	Same as "Stressed"	Pollutant load modeling
Development rights	Transferred out	None	Transferred in
Riparian buffers	Widest buffer network	Average bufferwidth	Greenways

watershed-based zoning are as follows. *First*, a community undertakes a comprehensive physical, chemical and biological monitoring program to asses the current quality of its entire inventory of streams. The data are used to identify the most sensitive stream systems and to refine impervious/stream quality relationships. *Next*, existing imperviousness is measured and mapped at the subwatershed level. Projections of future impervious cover due to forecasted growth are also made at this time.

The *third* step involves designating the future stream quality for each subwatershed based on some adaptation of the urban stream classification scheme presented earlier. The existing land use master plan is then modified to ensure that future growth (and impervious cover) is consistent with the designated stream classification for each subwatershed.

The *final* step in the watershed-based zoning process involves the adoption of specific resource objectives for each stream and subwatershed. Specific policies and practices on impervious cover limits, BMPs, and buffers are then instituted to meet the stream resource objective, and these practices directly applied to future development projects.

Watershed-based zoning should provide managers with greater confidence that resource protection objectives can be met in future development. It also forces local governments to make hard choices about which streams will be fully protected and which will become at least partially degraded. Some environmentalists and regulators will be justifiably concerned about the streams whose quality is explicitly sacrificed under this scheme. The explicit stream quality decisions which are at the heart of watershed-based zoning, however, are preferable to the uninformed and random "non-decisions" that are made every day under the present zoning system.

A cautionary note

While the research on impervious cover and stream quality is compelling, it is doubtful whether it can serve as the sole foundation for legally defensible zoning and regulatory actions at the current time. One key reason is that the research has not been standardized. Different investigators, for example, have used different methods to define and measure imperviousness. Second, researchers have employed a wide number of techniques to measure stream quality characteristics that are not always comparable with each other. Third, most of the studies have been confined to few ecoregions in the country. Little research has been conducted in the Northeast, Southeast, Midwest, and semi-arid Western regions. Lastly, none of the studies has yet examined the effect of widespread application of BMPs on impervious cover/stream quality relationships. Until studies determine how much BMPs can "cheat" the impervious cover/stream quality relationship, it can be argued that structural practices alone can compensate for imperviousness effects.

VOL 12 2 4 1 1 8

R0057410

On the positive side, it may be possible for a community to define the impervious cover/stream quality relationship in a short time and at relatively low cost. A suggested protocol for conducting a watershed monitoring study is presented in Table 4. The protocol emphasizes comparative sampling of a large population of urban subwatersheds of different increments of imperviousness (perhaps 20 to 50).

A rapid sampling program collects consistent data on hydrologic, morphologic, water quality, habitat and biodiversity variables within each subwatershed. For comparison purposes, series of undeveloped and undisturbed reference streams are also monitored. The sampling data are then statistically and graphically analyzed to determine the presence of imperviousness/stream quality relationships.

The protocol can be readily adapted to examine how BMPs can shift the stream quality/imperviousness relationship. This is done by adjusting the sampling protocol to select two groups of study subwatersheds—those that are effectively served by BMPs and those that are not.

Site designers can use a wide range of techniques to minimize impervious cover by 10 to 50%.

Minimizing impervious cover

Reducing impervious cover can be an effective element of the overall BMP system for a development site. As noted earlier, imperviousness need not be a fixed quantity. A site designer can utilize a wide range of techniques to minimize impervious cover at development site (Table 5) that collectively can reduce imperviousness by 10 to 50%. *(See Technical Notes 38 and 39 in this issue.)*

Table 4: Proposed protocol for defining functional relationships between watershed imperviousness and stream quality

- **General study design**
  A systematic evaluation of stream quality for a population of 20 to 50 small subwatersheds that have different levels of watershed imperviousness. Selected field measurements are collected to represent key hydrological, morphological, water quality, habitat and biodiversity variables within each defined subwatershed. The population of subwatershed data is then statistically analyzed to define functional relationships between stream quality and imperviousness.
- **Defining reference streams**
  Up to 5 non-urban streams in same geo-hydrological region, preferably fully forested, or at least full riparian forest coverage along same length. Free of confounding NPS sources, imperviousness less than 5%, natural channel and good habitat structure.
- **Basic Subwatershed Variables**
  Watershed area, standard definition and method to calculate imperviousness, presence/absence of BMPs.
- **Selecting subwatersheds**
  Drainage areas from 100 to 500 acres, known level of imperviousness and age, free of confounding sources (active construction, mining, agriculture, or point sources). Select three random non-overlapping reaches (100 feet) for summer and winter sampling of selected variables in each of five key variables groups:
  1. **Hydrology variables:** summer dry weather flow, wetted perimeter, cross-sectional area of stream, peak annual storm flow (if gaged).
  2. **Channel morphology variables:** channel alteration, height, angle and extent of bank erosion, substrate embeddedness, sediment deposition, substrate quality.
  3. **Water quality variables:** summer water temperature, turbidity, total dissolved solids, substrate fouling index, EP toxicity test, wet weather bacteria, wet weather hydrocarbon.
  4. **Habitat Variables:** pool- riffle ratio, pool frequency, depth and substrate, habitat complexity, instream cover, riffle substrate quality, riparian vegetative cover, riffle embeddeness
  5. **Ecological Variables:** fish diversity, macroinvertebrate diversity, index of biological integrity, EPA Rapid Bioassessment Protocol, fish barriers, leaf pack processing rate.

Table 5: Twenty-four strategies to minimize impervious area at the site level ***(adapted from City of Olympia, 1994; Schueler. 1995; and PZC, 1992)***

1. Narrower residential road widths
2. Reduced road lengths
3. Hourglass streets
4. Cluster development
5. Shared driveways
6. Angled parking with one way traffic flow
7. Smaller parking stalls
8. Reduced parking space ratios for some uses
9. Shared parking facilities in commercial areas
10. Shorter residential driveways
11. Reduced cul-de-sac radii
12. Cul-de-sac donuts
13. Vertical parking structures
14. Two and three story buildings
15. Stream buffers
16. Grass swales rather than curb/gutters
17. Open space requirements (residential)
18. Open space landscaping requirements (comm).
19. Sidewalks only on one-side of street
20. Reduced side and rear yard setbacks
21. Decrease distance between lots (frontage)
22. Hammerhead-shaped turnarounds
23. Rear yard grading to buffer
24. Permeable spillover parking areas

Conclusion

Research has revealed that imperviousness is a powerful and important indicator of future stream quality and that significant degradation occurs at relatively low levels of development. The strong relationship between imperviousness and stream quality presents a serious challenge for urban watershed managers. It underscores the difficulty in maintaining urban stream quality in the face of development.

At the same time, imperviousness represents a common currency that can be measured and managed by planners, engineers and landscape architects alike. It links activities of the individual development site with its cumulative impact at the watershed scale. With further research, impervious cover can serve as an important foundation for more effective land use planning decisions.

EXECUTIVE SUMMARY

... sewer systems. ... Best Management Practices Study was prepared by James M. Montgomery, Consulting Engineers, Inc. and Uribe & Associates for CCSF's Bureau of Environmental Regulation and Management (BERM).

STUDY OBJECTIVES

The principal objectives of this study were as follows:

- Comply with San Francisco Bay Basin Regional Water Quality Control Board (Regional Board) Order No. 90-093 to evaluate the cost-effectiveness of implementing eight optional Best Management Practices (BMPs).
- Determine CCSF's primary constituents of concern by comparing the discharge concentrations with existing and pending water quality limitations for San Francisco Bay and the Pacific Ocean.
- Identify the probable sources of CCSF's constituents of concern and develop an estimate of pollutant mass loadings from industrial, residential, and commercial discharge sources.
- Develop and evaluate additional dry and wet weather source control BMPs to reduce the sewer loadings of problem pollutants as close to their source as possible.
- Determine whether recommended BMP implementation measures would provide sufficient reductions of targeted pollutants to comply with effluent discharge limitations without installation of costly end-of-pipe treatment facilities.

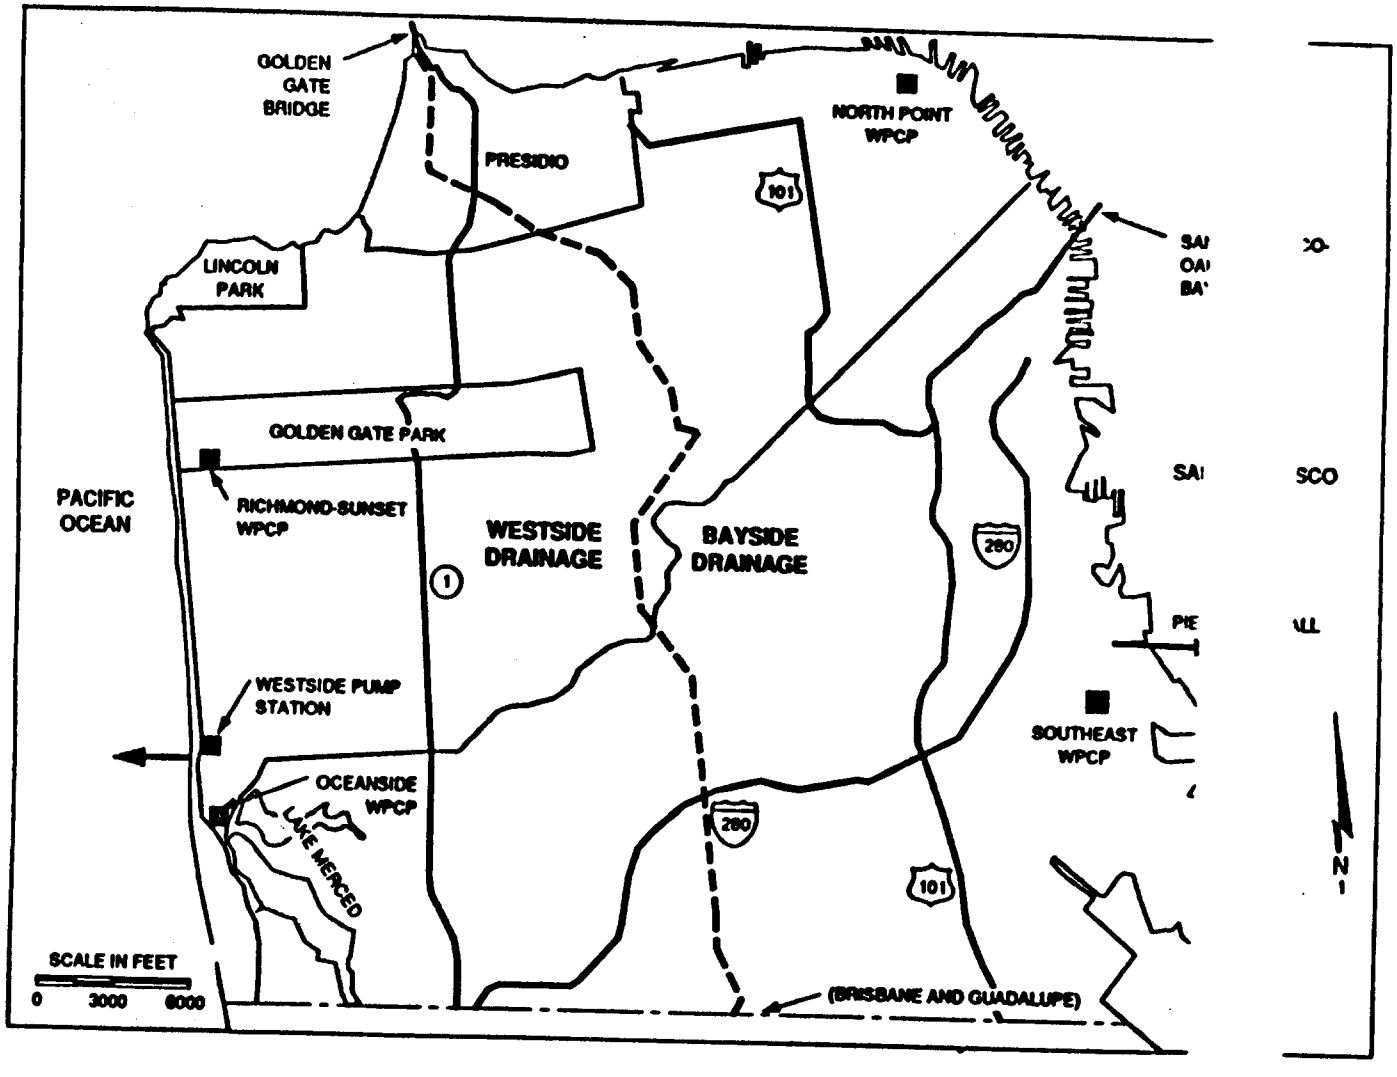
PROJECT BACKGROUND

CCSF operates and maintains a combined sewer overflow (CSO) system and three treatment facilities to handle its wastewater and wet weather flows. The sewer system is divided into two drainage basins, referred to as the Bayside and Westside drainage basins. The Richmond-Sunset Water Pollution Control Plant (RSWPCP), which services the Westside drainage area, is designed to provide primary treatment for an average dry weather flow (ADWF) of 22 million gallons per day (mgd), and discharges to the Pacific Ocean via a 4.5-mile outfall. The Southeast Water Pollution Control Plant (SEWPCP) has a capacity to provide primary and secondary treatment for a design ADWF of 85 mgd in the Bayside drainage area. The SEWPCP secondary effluent is discharged to San Francisco Bay through a deep water outfall at Pier 80 (Army Street terminal). The North Point wet weather treatment facility, which also discharges to the Bay, can provide up to 150 mgd of primary treatment for wet weather overflows exceeding the dry weather treatment capacities. A new Oceanside WPCP will replace the RSWPCP in 1994 and provide secondary treatment prior to discharging to the ocean outfall. A layout of the CCSF service area is illustrated in Figure ES-1.

In June 1990, RSWPCP received a revised NPDES discharge permit (EPA Permit No. CA0037681/Regional Board Order No. 90-093). Among the new permit conditions, CCSF was required to implement ten BMPs (referenced in this study as "Mandated BMPs"), to study the cost-

VOL 12 2 4 1 3 2

R0057424



CCSF SERVICE AREA

FIGURE ES-1

R0057425

effectiveness of implementing eight other BMPs suggested by the Regional Board (termed "Optional BMPs"), and to investigate additional measures to minimize the amount of pollutants in the wet weather overflows. These Mandated and Optional BMPs were originally intended to

In December 1991, the Regional Board adopted stringent effluent limits for toxic pollutants into the revised Basin Plan. The California State Water Resources Control Board (SWRCB) has not yet approved the Basin Plan. However, no changes to the numerical limits are expected prior to approval. In general, CCSF will have until April 2001 to comply with the Basin Plan. Before constructing costly end-of-pipe treatment facilities, dischargers are required to implement source control measures and BMPs designed to reduce the discharge of pollutants to the maximum extent possible. Dischargers are allowed until April 1996 to implement these measures and evaluate their effectiveness. The evaluations and recommendations for both the dry weather and wet weather BMP programs are described together in this report in order to consolidate the information and to present a unified and cohesive program.

EXISTING SERVICE AREA CONDITIONS

The CCSF service area consists of an approximately 900-mile underground sewer collection and conveyance system. All but one percent of CCSF's collection system serves as a combined sanitary-stormwater system, collecting stormwater runoff in the same set of pipes that transport sanitary waste. Commercial and industrial wastewaters are also serviced by this combined system.

Influent Flow Characteristics

Although the zoning characteristics of the two drainage basins are different, the composition of the influent wastewaters at the two treatment facilities is fairly similar. Table ES-1 lists the average 1991 concentrations of nine heavy metals in the SEWPCP and RSWPCP influents. No cyanide data were available from the RSWPCP facility.

The influent concentrations of the nine metals observed at RSWPCP and SEWPCP demonstrated a similar trend. In general, the two influents are fairly similar in terms of both average concentration and degree of variability throughout the year. Overall, the SEWPCP influent concentrations tend to be slightly higher and are characterized by more variability for the metals typically associated with commercial and industrial activities; such as silver, zinc, and lead.

Effluent Discharge Requirements

Table ES-2 presents the expected NPDES effluent discharge requirements for constituents of concern from the SEWPCP and the RSWPCP/OWPCP outfalls. The ocean discharge limits are currently in place, while the proposed Basin Plan limits (addressing Bay discharges) are expected to be incorporated into SEWPCP's 1994 NPDES permit revision. As seen from this table, the effluent limitations for Bay discharge are significantly lower than those required for ocean discharge. The SEWPCP effluent discharge requirements will therefore be the driving force behind CCSF-wide source reduction measures. Numerical limitations currently do not exist in San Francisco Bay for stormwater overflows of the CCSF combined sewer storage and transport system.

Focus of BMP Efforts on SEWPCP Requirements

Bayside drainage basin and the SEWPCP. Where applicable, the BMP implementation steps resulting from analysis of these data will be applied to CCSF as a whole.

ENVIRONMENTAL AWARENESS SURVEY

To assess the general knowledge of the CCSF public about Bay water quality and pollution issues, Public Affairs Management (PAM), in association with Public Research Institute (PRI) of San Francisco State University, conducted an environmental awareness telephone survey of CCSF households. To insure adequate representation of the city's diverse population, the survey employed random digit dialing and interviews were conducted in English, Spanish, and Cantonese. The survey response rate was 51 percent.

Survey Findings

The survey results generally suggested that a broad-based, CCSF-wide educational program aimed at increasing overall awareness about water quality issues and improving waste disposal practices would be quite effective. With a few notable exceptions, there was remarkably little variation seen in the neighborhood and demographic breakdowns in how the citizens who were surveyed responded to many questions. It was determined that a special targeting strategy aimed at specific groups or particular neighborhoods would not yield substantially better results than a broad based, CCSF-wide strategy. The findings from each of the survey focus areas are summarized below.

Household Use of Toxic Materials. The most commonly used toxic materials were nail polish removers (51%), motor oil (47%), and house paint (42%). Relatively small numbers of households used root eradicators (3%) and photographic chemicals (3%). Households that maintain a yard or garden were more likely than those that do not to report use of weedkillers, yard fertilizers, root eradicators, house paint, motor oil, antifreeze, and metal polishes. Households that have a garage used for storage were more likely than those that do not to report use of yard fertilizers, solvents, house paint, motor oil, antifreeze, metal polishes, and nail polish removers. Those with garages used as workshops reported highest use of solvents, paint, motor oil, nail polish removers, and art materials. In general, homeowners were much more likely than renters to report high rates of using various toxic materials, including house paint and motor oil.

Perceived Health Risks of Using Toxic Materials. More than two out of five respondents associated great health risks with solvents, drain cleaners, and pesticides. The smallest health risks were associated with yard fertilizers, metal polishes, and nail polish removers. Respondents admitted considerable ignorance regarding the health risks of certain products, particularly photographic chemicals and root eradicators. Nearly one in four respondents said they did not know the health risks of using motor oil. In general, female respondents were much more likely than male respondents to perceive great health risks in using various toxic materials. Age and education proved to be very weak predictors of perceived health risks.

Levels of Environmental Awareness. Overall, survey respondents displayed a very high level of awareness and concern for the environment. Three out of five respondents who regularly use public transportation said that one very important reason for doing so was to reduce pollution. Majorities or near-majorities of respondents said that they always read product labels for warnings, are aware of the provisions of Proposition 65, use the curbside recycling pickup services in their

VOL 12 2 4 1 3 7

R0057429

neighborhoods, and are aware of the Bay and Ocean pollution caused by disposal of toxic substances down the drains. Sizable numbers of respondents reported that they always make an effort to purchase non-toxic and environmentally safe products and that they are aware of the

as "inappropriate" if they involved dumping such materials down the drains, on the ground, or in the trash. The percentages of product users who employed such inappropriate disposal practices ranged from 8% in the case of antifreeze to 48% in the case of art materials. More than one in five house paint users practiced inappropriate disposal methods, and 10% of motor oil users said that they did so. No strong or consistent predictors of inappropriate disposal practices were found in the case of motor oil and house paint, although nonwhite race (African American, Latino, Asian and Other) and lower education were weak predictors of using such methods. Under the heading of inappropriate disposal practices, reported rates of drain or ground disposal were relatively low compared with rates of disposal in the trash. More than 70% of those who used inappropriate methods to dispose of motor oil and house paint said that they did so by using the trash. More than 40% of respondents said they were aware of the HHWCF, and nearly 20% said they had used that facility at least once during the past year. White respondents and homeowners who live in the southern parts of CCSF were most likely to report awareness and use of the HHWCF.

Willingness to Pay for New Disposal Services and Educational Programs. More than 70% of survey respondents said that they definitely would use a curbside pickup service for disposing of motor oil and latex paint if such a new service were offered. A large majority of those who would use such a service claimed to be willing to pay at least 25 cents/month in fees for it, and many would pay as much as 50 cents/month. The desire for this service appears to be very broad-based and CCSF-wide in its scope. Respondents also displayed overwhelming majority support for greater CCSF efforts to educate the public about toxic materials and their proper disposal and for more stringent regulatory policies. Most of those who expressed support for such initiatives said they would be willing to pay at least 25 cents/month to finance them. The desire for these new programs also is very broad-based and citywide in its scope.

Perceived Sources of Water Pollution. Majorities of survey respondents assigned greatest blame for water pollution to manufacturers, commercial businesses, and auto shops. Fewer than one in four respondents identified households themselves as a major source of water pollution. Although these opinions appear to be broad-based and CCSF-wide in scope, affluent and college-educated respondents were most likely to assign blame to government offices, manufacturers, and commercial businesses.

Sources of Information about Environmental Problems and Issues. Most household respondents (41%) said they rely mainly on newspapers as their primary source of information about environmental problems and issues, followed by television (21%), magazines (7%), word of mouth (3%), and radio (2%). A significant number of respondents (21%) said they rely mainly on "other" sources for such information. Analysis reveals that many of these respondents are members of environmental organizations and have access to valuable informational resources which are unavailable to nonmembers. Nonwhite respondents (African American, Latino, Asian and Other) and homeowners were most likely to depend on television for information about the environment, whereas upper-income and college-educated respondents were most inclined to use newspapers.

VOL 12 2 4138

R0057430

SELECTION OF DRY WEATHER BMPs

1) The problem pollutants for the CCSF service area were identified by comparing the SEWPCP effluent concentrations of eleven pollutants to the proposed Basin Plan limits. Table ES-3 compares the SEWPCP effluent concentrations in 1991 against the Basin Plan limits. Four pollutants were identified as exceeding the Basin Plan limits, and thus termed "primary pollutants of concern." These pollutants are listed below.

   - Copper.
   - Mercury.
   - Cyanide.
   - Polynuclear aromatic hydrocarbons (PAHs).

   In addition to the above pollutants, four other metals (lead, nickel, silver, and zinc) have also been considered in the evaluation of BMPs as their effluent concentrations were generally within 30 percent of the Basin Plan limits.

2) Extensive information collection efforts were undertaken, consisting of nation-wide telephone interviews of public agencies and a computerized literature search. CCSF sought to learn from the experiences of other municipalities facing similar permit conditions and requirements. While most of the agencies contacted conducted or planned to implement one or more BMPs or other source control measures, relatively few have comprehensive programs in place. The BMPs being implemented were targeted primarily at wet weather and non-point source runoff.

3) Contributions of problem pollutants to the SEWPCP influent loading from four major source categories (water supply, residential, industrial, and commercial/other businesses) were estimated. The percentages of influent loadings from each of these sources are presented in Figure ES-3. Review of contributions from these source categories indicated that source reduction efforts geared towards residential and commercial/other business sources would likely result in the greatest loadings reductions at the SEWPCP. Unidentified sources are included in the commercial/other businesses category.

4) Dry weather BMPs were selected for further evaluation based on an examination of the specific water supply, residential, and commercial/other business sources that needed targeting to obtain the greatest reduction in the identified problem pollutants. Table ES-4 lists the principal identified sources for the seven pollutants of concern with respect to the four major source categories. Industrial sources are already regulated very effectively by BERM. They were not considered for the detailed BMP investigations.

The eight Optional BMPs suggested by the Regional Board were divided between the dry and wet weather evaluations. Four of these Optional BMPs were included among the 13 dry weather BMPs, while the other four were evaluated among the wet weather BMPs.

CCSF is conducting a separate concurrent study to investigate the sources of cyanide in its wastewater streams. This effort included an extensive sampling of CCSF businesses for cyanide. However, this sampling effort did not identify any major contributors of cyanide that are currently unregulated. Potential cyanide sources considered in this BMP selection process were photoprocessing facilities, scrubber operations, and paint products.

(a) Shading denotes two principal source categories for each pollutant.

R0057435

Formation of PAHs may occur by the oxidation of saturated cyclic hydrocarbons in vegetative fuels, such as wood, foliage, and agricultural crop residues. Other sources may include: crude oil

PAHs may be present in some of the identified activities such as automotive service facilities, scrubber operations, and illegal dumping of used oil.

DEVELOPMENT OF DRY WEATHER BMPs

For the thirteen BMPs listed below; the targeted pollutants of concern, implementation measures required, estimated loading reductions, and estimated implementation costs were evaluated.

- BMP No.1 (Optional BMP E2) - Educate public regarding the potential environmental impacts of common household products and the availability of alternatives.
- BMP No.2 (Optional BMP P1) - Develop and implement an aggressive public program to report and prevent dumping of toxic pollutants into sewers and drainage channels.
- BMP No.3 - Ban the use of copper sulfate root killer and educate the public on alternative products.
- BMP No.4 - Educate residents and contractors on metals and cyanide in home improvement products and proper cleaning methods.
- BMP No.5 - Further regulate discharge of photographic wastes.
- BMP No.6 - Regulate automotive service facilities.
- BMP No.7 - Regulate commercial and medical laboratories.
- BMP No.8 - Coordinate with San Francisco Water Department to optimize corrosion control.
- BMP No.9 - Regulate cooling tower and scrubber discharges.
- BMP No.10 - Provide temporary storage of recycle flows during wet weather.
- BMP No.11 (Optional BMP P3) - Develop and implement a program which provides a means of recording the observations of field inspection and maintenance personnel, so this information can be used to help locate the source(s) of pollutants.
- BMP No.12 - Minimize impurities in treatment plant chemicals.
- BMP No.13 - Construct reverse osmosis facilities.

VOL 12 2 4 1 4 4

R0057436

The sum of these scores for each BMP would form an overall picture of its advantages and disadvantages. Based on their importance to the success and value of a given BMP, the evaluation criteria were divided into two tiers, Tier I and Tier II. The Tier I criteria are considered to be of greater importance in establishing the value of the BMPs.

Minimal empirical data were available on the reduction potential of BMPs. To estimate pollutant reductions, numerous suppliers, vendors, service contractors, business owners, CCSF staff, and Federal, State and local agencies were contacted. Any pertinent literature information was reviewed. Finally, best engineering judgement and reasonable assumptions were used to estimate the potential reductions. The estimates should be considered as reasonable for a cost-effectiveness comparison, but should not be used as definitive loadings. As more experience is gained from working with these sectors, their reduction estimates should be revised accordingly.

Agency cost estimates were prepared at current day value. They are order-of-magnitude estimates that are consistent with planning level analysis. Costs to businesses are expected to be highly variable, and will depend on specific compliance methods selected. These business costs were not included in this analysis.

Cost Effectiveness

Table ES-5 summarizes the estimated loadings and reductions for the thirteen dry weather BMPs. Reverse osmosis (BMP No.13) would have the highest reduction potential, approximately 27,000 pounds per year (lbs/yr) from the effluent loading. BMPs 11 (recording field observations) and 12 (treatment plant chemicals) would not reduce influent loadings to the plant. BMP No.11 would be extremely beneficial for implementation of other BMPs but would not directly result in any influent loading reductions. Among the other BMPs, the following observations on the primary pollutants of concern can be drawn.

- Copper Reduction - The BMPs with the highest reduction potential are water supply (No.8), cooling towers (No.9), public education (No.1), automotive service facilities (No.6), root killers (No. 3) and laboratories (No.7); in that order.
- Mercury Reduction - The BMPs that are expected to reduce mercury loadings are medical and commercial laboratories (No.7), public education (No.1), and home improvement products (No.4). CCSF's efforts to regulate dental facilities should provide additional mercury reduction.
- Cyanide Reduction - BMPs with cyanide reduction potential are public education (No.1), home improvement products (No.4), automotive service facilities (No.6), and laboratories (No.7). In general, the BMPs evaluated were not found to be major sources of cyanide. This concurs with CCSF's Cyanide Evaluation Study. Cyanide was not found in the wastewaters of many small quantity dischargers sampled.

(a) BMP No. 11 would not directly reduce pollutants of concern.

R0057438

- PAHs Reduction - There are minimal data available on the reduction and treatment of PAHs. PAHs are essentially by-products of combustion. The major source of PAHs is

been noted in the literature. However, there is no documentation of quantities in the literature or at other POTWs. In addition, since PAHs are by-products of the combustion process; reduction measures, other than reducing the sources of combustion, may not be readily available.

The cost effectiveness of the BMPs was evaluated in terms of the expected costs of BMP implementation measures per pound of pollutants expected to be removed. The total reductions of each BMP could be calculated as simply the sum of the expected reductions of the individual pollutants. However, this method would not account for the different degrees of toxicity for these compounds. As an example, zinc may be present in higher concentrations than copper prior to exerting the same level of health effects on certain aquatic organisms. This is reflected by their respective effluent limits: 840 µg/l for zinc and 17 µg/l for copper. Therefore, removal of the same quantities of these two compounds would not have the same environmental benefit. This disparity is further compounded by the fact that zinc is generally present in higher concentrations and is more easily removed.

In order to account for the differences in toxicity among the seven pollutants, the total reductions of the BMPs are normalized to a common standard. For this cost effectiveness analysis, copper is arbitrarily selected as the standard reference pollutant. The expected mass reductions of the six other (i.e., non-copper) pollutants analyzed were converted to a copper-equivalent mass reduction by scaling the reductions according to a toxicity conversion factor. The conversion factors used were based on the effluent concentration limits for each pollutant (relative to copper) as contained in the Basin Plan.

Once the expected mass reductions were normalized relative to the copper toxicity "standard," cost effectiveness of the BMPs was evaluated in two ways:

- Annual costs of each BMP were divided by the estimated annual (normalized) reductions of copper, cyanide, lead, mercury, nickel, silver, and zinc.
- Annual costs of each BMP were divided by the estimated annual (normalized) reductions of copper, cyanide, and mercury. These three pollutants are of primary concern for CCSF.

Table ES-6 presents a summary of the annual costs and the cost-effectiveness calculated for the thirteen BMPs. The two most costly options are the two structural BMPs, reverse osmosis (No. 13) and recycle flow storage (No. 10). At an annual cost of $86,900,000; reverse osmosis is the most expensive BMP evaluated. Due to the extremely high costs of BMP No. 13, it is important to note that if it were selected for implementation, fundings for the other BMPs would not be available. Therefore, the annual costs of BMP No. 13 can be used as the benchmark against which the costs of other BMPs can be compared. BMPs 3 (root killer) and 11 (record field observations) are expected to impose the lowest annual costs.

The cost-effectiveness of the non-structural BMPs can be directly compared in Table ES-6. These BMPs would reduce the influent loadings to the SEWPCP. The cost-effectiveness of BMP No.13 can not be directly compared to the non-structural BMPs since the reverse osmosis pollutant removals occur in the effluent loadings rather than by influent source reduction. The BMP cost-effectiveness evaluation is summarized below.

VOL 12 2 4 1 4 7

R0057439

TABLE ES-6

COST EFFECTIVENESS SUMMARY

BMP No.	Description	Annual Cost ($/yr)	Cost Effectiveness ($/lb removed)(a)	
			7 Pollutants (b)	3 Pollu
1	Educate Public on Household Products	360,000	331	?
2	Program to Report and Prevent Dumping	172,000	1,315	5.
3	Root Killers	7,000	35	
4	Home Improvement Products	37,000	182	1
5	Photographic Wastes	76,000	205	1
6	Automotive Service Facilities	89,000	187	?
7	Commercial and Medical Laboratories	81,000	58	
8	Corrosion Control with SFWD	320,000	112	1
9	Cooling Tower	101,000	119	1
10	Temporary Storage of Recycle Flows	552,000	26,699	55
11	Program to Record Field Observations	11,000	NA	1
12	SEWPCP Chemicals	150,000	NA	1
13	Reverse Osmosis	86,900,000	(d)	

(a) Pollutant reductions used for this ratio were normalized according to toxicity.
(b) Cost effectiveness calculated based on estimated reduction of all 7 pollutants of concern: copper, cyanide, lead, mercury, nickel, silver, and zinc.
(c) Cost effectiveness calculated based on estimated reduction of the 3 primary pollutants of concern: copper, cyanide, and mercury.
(d) The BMP No. 13 unit costs were not included in this comparison since the pollutant removals occur in the effluent loadings rather than by influent source reduction.
NA - Not Applicable. No reductions in this category are expected.

R0057440

84-79 2 NOV 27

Based on Reduction of All Seven Pollutants:

- BMPs 1 (public education), 2 (used oil collection), and 5 (photographic wastes) are slightly less cost-effective. However, their unit costs are still significantly less than the unit costs of the structural BMPs (10 and 13).
- A unit cost for BMPs 11 (record field observations) and 12 (SEWPCP chemicals) cannot be calculated. These BMPs would not reduce any of the pollutants of concern.

Based on Reduction of Three Primary Pollutants:

- BMPs 3 (root killer), 4 (home improvement products), 7 (medical and commercial laboratories), 8 (corrosion control), and 9 (cooling towers) are very cost effective.
- BMPs 1 (public education) and 6 (automotive service facilities), are slightly more costly. However, their unit costs are still significantly less than the unit costs of the structural BMPs.
- Unit costs for BMPs 5 (photographic wastes), 11 (record field observations), and 12 (SEWPCP chemicals) cannot be calculated. These BMPs would not reduce any of the primary pollutants of concern.
- The unit cost of BMP No. 2 (curbside oil collection) would be similar to that of reverse osmosis. However, BMP No. 2 would also reduce PAHs, organics, oil and grease to the treatment plants. In addition, the cost of this BMP could be reduced with a direct user fee. The environmental awareness survey determined that the public would be willing to pay directly for this service.

The cost effectiveness of these BMPs is shown graphically in Figures ES-4 and ES-5.

Non-Economic Evaluation

In accordance with the BMP Study Plan (CCSF 1991E), the BMP evaluation criteria were divided into two tiers, Tier I and Tier II, based on their importance to the success and value of a given BMP. These Tier 1 and Tier II non-economic criteria are listed below.

Tier I Non-Economic Criteria:

- Time to achieve results.
- Compatibility with other CCSF programs.
- Legal changes required.
- Effluent limits.

VOL 12 2 4149

R0057441

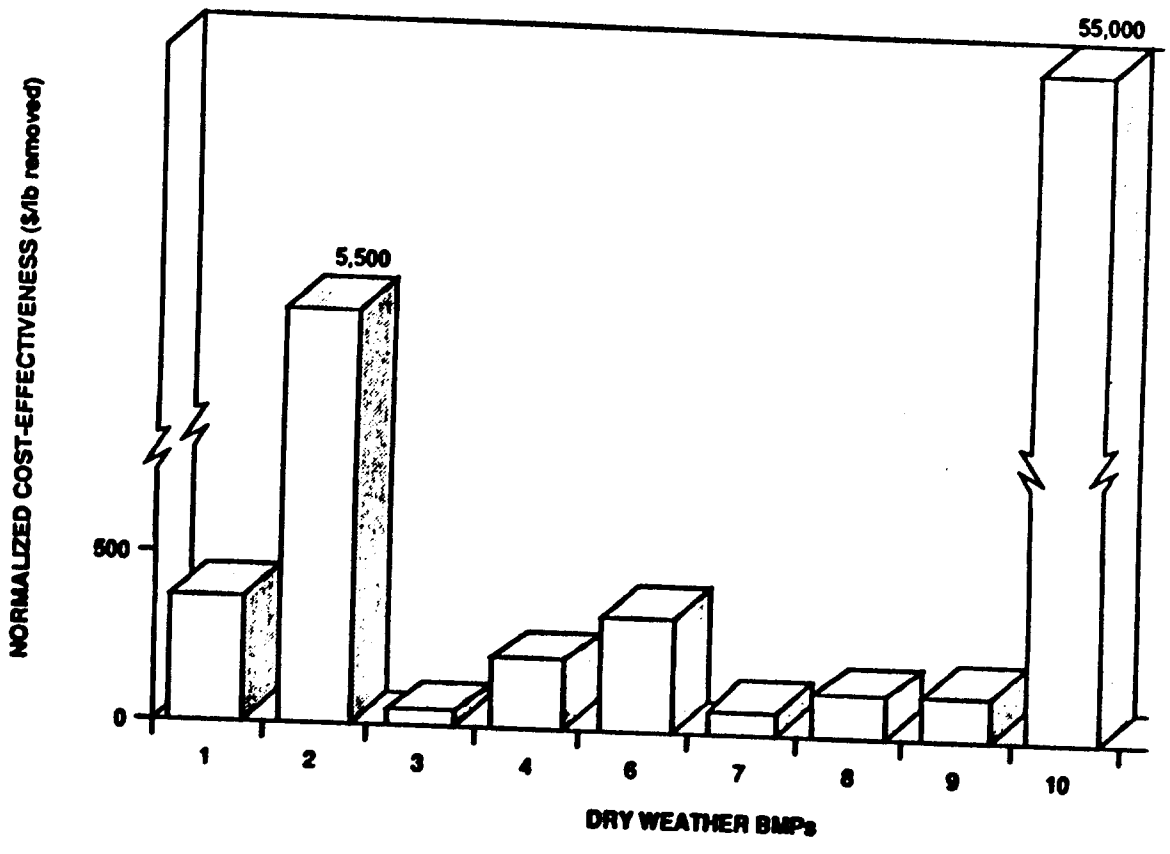
VOL 12 2 4-50



BMP COST EFFECTIVENESS
(Based on Three Primary Pollutants of Concern and Normalized by Copper-Equivalent Toxicity)

FIGURE ES-5

R0057443

Tier II Non-Economic Criteria:

- Environmental impacts
- Cross-media impacts
- Potential to reduce other pollutants

The results of the evaluations of the BMPs versus the Tier I and Tier II non-economic criteria are summarized in Tables ES-7 and ES-8, respectively.

RECOMMENDED DRY WEATHER BMPS

The results of the cost effectiveness and non-economic evaluation are summarized in Table ES-9. Based on the above evaluation, it is recommended that CCSF implement the following BMPs in a two-phased approach. The first phase BMPs should be implemented by the end of Fiscal Year 1993-94. The second phase BMPs should be implemented by the end of Fiscal Year 1995-96. This two-phased approach would allow CCSF to focus on measures that would have the most impacts. The experience gained from these initial BMPs can then be easily applied to subsequent BMPs.

The BMPs selected for Phase I implementation are cost effective and/or are rated as highly favorable among the non-economic criteria. These BMPs include the following:

- BMP No. 8 (corrosion control). This BMP would have the highest potential for significant reduction of copper. The unit cost of this BMP could increase depending on the results of the corrosion control study by SFWD.

- BMPs 6 (automotive service facilities), 7 (medical and commercial laboratories) and 9 (cooling towers). Laboratories and cooling towers are currently unregulated and may be significant contributors of copper and mercury. Radiator repair and car washes are currently regulated by BERM. However, many other businesses related to automotive service (auto dealers, body shops, gas stations, general repair, trucking, buses, and fleet services) may also be significant contributors.

- BMP No. 3 (copper sulfate root killer). This BMP represents the most easily identifiable residential contribution. Cost of implementation would be extremely low.

- BMPs 1 (public education), 2 (used oil collection), and 11 (record field observations). Although these BMPs are not considered especially cost effective in terms of pollutant reductions, they should be applied as general measures rather than to target specific pollutants. Additionally, a strong program focusing on residential contributions and reductions is an integral part of an overall source reduction program.

The single Phase II BMP will be BMP No.4 (home improvement products). This BMP is slightly more cost effective than some of the Phase I BMPs, but had slightly lower non-economic ratings. As part of BMP No. 4, boatyards within CCSF should be inspected and considered for regulation. This BMP should be initiated approximately two years after the Phase I BMPs.

NA - Not Applicable. No reductions in this category are expected.
(a) Normalized to a copper-equivalent.
(b) The sum of the Tier II and Tier I criteria scores.
(c) The BMP No. 13 unit costs were not included in this comparison since the pollutant removals occur in the effluent loadings rather than by influent source reduction.

R0057447

The following BMPs are not recommended for implementation by CCSF.

- BMP No.10 (recycle flow storage). This BMP would require significant physical facilities for minimal reduction. Implementation of this BMP would also reduce site availability at SEWPCP and limit future expansion flexibility.
- BMP No.12 (SEWPCP chemicals). The reduction potential of this BMP would be very minor. Depending on the results of the other BMPs, this BMP may be reviewed after several years for implementation.
- BMP No.13 (reverse osmosis). Capital and operating and maintenance (O&M) costs of this BMP are extremely high. Even with these expenditures, compliance with all the Basin Plan limits would be uncertain. There is no information on cyanide removal efficiency with reverse osmosis, and compliance with this limit may not be achievable. This BMP would generate significant negative impacts associated with high energy usage and generation of residual chemical sludge and concentrated brine that would require alternative disposal. Finally, due to its high annual costs, implementation of this BMP would likely eliminate the CCSF funding available for implementation of the source control BMPs discussed above.

Effluent Quality

Final effluent concentrations are dependent upon the influent loadings and the removal efficiencies at the treatment facilities. In general, removal efficiency is expected to decrease as influent concentration decreases. It is postulated that, at higher concentrations, a larger percentage of the pollutants is in the particulate form rather than the soluble form and is, therefore, more readily removed. For soluble pollutants such as cyanide, lower influent concentrations would result in less opportunities for adsorption and biodegradation. The influent concentrations of copper, cyanide, and mercury are plotted against their removal efficiencies in Figures ES-6 to ES-8. A logarithmic curve fit is shown for each pollutant. While the correlation of these variables are not very strong, the plots generally illustrate the trend of decreasing removal efficiency with lower influent concentrations.

Table ES-10 compares the current effluent 95th percentile concentrations of copper, mercury, and cyanide; their estimated concentrations after the implementation of the recommended BMPs; and the proposed Basin Plan limits. As shown on the table, the implementation of the BMPs may not reduce copper, mercury, and cyanide concentrations to below the Basin Plan limits. Due to the variability inherent in estimating loadings and reductions, the ability to comply with the proposed limits will only become apparent after implementation of these BMPs. However, it must be pointed out that these source reduction measures are the most environmentally acceptable methods to deal with the water quality requirements. There are no direct controls over effluent quality with influent source reduction measures. Final effluent quality is dependent upon influent concentrations and removal efficiencies at the treatment plant. Both factors are known to vary significantly on a day-to-day basis.

VOL 12 2 4160

R0057452

In addition to implementing source reduction measures, CCSF staff are also investigating other means to comply with the Basin Plan limits. These other potential means are listed below.

approach would consider all significant sources of pollutants (both point and non-point) and would focus on the sources that can most effectively be reduced to comply with the water quality objectives.

- Evaluation of a water reuse master plan to export wastewater from the greater Bay area to the central valley for irrigation reuse. If successful, this project would completely eliminate the discharge of toxic pollutants to San Francisco Bay.
- Evaluation of cross-town tunnel to deliver the entire SEWPCP effluent to an ocean outfall. As indicated earlier in this report, treated effluent from the CCSF wastewater treatment facilities would comply with the Ocean discharge requirements.

CCSF staff is actively participating in the development and evaluation of the above activities. These compliance options will continued to be pursued in conjunction with the implementation of the recommended BMPs.

Cost and Staffing Requirements

The total annual costs and staffing requirements for the recommended Phase I and Phase II BMPs are summarized in Tables ES-11 and ES-12, respectively. The total annual costs to implement all the recommended Phase I BMPs would be approximately $1.2 million per year. Implementation of Phase II (BMP No.4) would impose an additional annual cost of approximately $37,000. Additional staff would be required to implement these BMPs. A public education coordinator and a public education assistant have been listed for BMP No.1. In actuality, they will be providing public participation services for all the recommended BMPs.

Additional Recommendations

CCSF adopted new local limits for its pretreatment program in December 1991. These local limits were developed on a technical basis in accordance with EPA guidelines. However, the effluent limits used in that evaluation were based on the existing NPDES permits and the 1986 Basin Plan discharge limits. As discussed above, the 1991 Basin Plan has proposed significantly more stringent effluent limits. Although these limits are not currently in any CCSF permit, they are expected to be included in the SEWPCP permit when it is scheduled for renewal in 1994. Additionally, imminent changes to the 503 Sludge regulations may also have some impacts on the local limits.

Several of the recommended BMPs would require utilizing local limits as the means for regulation. Since these BMPs have been developed in response to the new Basin Plan, local limits should be re-evaluated. Notification of potential local limits revisions would be beneficial to businesses that are selecting treatment or disposal methods for their wastes.

R0057455

SELECTION OF WET WEATHER BMPs

their sources. In order to establish its pollutants of concern, San Francisco uses the following general set of criterion, ranked in order of importance:

1. Pollutants exceeding NPDES permit limits;
2. Pollutants potentially contributing to general receiving water problems (e.g. exceedances of water quality standards in either the Ocean Plan, the Enclosed Bays and Estuaries Plan, or the Region II Basin Plan);
3. Pollutants in compliance but near permit limits;
4. Pollutants contributing to bioaccumulation, and/or biomagnification; and
5. Pollutants contributing to existing and potential sediment toxicity problems.

The pollutants of most concern in the wet weather discharges are those that cause a violation of the City's discharge permits. These permits are issued by the Regional Water Quality Control Board (RWQCB) or, in the case of the discharge through the Southwest Ocean Outfall, by the U.S. Environmental Protection Agency (USEPA). Presently, none of the City's discharges during dry or wet weather violate permits or the associated compliance orders.

Although the City's wet weather discharges are currently in compliance, this situation may change as new water quality objectives are incorporated into permits in the coming years. There is an ongoing debate at both the national and state level as to whether and how these water quality objectives should apply to storm water discharges and combined sewer overflows. If these objectives are applied as written to the City's wet weather discharges, the City would be in significant noncompliance with several numerical limits.

To assess the potential for future noncompliance, several monitoring data sources were reviewed to compare pollutant concentrations in the overflow discharges to the selection criterion. The City compared Bayside overflow concentrations from 1989 to 1992 to water quality objectives in the Amendments of the Water Quality Control Plan for Enclosed Bays and Estuaries of California (SWRCB, 1992). As a result of this review, pollutants of concern were grouped into three tiers, in descending order of concern:

Tier 1 **Significant concern** - Three year mean pollutant concentration 10 times greater than potential water quality objective without dilution.

- Polynuclear Aromatic Hydrocarbons (PAHs)
- Copper
- Lead
- Cyanide

VOL 12 2 4164

R0057456

Tier 2 Moderate concern - Three year mean pollutant concentration greater than potential water quality objective without dilution.

- Nickel
- Silver
- Zinc

Tier 3 Little concern - Three year mean pollutant concentration less than potential water quality objective without dilution.

- Chromium
- Arsenic

It is clear that if the water quality objectives are included in the permits and applied to San Francisco's wet weather discharges, then the City will have a serious compliance problem. Therefore, the wet weather portion of the BMP Study focussed on reducing the Tier 1 and Tier 2 pollutants of concern namely PAHs, heavy metals, and cyanide.

Identification of Pollutant Sources

A literature search was conducted to identify the sources of these pollutants. The City reviewed City-specific reports as well as general literature sources on storm water runoff. In addition, City staff from the Bureau of Environmental Regulation and Management (BERM), the Bureau of Street Cleaning and Urban Forestry (BSCUF), and the Bureau of Street and Sewer Repair (BSSR) were interviewed regarding potential sources. As a result of the literature review and information gathering process, the City has identified two broad source classes, primary and secondary. The distinction between primary and secondary sources has been made to help focus the discussion of source control strategies. Pollutants of concern may be reduced more effectively by addressing each of the various pathways by which the pollutants may enter storm water. Primary and secondary sources are defined below.

Primary Sources - These are materials or material uses which provide the first opportunity in an urban setting for pollutant contact with rainfall or runoff. Examples of primary sources are automobiles (which contribute oil, grease, and metals through leaks, exhaust, metal corrosion, and tire wear), waste disposal practices, and raw products exposed to storm water.

Secondary Sources - Some sources of pollutants, termed secondary sources, are difficult to isolate and quantify. These include air-borne particulates and sediments which accumulate throughout CCSF's infrastructure (streets, catch basins, storage/transports, and low-flow sections of sewerage system). Some primary sources become secondary sources when they are not afforded direct entry into stormwater. For example, air-borne pollutants from automobile exhaust may become associated with road dust particules and eventually settle as sediments onto streets and in catch basins. These sediments become a source of pollutants in and of themselves because they may adsorb a certain amount of heavy metals and hydrocarbons under one set of chemical conditions (e.g., pH), and release these pollutants later as a result of changing conditions.

VOL 12
2
4165
R0057457

Primary Sources. Table ES-13 summarizes the primary sources of the City's wet weather pollutants of concern, including both general wet weather sources and commercial/industrial sources. The primary sources of pollutants of concern during wet weather may be grouped into

vehicle emissions are flushed away by rainfall and eventually end up in the sewer system.

- **Paints/Wood preservatives** - Paint and wood preservative products contain a number of heavy metals.
- **Businesses with outside exposure** - Other potential primary sources include businesses with outside storage or manufacturing yards. Businesses that generate and/or discharge pollutants of concern, which may come into contact with rainfall or runoff, are also potential primary sources. These businesses include those that use automotive or paint/wood preservative products such as auto repair shops, painting contractors, and equipment rental shops that often clean their equipment outside with water that later enters the sewer system as runoff.

Secondary Sources. The major secondary source of pollutants in San Francisco is sediment. Sediments occur in the following places throughout the City's wastewater and storm water collection system:

- streets and sidewalks,
- catch basins,
- sewer pipes,
- storage/transports,
- treatment plants, and
- outfalls.

The principal sources of the wet weather pollutants of concern are automotive-related activities, paint/wood preservative uses, businesses with outside exposure, and infrastructure sediments. Of these sources, automotive-related and paint/wood preservatives are discussed by specific best management practices in the dry weather sections (4-6) of this report. Therefore, the target sources for further development of wet weather BMPs are:

- Businesses with outside exposure, including those which use automotive or paint/wood preservative products, and
- Secondary sources (i.e., infrastructure sediments).

Selection of Wet Weather BMPs for Study

As described in the Study Plan, the Optional BMPs were selected from a list of BMPs developed by other Bay Area municipalities. Best management practices were determined to be more effective if based on information specific to San Francisco, including pollutants of concern, sources, and existing programs. Therefore, a screening process was applied to the Optional BMP

list to determine if any best management practices should be added or dropped from the original list. The data considered in the selection were primarily qualitative. The steps followed in the selection process are outlined below.

by comparing the Optional BMPs in the context of the City's existing BMP Implementation Program (CCSF, 1990b). The Optional BMPs were reviewed for their ability to compliment the Mandated BMPs for the pollutants of concern and their sources.

2. Data collection - The City gathered qualitative data on the Optional BMPs from City agencies, supported by quantitative data which were easy to gather, reliable, and complete.

3. Data analysis - The information collected was discussed with personnel from the Bureau of Water Pollution Control (BWPC), the Department of Public Health (DPH), the Solid Waste Management Program (SWMP), and the inter-agency BMP Review Committee.

4. BMP selection - Based on the screening process and discussions with City agencies, the City selected five best management practices for further study.

Table ES-14 lists the BMPs that emerged from the selection process and are reviewed in sections 8 and 9. The list includes the four Optional BMPs from the permit as well as an additional best management practice, P6, shown in italics. Each of these five wet weather best management practices appeared to complement the existing BMP Implementation Program either by addressing pollutant sources not covered by the existing program or by using a different means of implementation (e.g., public agency action versus education) to address a source.

DEVELOPMENT OF WET WEATHER BMPs

Having identified the pollutants of concern, their sources, and wet weather BMPs, the following information was developed for each BMP:

- A clear definition and purpose of the best management practice is given.
- Linkages between this best management practices and other BMPs are shown and described. The other BMPs may be Mandated BMPs and/or other Optional BMPs. The linkages may be in the form of target source and/or implementation method.
- A description of the pollutants of concern which the BMP addresses.
- Existing conditions in San Francisco related to this BMP are described. The best management practice is evaluated in part by the need for the BMP and by its "fit" with existing programs.
- Means of implementing the BMP are listed and described.
- Cost and expected reduction information is provided (if available).

VOL 12 2 4168

R0057460

TABLE ES-14

WET WEATHER

Educational Control Measures

E1 - Educate re: the environmental impacts which result from leaks and spills from gasoline, fuel oil, and chemical tanks (above and below ground).

Regulatory Control Measures

R1 - Develop and implement program to reduce the risk of toxic pollutant spills from commercial, industrial, and public facilities.

Public Agency Control Measures

P2 - Establish program to regulate cleaning of sewer inlets, catch basins, and drainage channels in areas where sediments and/or debris tend to accumulate.

P4 - Develop and implement an aggressive field program to search for, detect, and correct situations which rainfall and/or runoff presently contact potential contaminants.

P6 - Determine the effectiveness of various street cleaning practices and implement improved street cleaning programs where appropriate.

EVALUATION OF WET WEATHER BMPs

Evaluation Methodology

The non-economic criteria previously described and used for evaluating the dry weather BMPs was used to evaluate the wet weather BMPs. A ranking system was developed consisting of three possible values: "+", "0", and "-", defined as:

- "+" = Data indicates a positive outcome
- "0" = Insufficient data to determine outcome or criteria not applicable
- "-" = Data indicates a negative outcome

For example, if data indicates that a best management practice is particularly cost-effective, that BMP would be valued a "+" in the evaluation. Conversely, if data indicated that implementation would be relatively expensive, the best management practice would receive a value of "-". Inconclusive data would yield a value of "0". Values of "+" and "-" were only given when data was relatively conclusive, otherwise a value of "0" was recorded. For ranking purposes, the values were assigned the following numerical scores:

VOL 12 2 4169

R0057461

- "+" = 2 points

Each BMP was evaluated against each of the criteria and assigned one of the three possible values. The values were then tallied using the numerical scores. Scores on Tier 1 criteria were weighted twice as heavily as Tier 2 criteria scores. After the scoring, best management practices were ranked in order of decreasing final score. The higher the score, the higher priority a BMP is given for implementation. Table ES-15 is an evaluation matrix showing the scores assigned to each best management practice for the Tier 1 and Tier 2 criteria.

The scores for best management practices P4 and R1, as well as those for BMPs P6 and P2, were very close. As discussed in section 8, these two pairs of BMPs are closely linked, so it may not be surprising that their scores are similar. The reason for their linkage is that they are designed to achieve the same ends using different but complementary means.

Recommended Wet Weather BMPs

Based on the evaluation, the ranking of the BMPs and a recommendation is presented in Table ES-16. The BMPs are listed in order of decreasing overall benefit.

Cost and Staffing Requirements

The annual costs and staffing requirements for the recommended wet weather BMPs are presented in Tables ES-17 and ES-18, respectively. The total annual cost to implement the recommended best management practices would be approximately $200,000 per year. One additional BERM staff person would be required to implement these BMPs. The BERM inspector and the BSCUF operator are not expected to be new staff, instead, this staff time would be divided among the existing inspectors and operators.

Additional Recommendations

The City has limited knowledge regarding the concentrations of some of the pollutants of concern as they pass through the City's storm water runoff collection system prior to treatment at the Water Pollution Control Plants (WPCPs) and/or discharge to the Bay and ocean. An important issue to resolve is whether the pollutants of concern that are adsorbed to sediments are a threat to water quality. If much of the pollutants remain attached to sediments, increased cleaning of streets and catch basins may not be cost-effective, especially if most of the sediments travelling through the collection system end up in the grit chambers at the WPCPs and then are disposed of at a landfill. However, if pollutants of concern adsorbed to sediments are later released in significant amounts into runoff because of changing chemical conditions, then minimizing the amount and the residence time of sediments in the collection system may be an effective pollution prevention strategy.

In order to evaluate the effectiveness of wet weather BMPs P2 (Catch Basin Cleaning) and P6 (Street Cleaning), a long-term sampling study designed to gather meaningful quantitative data should be conducted. The resulting data would be used to analyze the effectiveness of street and/or catch basin cleaning in reducing the concentrations of the pollutants of concern in the overflow discharges.

SECTION 1

INTRODUCTION

that are not readily removed by conventional wastewater treatment methods, the City and County of San Francisco (CCSF) has undertaken a proactive effort to reduce the level of toxicants entering its sewer systems. This Best Management Practices Study was prepared by James M. Montgomery, Consulting Engineers, Inc. and Uribe & Associates for CCSF's Bureau of Environmental Regulation and Management (BERM).

STUDY OBJECTIVES

The principal objectives of this study are listed below.

- Comply with San Francisco Bay Basin Regional Board Order No. 90-093 requiring an evaluation of the cost-effectiveness of implementing eight optional Best Management Practices (BMPs).
- Determine CCSF's primary constituents of concern by comparing the historic discharge concentrations with existing and pending water quality limitations for San Francisco Bay and the Pacific Ocean.
- Identify the probable sources of CCSF's constituents of concern and develop an estimate of pollutant mass loadings from industrial, residential, and commercial discharge sources.
- Develop and evaluate additional dry and wet weather source control BMPs to reduce the sewer loadings of problem pollutants as close to their source as possible.
- Determine whether recommended BMP implementation measures would provide sufficient reductions of targeted pollutants to comply with effluent discharge limitations without installation of costly end-of-pipe treatment facilities.

PROJECT BACKGROUND

CCSF operates and maintains a combined sewer overflow (CSO) system and three treatment facilities (Southeast Water Pollution Control Plant, Richmond-Sunset Water Pollution Control Plant, and North Point) to handle its wastewater and wet weather flows. The Richmond-Sunset Water Pollution Control Plant (RSWPCP) provides primary treatment for an average dry weather flow of 22 million gallons per day (mgd). After primary treatment, the effluent is discharged to Pacific Ocean through a 4.5 mile long ocean outfall. Currently, CCSF is constructing the new Oceanside Water Pollution Control Plant, which is expected to be operational in 1994. When operational, the new Oceanside facility will treat all the flows currently routed to the RSWPCP. The Southeast Water Pollution Control Plant (SEWPCP) provides primary and secondary treatment for a design ADWF of 85 mgd. The secondary effluent is discharged to San Francisco Bay through a deep water outfall at Pier 80 (Army Street terminal).

During dry weather, all wastewater flows are treated at RSWPCP and SEWPCP prior to discharge at their respective outfalls. During wet weather, when the combined sewage and stormwater exceed the capacities of the treatment and sewer transport facilities, overflows are discharged to shallow water, near-shore locations. Overflows from the RSWPCP service area are discharged via

VOL 12 2 4174

R0057466

8 shoreline stations. Overflows from SEWPCP service area are discharged to Islais Creek via a near shore outfall at Quint Street.

Elimination System (NPDES) permits in accordance with EPA requirements. In June 1990, RSWPCP received a revised NPDES permit (EPA Permit No. CA0037681/Regional Board Order No. 90-093) to operate. Among the new permit conditions, CCSF was required to implement ten best management practices (BMPs), to study the cost-effectiveness of implementing eight other BMPs suggested by the Regional Board, and to investigate additional measures to minimize the amount of pollutants in the wet weather overflows.

The eighteen BMPs identified by the Regional Board for implementation or further evaluation are educational, regulatory, and public agency source control measures designed to minimize the amount of pollutants from entering the waste streams. On October 1, 1990, CCSF submitted an Implementation Plan for the ten BMPs required by the Regional Board. These ten BMPs are referenced in this report as the "Mandated BMPs." An annual report has since been submitted in August 1991.

A study plan to evaluate the eight additional BMPs (referenced as "Optional BMPs" in this report) was submitted to the Regional Board on February 1991. The study plan described the methodology to evaluate these BMPs and a schedule for the evaluation process. This report is being submitted to the Regional Board in compliance with the study plan schedule. It includes an evaluation of the BMPs and recommendations for additional implementation measures.

The eighteen BMPs were originally intended to focus on wet weather overflows in the RSWPCP service area. However, subsequent developments have caused CCSF to expand the scope of this evaluation to include both wet and dry weather flows for the entire CCSF service area. First, in October 1991, a Regional Board order (Order No. 91-153) was issued to implement interim measures for the wet weather overflows at Islais Creek. These interim measures include expanded source control activities and stormwater BMPs for the SEWPCP service area. Therefore, CCSF decided to implement the appropriate BMPs for the entire service area.

Secondly, several recently adopted State and local statues have acted to focus the attention on dry weather concerns. In April 1991, the State Water Resources Control Board (SWRCB) adopted water quality control plans for inland surface waters (fresh water) and enclosed bays and estuaries (salt water). These water quality control plans were adopted in response to the 1987 Amendment of the Clean Water Act. Of these two plans, the Enclosed Bays and Estuaries Plan (EBEP) directly affects the SEWPCP discharge. The RSWPCP discharge is already regulated by the Ocean Plan and is not directly affected by either newly adopted plans.

A major element of these state-wide water quality control plans is the adoption of numerical water quality objectives for toxic substances mandated by the Clean Water Act. Section 303 (c) (2) (B) of the Clean Water Act requires the State to adopt water quality criteria for the Section 307 (a) priority pollutants for which EPA has published criteria. For 10 trace metals and 30 organic compounds, the EBEP adopted the EPA criteria to protect aquatic life and human health. The State Board is currently revising the EBEP to include numerical objectives for the other compounds on EPA's Section 307 list. Of the compounds currently on and being included in the EBEP, the metals and cyanide objectives would have the greatest impacts on SEWPCP.

In December 1991, the Regional Board revised the San Francisco Bay Basin Plan to include the provisions of the state water quality plans and to establish effluent limits based on the numerical water quality objectives. The Basin Plan has not yet been approved by the SWRCB. However,

VOL 12 2 4 1 7 5

R0057467

the numerical limits established in the Basin Plan are unlikely to change prior to approval, and are expected to be incorporated into the SEWPCP NPDES permit at its next renewal in June 1994.

source control measures and BMPs designed to reduce the discharge of pollutants to the maximum extent possible. Dischargers are allowed until April 1996 to implement these measures and evaluate their effectiveness. The utilization of BMPs to comply with these new effluent limits is similar to the approach for the wet weather overflows. Therefore, CCSF expanded the scope of this study to include an evaluation of BMPs to reduce specific pollutants of concern in the dry weather flows.

CCSF retained two consultants to prepare this report. James M. Montgomery, Consulting Engineers, Inc. (JMM) was retained to evaluate BMPs relating to dry weather flows and compliance with the new Basin Plan limits. Uribe & Associates (U&A) was retained to evaluate BMPs relating to wet weather overflows. The results and recommendations of both the dry weather and wet weather programs are described together in this report in order to consolidate the information and to present a unified and cohesive program.

REPORT ORGANIZATION

Following this introduction, Sections 2 and 3 of this report provide additional background information relevant to this source control evaluation study. Section 2 describes the existing CCSF wastewater service area conditions, including descriptions of the drainage basins and wastewater treatment facilities, and a discussion of the influent and effluent flows and pollutant loadings observed at these facilities. Section 3 describes the methodology and results of an environmental awareness telephone survey designed to provide insight into the need for, and the most effective means of, dispersing educational information vital to source control efforts.

Sections 4 through 6 discuss the selection, development, and evaluation of the dry weather BMPs. Section 4 describes the BMP selection process, which was based on a mass balance analysis of identified CCSF problem constituents, and extensive information collection efforts. Section 5 presents a detailed discussion of each of the selected BMPs. Section 6 presents an evaluation and ranking of the dry weather BMPs on the basis of cost-effectiveness and 11 non-economic evaluation criteria. Similarly, Sections 7 through 9 present the selection, development, and evaluation of the wet weather BMPs.

Finally, Appendices A through F contain the literature references, background materials, and supplementary information utilized during the BMP Study effort. The applicability of these supplementary materials is referenced within the text of this report.

SECTION 2

EXISTING SERVICE AREA CONDITIONS

compartments of up to 44 feet by 25 feet. The majority of the sewer lines are composed of clay pipe with mortared joints, while the larger transport structures are reinforced concrete. All but one percent of the CCSF's collection system serves as a combined sanitary-stormwater system, collecting stormwater runoff in the same set of pipes that transport sanitary waste. (JMM 1990) Commercial and industrial wastewaters are also serviced by this combined system.

This section presents background information on the CCSF service area, including a description of the sewer drainage basins and wastewater treatment facilities, an assessment of the influent pollutant loadings at the treatment facilities, and an evaluation of CCSF's historic effluent discharge performance relative to recently proposed water quality standards.

DESCRIPTION OF CCSF DRAINAGE BASINS

San Francisco's combined sewer system is divided into two drainage basins, referred to as the Bayside and Westside drainage basins. These basins correspond to the natural topographical drainage patterns of CCSF, and are serviced year-round by separate wastewater treatment facilities. The Southeast Water Pollution Control Plant (SEWPCP) services the Bayside drainage basin, while Westside drainage flows currently enter the Richmond-Sunset Water Pollution Control Plant (RSWPCP). During wet weather, a third treatment plant (the North Point plant), located in the Bayside drainage area, provides treatment for flows exceeding the capacity of the SEWPCP and CCSF's extensive new wet weather storage and transport combined sewer overflow (CSO) facilities. Figure 2-1 presents a layout of the CCSF service area, including the two drainage basins and their respective wastewater treatment facilities.

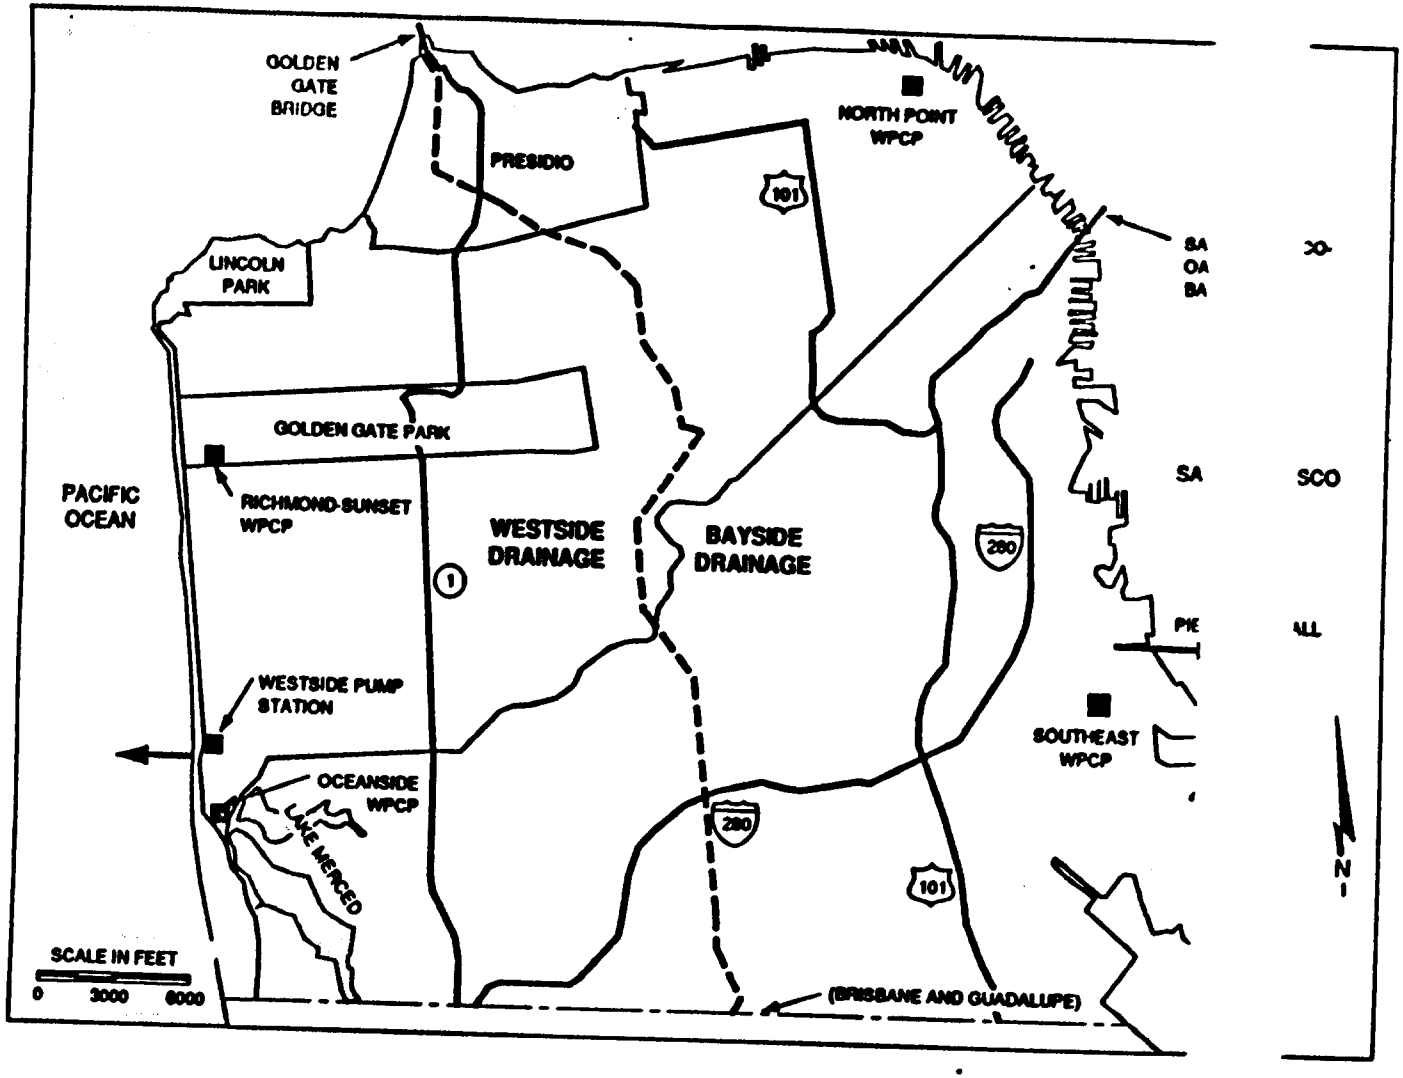
Bayside Drainage

The Bayside drainage, composed of the North Point and Southeast drainage areas, consists of nearly 19,000 acres, extending from the former marsh areas along the Bay to the steep hilly areas in the central and southern regions of the CCSF service area. The wastewater flow generated in this basin averaged approximately 62.2 million gallons per day (mgd) during 1991. This flow is composed of residential, industrial, and commercial discharges in addition to stormwater, groundwater, and bay water infiltration/inflows. During dry weather periods, the entire Bayside flows enter the SEWPCP for secondary treatment prior to discharge to San Francisco Bay. Wet weather flows in the north shore area of CCSF receive primary treatment at the North Point plant prior to Bay discharge once the capacities of the SEWPCP and the CSO storage and transport facilities are exceeded.

The Bayside drainage basin collects wastewater from 50 significant industrial users (SIUs). SIUs are defined under CCSF's industrial waste sewer use ordinance as being either subject to federal categorical standards; discharging greater than 25,000 gallons per day; contributing greater than 5 percent of the hydraulic or organic plant capacity; or discharging a wastestream that may otherwise impact the treatment facilities. These SIUs are regulated under CCSF's Industrial Waste Pretreatment Program (IWPP) and contribute approximately 4.35 mgd, or seven percent of the Bayside flow. (CCSF 1991A) The bulk of CCSF's unregulated industrial and commercial establishments are also located in this drainage basin, contributing an estimated 32.3 mgd (52

VOL 12 2 4178

R0057470



CCSF SERVICE AREA

FIGURE 2-1

R0057471

percent), of the Bayside flow. The remaining 41 percent of the Bayside flow (approximately 25.5 mgd) is estimated to be residential flow.

Ocean and past Lake Merced in the south. The average wastewater flow generated in this area was approximately 16.6 mgd in 1991. This flow currently enters the Richmond-Sunset WPCP for primary treatment prior to discharge via the 4.5 mile-long Southwest Ocean Outfall to the Pacific Ocean. This flow will soon be diverted to the new Oceanside Treatment Plant, scheduled for completion in 1994, which will replace the Richmond-Sunset Plant and provide secondary treatment prior to discharge out the same outfall.

Wastewater generated in this drainage area is principally residential flow. Based on a residential population of approximately 228,000, the residential flow is estimated to be 11.4 mgd, or 69 percent of the total influent flow into the RSWPCP. Only ten regulated SIUs (all hospitals) are located in the Westside basin, contributing less than 4 percent (0.6 mgd) of the influent flow. (CCSF 1992) A review of the June 1990 City zoning maps indicated that the commercial zones in this area are mostly limited to neighborhood commercial businesses and fast food restaurants. These businesses contribute an estimated 4.6 mgd (28 percent) of the RSWPCP influent.

REVIEW OF CCSF WASTEWATER TREATMENT PLANTS

This section describes the treatment processes and effluent requirements of the dry and wet weather wastewater treatment facilities. During dry weather conditions, wastewater flows are treated at the Southeast Water Pollution Control Plant (SEWPCP) and the Richmond-Sunset Water Pollution Control Plant (RSWPCP). A new Oceanside facility, currently under construction, will replace the RSWPCP in 1994. Wet weather flows in excess of dry weather treatment capacities are treated at the North Point wet weather treatment facility. Each of these facilities are described below along with a discussion of CCSF's staged response to increasing wet weather flow levels.

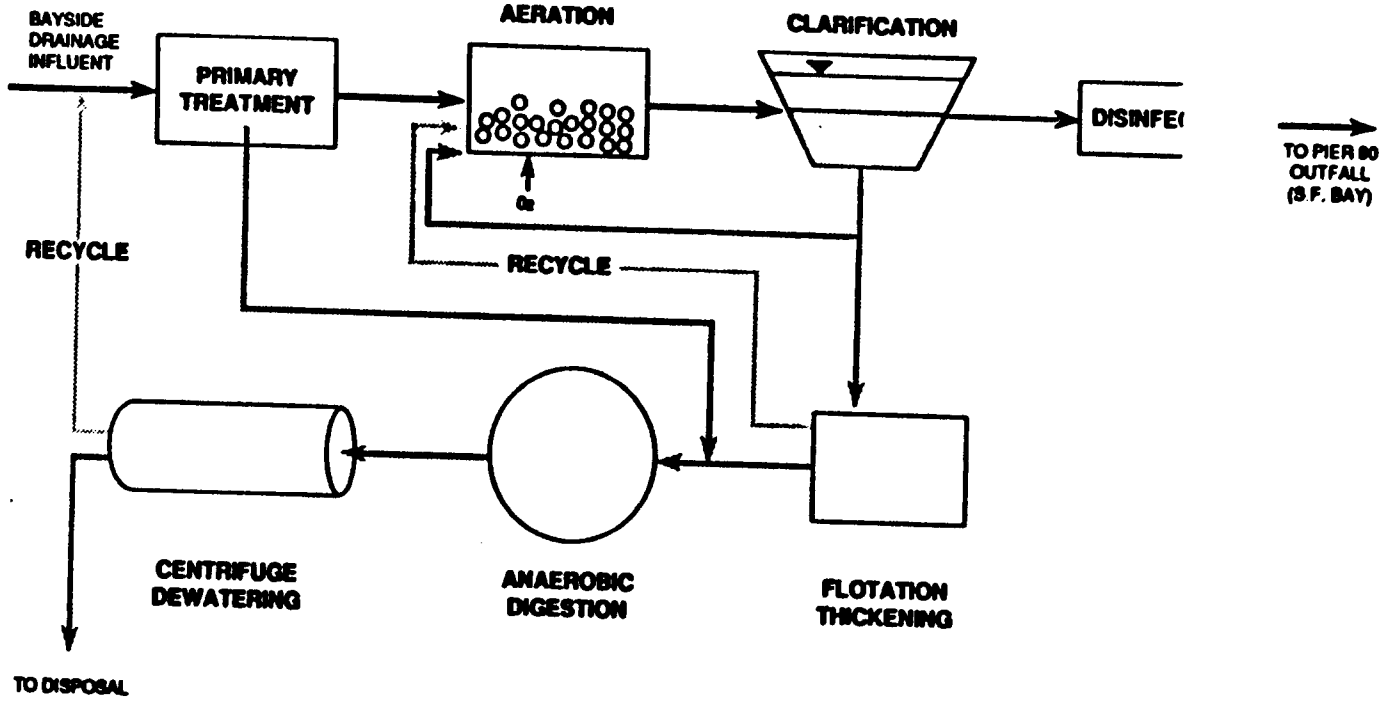
Southeast Water Pollution Control Plant (SEWPCP)

The SEWPCP is located near Hunters Point in the southeast section of CCSF (See Figure 2-1). The largest dry weather treatment plant in CCSF, the SEWPCP provides primary and secondary treatment for a design dry weather capacity of 85 mgd. During wet weather, the plant can provide primary treatment for a maximum flow rate of 210 mgd. In addition to serving CCSF, this plant treats flows from the Bayshore Sanitary District, Guadalupe Valley Municipal Improvement District, and a portion of the North San Mateo County Sanitation District.

The SEWPCP primary treatment process train consists of screening, grit removal, and sedimentation. Following these steps, secondary treatment consists of a high purity oxygen activated sludge system followed by final clarification and effluent disinfection with sodium hypochlorite (chlorination) and sodium bisulfite (dechlorination). Sludge treatment consists of dissolved air flotation (DAF) thickening, anaerobic digestion, chemical conditioning, and centrifuge dewatering. Figure 2-2 presents a schematic flow diagram of the treatment processes and the major recycle streams at the SEWPCP.

VOL 12 2 4180

R0057472



SCHEMATIC FLOW DIAGRAM FOR SOUTHEAST WPCP

FIGURE 2-2

R0057473

Richmond-Sunset Water Pollution Control Plant (RSWPCP)

Westside Transport to the Southwest Ocean Outfall for deep-water ocean discharge. Built in 1936, the RSWPCP is scheduled to be replaced in 1994 by the Oceanside plant, described below.

Oceanside Water Pollution Control Plant (OWPCP)

The OWPCP will be located directly south of the San Francisco Zoo, near the head of the Southwest Ocean Outfall. This plant will provide primary and secondary treatment for all of the Westside flow currently entering the RSWPCP and will have a design dry weather capacity of 43 mgd. (JMM 1990)

The process flow at the OWPCP will be very similar to that occurring at the SEWPCP. Primary treatment will include grit removal, screening, and sedimentation; secondary treatment will consist of high purity oxygen activated sludge followed by final clarification and effluent chlorine disinfection using sodium hypochlorite and sodium bisulfite. Sludge treatment at the OWPCP will consist of gravity belt thickening, anaerobic digestion, chemical conditioning, and belt press dewatering. (CH2M HILL 1988) Similar to the SEWPCP, the recycle streams at the OWPCP will return liquids from the sludge thickening and dewatering steps to the aeration basins and primary treatment facilities, respectively.

Wet Weather Flow Facilities

Due to CCSF's combined stormwater-sanitary sewer collection system, significant increases in wastewater flows occur during wet weather storm events. In the past, peak wet weather events have overloaded the collection systems and treatment plants, resulting in the discharge of untreated sewage to CCSF's shorelines. These overflows pose a potential human health risk from the release of pathogen-containing untreated sewage, and a potential threat to Bay and ocean water quality due to the significant quantities of particulates and toxicants, including heavy metals and organic compounds, that are contained in stormwaters.

To address these potential impacts from increased flows that occur during wet weather periods, CCSF has undertaken an extensive construction effort to prevent combined sewer overflows by installing pump stations and long, underground box-like storage/transport structures along the shorelines of CCSF. The CSO facilities are over 60 percent complete, and are expected to be completely operational by 1996. However, over 30 shoreline discharge events still occur each year. These discharges are primarily in areas where new CSO facilities have not yet been constructed. The following wet weather response measures occur at the onset of a storm:

- **Wet weather pump station startup.** Pump stations move the combined flows toward the treatment plants or to available storage/transports. Pumping rates are adjusted according to the specific patterns of individual rainfall events.
- **Increased treatment rates at SEWPCP and OWPCP.** The treatment rates at these facilities are increased to a wet weather (maximum) rate until the storm is over and the stored wastewater from the storage/transport structures has been treated.
- **Activation of North Point Facility.** This facility goes online during the storm and provides primary-level treatment and disinfection for northern area flows.

VOL 12 2 4 1 8 2

R0057474

- **Storage in the Storage/Transports.** Up to 193 million gallons of combined sewage and storm water is stored in these structures and in the sewer lines for later treatment.

discharge occurs to the ocean outfall. This decant discharge has received flow-through treatment within the storage/transport structure.

- **Shoreline Discharge from Storage/Transport Structures.** When all storage elements are full and rain continues, shoreline discharge occurs. This discharge consists of approximately 6 percent sewage and 94 percent stormwater, and has received flow-through treatment in the storage/transports. This flow-through treatment incorporates weirs and decant structures to minimize the suspended solids and floatable materials passing to the Bay or ocean.

INFLUENT FLOW CHARACTERISTICS

Although the zoning characteristics of the two drainage basins differ considerably, with the Westside drainage handling the bulk of the industrial and commercial flow, the composition of the influent wastewaters at the two treatment facilities is fairly similar. Table 2-1 lists the average 1991 concentrations of nine heavy metals and cyanide contained in the influent wastestreams of the SEWPCP and RSWPCP facilities. No cyanide data were available from the RSWPCP facility.

Based on approximately 25 data points taken at each facility during 1991, less than a fifty percent difference in the influent concentrations was observed for each of the nine metals at the two facilities. Arsenic and mercury concentrations were particularly comparable, with only a 3 and 7 percent difference, respectively. Lead, silver, and zinc concentrations were 38 to 46 percent higher at the SEWPCP, likely due to the greater industrial and commercial contributions of these metals. Chromium, nickel and cadmium concentrations at RSWPCP are slightly higher than at SEWPCP. This is somewhat unexpected given the lower commercial and industrial flows in the Westside drainage basin. However, the differences between the actual values are relatively minor and may not be statistically significant.

The influent concentrations of the nine metals observed at the RSWPCP and SEWPCP facilities during 1991 demonstrate a similar trend. In general, the two influents are fairly similar in terms of both average concentration and degree of variability throughout the year. Overall, the SEWPCP influent concentrations tend to be slightly higher and are characterized by more variability for the metals typically associated with commercial and industrial activity, such as silver, nickel, and lead. The data plots used for this comparison are contained in Appendix E for reference.

EFFLUENT DISCHARGE REQUIREMENTS

Wastewater discharges from the Bayside and Westside treatment facilities described above are required to meet the numerical effluent limitations contained in their respective National Pollutant Discharge Elimination System (NPDES) permits. Permit limitations are developed and enforced by the San Francisco Bay Regional Water Quality Control Board in consideration of the objectives and beneficial uses of the receiving waters. NPDES permits for Bay discharges from the SEWPCP are regulated in accordance with the San Francisco Bay Basin Plan (Basin Plan), while ocean discharges from the RSWPCP are subject to the California Ocean Plan.

Table 2-2 presents the NPDES effluent discharge requirements for constituents of concern from the SEWPCP and the RSWPCP/OWPCP outfalls. The Bay discharge limits were proposed by the

requirements will therefore be the driving force behind CCSF-wide source reduction measures. These daily average Bay discharge limits are geared towards dry weather discharge practices. There are currently no numerical limits for stormwater discharges from overflows of the CCSF CSO facilities.

Focus of BMP Efforts on SEWPCP Requirements

In light of the higher density of commercial and industrial facilities and the typically higher metals concentrations in Bayside influent flows, combined with the more stringent NPDES discharge standards applied to Bay discharges, the BMP investigative efforts focused on data obtained from the Bayside drainage basin and the SEWPCP. Where applicable, the BMP implementation steps resulting from analysis of these data will be applied to CCSF as a whole. Pollutant removal efficiencies occurring at the Bayside and Westside treatment plants can be expected to be similar as the treatment processes at the SEWPCP and the new OWPCP are identical.

SECTION 3

ENVIRONMENTAL AWARENESS SURVEY

This is a report of results obtained from the Public Research Institute's telephone sample survey of San Francisco households on the general topics of environmental awareness, perceptions of health risk awareness, perceptions of health risks associated with household toxic materials, the use and disposal of such materials, levels of support and willingness to pay for new disposal services and educational programs, sources of information on environmental problems, and views on the causes of water pollution. These survey findings should be useful in developing new educational programs, disposal services, and targeting strategies that meet Best Management Practices guidelines serving the needs of San Francisco residents.

SAMPLING AND METHODOLOGY

A random-digit sample of 2801 San Francisco telephone numbers was obtained from Survey Sampling, Inc. This sample provided a representative cross-section in our survey of all residential households with phones in the City of San Francisco. To increase the participation of non-English speaking households in the survey, the questionnaire instrument was translated into Spanish and Cantonese. Four bilingual interviewers were hired to conduct foreign language interviews by callback or appointment when initial contact with household respondents produced language difficulties in communication.

The interviewing took place during the period April 8-25, 1992. Interviews were conducted at the Public Research Institute's Computer Assisted Telephone Interviewing (CATI) facility. The questionnaire was programmed with the Sawtooth Software Ci2/CATI system for complete automation of data collection and call scheduling. Interviewing took place on weekdays from 10:00 AM to 1:00 PM and from 4:30 PM to 8:30 PM; and on Saturdays from 10:00 AM to 4:00 PM. The following table presents cumulative disposition codes at the end of the survey. Please note that the numbers in the table refer to numbers of calls, which may or may not be the same as the number of telephone numbers or households in a category. Each telephone number was called a maximum of 10 times.

Final Call Dispositions

	Count	Percent
No Answer/Busy/Answering Machine	3940	58.8
Call Back	691	10.3
Interview Complete	602	8.9
Not a Household	289	4.3
Refused Interview	566	8.4
Disconnected Number	526	7.8
Other	84	1.2
Total	6698	100.0

The final response rate was calculated by dividing the number of completed interviews by the total number of eligible respondents (completes plus refusals):

$$602 / (602 + 566) = .51$$

VOL 12 2 4 1 8 7

R0057479

The approximate numbers of interviews conducted in Chinese and Spanish were, respectively, 61 (10%) and 25 (4%). These were interviews that almost certainly would have been missed if the interviews had been conducted only in English.

Sampling Error

Given a total sample size of 602, the estimated sampling error for percentages is plus or minus 4% at the 95% confidence level. This means that we can be 95% sure that all San Francisco households would produce responses to survey questions within plus or minus 4 percentage points of the statistics for the total sample reported here. Sampling errors are larger for sample subgroups. Non-sampling errors that might result from poor question wording, non-response bias, data entry mistakes, etc., were minimized by means of extensive pre-testing of the questionnaire instrument, numerous callbacks, foreign language interviewing, and quality control supervision.

Comparisons of sample statistics with 1990 Census data for San Francisco indicate that sample respondents are demographically representative of the city's population in terms of gender, housing tenure, and race/ethnicity. For example, 48% of the sample respondents are male, 52% female -- virtually identical to the male/female ratio reported in the 1990 Census. Also, 35% of sample respondents are homeowners and 65% are renters. These figures exactly match the owner/renter ratio of 35/65 reported in the 1990 Census. Further, 55% of sample respondents are white and 45% are non-white, the latter group including 6% African Americans, 9% Latinos, 23% Asians, and 7% other or unknown. Comparable 1990 Census figures are 47% white and 53% non-white, the latter including 11% African Americans, 14% Latinos, 28% Asian, and less than 1% other or unknown. Since the racial/ethnic breakdown for the sample is based on adult respondents while the Census figures are for the total population, and since the total population includes higher proportions of non-whites among children, we are confident that the racial/ethnic composition of sample respondents is very similar to that of San Francisco's adult population.

To allow a breakdown of survey results by geographic area, sample respondents were coded into one of six (consolidated) Pacific Bell central station jurisdictions defined by telephone prefix numbers. In the Map that follows, the city neighborhoods located within each area are shown in the accompanying legend.

The raw counts and percentages obtained for each question asked in the survey are provided in the Appendix along with the complete text of the questionnaire itself. In this main report we provide an overview of the survey results and summarize the findings of crosstabulations and logistic regression analyses under the following headings: (1) use and perceived risk of household toxic materials; (2) levels of environmental awareness; (3) disposal practices; (4) willingness to pay for disposal services and educational programs; (5) perceived sources of water pollution in San Francisco; (6) sources of news and information about environmental issues and problems; (7) neighborhood differences in survey response, and (8) implications of the survey results for educational programming and targeting strategies.

Before discussing those findings, however, it is necessary to provide a brief explanation of logistic regression and of the odds-ratios it produces as output for analysis. (The reader who is familiar with these methods can skip directly to the next section.)

VOL 12 2 4188
R0057480

A Note on Logistic Regression and Odds-Ratios

Logistic regression is a powerful statistical method that allows one to measure the separate and

A major advantage of logistic regression over standard two-variable cross-tabulation is that it allows multivariate analysis with rigorous statistical controls. Thus the effects of a given factor (e.g., homeownership) on opinion or behavior can be estimated from the data while statistically controlling for the potentially confounding effects of other factors (e.g., race, gender, age, income). For example, consider the possible confounding effects of race on an analysis of the relationship between house paint use and homeownership. Cross-tabulations might show (a) that whites are more likely than nonwhites to use house paint, and (b) that homeowners are more likely than renters to use house paint. If the cross-tabulation analysis also shows (c) that whites are more likely than nonwhites to be homeowners, it could be that racial differences are only indirectly linked to variations in house paint use as a result of the links between race and homeownership and between homeownership and house paint use. In other words, whites tend to be homeowners, and homeowners tend to use house paint, thus interpreting the relationship between race and house paint use. But it could also be that race has a direct effect on house paint use separate from its indirect effect via homeownership. Cross-tabulation analysis is an unwieldy tool for sorting out the separate effects of race and homeownership in this example. Multivariate logistic regression is superior to cross-tabulation because it allows estimation of the independent direct effects of many different factors simultaneously.

One measure of effect that can be estimated from survey data using logistic regression is the "odds-ratio." Analogous to betting odds at the race track, the *odds* that something will happen are calculated simply by dividing the probability (P) that it will happen by the probability (1-P) that it will not happen. For example, if there is a 20% probability that John Q Resident uses house paint and an 80% probability that he does not, the odds that he uses house paint are .25 (i.e., .2/[1-.2] =.2/.8 = .25). In the case of dichotomous variables such as gender (female/male) or housing tenure (own/rent), the *odds-ratio* is simply the ratio of the odds that a member of one group (e.g., females) does something to the odds that a member of the complementary group (i.e., males) does that same thing. For example, if the odds that females use house paint are .25 and if the odds that males use house paint also are .25, then the odds-ratio for females (versus males) is .25/.25 = 1.00. In other words, the odds are exactly the same for females as for males, i.e., there is no correlation between house paint use and gender. An odds-ratio less than 1.00 would indicate (in this example) that females are less likely than males to use house paint. An odds-ratio greater than 1.00 would indicate that females are more likely than males to use house paint.

If the logistic regression model includes several predictors simultaneously (e.g., gender and race and housing tenure), the odds-ratio estimated for a given predictor is statistically adjusted for the possible confounding effects of other predictors in the model. In such a multivariate logistic regression, for example, an odds-ratio of 2.00 for the predictor "female" would indicate that females are twice as likely as males to use house paint whether they are white or non-white, homeowners or renters.

Since the odds-ratios reported below are estimated from sample survey data, sampling error must be taken into account when evaluating their statistical significance. The so-called "null hypothesis" is that the (unknown) odds-ratio for a given predictor for all households in the survey population is 1.00 and that a sample odds-ratio different from 1.00 merely reflects the luck of the draw. Only if $p < .10$ for the sample odds-ratio can we reject the null hypothesis. In what follows, odds-ratios that appear with an asterisk (*) are considered statistically significant at the $p < .10$ level. In non-

VOL 12 2 4189

R0057481

technical terms, an asterisk means there is less than a 10% chance that an odds-ratio of that magnitude could have been obtained for a sample of this size drawn randomly from a population of households in which the odds-ratio is in fact 1.00. Although the odds-ratio reported for some

USE AND PERCEIVED RISK OF HOUSEHOLD TOXIC MATERIALS

As shown in Figure 3-1, the toxic materials most commonly found in San Francisco households are nail polish removers (51% of households), motor oil (47%), drain cleaners (47%), and house paint (42%). Least common are root eradicators (3%) and chemicals for photography (3%). Given the potent toxicity of photographic chemicals, it is worth noting that even this small incidence of household use can produce a large problem of waste management when aggregated over all San Francisco households. For example, although only 3.3% of sample households (20 respondents) reported use of photographic chemicals, that same proportion multiplied by San Francisco's 305,584 households yields an estimated aggregate total of 10,084 household users of such chemicals. Placing 95% confidence intervals around that estimate, we can be very confident that at least 5,500 households use such chemicals and possibly as many as 14,900.

What types of San Franciscans are most likely to use each of these household toxic products and materials? Here and throughout this report we systematically examine the impacts of seven different sociodemographic factors in shaping patterns of product use and perceptions of health risk. These factors are: gender, age, housing tenure (owner/renter status), education, income, race, and area of residence. (One additional factor we considered, length of residence, is strongly correlated with respondents' age and so was dropped from analysis.) The respondent's area of residence is an important predictor of some practices and opinions, and we discuss these findings at different places in the text and in the next to last section of this report. On the whole, however, few significant geographic differences were observed in our survey findings.

Table 3-1 summarizes the results of a multivariate logistic regression analysis of reported levels of use of household toxic products and materials.

As shown in Table 3-1, the use level predictors analyzed are gender (female=1, male=0), age (40+ years=1, less than 40=0), housing tenure (owner=1, renter=0), education (college degree or graduate work=1, high school or some college=0), income ($40,000 or more=1, less than $40,000=0), and race (each non-white race [African American, Latino, Asian, and Other] also measured by so-called "dummy" variables -- i.e., those measured as 0 or 1). This same set of predictor variables will be used repeatedly in the analyses that follow here and throughout the text.

To illustrate how to "read" the odds-ratios produced by the logistic regression analysis, look at the row for "Motor Oil" use. Reading across the row of numbers, females are about seven-tenths as likely as men (odds-ratio=.71) to report using motor oil; older respondents are about one-third as likely as younger respondents (odds-ratio=.37) to report using motor oil; and home owners are nearly twice as likely as renters (odds-ratio=1.79) to report using motor oil. These are the only odds-ratios shown for motor oil use that are statistically significant (i.e., are unlikely to be the result of sampling variation). These estimated effects of gender, age, and housing tenure on motor oil use are statistically adjusted for the possible confounding effects of other variables in the model. Thus we can be confident in this case that the odds-ratio for "40+ years" is not merely masking the effects of some other variable, such as race. For any race, for any gender, for any housing tenure, the estimated odds-ratio for respondents who are "40+ years" remains .37 in this case. With this discussion as background, we turn now to interpret the results of Table 3-1.

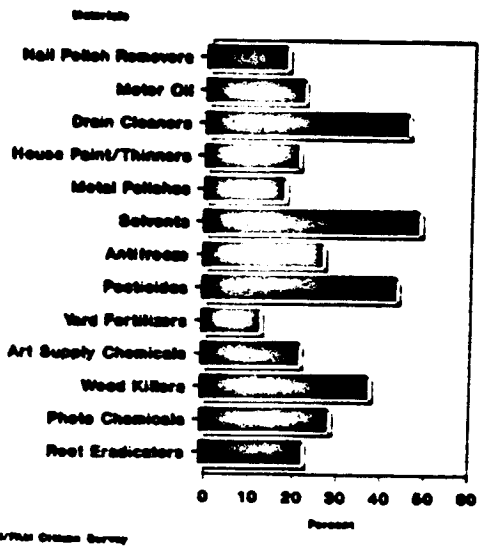
Percent of San Francisco Households
That Perceived a "Great" Risk



VOL 12 2 4192

R0057484

With a focus on statistically significant predictors, we see in Table 3-1 that: (1) Homeowners are more likely to use pesticides than are renters, and Asians more than Whites. (2) Females are less likely than males to use weedkillers, older respondents more likely than younger ones, homeowners more than renters, and Asians more than Whites. (3) More educated respondents are

solvents, homeowners are nearly four times as likely as renters to use such products, and Asians are about half as likely as Whites to use them. (6) Females also are much less likely than males to use house paint, homeowners are much more likely than renters, and Asians are less likely than Whites. (7) As discussed in the example above, females are less likely than males to use motor oil, older respondents much less likely than younger ones, and homeowners more likely to do so than renters. (8) No statistically significant predictor is found for antifreeze use, which might suggest that patterns of antifreeze use are very diffuse throughout all social classes, races, etc. (9) Older respondents are more likely than younger ones to use metal polish, homeowners more than renters, and Blacks, Asians, and Other Races much less likely to do so than Whites. (10) Females are about three times more likely than males to use nail polish, homeowners nearly twice as likely as renters, and there are no other predictors. (11) College-educated respondents are more likely to use drain cleaners than are the non-college-educated, and Hispanics more than Whites. (12) Females are about one-fourth as likely as males to use photochemicals, and that is the only significant predictor. (13) College-educated respondents are more likely than the non-college-educated to report using arts materials. Reviewing these findings as a whole, we see that gender, housing tenure, and Asian race are the most consistent predictors, followed by age and education. Interestingly, income differences are a consistently poor predictor of use of these products.

Are use levels of household toxic products higher in households that have gardens and yards, or that have garages used for storage or workshops? Table 3-2 provides some answers from our sample survey data. Maintaining a yard or garden appears to be linked to greater use of weedkillers, yard fertilizers, root eradicators, house paint, motor oil, antifreeze, and metal polish. Having a garage that is used for storage is linked to greater use of yard fertilizers, solvents, house paint, motor oil, antifreeze, metal polish, and nail polish remover. Garage owners who say they use their garage as a workshop are more likely than those who do not to make greater use of solvents, paint, oil, antifreeze, nail polish remover, and art materials. It should be noted here that all three sets of findings are bound to be linked to homeownership: 88% of homeowners have garages compared to only 31% of renters, and 81% of homeowners have yards and gardens compared to only 49% of renters. (Interestingly, renters with garages are nearly as likely as homeowners with garages to use them as workshops: 23% versus 26%.)

Figure 3-2 shows the variation among respondents in assessing the health risks associated with product use. Survey respondents perceived that "great risk" was associated most with solvents (49%), drain cleaners (46%), pesticides (44%), and weed killers (38%). Figure 3-2 also reveals that many respondents felt completely ignorant or uninformed about the risks associated with some products and materials. For example, although only 22% of the total sample perceived a "great" risk in using motor oil, 24% admitted they simply did not know what the risks might be. In the case of risks associated with photographic chemicals, fully 41% of sample respondents said they did not know. Although only 29% of the total sample said the risk was great, that figure jumps to 41% if the "don't knows" are excluded from the calculations.

VOL 12 2 4194

R0057486

Table 3-3 summarizes information from our survey about perceptions of health risks associated with different household toxic products. Regarding each product, respondents were asked whether they thought it posed a very slight, moderate, or great health risk. Table 3-3 shows the odds-ratios obtained from logistic regressions predicting the probability that respondents would say "don't

Females are about half as likely as males to see only a "slight" risk in the use of pesticides, weedkillers, motor oil, and antifreeze, and are about two-thirds as likely to do so with yard fertilizers. Age differences are not linked to variations in perception of risk by this measure. Homeowners are more likely than renters to see only a "slight" risk in the use of pesticides and house paint. Educational differences do not appear to be much of a factor in shaping risk evaluations, except in the case of solvents. College-educated respondents see less risk in using root eradicators than do the non-college educated. Upper-income respondents are more likely than lower-income respondents to see only a slight risk in using yard fertilizers and nail polish removers, but they are less likely to do so in use of solvents and drain cleaners. Racial differences in risk perception are not apparent except for the case of Asians, who are more inclined than Whites to see only a slight risk in using pesticides, root eradicators, drain cleaners, and photo chemicals. It is interesting and also somewhat surprising that age and education appear to play hardly any role in risk perception regarding use of these products.

Survey respondents had the option of simply saying "don't know" in making risk assessments of these products. In the case of some products the percentage saying "don't know" was large: 45% said this about root eradicators, for example, and 41% admitted ignorance about the risks of photo chemicals. As a check on the correlates of self-admitted ignorance about health risks, Table 3-4 shows the odds-ratios obtained from logistic regressions predicting the probability that respondents would say "don't know" when asked to assess the risk of using each product.

Several conclusions can be drawn from the results shown in table 3-4. For example, upper-income respondents are consistently less likely than lower-income respondents to say "don't know." (Conversely, this means that lower-income respondents are more likely than upper-income respondents to do so.) Further, older respondents are much more likely than younger ones to say "don't know" when assessing risks, particularly in the case of weedkillers, fertilizers, root eradicators, solvents, paint, motor oil, art materials, and especially antifreeze. Homeowners are three times as likely as renters to express ignorance about the risks of pesticides. Females are more likely than males to say they did not know the risks associated with paint, motor oil, antifreeze, and drain cleaners. Although all but one of the odds-ratios for college-educated are below 1.00, none is significant. Once again, racial differences are not a factor predicting this response, except for Asians, who are consistently more likely than Whites to express uncertainty about the risks associated with pesticides, weedkillers, yard fertilizers, solvents, antifreeze, nail polish remover, drain cleaners, and art materials. In our interpretation of these results, we cannot rule out the possibility that certain groups of respondents are simply more honest than others about admitting a degree of ignorance which others might feel, yet are afraid to divulge.

[a]Note: The general model tested is Prob { Y = "Don't Know" } = 1/(1+exp(-(XB))), where Y = estimated probability will answer "Don't Know" to a question about a product's health risk, X is a vector of dummy variable predictors, and logistic regression coefficients estimated using maximum likelihood methods on sample survey data. Entries are estim for specified groups indicating the likelihood that members of a specified group (e.g., females) will answer "Don't K that same likelihood for a reference group (e.g., males). An odds-ratio of 1.0 indicates that the relative likelihoo reference group are equal. The odds-ratios shown are for females vs. males, older vs. younger, home owners vs. income vs. lower income, Hispanics vs. Whites, Blacks vs. Whites, Asians vs. Whites, Other Races vs. Whites. The Whites (the racial reference group) are 1.00 in all cases. These estimated odds-ratios are statistically adjusted for the ef predictors. The Pseudo-R^2 measures the model's goodness-of-fit. Sample n = 439.

LEVELS OF ENVIROMENTAL AWARENESS

Based on the evidence of our survey results, the level of environmental awareness and concern about pollution is very high in San Francisco. Examples:

important reason for doing so.

2. 59% of respondents said that they "always" read the product label for warnings and directions when using products like pesticides, house paint, and cleaners -- and another 15% reported that they do so "most of the time."

3. 27% of respondents said they "always" make a special effort to purchase items that are non-toxic or environmentally safe, and an additional 33% claimed to do so "most of the time".

4. Nearly half (48%) of all respondents said they were aware of Proposition 65, which required producers to place warning labels on products containing chemicals known to cause cancer.

5. Nearly two out of five respondents (39%) said they were aware of the Household Hazardous Waste Collection Facility (HHWCF). Of those who were aware of the HHWCF, 41% reported that they had taken something to that facility over the last year. (Note: these figures include the 63 respondents who spontaneously mentioned taking materials to the HHWCF as a method of disposal in answers to Questions 5-11.)

6. Nearly nine out of ten respondents (88%) said they were aware of the curbside recycling pick-up in their neighborhoods. Of those who were aware of that program, 91% reported that they normally put things out to be picked up.

7. 70% of respondents said they were aware of the fact that materials such as used motor oil and paint cannot be removed by water treatment plants and that these materials end up in the Bay or Ocean if poured down the drain or otherwise improperly disposed of.

8. Nearly one out of six respondents (16%) said that at least one household member belonged to an environmental organization.

9. One final indicator of environmental awareness and concern is the fact that 56% of respondents said "yes" when asked whether they would like the phone number of the City's Hazardous Waste Hotline to get information on proper disposal of household toxic materials.

DISPOSAL METHODS; APPROPRIATE AND INAPPROPRIATE

Respondents who reported that they used certain products around the home during the past year were asked how they "normally" disposed of old, excess or leftover quantities of that product. This follow-up question was asked specifically about six products: motor oil, antifreeze, house paints, pesticides, art supplies, and photographic chemicals. Figures 3-3A through 3-3F visually summarize the frequency distribution of disposal practices for each of these products.

Cross-tabulation Results: A Summary:

Cross-tabulations were calculated to detect variations in disposal practices according to housing tenure. There was statistically significant variation in motor oil disposal practices only with regard to neighborhood location, race, and gender. There was no statistically significant variation with regard to income, education, age, length of residence, or housing tenure.

With regard to motor oil disposal and neighborhood location, residents in neighborhoods 3 and 4 were more likely to take their used motor oil to the hazardous waste facility than were residents in other neighborhoods. Twenty-seven percent in neighborhood 3 and eighteen percent in neighborhood 4 used the facility in comparison with the fourteen percent overall average.

With regard to motor oil disposal and race, whites were more likely to use the hazardous waste facility than were members of other racial groups. Whites were also more likely to take used oil to a gas station. With regard to gender, men were more likely to use the hazardous waste facility than women.

Question 6 asked how used anti-freeze was disposed of, and responses to this question were broken down according to the same neighborhood and demographic characteristics. There was no statistically significant variation in anti-freeze disposal practices with regard to neighborhood location, income, education, race, age, length of residence, or housing tenure. With regard to gender, women were much more likely not to know how their household disposed of anti-freeze than were men.

Question 7 asked how used paints and thinners were disposed of, and responses to this question were broken down according to the same neighborhood and demographic characteristics. There was statistically significant variation in paint and thinner disposal practices according to income and housing tenure status, but there was no statistically significant variation according to neighborhood location, education, gender, race, age, or length of residence. Households with higher incomes and homeowners were more likely to use the hazardous waste facility than were households with lower incomes or renters.

Other questions were asked about the disposal practices for pesticides, yard fertilizers, art supplies, and photographic chemicals, but in all of these cases there were not enough responses to calculate statistically meaningful cross-tabulations.

Patterns and correlates of "inappropriate" disposal practices:

"Inappropriate" disposal methods include pouring excess or leftover materials on the ground, down the street drain, down the kitchen or bathroom drains, burying such materials, or placing them in the trash. Forty-eight percent of survey respondents who used art products reported one of these inappropriate practices in normally disposing of excess of leftover materials; 45% of photo chemical users reported the same (but note the very small n of 20), 28% of pesticide users, 22% of paint users, 10% of motor oil users, and 8% of those who used and disposed of antifreeze.

Table 3-5 reports breakdowns of the incidence of inappropriate disposal practices of motor oil and house paint by area of residence and by selected sociodemographic categories.

Based on these cross-tabulations, no clear pattern can be seen linking housing tenure, length of residence, income, or gender to inappropriate disposal practices in the case of oil and paint. Sample respondents living in Area 5 appear to show an unusually high rate of using inappropriate practices

VOL 12 2 4203

R0057495

to dispose of motor oil, and those in Area 4 show an unusually low rate of using inappropriate practices to dispose of house paint. The cross-tabulations also suggest that race, age, and education are predictors of inappropriate disposal practices in the case of oil or paint or both. Multivariate

likely to do so than younger respondents. In the case of paint, older respondents are more likely than younger ones to use inappropriate disposal practices, and college educated respondents are less likely to do so than those who lack a college degree. None of these results is statistically significant at $p < .10$, however, because of the small sample sizes involved. (The estimated odds-ratio of .51 for the College Degree + comes closest to statistical significance [$p < .102$] in predicting inappropriate practices in disposing of house paint.

Drain/ground disposal versus trash disposal:

Inappropriate disposal methods that pose a particular danger to the Bay and Ocean include pouring hazardous substances down the drains or on the ground. Relatively small fractions of survey respondents reported using these particular disposal methods. Only 2% of users said they practiced such methods to dispose of motor oil and pesticides; 5% in disposing of paints; 6% in disposing of antifreeze; and 8% in the case of art materials. Although 35% of photo chemical users reported using these methods, the actual number doing so is small (7 out of 20 in the sample).

Under the category of inappropriate disposal practices, trash disposal is the method used most often by users to dispose of unwanted motor oil and house paint in unsafe ways. Of the 282 responses received from motor oil users regarding disposal practices, 27 reported "inappropriate" disposal practices as defined above, and 21 of those 27 (78%) said they used trash disposal as their normal method. Of the 251 responses received from house paint users regarding disposal practices, 54 reported "inappropriate" disposal practices, and 39 of those 54 (72%) said they used trash disposal as their normal method. To convey a rough estimate of the aggregate numbers of households using these inappropriate practices in disposing of motor oil and house pain, we can use the sample proportions as multipliers on the total population of 305,584 households. Here are the results (with 95% confidence intervals) for inappropriate disposal practices generally and for trash disposal in particular:

MOTOR OIL:

Proportion of total sample respondents (602) who:

use inappropriate disposal methods: .045.
use trash disposal methods: .035.

Estimated number of households that:

use inappropriate disposal methods: 13,706 (8,679 to 18,824).
use trash disposal methods: 10,660 (6,173 to 15,157).

HOUSE PAINT:

Proportion of total sample respondents (602) who:

use inappropriate disposal methods: .090.
use trash disposal methods: .065.

VOL 12 2 4204
R0057496

Estimated number of households that:
use inappropriate disposal methods: 27,411 (20,444 to 34,378).
use trash disposal methods: 19,797 (13,782 to 25,822).

[illegible] questions about normal disposal methods.

As noted earlier, 71% of survey respondents said that they were aware that materials like motor oil and paint cannot be removed by water treatment plants when poured down any drain and that these substances eventually flow into the Bay or Ocean. Is such awareness linked to safer disposal practices as reported by our respondents? Table 3-6 compares rates of "inappropriate" disposal practices for those who said they were aware of the consequences with those for respondents who admitted they were not aware.

As shown in Table 3-6, the differences in rates are small but are all (with one exception) in the right direction. These results suggest that educational programs promoting environmental awareness have the potential to make at least marginal improvements in reducing the incidence of dangerous disposal practices. Further, although the rate differences are small, they could have a sizeable aggregate impact on the city's 305,000 households. (To illustrate, if we assume that the rates shown in Table 3-6 hold for all the city's households, and if we assume that educational programs could reduce the rate of drain/ground disposal of motor oil from the rate of 4.48% to a rate of 1.42% (see Table 3-6), calculations reveal that more than 1,000 households would cease this dangerous practice.)

Use of HHWCF

Of particular interest under the heading of disposal practices are reports of use of San Francisco's new Household Hazardous Waste Collection Facility (HHWCF). The percentages of survey respondents who reported disposing of excess or leftover materials at the HHWCF range from a low of 5% (photo chemicals) to a high of 18% in disposing of house paints. Seven percent of pesticide users reported that they "normally" use the HHWCF to dispose of unwanted pesticides, 11% of those using arts materials, and 13% of motor oil users. These utilization rates were obtained from spontaneous open-ended answers to questions about normal disposal practices. Respondents who did not mention the HHWCF in describing normal disposal methods were asked later in the interview whether they were aware of the HHWCF and, if so, whether they had used it for anything during the past year. Combining these two sets of responses (spontaneous open-ended plus follow-up), the actual level of awareness of the HHWCF is 41% and the reported utilization rate is 19% for the entire sample.

Table 3-7 reports these HHWCF awareness and utilization rates broken down by area of residence (see Map later in this report) and by various sociodemographic categories. As shown in Table 3-7, there are significant variations in awareness and use of the HHWCF by area, owner/renter status, length of residence, and race. Figure 3-4 shows a stacked bar graph indicating the percentage of respondents in each of the six city areas who reported (1) using the HHWCF, (2) being aware of the HHWCF but not using it, and (3) being unaware of the facility. It is clear that respondents living in Areas 3 and 4 in the southern part of the city nearer the facility are both more aware of it and are more likely to use it than are those living in other parts of the city.

Of the three factors found to be linked to awareness and use of the HHWCF, those of housing tenure and race hold up even controlling for area of residence. Table 3-8 breaks down awareness and utilization rates (1) by owner/renter status and (2) by white/non-white race (African American, Latino, Asian and Other) within each area. As shown, independent of the area of residence,

R0057501

respondents who are homeowners and/or who are white are more likely to be aware of the HHWCF and to use it than are renters and/or non-whites (African Americans, Latinos, Asians and Other).

When asked whether they would use a curbside pick up service for motor oil and latex paint if it were offered, 71% of the survey respondents said that they definitely would use it and another 5% said maybe. Of those who said they definitely would use it, 83% said they would be willing to pay the city and extra 25 cents each month for this new service. And of those who would be willing to pay the 25 cent/month fee, 71% said they would be willing to go as high as 50 cents/month. These results indicate solid support for such a new expanded pick up service backed up by a substantial willingness to pay for it.

The breakdowns shown in Table 3-9 reveal that the popular support for such a new service (and the willingness to pay for it) is spread fairly evenly throughout the city, although owners appear to be a bit more enthusiastic than renters, and men appear more supportive than women.

Survey respondents also were quite supportive of greater efforts on the part of the city to do more to improve water quality in the Bay and Ocean (77%), to do more to promote awareness of toxic materials and their disposal (84%), and to do more to regulate practices involving toxic materials and their disposal (77%). Further, 80% of those who support these programs would be willing to pay 25 cents each month for them, and of those who would pay this much, 76% would be willing to pay 50 cents a month.

The breakdowns in Table 3-10 show that these levels of support are high in all parts of the city and in all sociodemographic groups, although older respondents were noticeably less enthusiastic than were younger ones.

Given the importance of the community's willingness to pay for these kinds of new services and educational programs, a more rigorous multivariate analysis of the responses is required before drawing any firm conclusions. The logistic regression analyses reported in Table 3-11 provide this. As shown by the odds-ratios under each "model" in Table 3-11, respondents who live in Area 5 are particularly more likely than those who live in Area 1 (the reference group) to support and pay for these various programs. The only other factor that predicts support or opposition is age (see results under models 1 and 3), in this case indicating that older residents (everything else the same) are about two-thirds as likely as younger residents to be willing to pay the 25 cents/month fee. On the whole, the results shown in Table 3-11 corroborate the evidence presented earlier indicating citywide support for these programs in almost all areas and in almost all social classes and racial/ethnic groups.

PERCEIVED SOURCES OF WATER POLLUTION

To provide a different perspective on the community's environmental awareness, survey respondents were asked to estimate the contribution of several different entities (households, government offices, auto mechanic and body shops, hospitals, manufacturing business, and commercial businesses) to water pollution. Figure 3-5 shows clearly that respondents view household residents themselves as a relatively minor contributor to water pollution compared to the perceived importance of manufacturers, commercial businesses, auto shops, and hospitals.

R0057505

Table 3-12 shows the results of a logistic regression analysis predicting the probability a respondent would consider a given entity's contribution to be "large." As seen in Table 3-12, no factor predicts in the case of households as contributors to pollution -- i.e., the perception that

likely than Whites to blame hospitals. Females are less likely than males to blame manufacturing businesses, as is true of Asians compared to Whites. On the other hand, upper-income respondents are more likely than lower-income ones to blame manufacturers for the pollution. Upper-income respondents are more likely than lower-income respondents to blame commercial businesses, and Asians are less likely than Whites.

SOURCES OF INFORMATION ABOUT ENVIROMENTAL PROBLEMS

When asked about their primary source of information on environmental problems and issues, 42% of survey respondents mentioned newspapers, 21% television, 7% magazines, 3% word of mouth, 2% radio, and 21% "other." The large "other" category certainly includes information gained through participation in environmental groups and organizations, a category which we now realize should have been included in the questionnaire. Evidence for this is the fact that 34% of the 95 respondents who said they belonged to an environmental organization picked "other" as their main source of information as compared with only 20% of those who do not belong to such organizations.

Table 3-13 reports the results of a logistic regression analysis predicting choice of newspapers, television, and "other," respectively, as the primary source of information. An analysis also is shown predicting membership in environmental organizations. Non-white respondents, particularly Hispanics and Asians, are less inclined to rely upon newspaper than are Whites and are much more inclined than Whites to rely upon television for information about the environment. Homeowners are less likely than renters to rely upon newspapers and more likely to use television. Upper-income and college-educated respondents are more likely to rely upon newspapers than are lower-income and non-college-educated respondents, respectively. Members of environmental organizations are less likely than non-members to rely either upon newspapers or television and are three times more likely to rely upon "other" sources of information. Based on the results shown in the last column of Table 3-13, Asians are only a fifth as likely as Whites to join environmental organizations (also note the low odds-ratios for Hispanics and Blacks), college-educated respondents are nearly three times more likely than the non-college-educated to join such organizations, and upper-income are more than twice as likely than lower-income respondents to join.

NEIGHBORHOOD DIFFERENCES IN THE SURVEY RESPONSE

Six areas of the city were studied in this survey (see map below). Table 3-14 gives each area's profile of descriptive social statistics and illustrates considerable variation among the six areas in social and ethnic composition. Table 3-15 gathers together the main survey results that appeared to be correlated with area of residence. These include area variations in use of weedkillers, yard fertilizers, and house paints (clearly linked to high levels of homeownership in Areas 3 and 4), in methods normally used to dispose of motor oil (greater use in Areas 3 and 4 of the HHWCF due to its proximity), and greater awareness in Areas 3 and 4 of the polluting effects of dumping toxic substances down drains. Other findings linked to area of residence were discussed earlier in this report.

VOL 12 2 4219

R0057511

IMPLICATIONS FOR EDUCATIONAL PROGRAMMING AND TARGETING STRATEGIES

questions. We conclude that a special targeting strategy aimed at specific groups or particular neighborhoods would not yield substantially better results than a broad based, city-wide strategy.

While San Franciscans generally have a high level of environmental awareness as indicated in this report, many respondents are still unsure about the degree of risk associated with the handling and disposal of common household products. Small percentages of respondents appear to dispose of household toxic products in particularly harmful ways, but as shown earlier in this report, awareness of the consequences of improper disposal tends to reduce its occurrence. Clearly there is potential here to increase public awareness and improve practices through a broad based educational program.

In a few limited instances, special targeting might be appropriate. As noted earlier, respondents who reside in Areas 3 and 4 in the southern part of the city were both more likely to be aware of the HHWCF and to dispose of toxic materials there. Figure 4 showed that more than half of the residents in the other areas of the city were unaware of the HHWCF and over 80% said they had never used it. If unused capacity exists, an educational outreach program to make residents aware of the HHWCF could increase use of that facility.

There is little apparent variation throughout the city in the generally high level of enthusiasm for curbside pick up of oil and paint. Nor is there much variation in the willingness of residents to pay additional fees for this added service. Consistent with this, there is also little variation by area or demographics in the tendency of residents to support "more" city efforts to improve water quality and promote environmental awareness. Our survey demonstrates an evident willingness to pay for these efforts. Again, this suggests that a broad based, city-wide educational effort would be most effective, and that there are no particular neighborhoods or groups in need of special targeting.

When it comes to choosing which media to use to reach certain demographic groups in educational outreach programs, the survey results do provide some guidance. In terms of where respondents received news and information on environmental issues, there was meaningful variation according to social class, race/ethnicity, and environmental activism. Respondents who reported higher income and education levels are more likely to read newspapers for information on environmental issues; those reporting lower levels of income and education rely more upon television. The environmental activists interviewed in our survey clearly rely on neither of these, preferring the information channels provided by their environmental organizations and activities. This suggests that both print and broadcast media should be used selectively, perhaps in joint efforts with environmental groups, to promote citywide awareness of environmental problems.

Whatever educational programs are developed to promote best management practices in San Francisco, we strongly recommend that follow-up studies and surveys be conducted at regular intervals to assess the impacts of such programs on attitudes and behavior relative to the baseline results reported here.

VOL 12 2 4220

R0057512

SECTION 4

SELECTION OF DRY WEATHER BMPs FOR EVALUATION

below.

- Identify the CCSF constituents for which dry weather source control efforts are most critical based on effluent discharge water quality criteria.
- Review BMPs developed elsewhere for these constituents based on telephone interviews with public agencies and a computerized literature search.
- Develop pollutant loading estimations from CCSF's four major source categories (water supply, residential, industrial, and commercial/other businesses).
- Identify the potential specific sources of the identified constituents of concern in each of the four source areas.
- Incorporate the appropriate Optional BMPs suggested by the Regional Board.

A schematic illustration of the dry weather BMP selection process is presented in Figure 4-1.

Previous CCSF efforts (CCSF, 1991E) evaluated a variety of organic and inorganic constituents contained in CCSF's influent wastewaters in relation to several effluent discharge water quality criteria. These criteria included: effluent concentrations at or approaching discharge limits, and the potential for bioaccumulation, biomagnification, sediment toxicity, and/or other general receiving water problems. As a result of these efforts, eight constituents were identified as "targeted constituents" by CCSF. These eight targeted constituents are listed below.

- Copper
- Lead
- Mercury
- Nickel
- Silver
- Zinc
- Cyanide
- Polynuclear aromatic hydrocarbons (PAHs)

IDENTIFICATION OF PROBLEM CONSTITUENTS

To confirm the selection of these targeted constituents, the 1991 SEWPCP effluent discharge concentrations of these constituents plus three other heavy metals (arsenic, cadmium, and chromium) were examined relative to Basin Plan limits recently proposed by the Regional Board. This examination also provided a baseline for establishing the necessity of certain source reduction efforts and determining the expected impacts of proposed BMPs.

Table 4-1 compares the average, 95th percentile, 99th percentile, and maximum effluent concentrations in 1991 for the eleven constituents against the Basin Plan limits. The 95th and 99th percentile data represent the effluent concentration values that are statistically not expected to be exceeded 95 and 99 percent of the time, respectively. The Basin Plan limits are calculated based on water quality objectives in the receiving water, ambient levels, and a dilution factor of 10:1 for deep water outfalls. These water quality objectives, as published by EPA, theoretically should not be exceeded more than once every three years. Currently, the Regional Board has not specified whether this guideline will be used as the measuring device for discharge non-compliance.

(b) A probability-based analysis of the PAH data was not conducted due to the low number of samples where PAH was detected during 1991.
Note: Shading denotes constituents exceeding Basin Plan Limits.

R0057515

However, it is likely that a high compliance rate, such as 95 to 99 percent of the time, will be required. Therefore, the 95th and 99th percentile values are listed in Table 4-1 for comparison

compliance roughly 99 percent of the time. As seen from Table 4-1, SEWPCP's 1991 95th and 99th percentile data for copper, mercury, and cyanide would exceed the Basin Plan limits. The standard for PAHs would also be exceeded on occasion. Interpretation of the PAH data is more difficult, however, due to the prevalence of data points approaching their detection limits (approximately 1 to 2 µg/L), while the effluent limit is at 0.31 µg/L. Effluent concentrations for the other targeted metals identified by CCSF (lead, nickel, silver, and zinc) would be significantly less than their respective Basin Plan limits.

Based on this evaluation of SEWPCP effluent concentrations and discussions with CCSF staff, it was decided that BMP efforts should focus on copper, mercury, cyanide, and PAHs as the primary pollutants of concern. While these constituents would be the primary focus, in evaluating the benefits of various BMPs, the impacts on the previously identified targeted pollutants (lead, nickel, silver, and zinc) would also be considered since their effluent concentrations are generally within one-third of the Basin Plan limits. Incidental reductions would occur for these previously targeted pollutants as a result of specific BMP efforts aimed at reducing copper, mercury, cyanide, and PAH. Effluent concentrations of arsenic, cadmium, and chromium are significantly below their Basin Plan limits; they are not considered as pollutants of concern.

INFORMATION COLLECTION EFFORTS

In the next step in selecting BMPs for detailed evaluation, two tasks were conducted concurrently to determine whether specific BMPs had already been implemented by other agencies for these identified problem constituents. These two information collection efforts consisted of a nation-wide telephone survey of public agencies, and a computerized literature search of two scientific databases. CCSF sought to learn from the experiences and operations of other municipalities facing similar permit conditions and requirements. The results of the telephone survey and literature search are described below.

Public Agency Telephone Survey

As a first step in this effort, a survey questionnaire was developed to be asked of public agency staff and/or serve as a guideline for the telephone interviews. The questionnaire focused on the five following areas of concern:

- Whether the public agency faced environmental and regulatory conditions similar to those confronting CCSF (e.g. regulatory requirements and/or mandates, discharge procedures, pollutant priorities and constituents of concern, infrastructure conditions, etc).
- Specific BMPs and other source control measures implemented by the public agency.
- Effectiveness and costs associated with these measures.
- Public education and outreach efforts conducted.
- Effectiveness and costs of public education measures and the level of public response and receptiveness to these measures.

VOL 12 2 4224

R0057516

The initial list of pubic agencies to be contacted consisted of those known by JMM and CCSF staffs to have established source control programs. Additional contacts were recommended by the

Protection Agency were consulted as well. In total, contact was made with 42 separate municipal agencies and private organizations. Appendix F contains a list of the contact names and telephone numbers of the agencies and organizations contacted, as well as a copy of the interview questionnaire.

Summary of Telephone Survey Results. The information collected from the telephone surveys is outlined below under three categories that were determined to be of concern to CCSF.

Regulatory Issues. Most of the agencies contacted did not face National Pollutant Discharge Elimination System (NPDES) BMP requirements similar to those facing CCSF. Those with NPDES mandated requirements included St. Johns Michigan, Portland Oregon, Massachusetts Water Resources Authority, Los Angeles County, Seattle Washington, and Milwaukee Wisconsin. Municipality of Metropolitan Seattle and Los Angeles County appear to have the most comprehensive BMP programs in place. Los Angeles County's program targets urban and stormwater runoff pollution and is being implemented in three phases over three years. The three phases include: data collection, storm drain mapping and early action BMPs; additional BMPs and ordinance changes necessary for strengthened legal authority; and re-evaluation and refinement of the program based on data collection. Several agencies expected to receive new requirements in the near future, and the majority already conducted or were planning and/or implementing source control measures. With the exception of those listed above, most agencies did not face a major problem with heavy metals. Mercury, silver, lead, copper, zinc, chrome and cyanide were mentioned as constituents of concern. Most agencies divided responsibility for storm drain and sanitary sewer efforts.

BMPs and other Source Control Measures. Virtually all of the agencies contacted conducted or were planning to implement source control and related BMP efforts. The importance of frequent and accurate monitoring of influent was commonly mentioned. Several agencies reported that problem industries were monitored frequently and were charged for the cost of the monitoring. The importance of setting up a comprehensive database was emphasized, as was the value of assuring that all data collected is consistent to maximize its value. Several agencies reported that periodic dry weather monitoring at various points throughout the system helped to identify illegal dumping. Besides such monitoring and storm drain stencilling programs (which were common among the agencies contacted), most agencies did not have a specific program to identify illegal dumping. As part of its BMP program, Los Angeles County will map its storm drain system with geographic information system. Once completed, the County will be able to identify illegal hook-ups and problem discharges.

Many of the agencies had programs to work with businesses, including workshops, waste minimization materials and cooperative procedures for reaching compliance. Several agencies emphasized the importance of establishing positive and cooperative relationships with businesses. If compliance is not achieved, however, most of the agencies had the authority to issue citations and impose compliance schedules. The County Sanitation District of Orange County reported having reduced heavy metals in its influent by 50 percent since 1984 through waste minimization efforts, which were cited as a valuable tool for bringing businesses into compliance.

VOL 12 2 4225

R0057517

Spill reporting requirements (with accompanying monitoring and spill "hot lines") were cited by several agencies as important programs for reducing and treating the discharge of

Santa Monica, Portland, Santa Clara, Palo Alto, Seattle, Alameda County and the City of Los Angeles cited efforts to control erosion and run-off as important parts of their programs. Emphasis was placed on prohibiting any substances from entering the storm drain system except for wet weather run-off. Specific measures included requiring parking lots and car washes to have tanks to collect wash water. Santa Monica and Alameda County have urban run-off ordinances and Los Angeles issues a stormwater pollution abatement charge to all properties, which averages $17 per year and is reported to cover most of the City's wet weather BMP costs. The Alameda County Ordinance requires businesses to prepare Stormwater Management Plans, and fines and inspections are additional parts of the program.

Several agencies expressed the desire to extend their enforcement authority to additional classes of businesses producing point source pollution, and to modify ordinances and codes to better address non-point source pollution. Enforcement was cited as being expensive, however, and most of those interviewed emphasized public education as a means of raising public awareness and reducing non-point source pollution.

Public Education and Outreach. Most of the agencies contacted conducted some form of public education or outreach on pollution control. Several mentioned new efforts or programs that were being implemented or planned.

Most agencies had in place or were implementing a storm drain stenciling program to reduce wet weather non-point source pollution. This was considered important both to prevent toxic substances from entering the storm drain system and to educate the public on the effects of illegal dumping into storm drains. Working with Boy and Girl Scout troops and other youth and/or environmental organizations was cited as one approach to storm drain stenciling.

Most agencies also produced one or more forms of educational materials, including guides to household hazardous waste (HHW) and alternatives, brochures, flyers and utility bill inserts notifying residents of HHW and/or oil collection facilities or events, school curriculums and videos. Several agencies reported that such materials were obtained from a state agency. Most of those interviewed did not feel that there was a high level of public awareness concerning HHW and other source control issues, and that education and outreach efforts were necessary and effective. One or more staff were often devoted solely to these programs.

HHW and waste oil collection efforts were a part of most agency's programs. Due to the higher cost and danger associated with HHW, permanent waste oil collection sites were more common than permanent HHW collection sites. Temporary (e.g. one day or week per year) HHW collection efforts were cited by many agencies. Spring was cited as the best time of the year for HHW collection days, and one agency coordinated its collection of large solid waste items with its HHW collection day. While such efforts were well-utilized by the public, they were also reported as being very expensive, with Rockford, IL spending $250,000 for a one-day effort. Several agencies expressed a desire and preference for a permanent HHW collection facility, both to reduce costs and raise public

VOL 12 2 4226

R0057518

awareness. Many agencies have conducted surveys to assess public awareness of non-point source pollution and methods and alternatives for reducing it. Surveying residents using collection facilities was cited by several agencies.

county by county, will promote the issue as one that should be of concern to all Bay area residents. In addition, funds could be pooled together to conduct larger scale projects such as major media advertising.

The majority of the agencies contacted felt that the best approach to public education is to implement a campaign aimed at raising the general public's awareness of the need for source control efforts. Using a range of communication techniques (newsletters, ads, public service announcements (PSAs), etc.) will maximize the opportunity to reach all target audiences. By reaching the general public first, specific target audiences will already be aware of the need and purpose for the project when they are contacted, and will be more amenable to changing their habits in a manner which will enhance source control efforts.

Computerized Literature Searches

Based on the identified pollutants of concern and general source categories for these pollutants, a list of key words was developed for use in the computerized database search. The National Technical Information Service (NTIS) database was selected due to its diversity and comprehensiveness relative to the broad areas of interest potentially encompassed by BMPs. This database consists of government sponsored research, development, and engineering, plus analyses prepared by federal agencies, their contractors, and grantees. NTIS is considered to be a multi-disciplinary database covering a wide spectrum of subjects, including administration and management, agriculture and food, behavior and society, building, business and economics, chemistry, civil engineering, materials science, and transportation.

Various combinations of keywords were utilized in multiple database searches, with each search incorporating the pollutants of concern. The primary keywords used for the literature search are listed below.

- Pollutants (copper, cyanide, lead, mercury, nickel, silver, and zinc.
- Best management practices or source reduction or waste minimization.
- Household products or consumer products or commercial products.
- Water supply piping or plumbing or faucets.
- Human diet or food or human waste.
- Residential contributions or grey water or laundry.
- Commercial contributions.
- Environmental awareness surveys.

VOL 12 2 4 2 2 2 1

R0057519

The NTIS search examined sources dating from 1980 to the present. During the search, it was determined that numerous extraneous sources were being recovered. In response, additional computer literature search. The bulk of the literature pertaining to BMPs focused on non-point source controls; little has been written about the development of point-source, dry weather BMPs. Documents were obtained discussing waste minimization efforts at industries and commercial businesses of concern to this study, but these often pertained primarily to solid waste efforts. The most applicable documents referenced in the literature searches were, for the most part, already available through in-house material gathering efforts. The most valuable result of the literature search was to verify that source reduction efforts, such as this one undertaken by CCSF, have not been implemented to a significant extent elsewhere.

Conclusion of Information Collection Efforts

The public agency interviews and computer literature search provided a solid overview of the elements to be found in other source control programs as well as the general views and concerns of agency staff working in the area of water pollution control. The amount of specific data and cost figures received was very limited. While most of the agencies contacted are planning to implement one or more BMPs or other source control measures, few of the agencies has a comprehensive BMP program in place. In addition, the BMPs being implemented were targeted primarily at wet weather, non-point source runoff. Finally, a wide variety of public education materials were gathered on pollution control efforts. These materials should be of particular value as CCSF proceeds with its own public education program.

In light of the little concrete information available from literature sources and other agencies, the BMP selection process focused more on researching specific industries and commercial businesses that were identified as potentially contributing to the CCSF influent pollutant loadings. This process began with an evaluation of constituent source contributions.

EVALUATION OF CONSTITUENT SOURCE CONTRIBUTIONS

An evaluation of the contributions of targeted constituents to the SEWPCP influent loadings from four principal sources (water supply, residential, regulated industrial, and unregulated commercial/other businesses) was performed. Category-specific data were unavailable for PAHs, thus this analysis was limited to the six targeted heavy metals (copper, lead, mercury, nickel, silver, and zinc) and cyanide. Assessing the metals contributions from each of these sources provided a means of identifying the significant sources of problem constituents on which to focus the BMP investigative efforts.

An analysis of influent loadings of the targeted metals to the SEWPCP was prepared in conjunction with CCSF staff. This analysis attempted to determine the origins of the observed SEWPCP influent metals loadings (on a pounds per day basis) from among the four principal sources: water supply, residential, industrial, and commercial/other business sources. The SEWPCP performs 24-hour composite analyses of the influent heavy metals concentrations once every two weeks; effluent heavy metals are measured on a weekly basis. All of the 1991 concentration data were averaged and multiplied by the annual average flow of 62.2 mgd to determine influent and effluent mass loadings.

VOL 12 2 4228

R0057520

each compound. The commercial/other businesses category includes any unidentified influent loading sources that were not accounted for by the water supply, residential, and industrial loading estimates. A breakdown of the cyanide commercial/other businesses contribution into commercial sources and unidentified sources is contained in CCSF's Cyanide Evaluation Study, which is being submitted under separate cover.

Interpretation of sample data where the concentration of a pollutant was lower than the analytical detection limit, and thus not detected in the sample (termed "non-detects") was handled as follows:

- Residential and industrial sample non-detects were considered equal to the detection limit for all of the pollutants examined.
- Water supply sample non-detects were considered equal to one-half the detection limit for each pollutant with the exception of cyanide. Cyanide was not sampled in the tap water analyses and is assumed to not be present in the CCSF water supply.

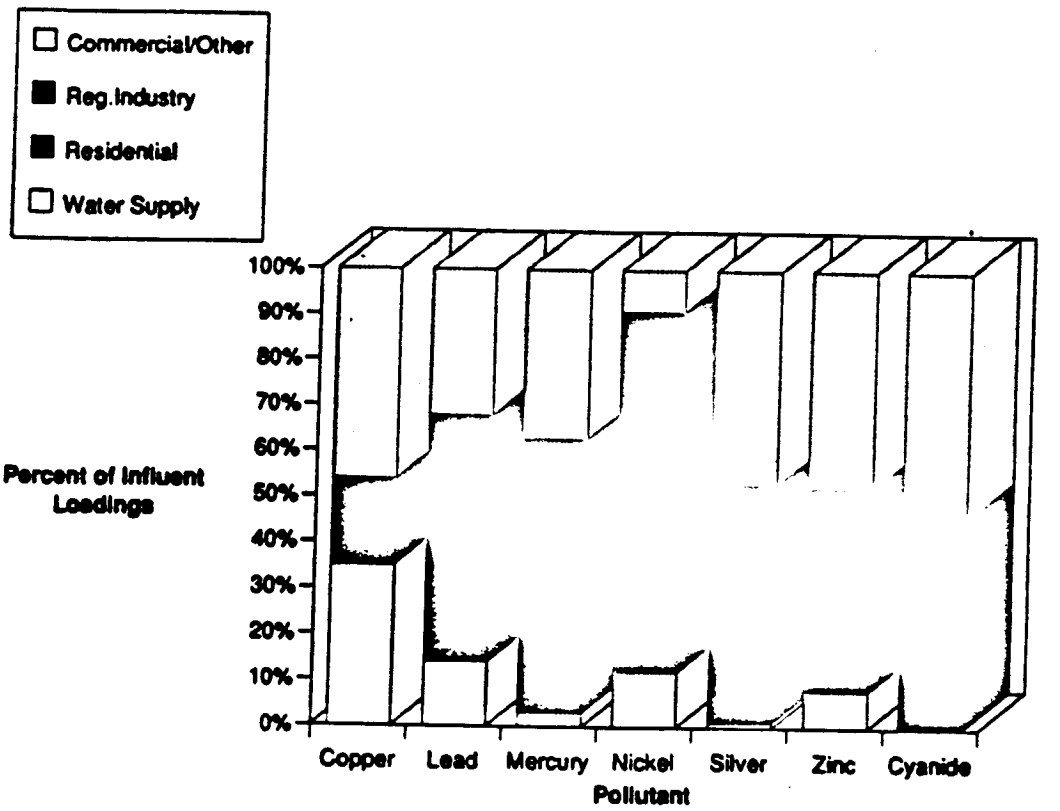
As seen in Figure 4-2, contributions from the commercial/other business sources may represent at least 30 percent of the influent mass loadings of each of the targeted metals with the apparent exception of nickel. Nearly 50 percent of the copper, silver, zinc, and cyanide influent loadings may stem from these sources. Regulated industrial sources seem to contribute most heavily to the silver, nickel, lead, and cyanide loadings at SEWPCP (approximately 46, 29, 28, and 27 percent respectively), but only represent a minor portion of the copper, mercury, and zinc loadings. Residential sources seem to contribute most heavily to the influent mass of mercury, nickel, and zinc, comprising roughly 50 percent of the influent nickel loadings. The CCSF water supply appears to provide a substantial (35 percent) contribution to the influent copper loadings, but appears to be only a minor source of the other targeted metals. The methodology used to estimate the influent loading contributions from each of these sources is summarized below.

Water Supply. An examination of San Francisco Water Department sampling data, consisting of raw water and tap water samples, indicated that CCSF's potable water supply may be a significant source of copper and potentially other metals found in the SEWPCP influent wastewater. CCSF analyzed tap water samples from 38 locations within its service area. At each of these locations, "initial flush" and "running" water samples were taken for both cold and hot tap waters. The initial flush samples represented the first flow out of the taps after over six hours of no flow. The running samples were taken after three minutes of continuous flow. A composite water supply concentration for each metal was determined from the 186 total samples by applying the following weighting factors to the tap water data:

- Cold water, initial flush: 0.2
- Cold water, running: 0.3
- Hot water, initial flush: 0.2
- Hot water, running: 0.3

VOL 12 2 4229

R0057521



SOURCES OF TARGETED POLLUTANTS IN SEWPCP INFLUENT

FIGURE 4-2

VOL 12 2 4230

R0057522

These weighting factors assume equal hot and cold water usage, and that 40 percent of water used are "initial flush". Analyses of alternate weighting factors did not have a significant impact on the resultant composite concentrations determined. A total water supply flow value equal to the

filtration plants in the system, and 2) pipeline corrosion occurring in the distribution system itself. Together, these sources make up between 1 and 35 percent of the influent loadings of six targeted metals at the SEWPCP. It is important to attempt to delineate between the contributions from these two sources in order to effectively direct any potential BMP efforts. Each of these sources are discussed below.

Raw Water Supply. CCSF's raw water supply is derived primarily from the Hetch-Hetchy reservoir, which is supplied by snow melt and rainfall in the Sierra Mountains, and a minor contribution arrives from local reservoirs located in Alameda County and on the San Francisco Peninsula. Roughly 70 percent of San Francisco's water typically arrives directly from the Hetch-Hetchy project, having only received in-line treatment consisting of pH control and disinfection. The remaining 30 percent stems from the local reservoirs (some of which can be fed by the Hetch-Hetchy aqueduct) and passes through one of two local water filtration plants. The Sunol Valley and San Andreas water filtration plants filter and disinfect the water from the local reservoirs prior to mixing it with the remaining San Francisco supply. Figure 4-3 presents a schematic illustration and typical flow breakdown of the sources supplying water to CCSF. In addition to naturally occurring metals in the raw source waters, CCSF's Water Department adds approximately 62,000 pounds of copper sulfate per year to the Alameda and peninsula local reservoirs for algae control. This issue is discussed further in Section 5 of this Study.

Distribution Pipeline Corrosion. Corrosion in San Francisco's water distribution system is likely a principal source of copper, lead, and zinc appearing in the CCSF water supply, and contributes ultimately to the metals loading in CCSF's wastewaters. Many different forms of corrosion processes can occur in distribution systems, including: uniform corrosion, erosion corrosion, galvanic corrosion, and rapid pitting corrosion. The corrosivity of a given system may depend on the piping materials present and numerous water quality parameters, including: pH, alkalinity, water temperature, conductivity, dissolved oxygen, hardness, and free chlorine. Water velocity may also play an important role, particularly in erosion corrosion. (AWWA 1985, EOA 1991) Corrosion-induced metals loadings to the wastewater system can be calculated by subtracting the loadings of the raw source water metals from the total tap water metals loading previously calculated by CCSF staff. This issue is discussed further in Section 5.

Estimated Water Supply Loadings. Table 4-2 lists the estimated mass loadings of the six targeted metals and cyanide contained in the CCSF water supply along with their estimated percentage contribution to the total mass of each metal contained in the SEWPCP influent. These loadings are based on tap water data collected by CCSF staff. As seen from this table, only copper in the water supply appears to contribute a significant percentage (35 percent) of the SEWPCP influent wastewater loadings. Lead in the water supply contributes approximately 14 percent of the influent SEWPCP loadings. Cyanide was not analyzed in the tap water supplies.

R0057525

Residential Sources. Residential contributions to the SEWPCP's influent loadings of problem constituents stem primarily from human excrements and the use and sewer-disposal of household

flow occurring in the lower Vicente district of CCSF since November 1990. Vicente is the only area where sanitary flow is not combined with stormwater runoff, and therefore provides the best available sample of residential metals contributions to SEWPCP influent flow. Although only two years of data are available, comparisons performed by CCSF staff have determined the Vicente data to closely match results from historic residential sampling efforts conducted throughout CCSF during the last five (relatively dry) years.

Residential metals mass loadings have been calculated by multiplying the concentrations found in the Vicente sewer samples by a per capita residential flow rate of 49.9 gallons per capita per day. Assuming roughly 512,000 people in the SEWPCP service area, this amounts to an estimated daily flow of 25.5 mgd. These residential samples consist of pollutants derived from home consumption and product disposal as well as contributions from the water supply. To account for the overlap of water supply and residential metals contributions, net residential mass loadings were calculated by subtracting the estimated water supply contribution from these calculated total residential loadings. Table 4-3 lists the estimated residential total and net residential metals and cyanide contributions relative to the influent loadings received at SEWPCP. Cyanide loadings were determined based on separate data collected by CCSF as part of their Cyanide Source Evaluation efforts.

As seen from Table 4-3, residential loadings appear to account for between 6 and 50 percent of the influent loadings for the six targeted metals and cyanide found in the SEWPCP influent. Of the targeted metals, mercury, nickel, and zinc have the highest percentage of residential influent loadings. As depicted in Figure 4-2, residential sources appear to account for the greatest percentage (44 percent) of the mercury influent loadings.

Based on CCSF's "Consumer Products Heavy Metals Inventory Report" (CCSF 1991B), a substantial portion of the residential loadings (derived from a previous mass loadings analysis similar to the one conducted for this study) remained unaccounted for among the three source categories of water supply, human excrement, and household products. Greater than fifty percent of the residential loadings were unaccounted for among all of the targeted metals, with the exception of mercury for which only 18 percent was unaccounted. Further research in this area may be necessary if residential sources are determined to be significant in this BMP development effort.

Regulated Industries. Major industrial dischargers to the CCSF sewer system are regulated under CCSF's Industrial Waste Pretreatment Program (IWPP), which was approved by the U.S. Environmental Protection Agency (EPA) in 1983, and is under the jurisdiction of CCSF's Bureau of Environmental Regulation and Management (BERM). The Bayside drainage basin, feeding the SEWPCP, contains 50 significant industrial users (SIUs) regulated under this program, of which 13 are regulated under federal categorical standards and 37 are considered "significant non-categorical" industries. Major industries in CCSF include hospitals, linen supply, metal plating, and food-related industries. The regulated industries account for approximately seven percent of SEWPCP's average influent flow.

(b) Net loadings exclude the estimated contribution from the water supply to the total residential loadings.

VOL 12 2 4235

R0057527

As part of the IWPP, regulated industries are required to report metals concentration and flow data to CCSF on a quarterly basis. As a result, the metals contributions from these sources are the most

loadings contributed by the industries. Industrial cyanide loadings were based on separate data collected by CCSF as part of its cyanide source evaluation efforts.

Table 4-4 lists the estimated SEWPCP targeted metals and cyanide loading from industrial sources, including their percentage contribution to the total influent loading. This table depicts significant industrial contributions of lead, nickel, and silver. Detection limits used in analyzing industrial samples have historically been higher than those used to analyze tap water samples and plant influent wastestreams. As a result, when concentrations below these high detection limits are present, interpretation of these "non-detects" as representing concentrations at the detection limit or even one-half the detection limit can result in misleading data values. CCSF staff have indicated that in the upcoming year, metals concentrations for all sample types (i.e., industrial, residential, commercial/other businesses, and influent samples) will be measured by the same technique to assure consistent analysis and interpretation of detection limits.

Unregulated Commercial/Other Business sources. Based on the influent pollutant loadings observed at SEWPCP, and the associated estimated contributions from residential and industrial discharges, it appears that significant mass loadings of pollutants stem from commercial businesses, smaller industries, and other non-residential small quantity dischargers (SQDs) of wastewater that are not regulated under CCSF's IWPP. For the purposes of this Study, these contributors were collectively categorized under the unregulated commercial/other businesses source category, which includes such dischargers as vehicular service facilities, photo finishing shops, painters, and print shops.

Due to the unregulated nature of, and relatively recent concern over, discharges from these SQDs, very little data are available describing their contribution of problem pollutants. CCSF's "Targeting Small Quantity Generators of Toxic Waste" (Spring 1991) presents a first-cut effort at identifying the types of SQDs that are likely to be significant metals contributors. This initial screening was based on metals concentration sampling at commercial dischargers and review of a data base containing information on the types and amounts of products used by businesses in CCSF. However, no data were available on the flows of wastewater from these businesses, and therefore a mass loadings estimation was not possible. Furthermore, the total number of SQDs in the CCSF service area is not yet known to estimate the total loading from this source category.

CCSF/BERM staff have developed a strategy to refine the estimate of mass loadings from these sources. This strategy, contained in the "Islais Creek Interim Measures Implementation Plan" (January 1992), includes taking the following important actions towards implementing source control for these dischargers:

- Developing a comprehensive SQD database to identify potentially significant dischargers of problem constituents; and
- Collecting mass loadings data by sampling concentrations and flow rates at targeted SQDs.

VOL 12 2 4236

R0057528

TABLE 4-4

ESTIMATED SEWPCP LOADING FROM INDUSTRIAL SOURCES

Parameter	Total Industrial Loadings (a) (ppd)	Net Industrial Loadings (b) (ppd)	Net Percentage of Influent Loadings (%)
Copper	5.6	4.1	7
Lead	5.2	5.0	28
Mercury	0.1	0.1	16
Nickel	2.4	2.4	29
Silver	3.7	3.7	46
Zinc	19.1	18.1	10
Cyanide	2.0	2.0	27

(a) Assumes an average industrial flow rate of 4.35 mgd.
(b) Net loadings exclude the estimated contribution from the water supply to the total industrial loadings.

VOL 12
2
4237
R0057529

Until these actions are completed, contributions from these unregulated commercial/other business sources will be estimated by subtracting the (more defined) estimated net loadings of industrial and

copper, silver, and zinc having the highest percentages.

Table 4-5 also depicts the estimated average concentrations derived from these mass loadings from unregulated commercial/other business sources. These concentrations are low relative to the maximum concentrations obtained in the sampling effort conducted as part of the "Targeting Small Quantity Generators of Toxic Waste" report (CCSF 1991C). This may indicate that high volume SQDs are discharging a relatively dilute wastestream.

Conclusion of Source Identification Evaluation

The principal conclusions of this review of CCSF's source control data can be summarized as follows:

- Of the four primary source categories contributing problem pollutants to the CCSF sewer system, the most significant data deficiencies exist for the unregulated commercial/other business sources. Without any mass loading data describing these sources, the influent contributions related to commercial/other business sources can only be estimated by subtracting the contributions of the water supply, regulated industries, and residential loadings from total influent loadings observed at the treatment plant.

- The estimated pollutant loadings from regulated industries are fairly well documented due to the IWPP reporting requirements. Future implementation of consistent sampling analytical methods and detection limits interpretation will increase the value of industrial sampling data efforts.

- Residential and water supply pollutant loading data for CCSF are more sparse than the IWPP data, but appear sufficiently representative of these contributions for the purposes of this BMP development effort. By comparing raw water supply metals data to the tap water samples, it is be possible to delineate between corrosion-induced metals loadings and metals originating at the raw water sources.

- Few data appear to exist describing the likely contribution of pollutants from infiltration and inflow into the CCSF collection system. Refinements of inflow estimates would refine the flow breakdown for the SEWPCP and thus influence the projected (flow-based) water supply and commercial/other businesses loadings contributions. Additionally, groundwater sampling from operating wells in the CCSF service area could determine if CCSF should be concerned with metals leaching from the soils into the combined sewer system. However, these adjustments to the "mass balance" are unlikely to significantly impact the existing data or alter the focus of BMP efforts.

R0057531

SPECIFIC SOURCE TARGETS

Based on the preceding analyses of the effluent concentrations observed at the SEWPCP relative to the Basin Plan limits (see Table 4-1) and the sources of SEWPCP's influent metals loadings (see Figure 4-2), target sources for BMP development were identified. Of the pollutants previously targeted by CCSF (copper, lead, mercury, nickel, silver, zinc, cyanide, and PAHs), copper, mercury, cyanide, and PAHs are the only compounds that are expected to exceed the effluent water quality limits established by the Basin Plan. The sources of these "primary" pollutants should thus be given the highest priority for BMP development. However, since higher effluent concentrations of other targeted metals (e.g., silver) have previously been reported, and BMP efforts typically address many metals simultaneously, the BMPs developed as a result of this study would also encompass the other four metals previously targeted.

The primary and other targeted pollutants are listed below with the principal categories contributing the highest percentage of their respective influent loadings:

Primary Pollutants

- Copper -- water supply and commercial/other businesses
- Mercury -- residential and commercial/other businesses
- Cyanide -- commercial/other businesses and industrial
- PAHs -- Unknown (No data available)

Other Targeted Pollutants

- Lead -- residential and commercial/other businesses
- Nickel -- residential and industrial
- Silver -- commercial/other businesses and industrial
- Zinc -- residential and commercial/other businesses

This listing indicates that residential and commercial/other businesses BMP source reduction efforts would likely impose the greatest overall reductions in metals loadings to the SEWPCP. The implementation of metals reduction measures from these sources would likely have more far reaching impacts on the reductions of other metals than minor improvements to CCSF's already established industrial pretreatment program. However, much is still unknown about residential and commercial/other business sources; a large percentage of the residential loadings for these six metals are yet unaccounted for, and significant data deficiencies exist describing the unregulated commercial/other businesses source category.

CCSF is conducting a separate concurrent study to investigate the sources of cyanide in the its wastewater streams. This effort consists of an extensive literature review examining cyanide sources, an analysis of SEWPCP treatment process chemicals that contribute to cyanide concentrations in the effluent wastestream, and an extensive sampling of CCSF businesses for cyanide. The *Cyanide Source Evaluation Study* is being submitted separately by CCSF to the Regional Board in August 1992. The sampling effort did not identify any major contributors of cyanide that is currently unregulated. Potential cyanide sources considered in this BMP selection process were photoprocessing facilities, scrubber operations, and paint products. These potential sources are discussed in detail in Section 5.

VOL 12 2 4240

R0057532

Polynuclear aromatic hydrocarbons (PAHs) may be present in wastewaters via the surface runoff of byproducts of combustion processes (e.g., automobiles) and other applications. Direct

expected to be related in any significant degree to dry weather discharges to the SEWPCP. Accordingly, PAHs were excluded from consideration in the selection of the dry weather BMPs. PAHs are addressed to a more substantial degree by the wet weather BMPs discussed in Sections 7 through 9 of this Study. However, PAHs may be present in some of the identified activities such as automotive service facilities, scrubber operations, and illegal dumping of used oil.

Based on the information collection efforts described earlier in this section, Table 4-6 lists the principal identified sources for each of the six targeted heavy metals with respect to the four CCSF source areas: water supply, residential, regulated industrial, and commercial/other businesses. Shaded areas of this table mark the two source areas that contribute the greatest percentage of the influent loading for each metal (See Figure 4-2). For the reasons discussed above, the sources of copper and mercury listed in this table were given the highest priority in selecting the BMPs for further evaluation. Incidental loading reductions for the other targeted pollutants can be expected through BMPs focusing on the primary pollutants.

DRY WEATHER BMPs SELECTED FOR DETAILED EVALUATION

Based on the screening steps described at the beginning of this section, the thirteen dry weather BMPs selected for detailed evaluation are listed in Table 4-7. Four of the Optional BMPs have been included for detailed evaluation. Where appropriate, the wording of the Optional BMPs was modified slightly to streamline the focus of the evaluation process. Optional BMP P5 was not directly evaluated; it was expanded into multiple BMPs to evaluate currently unregulated sources of toxic pollutants.

These BMPs have been primarily targeted towards reducing the dry weather influent loadings of copper, mercury, and cyanide in light of the SEWPCP effluent discharge limits discussed previously. In addition to impacting these three pollutants, it is expected that "incidental" reductions in the loadings of the other heavy metals and PAHs will occur as a result of these BMPs. A detailed discussion of each of the BMPs is presented in Section 5.

Other Potential Sources

The thirteen selected BMPs address nearly all of the principal sources identified in Table 4-6. Five other sources were identified, but not addressed specifically as part of the detailed BMP development effort. These other sources are briefly described below.

Cleaners/laundry facilities. Industrial laundering facilities are currently regulated under CCSF's Industrial Pretreatment Program. The smaller commercial cleaning/laundry facilities were viewed as a potential pathway to the sewer, but not a major source of problem pollutants in themselves. To conform with the idea of source control, control measures should be implemented as close to their source as possible. Pathways such as these facilities may be considered as part of secondary source control efforts if reductions at the primary sources prove insufficient. A recent study on heavy metals in household cleaning products (REED, 1990) indicated that laundry products are not a major source of heavy metals.

R0057535

Foods. Metals and cyanides are present in small concentrations in many foods. However, reductions in the consumption of any particular food items were not considered as a feasible

potential source of metals to the wastewaters. The data from this report were considered uncertain, and were believed to be taken from small machine shops. To the extent these facilities are present in CCSF, they should be regulated as part of CCSF's expanded pretreatment program efforts.

Dentists. Dentists are a potential source of silver and mercury to the influent wastestream. BERM recently completed a separate study of these facilities (CCSF, 1992I), and the results of BERM's sampling efforts are discussed under BMP No.7 in Section 5.

Equipment Rental. Although not specifically covered by the selected BMPs, educational measures at paint equipment rental facilities are incorporated into the BMP No.4 implementation measures.

VOL 12 2 4244

R0057536

SECTION 5

DEVELOPMENT OF DRY WEATHER BMPs

and then each of the dry weather BMPs are discussed in detail. For each of the BMPs, the targeted pollutants of concerns, the implementation measures required, the estimated reductions, and the estimated costs are described. Detailed calculations and pertinent information relating to the BMPs are included in Appendix C for reference. The 8 Optional BMPs suggested by the Regional Board have been separated between dry and wet weather analysis. Four of these BMPs are evaluated in this section. The other four are evaluated in Sections 7 through 9 of this report.

The methodology for estimating reductions and costs requires some discussion. As discussed in the previous section, there is minimal empirical data available on reduction potential of BMPs. Most of the BMPs discussed in this report are directed at the residential and commercial sectors of the communities. Up to now, little attention has been paid to these sectors in terms of pollutants loadings, pollutant sources, and reduction potential. CCSF's "Small Quantity Generators" and "Household Products Inventory" studies have advanced the understanding and knowledge of these newly recognized sectors. Other agencies and POTWs are beginning to focus in these areas also. Central Contra Costa Sanitary District is initiating an aggressive Residential Metals Study in August 1992. Several other POTWs are regulating automotive service facilities and photofinishers. However, most of these programs have only been recently initiated. No information on their effectiveness in reducing pollutant loadings is available.

To estimate the reductions described below, numerous suppliers, vendors, service contractors, business owners, CCSF staff, and Federal, State and local agencies were contacted. Any pertinent literature information was reviewed. Finally, best engineering judgement and reasonable assumptions were used to estimate the potential reductions. The estimates should be considered as reasonable for a cost-effectiveness comparison, but should not be used as definitive loadings. As more experience is gained from working with these sectors, their reduction estimates should be revised accordingly.

Agency cost estimates were prepared at current day value. They are order-of-magnitude estimates that are consistent with planning level analysis. Costs to businesses are expected to be highly variable, and will depend on specific compliance methods selected. These business costs were not included in this analysis.

In order to have a common basis for comparison, annual agency costs have been prepared for each BMP. Where appropriate, the capital or startup costs have been amortized at an interest rate of 8 percent over 20 years. Estimates have been prepared for the ADWF design capacity of 85 mgd for the SEWPCP.

VOL 12 2 4245

R0057537

BMP NO. 1 (OPTIONAL BMP E2)

EDUCATE THE PUBLIC REGARDING THE POTENTIAL ENVIRONMENTAL...

Any effort to reduce the level of toxic pollutants entering the combined sewer system -- and ultimately the San Francisco Bay and the Pacific Ocean -- must address the general public as a source of such pollutants. The general public uses a wide variety of products which contain toxic substances, ranging from common household cleaners; personal hygiene products; paints and solvents; pesticides; insecticides; fertilizers; and auto products such as oil, antifreeze, steering and brake fluid; and gasoline. In normal usage, or when disposed of improperly, these products have the potential to enter the combined sewer system. This results in the introduction into the treatment system of heavy metals and other compounds identified as constituents of concern to CCSF..

The types of products listed above are widely available and are found in most households. While such products are known to contain toxic substances, addressing them is particularly challenging given their widespread use by the general public. Beyond noting that they are used by the "general public," the source of household products, which are a source of copper and zinc, can not be more specifically identified. Thus, addressing the general public as a source of toxic pollutants requires a more broad based program aimed at raising general awareness and changing behavior patterns related to the use and disposal of household cleaners and other products containing toxic substances.

Education is the most fundamental component of any effort which seeks to change public behavior patterns. With regard to household hazardous waste (HHW) and other products containing toxic substances found in the home, the public must be educated in at least four key areas:

- Water pollution issues in general and the need to preserve the environment of the San Francisco Bay and the Pacific Ocean.
- Sewers and storm drains have a pathway to the Bay and Ocean and that the treatment plants cannot remove 100 percent of toxic pollutants before discharging into the Bay and Ocean.
- Many common household products contain highly toxic chemicals which are potentially harmful to both human health and the environment.
- The safe alternatives to both the use of products containing toxic substances and their improper disposal.

A successful public education effort must rely upon a heightened awareness and sensitivity to water pollution control and environmental preservation. This awareness and sensitivity will serve as the foundation upon which more specific educational messages and activities are built. The environmental survey conducted of CCSF residents (see Section 3 of this report) found, for example, that respondents reporting a higher level of knowledge about toxic pollutants were less likely to improperly dispose of such pollutants. It is also important that feasible and convenient alternatives be provided for the behavior being discouraged. In short, the public must be made to realize that their use and disposal of HHW has a direct impact on water pollution in the Bay and Ocean and that alternatives are available to avoid practices which cause such pollution. The public must clearly view the connection between their activities and pollution in the Bay and Ocean, and they must understand how they can make a difference.

VOL 12 2 4246

R0057538

The environmental survey found a relatively high level of awareness of environmental and water pollution related issues. The survey results suggest that a broad based, city-wide educational program aimed at further increasing overall awareness about water quality issues and improving neighborhoods or groups would not produce substantially better results than a broad based, city-wide program.

Finally, the environmental survey found a high level of support for City-sponsored efforts to address environmental issues. Survey respondents supported greater efforts on the part of CCSF to improve water quality (77 percent), to promote awareness of toxic materials and their disposal (84 percent), and to regulate practices involving toxic materials and their disposal (77 percent). Of those supporting additional efforts, 80 percent said they were willing to pay 25 cents per month for them, and of those, 76 percent were willing to pay 50 cents a month. This support was found in all areas of the City and in all sociodemographic groups, although older residents were less supportive than younger residents. It thus can be expected that the public will be receptive to the activities included in BMP No. 1 and in the broader Public Education Plan.

BMP No. 1 will address the full range of products which contain toxic pollutants. These measures are included in the Public Education Plan currently being developed for the Department of Public Works (DPW). The overall goal of the Public Education Plan is to design a program which educates and informs the public and the business community regarding the importance of protecting the environment and public health from the improper use, storage and disposal of toxic products and wastes produced by households, businesses, Small Quantity Generators (SQG) and Conditionally Exempt Small Quantity Generators (CESQG). The Plan focuses on promoting safe waste management, including source reduction, waste minimization, recycling and proper waste disposal.

POLLUTANTS OF CONCERN

The activities recommended as part of BMP No. 1 will address the full range of products containing toxic pollutants. The public education measures would likely address most of the constituents of concern. Because of the volume consumed and disposed of by the public, certain products, such as paints, solvents, and oil, can be expected to be impacted by the public education program more than others. The pollutants contained in these products; mercury, lead, and nickel; may achieve greater percentage reductions than pollutants found in other HHW. For example, the CCSF Household Hazardous Waste Collection Facility (HHWCF) reported that paint and oil products accounted for 57 and 12 percent, respectively, of the containers received at the facility (CCSF 1992B). Cleaners accounted for only 2 percent of containers received.

EXISTING CONDITIONS

CCSF currently conducts several efforts to educate the public about HHW. A brochure entitled "Your Guide to Less Toxic Shopping" explains what HHW is and discusses safer alternatives to products containing toxic substances. The pamphlet is distributed by the Chief Administrators Office (CAO) by request and at environmental fairs and other special events. CAO also operates a HHW hotline through which residents can request information and obtain the address of the HHWCF. An additional pamphlet entitled "Garbage Cans and Can'ts" explains which products and substances should not be disposed of through the solid waste stream and directs residents to the HHWCF. An agrichem brochure is currently being developed which will address pesticides.

VOL 12 2 4247

R0057539

Materials promoting recycling are also produced and distributed by the CAO. A quarterly newsletter is produced which assists small businesses in reducing and properly disposing of hazardous waste. Finally, CCSF schools use a "4th R Recycling Curriculum" to teach K-5th

Existing CCSF programs and materials can be modified to emphasize the specific impacts of certain toxic products on the sewer system and human health and the environment. The promotion and distribution of the materials would be enhanced to reach a broader segment of the general public and presentations to community groups would be expanded. Whenever possible, community organizations and special interest groups will be used to distribute program materials. These, and other efforts, are addressed in the Public Education Plan. Elements of the Plan which apply to BMP No. 1 are listed below.

The Public Education Plan provides a comprehensive program for raising general awareness and reaching out to and educating the general public, small businesses, and selected target audiences on the environmental impacts of the improper use and disposal of toxic substances. The activities listed below are components of the Plan which address the general public and non-permitted businesses and commercial establishments, and which could be used to address household cleaners and other sources of HHW. A brief description of each activity is provided. The Public Education Plan should be consulted for a complete explanation of the activities, the schedule for their implementation, and the materials and organizational support needed.

Program Theme and Logo

A program theme and logo graphic will be designed and will be integrated into all written and promotional materials. The graphic will ensure that all materials have a consistent, positive and compelling image.

Toxic Free Neighborhood Program

The Toxic Free Neighborhood Program will involve the targeting of specific neighborhoods and aggressive promotion of the program's message and accompanying educational materials. This will include media advertising in neighborhood newspapers and publications, presentations to community groups and distributing materials at special events. Neighborhood targeting may be an effective means of reaching home owners, as opposed to renters. The environmental survey found that home owners are more likely to use a number of products containing toxic substances, such as motor oil, house paint and solvents. Thus, neighborhoods with a high rate of home ownership can be targeted with materials addressing these products.

Publications

Fact sheets, brochures, newsletters and informational folders will be developed addressing key issues. These materials will provide general and targeted information to both the general public and selected audiences. Fact sheets will target specific topics and brochures will give general information about specific programs. A bi-annual newsletter will update CCSF staff working on environmental issues on the BMP program and other related activities. The informational folder will be used to distribute program information and materials in an organized and attractive manner.

VOL 12 2 4248

R0057540

appropriate locations. One component proposed for the Environmental Booth is an "Environmental Kitchen" display discussing safe alternatives to products containing toxic substances commonly used in the kitchen.

A Toxic Free Home Tour exhibit is being developed for the Department of Public Works by the Clean Water Fund. The Toxic Free Home Tour will consist of a portable, 3-dimensional home display explaining the problems associated with toxic and environmentally harmful products found in each room. The display exhibit will be accompanied by educational materials discussing safe, non-damaging alternatives to products containing toxic substances as well as the proper disposal methods for household hazardous waste. The Toxic Free Home Tour display exhibit will be made available for display in libraries, schools, government and corporate buildings, conventions, street fairs and community meetings.

Home Toxics Checklist

A self conducted Home Toxics Checklist will be distributed to school children and at special events. The Checklist will make residents aware of toxic substances used and stored around the home. The proper use, storage and disposal of the substances will also be explained. Encouraging reduction in the amount of products used which contain toxic substances will be emphasized.

Speaker's Bureau/Informational Presentations to Special Groups

A Speaker's Bureau Program will be developed and coordinated between the Department of Public Works and the Chief Administrator's Office. The Speaker's Bureau will make educational presentations to groups and organizations such as the League of Women Voters, Kiwanis Clubs, Boy and Girl Scouts and the Chamber of Commerce. The presentation made will be tailored to the groups being addressed, but will generally explain the purpose and need for the BMP program and discuss actions that residents and businesses can take to reduce the amount of toxic substances entering the City's treatment system.

Point of Purchase (POP) Displays

POP displays will be designed targeting specific products of concern (e.g. paints and solvents, pesticides and lawn and garden products, motor oil, photography products and household cleaning products) and will be distributed to stores that specialize in selling these products. The POP displays will educate consumers on the proper use and disposal of the specific product addressed and will provide the address and directions to the HHWCF.

Grocery Bag Program

Grocery bags containing an educational message about water pollution prevention and toxic waste disposal will be produced and distributed to major grocery retailers in CCSF.

VOL 12 2 4249

R0057541

School Education Program

with an early education concerning the need to reduce the amount of products used containing toxic substances as well as the potential harm they can cause to human health and the environme

Poster Calendar Contest

A poster contest will be held in September of each school year with all CCSF elementary schools. Children will be asked to graphically illustrate the activities that contribute to pollution in the Bay and Ocean and what can done to prevent such pollution. The posters will be judged and the 12 winning entries will be incorporated into a calendar. Businesses will be asked to co-sponsor the program.

CCSF Employee Training Programs

Training will be provided to all CCSF employees on the need to reduce and eliminate the use of products containing toxic substances, both on the job and at home. Employees who work with toxic substances will be provided with specialized training as appropriate. BERM, DPH, DPW, Fire and Police Department employees will be taught to identify and report hazardous spills and illegal dumping.

Green Ribbon Program

San Francisco Green Ribbon Panel was formed under the guidance of the City's Small E ness Advisory Commission to help business owners contribute to the overall health and pr uctivity of the Bay region. The Department of Public Works will work with the Green Ribbon Panel to develop a "Green Business" program. The program will provide merchants, small businesses and offices with the educational materials necessary to reduce their use of products containing toxic constituents. Participating businesses will be provided with a decal promoting them as a "Green Business." The program is intended to educate and reach out to businesses and offices in a similar manner as activities aimed at residents. The Department of Public Works will ensure that all information distributed by the Green Ribbon Panel incorporates the message of the BMP Program.

Cable Television

Educational videos on HHW and other environmental issues will be produced and aired on local cable television channels, such as SFCityTV. Videotexts will be used to advertise the HHWCF and other programs and materials. CCSF staff can arrange to appear on community interest programs, such as "Inside City Limits," to discuss water pollution prevention and promote program activities and materials. Public service announcements (PSAs) will also be prepared for cable TV, broadcast TV and radio.

Promotion s

Each activity will be accompanied by the necessary promotion and publicity through special inte: groups, business and trade organizations, and community/neighborhood groups. Overall prog: publicity and general public educational messages will be conducted through media advertising.

VOL 12 2 4250

R0057542

PSAs, and billboards. The majority of respondents to the environmental survey reported receiving information on environmental issues through newspapers and television (42 and 21 percent, respectively). Non-whites, particularly Hispanics and Asians, are more inclined to receive

Can'ts"

Using survey data, monitoring data, and mailing lists developed through other program activities and special events, these and other educational materials will be distributed to target areas and/or groups. A special effort will also be made to make educational materials available at large supermarkets and grocery stores. All materials will be translated into foreign languages as appropriate.

The survey results suggest that environmental organizations are an important source of information for many residents. Sixteen percent of the survey respondents reported that at least one member of the household was a member of an environmental organization. Thus, environmental organizations will be used as a means of distributing program materials and promoting program activities. Given their interest in environmental issues, these organizations can be expected to be cooperative in this regard.

EXPECTED REDUCTIONS

The estimated reductions of BMP No. 1 are summarized in Table 5-1A. Detailed calculations are included in Appendix C-1. The estimates are based on the assumptions that 50 percent of the public will be reached by the public education program, 50 percent of those reached will participate in the reductions, and 20 percent reductions can be achieved on an individual basis. These assumptions equate to an overall 5 percent reduction in the pollutants contributed by residential sources. At this time, the specific products, their pollutants of concern, and reduction potential are uncertain.

ESTIMATED AVERAGE ANNUAL COSTS

Estimating a precise implementation cost for BMP No. 1 is difficult as it depends on a number of variable factors. The activities included in BMP No. 1 are drawn from the Public Education Plan being developed for the Department of Public Works, which recommends a three year public outreach program. An average annual cost estimate is provided below for production, distribution, promotion and staffing costs. A detailed list of the materials and staffing needed for each activity and their estimated average annual costs is provided in cost tables included in the Appendix C-1. In this listing, the budgetary contributions of other departments participating in specific activities are noted and subtracted from the total. The estimated costs are summarized in Table 5-1B. Each of the cost components are described below.

VOL 12 2 4251

R0057543

TABLE 5-1A

ESTIMATED ANNUAL REDUCTIONS

Pollutant	Reductions (lb/yr)
Copper	400
Lead	140
Mercury	6
Nickel	110
Silver	10
Zinc	1720
Cyanide	50

VOL 12 2 4252

R0057544

TABLE 5-1B

ESTIMATED ANNUAL COSTS

Implementation Measures	Cost
Annual Operating Costs:	
Staffing	$193,000
Promotion	$94,000
Production	$66,000
Distribution	$7,000
Total Annual Cost	$360,000/yr

VOL 12 2 4253

R0057545

Staffing

multiplier of 2.2 is used to account for benefits, office space, materials and other overhead costs. Staffing costs will depend on the size and scope of the public education program ultimately adopted by DPW. The use of outside consultants will decrease the staff needed for the program.

Promotion

Average annual promotional costs for BMP No. 1 are estimated to be approximately $94,000. Staff and labor costs are not included in this estimate. Advertising and promotional costs may vary widely depending on the amount of paid advertising used to promote activities. The costs for major media advertising that reaches the entire Bay region may be divided with other municipalities. The use of smaller, neighborhood newspapers will further reduce promotional costs.

Production

Average annual production costs for BMP No. 1 are estimated to be approximately $66,000. This includes the design and production of all written materials and literature, decals, videos and other materials needed. The number of each type of publication produced (different brochures and fact sheets), their size, format, and graphic content, and the number printed will affect production costs. Materials produced for one program may be used for other programs, thus reducing costs.

Distribution

Average annual distribution costs for BMP No. 1 are estimated to be approximately $7,000 per year. Distribution costs may vary for specific materials. The cost of distributing materials through existing organizations and at special events may be minimal. Postage costs for mailed materials could be significant.

VOL 12 2 4254

R0057546

BMP NO. 2 (OPTIONAL BMP P1)

DEVELOP AND IMPLEMENT AN AGGRESSIVE PUBLIC PROGRAM TO REPORT AND PREVENT DUMPING OF TOXIC POLLUTANTS INTO SEWERS

A key goal of this study is to examine ways of preventing toxic substances from entering the sewer and storm drain systems. Illegal dumping is one way in which toxic substances are afforded a pathway to the treatment plants, and ultimately, the Bay and Ocean. BMP No. 2 seeks a means by which the general public can prevent illegal dumping and report it to the proper authorities when it is witnessed.

Illegal dumping can stem from either private citizens disposing of used or excess toxic materials such as oil or paint, or businesses disposing of chemicals or substances which are byproducts of their production process. The cost of properly disposing of industrial hazardous waste can be high for some businesses. As such, illegal dumping may be viewed by some as a means of disposing of waste material, even with the attendant risk of being caught and fined. Illegal dumping by private citizens may result from ignorance of the adverse environmental impacts of dumping toxic substances into sewers or storm drains, lack of awareness of the availability of proper disposal options such as the Household Hazardous Waste Collection Facility (HHWCF), or a simple unwillingness to make the extra effort to properly dispose of toxic products or waste.

Public education and outreach are the appropriate means of addressing instances where citizens are unaware of safe alternatives to products containing toxic substances, the adverse environmental impacts of dumping toxic substances into sewers or storm drains, or the availability of proper disposal options. Proper reporting and enforcement procedures are necessary to address illegal dumpers who do not wish to pay the cost or make the effort to properly dispose of toxic substances. The educational activities needed to discourage and prevent illegal dumping have been outlined in BMP No. 1. The activities discussed below provide a means of preventing illegal dumping by providing the public with convenient disposal alternatives, and a mechanism through which the public may report illegal dumping.

POLLUTANTS OF CONCERN

Any variety of toxic pollutants can potentially enter sewers and storm drains as a result of illegal dumping. As a practical matter, however, certain toxic substances are dumped illegally more often than others. An audit conducted of spill investigations and retrieval reports from the Department of Public Health (DPH) and the Bureau of Environmental Regulation and Management (BERM) found that oil and paint are the substances most commonly dumped or spilled in the City and County of San Francisco. Between 1990 and 1992 paint and oil accounted for 22 and 21 percent, respectively, of BERM's spill investigations. In the case of DPH, oil accounted for 39 percent of spill retrievals and paint for 22 percent. BERM also reported a high incidence (21 percent of investigations) of dumping of cement and/or concrete. The Bureau of Street Cleaning and Urban Forestry (BSCUF) has also reported that containers of oil and paint, or spilled oil, are often found in certain parts of the City. Paint and oil also represent the vast majority of containers received at the City's HHWCF (57 and 12 percent, respectively; CCSF, 1992B).

This data, and the experiences of City workers, suggest that oil and paint are the products that will be most affected by efforts to prevent and reduce illegal dumping of toxic substances. Thus, to the degree that BMP No. 2 and related efforts are effective in reducing illegal dumping, it can be expected that the pollutants found in paints, oil and other automotive products (mercury, copper, lead and nickel) will be affected.

VOL 12 2 4255

R0057547

Industrial, Small Quantity Generators (SQG) and Conditionally Exempt Small Quantity Generators (CESQG) can potentially be the source of a wide variety of illegally dumped substances. San

metal platers; and medical and dental wastes. Businesses were the source of over two thirds (68 percent) of the spill investigations conducted by BERM.

Data provided by the Metropolitan Water Reclamation District of Greater Chicago, which established a public illegal dumping hotline in 1989, shows that a wide variety of substances are reported to be illegally dumped (MWRD, 1991). All of the substances listed above were illegally dumped, as well as several incidents in which acids and septic material were dumped into sewers or storm drains.

The greater Chicago area is not similar to CCSF in terms of the mixture of businesses and industries represented, however. As stated above, San Francisco has a smaller percentage of large industries, and a larger percentage of SQGs than most cities. Thus, it can be expected that non-residential illegal dumping would result most commonly from the City's many printing, photographic, automotive service facilities and restaurants that improperly dispose of oil and grease. The pollutants of concern found in wastes produced by these businesses include copper, silver, nickel, zinc, and lead.

EXISTING CONDITIONS

CCSF does not currently have a formal illegal dumping hotline. The CAO operates hotlines on composting, recycling, the HHWCF and informational requests. The CAO receives approximately two to four calls per month reporting illegal dumping. These calls are referred to DPH.

The Bureau of Street and Sewer Repair (BSSR) has an emergency service telephone number which is staffed 24 hours a day (7:00 am to 4:00 pm at the Maintenance Yard at 2323 Army Street and 4:00 pm to 7:00 am at the Fire Department Central Dispatch at 1003 Turk Street). Periodically, this telephone number has received calls reporting illegal dumping and hazardous spills. These reports are referred to BERM or the Fire Department, which in turn contact DPH as necessary. Whenever staff is available, BERM sends an inspector to investigate illegal dumping incidents. A report is completed on the investigation, although no further action is taken.

The majority of the calls received on this line involve requests for other telephone numbers and the staff responsible for answering the line is simultaneously responsible for several other phone lines as well as radio dispatch for BSSR. Significant delays in responding to calls to this line have been reported.

The Fire Department has the authority to issue citations for illegal dumping. The possibility of giving BERM inspectors with citation authority is being investigated. Issuing citations for illegal dumping is considered difficult because the individual must actually be caught "in the act." BERM staff believes that, even if citing the alleged violator is not always possible, making a "show of force" is effective in showing residents that illegal dumping is taken seriously by the City.

In addition to education, the most effective means of preventing and reducing illegal dumping is to provide the public with a convenient means of properly disposing of toxic substances. Proper disposal alternatives must be made available and the public must be made aware of them.

VOL 12 2 4256

R0057548

A convenient means of properly disposing of HHW is provided to San Francisco residents by the HHWCF operated by the Sanitary Fill Company. The facility is located at 501 Tunnel Avenue, within ten miles of any residence in the City. It is open from 8 am to 4 pm, Thursday through

increase of between 19 and 27 percent (CCSF, 1992B). The HHWCF has been a highly e..ective means of providing a proper disposal option for hazardous substances for San Francisco residen Had the facility not been available, it can be assumed that at least some portion of the wast disposed there would have been dumped illegally into sewers or storm drains or the solid waste stream.

The CAO also plans to sponsor a Household Hazardous Waste collection day once per year in different parts of the City. One such collection day has been held to date. Approximately 500 people participated in the one day collection effort, which cost $65,000. One collection day per year is currently budgeted. No additional household collection effort will be included as part of this BMP.

IMPLEMENTATION MEASURES

Implementation measures for this BMP include establishing a curbside waste oil collection program, an illegal dumping hotline, and investigating authorizing citation authority for BERM inspectors.

Curbside Motor Oil Collection Program

Implementing a curbside collection program for used motor oil will be a major focus of BMP No. 2. This type of program has been succes..ul in other Bay area counties and, as indicated above, will address one of the most common sources of illegal dumping. The City of San Jose's experience with curbside oil collection is illustrative: The program collects an average of 495 gallons of used oil per day with a total of 53,562 gallons of used motor oil collected between January 2 and July 29, 1991. The program currently collects used motor oil only from single family residences, and enjoys a participation rate of 45 to 50 percent. It is estimated that an average of one gallon of used motor oil is collected per year from each household.

Public participation in a curbside collection program is expected to be high. An environmental survey was conducted of CCSF residents (see Section 3 of this report) concerning their attitudes and habits with regard to environmental awareness, hazardous waste, and disposal alternatives. The survey found that 88 percent of respondents were aware of curbside recycling in their neighborhood and that, of those, 91 percent normally put things out to be picked up. Addit..nally, over 70 percent said they would use curbside motor oil collection and, of those, 83 percent said they wo..d be willing to pay an extra amount for the service.

Once in place, the curbside oil collection program can be expanded to include other recyclable products, such as anti-freeze and latex paint. In addition to ensuring the proner disposal of the products involved, the curbside collection program has the added benefit of reinforcing the message that using non-toxic or recyclable products is the preferred approach to pollution contr The high cost of final disposal of non-recyclable toxic materials dictates that non-toxic or recyclab.e products be emphasized whenever possible.

VOL 12 2 4 2 5 7

R0057549

The curbside oil collection program will be promoted through news stories, utility bill inserts and paid advertisements in local newspapers. With regard to promotion, 67 percent of participants

San Jose program uses brochures, door hangers and paid advertisements in local neighborhood newspapers to promote the program. Route audits are conducted to determine areas with low participation. These areas are subsequently targeted for aggressive promotional efforts, such as door hangers and additional advertising in local newspapers. The use of neighborhood newspapers was found to be particularly effective.

Illegal Dumping Hotline

Members of the general public commonly report spills and illegal dumping of toxic substances. The public was the source of 43 percent of the illegal dumping/spill incidents investigated by BERM and 24 percent of those investigated by DPH. San Francisco does not, however, currently operate an illegal dumping hotline specifically oriented to the general public. Such a hotline will be established as part of BMP No. 2. During normal working hours, the hotline will be answered at BERM, with referrals to DPH, Fire Department, and the Bureau of Street Cleaning and Urban Forestry, as necessary. Being answered first at BERM will allow an appropriate response to be coordinated, while maximizing the possibility of catching the dumper "in the act" and citing them. A standard procedure will be established through which illegal dumping reports received by other City agencies are transferred to BERM. Other citys' experiences with illegal dumping hotlines suggest that once established and publicized, fewer public calls will come through other lines.

The illegal dumping hotline will be aggressively publicized and promoted. Whenever possible, the hotline number and message (e.g. "Report All Illegal Dumping!") will be integrated with other program activities. All public education materials produced will prominently list the hotline number and to encourage its use. Environmental groups, community organizations and other groups will be notified of the hotline and asked to promote it through their newsletters and activities. Neighborhood watch groups will be provided with background materials on illegal dumping and the hotline and encouraged to watch out for illegal dumping as part of their activities. (Neighborhood watch groups must be reached through the Police Department.) Senior citizens groups will also be educated about the hotline. Finally, a bumper sticker will be developed which prominently displays the hotline number with an accompanying message to report illegal dumping. Bumper stickers will be applied to all City vehicles and distributed to environmental groups, schools, community organizations and at special events.

Additional publicity, in the form of Public Service Announcements (PSAs) on local TV and radio stations, and paid advertisements in print media, on billboards, bus stops and in mass transit vehicles will also be arranged as practicable. One means of funding such advertising is to arrange for fines levied against businesses for illegal dumping or other hazardous materials-related violations to be "set aside," with the guilty party sponsoring a billboard or other form of advertising carrying the hotline number and message. This program is used successfully in Sacramento County and allows the fines to be used directly for program-related advertising rather than going into the general fund where they might not be readily available for the public education program.

A potential option that has been suggested for an illegal dumping hotline would be to develop an integrated "environmental hotline" to which residents could call concerning the full range of environmental issues. The integrated environmental hotline would consolidate hotlines currently being operated by the CAO as well as the new illegal dumping hotline. Callers would be provided

VOL 12 2 4258

R0057550

with a menu through which they would be transferred to either existing recordings, voice mail, or, as with the illegal dumping hotline, to staff at either BERM or the Fire Department. Consolidating the existing hotlines into a single "environmental hotline" would reduce confusion among the

Several factors undermine the feasibility of an integrated "environmental hotline," however. The public may not be receptive to an extended menu, especially when calling for a specific purpose. Additionally, the cost of such a system could be prohibitive. The CCSF's Bureau of Telecommunications has reported that such a system would have to be arranged through Pacific Bell's California Call Management Program. This program charges $250 per month for every incoming and outgoing phone line, or "port." Multiple incoming lines would be necessary to ensure that residents do not receive a busy signal. Transfers to a recording or voice mail cost only $8.50 per month. While a traffic survey of existing lines would be needed to determine the exact number of incoming lines necessary for an integrated "environmental hotline," it can be assumed that at least four lines would be needed as well as one outgoing line for transferring illegal dumping reports to BERM or the Fire Department. This arrangement alone would cost at least $1250 per month. Given the level of use that could be expected for an integrated "environmental hotline," the actual cost could be much higher. It is thus assumed that this option would be infeasible for cost reasons.

Citation Authority for BERM Inspectors

BERM will investigate providing its inspectors with the authority to cite illegal dumpers. The legal authority, fining structure, and appeal process will be similar to the Fire Department procedures and will be based on advice from CCSF's legal departments. Even if citation is not possible, BERM should respond to major illegal dumping reports with an appropriate "show of force" to convey to residents the seriousness of dumping toxic substances into sewers and storm drains and to warn the violator against repeating the action.

EXPECTED REDUCTIONS

Reductions due to the illegal dumping hotline and the citation authority for BERM inspectors would be highly variable. Reductions from this BMP would be primarily due to the proper disposal of used motor oil. Based on the San Jose program results (one gallon per household per year with 50 percent of households participating), approximately 157,000 gallons of used oil per year would be collected. Some of that oil would normally have been disposed of properly. California Integrated Waste Management Board estimated that approximately 46 percent of used oil was disposed of illegally in 1990. Therefore, approximately 70,000 gallons per year would have been illegally disposed if curbside collection were not available. Table 5-2A summarizes the reductions of toxic pollutants by collecting the illegally disposed used oil. The amounts of metals in used oil were estimated based on discussions with a local used oil recovery company and are summarized in Appendix C-2. In addition to the metals shown on Table 5-2A, PAHs and other organic compounds present in used oil would also be reduced. However, their loadings are unknown at this time.

BMP NO. 3

BAN THE USE OF COPPER SULFATE ROOT KILLERS AND EDUCATE THE PUBLIC ON ALTERNATIVE PRODUCTS

Generally speaking, most of these products do not have a direct pathway to the treatment plants. Some of these compounds used in CCSF may contribute to the wet weather loadings. An exception in this regard are root killers.

Chemical root killers are used to kill or retard roots which, attracted by moisture, have grown into sewer lines through small cracks, fissures, or separations at joints. The majority of chemical root killer products sold to the general public are composed of copper sulfate and are applied directly to the sewer line by flushing the product down the toilet. Product directions recommend using an entire two pound bottle in each application with one application per year suggested. Given that copper sulfate is approximately 40 percent elemental copper, approximately 0.5 pound of copper would be added for each application.

The use of copper sulfate root killers can be found in three areas: consumers who purchase and use the product themselves; plumbing and sewer repair businesses that use the product as part of their work or sell it to customers following mechanical removal of roots, and; CCSF's Department of Public Works which may use the product in municipal sewer lines.

An informal survey of plumbing and sewer repair businesses suggests that copper sulfate root killers are not widely used. Most of the businesses contacted reported that mechanical cutting is the primary means of removing roots from sewers. Copper sulfate is sometimes recommended as a secondary or maintenance treatment to retard roots that have already been cut. This conclusion confirms a study conducted in Palo Alto, CA, which interviewed 13 sewer clearing and plumbing businesses. Of the 13, only one reported using copper sulfate, with only ten pounds used during 1990 (SRI, 1991B). Commercial plumbers and sewer repair companies are thus not considered a major contributor of copper sulfate root killers.

Copper sulfate root killers are widely available to consumers at hardware and plumbing shops. The ease with which the product can be applied suggests that it could be widely used by consumers. Without conducting a detailed survey of hardware and plumbing stores in CCSF, it is impossible to know exactly how much copper sulfate root killer is sold and used. In the public awareness survey conducted, root killers were reported to be used by 3 percent of CCSF households. Copper sulfate had the lowest usage rate reported for any of the toxic materials covered by the survey. If 3 percent of CCSF's approximately 300,000 households each made one, two-pound application of copper sulfate root killer per year, over 7,200 pounds of copper would enter the sewer system. The accuracy of this figure may be questionable, however. Survey respondents may have associated "root eradicators" (the term used in the survey questionnaire) with weed killers and other products applied directly to plants in the lawn or garden. This is supported by the survey's finding that having a yard or garden was linked to greater use of root eradicators. Lawn and garden root killers and related products do not have a direct pathway to the sewer system during dry-weather conditions and thus are not addressed by BMP No. 3.

The SRI study cited above estimated that copper sulfate root killers contributed between 36 and 42 pounds of elemental copper in Palo Alto in 1990. By projecting this usage based on population, copper sulfate root killers may be the source of 300 to 400 pounds of elemental copper entering the SEWPCP system in 1990. This range is likely to be an over-estimate, however, as Palo Alto residents may use more of this product due to the area's higher percentage of detached single family homes and garden landscaping. A more realistic loading may be 50 percent of the above

VOL 12 2 4263

R0057555

estimate, or 200 pounds per year. The west coast distributor of a prominent brand of root killer (Roebic Root Killer K-77) was contacted and suggested that the relative scarcity of trees in CCSF minimized sales of the product. A rough estimate was given that approximately 400 to 500, two

The Bureau of Street and Sewer Repair was interviewed with regard to its use of the product and it was reported that no copper sulfate root killers are used. The Bureau has a Vaporooter machine which uses a foaming herbicide containing sodium methyldithiocarbamate and dichlorobenzonitrile. Due to employee complaints, this technique is not used. Mechanical cutting is the primary method used for removing roots which have grown into municipal sewer lines.

POLLUTANTS OF CONCERN

The most commonly used chemical root killers are composed of copper sulfate, which is 25 percent elemental copper. Thus, copper is the only pollutant of concern addressed by BMP No. 3.

Dichlorobenzonitrile, used in Vaporooter machines, may contribute a slight amount of cyanide. However, based on residential sampling results, cyanide from root killers and other residential sources appears to be minimal. This process is also not widely used by sewer clearing companies. Therefore, cyanide is not expected to be reduced by controlling root killers.

EXISTING CONDITIONS

The "Guide to Less Toxic Shopping" produced and distributed by the CAO's office discourages the use of copper sulfate-based root killers. The Guide recommends that roots be removed through mechanical cutting and non-metallic foaming herbicides, and that breaks in sewer lines be repaired to prevent further entry of roots. The agrichem brochure being developed does not address roots in sewers.

IMPLEMENTATION MEASURES

After its investigation into copper sulfate root killers, Palo Alto banned the use of this product in its sewer system. Its sewer use ordinance was modified to implement this practice. Several other agencies in the Bay area, including Central Contra Costa Sanitary District, will be implementing the same policy. It is recommended that CCSF ban the use of copper sulfate root killers as the primary measure of this BMP.

A ban of the use of this product would require educating the potential users. It is apparent that the use of copper sulfate root killers stems predominantly from residential sources, which are thus the focus of BMP No. 3. With regard to municipal use of such products, CCSF should maintain its current practice and ensure that it is not used by DPW or its contractors. Due to the low use of copper sulfate root killers by plumbers and sewer repair businesses, minimal outreach would be required in this area. If resources permit, a minimal outreach effort to this group will include a mailing explaining the adverse environmental impacts of copper sulfate root killers and the use of non-toxic alternatives only, such as mechanical cutting or sodium hydroxide root killers.

VOL 12 2 4264

R0057556

With regard to education and outreach to the general public, the agrichem brochure being developed will be modified to include information banning the use of copper sulfate root killers and

and where root obstruction of sewers could be expected to be most common. The "Guide to Less Toxic Shopping" or educational material specifically focused on copper sulfate root killers can be distributed in these areas. Finally, when residents contact CCSF concerning problems with their sewer line, they will be instructed to utilize non-toxic alternatives. CCSF staff, such as in the Bureau of Street and Sewer Repair, will be educated on the issue and instructed to recommend non-toxic alternatives for root control when speaking with residents.

Workshops conducted for lawn and garden shops, hardware stores, nurseries and plumbing and sewer maintenance businesses will include a discussion of non-toxic approaches to root control and educational materials will be provided encouraging the promotion of non-toxic alternatives to copper sulfate root killers. Sodium hydroxide-based root killers, for example, should be recommended to their customers.

EXPECTED REDUCTIONS

The data discussed above suggests that the amount of copper entering SEWPCP from copper-based root killers may be approximately 200 pounds per year. By banning the use of this product, the entire loading could be eliminated.

ESTIMATED COSTS

The estimated costs for BMP No. 3 are summarized in Table 5-3A. The implementation costs include expenditures for revising the existing sewer ordinance to ban the use of copper sulfate root killers. The program of outreach to businesses, nurseries, and residences are expected to continue for two years after the ban is in order to fully implement this BMP. The total costs over these two years are amortized for direct comparison with other BMPs. The detailed cost estimates are included in Appendix C-3 for reference.

VOL 12 2 4266

R0057558

BMP NO.4

Metals and cyanide compounds contained in paints and other home improvement products (e.g., spackling paste, wallpaper adhesives, etc.) may be discharged to the sewer through routine cleanup and disposal procedures practiced by commercial contractors and residents. Of the pollutants targeted in this BMP study; copper, mercury, zinc, and cyanide compounds are commonly used in paints and/or other home improvement applications such as preservatives, biocides, mildewicides, and in paint and pigment formulation. This BMP would attempt to reduce the pollutant loadings from these sources by implementing educational measures and suggesting alternatives to specific products and disposal practices.

POLLUTANTS OF CONCERN

CCSF's "Small Quantity Generators" report identified painting and wallpaper hanging contractors as a potentially high sources of toxic pollutants, especially mercury and zinc. The uses of mercury, copper, zinc, and cyanide compounds in home improvement products are discussed below.

Mercury

Historically, mercury in the form of phenyl mercuric acetate (PMA) was commonly used as an in-can preservative to prevent bacterial and fungal growth and as a mildewicide for interior and exterior paints, spackle and wall paper adhesives. Prior to June 1990, mercury limitations in paint were set at 200 ppm in interior paints and 1500 ppm in exterior paints. Following an incident of mercury poisoning in a four-year old child resulting from mercury in paint, EPA promulgated the following regulatory restrictions on mercury sales and uses:

- As of August 20, 1990, mercury was banned in paints intended for interior use, but could still be used on exterior surfaces in concentrations of up to 200 ppm. Paint distributors were required to re-label all mercury-containing paints "for exterior use only." (55 FR 26754)

- As of September 30, 1991, the use of mercury was banned by EPA for all interior and exterior applications. Paint manufacturers were allowed to purchase mercury until this date, and were permitted to subsequently deplete their stocks through continued use in the manufacturing process.

According to a Kelly-Moore representative, this PMA stock depletion phase would last approximately 9 to 12 months from September 1991, assuming normal paint sales and consumption. Therefore, exterior paint sold in stores today would likely contain mercury. In response to the regulatory measures, paint manufacturers have switched to organic-based mildewicides. (H. Champeny, pers. comm. 1992)

The common spackling and wallpaper materials currently being sold in California do not appear to contain mercury or any of the other targeted compounds. Conversations with several manufacturers of leading spackling and wallpaper adhesive products (Synkoloid Co., Custom Building Products, and Wall Tite, Inc.) indicate that these products used to contain mercury until a

VOL 12 2 4267

R0057559

few years ago, but have since switched to organic, amine-based biocides such as azoniaadamantane chloride. (J. Avelar, pers. comm. 1992)

cupric acetoarsenate and copper phthalocyanine, which are used in formulating deep blue and green paint pigments, and cupric sulfide, which is used to form a copper blue coloring in linseed oil varnishes. (Gosselin, et. al. 1984; D. Radke, pers. comm. 1992)

Copper is also used in the form of cuprous oxide (Cu_2O) as a biocide in marine paints. These marine paints are designed to slowly release copper in ionic form in order to prevent the growth of organisms such as barnacles on the underside of boats. These paints may consist of 20 to 70 percent by weight of cuprous oxide (Datta, personal comm., 1992).

Zinc

Zinc oxide is a common ingredient for many oil-based and water-based (latex) house paints, with weight percentages reportedly ranging between 0 and 25 percent (Gosselin, et. al. 1984). Zinc oxide contributes to the hardness and gloss retention of the paint film, as well as enhancing ultraviolet light protection, chalk control, and mildew resistance (Patton, 1973).

Cyanide

Cyanide compounds such as ferrocyanide are used in the formulation of certain deep blue pigments such as iron blue. (Gosselin, et. al. 1984) Little data are available describing the percentage of paints that contain these pigments. However, pigment manufacturing information (Patton, 1973) indicates that the cyanide weight percentage contained in certain deep blue pigments may be between 5 and 30 percent. Paint contractors and sales persons contacted could not provide information on sales of paints containing cyanide.

Other Compounds

Lead is the only other metal banned by EPA for use in paints. Lead restrictions were passed in 1978. Regulations may be forthcoming for tributyl tin oxide, but no other intended metals restrictions are known at this time. (B. Edwards, pers. comm. 1992)

EXISTING CONDITIONS

Painting contractors, distributors, and homeowner "do-it-yourselfers" practice a wide range of disposal methods for their paint-related products. Sink and storm-drain disposal of excess paints; brush, roller, and spray equipment rinsewaters; and home laundering of paint-covered materials are common pathways for pollutant-laden paints to enter the sewer system.

Although waste minimization is widely practiced by painting contractors as a cost-savings measure, proper paint cleanup procedures with respect to minimizing sewer loadings are not as common. Many contractors are unaware that paints contain metals and other pollutants of concern, and are unaware that storm drain/sewer disposal is not appropriate. Some contractors contacted were unsure of the precise equipment cleaning procedures of their work teams and reported various improper procedures such as rinsing equipment into the soil and evaporating paints for disposal as a solid waste rather than paying for hauling of liquid hazardous wastes. Rinsing of equipment to

VOL 12 2 4268

R0057560

the soil, "work" sinks, or storm drains was also reported "so as not to leave a noticeable mess". While some contractors are careful to dispose of their thinners that are used in cleaning oil-based paints, others are less aware of proper disposal procedures. Residential "do-it-yourself" painters

residential "do-it-yourselfers." Educational materials describing proper waste minimization and cleanup/disposal procedures are not readily available.

In light of the high cuprous oxide content of marine paints, boatyards were identified as a potential source of copper to the SEWPCP. Boat scraping and painting operations at the yards may provide a potentially significant source of copper through routine, dry weather rinsing and cleaning operations.

BERM recently conducted inspections at each of the boatyards in the CCSF for the Port of San Francisco in anticipation of upcoming stormwater permitting requirements. Based on information gathered through these inspections, the boatyards are typically in a state of severe disrepair with very few measures taken to prevent or minimize the disposal of paints and related pollutants into facility storm drains. However, of the 10 boatyards inspected, only two currently are equipped to pump facility rinse and washwater to the SEWPCP collection system from the waterfront. Most facilities only have sanitary hookups to the SEWPCP, but drain all of their working washwaters directly to the Bay. Most of these boatyards, therefore, do not comprise a current source of copper to the SEWPCP. However, as a result of pending stormwater permitting actions, CCSF's boatyards may be discharging to the SEWPCP in the future. Boatyard operating personnel should thus be included in the educational measures conducted for this BMP.

Estimated Loadings From Home Improvement Products

Little data are available to estimate the quantities of paints and pollutants entering the sewer as a result of painting contractor and residential disposal practices. Paints are typically shipped to the stores as a white paint and then mixed with colorants according to customer preference. The liquid colorants are often produced at a paint manufacturer from dry pigments purchased from a pigment supplier. The highest degree of uncertainty in these loading estimates relates to the portion of the sewer bound paints that contain each metal. For copper and cyanide, loadings from house paints would depend on the pigments used and the weight percentage of pigments mixed into the paints. The weight percentage of pigments in paints tends to vary between 10 and 50 percent, depending on the coating type and color, and the strength of the pigment used. Copper and cyanide compounds, in turn, may comprise between 5 and 30 percent by weight of the pigment. (Patton, 1973)

A detailed market analysis of paint and pigment sales was not conducted for this study. Such an analysis would be necessary to more accurately refine the loading estimates of metals and cyanides from paints. Representatives from two national painting trade associations, National Paint and Coatings Association (NPCA) and Painting and Decorating Contractors of America (PDCA), would not supply information to non-members for use in this study.

Based on discussions with paint contractors regarding the approximate number of commercial painters operating in CCSF and the amount of paint being discharged to the sewer from typical disposal practices, nearly 60,000 pounds of paint per year are estimated to be disposed of to the SEWPCP. Metals loadings were estimated from the portions of these paints that are believed to contain the targeted pollutants. These estimated loadings are listed below.

VOL 12 2 4269

R0057561

- Copper 40 pounds per year
- Mercury 10 pounds per year

derived from residents equal one-half of the loadings derived from contractors. Other specific assumptions used to estimate paint loadings to the SEWPCP are included in Appendix C-4 for reference.

IMPLEMENTATION MEASURES

The implementation of this BMP will focus on educating painting contractors and residents. Paint contractors pose a problem for dispensing educational measures due to the decentralized worker population, and the large number of unlicensed (unregistered) working contractors. Contractors contacted during this study estimated that as many as half of the commercial painters operating in CCSF could be unlicensed.

Due to the high number of unlicensed contractors, the high turnover of businesses, the mobility of the business, and the number of residential contributors, traditional regulation relying on permitting and sampling for compliance would not be appropriate. Education of both businesses and residents would be more effective. The Green Business Program, discussed under BMP No.1, would be extremely effective. The implementation measures recommended for this BMP are listed below.

- **Develop Database.** Compile a comprehensive, current database of all licensed painting contractors, equipment rental shops, boatyards, home improvement/hardware stores, and home improvement classes operating in CCSF. This database would define the target audience for this BMP. It should be developed based on a review of CAO's existing database, the yellow pages, the Construction Blue Book, the East Bay Painting Contractor Association, and other available listings.

- **Compile Technical Information.** Information would be compiled on problem paint types, recommended cleanup techniques and disposal procedures, recycling of paint thinners, and waste hauling options. Recommended cleanup measures would need to be catered to specific coating types and working environments. For example, recommendations for proper painting procedures may include the following:

  -- Avoid exterior paints and finishes containing mercury.
  -- Minimize use of paint (e.g., only buy what you need; use water-based paints and whitewash where possible; explore reuse options).
  -- Practice proper paint stripping and removal (e.g., use heat gun or hook scraper).
  -- Practice proper cleanup procedures (e.g., use brush "spinners" and rags to remove excess paint from brushes; designate an "initial rinse" bucket to be hauled to a hazardous waste facility; separate and reuse paint thinner; wash clothes at industrial laundry facility; etc.)

- **Coordinate with other POTWs that are Regulating the Painting Industry.** Most painters, by necessity, are highly mobile and may work in and out of CCSF. To facilitate compliance for this industry, requirements among different POTWs should be as similar as possible.

VOL 12 2 4270
R0057562

- **Identify Workshop Participants.** Identify contractors, hardware/paint store managers, equipment rental shops, and boatyard managers to invite to the educational workshops. Prepare and mail workshop invitations, providing two alternative dates for

describe the concerns associated with improper paint disposal, and provide simple instructions as to proper cleanup and disposal methods. References to CAO literature such as "Your Guide to Less Toxic Shopping," and directions to the household hazardous waste facility will be provided on these materials.

- **Conduct Workshops.** BERM would provide two educational workshops for painting contractors, hardware store managers, boatyard managers, and paint equipment rental shops to discuss recommended waste minimization, cleanup, and disposal practices.

- **Distribute Fact Sheets and POP Displays.** Fact sheets and point of purchase displays will be finalized following review at the workshops. These will be distributed to hardware stores, paint stores, and equipment rental shops. Retain extra fact sheets for distribution at fairs, community events, and/or as utility bill inserts.

- **Implement a Green Business Program.** Contractors employing proper cleanup and disposal practices can promote themselves as a "Green Business." The Mayor's "Green Ribbon Panel" will be used to promote and coordinate this program. Permitting and inspection procedural details will need to be coordinated to ensure continued practice of the proper procedures.

- **Educate Residents on Proper Cleanup Practices and also on Selecting Green Business Contractors.** As part of the public education tasks described under BMP No.1 and the point of purchase displays at paint and hardware stores, residents will be instructed to follow proper cleanup and disposal procedures, and to only select certified "Green Business" contractors.

EXPECTED REDUCTIONS

Table 5-4A presents the expected mass loading reductions to occur through the implementation of BMP No.4. These reductions assume a 60 percent reduction of mass loadings from paint contractors, and a 50 percent reduction from residents. These reduction estimates assume that the painting contractors are an easier group to reach with the educational measures than the resident "do-it-yourselfers." However, since contractors tend to waste less paint than residents, the difference in expected future reductions is fairly small.

ESTIMATED COSTS

The implementation costs for this BMP are summarized in Table 5-4B. Detailed cost estimates are included in Appendix C-4 for reference. Costs for implementing this BMP are estimated to be nearly $37,000 annually. These costs assume one-time costs of presenting the four workshops and developing 1,000 point of purchase displays, and annual production of 10,000 fact sheets.

R0057565

BMP NO.5

FURTHER REGULATE DISCHARGE OF PHOTOGRAPHIC WASTES

Quality Control Plant. In addition to silver, a number of other pollutants are also present in various photographic wastes. CCSF has been regulating the larger photofinishers within its service area for a number of years. This BMP evaluates implementing additional regulations on this business category.

Photographic materials (film, paper, etc.) and solutions contain a number of organic and metallic compounds. Table 5-5A lists some of the chemicals found in photographic solutions. Many of these solutions are discharged into the sewer system and have a direct pathway to the environment. The negative impacts of these wastes into the environment have been recognized. For a number of years, the photographic industry has reformulated certain products with less toxic components and has developed various recycle and treatment schemes to reduce the loadings of these toxic pollutants.

POLLUTANTS OF CONCERN

The pollutants of concern identified at CCSF that are typically associated with the photographic processes include silver and cyanide. Mercury was initially thought to be a compound used in photographic processing. Chromium and selenium are also present in some of the solutions. The use of these pollutants are briefly discussed below.

Silver

Silver is the most prominent pollutant of concern from the photographic processes. It is contained within the film and prints in the forms of silver chloride, silver bromide, and silver iodide. The use of silver in photography is briefly described below.

The initial step in photography is the exposure of a film to a light source. The plastic film is covered with a light-sensitive coating called a photographic emulsion. This emulsion is usually composed of silver halide salts in gelatin. Silver halides include silver chloride, silver bromide, and silver iodide. Most photographic films are made of polyester or cellulose acetate. To produce the photographed image, the film is commonly developed into a negative and then into prints. The major steps in film processing include developing, bleaching, fixing, and washing.

Developing. Chemical oxidation and reduction reactions develop an exposed photographic emulsion. Black and white (B/W) and color processing are different and are described separately. The photoactive medium used for black and white processing is an emulsion composed of a dispersion of silver halide crystals in a gelatinous matrix. Brief exposure to light produces a chemical change in the silver halide crystals. When the film is subsequently immersed in the developing solution, the exposed silver molecules are converted to metallic silver. The metallic silver is dark in color and produces a negative image.

Film and paper used for color photography consist of three separate layers of photoactive emulsion with intermediate layers. Each layer is sensitive to either red, green, or blue light due to the presence of selective dyes in the emulsion. Intermediate layers filter out other wavelengths, so that the silver halides in each layer are only exposed by the light of the specific color. A colorless dye-forming coupler is present along with the silver halide crystals in each emulsion layer. When

VOL 12 2 4275

R0057567

processed in the developer solution, the exposed silver molecules are converted to metallic silver, while simultaneously producing oxidized developer molecules. These developer molecules react

Stopping. A stop bath is used immediately after the developer bath for B/W film development and print making. If the film were kept in the developer bath, even the silver molecules not exposed to light can be converted to metallic silver by the developer solution. To prevent this from happening, the chemical reaction of the developer is arrested by the stop bath. The stop bath is a weak acid solution (usually acetic acid) which neutralizes any of the alkaline developer carried over on the surface of the film or in the wetted gelatin layer.

Bleaching. A bleach solution is rec only with color processing. It renders the color image visible by removing the b ack metallic r from the photographic emulsion. The bleach converts the metallic silver back into silver halides. All of the silver halides on the film, whether a part of the exposed image or not, can then be dissolved and removed in the fixing step. The dye is retained in each layer of the film so that a negative color image exists.

Fixing. After the developing and bleaching steps, the photographic image on the negative is visible but very perishable. If exposed to light, the entire negative will turn dark. To prevent this, the fixer sets the image permanently on the film. The fixing agent is needed because the negative image contains unexposed silver halides from the black and white processing and reconverted silver halides from color processing. These crystals are still light sensitive and, if allowed to remain, would cloud the image.

The fixing solution is usually comprised of sodium thiosulfate (hypo). Ammonium thiosulfate or sodium hyposulfate is also used. The fixing solution converts the silver halides to soluble complexes and dissolves them out of the emulsion into the solution. The majority of the silver from photographic processing is contained in the fix and bleach-fix (blix) solutions.

Washing. After a film is fixed some of the chemical, including hypo, remain on the gelatin emulsion layer. If it is not removed, it can react with any remaining silver to form yellowish-brown silver sulfide, which impairs the quality of the image. To prevent sulfide formation, fixing chemicals are washed from the emulsion. Films are washed in a water bath that dissolves the hypo from the emulsion. Usually, a hypo neutralizing agent and a wetting agent, to prevent water from spotting the film, are added to the wash water.

Mercury

Mercury was initially identified as a potential pollutant from the photographic process. In a review of the "Clinical Toxicity of Commercial Products" (Gosselin et al., 1981), a Kodak intensifier with a mercury concentration of 16,650 mg/l was listed. An intensifier is used to increase the contrast between light and shadow areas in B/W photography. It is typically used in artistic photography rather than in general consumer photographic processing.

The Eastman Kodak Company was contacted to verify whether this product is still used. Based on discussions with the manager of the Kodak Imaging Environmental Support Services, Eastman Kodak does not currently, and has never, marketed a mercury intensifier. Kodak apparently reported a formula for the mercury intensifier in a trade journal in the 1970's (Dagon, 1992). The unavailability of a mercury intensifier was confirmed in discussions with the environmental manager of Fuji Photo Film U.S.A. Inc. Based on the current regulations limiting the use of

VOL 12 2 4276

R0057568

mercury in general and an absence of demand, photographic processing is not expected to be a source of mercury.

photographic industry has switched to alternative bleach solutions. The majority of bleach solutions used today contain ferric EDTA (ethylenediaminetetraacetic acid) as the oxidizing agent. Currently, there are only three processes that require the use of ferricyanide bleach:

- Kodachrome K-6 (slide film).
- Aerial Ektachrome EA-5 (aerial photography and satellite pictures).
- VNF (video news film).

Certain motion picture and cinemagraphic processing still utilize ferricyanide bleach; however, most of that processing is performed with a persulfate (sulfuric acid) bleach. Based on discussion with BERM's Pretreatment Enforcement Section (PES) staff, none of the major photoprocessors within CCSF utilizes ferricyanide bleach.

Other Chemicals

Although not identified as pollutants of concern at CCSF, chromium and selenium are present in other chemicals used in photographic processing. Table 5-5B lists certain products reported in the "Clinical Toxicity of Commercial Products" and their expected concentrations. These compounds are not used extensively in consumer photographic processing and their overall usage may be small. However, as shown on the table, the working concentrations of pollutants in these products are significantly above their respective local limits.

EXISTING CONDITIONS

BERM's PES has been sampling and regulating photographic processing businesses since the 1970s. This sampling and regulating effort has been directed towards the significant industrial users (SIUs). Recently, PES staff has performed a comprehensive survey to identify all photographic processing operations within CCSF. This survey includes commercial photographic finishers, printers, and micro-filming operations. A complete listing of the 291 establishments that are in the PES photographic data base is included in Appendix C-5 for reference.

BERM adopted new technically-based local limits December 18, 1991. The new limit of 0.5 mg/l of silver is being imposed on all silver dischargers within CCSF. So far, the PES has utilized this transition period to educate dischargers on treatment and disposal methods available to comply with the new limits.

Of the 291 establishments identified in the database, 67 have been sampled for compliance and another 94 dischargers have been inspected by PES staff at least once since 1991.

VOL 12 2 4278

continued. In addition, several additional measures could be added to the existing program. However, it should be noted that silver is not currently a major pollutant of concern for CCSF. The 99th percentile effluent in 1991 was 9.1 µg/l as compared to the new Basin Plan limit of 23 µg/l. However, as the SEWPCP effluent already would comply with the new limit, regulation of these additional minor sources would have no effect on compliance.

- **Regulate Dental Offices and X-Ray Laboratories.** The PES staff has done an exemplary job in the identification, sampling, and inspection of a large number of photographic waste dischargers. An expansion of the current program could include the regulation of dentist offices, dental laboratories, and x-ray laboratories. A review of the PacBell Yellow Pages indicated that there are over 900 dentists and dental laboratories within CCSF. X-ray laboratories could expand this listing considerably. Prior to regulating these businesses, a comprehensive survey of these businesses would have to be performed

- **Regulating and Monitoring.** The current local limits would be used as the mechanism for regulating these businesses. As many of these businesses are small, off-site hauling may be the more appropriate means of disposal than treatment. Therefore, most facilities would not require sampling, but rather, periodic inspection of hauling records and education assistance would be required. Due to the potentially large number of these facilities, a comprehensive computer scheduling program to schedule sampling/inspection and to track violation notices/responses would be a necessity.

- **Regulate Other Photographic Wastes.** In addition to bleach and fix, other photographic solutions (toners, reducers, and tray cleaners) contain pollutants with concentrations higher than their respective local limits. The pollutants in these solutions include chromium, selenium, and silver. They should be regulated in a similar manner to silver. Since most of these solutions are used infrequently or in smaller quantities, expected reductions may be minimal. As there is no residual value for the non-silver wastes, cost of its off-site hauling could be significantly higher than the bleach and fix solutions.

- **Provide Residential Drop-Off Locations.** Based on discussion with PES staff, a major improvement to the existing silver control program would be to have more drop-off locations available. The existing Hazardous Waste Collection Center is located at the southern boundary of CCSF and is not convenient for many residents. Availability of drop-off sites at the SEWPCP and RSWPCP would facilitate proper disposal. An area at each plant could have to be constructed for accepting the silver wastes. Staffing of the disposal areas would also be required. In order to maximize convenience, the drop-off sites should be open to the public for at least six days a week. Silver wastes collected at these sites would be hauled off-site for reclamation and proper disposal.

VOL 12 2 4219

R0057571

EXPECTED REDUCTIONS

approximately 62 percent, from 34 µg/l to 13 µg/l. The PARWQCP silver reduction program regulates dentists and x-ray laboratories as well as commercial photofinishers.

Implementation of the above measures would achieve lower percent reductions, primarily due to the silver waste control practices that are already in place. The average SEWPCP influent silver concentrations have decreased from 25 µg/l to 15 µg/l from 1990 to 1991. The results indicate that the current program (regulating the largest discharges) is already very successful. Further regulation, as recommended by this BMP, may not result in noticeable reductions. Assuming an additional 5 percent reduction, silver loadings would be reduced by 500 pounds per year. Reductions in other pollutants such as chromium and selenium would be very limited.

ESTIMATED COSTS

The estimated costs of BMP No.5 are summarized in Table 5-5C. A larger number of small businesses would be regulated under the new measures described above. After these businesses are identified, one PES source reduction specialist would be required on a half-time basis to develop specific regulatory steps, educate and assist business operators, and inspected and monitor these facilities.

R0057573

number of pollutants to sanitary sewers. The term "automotive service facilities" encompasses many types of businesses: general automotive repair shops: brake, radiator, or transmission repair facilities; automotive detailing facilities; car washes; engine steam cleaning facilities; automotive body repair shops; automotive upholsterers; air conditioning servicing shops; and gasoline/service stations. As described in a subsequent subsection, CCSF is currently regulating all radiator repair and car washing facilities. For the purpose of this evaluation for CCSF, "automotive service facilities" is used collectively to designate all of the above facilities, with the exception of radiator repair shops and car washes.

Most of these businesses generate some of the following types of waste: waste oil, used lubricants and transmission fluids, spent solvents, spent caustic parts washing solution, parts cleaning tank sludge, oily waste sump sludge, used antifreeze, and used lead acid batteries. Improved control of waste from automotive service facilities can be achieved by implementing several straightforward management practices and shop operating procedures. Included in this section are a summary of background information on CCSF's current source control efforts in this area including automotive service facilities inventory and education efforts, a description of the sources of pollutant loading from automotive service facilities, an estimate of pollutant loading, guidance for implementing specific procedures to minimize loading, and an estimate of expected pollutant loading reductions.

POLLUTANTS OF CONCERN

A variety of activities are carried out in automotive service facilities. If not managed carefully, these activities provide routes for commonly used products to reach the storm drains or sanitary sewers. For example, if, while performing engine repairs, used motor oil is allowed to drip onto the shop floor, the floor is washed down, and the wash-water flows to the floor drain which discharges to the sewer, a route is established for used motor oil to reach the sewer. Automotive service facilities therefore represent potential sources of heavy metals, oils, grease and other pollutants to San Francisco's sewer collection system. A number of common activities and associated wastes are summarized in Table 5-6A.

Many of the products used in automotive service facilities are petroleum products or distillates distilled from crude oil and chemically treated with additives. Automotive oil is usually refined from base or crude petroleum, often with additives such as heavy metals, mono- and polycyclic aromatic hydrocarbons, halogenated hydrocarbons, phthalates, phosphates, phenols, amines, and amine derivatives, detergents and dyes (Municipality of Metropolitan Seattle, 1982) In addition, waste oil contains heavy metals as contaminants from engine wear and combustion. Gasoline is composed of hydrocarbons derived from distilled crude petroleum. It is chemically modified and blended, and may contain additives such as anti-knock agents, anti-rust agents detergents, and dyes. Transmission fluid also has a hydrocarbon base. In addition, several non-petroleum based products are commonly used, such as antifreeze and brake fluids. Antifreeze is used in radiators to prevent overheating or freezing, and the major ingredient is ethylene glycol. Brake fluids are composed primarily of glycol ethers. (Municipality of Metropolitan Seattle, 1982) Environmental problems associated with antifreeze and brake fluids appear to be with the used product, which can often be contaminated by heavy metals.

TABLE 5-6A

AUTO SERVICE FACILITY ACTIVITIES AND ASSOCIATED WASTES

Activity	Associated Materials Potentially Discharged
Changing automotive fluids	Motor oil, coolant, antifreeze, brake fluid, transmission fluid, radiator flushing fluid, freon other refrigerant
Fueling vehicles	Fuel
Removing and storing batteries	Acid and lead
Parts cleaning	Solvents, cleansers, degreasers
Metal grinding and finishing	Metal filings
Brake shoe filing	Asbestos filings
Engine cleaning and automotive steam cleaning	Oil and grease, volatile organic compounds
Engine and transmissions work, miscellaneous repairs	Leaking or dripping oil, etc.
Auto body work	Paints, thinners, solvents

R0057575

mailed questionnaires. Several follow-up mailings were necessary to obtain responses from all but approximately 200 businesses. These 200 businesses were notified by registered mail that they would be considered as zero-dischargers. The facilities that provided information were classified as one of three groups: non-applicable, zero-dischargers, or permitted. Between 500 and 1000 facilities are regulated as zero-dischargers. Facilities classified as zero-dischargers would be restricted from discharging any process-related wastes to the sewer system. The permitted facilities are issued standard industrial permits, requiring testing and self-monitoring. All radiator shops are permitted.

Santa Rosa permits all facilities related to automotive service. They have issued between 140 and 200 permits. Every permit has discharge limits and a set of special conditions pertaining to the specific type of facility. Santa Rosa has been primarily concerned with the discharge of organic compounds from these facilities. Metals and cyanide discharged from these facilities are not being regulated at this time.

Palo Alto is currently revising their sewer use ordinance to include BMPs for automotive service facilities. The revised ordinance will be finalized in October 1992. Each of the approximately 400 automotive service facilities in Palo Alto Regional Water Quality Control Plant's service area will be visited to provide free consultation and information, and to be evaluated. Those shops in compliance by 1 October 1992 will be recognized as "Clean Bay Shops." All automotive service facilities will be required to either become a zero discharger or to obtain a discharge permit. The permit will require self-monitoring to meet discharge limits. Sampling information is not yet available.

EXISTING CONDITIONS

Currently, CCSF regulates radiator shops and car washes. Radiator shops are permitted for zero discharge and are required to have closed-loop treatment/recycling systems. BERM's Pretreatment Enforcement Section (PES) staff have inspected and sampled all CCSF's radiator shops to confirm that they have achieved zero-discharge. Car washes are also permitted. Discharge from car washes is required to meet local industrial limits, and all car wash discharge permits are currently being updated accordingly. The car washes are inspected and sampled regularly.

The CAO is currently undertaking a program to provide information to automotive repair businesses to help them manage their waste, and to assess how wastes are generated in the automotive service sector. As a part of this program, an inventory of CCSF automotive repair facilities has been developed. Based on the current inventory, there are 149 fuel and/or service stations, and 500 general automotive repair shops, which include automotive body shops, machine shops, and transmission and brake repair facilities.

In addition to developing the inventory, automotive service facilities workshops have been conducted. At these workshops and in newsletters and mailers, the automotive service facilities were offered waste consultations. The consultations are provided at no charge by the CAO staff to those automotive service facilities requesting assistance. The purposes of the consultations are to educate and provide information to automotive repair facility staff, and gather information about the manner in which wastes are generated. A copy of the Waste Consultation Form used for the

VOL 12 2 4284

R0057576

automotive service sector is included in Appendix C-6. The summary of information developed through consultations is not yet available. Approximately 60 facilities have requested the consultation to date.

facilities. Flow data were not available at these sites, and thus no mass loadings were calculated as part of the SQG Report.

Estimated Loadings

There are minimal published information on the waste characteristics and loadings from automotive service facilities. Several Bay area POTWs (East Bay Municipal Water District, San Jose/Santa Clara, Palo Alto, Central Contra Costa Sanitary District, and Santa Rosa) currently regulating automotive service facilities were contacted. However, as many of these programs have only been recently implemented; information on waste characteristics, flow rates, and reduction potential was generally not yet available.

As mentioned previously, mass loading data from automotive service facilities were not available from the sampling efforts conducted to date in CCSF. The San Jose/Santa Clara Water Pollution Control Plant (CH_2MHill, 1989) reported sampling results from an automotive repair facility. Table 5-6B represents a compilation of the concentration data from the CCSF and San Jose/Santa Clara sampling efforts. Concentrations of copper, lead, nickel, and zinc for this table were taken from CCSF SQD Report data (CCSF, 1991C). The remaining concentrations are based on data from San Jose/Santa Clara.

The facility sampled in San Jose was a large automobile dealership that sells and services automobiles. There were two automobile washing stations that discharge wash water through a four-stage grease trap and then to the sanitary sewer. Samples were collected from the bottom of the fourth stage just before the water enters the sewer. Waste water flow was estimated to be approximately 4,000 gallons per day (gpd), which is much higher than that of a typical automotive repair shop. As the majority of the discharge water is from the car washing activities, these concentrations should not be totally representative of all automotive service facilities. However, in the absence of extensive sampling data, the concentrations listed in Table 5-6B were used to develop a preliminary estimate of the loadings. As site-specific sampling information becomes available, this loading estimate should be refined and reevaluated.

Flow data for specific automotive facilities were not available from the CAO inventory. The San Jose/Santa Clara study reported a flow rate of 450 gpd for a radiator repair shop. This flow rate is more likely to represent the average flow from automotive repair facilities. The loading calculation was based on 649 automotive service facilities identified in the CAO inventory. The preliminary loading estimates for CCSF automotive service facilities are presented in Table 5-6C.

IMPLEMENTATION MEASURES

Under this BMP, CCSF would regulate the remaining automotive service facilities in its service area. The mechanism for regulations would be the existing local limits. The specific implementation measures are discussed below.

- **Update Existing List.** Utilizing CAO inventory as a starting point, BERM would utilize the current PacBell Yellow Pages to update the list of automotive service facilities.

- **Survey Identified Businesses.** A mail survey would be developed and mailed out to

  - Types and amounts of chemicals used.
  - Types and amounts of wastes generated.
  - Current waste disposal practices.
  - Water usage.

- **Develop Regulatory Strategy.** A regulatory strategy will be developed. It is expected that many facilities may qualified as zero-dischargers. These may include gas stations that do no perform any repair services and service facilities that dispose of their waste by hauling offsite. For these zero-dischargers, a set of BMPs would be required. These BMPs will focus on the following:

  - Clean up leaks, drips and other spills without water.
  - Seal off floor drains in service areas.
  - Use recyclable or reusable materials whenever possible.
  - Train all employees so that they understand and implement the BMPs.

  Zero-dischargers will also be required to submit hauling records. They will be also inspected periodically to review records and for compliance with the required BMPs. Dischargers would be issued permits for compliance. Permitting, monitoring, and reporting procedures will be established. Dischargers will be required to self-monitor to demonstrate compliance.

- **Prepare Information Packets.** BERM will prepare information packets that contain detailed BMP procedures, disposal services and recyclers, emergency telephone numbers, information on pollution control agencies, and pretreatment information. The packets will be distribute to all automotive service facilities by mail and through the workshops. The packet developed for Santa Clara Valley Nonpoint Source Pollution Control Program has been included in the Appendix C-6 for reference.

- **Conduct Workshops.** BERM staff will conduct workshops to explain regulatory strategy, compliance requirements, and compliance schedules. The other main reason for the workshops is to obtain input, comments, and suggestions from the regulated community.

- **Confirm Status of Automotive Service Facilities.** BERM staff will inspect all facilities to confirm their status. For example, if a facility is to be designated as a zero-discharger, confirm that floor drains in work areas are sealed. During these visit, BERM's PES staff will also serve as the avenue of information exchange. Suggestions on methods to comply (opting for zero-discharge or treatment methods) with the new requirements will be provided to the facility owners at their requests.

VOL 12 2 4288

R0057580

- **Perform Periodic Site Inspections.** BERM staff will inspect all automotive service facilities on a periodic basis. Zero-discharge facilities will be inspected to ensure

facilities, and confirm BMP implementation and zero discharge status. Prepare inspection to provide information and guidance, as requested, to automotive service facilities regarding BMP implementation.

EXPECTED REDUCTIONS

The wastewater characteristics shown in Table 5-6B were compared against the CCSF local limits. The wastewater concentrations reported would comply with the current local limits. Therefore, significant reductions may not be achieved by regulating these additional automotive service facilities. As expected, the categories that are expected to discharged the highest loadings, radiator repair and car washing, are already regulated. A smaller reduction potential of 20 percent was assumed for this analysis. Table 5-6D presents the expected reduction in mass loading from regulating automotive service facilities.

ESTIMATED COSTS

The estimated costs for BMP No. 6 are shown in Table 5-6E. A breakdown of the specific tasks and level of effort associated with this cost are included in Appendix C-6 for reference. Due to the large number of automotive service facilities, an equivalent time of one source reduction specialist working for twelve months would be required to implement the program. After implementation, a source reduction specialist working on a half-time basis would be required.

R0057583

throughout CCSF. Laboratory wastewater flows may contain metals and cyanide as a result of routine analyses performed. Certain analyses may require metal or cyanide containing reagents or may involve the testing of samples containing the targeted pollutants. Additionally, spills and equipment breakages in the laboratory may result in the discharge of concentrated stock solutions or rinsewaters.

This BMP would minimize the pollutant loadings from CCSF laboratories through the implementation of "good housekeeping" requirements that would include recommended practices for proper chemical handling, storage, disposal, and waste minimization. Proposed source control measures would include educational workshops to be conducted for medical laboratory personnel, and development of an informational packet to be distributed to each known CCSF laboratory. This packet will be designed to provide education and guidance for implementing the recommended procedures.

POLLUTANTS OF CONCERN

Analytical procedures often require sample standards of a given pollutant in order to test for its presence in a water or wastewater sample. Additionally, some pollutants (e.g., mercury) are commonly used as sample preservatives and/or chemical reagents in the testing for other compounds, and thus would be expected in higher concentration in laboratory wastestreams. All of the targeted metals and cyanide are expected to be present in laboratory discharges.

A review of the water and wastewater analytical test methods that involve the use of mercury, cyanide, or copper indicated that pollutant concentrations used in the preparation of reagent stock solutions often exceed 1 gram per liter (g/L), and the pollutant mass used in some single tests may exceed 500 milligrams. An example of a common test that involves substantial quantities of mercury is the Closed Reflux Colorimetric Method for measuring chemical oxygen demand, as described in *Standard Methods for the Analysis of Water and Wastewater*.(Clesceri, L.S., et. al. 1989) This method utilizes a 33.3 g/L stock solution of mercuric sulfate ($HgSO_4$), with an estimated mass loading of 33.8 mg per analysis. Direct discharge of solutions would violate CCSF's local limits. Table 5-7A lists some standard analytical test methods that use copper, mercury, and cyanide reagents.

In addition to the reagents, other types of laboratories also utilize heavy metals and cyanide in their test procedures. For example, cyanide is used in medical labs for such practices as determining hemoglobin content and identifying iron deficiency anemia. Both of these tests involve the staining and coloring characteristics of ferrocyanide. Medical laboratories also use a mercury-containing Thimerosal solution, which is a preservative used to inhibit the growth of bacteria in protein-based reagents used in most biological testing (e.g., blood bank typing). Thimerosal typically contains approximately 0.01 percent mercury (100 ppm). (B.Brunell, 1992)

R0057585

have just been adopted for these facilities in December 1991. Discussions with personnel at medical and analytical laboratories, in coordination with a desk-top review of laboratory methods for examining water and wastewater samples, indicate that the potential exists for significant pollutant discharge to the sewer as a result of routine or accidental laboratory disposal practices. Over 70 commercial laboratories operate in the CCSF service area, of which nearly 60 service hospital or other medical facilities.

Some laboratories in CCSF may already be practicing proper chemical handling and disposal procedures. For example, the SEWPCP analytical laboratory provides storage for all standards, spent reagents, and analyzed samples in plastic containers (segregated into COD, heavy metals, and trace organics testing wastes) prior to hauling the liquid wastes to a hazardous waste disposal facility. Little is known as to how many of the CCSF labs are disposing of their liquid wastes in this manner, or whether these wastes are commonly discharged to the sanitary sewer.

Estimated Loadings

Estimated loadings from CCSF laboratories were calculated based on sampling data obtained as part of CCSF's SQD Report (CCSF, 1991C), sampling data obtained from the Palo Alto Regional Water Quality Control Plant (PARWQCP), and water metering data from CCSF laboratories. The SQD Report only contained concentration data for mercury and silver. The remaining concentrations used for the loading estimates were based on PARWQCP data. The water metering data typically represented the total flow from a facility (i.e., including sanitary and process flow), therefore estimates were made as to the portion of total flow that was composed of the (potentially metal-containing) process flow. Some available laboratory process flow data from PARWQCP sampling efforts also helped to define these estimates. (Ghaffari, J., pers. comm. 1992)

In general, higher metals concentrations and higher discharge flow rates were observed at medical laboratories compared to non-medical (e.g., analytical) laboratories. Table 5-7B compares the estimated pollutant loadings from medical versus non-medical laboratories. The substantially greater loadings apparent at medical facilities indicate that more attention should be focused on these sources. It should be noted that these estimates are very preliminary. Many details such as the specific tests being conducted and the extent to which these laboratories utilize similar disposal practices are unknown. No cyanide data were recorded from the PARWQCP laboratory discharge sampling efforts.

The metals loadings observed through the PARWQCB sampling efforts do not, on average, exceed existing CCSF local limits. However, in light of the high potential for spills or routine discharges of concentrated stock solutions, BMP requirements at medical laboratories would likely result in substantial metals loading reductions to the SEWPCP.

Dental Facilities. In a separate effort, CCSF (in association with the Worcester Polytechnical Institute) examined the mass contributions to the SEWPCP from dental facilities within its service area (CCSF, 1992I). CCSF's study determined that dental wastes contribute a significant portion (eight percent) of the SEWPCP influent mercury loadings. Based on these results, dental facilities should be incorporated into the implementation program for the BMPs recommended as part of this study.

IMPLEMENTATION MEASURES

Given the specialization within laboratory facilities, it would be impractical to restrict the reagent used or alter any specific analytical methods. Such steps would be met with considerable resistance by laboratory personnel (from whom cooperation is fundamental for effective source control) and, more importantly, are not necessary for effective source control at these laboratories.

Metals discharge at laboratories can be effectively controlled by controlling the handling of the chemicals before, during, and after experimentation. This includes proper storage measures to reduce the likelihood of spills and to prevent spills from entering the drain, combined with disposal measures that involve collection of all sample preparations, spent reagents, and unused sample portions for off-site hauling as a hazardous waste. Each of these measures would, in some cases, replace the practice of routine sewer discharge, and thus reduce the overall metals and cyanide loading from these facilities. The implementation measures recommended for this BMP are listed below.

- **Develop Laboratory Database.** The first step in this BMP is to develop a database of of all licensed laboratories operating in CCSF. A preliminary review of laboratories in the PacBell Yellow Pages indicated that there are approximately 80 laboratories operating in CCSF. Special emphasis should be placed on identifying all medical and hospital related laboratories.

- **Develop Regulatory Strategy.** A regulatory strategy for laboratories will be developed. Some laboratories may qualify as zero dischargers, while others will need to be issued permits for compliance with local limits. Permitting, monitoring, and reporting procedures will be established. Dischargers will be required to self-monitor to demonstrate compliance. Preexisting permits for medical laboratories will be modified to include metals and cyanide.

- **Prepare information packets.** BERM will prepare information packets for distribution/review at the educational workshops. These packets will contain information describing the origin and importance of local limits compliance requirements, and BMPs for proper storage and cleanup procedures, available disposal methods, and potential waste haulers to be contacted. These BMPs will focus on the following:

  -- Avoid storage of chemicals above sinks or drains.
  -- Provide secondary containment of chemicals.
  -- Seal off floor drains.
  -- Provide plastic containers for segregated liquid waste disposal.
  -- Practice dry cleanup techniques for chemical spills.
  -- Train all employees to understand and implement the BMPs.

- **Conduct Workshops.** BERM staff will provide two educational workshops with personnel from hospital and other medical laboratories. These workshops will stress the importance of reduced metals and cyanide discharges, and allow discussion of recommended storage and disposal practices at medical and other laboratories. BERM will present the recommended practices, perhaps with the assistance of a laboratory manager that has established, or is in the process of establishing, a "model" laboratory.

VOL 12 2 4296

R0057588

- **Distribute information packets.** The information packets will be revised as necessary following input from the workshops, and distributed to all medical and non-medical facilities on a periodic basis. Zero-discharge facilities will be inspected to ensure compliance with the housekeeping BMPs and to verify hauling records. Dischargers will be inspected for compliance with the general pretreatment program. Prepare a program for regular site inspections of all laboratory facilities to conduct sampling of permitted facilities, and confirm BMP implementation and zero-discharge status. Prepare inspectors to provide information and guidance, as requested, to facilities regarding BMP implementation.

EXPECTED REDUCTIONS

Table 5-7C presents the estimated reductions of BMP No.7. These reductions assume a 50 percent mass reduction from medical and non-medical facilities for each targeted pollutant. This estimate assumes that many labs would elect to be zero dischargers to avoid self-monitoring and reporting requirements. As seen from this table, over 150 pounds per year of each copper, nickel, and zinc loadings are expected to be removed through the implementation of this BMP. Such high reductions appear feasible due to the simplicity, low capital cost requirements, and potential for near-zero discharge available with proper storage and disposal practices.

ESTIMATED COSTS

The implementation costs for this BMP are estimated to be roughly $81,000 annually. These costs assume one-time expenditures for workshop presentations and informational packet distributions, and regular semi-annual inspections of medical laboratories. The itemized costs for the proposed measures listed above are shown in Table 5-7D.

BMP NO.8

REVIEW METHODS OF CORROSION CONTROL

Metals in the water supply distribution system stem from three potential sources: 1) background concentrations present in the raw water supply; 2) chemicals added for water treatment or for corrosion protection; and 3) corrosion in the distribution system piping, service connections, and customer plumbing systems. As discussed in Section 4, the water supply could be a significant contributor of the copper loadings to the SEWPCP. Of the three potential sources listed above, metals in the raw water are generally considered as uncontrollable. However, metals added as part of treatment or corrosion control and metals resulting from pipeline/plumbing corrosion may be controllable, and should be evaluated.

POLLUTANTS OF CONCERN

Copper, lead, nickel, and zinc are CCSF's primary pollutants of concern in the water supply (from a wastewater treatment perspective). In addition to being naturally present in the raw water supply, these chemicals can also be added as part of treatment chemicals. Copper sulfate is commonly used as an algicide in water storage reservoirs. Zinc orthophosphate is used by many purveyors as a corrosion protection agent. All four pollutants may be present in tap water from pipeline/plumbing corrosion.

Algae Control

Although a number of other compounds can be used as algicides, copper sulfate almost exclusively dominates the field of potable water treatment. Presently, copper sulfate and chlorine are the only effective algicides that satisfy all necessary legal requirements. Other synthetic algicides involve the use of mercury or tertiary and quaternary amines. Algicides are added on an as-needed basis, during periods of algal bloom.

Based on field experience, a copper residual between 0.1 mg/l and 0.2 mg/l for several hours is necessary for algae control. In order to maintain this residual, ordinarily a copper dose of 0.5 mg/l is required. One of the principal problems in copper sulfate treatment is very little of the copper added is present as free copper ion; the majority settles to the bottom as a precipitate.

Copper and other heavy metals kill algae by combining with the sulhydryl (SH) groups of many enzymes that play an important role in cell catalysis and energy-yielding metabolism. In order to accomplish this, copper must diffuse through the cell wall. It is most likely that only the soluble copper species directly participate in this activity. Thus, the efficiency of algal control with copper sulfate addition is limited since most of the copper added is lost through precipitation and sedimentation.

Chlorine may also be used for the control of algal growth in water storage reservoirs. Its usefulness, however, is impaired by difficulty in maintaining adequate residuals and the potential for forming chlorinated organic compounds (e.g., trihalomethanes) in the treated water. Residuals are difficult to maintain because the chlorine reacts rapidly with naturally occurring aquatic humus and spontaneously decomposes in the presence of light. Artificial mixing of storage reservoirs (e.g., with compressed air) is another potential means of preventing algal blooms, and thus minimizing the need for copper sulfate use.

R0057592

VOL 12 2 4300

Corrosion Control

Corrosion occurs when corrosive anions (such as dissolved oxygen and chloride ion) in a water supply attack and oxidize the metallic cations at the surface of water pipes and other fixtures. Most metals are not stable when exposed to water and are subject to corrosion. Oxidation-reduction (electrochemical) reactions are the primary reactions involved in corrosion. Once these reactions have begun, metal ions enter the water and attempt to reach chemical equilibrium with the other ions in solution. Chemical equilibrium reactions determine whether the soluble or insoluble forms of a metal are the most stable form under a given set of chemical conditions. If a soluble species is stable, metals may corrode rapidly into an aqueous form. If an insoluble species is stable, a natural scale may form inhibiting corrosion.

Corrosion leads to the dissolution of metals into the drinking water and reduces drinking water quality. Four commonly used corrosion control measures are listed and briefly described below.

- pH adjustment and carbonate addition
- Zinc orthophosphates addition
- Polyphosphates addition
- Silicate addition

pH Adjustment and Carbonate Addition. Adjustment of pH is effective for corrosion control in some waters because the electrochemical potential between the metal surface and the surrounding solution (the driving force behind the corrosion reaction) is a function of pH. SFWD practices pH adjustment. Hydrated or slaked lime ($Ca(OH)_2$) or caustic soda (NaOH) are used to raise the pH of water for corrosion control. A small amount of protective calcium carbonate scale can thus form inside of water pipes, which prevents contact between the pipe and the anions in the water. Equilibrium between calcium and carbonate ions also helps prevent dissolution of materials from reinforced concrete pipes.

The pH range of lowest solubility for most metal species is pH 8 to 10. If pH slightly above 7.0 (neutral) can be maintained, the ability of water to dissolve metals in piping is diminished. Copper corrosion is particularly pH dependent in soft, low mineralized water, and corrosion decreases substantially at pH levels above 7.0. However, for utilities using chlorine for disinfection, elevated pH levels can encourage the formation of trihalomethanes.

Zinc Orthophosphates Addition. Zinc orthophosphates form a thin film on the inside of water pipes to prevent corrosion by the oxygen and hydroxide ions. This type of inhibitor has been used in industrial systems since the 1930's and has been used in drinking water systems since 1970. A number of zinc orthophosphates blends are available on the market, varying in their zinc:orthophosphate ratio. Typical dose rates are 0.3 to 0.6 mg/L as zinc. These compounds are considered by AWWA to be the most effective corrosion inhibitor. Zinc and orthophosphates can be used separately for corrosion control in certain water supplies.

VOL 12 2 4301

R0057593

Polyphosphates Addition. Polyphosphates are a third type of corrosion inhibitor. This class of compounds sequesters, or ties up, ferric ions in drinking water and forms a protective coating

One main application of this corrosion inhibiting chemical is recirculating industrial water systems. Manufacturers of corrosion inhibitors are beginning to promote the use of polyphosphates for municipal water supplies. Polyphosphates are not an effective corrosion inhibitor in still waters, however; its corrosion protection properties increase with water velocity. Polyphosphates may not be effective in dead ends of water distribution systems. In some waters, the compound may increase corrosion rates. Another concern with polyphosphates is that they have not yet been proven useful for reducing the solubility of lead. Reducing lead corrosion must be one of the goals of any effective corrosion control strategy.

Silicate Addition. Sodium silicate addition, like other corrosion inhibitors, prevents corrosion by forming a thin protective colloidal film inside of pipes. Metal ions from the water supply can be incorporated in this film. Diffusion of oxygen to the surface of metal pipes and corrosion is inhibited once the film forms. This compound was first used in the 1920's to reduce the corrosion of lead piping. Typical dose rates are 8 to 12 mg/L as SiO_2. The effectiveness of silicate as a corrosion inhibitor is enhanced by calcium ions in the water supply, but its effectiveness is decreased by magnesium ions. For silicates to be effective, a pH near 8.5 is the most appropriate. The evidence for the effectiveness of silicate inhibitors is mixed, but recent investigations indicate that silicates provide little or no benefits in reducing corrosion of copper, zinc, iron, or lead piping materials. However, silicate inhibition is well documented in protecting asbestos/cement (A/C) pipes. Dosage rates are very important for silicates; underdosing with silicates can increase corrosion while overdosing can produce taste and color problems.

EXISTING CONDITIONS

Water supply data were analyzed to estimate the uncontrollable (raw water) and the controllable (algicide and corrosion) portions of the pollutants. As discussed in Section 4, water in CCSF is provided by the Hetch-Hetchy aqueduct, the Sunol Water Filtration Plant, and the San Andreas Water Filtration Plant. Unfortunately, the database for metals in the raw water supply is not very extensive. SFWD is only required to sample Hetch-Hetchy supply and its local reservoirs once annually. Several local reservoirs were sampled as part of this study to determine metals concentrations in the raw water supply. Utilizing these data, weighted average concentrations of metals from the three sources are calculated and shown in Table 5-8A. Actual raw water data are included in Appendix C-8 for reference.

Based on discussions with SFWD staff, approximately 62,000 pounds of copper sulfate were added to local reservoirs for algae control in 1991. Assuming that five percent of the copper added remains in the soluble form, approximately 1,200 pounds of elemental copper were added to the water used within CCSF. Copper contributed by algicide would be approximately 3 pounds per day.

Metal loadings in the raw water supply and algicides were subtracted from the point-of-use water supply data. The point-of-use concentrations are a composite of hot/cold water and standing/running water data. The composite method was previously discussed in Section 4. Table 5-8B summarizes the various contributions. As shown in the table, approximately 85 percent of the copper in the tap water may be controllable, either by substitution of alternative algicides or by

improved corrosion control. Approximately 75 percent of the zinc may be contributed by corrosion of galvanized piping. Household plumbing is likely the major source of lead and copper

On May 6, 1991 EPA finalized drinking water regulations for lead and copper as mandated by the Safe Drinking Water Act of 1986.(56 FR 26460) According to these regulations, all large systems (serving greater than 50,000 people) will be required to perform corrosion control studies and installation of optimized control system, unless either of the following conditions, which demonstrate that corrosion control has already been optimized, are met:

- Demonstrates that the difference between the highest level of lead measured in source water and the 90th percentile level measured at taps in homes is less than the practical quantitation level (5 ug/L) during two consecutive six-month monitoring periods. This system would be considered to have optimized corrosion control.

- Demonstrate that it has already conducted steps equivalent to the corrosion control steps outlined in the regulation, thus demonstrating it has optimized corrosion control.

According to the compliance schedule set by EPA, if a large system must perform the corrosion control treatment steps, then the following dates would apply:

- By January 1, 1993 the system must have completed two monitoring periods of tap sampling (lead and copper) and two six-month monitoring periods for water quality parameters (pH, alkalinity, calcium, conductivity, water temperature, orthophosphate, when an inhibitor containing phosphate compound is being used, and silica, when an inhibitor containing silicate is being used). Samples for analyzing water quality parameters are to be collected from entry points to distribution system and from within the distribution system (EPA suggests using same sites where coliform samples are collected).

- System must complete corrosion control studies and recommend to the State (or primary agency) what constitutes optimal corrosion control for that system by July 1, 1994.

- Based on results of system's monitoring and system's recommendation, the State must designate optimal corrosion control treatment by January 1, 1995.

- System must install optimal corrosion control treatment by January 1, 1997.

- After installation, the system must complete follow-up sampling by January 1, 1998 (two consecutive six-month monitoring periods for lead and copper at taps and water quality parameters in distribution system).

- By July 1, 1998 the State must designate optimal water quality control parameters. These optimal water quality control parameter may include: 1) minimum or range of values for pH, 2) a minimum or range of values for corrosion inhibitor, 3) a minimum or range of values for alkalinity, 4) minimum or range of values for calcium, and 5) state may designate other parameters for monitoring.

- The system must operate in compliance with the State-specified optimal water quality control parameters.

VOL 12 2 4305

R0057597

BERM and SFWD recently completed separate testing programs for lead and copper in tap water at residences throughout CCSF. The average and 90th percentile concentrations detected from these

negotiating potential variances from EPA's requirements. If implementation of these regulations is delayed due to these negotiations, the schedule listed above may be altered. Nevertheless, it appears that performance of corrosion control studies ultimately will be required by SFWD.

It is also noteworthy that with optimized corrosion protection (e.g., with zinc orthophosphate), there may be a trade-off between elevated zinc loadings and elevated loadings of lead and copper. However, it is possible that corrosion reductions could be achieved through the application of the non-metallic corrosion inhibitors (carbonates, silicates, polyphosphates) discussed above. Cooperation between BERM and SFWD will be necessary in this regard.

IMPLEMENTATION MEASURES

The SFWD must assume the lead role in the implementation of this BMP. SFWD will likely be proceeding with an evaluation of lead control measures. In order to promote and demonstrate an overall commitment to environmental health, it will have to also evaluate methods for maximum reduction of copper at the same time. Implementation measures for this BMP are described below.

- **Sample Raw Water Supplies.** The raw water supply concentrations estimated in the analysis were based on only a few data points. To better define the raw water characteristics, additional samples should be taken and analyzed. BERM should assume the sample collection and analysis. The raw water data would be analyzed with the same test methods and analytical detection limits as the point-of-use data, and would allow a direct comparison.

- **Review Results With SFWD.** Using the new raw water data, the contributions of controllable and uncontrollable portions of the metals should be re-analyzed. BERM should then meet with the SFWD to discuss areas of cooperation and coordination.

- **Perform Corrosion Control Study.** This implementation task must be performed by the SFWD. BERM may assist in the study, where appropriate and at the request of the water department. SFWD must balance the reduction of copper and lead against increases in other pollutants.

- **Evaluate Alternative Algicides and Algae Prevention Techniques.** This implementation task must also be performed by the SFWD. Practical effects of other algicides (e.g., chlorine) or artificial mixing methods should be investigated.

- **Implement Recommended Measures.** SFWD should implement the recommended measures to comply with the SDWA and to assist in compliance with the Basin Plan limits.

ESTIMATED REDUCTIONS

of the algae control and corrosion practices. For the purpose of this evaluation, it is assumed that copper input from algicides can be reduced by one-half, assuming that some degree of substitute algicides or algae-prevention techniques could be used. Metals loadings from corrosion are assumed to be reduced by one-quarter. The estimated reductions are summarized on Table 5-8D.

ESTIMATED COSTS

Costs of this BMP will include the expenditures for evaluation and implementation of corrosion control measures and alternative algicides. Implementation costs cannot be determined until the evaluation has been completed. Costs for a comprehensive evaluation study will be in the range of $500,000. Since SFWD will likely have to perform the corrosion study to comply with the lead limit in the SDWA, the full cost should not be assigned to this BMP. For this evaluation, it is assumed that half of the cost, $250,000, will be assigned to this BMP. The amortized cost is about $25,000 per year. This cost will increase substantially if new corrosion control systems are required. The actual corrosion control system required will depend on the results of the corrosion studies. The potential costs of a new chemical addition system is shown in Table 5-8E.

R0057602

buildings and hotels that have a significant air conditioning or refrigeration demand. They are also a standard component of industrial processes that require the cooling of air or process waters. The primary metals of concern in cooling tower discharges are copper and zinc, though low concentrations of other metals have also been detected. Cooling tower blowdown may contain copper and zinc corrosion by-products as well as ions derived from metal-based chemicals added for water treatment purposes. Scrubber processes use recirculated water or a caustic solution to remove airborne particulates from incineration emissions. Metals, cyanides, and PAHs are removed from the air by the scrubber waters and discharged as part the scrubber water blowdown.

This BMP would minimize the pollutant loadings from scrubbers and cooling towers. Discharge limits from these sources would be included in sewer use permits, and specific testing, operating, and corrosion-prevention procedures would be required under the permit. Educational workshops would be conducted for cooling tower and scrubber operators, and service personnel. Prior to implementation of these measures, CCSF would need to sample a series of cooling towers and scrubbers to verify the loading assumptions used for this analysis.

POLLUTANTS OF CONCERN

Pollutants of concern from cooling tower and scrubber discharges are described below.

Cooling Towers

Cooling towers may increase the pollutant loadings discharged to the sewer system in three ways:

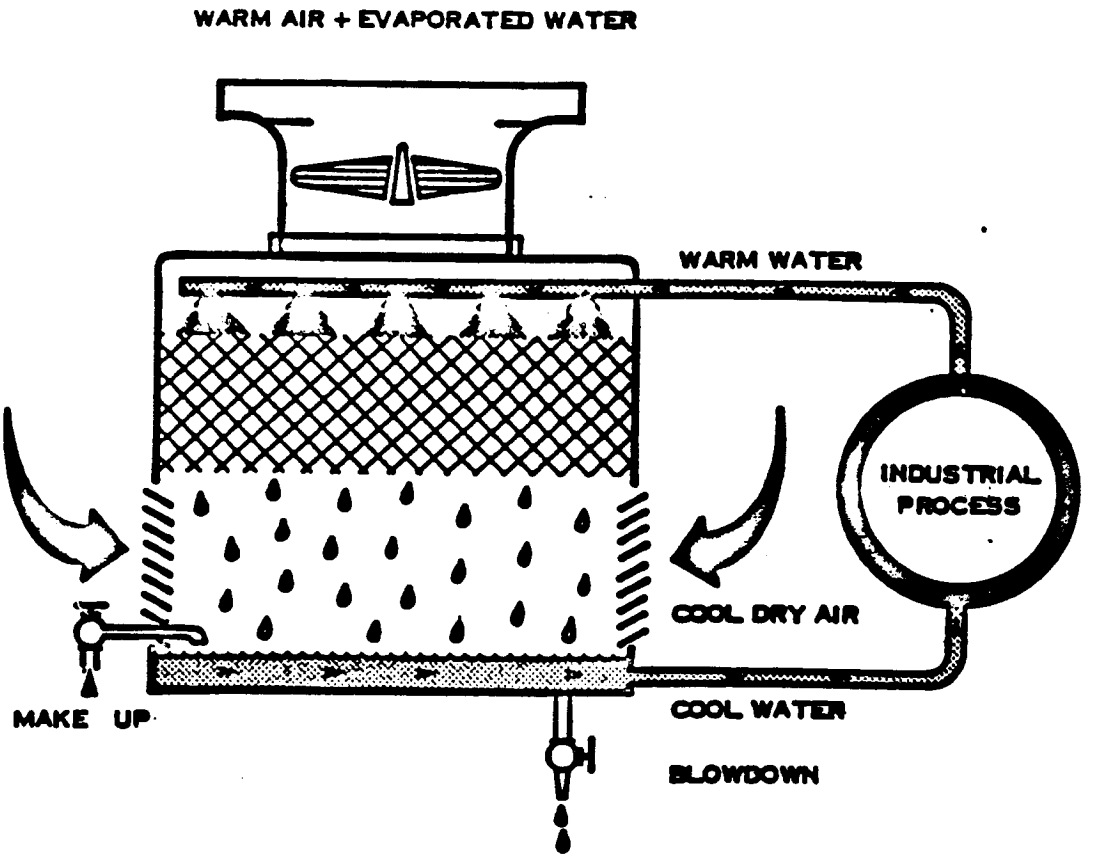
- Corrosion of zinc-galvanized piping and/or the copper piping in the heat exchange units of cooling tower systems.
- Concentration of the cooling tower source water (which contains trace levels of pollutants) through evaporation and recirculation of the process waters through numerous cycles of concentration.
- Addition of water treatment chemicals for biocidal, corrosion-prevention, and/or scale-prevention purposes.

The operations of a typical cooling tower system are described below.

Operations. Cooling towers operate by running water counter-current with air in a packed column containing assorted media that provide high surface area to enhance water evaporation. As water passes down through the tower, heat is transferred to the air (flowing upward). Cooled water exits the bottom of the cooling tower, from which it is recirculated through the industrial process, and warm, moist air exits the top of the cooling tower. Heat is transferred from the water to warm the air and, mainly, as a result of water evaporation. Due to the high heat of evaporation of water, the evaporation of one gallon of water will lower the temperature of 100 gallons by approximately 10 °F. Figure 5-9A presents a schematic illustration of a typical cooling tower system.

VOL 12 2 4311

R0057603



SCHEMATIC DIAGRAM OF COOLING TOWER SYSTEM

FIGURE 5-9A

VOL 12 2 4312

The loss of relatively pure water through evaporation reduces the cooling water volume, causing a buildup of the total dissolved solids (TDS) concentration, including metals, in the remaining water. To prevent overly high concentrations of dissolved solids (leading to potential precipitation/scaling

typically run 4 to 6 cycles of concentration, while commercial air conditioning systems often run 8 to 10 cycles.

Three types of chemicals are typically added to the cooling tower makeup water:

- Dispersants, which prevent the precipitation of minerals in the system piping.
- Biocides, to prevent microbiological growth.
- Corrosion control chemicals.

Of primary significance to this study are the biocides, which may be copper-based products, and the corrosion control agents, which may contain zinc. Additionally, the typically organic dispersant additives could contain trace levels of pollutants such as organically-bound cyanides (e.g., nitriles). However the presence of cyanide in these organic chemicals has not been verified at this time.

EXISTING CONDITIONS

Cooling tower discharges are not currently regulated by CCSF and minimal data on flows and pollutant characteristics are available. The population of cooling towers in CCSF is largely unknown. Based on conversations with cooling tower service vendors, cooling towers are present in nearly every large office building, hotel, and supermarket in the City to handle office air conditioning and/or refrigeration demands, which can vary according to the number of persons or machines (e.g., computers) served. Hotels may have significant cooling demands; the largest hotel in the City, the San Francisco Hilton, has four cooling towers.

Flow estimates from commercial and industrial cooling towers were based on estimates of the number of facilities in the City likely to have high cooling demands. Discussions with the San Francisco Hotel Council, the Building Owners and Management Association, and a review of the PacBell yellow pages formed the basis for an estimated 610 office buildings, hotels, and supermarkets that had cooling towers discharging to the SEWPCP. For industrial cooling tower flow estimates, it was assumed that 60 cooling towers existed at 50 SIUs monitored under the Industrial Pretreatment Program. Flow estimates supplied by service vendors dictated that the estimated 670 cooling towers in CCSF discharge a total of approximately 2.5 mgd of blowdown water to the SEWPCP.

Sampling data from industrial cooling tower facilities in Palo Alto was used to estimate the pollutant loadings at CCSF. Using these data to estimate CCSF loadings is considered reasonable as the source waters for both Palo Alto and CCSF are very similar (Palo Alto is almost entirely supplied by SFWD) and industrial cooling tower operations are expected to be similar. CCSF has recently sampled the blowdown from five cooling towers in the SEWPCP service area; when made available, data from these samples will be used to confirm the loading estimates applied in this analysis. Blowdown concentrations may vary significantly among cooling towers, depending on the level of service and appropriateness of design for each system. For example, many of the

VOL 12 2 4313

R0057605

smaller cooling systems (e.g., supermarkets) reportedly spend little effort in maintaining efficient, corrosion-free systems.

pounds per year of total copper loading estimated, the net copper loadings comprise approximately 55 percent (1,600 lbs/year). The remainder is inherent in the raw water supply. In contrast, the net zinc loadings constitute nearly 80 percent of the roughly 6,000 lbs/year of zinc estimated. The primary source of zinc in these discharges is likely the use of zinc-containing corrosion inhibitors. If non-zinc inhibitors (sodium orthophosphates) or pH adjustment chemicals were used, corrosion may still be controlled without increasing zinc loadings. Cyanide data were not available for consideration in this analysis. The estimated net loadings of zinc and copper from cooling tower blowdown water are presented in Table 5-9A.

An examination of the net loadings provides an indication of the portion of the total metals loadings that can be controlled through improved cooling tower operations. Efforts to reduce the levels of metals in the water supply are addressed under BMP No.8. Boilers located at industrial and commercial facilities may contribute to the metals loadings in a similar fashion to that observed with cooling tower blowdown. Although these facilities were not investigated in detail as part of this BMP, consideration of these facilities during cooling tower inspection and monitoring efforts may be worthwhile.

Scrubbers

There appears to be less than five scrubber facilities in the CCSF service area. While the number of these facilities is minimal, they may be one of the few potential dry weather sources of combustion products such as cyanides and PAHs to the sewer. Data from scrubber water blowdown at the PARWQCP sludge incineration facility indicate that cyanides and heavy metals are present in scrubber water blowdown. No PAH data were available from Palo Alto, but as a combustion product, its presence in these discharges is considered likely.

Similar to cooling tower operations, periodic blowdowns from incinerator scubbers are the origin of contaminants from these sources. Unlike cooling towers, where the air running countercurrent to the water is relatively clean and is intended to expedite evaporation, scrubber facilities are designed to transfer particulates, heavy metals and other pollutants into the liquid stream.

Little data are available from scrubber facilities in CCSF. Given the small number of scrubbers expected, these facilities are not considered a major source of the pollutants of concern and have not been included in this analysis. However, they should be identified during the implementation phase of this BMP.

IMPLEMENTATION MEASURES

The implementation of this BMP will focus on regulating the operation and maintenance of CCSF cooling tower and scrubber systems to reduce targeted pollutant loadings. The implementation of educational and operational BMPs with regard to diagnostic indicators of excessive corrosion, proper chemical treatment additives, and appropriate operating strategies will minimize the metals loadings from these sources.

R0057607

The implementation measures recommended for this BMP are listed below.

group.

- **Develop Database.** Develop a database of facilities with cooling towers and scrubbers based on the survey results, a search of the Bay Area Air Quality Management District databases, a review of the PacBell yellow pages and business licensing boards, and discussions with labor organizations and service vendors.

- **Compile Technical Information.** Compile information in preparation for workshops on the causes and extent of cooling tower metals loadings, and educational information describing proper system diagnostic measures, water treatment methods, safe chemical usage, and water sampling and analytical methods.

- **Develop Regulatory Strategy.** A regulatory strategy will need to be developed to determine the population of facilities to be regulated, as well as the optimum sampling, reporting, and monitoring requirements. Since cooling tower discharges are likely to be well within local limits, permit requirements may require that certain diagnostic measures are performed regularly, copper-based biocides are not used, and that corrosion prevention steps are taken as necessary.

- **Prepare Guidance Packets.** Easy-to-use guidance packets will be prepared to instruct operators on how to evaluate their systems for excessive corrosion or improper chemical usage. Drafts of these items will be available for review at the workshops.

- **Conduct Workshops.** BERM will provide two educational workshops to stress the importance of reduced metals and cyanide discharges from cooling towers and scrubbers, and to discuss recommended operational practices. Invitees will include service vendors, industrial cooling tower and scrubber operators, and large hotel and commercial building engineers. These personnel will represent the managers of larger cooling systems in CCSF. Two alternative dates for attendance will be provided. Additional information from each facility will be requested at the workshops (e.g., flows, chemicals added, etc.). Each of these large system operators will be requested to review their system for diagnostic indicators of a poorly running system (e.g., high blowdown metals concentrations, high pH, high water velocities). Assistance from a service vendor may be useful in developing and presenting these workshops. Feedback on the guidance materials will be obtained during the workshop.

- **Distribute Guidance Packets.** Guidance packets (modified based on feedback obtained at the workshops) will be mailed to all cooling tower and scrubber system operators identified by CCSF/BERM. These operators will be informed of local limits compliance requirements, diagnostic indicators, proper operational procedures, and available information resources.

- **Additional Scrubber System Monitoring.** Monitoring of scrubber systems should occur through an expansion of the routine inspections carried out as part of the industrial pretreatment program. Permitted facilities with scrubber systems will be asked to periodically sample their blowdown water and report the results as part of their self-monitoring reporting effort. This should involve little additional effort on the part of CCSF/BERM.

VOL 12 2 4316

R0057608

- **Perform Periodic Site Inspections.** Periodic inspections of cooling tower and scrubber facilities identified by CCSE should be conducted to verify that the recommended

EXPECTED REDUCTIONS

Table 5-9B presents the expected mass loading reductions to be obtained at cooling towers through the implementation of BMP No.9. Improved corrosion reduction measures and reduced usage of copper-based biocides are estimated to result in a 50 percent reduction in the copper net loadings and a 50 percent reduction in the zinc net loadings. These high reductions may be possible given that no attention has previously been paid to discharges from these facilities. Total estimated copper and zinc mass reductions from cooling tower implementation measures are expected to be approximately 800 and 2,300 pounds per year, respectively.

ESTIMATED COSTS

The implementation costs for this BMP are shown in Table 5-9C. The annual cost of $101,000 for the BMP No.9 implementation measures assume one-time expenditures for workshop presentations and informational packet distributions, and additional inspections and sampling of 100 cooling towers annually. The itemized costs for the proposed measures listed above are contained in Appendix C-9.

BMP NO.10

PROVIDE TEMPORARY STORAGE OF RECYCLE FLOWS DURING WET

Although a conventional wastewater treatment plant like SEWPCP is not designed for removal of metals and other toxic pollutants, a significant portions of these pollutants in the influent wastewater is removed through the treatment units. The basic mechanisms for removal are sedimentation of insoluble metals in the primary clarifiers; biological uptake, degradation, and adsorption in the aeration basins; and subsequent sedimentation of the biological flocs in the secondary clarifiers. However, since pollutants removal are incidental to the treatment processes, there are no direct operating strategies to control their removal efficiencies.

This BMP would maximize the pollutant removal efficiency at the SEWPCP. Metals and other pollutants are typically found in the recycle flows at SEWPCP. During periods of high wet weather flows into the plant, these recycle flows would be routed to temporary storage tanks. After the higher flow rates have passed, the stored recycle flow would be returned to the plant to take advantage of presumably higher removal efficiencies that are expected to occur during periods of lower flow. This BMP assumes that metals removal efficiency is a function of hydraulic flow rate, with longer hydraulic detention time in the treatment processes translating to greater metals removal across the SEWPCP. Although hydraulic detention time is likely to be one of the factors, multiple inter-related factors are expected to ultimately affect the removal efficiency.

EXISTING CONDITIONS

Figure 5-10A is a flow schematic of the existing recycle flow system at SEWPCP. Overflow from the anaerobic digesters is routed to the old pumped plant recycle (PPR) sump and is then piped by gravity to the Quint Street sewer at the influent to the plant. Centrate, building washdown, and drainage flows are routed to the new PPR sump and are then pumped to the primary sedimentation tanks. Total recycle flows at SEWPCP are approximately 0.6 mgd.

The recycle flows were sampled periodically between 1985 and 1988. Table 5-10A summarizes the average concentrations and loadings of metals in the recycle flows. The entire recycle flow data is included in Appendix C-10 for reference. The available sampling data were collected prior to the construction of the new PPR sump. However, there has been no major process change at SEWPCP and the characteristics of the recycle flows should be similar.

Evaluation of Wet Weather Removal Rates

The removal rates of six metals (copper, lead, mercury, nickel, silver, and zinc) were plotted against their respective effluent flow rates in Figures 5-10B to 5-10G. 1991 data are used in the analysis. As shown in the figures, there are no discernible correlations between removal rates and flows. The data exhibit a wide range of scatter and suggest that other factors are involved in the removal of metals at SEWPCP.

The metals removal rates were also compared with the dry and wet weather conditions at SEWPCP. For this analysis, a wet weather condition is defined as the day(s) that rain was actually measured at SEWPCP and the day immediately following. In 1991, both influent and effluent concentrations were available for 24 days. Of these 24 days, rainfall was measured on six separate days at SEWPCP. Table 5-10B compares the metals removal rate for the dry and wet weather conditions. A complete analysis of the data is also included in Appendix C-10 for reference. The results shown in Table 5-10B indicate slightly higher removal rates during the non-rainfall condition.

A schematic diagram of the recycle flow storage system is shown in Figure 5-10H. As shown in the figure, the existing PPR facilities would be used to deliver recycle flows to the new storage tanks. After wet weather flows has passed, the recycle flows would be pumped back into the primary sedimentation tanks for treatment. The recycle flow storage system would be based on the following design conditions.

- Three-day storage capacity (1.8 million gallons) would be provided.
- Four 70-feet diameter steel tanks would be used for storage.
- Tanks would be located in the area north of the existing oxygen generation facilities.
- Aeration at the storage tanks would be required to minimize anaerobic conditions.

The cost estimated in also included in Appendix C-10 for reference.

ESTIMATED REDUCTIONS

If the recycle flows at SEWPCP were stored during wet weather and then returned to the liquid stream after the flow has decreased and the plant operation has stabilized, some additional removal of the metals in the recycle streams can be expected to occur. Table 5-10C summarizes the expected increased reductions for the six parameters of concern. The estimated reductions are based on the following assumptions.

Existing Conditions:

- On a wet weather day, the influent and recycle metals loadings would be removed at the wet weather removal rate.
- On the subsequent dry day, the influent and recycle metals loadings would be removed at the dry weather removal rate.

After Construction of the Recycle Flow Storage Facilities:

- On a wet weather day, the influent metals loadings would be removed at the wet weather removal rate. The recycle flows would be stored.
- On the subsequent dry weather day; the influent loadings, the normal recycle metals loadings, and the stored recycle metals loadings would be removed at the dry weather removal rate.

As shown in Table 5-10C, the expected reductions would be minimal. The increased reductions would be less than one percent of the average influent loadings for the six parameters of concerns. For mercury, nickel, and silver, their wet weather removal efficiencies were equal to or higher than their dry weather efficiencies. Therefore, no reductions would be expected. It should be noted that there is no empirical evidence that storage of recycle flow would directly result in the increased

R0057626

BMP NO. 11 (OPTIONAL BMP P3)

[illegible] LOCATE THE SOURCES OF POLLUTANTS

Identifying and addressing pollutant sources which can not be traced to a specific business or type of business is particularly challenging. Knowing the sources of pollutants, however, would greatly contribute to efforts to reduce both the amount of toxic substances used and the amount discharged into the sewer system. The efficiency of public education and outreach will be enhanced if specific target audiences and areas of CCSF can be identified as significant or frequent sources of toxic pollutants.

Personnel from various CCSF departments have daily contact with the sewers, storm drains and city streets and have the potential to observe incidents of illegal dumping. These individuals represent a valuable source of information concerning spills and illegal dumping of toxic substances. If this information were consistently and systematically collected, and centrally compiled and analyzed, it could be used to target educational or enforcement efforts accordingly. BMP No. 11 establishes a process through which this can be accomplished.

POLLUTANTS OF CONCERN

The pollutant sources addressed by BMP No. 11 are similar to those addressed by BMP No. 2. Any pollutant or combination of pollutants that can potentially be addressed by BMP No.2 will be included in BMP No. 11. Certain toxic substances are dumped illegally more often than others and thus can be expected to be more commonly observed and reported by City staff. Personnel from the Bureau of Street Cleaning and Urban Forestry (BSCUF) report finding discarded or spilled motor oil and paint in certain parts of the City. Personnel from the Bureau of Street and Sewer Repair (BSSR) may observe a wider variety of illegally dumped substances, such as toxic wastes dumped directly into the sewer system from within a business. As discussed in BMP No. 2, paint and used motor oil are the two substances that are most commonly dumped illegally.

EXISTING CONDITIONS

There currently is no centralized reporting procedure or database for illegal dumping or spill reports observed or addressed by various CCSF departments. The Department of Public Health (DPH) maintains a file of reports involving toxic spills and is currently developing a central database for use by the Fire Department in tracking spills. The Fire Department files standard incident forms recording spills and has separate forms for fires and hazardous materials incidents. A computer is being installed in the Department's Emergency Response Vehicle through which the DPH spill database will be accessed. Potentially hazardous pollutant spills encountered by BSCUF and the BSSR are reported to DPH or the Fire Department. Non-hazardous spills or chemicals are retrieved, however reports of these incidents are not maintained. Illegal dumping reports received by BERM are recorded and filed, although no further action is taken. Unless BERM requests such records or responds to incidents along with DPH or the Fire Department, reports are not normally forwarded to its offices.

VOL 12 2 4335

R0057627

Under existing conditions, records of emergency spill reports and hazardous materials incidents are maintained. Records concerning the retrieval of non-hazardous pollutants, such as used motor oil

In July, 1992 a special report was prepared on spill investigations and retrievals conducted by BERM and DPH between 1990 and 1992. Analysis of BERM's records (a total of 68 complaints) indicated that the majority of reports were received in the Summer and Fall; 37 percent and 31 percent, respectively. Approximately two thirds (64 percent) of the incidents involved paint, oil and cement/concrete (approximately 21 percent each). Illegal dumping of paints was most frequently reported in the spring, summer and fall; oils in the summer and fall; and cement/concrete in the summer, fall and winter. Geographically, most illegal dumpings occurred in the Channel Basin area. The Oceanside District had the most instances of illegal discharges, but is so much larger than other districts that it is not considered equal to the other districts. The sub-basin with the highest number of illegal discharges was the North Point Sub-basin, and the specific district with the most illegal discharges is the South of Market district. A general trend was identified in which the largest number of illegal discharges took place in business/industrial areas, while the least amount of illegal discharges were found in residential areas.

The DPH data analysis (1429 spill retrievals) revealed similar patterns in several instances. Close to two thirds of DPH spill retrievals involved oil or paint (39 and 22 percent, respectively) and most were in the Channel Basin and South of Market areas. In contrast to the BERM data, however, DPH reported the majority of its retrievals in the Fall and Winter (30 and 27 percent, respectively).

As is clear from the above discussion, valuable information can be obtained by analyzing the illegal dumping/spill reports of CCSF departments. This type of analysis is not routinely conducted, however, and reports from various CCSF departments are not standard in format nor are they automatically forwarded to a centralized database.

IMPLEMENTATION MEASURES

A procedure will be established through which all reports concerning toxic spills and illegal dumping are compiled into a centralized database. This can be accomplished either by forwarding copies of each department's incident reports to BERM once a year, or forwarding a copy of each individual report as they are produced. Regardless of which procedure is followed, incident reports must contain consistent and useful information. This will include, at a minimum, the date, time, substance spilled or illegally dumped, the quantity of the substance and its source, the location, response and the source of the report. BERM, CAO and other CCSF staff involved in educational and enforcement efforts will determine what additional information will be included so that an annual analysis, or audit, of incident reports can be used effectively in addressing problem areas, substances, or target audiences. Appropriate computer software will be used in establishing a database.

Reports will be also be filed when non-hazardous spills or illegal dumping incidents are observed. This will include situations where BSCUF or BSSR personnel retrieve spilled motor oil or abandoned cans of paint or other non-hazardous substances, or otherwise observe or encounter improper disposal practices which do not require the involvement of DPH or the Fire Department. While such situations are not currently recorded, such information can help in directing educational and enforcement actions and should be included in the centralized database.

VOL 12 2 4336

R0057628

Personnel from BERM, DPH, BSCUF, BSSR, and the Fire Department will be trained to identify and report toxic spills and illegal dumping. The special report on BERM and DPH illegal dumping/spill reports cited above found that CCSF personnel are an important source of such

ensure not only that such incidents are consistently reported but also that the personnel themselves understand the need and purpose of the broader public education program. DPH currently conducts education and training programs for all CCSF employees and will integrate spill and illegal dumping reporting accordingly. Employees not directly involved with environmental or maintenance work will be encouraged to use the illegal dumping hotline. Other employees will receive more specific training as appropriate.

The spill/illegal dumping database will be analyzed on an annual basis. This analysis will determine if patterns exist with regard to the following:

- Toxic substances which are spilled or dumped illegally.
- The season and time of day when spills and illegal dumping incidents occur.
- Areas of CCSF where incidents are most common.
- The source of reports.
- The response taken to the reports.

Using this information, BERM and other appropriate staff will determine what targeted educational or enforcement actions are necessary. This may involve the targeted distribution of educational materials to certain audiences or neighborhoods, enhanced surveillance of areas where illegal dumping is common, improved disposal alternatives, or increased outreach and regulation of businesses involved in illegal dumping or spill incidents.

EXPECTED REDUCTION

This BMP, in and of itself, would not directly result in any reduction of pollutants into the CCSF sewer collection system. However, it would be extremely beneficial to BMPs 1 and 2 and most of the wet weather BMPs. For this purpose, the expected reductions from this BMP are designated as zero.

ESTIMATED COSTS

The implementation costs of BMP No. 11 are shown in Table 5-11A. The estimated annual cost is $11,000 per year. This cost stems entirely from the development of a centralized spill/illegal dumping report database, regular data entry, and data analysis.

VOL 12 2 4338

R0057630

Five chemicals are used at the CCSF wastewater treatment plants: sodium hypochlorite for disinfection; sodium bisulfite for dechlorination; ferric chloride; and two different polymers for sludge conditioning. This BMP investigate whether the pollutants of concern are present in these chemicals and contribute to the effluent loadings.

POLLUTANTS OF CONCERN

Hypochlorite is one of the first known uses of chlorine for disinfection. The application of hypochlorite in wastewater treatment achieves the same results as does that of chlorine gas: sodium hypochlorite or calcium hypochlorite. The active ingredient is the hypochlorite ion, which hydrolyzes to form hypochlorous acid. For reasons relating to safety, CCSF has been utilizing sodium hypochlorite and sodium metabisulfite for disinfection and neutralization.

Sodium hypochlorite is generally used in the liquid form; the dry chemicals are very difficult to handle and store. The stability of hypochlorite solutions is greatly affected by heat, light, pH, and the presence of heavy metals. Iron, copper, nickel, and cobalt catalyzes the rate of deterioration of hypochlorite. Copper is generally present in concentrations of 1 mg/l or less. It is present because of the flexible copper connections and brass body line valves used in the chlorine supply system. Liquid chlorine is commonly used to generate sodium hypochlorite.

Ferric chloride and polymers are commonly used for sludge conditioning in the thickening and dewatering processes. The fundamental objective of conditioning is to aggregate the fine solids by coagulation with inorganic chemicals and flocculation with organic polymers. Ferric chloride hydrolyzes in water, forming charged soluble iron complexes. It is postulated that the ionized iron will enter the outer layer of the negatively charged sludge solid, neutralize surface charges, and thereby allow solids to aggregate.

Organic polymers used for sludge thickening and dewatering are long-chained, water-soluble, synthetic organic chemicals. Due to the organic nature of these compounds, it was postulated that forms of cyanide may be present. The chemical reactions involving organic polymers are similar to those for ferric chloride. Neutralization of the negative electrical charges of the sludge particle by the positive charge of the polymer leads to a reduction of the electrostatic repulsion between particles and thus encourages aggregation. Because most sludge solids are negatively charged, the cationic polymers are most commonly used for sludge applications. In polymer bridging, the long polymer molecule attaches itself by adsorption to two or more sludge particles at the same time. Flocs formed by particle bridging tend to have a higher resistance to shear than flocs formed by charged by charged neutralization.

EXISTING CONDITIONS

The approximate amounts of these chemicals used in 1991 are presented in Table 5-12A. These chemicals are industrial grade quality. In order to assess the presence of metals and cyanide, samples of these five chemicals were collected by SEWPCP staff and delivered to Montgomery Laboratories for analysis.

VOL 12 2 4339

R0057631

TABLE 5-12A

CHEMICAL USAGES AT SEWPCP

Chemicals	1991 Usage (lbs/yr)
Sodium Hypochlorite $NaOCl$	3,246,700
Sodium Bisulfite Na_2SO_3	1,564,200
Ferric Chloride $FeCl_3$	2,214,526

Clarifloc LA-1681 Polymer Centrifuges	179,400

VOL 12 2 4340

R0057632

The results of the laboratory analysis are shown in Table 5-12B. As shown on the table, cyanide and metals were found to be present in some of these chemicals. However, most of the these

Table 5-12C summarizes the amount of pollutants that may be added to the SEWPCP influent and effluent by the chemicals. Sodium hypochlorite and sodium bisulfite, and their associated contaminants, are added directly to the effluent stream. However, ferric chloride and the two polymers are used in the sludge handling processes. These chemicals are used in the binding of the sludge flocs. Therefore, it is expected that the majority of these chemicals, and their associated contaminants, would remain with the sludge solids. For this analysis, 80 percent of chemicals are assumed to be bounded with the sludge. The remaining pollutants, 20 percent, are returned to the headworks as part of the recycle flows.

IMPLEMENTATION MEASURES

Of the five chemicals used at the CCSF wastewater treatment plants, ferric chloride is the only notable contributor; the copper and lead contributions would be 20 lbs/yr and 10 lbs/yr, respectively. The other chemicals contribute minimal amounts of pollutants. These contributions are calculated based on the assumption that 20 percent of the copper and lead (and ferric chloride) would be returned to the plant headworks as part of the recycle flow. The other 80 percent is assumed to be bound with the sludge solids.

The chemical supplier, Imperial West Chemical Company, was contacted about alternative grades of ferric chloride. The grade used at SEWPCP is formulated in accordance with American Water Works Association (AWWA) Standard B-407. It is widely used for coagulation in water treatment applications. A copy of AWWA Standard B-407 is included in Appendix C-12 for reference. In general, the amounts of contaminants added by the chemicals cannot exceed 10 percent of the drinking water maximum contaminants levels (MCLs). An electronics grade of ferric chloride is available in the market. This grade has a higher iron content and is used for etching circuit boards in the electronics industry. There are no differences between the two grades in terms of metals concentration. On the other hand, several manufacturers recycle used ferric chloride and a lower quality product, with higher contaminant levels, is available.

EXPECTED REDUCTIONS

Using a different grade of ferric chloride would not reduce the amount of pollutants of concern.

ESTIMATED COSTS

The electronics grade of ferric chloride is about $100 per ton more expensive than the grade currently used at SEWPCP. Based on a project ultimate usage of 1500 tons per year, the estimated cost of using a different grade of ferric chloride would be $150,000 per year.

(a) Influent loadings from SEWPCP chemicals were based on 20 percent of loadings contained in ferric chloride and polymers (added for solids conditioning) would be returned to influent stream.

(b) Effluent loadings consist of 100 percent of chemicals contained in hypochlorite and bisulfite solutions.

VOL 12 2 4343

R0057635

facilities. The treatment facilities, when designed and operated properly, would provide a positive means of controlling the quality of effluent discharged to the Bay. The other BMPs discussed above have varying effectiveness and also would have no direct control over the effluent quality.

Based on the levels of pollutants in the SEWPCP wastewater, a lime precipitation process would be required in combination with the reverse osmosis (RO) process in order to reduce pollutants to the levels required by the Basin Plan. The lime precipitation process would be installed upstream of the RO process for two reasons:

- Additional removal of the metals due to the extremely stringent discharge requirements.
- Pretreatment step for the RO process.

RO has been successfully used in industrial applications for metals removal and recovery in highly concentrated waste streams. Its use in municipal wastewater treatment, and for metals removal from dilute waste streams in general, is extremely limited. There are several small RO facilities in California treating secondary effluent for irrigation. However, their emphasis is removing total dissolved solids (TDS) rather than metals. Only one full-scale facility in the United States; Water Factory 21 in Orange County, California; provides a basis for estimating the process performance of RO and lime precipitation. Water Factory 21 utilizes lime precipitation and RO to treat 5 million gallons per day (mgd) of secondary effluent.

PROCESS DESCRIPTION

Figure 5-13A is a flow schematic of the full scale treatment option for metals reduction at SEWPCP. Secondary effluent (85 mgd ADWF design capacity) would be routed to the lime precipitation process for coagulation, flocculation, and clarification. The clarified effluent would then be recarbonated and routed to new dual media filters for additional solids removal. The filtered effluent would then be treated by the RO process. The purified water (permeate) would be routed for discharge at the current outfall location.

The concentrated brine stream from the RO process would be sent through a smaller lime precipitation unit to transfer the majority of the metals into a solid phase. The clarified supernatant from lime precipitation would be recarbonated to lower the pH, filtered and then sent through a secondary RO unit for further metals and volume reduction. Permeate from the secondary RO system would be blended with permeate from the main RO system. The volume of the concentrated brine from the secondary RO unit would be transported via a fifteen-inch diameter pipeline traversing west through the City. At the Oceanside WPCP, the brine would be combined with the secondary effluent and pumped to the deep-water ocean outfall for disposal.

The solids generated from both lime precipitation processes would be sent through a solids handling process for volume reduction. The dewatered chemical sludge cake would then be hauled off-site for disposal in a landfill. Filtrate removed by the dewatering processes would be routed back to the SEWPCP headworks.

VOL 12 2 4344

The lime precipitation, RO, and residual handling processes are discussed in more detail in the following subsections.

heavy metals. It is a physical/chemical treatment method that separates and removes metallic contaminants by altering the ionic equilibrium of a metallic compound to produced an insoluble precipitate. Typically, the wastewater solution is made alkaline by adding lime to lower the solubility of metallic constituents. At high pH levels (9 to 11), dissolved heavy metals ions may be chemically precipitated as insoluble hydroxides and removed by physical means such as sedimentation or filtration. The metal precipitates settle out in a sludge that must be dewatered prior to disposal. The clarified product water is neutralized to an acceptable pH level and routed to downstream process for filtration.

The preliminary design criteria is shown in Table 5-13A. The primary components include a lime addition and pH control system to adjust the pH for optimal precipitation of the metals. This can be done in a precipitation reactor or a separate tank. A sedimentation unit must follow the precipitation reactor to remove the metal precipitates. Final pH adjustment (recarbonation) and polishing with filters are then required for the clarified effluent. A flow equalization tank is also necessary if wide variations in wastewater flow or pollutant concentrations are expected. A typical flow schematic for the lime precipitation process is shown in Figure 5-13B. The removal efficiency for the pollutants of concern are summarized in Table 5-13B. Since this process removes metals through the formation of metal precipitates, it is not expected to have any effect on the cyanide concentration. The removal efficiencies are estimated based on data from Water Factory 21 and pilot studies performed by JMM.

The calcium carbonate and metal hydroxide sludge formed in the lime precipitation process would be dewatered and hauled off-site for disposal. A flow schematic of the solids dewatering system is shown in Figure 5-13C. Approximately 2,500 pounds of sludge (dry weight) would be produced per million gallons of wastewater. Filter presses would be used for dewatering the lime sludge. Operating at higher pressures, filter presses have been reported to dewater lime sludges to about 50 percent solids. A 45 to 50 percent solids concentration is required for waste disposal in a Class III landfill in California. At a capacity of approximately twenty (20) tons per truck, approximately thirteen truckloads per day would be necessary to transport this solid waste product off-site.

The metals concentrations in the resulting sludge are estimated in Table 5-13C. This dewatered sludge (50 percent solids) would have significant volume but would be low enough in metals to be classified as non-hazardous. Lime sludge from both lime precipitation processes would be combined and disposed of in a Class III landfill.

The exact location for disposal of this material is unknown at this time. Identifying a landfill that is willing to accept this magnitude of waste on a long-term basis will be difficult. A determination of the exact location for disposal was not attempted in this evaluation.

Reverse Osmosis

RO treatment uses a semi-permeable membrane perforated with microscopic pores to separate the larger soluble ions and molecules from the water. The RO removes dissolved solids from solution by forcing water through a semi-permeable membrane under high pressure. The pressure required to permit passage of water through a membrane is a function of the osmotic pressure of the solution, which in turn is a function of the solute concentration. In order to reverse this natural phenomenon, a pressure greater than the osmotic pressure must be applied to the high

concentration side of the membrane before any flow through the membrane in a reverse direction will occur.

scaling, clogging, fouling by colloids, metal oxides, and microorganisms. Salts with low solubilities could precipitate on the membrane during the treatment process, resulting in decreased efficiency. Therefore, the RO treatment requires extensive pretreatment and post treatment. The influent to the RO units must be low in suspended solids and turbidity to prevent clogging of the membranes. Typically, feedwater to the RO units should have less than 1 turbidity unit. Therefore, microfiltration is required to polish the influent. The lowest fouling rate generally occurs on cellulose acetate membranes when a total chlorine residual of 5 to 10 mg/L is maintained in the RO feed water. Depending on the type of membranes selected, chlorinated wastewater may be routed to the RO units to ensure that the feed water contain the necessary chlorine residual. To control metal oxide formation, pH adjustment to levels between 4 and 6 would be necessary. This would be accomplished by adding sulfuric acid to the feed water. Scale inhibition would be achieved by adding complexing agents, such as sodium hexametaphosphate.

The RO process would consist of 30 parallel trains treating 85 mgd. Each train would consist of 140 pressure vessels arranged in three stages to form an 80:40:20 array of vessels. Each vessel would contain 4 membranes in 60-inch lengths. Downstream of the existing filters, the entire influent flow would be routed to the first 80 vessels in Stage 1. The brine generated from the Stage 1 vessels would be routed to the next 40 vessels in Stage 2. The Stage 2 brine would be subsequently routed to the last 20 vessels in Stage 3 for further concentration. The concentrated brine from the Stage 3 vessels would be approximately 20 percent of the total influent flow, resulting in 80 percent recovery of the influent flow. The percent recovery is dependent on the amount of dissolved solids (calcium sulfate, barium sulfate, and silicates, in particular) in SEWPCP wastewater and the effectiveness of the lime precipitation process in removing these ions.

The RO treatment train would have an operating pressure of approximately 250 to 300 pounds per square inch (psi), at a minimum wastewater temperature of 17 degrees Celsius (°C). The proposed design membrane flux rate, or surface loading rate is 9 to 10 gallons per square foot of membrane per day (gfd). A membrane cleaning system would be required for periodic cleaning and to maximize membrane life. In general, the useful life of the membrane is approximately 2 to 5 years. They must be replaced at the end of that period. The estimated removal rates for the pollutants of concern are shown in Table 5-13E. These removal efficiencies are estimated based on data from Water Factory 21 and pilot studies performed by JMM.

The RO effluent would be acidic, have very little hardness, and be almost mineral free. Lime addition may be a convenient way to de-acidify the RO effluent while also increasing the alkalinity and hardness of the final product water, thereby reducing its corrosiveness and attraction to minerals, and creating a more stable final effluent.

Brine Disposal

The quantity of concentrated brine generated from the RO process would be significant. Assuming a maximum product recovery of 80 percent, approximately 17 mgd would be rejected by the membranes as brine. This brine must be further treated for volume reduction and to facilitate final disposal.

Secondary Lime precipitation. The RO brine would be treated by lime precipitation to remove a majority of the metals. For this application, the lime precipitation process would be could be lower than normally expected. Additionally, highly solubilized metals in the brine, such as nickel, would not be affected by the precipitation process. The metals remaining in the clarified effluent cannot be returned directly to mix with SEWPCP effluent. The clarified effluent must be filtered and then routed to a secondary RO process for additional metals removal.

The calcium carbonate and metal hydroxide sludge formed in the lime precipitation process would also be dewatered and hauled off-site for disposal. Water removed by the filter presses would be routed back to the SEWPCP headworks.

Secondary RO. The secondary RO unit is designed to remove the residual metals from the lime precipitation step and to further concentrate the volume of brine for disposal. Approximately 13.6 mgd of product water and 3.4 mgd of a secondary brine would be produced in this process. The product water would be routed to mix with product water from the main RO process, and then discharged to the Bay.

Brine Disposal. The 3.4 mgd of brine produced by the secondary RO system could be transported through a 15-inch diameter pipeline, traversing approximately 37,400 feet westward across the City, to mix with the new Oceanside WPCP effluent for discharge via the 4.5-mile long Southwest Ocean Outfall to the Pacific Ocean. The estimated concentrations of pollutants in this mixture are shown in Table 5-13F. They are expected to be below the limits for ocean discharge. The 1991 data from Richmond-Sunset were used for estimating the concentrations of the brine/effluent mixture. Since the new Oceanside facility will produce a secondary effluent, the actual concentrations would likely be lower than shown on Table 5-13F.

A full-scale RO treatment process at SEWPCP would require major construction. Based on the capacity requirements, a total area of 300, 000 square feet of space would be needed. However, the only space available at the existing site is about 36,000 square feet. CCSF would have to acquire significant amount of the adjacent areas in order to implement this structural BMP.

EXPECTED REDUCTIONS

Table 5-13G summarizes the capabilities of full-scale lime precipitation and RO to remove pollutants from the current SEWPCP effluent. The Basin limits for most of the target pollutants can be met with the exception of cyanide and mercury. Because of the minimal to low cyanide reduction potential of the RO and lime precipitation processes, the 10 µg/L effluent limit for cyanide may not be achievable. Compliance with the mercury limit would also be marginal. However, that may be an artifact of the limits of detection for mercury.

ESTIMATED COST

The estimated costs of the full scale lime precipitation and RO facilities are summarized in Table 5-13H. In addition to the capital costs, this BMP would also require significant annual operating and maintenance (O&M) expenditures. The major O&M costs would be for electrical energy and chemicals (lime and sulfuric acid).

R0057651

SECTION 6

EVALUATION OF DRY WEATHER BMPs

and non-economic criteria. These evaluation criteria were developed to provide a quantitative system of ranking the BMPs such that favorable BMPs could be recommended for implementation.

Cost-effectiveness is measured by the cost of each BMP to reduce the pollutants of concern. The non-economic evaluation is based on an assessment of whether a BMP would have a positive effect ("+"), a negative effect ("-"), or no effect ("0") on eleven non-economic criteria. The sum of these scores for each BMP would form an overall picture of its advantages and disadvantages.

In accordance with the BMP Study Plan (CCSF 1991E), the BMP evaluation criteria were divided into two tiers, Tier I and Tier II, based on their importance to the success and value of a given BMP. Each of the criteria in these tiers is discussed below in relation to the thirteen BMPs. A summary of the evaluation, the recommended BMPs, their cumulative effect on SEWPCP's final effluent, and the costs and staffing requirements are presented at the end of this section.

TIER I EVALUATION CRITERIA

The Tier I evaluation criteria are considered to be of greater importance to the success and value of a BMP. These criteria include cost-effectiveness, time to achieve results, compatibility with other CCSF source reduction programs, requirement for legal changes, and effect on effluent limits.

Cost Effectiveness

Table 6-1 summarizes the estimated loadings and reductions for the thirteen dry weather BMPs. Reverse osmosis would have the highest reduction potential, approximately 27,000 pounds per year (lb/yr) from the effluent loading. BMPs 11 (recording field observations) and 12 (treatment plant chemicals) would not reduce influent loadings to the SEWPCP. BMP No.11 would be extremely beneficial for implementation of other BMPs, but would not directly result in any influent loading reductions. Among the other BMPs, the following observations on the primary pollutants of concern can be drawn.

- Copper Reduction - The BMPs with the highest reduction potential are water supply (No. 8), cooling towers (No. 9), public education (No. 1), automotive service facilities (No. 6), root killers (No. 3) and laboratories (No. 7); in that order.

- Mercury Reduction - The BMPs that are expected to reduce the mercury loadings are medical and commercial laboratories (No. 7), public education (No. 1), and home improvement products (No. 4). CCSF's efforts to regulate dental facilities should provided additional mercury reduction.

- Cyanide Reduction - BMPs with cyanide reduction potential are public education (No.1), home improvement products (No. 4), automotive service facilities (No. 6), and laboratories (No.7). In general, the BMPs evaluated were not found to be major sources of cyanide. This concurs with CCSF's Cyanide Evaluation Study. Cyanide was not found in the wastewaters of many small quantity generators sampled.

(a) BMP No. 11 would not directly reduce pollutants of concern.

R0057653

- PAHs Reduction - There are minimal data available on the reduction and treatment of PAHs. As stated in Section 4, PAHs is essentially a by-product of combustion. The major

scrubbers (No. 9) could potentially reduce PAHs. Of these three potential sources, the presence of PAHs has been noted in the literature. However, there is no documentation of quantities in the literature or at other POTWs. In addition, since PAHs are by-products of the combustion process; reduction measures, other than reducing the sources of combustion, may not be readily available.

Table 6-2 presents a summary of the pollutant reductions expected from the implementation of the source reduction BMPs (Nos. 1 through 12). This table indicates that source reduction measures would have the greatest impacts on the copper, lead, and zinc influent loadings.

The cost effectiveness of the BMPs was evaluated in terms of the expected costs per pound of pollutants expected to be removed. The total reductions of each BMP could be calculated as simply the sum of the expected reductions of the individual pollutants. However, this method would not account for the different degrees of toxicity for these compounds. As an example, zinc may be present in higher concentrations than copper prior to exerting the same level of health effects on certain aquatic organisms. This is reflected by their respective effluent limits: 840 µg/l for zinc and 17 µg/l for copper. Therefore, removal of the same quantities of these two compounds would not have the same environmental benefit. This disparity is further compounded by the fact that zinc is generally present in higher concentrations and is more easily removed.

In order to account for the differences in toxicity among the seven pollutants, the total reductions of the BMPs are normalized to a common standard. For this cost effectiveness analysis, copper is arbitrarily selected as the standard reference pollutant. The mass reductions of the six other pollutants analyzed were converted to a copper-equivalent mass reduction by scaling the reductions according to a toxicity conversion factor. The conversion factors used were based on the effluent concentration limits of each pollutant (relative to copper) as contained in the Basin Plan. These conversion factors are listed in Table 6-3. For example, the lead conversion factor of 0.32 is derived from the effluent limit for copper (17 µg/L) divided by that for lead (53 µg/L). This ratio is then multiplied by the expected lead mass reductions for a given BMP to obtain the expected copper-equivalent mass reductions.

Once the expected mass reductions were normalized relative to the copper standard, cost-effectiveness was calculated as follows:

- Annual costs of each BMP were divided by the estimated annual normalized reductions of copper, cyanide, lead, mercury, nickel, silver, and zinc. These seven pollutants are all of some concern to CCSF.

- Annual costs of each BMP were also divided by the estimated annual normalized reductions of copper, cyanide, and mercury. These three pollutants are of primary concern for CCSF to comply with the proposed Basin Plan limits. This second method was used to eliminate biases in the unit cost calculations due to certain pollutants such as zinc. Certain BMPs may reduce high amounts of zinc but would not significantly reduce copper, mercury, or cyanide.

Table 6-4 presents a summary of the annual costs and the cost-effectiveness calculated for the thirteen BMPs. The two most costly options are the two structural BMPs, reverse osmosis (No

available. Therefore, the annual costs of BMP No. 13 can be used as the benchmark against which the costs of other BMPs can be compared.

The cost-effectiveness of the non-structural BMPs can be directly compared in Table 6-4. These BMPs would reduce the influent loadings to the SEWPCP. BMPs 3 (root killer) and 11 (record field observations) are expected to impose the lowest annual costs. The cost-effectiveness of BMP No.13 can not be directly compared to the non-structural BMPs since the reverse osmosis pollutant removals occur in the effluent loadings rather than by influent source reduction. The BMP cost-effectiveness evaluation is summarized below.

Cost effectiveness Based on Reduction of All Seven Pollutants:

- BMPs 3 (root killer), 4 (home improvement products), 6 (automotive service facilities), 7 (medical and commercial laboratories), 8 (corrosion control), and 9 (cooling towers) are very cost effective.
- BMPs 1 (public education), 2 (used oil collection), and 5 (photographic wastes) are slightly less cost effective.
- A unit cost for BMPs 11 (record field observations) and 12 (SEWPCP chemicals) cannot be calculated. These BMPs would not reduce any of the pollutants of concern.

Cost effectiveness Based on Reduction of Three Primary Pollutants:

- BMPs 3 (root killer), 4 (home improvement products), 7 (medical and commercial laboratories), 8 (corrosion control), and 9 (cooling towers) are very cost effective.
- BMPs 1 (public education) and 6 (automotive service facilities), are slightly less cost effective.
- Unit costs for BMPs 5 (photographic wastes), 11 (record field observations), and 12 (SEWPCP chemicals) cannot be calculated. These BMPs would not reduce any of the primary pollutants of concern.
- The unit cost of BMP No. 2 (curbside oil collection) would be similar to that of reverse osmosis. However, BMP No. 2 would also reduce PAHs, organics, oil and grease to the treatment plants. In addition, the cost of this BMP could be reduced with a direct user fee. The environmental awareness survey determined that the public would be willing to pay directly for this service.

A comparison of the cost effectiveness of the BMPs is shown graphically in Figures 6-1 and 6-2.

Time to Achieve Results

BERM decides to proceed with the implementation of a given BMP (i.e., beginning to compile mailing lists, or arranging for design efforts to be initiated). For this criterion, a "+" score was given if results (i.e., reduced loadings) could be expected to be achieved within a year or two of implementing the BMP. Longer term reduction measures were scored with a "-" sign. Table 6-5 presents the evaluation and comparison of the thirteen BMPs in terms of this criterion.

BMPs 2, 3, 6, 7, 9, and 11 would all achieve some level of reductions within a short time of implementation. BMP No. 2 would be effective as soon as a curbside program is in place. Banning of copper sulfate in BMP No. 3 would also have an immediate effect on copper loadings from this source. For BMPs 6, 7, and 9; reductions would be expected within a year after regulation of these businesses. It is expected that identifying businesses for regulation, establishing detailed criteria, and educating the business operators would be performed within the first year. While BMP No. 11 would not directly result in any reduction, its implementation would be very valuable to the other BMPs (1, 2, 3, and 4). Therefore, it is considered to have a positive impact with respect to this criterion.

BMPs 8, 10, and 13 would require a moderate time period for results to be achieved. For BMP No. 8, SFWD is required to monitor its water supply and then perform corrosion control studies to comply with the Safe Drinking Water Act, . Based on the results of corrosion control studies, design and construction of new facilities or replacement pipelines may be required. The whole process may require three or more years to complete. Design and construction of storage facilities (BMP No. 10) or reverse osmosis facilities (BMP No. 13) would take two to four years. Once these facilities were in place, however, results would be achieved immediately.

Longer response times could be expected from BMPs 1, 4 and 5. BMPs 1 and 4 would rely upon increasing public awareness, educating public on environmentally beneficial alternatives, and modifying behavior patterns. It is expected longer time frame would be necessary implement these measures and to achieve significant results. Current regulation of photographic discharger have already reduces SEWPCP loadings significantly. Further regulation of the smaller dischargers in BMP No. 5 would have minimal impact. An extensive effort to control all these minor dischargers may be required before any notable reductions.

BMP No. 12 would not achieve any reductions.

Compatibility with Other CCSF Programs

The evaluation of the BMPs in terms of this criterion is also shown in Table 6-5. Of all of the BMPs, only BMPs 10 and 13 would be considered as incompatible with the other ongoing CCSF programs. The storage facilities proposed in BMP No. 10 would reduce the flexibility for expansion or addition of new facilities at SEWPCP by taking up valuable space on a limited site.

CCSF agencies is implementing a well-developed source reduction program that covers several medium (water, sludge, and solid waste). Due to its high costs, BMP No. 13 would necessarily result in the abandonment of these waste reduction programs that are favored by CCSF as environmentally-sound solutions. Due to its high cost and amount of residuals generated, BMP No. 13 would be incompatible with the source reduction and waste minimization approach recommended by EPA, the State Board, and the Regional Board.

(a) Total is the average of Tier I Criteria, multiplied by a factor of 2; where "+" is assigned a value of 2, "0" is assigned a v: and "-" is assigned a value of 0.

R0057662

The educational and administrative activities included in BMPs 1, 2, 3, and 11 would be compatible with other CCSF programs. The public outreach efforts, illegal dumping/spill

would have no negative impacts on other CCSF programs. BERM is currently conducting the

discharge of large photographic dischargers. This BMP would add additional resources to expand the current program. BMPs 6, 7, and 9 would also include additional facilities for regulation. These additional facilities can be easily regulated under BERM's existing requirements. BMP No. 8 would be compatible with the SFWD's corrosion reduction efforts as part of complying with the Lead and Copper Rule in the SDWA.

BMP No. 12 would have no effect on other CCSF source reduction programs.

Requirement for Legal Changes

The evaluation of the BMPs in terms of this criterion is also shown in Table 6-5 Of the 13 BMPs, legal changes would only potentially be required for BMPs 2, 5, and 13. Providing citation authority for BERM inspectors as part of BMP No. 2 would require statutory changes to CCSF ordinances with regard to which personnel are permitted to issue citations. The curbside motor oil collection program may require revisions and/or coordination with CCSF Fire, Building and Safety, and Health Codes. Contractual arrangements will be needed with private collection companies hired to operate the programs. For BMP No. 5, regulatory changes would be required in order to allow the collection of residential photographic wastes at the two treatment plants. However, regulatory approval has already been given to a similar collection facility at the Palo Alto Regional Water Quality Control Plant. Approval from the Department of Toxic Substances Control would also be required as part of this BMP.

BMP No. 13 would require large increases in sewer charges or a bond issue. Significant permitting requirements or legal changes would be required for construction for a cross-town brine pipeline, disposal of a concentrated brine in the ocean outfall, and disposal of large quantities of chemical sludge.

Impact on Effluent Limits

The evaluation of the BMPs in terms of this criterion is also shown in Table 6-5. This criterion addressed the effectiveness a BMP would have on complying with the new Basin Plan effluent limits. By design, all of the BMPs would contribute towards compliance; but some would have more impacts than others. SEWPCP is currently meeting effluent limits for all pollutants except for copper, mercury, cyanide, and PAHs. This criterion specifically looks at whether BMPs have a high mass reduction potential for these pollutants.

Of the 13 BMPs, reverse osmosis would have the most reliable, directly controllable mechanisms for reducing the pollutants of concern. However, even the implementation of this BMP may not result in full compliance with the cyanide and mercury limits. Currently, adequate data is not available to verify the performance of the reverse osmosis at these extremely low effluent concentrations.

BMPs 2, 3, 6, 7, 8, and 9 would have positive impacts on complying with the effluent limits. All these BMPs would utilize direct measures, either by providing alternative disposal methods, or by permitting and monitoring, to reduce their targeted pollutants of concern. Corrosion in the water

VOL 12 2 4371

R0057663

supply piping has been identified as the largest single source of copper; BMP No. 8 would have significant impacts on meeting the Basin Plan limits for copper.

The BMPs least likely to impact effluent limit compliance would be BMPs 5, 10, and 12. Silver is the only pollutant affected by BMP No. 5. Since SEWPCP would already comply with the new Basin Plan limit, this BMP would have no impact on this criterion. Due to its low reduction potential, BMP No. 10 would not contribute to meeting the new effluent limits. It would also contribute minimally even in conjunction with other BMPs. The main reason being that removal efficiencies at SEWPCP are not directly controllable. Finally, there is no reduction potential for BMP No. 12.

TIER II EVALUATION CRITERIA

The Tier II evaluation criteria are considered to be of secondary importance to the ranking of a BMP. These criteria include ease of implementation, ability to measure results, public acceptance, promote public awareness, environmental impacts, cross media impacts, and potential to reduce other pollutants. Each of these Tier II criteria are discussed below.

Ease of Implementation by BERM

The evaluation of the BMPs in terms of this criterion is shown in Table 6-6. BMPs 2, 3, 5, 6, 7, 8, 11, and 12 would all be easily implemented by BERM. The BMP No. 2 illegal dumping/spill report hotline and database, and citation authority for BERM inspectors can be implemented relatively easily. Coordination among the departments receiving illegal dumping and spill reports will be required for the database to be comprehensive and effective. The curbside motor oil collection program would require significant preparation, planning and coordination with private collection companies. Publicity and promotion would be required. The activities included in BMP No. 3 will be relatively easy to implement. The activities are consistent with and can be coordinated with other public education and outreach efforts. BMPs 5, 6, 7, and 9 would require significant staffing but could be implemented relatively simply. All the procedures for businesses identification, survey, permitting, monitoring, and enforcement are already in place and being practiced by all PSE staff. BERM would have reduced involvement with BMP No. 8. However, BERM must coordinate between the SFWD and the Regional Board to establish the importance of the potable water quality in complying with the copper. The procedures for data entry and analysis in BMP No. 11 are already established and can be implemented relatively easily. BMP No. 12 can also be easily implemented. Different grade chemicals can be ordered directly from suppliers. There should be no effect on SEWPCP operations; the same chemical feed systems would be used for the new chemicals.

BMPs 1 and 4 would be moderately difficult to implement. Implementing the activities in these BMPs would entail significant amount of time and effort. Numerous individual activities must be organized, planned and implemented and a variety of educational materials must be produced. The activities are part of an ongoing program that will require full time staff support and budgetary resources for materials production, distribution and publicity.

12	SEWPCP Chemicals	+	-	0	-	0	+	0	1.0
13	Reverse Osmosis	-	+	-	-	-	-	+	0.6

(a) Total is the average of Tier II Criteria, where "+" is assigned a value of 2, "0" is assigned a value of 1, and "-" is assigned a value of 0.
Example: Average of BMP No.1 scores (1 "0", 1"-", and 5"+") = 11/7 = 1.6.

R0057665

BMPs 10 and 13 would be difficult to implement. Both BMPs would require significant space at the SEWPCP site which is not available. In addition to normal construction-related disruptions,

considerable attention.

Ability to Measure Results

The evaluation of the BMPs in terms of this criterion is also shown in Table 6-6. For many of the BMPs, it would be difficult to positively measuring their effects on the effluent limits. There are two factors that would prevent easy measurement of results:

- Quantifying reduced loadings from numerous small sources.
- Establishing the effects on these reduced loadings on effluent concentrations.

Only BMP No. 13 (reverse osmosis) would allow definitive measurements of results. The reductions from BMP No. 12 can be easily quantified by tracking the amounts of chemicals used on an daily basis. The reductions from BMP No. 13 can be easily quantified by monitoring pollutants concentrations at the influent and effluent of the lime precipitation and RO facilities. BMP No. 12 (SEWPCP chemicals) would not reduce any pollutants.

Other "point source" BMPs; such as those regulating photoprocessing facilities (BMP No. 5), auto service facilities (BMP No. 6), laboratories (BMP No. 7), and cooling towers (BMP No. 9) would allow some level of compliance measurement. They would have sampling points for compliance monitoring or documentation for zero discharge. However, it would be difficult to correlate reductions at these sources to lower influent loadings.

It will be very difficult to measure results from the BMPs that focus on the residential sources (BMPs 1, 2, 3, 4, and 11). Successful implementation of these BMPs would result in small reductions across the entire CCSF. Although the amount of used oil collected in BMP No. 2 can be easily quantified, the amount that would have been illegally discharged, if curbside collection were not available, cannot be accurately measured. As stated previously, BMP No. 11 would not result in any direct reductions. Therefore, its successful must be evaluated as part of the effectiveness of the public education programs. Long-term sampling of solely residential areas may be the only means of determining the effectiveness of these BMPs. A periodic (every 3 to 5 years) environmental awareness survey would also be another measure of their success.

Results from BMP No. 8 would be difficult to measure. Direct measure would require a periodic sampling of tap water at the point-of-use. The sampling effort would have to be similar in scope to the recently completed program. Reductions in the water supply would result in lower influent concentrations; however, whether the reductions are due to the water supply or other source reduction measures would be difficult to differentiate.

The results or effectiveness of BMP No. 10 would be difficult to measure. Pollutant removal efficiencies at a treatment plant depend upon a number of operational factors. Typically, removal efficiencies can vary on a daily basis. Any reductions noted in the final effluent cannot be attributed directly to the storage of the recycle flows.

VOL 12 2 4374

R0057666

Public Acceptance

impact as it would provide further reduction of a pollutant that is not of concern at this time. The expenditures of this BMP could be better utilized for other measures. BMP No. 13 would have a very low public acceptance due to its high cost, high consumption of chemicals and electrical energy, high volume of solids waste generated, and negative impact on the Oceanside discharge.

With the exception of providing citation authority to BERM inspectors, the public can be expected to readily accept the activities included in BMPs No. 1, 2, and 3. Survey results show widespread public support for increased city-sponsored pollution prevention efforts. Over 70 percent of respondents in the environmental survey said that they would use a curbside motor oil collection program. The public may not be receptive to being issued citations by BERM inspectors for improper disposal of toxic substances into storm drains. BMPs 4, 6, 7, and 8 would also have positive impacts as they are concrete steps to reduce pollution and to protect the sensitive Bay environment.

BMPs 10 and 12 would have no impact on public acceptance.

Promote Public Awareness

The evaluation of the BMPs in terms of this criterion is also shown in Table 6-6. BMPs 1 through 6 are expected to have a positive overall effect on promoting public awareness of pollutant loadings to the San Francisco Bay and the positive steps that CCSF are undertaking to control these sources. These BMPs involve direct public and residential outreach activities. The are also associated with businesses (photoprocessing and auto service) that the public has a great deal of contact with.

The more esoteric BMPs, such as those addressing medical labs and cooling towers (BMPs 7 and 9), would have very little impact on public awareness. Similarly, the corrosion control activities under BMP No. 8 will have little impact on public awareness.

The BMPs that only involved BERM and SEWPCP personnel (BMPs 10, 11, 12, and 13) would not promote public awareness of the BMP or source reduction program.

Environmental Impacts

The evaluation of the BMPs in terms of this criterion is also shown in Table 6-6 With the exception of reverse osmosis (BMP No. 13), most of the BMPs, by design, are expected to have a positive impact on the environment. BMP No. 13 would have severe negative environmental impacts due to its high consumption of chemicals and electrical energy, high volume of solids waste generated, and negative impact on the Oceanside discharge. Due to their low reduction potential, BMPs 10, 11, and 12 would have no impact on the environment.

Cross-Media Impacts

The evaluation of the BMPs in terms of this criterion is also shown in Table 6-6. Some BMPs, by reducing the amount of pollutants in the wastewater discharges, could result in increases of pollutants to other media (air or solid wastes).

VOL 12 2 4375

R0057667

BMPs 1, 2, 3, 5, 8, 9, 11, and 12 are not expected to have any cross media impacts. All these BMPs would result in reduced usage of pollutants. No additional pollutants would be transferred or generated. In BMP No. 2, the curbside motor oil collection program would collect used oil that

processed for silver recovery, they would be no significant additions to the other media.

The activities of BMPs 4, 6, 7, and 10 could increase loadings to the solid waste stream. BMPs 4, 6, and 7 could result in additional wastes to be transported and disposed of as liquid hazardous waste. BMP No. 10 would have a small negative impact on cross-media concerns. Any reduction in the liquid streams would be added to the solids stream. However, since the reduction potential is low, any negative impact would be minimal.

BMP No. 13 would have significant cross media impacts. Pollutants removed from the SEWPCP liquid streams would be transfer to the chemical sludge and to the Oceanside outfall. There would be no overall reduction in pollutants discharge to the environment.

Potential to Reduce Other Pollutants

The evaluation of the BMPs in terms of this criterion is also shown in Table 6-6 BMPs 1, 2, 4, 5, 6, 7, and 13 have the potential to reduce compounds other than copper, mercury, cyanide, and PAHs. BMP No. 1 has the potential to reduce the amount of all constituents of concern entering the CCSF treatment system. BMP No. 2 would reduce organics, oil and grease, and PAHs as a result the curbside motor oil collection program. BMPs 4, 6, and 7 have the potential to reduce other organic and inorganic pollutants entering the SEWPCP from paints, automotive shops, and various laboratory reagents, respectively. In addition to being a copper source, automotive shops are expected to be significant contributors of organics and oil and grease. BMP No. 5 would have the potential to reduce other pollutants such as chromium and selenium from photoprocessing operations. However, the potential reduction would be fairly small. Reverse osmosis activities as a result of BMP No. 13 could be expected to remove many other pollutants from the effluent wastestream. The RO membranes remove the soluble pollutants by size, so any larger organics or metal compounds comparably sized to the targeted compounds would be likewise removed.

BMPs 3, 8, and 9 are targeted to specific pollutants, with a particular focus on copper. BMPs 8 and 9 may result in reductions in the loadings of some other corrosion by-products (e.g., iron and lead), but these reductions are expected to be minimal. BMP No. 9 may have substantial impacts on zinc loadings, but will have little impact on other compounds.

Reductions from BMPs 10, 11, and 12 are expected to be so low that the potential to reduce other pollutants should be considered as negligible.

RECOMMENDED DRY WEATHER BMPs

The results of the cost effectiveness and non economic evaluation are summarized in Table 6-7. Based on the above evaluation, it is recommended that CCSF implement the following BMPs in a two-phased approach. The first phase BMPs should be implemented by the end of Fiscal Year 1993-94. The second phase BMPs should be implemented by the end of Fiscal Year 1995-96. This two-phased approach would allow CCSF to focus on measures that would have the most impacts. The experience gained from these initial BMPs can then be easily applied to the subsequent BMPs. Table 6-8 lists the total reductions expected from all of the recommended dry weather BMPs.

VOL 12 2 4376

R0057670

VOL 12 2 4378

The BMPs selected for Phase I implementation are cost effective and/or are rated as highly favorable among the non-economic criteria. These BMPs include the following:

the corrosion control study by SFWD.

- BMPs 6 (automotive service facilities), 7 (medical and commercial laboratories) and 9 (cooling towers). Laboratories and cooling towers are currently unregulated and may be significant contributors of copper and mercury. Radiator repair and car washes are currently regulated by BERM. However, many other businesses related to automotive service (auto dealers, body shops, gas stations, general repair, trucking, buses, and fleet services) may also be significant contributors.

- BMP No. 3 (copper sulfate root killer). This BMP represents the most easily identifiable residential contribution. Cost of implementation would be extremely low.

- BMPs 1 (public education), 2 (used oil collection), and 11 (record field observations). Although these BMPs are not considered especially cost effective in terms of pollutant reductions, they should be applied as general measures rather than to target specific pollutants. Additionally, a strong program focusing on residential contributions and reductions is an integral part of an effective overall source reduction effort.

The single Phase II BMP will be BMP No.4 (home improvement products). This BMP is slightly more cost effective than some of the Phase I BMPs, but had slightly lower non-economic ratings. As part of BMP No. 4, boatyards within CCSF should be inspected and considered for regulation. This BMP should be initiated approximately two years after the Phase I BMPs.

The following BMPs are not recommended for implementation by CCSF.

- BMP No.5 (photographic wastes). CCSF already has a successful program in place to regulate the large photographic waste dischargers. SEWPCP would easily comply with the new Basin Plan limit for silver. Additional regulations as part of this BMP would have minimal benefits.

- BMP No.10 (recycle flow storage). This BMP would require significant physical facilities for minimal reduction. Implementation of this BMP would also reduce site availability at SEWPCP and limit future expansion flexibility.

- BMP No.12 (SEWPCP chemicals). The reduction potential of this BMP would be very minor. Depending on the results of the other BMPs, this BMP may be reviewed after several years for implementation.

- BMP No.13 (reverse osmosis). Capital and operating and maintenance (O&M) costs of this BMP are extremely high. Even with these expenditures, compliance with all the Basin Plan limits would be uncertain. There is no information on cyanide removal efficiency with reverse osmosis, and compliance with this limit may not be achievable. This BMP would generate significant negative impacts associated with high energy usage and generation of residual chemical sludge and concentrated brine that would require alternative disposal. Finally, due to its high annual costs, implementation of this BMP would likely reduce the CCSF funding available for implementation of the source control BMPs discussed above.

VOL 12 2 4379

R0057671

pollutants is in the particulate form rather than the soluble form and is, therefore, more readily removed. For soluble pollutants such as cyanide, lower influent concentrations would result in less opportunities for adsorption and biodegradation. The influent concentrations of copper, cyanide, and mercury are plotted against their removal efficiencies in Figures 6-3 to 6-5. A logarithmic curve fit is shown for each pollutant. While the correlation of these variables are not very strong, the plots generally illustrate the trend of decreasing removal efficiency with lower influent concentrations.

Table 6-9 compares the current effluent 95th percentile concentrations of copper, mercury, and cyanide; their estimated concentrations after the implementation of the recommended BMPs; and the proposed Basin Plan limits. As shown on the table, the implementation of the BMPs may not reduce copper, mercury, and cyanide concentrations to below the Basin Plan limits. Due to the variability inherent in estimating loadings and reductions, the ability to comply with the proposed limits will only become apparent after implementation of these BMPs. However, it must be pointed out that these source reduction measures are the most environmentally acceptable methods to deal with the water quality requirements. There are no direct controls over effluent quality with influent source reduction measures. Final effluent quality is dependent upon influent concentrations and removal efficiencies at the treatment plant. Both factors are known to vary significantly on a day-to-day basis.

In addition to implementing source reduction measures, CCSF staff are also investigating other means to comply with the Basin Plan limits. These other potential means are listed below.

- Development of a watershed management approach to toxicity control as proposed jointly by the League of California Cities, California Association of Sanitation Agencies, and the California Water Pollution Control Association (Tri-TAC). The watershed management approach would consider all significant sources of pollutants (both point and non-point sources) and would focus on the sources that can most effectively be reduced to comply with the water quality objectives.

- Evaluation of a water reuse master plan to export wastewater from the greater Bay area to the central valley for irrigation reuse. If successful, this project would completely eliminate the discharge of toxic pollutants to San Francisco Bay.

- Evaluation of cross-town tunnel to deliver the entire SEWPCP effluent to an ocean outfall. As indicated earlier in this report, treated effluent from the CCSF wastewater treatment facilities would comply with the Ocean discharge requirements.

CCSF staff is actively participating in the development and evaluation of the above activities. These compliance options will continued to be pursued in conjunction with the implementation of the recommended BMPs.

R0057676

recommended Phase I BMPs would be approximately $1.2 million per year. Implementation of Phase II (BMP No.4) would impose an additional annual cost of approximately $37,000. Approximately 2.5 source reduction specialists would be required to implement these BMPs. A public education coordinator and a public education assistant have been listed for BMP No. 1. In actuality, they will be providing public participation services for all the recommended BMPs.

ADDITIONAL RECOMMENDATIONS

CCSF adopted new local limits for its pretreatment program in December 1991. These local limits were developed on a technical basis in accordance with EPA guidelines. However, the effluent limits used in that evaluation were based on the existing NPDES permits and the 1986 Basin Plan discharge limits. As discussed above, the 1991 Basin Plan has proposed significantly more stringent effluent limits. Although these limits are not currently in any CCSF permit, they are expected to be included in the SEWPCP permit when it is scheduled for renewal in 1994. Additionally, imminent changes to the 503 Sludge regulations may also have some impacts on the local limits.

Several of the recommended BMPs would require utilizing local limits as the means for regulation. Since these BMPs have been developed in response to the new Basin Plan, local limits should be re-evaluated. Notification of potential local limits revisions would be beneficial to businesses that are selecting treatment or disposal methods for their wastes.

SECTION 7

SELECTION OF WET WEATHER BMP FOR EVALUATION

This is the first of three sections (7-9) addressing wet weather best management practice (BMP) selection and evaluation. The content and format of these wet weather sections generally follows that of dry weather sections 4-6. Section 7 discusses the initial selection of BMPs; section 8 describes the best management practices in more detail; and section 9 presents the results of the final evaluation, including BMPs recommended for implementation.

This section accomplishes the following:

- Identifies the City's wet weather pollutants of concern;
- Identifies the principal sources of the pollutants of concern; and
- Selects best management practices for further development (section 8) and evaluation (section 9).

BACKGROUND

San Francisco has a system of underground sewer lines that collect domestic sewage and industrial wastewater and transport it to the City's Water Pollution Control Plants (WPCPs) for treatment. As in most older cities in the United States, these sewer lines also receive street runoff and other storm water. During rainy periods, the storm water flow rate can reach 60 times the dry weather rate. To handle this huge storm water flow combined with sewage, San Francisco's combined system includes a series of long, underground box-like structures known as storage/transports which ring the City like a moat.

By 1996, when San Francisco completes its wastewater facility improvement program, approximately 66% of the storm flow will be held for secondary level treatment at the Southeast or Oceanside WPCPs. The remaining 34% of the storm flow will receive flow-through treatment within the storage/transports or primary treatment and disinfection at the North Point WPCP. Flow-through treatment is accomplished by passing the storm flow through a baffle and weir system within the storage/transports before discharging the flow either through the Southwest Ocean Outfall or as combined sewer overflows (CSOs) via shoreline overflow points. These wet weather overflows and their associated pollutants are the focus of the wet weather portion of this BMP Study. The wet weather best management practices being studied focus on preventing pollutants of concern from entering the combined sewer system via storm water runoff.

IDENTIFICATION OF POLLUTANTS OF CONCERN

Studies in many urban areas have shown that urban runoff typically contains significant quantities of the same general types of pollutants that are found in wastewaters discharged by Publicly-Owned Treatment Plants (POTWs) and industries, and that they cause similar water quality problems. The National Urban Runoff Program (NURP) has shown that storm water from residential and commercial areas can contain a variety of pollutants, including heavy metals, fecal coliforms, pesticides, suspended solids, nutrients, and floatables (USEPA, 1983A).

VOL 12 2 4388

R0057680

A recent study conducted by Santa Clara County indicated that storm water is a significant contributor of sediment and heavy metals such as chromium, copper, lead, nickel, and zinc (Santa Clara Valley Nonpoint Source Control Program, 1990).

1. Pollutants exceeding NPDES permit limits;
2. Pollutants potentially contributing to general receiving water problems (e.g. exceedances of water quality standards in either the Ocean Plan, the Enclosed Bays and Estuaries Plan, or the Region II Basin Plan);
3. Pollutants in compliance but near permit limits;
4. Pollutants contributing to bioaccumulation, and/or biomagnification; and
5. Pollutants contributing to existing and potential sediment toxicity problems.

The pollutants of most concern in the wet weather discharges are those that cause a violation of the City's discharge permits. These permits are issued by the Regional Water Quality Control Board (RWQCB) or, in the case of the discharge through the Southwest Ocean Outfall, by the U.S. Environmental Protection Agency (USEPA). Presently, none of the City's discharges during dry or wet weather violate permits or the associated compliance orders.

Although the City's wet weather discharges are currently in compliance, this situation may change as new water quality objectives are incorporated into permits in the coming years. There is an ongoing debate at both the national and state level as to whether and how these water quality objectives should apply to storm water discharges and combined sewer overflows. If these objectives are applied as written to the City's wet weather discharges, the City would be in significant noncompliance with several numerical limits.

To assess the potential for future noncompliance, several data sources (SWRCB, 1991; SWRCB, 1992; City and County of San Francisco (CCSF, 1990A; CCSF, 1991D; CCSF, 1992) were reviewed to compare constituent concentrations in the overflow discharges to the selection criterion (Appendix D). The City compared Bayside overflow concentrations from 1989 to 1992 to water quality objectives in the Amendments of the Water Quality Control Plan for Enclosed Bays and Estuaries of California (SWRCB, 1992). As a result of this review, pollutants of concern were grouped into three tiers, in descending order of concern:

Tier 1 **Significant concern** - Three year mean pollutant concentration 10 times greater than potential water quality objective without dilution.

- Polynuclear Aromatic Hydrocarbons (PAHs)
- Copper
- Lead
- Cyanide

VOL 12 2 4389

R0057681

Tier 2 **Moderate concern** - Three year mean pollutant concentration greater than potential

- **Mercury**
- **Nickel**
- **Silver**
- **Zinc**

Tier 3 **Little concern** - Three year mean pollutant concentration less than potential water quality objective without dilution.

- **Chromium**
- **Arsenic**

It is clear that if the water quality objectives are included in the permits and applied to San Francisco's wet weather discharges, then the City will have a serious compliance problem. Therefore, the wet weather portion of the BMP Study focussed on reducing the Tier 1 and Tier 2 pollutants of concern namely PAHs, heavy metals, and cyanide.

IDENTIFICATION OF POLLUTANT SOURCES

Source Identification Methodology

A literature search was conducted to identify the sources of these pollutants. The City reviewed City-specific reports as well as general literature sources on storm water runoff (City of Puyallup, 1988; City of Seattle, 1989; Minnesota Pollution Control Agency, 1989; Natural Resources Defense Council and Chesapeake Bay Foundation, 1990; USEPA, 1990; USEPA, 1991; Citizens for a Better Environment, 1991; Santa Clara Valley Nonpoint Source Control Program, 1990; Washington Department of Ecology, 1992). In addition, City staff from the Bureau of Environmental Regulation and Management (BERM), the Bureau of Street Cleaning and Urban Forestry (BSCUF), and the Bureau of Street and Sewer Repair (BSSR) were interviewed regarding potential sources.

Review of Pollutant Sources

As a result of the literature review and information gathering process, CCSF has identified two broad source classes, primary and secondary. The distinction between primary and secondary sources has been made to help focus the discussion of source control strategies. Pollutants of concern may be reduced more effectively by addressing each of the various pathways by which the pollutants may enter storm water. Primary and secondary sources are defined below.

Primary Sources - These are materials or material uses which provide the first opportunity in an urban setting for pollutant contact with rainfall or runoff. Examples of primary sources are automobiles (which contribute oil, grease, and metals through leaks, exhaust, metal corrosion, and tire wear), waste disposal practices, and raw products exposed to storm water.

VOL 12 2 4390

R0057682

Secondary Sources - Some sources of pollutants, termed secondary sources, are difficult to isolate and quantify. These include air-borne particulates and sediments which accumulate throughout CCSF's infrastructure (streets, catch basins, storage/transports, and low-flow sections of sewerage system). Some primary sources become secondary sources when they are not

because they may absorb a certain amount of heavy metals and hydrocarbons under one set of chemical conditions (e.g., pH), and release these pollutants later as a result of changing conditions.

Primary Sources. Table 7-1 summarizes the primary sources of the City's wet weather pollutants of concern, including both general wet weather sources and commercial/industrial sources. The primary sources of pollutants of concern during wet weather may be grouped into three general categories:

- **Automotive-related** - Motor vehicles deposit oil and grease, tire particles, and metals directly on the roadways. These pollutants and others, such as cyanide and PAHs, from vehicle emissions are flushed away by rainfall and eventually end up in the sewer system.
- **Paints/Wood preservatives** - Paint and wood preservative products contain a number of heavy metals.
- **Businesses with outside exposure** - Other potential primary sources include businesses with outside storage or manufacturing yards. Businesses that generate and/or discharge pollutants of concern, which may come into contact with rainfall and/or runoff, are potential primary sources. These businesses include those that use automotive or paint/wood preservative products such as auto repair shops, painting contractors, and equipment rental shops that often clean their equipment outside with water that later enters the sewer system as runoff.

Secondary Sources. The major secondary source of pollutants in San Francisco is sediment. Sediments occur in the following places throughout the City's wastewater and storm water collection system:

- streets and sidewalks,
- catch basins,
- sewer pipes,
- storage/transports,
- treatment plants, and
- outfalls.

The principal sources of the wet weather pollutants of concern are automotive-related activities, paint/wood preservative uses businesses with outside exposure, and infrastructure sediments. Of these sources, automotive-related and paint/wood preservatives are discussed and include specific best management practices in the dry weather sections (4-6) of this report. Therefore, the target sources for further development of wet weather BMPs are:

- Businesses with outside exposure, including those using automotive or paint/wood preservative products, and
- Secondary sources (i.e., infrastructure sediments).

VOL 12 2 4392

SELECTION OF WET WEATHER BMP FOR STUDY

The Best Management Practices Study Plan for Water Pollution Prevention (Study Plan) (CCSF, 1991B) describes the City's plan for this study of eight best management practices (referred to as Optional BMPs) in addition to the ten best management practices already being implemented (referred to as Mandated BMPs) by San Francisco. The Mandated BMPs were described in Provision E.8.a of RWQCB Order 90-093, while Provision E.8.b described the Optional BMPs. Of the eight Optional BMPs, four are targeted primarily at wet weather conditions (Table 7-2). The other four best management practices focus on dry weather conditions and are discussed in sections 4-6 of this report.

As described in the Study Plan, the Optional BMPs were selected from a list of BMPs developed by other Bay area municipalities. Best management practices were determined to be more effective if based on information specific to San Francisco, including pollutants of concern, sources, and existing programs. Therefore, a screening process was applied to the Optional BMP list (Table 7-2) to determine if any best management practices should be added or dropped from the original list.

Selection Methodology

The data considered in the selection were primarily qualitative. The steps followed in the selection process are outlined below.

1. Review Optional BMPs against Mandated BMPs - Because the Mandated BMPs required in the permit and now being implemented were focussed primarily on wet weather conditions, the City began the screening process by comparing the Optional BMPs in the context of the City's existing Best Management Practices Implementation Program (CCSF, 1990E). The Optional BMPs were reviewed for their ability to compliment the Mandated BMPs for the pollutants of concern and their sources.

2. Data collection - The City gathered qualitative data on the Optional BMPs from City agencies, supported by quantitative data which were easy to gather, reliable, and complete.

3. Data analysis - The information collected was discussed with personnel from the Bureau of Water Pollution Control (BWPC), the Department of Public Health (DPH), the Solid Waste Management Program (SWMP), and the inter-agency BMP Review Committee.

4. BMP selection - Based on the screening process and discussions with City agencies, the City selected five best management practices for further study.

Wet Weather BMPs Selected for Detailed Review

Table 7-3 lists the five BMPs that emerged from the selection process and are reviewed in sections 8 and 9. The list includes the four Optional BMPs from the permit as well as an additional best management practice, P6, shown in italics. Each of these five wet weather best management practices appeared to complement the existing BMP Implementation Program either by addressing pollutant sources not covered by the existing program or by using a different means of implementation (e.g., public agency action versus education) to address a source.

R0057685

TABLE 7-2

Educational Control Measures

E1 - Educate re: the environmental impacts which result from leaks and spills from gasoline, fuel oil, and chemical tanks (above and below ground).

Regulatory Control Measures

R1 - Develop and implement program to reduce the risk of toxic pollutant spills from commercial, industrial, and public facilities.

Public Agency Control Measures

P2 - Establish program to regulate cleaning of sewer inlets, catch basins, and drainage channels in areas where sediments and/or debris tend to accumulate.

P4 - Develop and implement an aggressive field program to search for, detect, and correct situations which rainfall and/or runoff presently contact potential contaminants.

SUMMARY

1. The wet weather portion of the BMP Study focussed on reducing the Tier 1 and Tier 2 pollutants of concern namely PAHs, heavy metals, and cyanide.

2. The target sources for further development of wet weather best management practices are:

   - Businesses with outside exposure, including those which use automotive or paint/wood preservative products, and
   - Secondary sources (i.e., infrastructure sediments).

3. The five wet weather best management practices selected for in depth review include the four Optional BMPs, plus a best management practice directed at improved street cleaning.

SECTION 8

DEVELOPMENT OF WET WEATHER BMPs

This section defines and describes each of the five wet weather best management practices (BMPs) selected for detailed review. The following information is provided for each BMP:

- A clear definition and purpose for the best management practice is given.
- Linkages between the best management practice and other BMPs are shown and described. These other BMPs may be Mandated BMPs and/or Optional BMPs. The linkages may be in the form of target source and/or implementation method. Figure 8-1 shows the linkages between some of the wet weather Optional BMPs and other best management practices.
- A description of the pollutants of concern which the BMP addresses.
- Existing conditions in San Francisco related to each BMP are described. The best management practice is evaluated in part by the need for the BMP and by its "fit" with existing programs.
- Means of implementing the BMP are listed and described.
- Cost and expected reduction information is provided (if available).

VOL 12 2 4396

R0057688

BEST MANAGEMENT PRACTICE E1 - LEAK/SPILL IMPACT

EDUCATE THE PUBLIC REGARDING THE ENVIRONMENTAL IMPACTS THAT

INTRODUCTION AND PURPOSE

The purpose of this best management practice is to implement an education program to increase awareness among the general public about the environmental impacts that result from leaks and spills of gasoline, fuel oil, and chemicals from above and below ground tanks. CCSF did not address ground water contamination from leaking underground storage tanks (USTs), as this issue is adequately addressed by other regulatory programs. In CCSF, the Department of Public Health (DPH) oversees cleanup activities through implementation of the Local Oversight Program (LOP).

CCSF evaluated this BMP on its cost-effectiveness in protecting surface water during wet weather conditions. The focus of this best management practice is defined by the City as exposure of rainfall and runoff to leaks and spills from above-ground storage tanks.

LINKS TO OTHER BMPs

This BMP is linked to the following best management practices (see Figure 8-1):

- *P3- Hazards Tracking (dry weather BMP No. 11 in this report):* Develops a centralized database for tracking hazards from spills, exposed contaminants, and illegal dumping incidents. This helps to identify the biggest problems and to target programs accordingly.
- *E4-Rainfall/Runoff Protection (Implementation Program BMP):* Educates the public regarding the need to keep rainfall and/or runoff from contacting potential contaminants.
- *R1-Spill Risk Prevention:* Increases inspection and monitoring of facilities with potential to contribute pollutants of concern in their storm water discharge through spills or lack of physical barriers to keep contaminants from contacting storm water and/or runoff.

POLLUTANTS OF CONCERN

This BMP addresses the following sources of pollutants of concern:

- Gasoline - lead and PAHs, and
- Motor oil - zinc (USEPA, 1975).

Gasoline, motor oil, and diesel fuel also contain trace amounts (< 20 ug/g) of other heavy metals as shown in Table 8-1. It should be noted that lead concentrations in gasoline have been reduced significantly with the mandated introduction of unleaded fuels in the late 1970s.

Source: USEPA, 1975

EXISTING CONDITIONS

The following information summarizes current findings regarding storage tanks:

- There are 1,500-1,600 active tanks being used throughout CCSF, but no readily available information on how many tanks are above-ground versus below ground, or on the materials contained in these tanks (Lum, 1992).
- There are an estimated 15,000 inactive USTs formerly used for home heating fuel oil (Lum, 1992).
- The Office of the Chief Administrative Officer (CAO), distributes a brochure to underground storage tank owners through workshops and direct mailings.
- Operating permits, pursuant to the Hazardous Materials Ordinance, are required for all underground storage tanks, and for above-ground storage tanks whose capacity exceeds 10,000 gallons (Lum, 1992).
- Secondary containment is required for above-ground tanks (Grey, 1992).
- Storage permits, issued by DPH and approved by the Fire Department, are required for all facilities storing hazardous materials (CCSF, 1991E).
- Most above-ground tanks contain diesel or motor oil, although gasoline is stored in limited quantities (Lum, 1992).

IMPLEMENTATION MEASURES

Implementation of this BMP would involve a public outreach to the owners and operators of above and below ground chemical storage tanks. CCSF would employ a targeted approach to reach the small number of storage tank owners, as opposed to a broad public education campaign. Outreach materials would be developed and CCSF's list of owners and operators would be used to distribute these materials.

VOL 12 2 4399

R0057691

EXPECTED REDUCTIONS

Information gathered during the screening procedure revealed that this BMP may be favored as

quantity the expected reductions from implementing this BMP. However, the following existing conditions seem to indicate that leaks and spills from above-ground tanks are adequately addressed and that expected pollutant reductions from an educational outreach would be minimal:

- Operating permits for large above-ground tanks;
- Secondary containment required for above-ground tanks; and
- Storage permits required for hazardous materials.

It appears that training CCSF employees as part of R1 (Spill Risk Prevention) and recording spill information (Dry Weather BMP P3 (No. 11)-Hazards Tracking) may be more cost-effective means for increasing awareness among groups who come into direct contact with leaks and spills from storage tanks.

ESTIMATED COSTS

The cost to develop an outreach piece, to maintain an accurate mailing list, and to conduct a one time mailing to about 1,500 addressees would be on the order of $5,000 to $10,000, depending on the sophistication of the outreach piece and the initial condition of CCSF's owner/operator list. No additional staff would be required to implement this BMP.

VOL 12 2 4400

R0057692

BEST MANAGEMENT PRACTICE R1 - SPILL RISK PREVENTION

DEVELOP AND IMPLEMENT A PROGRAM TO REDUCE THE RISK OF TOXIC

INTRODUCTION AND PURPOSE

The original purpose of this best management practice was to develop and implement a regulatory program that would reduce the risk of toxic pollutant spills from commercial, industrial, and public facilities, and was therefore fairly limited in scope. For this study, CCSF expanded the scope to investigate the potential of implementing an Enhanced Pretreatment Program supported by an amended wastewater discharge permit application (CCSF, 1992D). The Enhanced Pretreatment Program would require storm water controls on commercial, industrial, and public facilities to reduce pollutants of concern in urban runoff. The implementation of R1 complements BMP R4 of the Implementation Program, which requires covers to prevent runoff from contacting potential pollutants, and P4 of the present study, which implements a field program to search for, detect, and correct situations where rainfall and/or runoff contact potential pollutants (see Figure 8-1).

LINKS TO OTHER BMPs

This BMP is linked to the following best management practices (Figure 8-1):

- *R4-Rainfall/Runoff Protection (from the Implementation Program)*: Requires landowners and/or tenants to provide covers to keep rainfall/runoff from contacting potential contaminants; and to keep runoff from draining through areas that contain contaminants.
- *P1-Illegal Dumping Control (dry weather BMP No. 2 in this report)*: Is designed to prevent the dumping of pollutants of concern into the sewer system through the implementation of an aggressive reporting campaign. By extension, this best management practice helps keep litter off the streets where storm water and/or runoff could come into contact with potential pollutants.
- *P3-Hazards Tracking (dry weather BMP No. 11 in this report):* Develops a centralized database for tracking hazards from spills, exposed contaminants, and illegal dumping incidents. This helps to identify the biggest problems and to target programs accordingly.
- *P4-Rainfall/Runoff Protection:* Implements a field program to search for, detect, and correct situations in which rainfall or runoff contact potential contaminants. Combines elements of education (employee training), hazards tracking (recording observations of field personnel), and enforcement.

POLLUTANTS OF CONCERN

This best management practice addresses all the wet weather pollutants of concern; metals, PAHs, and cyanide. In a city the size of San Francisco, with the diversity of businesses present, it is likely that all of the pollutants of concern are at risk of being spilled or otherwise contacting rainfall and/or runoff. Without doing an inventory of the amounts and types of chemicals used

VOL 12 2 4401

R0057693

and/or stored outdoors in the City, it is impossible to determine for which pollutant(s) of concern this BMP may have the greatest impact.

The following is a summary of current findings on existing spill prevention activities:

- The Hazardous Materials Ordinance, enforced by DPH, has provisions for spill prevention, containment, and reporting of hazardous materials (CCSF, 1991E).
- A spill prevention plan is required in CCSF's industrial wastewater discharge permit application (CCSF, 1992D).
- CCSF inspects approximately 700 industrial dischargers annually in its current pretreatment program (CCSF, 1992E).

IMPLEMENTATION MEASURES

CCSF has developed the following ways to implement this best management practice:

- **Enhanced Pretreatment:** Develop an Enhanced Pretreatment Program directed at facilities already in CCSF's pretreatment program and others likely to contribute pollutants to runoff. The program will add spill prevention and runoff protection requirements to more traditional pretreatment requirements.
- **Enforcement Authority:** Invest CCSF inspectors with the authority to issue citations to enforce the enhanced pretreatment requirements.

Following is a more detailed discussion of these implementation measures.

Enhanced Pretreatment

The Enhanced Pretreatment Program proposed by CCSF introduces industrial storm water runoff controls similar to those that are required in municipalities with separate storm sewer systems pursuant to the requirements from the State's General Industrial Storm Water Permit (SWRCB, 1991E). San Francisco's combined sewer system is not subject to the storm water regulations (40 CFR 122.26(a)(7)). However, CCSF has determined that regardless of the type of sewer system, commercial, industrial, and public facilities are likely to contribute pollutants to runoff. Table 8-2 lists businesses, identified by their Standard Industrial Classification (SIC) Code, that are targeted by CCSF's Enhanced Pretreatment Program. The list is divided into tiers based on priority for inclusion in the program. The tiers listed in descending priority are:

- Tier 1 - Businesses that are already in CCSF's pretreatment program and would be covered under the Federal regulations for storm water if the City were not exempt. As indicated in Table 8-2, some of the businesses would be subject to Federal storm water regulations only if their pollutants are exposed to storm water. Therefore, these businesses should undergo an initial inspection to determine whether or not there is storm water exposure.

VOL 12 2 4402

R0057694

- **Tier 2** - Businesses in CCSF's pretreatment program which, although they would not be covered under Federal regulations if the City were not exempt and that are not in CCSF's pretreatment program, but have the potential to contribute pollutants of concern to storm water.

- **Tier 3** - Businesses that would be covered under Federal regulations if the City were not exempt and that are not in CCSF's pretreatment program, but have the potential to contribute pollutants of concern to storm water.

CCSF's Enhanced Pretreatment Program would address both dry weather and wet weather sources of pollutants. Figure 8-2 illustrates the relationship between the dry weather and wet weather portions of CCSF's program. The dry weather aspects are discussed in the Waste Minimization Program Plan (CCSF, 1992F). The wet weather portions would include requirements similar to those in the State General Industrial Storm Water Permit (SWRCB, 1991E). A Storm Water Pollution Prevention Plan (SWPPP) would be required from some of CCSF's Significant Industrial Users (SIUs) and other Industrial Users (IUs), depending on the which tiers are included in the program. Table 8-3 is a checklist of requirements that will be incorporated into each facility's SWPPP, or Storm Water Plan. This checklist may also be used by CCSF inspectors to document compliance and as a guide to help businesses complete the industrial discharge permit application. CCSF proposes to require Storm Water Pollution Prevention Plans to be developed, implemented, and available for review on-site by October 1, 1993.

Enforcement Authority

CCSF inspectors would have the primary responsibility of ensuring the proper implementation of the Enhanced Pretreatment Program, since they would have the capability and training necessary to detect storm water violations. In addition, by citing illegal dumpers, CCSF inspectors would also be enforcing dry weather BMP P1 (No. 2 in this report)-Illegal Dumping Control, which involves developing an aggressive public program to report and prevent dumping of toxic pollutants into sewers and drainage channels. In order to ensure that new potential storm water quality threats do not develop, it is advisable for CCSF inspectors to monitor the businesses determined to be exempt from the Enhanced Pretreatment Program. Businesses that repeatedly violate their waste minimization or storm water plan requirements should be prosecuted by the City Attorney.

TABLE 8-3 STORM WATER POLLUTION PREVENTION PLAN CHECKLIST

ELEMENTS	COMPLETED? (Check if yes)
* Paved areas and buildings;	
* Areas of pollutant contact, actual or potential;	
* Location of existing storm water structural control measures;	
* Surface water locations;	
* Areas of existing and potential soil erosion;	
* Vehicle service areas.	
(2) A narrative description of the following: * Materials and practices used to minimize contact of significant materials with storm water discharge;	
* Material loading, unloading, and access areas;	
* Existing structural and non-structural control measures (if any) to reduce pollutants in storm water discharge;	
* Industrial stom water discharge treatment facilities (if any);	
* Methods of onsite storage and disposal of significant materials;	
* Outdoor storage, manufacturing, and propcessing activities.	
(3) A list of pollutants likely to be present in significant quantities, and an estimate of the annual quantities of these pollutants in storm water discharge.	
(4) An estimate of the size of the facility (in acres or sq. ft.) and the percent of the facility that has impervious area.	
(5) A list of significant spills or leaks of toxic or hazardous pollutants to storm water that have occurred after Oct. 1, 1990. The list must include: * Toxic chemicals (listed in 40 CFR 372) that have been discharged as reported on EPA Form R;	
* Oil or hazardous substances in excess of reportable quantities (see 40 CFR 110, 117 or 302).	
(6) A summary of existing sampling data (if any) describing pollutants in the storm water discharge.	
DESCRIPTION OF STORM WATER MANAGEMENT CONTROLS	
(1) Identify specific individuals (and job titles) who are responsible for developing, implementing, and revising the Storm Water Plan.	
(2) Describe preventive maintenance measures, including inspection and maintenance of storm water conveyance system devices and inspection and testing of plant equipment and systems that could fail and result in discharges of pollutants to storm water.	
(3) Describe housekeeping practices, which include: * Maintenance of clean, orderly facility areas that discharge storm water;	
* Inspection and cleaning of material handling areas.	

R0057698

VOL 12 2 4406

TABLE 8-3 STORM WATER POLLUTION PREVENTION PLAN CHECKLIST (Continued)

ELEMENTS (continued)	COMPLETED? (Check if yes)
(4) Identify areas where significant materials can spill into or otherwise enter	
* Establish internal reporting procedures for spills of significant materials.	
(5) Describe storm water management practices, which include:	
* Installation of oil and grit separators;	
* Diversion of storm water into retention basins, etc.;	
* Additional measures based on an assessment of the potential of various sources to contribute pollutants to storm water discharges.	
(6) Describe employee training program for all personnel responsible for the Implementation of the Storm Water Plan, and identify periodic dates of training. Training should address:	
* Spill response,	
* Good housekeeping,	
* Material management practices,	
(7) Describe inspection practices, which should include:	
* Assurance that all inspections shall be done by trained personnel,	
* Use of a tracking or follow-up procedure;	
* Documentation of all inspections and maintenance activities;	
* Statement that all inspection records shall be retained for five years.	
ANNUAL FACILITY INSPECTION	
An annual facility inspection shall be conducted to:	
* Verify that all elements of the Storm Water Plan are accurate;	
* Retain any observations and responses as part of the Plan.	
REFERENCE OTHER PROGRAM REQUIREMENTS	
The Storm Water Plan may incorporate, by reference, the appropriate elements of other program requirements, such as the SPCC plans under Section 311 of the CWA.	
INCLUDE SIGNATURE AND TITLE OF AUTHOR(s), DATES OF INITIAL PREPARATION AND AMENDMENTS	

VOL 12 2 4407

R0057699

... ... the pollutants of concern from implementing this BMP are difficult to calculate. There is little or no baseline data available on the types and concentrations of pollutants in runoff from particular industrial sites. Instead, reductions would be demonstrated primarily by nonconventional monitoring as opposed to traditional water quality monitoring. Nonconventional monitoring would consist of recording information on the following:

- Number of businesses with pollutant exposure to rainfall/runoff,
- Volume and types of materials/wastes with exposure to rainfall/runoff,
- Concentrations of materials/wastes with exposure to rainfall/runoff, and
- Level of compliance with the amended sewer use ordinance.

CCSF would gather data in the first year of the Enhanced Pretreatment Program to establish a baseline. Information from subsequent years would be used to document pollutant reductions. Nonconventional monitoring would include noting any decreases in the volume and concentration of pollutants exposed to rainfall/runoff as a result of best management practice implementation. Reductions noted would be compared with the implementation costs to calculate cost-effectiveness.

ESTIMATED COSTS

The program's effectiveness would be significantly enhanced by ensuring that program staff have the time and training necessary to provide useful storm water protection advice. Consequently, the major costs associated with an Enhanced Pretreatment Program are estimated below.

Staff Time

Legal staff time is needed to prosecute offenders. The incremental cost of City Attorney time is estimated as $6,000 (40 hours * $150/hr).

The incremental cost to add storm water exposure to a compliance inspection depends on several factors including:

- Which tiers in Table 8-2 to inspect for storm water exposure,
- Number of businesses in selected tier(s),
- Size of facilities,
- Frequency of inspections, and
- Length of inspection.

To help determine costs, CCSF has made the following assumptions:

- Tier 1 and tier 2 businesses will be inspected for storm water exposure,

VOL 12
2
4408
R0057700

- An additional 30 minutes per inspection will be requ... exposure and to provide technical assistance when needed, and
- Cost of inspector including benefits is $90,000/year.

Calculation: 750 businesses * 2 inspections/year * 0.5 hours/inspection = 750 hours
750 hours / 2,080 hours/year * $90,000 = $32,500

Training Costs

Training costs can involve staff participation in workshops and seminars, self-study time, observation sessions in the field, and preparation time prior to inspections. An Enhanced Pretreatment Program would require an increased understanding of processes, chemical usage, point and nonpoint source wastestreams, and waste minimization technologies on an industry and process-specific basis. To reduce training and program costs, larger POTWs have suggested that individual staff specialize in one particular industry or process and then serve as a resource for their fellow workers (Local Government Commission, 1988). CCSF estimates the training time required by this new program will require about 15% of each inspector's time in the first year.

Calculation: 15% * $90,000 * 4 inspectors = $54,000

The estimated annual cost to implement this best management practice is shown in Table 8-4.

TABLE 8-4

ESTIMATED ANNUAL COST - BMP R1

Implementation Measure	Cost
Annual Operating Costs:	
Legal Staff	$6,000
Inspectors	$32,500
Training	$54,000
Total Annual Cost	**$92,500**

VOL 12 2 4409

BEST MANAGEMENT PRACTICE P2 - CATCH BASIN CLEANING

INTRODUCTION AND PURPOSE

The purpose of this BMP is to establish a program that will regulate the cleaning of catch basins in areas where sediment concentrations of pollutants of concern are sufficiently high for the sediments to potentially act as a secondary source. Catch basins are chambers or sumps installed in a storm sewer, usually at the curb, which allow surface runoff to enter the sewer. Many catch basins have a low area intended to retain sediment. By trapping coarse sediment, the catch basin prevents trapped solids from clogging the sewer or being washed into receiving waters. However, these low areas must be cleaned periodically to maintain their sediment-trapping abilities and to prevent resuspension of sediment. It is also important to clean catch basins to provide liquid storage capacity, since the volume of storm water detained in a catch basin will reduce the amount of wet weather flow by that amount.

LINKS TO OTHER BMPs

This BMP is linked to the following best management practices (Figure 8-1):

- *P1-Illegal Dumping Control (dry weather BMP No. 2 in this report):* Is designed to prevent the dumping of pollutants of concern into the sewer system through the implementation of an aggressive reporting campaign. By extension, this best management practice helps keep litter off the streets where storm water and/or runoff could come into contact with potential pollutants.

- *P3-Hazards Tracking (dry weather BMP No. 11 in this report):* Develops a centralized database for tracking hazards from spills, exposed contaminants, and illegal dumping incidents. This helps to identify the biggest problems and to target programs accordingly.

- *P6-Street Cleaning:* Street and catch basin cleaning have the common function of removing sediments, including bound metals and PAHs, from CCSF's combined sewer system. Removing sediments reduces their residence time in the system and eliminates the possibility of their acting as a secondary source. The optimal coordination of sweeping, flushing, and catch basin cleaning to remove sediments in the most effective and timely manner, may protect water quality and reduce unnecessary treatment costs.

POLLUTANTS OF CONCERN

This best management practice addresses those pollutants of concern that may adsorb to sediments in the catch basins including PAHs and heavy metals. Various studies of marine sediments indicate that lead, copper, and zinc tend to precipitate out of the water column more rapidly than nickel, arsenic, and cadmium (Jones, 1992). Although it is not possible to directly extrapolate from this information how bound metals would behave in the catch basins, it is likely that metals may be released to some degree into storm water runoff under changing chemical or physical conditions.

VOL 12 2 4 4 1 0

R0057702

over the course of seven years (O'Neil, 1992). The cleaning operation involves vacuuming sediments, leaves, and street debris out of catch basins and disposing of the debris at Sunset Scavenger Co. facilities in CCSF. Following is a summary of findings regarding the cleaning of catch basins and drainage channels:

- CCSF's 50,000 catch basins are cleaned over the on a schedule of 1-7 years (O'Neil, 1992).
- Although sizes vary, the typical catch basin in San Francisco is six feet deep and 33 inches wide, with the outlet pipe located 24 inches from the top and 48 inches from the bottom of the catch basin (O'Neil, 1992).
- The current cost to clean a catch basin is approximately $42 (O'Neil, 1992).
- Westside Storage Transport (considered to be a "drainage channel") is flushed on an as-needed basis to remove sediments left behind by storms (Kenck, 1992).

The following is a discussion of catch basin effectiveness, based on a review of available studies.

Pollutant Removal

Although it is not possible (based on the data currently available) to quantify the water quality benefits of catch basin cleaning, such cleaning does provide benefits. These benefits include removing pollutant loads from the sewer system, reducing high pollutant concentrations during the "first flush" of a storm, preventing clogging of the downstream storm water conveyance system, and restoring the sediment trapping capacity of the catch basin.

Typical catch basins have been estimated to retain up to 57 percent of coarse solids and 17 percent of equivalent biological oxygen demand (BOD) (a measure of the relative oxygen requirement of a sample as determined by its biological composition). A study conducted in the West Roxbury section of Boston showed that catch basins retained 54-88% of BOD, 10-56% of chemical oxygen demand (COD) (a measure of the relative oxygen requirement of a sample as determined by its chemical composition), 48-97% of volatile suspended solids, and 60-97% of suspended solids (Moffa, 1990). Two large sumps installed in storm sewers as part of the Lake McCarron wetland treatment system retained as much as 75 percent of solids in runoff although the typical efficiency was much less (Minnesota Pollution Control Agency, 1989).

In the absence of cleaning, catch basins may actually make water quality conditions worse. It has been reported that once a sump is 40-50 percent full, any inflow could have a flushing effect and actually generate a sediment loading while passing through the catch basin. Also, the material which accumulates in catch basins undergoes decay, and the first flush of stagnant water and debris by storm water runoff in the sewer system may contain a high concentration of pollutants (Minnesota Pollution Control Agency, 1989). The average concentration of pollutants in catch basin liquid discharged during storms is similar to concentrations of untreated sewage (Minnesota Pollution Control Agency, 1989).

VOL 12 2 4 4 1 1

R0057703

Frequency of Cleaning

might become blocked. Recommended catch basin cleaning frequencies vary from once to twice a year, depending upon conditions (Moffa, 1990, USEPA, 1983B). In general, if the contributing watershed has active construction or other land uses creating high sediment loads, the catch basin should be cleaned more often than in stabilized areas. In order to minimize the quantity of dirt collecting in catch basins, a recommended practice is to sweep the streets just prior to flushing or wet weather. In that case, the sweeper collects the bulk of the litter while the flusher truck or rainfall moves the fine materials into the drainage system (Federal Water Quality Administration, 1971).

IMPLEMENTATION MEASURES

CCSF is already implementing catch basin cleaning; however, the frequency of cleaning varies from once a year to once every seven years, which may or may not be sufficient to maintain the optimal efficiency of the catch basins. Given that catch basin cleaning is costly and labor-intensive, CCSF began a study of existing conditions in order to design a site-specific program of catch basin cleaning that will meet CCSF's goal of reducing pollutants of concern. CCSF sampled two sets of catch basins one for quantity and the other for quality of sediments.

Sediment Quantity

CCSF conducted a preliminary assessment of sediment loading by measuring the level of sediments accumulated in the sumps of 35 residential and industrial catch basins chosen on the basis on their last cleaning. This selection method did not necessarily result in a random selection of catch basins versus land use type. However, as indicated in Table 8-5 and Figure 8-3, there is a general correlation between the sediment levels and number of wet seasons since cleaning.

Sediment Quality

CCSF also collected some preliminary data on sediment quality for a set of fourteen catch basins (different from the data set above) in residential, transportation, commercial, and industrial land use areas in the City. Table 8-7 presents the data for oil, cyanide, and heavy metals. No clear trends were established. There was wide variation across pollutants within a single catch basin, and within land use categories. In addition, the results were further skewed by data indicating particularly high levels for one or more pollutants from some catch basins.

EXPECTED REDUCTIONS

As is the case for most source controls, the expected reductions in the pollutants of concern from implementing this BMP are difficult to calculate. San Francisco has only preliminary data on the types and concentrations of pollutants of concern in catch basin sediments in the City. Furthermore, little data exists to describe the quantity or chemistry of sediments in catch basins under varying conditions. It is not clear if and when sediments act as a secondary source by leaching out previously bound pollutants into storm water runoff. If this BMP were chosen for further study, CCSF would gather initial data to establish a baseline, conduct experiments, and then compare subsequent data to document any concentration changes.

which make it difficult to calculate the cost of implementing this BMP. These cost factors include:

- Number of additional catch basins,
- Location of additional catch basins,
- Sediment loading characteristics,
- Type of sediment and debris accumulated, and
- Time since last cleaning.

If this BMP were chosen for further study, the data gathered on these cost factors would help determine the actual the cost of implementing this best management practice.

VOL 12 2 4417

R0057709

BEST MANAGEMENT PRACTICE P4 - RAINFALL/RUNOFF CONTACT

DEVELOP AND IMPLEMENT AN AGGRESSIVE FIELD PROGRAM TO SEARCH

INTRODUCTION AND PURPOSE

The purpose of this best management practice is to develop and implement an aggressive program to search for, detect, and correct situations in which rainfall and/or runoff presently contact potential contaminants. To distinguish this best management practice from BMP R1, CCSF has defined this best management practice's focus to be pollutants encountered on CCSF streets and other public areas. The focus of BMP R1 is pollutants from commercial, industrial, and public facilities.

LINKS TO OTHER BMPs

This BMP is linked to the following best management practices (Figure 8-1):

- *R1-Spill Risk Prevention:* Increases inspection and monitoring of facilities with potential to contribute pollutants of concern in their storm water discharge through spills or lack of physical barriers to keep contaminants from contacting storm water and/or runoff.
- *R4-Rainfall/Runoff Protection (from the Implementation Program):* Requires landowners and/or tenants to provide covers to keep rainfall/runoff from contacting potential contaminants; and to keep runoff from draining through areas that contain contaminants.
- *P1-Illegal Dumping Control (dry weather BMP No. 2 in this report):* Is designed to prevent the dumping of pollutants of concern into the sewer system through the implementation of an aggressive reporting campaign. By extension, this best management practice helps keep litter off the streets where storm water and/or runoff could come into contact with potential pollutants.
- *P3-Hazards Tracking (dry weather BMP No. 11 in this report):* Develops a centralized database for tracking hazards from spills, exposed contaminants, and illegal dumping incidents. This helps to identify the biggest problems and to target programs accordingly.

With its three components: search, detect, and correct, BMP P4 links other best management practices together into a comprehensive program of education, regulation, and monitoring that effectively addresses the source and elimination of wet weather pollution. The *search* component involves training CCSF employees and the public to recognize potentially harmful situations and to report them. The *detect* component involves recording observations of field personnel and public complaints into a centralized database for tracking hazards from spills or illegal dumping incidents. The *correct* component involves granting key CCSF personnel the authority to cite people for illegal dumping and/or for creating situations where rainfall and/or runoff can contact pollutants of concern.

R0057710

VOL 12 2 4418

rainfall and/or runoff. Without doing an inventory of the amounts and types of chemicals used and/or stored outdoors in CCSF, it is impossible to determine for which pollutant(s) of concern this BMP may have the greatest impact.

EXISTING CONDITIONS

Following is a summary of findings regarding rainfall/runoff protection:

- Currently there is no consistent reporting procedure or centralized database for illegal dumping or spill reports handled by various CCSF departments (Lum, 1992).
- The Bureau of Street Cleaning and Urban Forestry (BSCUF) directs hazards to DPH and only picks up used batteries and paint containers (Shaw, 1992).
- DPH identifies and hauls hazardous waste (Shaw, 1992).
- The Fire Department responds to spills threatening public safety and has the authority to issue citations for illegal dumping, although it rarely receives calls reporting illegal dumping (Grey, 1992).
- A force of three Environmental Patrol Officers (working in the Department of Public Works (DPW) issues citations enforcing municipal litter codes (Shaw, 1992).
- The Bureau of Environmental Regulation and Management (BERM) inspects chemical storage areas for secondary containment as part of its existing pretreatment program (Rourke, 1992).

Currently, CCSF addresses the problem of rainfall or runoff contacting pollutants of concern in two ways, one reactive and one proactive. The first means is by picking up and removing abandoned hazardous waste from CCSF streets and other CCSF property. In January 1989, CCSF, at its own request, received a variance from the vehicle inspection and manifest requirements of the California Department of Health Services, contained in Title 22, Section 66310(a)(1) California Code of Regulations (CCR). This variance allows CCSF employees to use CCSF vehicles to remove abandoned hazardous waste instead of licensed hazardous waste haulers. By allowing CCSF employees to remove wastes soon after their discovery, wastes are removed several hours and often days faster than if the CCSF used licensed haulers. As a result, during the rainy season, the potential for contact between rainfall and/or runoff with abandoned wastes (which even when contained are often leaking) is significantly reduced (CCSF, 1991E).

Hazardous wastes are removed from CCSF streets by personnel from the Fire Department, the Department of Public Health or the Bureau of Street Cleaning and Urban Forestry. Hazardous spills or abandoned hazardous materials are usually detected by BSCUF personnel during their street cleaning routines. BSCUF staff cleans up minor spills of diesel and paint, and also picks up used batteries and paint containers. The Bureau of Street Cleaning and Urban Forestry reports that oil and paint spills or containers are often found in busy parts of CCSF, such as around Selby and Mission streets. All other reported spills are cleaned up by the Fire

VOL 12 2 4419

R0057711

Department and all hazardous materials are ...

approximately 750 regulated industrial users. BERM checks to see that these areas are surrounded by a berm which, although it may not prevent rainfall/runoff from contacting potential contaminants, does restrict any potentially contaminated runoff from moving off-site (Rourke, 1992). The implementation of an Enhanced Pretreatment Program under best management practice R1 would further ensure that rainfall and/or runoff does not contact pollutants of concern.

IMPLEMENTATION MEASURES

Best management practice P4, along with its related best management practices, would be implemented via the following three measures targeted at situations in which rainfall and/or runoff contact pollutants of concern:

- search,
- detection, and
- correction.

These measures are described below.

Search for Potential Hazards

CCSF employees who have daily contact with the City's sewers, catch basins, and streets are in the best position to observe incidents in which toxic substances are illegally dumped or improperly discharged. These personnel could be trained via the following steps to search for and to recognize situations in which rainfall and/or runoff could contact potential contaminants:

- Materials and wastes containing pollutants of concern (e.g, batteries, tire weights) would be identified on a material "hit list".
- Effects of these pollutants to the CCSF's sewer system and the environment would be defined.
- The above information would be incorporated into the current training schedule for DPW personnel.

In addition, the community could be involved in the detection of potential hazards through a neighborhood watch program. Citizens could be encouraged to report the improper use, storage, or disposal of materials/wastes containing the pollutants of concern. CCSF could implement the program by:

- Developing a door knob hanger to be placed on doors near a spill,
- Distributing the hanger to interested neighborhood, school, and community groups, and/or

R0057712

VOL 12 2 4420

... concerns into the "Neighbors for Neighborhoods" ... report spills

Detect Potential Hazards

CCSF employees would be trained to forward their observations to a centralized database, developed as part of dry weather BMP P3 (No. 11 in this report). As part of another dry weather BMP, P1 (No. 2 in this report), the community would be encouraged to report the improper use, storage, or disposal of pollutants by calling a "hotline" telephone number. Information provided by the caller would also be entered into the centralized database.

Correct Potential Hazards

Correcting potential hazards involves educational outreach coupled with enforcement action. Although current CCSF practices address the cleanup of spills and hazards before they reach storm drains, improved search and detection methods would further ensure timely and efficient cleanup. Adequate prevention of hazards may be achieved by granting more CCSF personnel with the authority to cite for environmental infractions, such as dumping waste in a catch basin, and by prominently publicizing the consequences of committing environmental infractions. The DPW force of uniformed Environmental Patrol Officers, who currently cite for littering, could be increased and their authority expanded to address a wider range of environmental infractions. In addition, BSCUF, BSSR, and BERM personnel could also be invested with enforcement authority. Even though issuing citations is not always practical (individuals must be caught "in the act"), making a "show of force" may be an effective way of showing residents and municipal staff that illegal dumping is taken seriously by CCSF.

EXPECTED REDUCTIONS

As is the case for most source controls, the expected reductions in the pollutants of concern from implementing this BMP are difficult to calculate. There is little or no baseline data available on the types and concentrations of pollutants in runoff from CCSF streets and public areas. Instead, reductions would be demonstrated primarily by nonconventional monitoring as opposed to traditional water quality monitoring. Nonconventional monitoring would consist of recording information on the following:

- Number of reports from CCSF personnel of incidents in which toxic substances are illegally dumped or improperly discharged,
- Number of reports from citizens of incidents in which toxic substances are illegally dumped or improperly discharged,
- Number of requests for additional door knob hangers, and
- Number of environmental citations.

CCSF would gather data in the first year of the program to establish a baseline. Information from subsequent years would be used to document pollutant reductions. Nonconventional monitoring would include noting any increases in the number of reports or violations as a result of BMP implementation. Reductions would be calculated from the number of reported/cited incidents that were cleaned up. The assumption would be that the level of pollutant reduction is dependent on the volume and type of spill reported and cleaned up. CCSF would have to conduct some research and perform some calculations to establish that relationship. Reductions

R0057713

VOL 12 2 4421

noted would be compared with the implementation costs to retroactively calculate cost-effectiveness.

The major costs associated with implementation are estimated below.

- Development of a material hit list and additional training for City personnel is expected to require an additional one-half time staff person at BERM for the first year at a cost of about $15,000.
- Development and distribution of a door knob hanger would be on the order of $5,000.
- Incorporating pollution prevention concerns into the "Neighbors for Neighborhoods" program is expected to require an additional one-quarter time staff person at BERM for the first year at an incremental cost of about $7,500.
- Expanding environmental citation authority to other CCSF personnel would require training as well as implementation costs. The training costs would be incurred primarily in the first year and are estimated to be the equivalent of one-quarter time staff person at about $7,500. The continuing cost of implementation is estimated to require about 2.5% of each participating staff person's time at BERM (5 people), BSSR (5 people), and BSCUF (125 people). The average cost of a staff person at the three bureaus including benefits is $90,000/year.

  Calculation: 2% * $90,000 * 135 staff = $243,000

The total cost to implement this best management practice is shown in Table 8-8.

TABLE 8-8

ESTIMATED ANNUAL COST - BMP P4

Implementation Measure	Cost

VOL 12 2 4422

BEST MANAGEMENT PRACTICE P6 - IMPROVED STREET CLEANING

INTRODUCTION AND PURPOSE

The purpose of this best management practice is to implement an improved street cleaning program in areas where sediment concentrations of pollutants of concern are sufficiently high for the sediments to potentially act as a secondary source. Streets may be cleaned by sweeping and/or flushing. Street sweeping, which may be conducted with mechanical brooms or a vacuum system, removes grit, debris, and trash from urban impervious areas such as streets, parking lots, and sidewalks. Street flushing is the process of washing the pavement and forcibly pushing the street dirt toward the curb.

The specific pollutants generally reduced by street sweeping and flushing include sediments (to which PAHs and metals are often bound), nutrients, and oxygen-demanding substances. The effectiveness of sediment removal depends on particle size, with the concentration of pollutants in sediments varying inversely with particle size (American Public Works Association, 1978). Vacuum sweeping and flushing are both more effective than mechanical sweeping at removing the finer sediments (less than 43 microns), which are less susceptible to broom action. Limited testing of a conventional flusher truck resulted in overall particle removal rates of about 30 percent for a single pass and 80 percent for a sweeper followed by a flusher truck (American Public Works Association, 1978).

LINKS TO OTHER BMPs

This best management practice is linked to the following BMPs (Figure 8-1):

- *P2-Catch Basin Cleaning* - Street and catch basin cleaning have the common function of removing sediments, including bound metals and PAHs, from CCSF's combined sewer system. Removing sediments reduces their residence time in the system and eliminates the possibility of their acting as a secondary source. The optimal coordination of sweeping, flushing, and catch basin cleaning to remove sediments in the most effective and timely manner, may protect water quality and reduce unnecessary treatment costs.

POLLUTANTS OF CONCERN

This best management practice addresses those pollutants of concern that may adsorb to sediments in the catch basins including PAHs and heavy metals. Various studies of marine sediments indicate that lead, copper, and zinc tend to precipitate out of the water column more rapidly than nickel, arsenic, and cadmium (Jones, 1992). Although it is not possible to directly extrapolate from this information how bound metals would behave in the catch basins, it is likely that metals may be released to some degree into storm water runoff under changing chemical or physical conditions.

R0057715

VOL 12 2 4423

- Vacuum sweepers are used during the day and mechanical sweepers are used at night (Dahl, 1992).
- Sweeping is conducted on the following schedule (Dahl, 1992):
  - residential: once a week
  - commercial: 2-3 times a week
  - industrial: once a week (only at night)
- Flushing is conducted regularly, but not coordinated with sweeping (Dahl, 1992).
- Annual curb-miles swept is 105,341 (CCSF, 1991F).
- Approximate cost per curb-mile swept is $109 (Busher, 1992).

The status of CCSF programs is further discussed below, followed by a discussion of street sweeping effectiveness as investigated by several studies.

Status of Street Sweeping

CCSF's Bureau of Street Cleaning and Urban Forestry is responsible for the removal of litter from streets. Litter is collected from three sources; illegal dumpings, trash receptacles, and street sweeping. The average annual weight of material collected from these three sources is between 40,000 and 50,000 tons. Of that total, about 21,000 tons comes from the street sweeping operations. Approximately 12,000 tons or 60% of the street sweeping material is classified as sediments (Busher, 1991). The Department of Public Works enforces litter codes with a three-person force of uniformed Environmental Patrol Officers, who issue citations to anyone caught littering the streets and sidewalks of CCSF (Shaw, 1992).

Of CCSF's 40 street sweepers, 75% are of the vacuum type and 25% are of the mechanical type. During the day, CCSF uses vacuum sweepers in residential and commercial areas because they generate less dust and are more effective for removing fine particles than mechanical sweepers. In addition, vacuum sweepers retain their cleaning capacity on crests and depressions of the street surface. However, vacuum sweepers have the disadvantage of being ineffective at cleaning wet surfaces and at removing large debris such as wood, cardboard, and miscellaneous trash. Vacuum sweepers usually have to be preceded by litter trucks to ensure the removal of bulky debris that can impair the vacuum mechanism (Dahl, 1992).

In industrial areas and certain sections where sweeping during the day is impractical, CCSF sweeps at night using mechanical sweepers. Mechanical sweepers, although more costly to maintain than vacuum types, are more effective than vacuum sweepers at picking up trash and other large debris. By eliminating the need for an accompanying litter truck, mechanical sweepers have the advantage or requiring less personnel and generating less noise than vacuum sweepers (Dahl, 1992). Table 8-9 summarizes the status of CCSF's street sweeping practices.

Tons of Debris Removed	18,763 (1990-91)
Cost ($/Curb Mile):	$109

Sources: Dahl, 1992; CCSF, 1991H; Busher, 1992

Status of Street Flushing

CCSF also uses flusher trucks on a regular basis, although flushing is not coordinated with sweeping. A flusher truck consists of a tank mounted on a truck or trailer, for holding a supply of water; an engine driven pump for supplying pressure; and three or more nozzles for spreading the water as directional sprays. The capacity of the water tank on a street flusher varies from 800 to 3,500 gallons, and the nozzle pressure of the water is usually between 30 and 55 pounds per square inch. The amount of water delivered must be proportional to the speed of the vehicle and the pumps must be capable of supplying sufficient water at suitable pressures.

Effectiveness of Street Sweeping

Street sweeping effectiveness is a function of 1) initial sediment loadings and erosion conditions, 2) pavement type and condition, 3) cleaning frequency, 4) number of passes, 5) equipment speed, 6) sweeper efficiency, and 7) equipment type. In general, if the contributing watershed has active construction or other land uses creating high sediment loads, the streets should be cleaned more often than in stabilized areas. It is also true that the less sediment there is on the street to begin with (sediment load), the harder it is to remove a high percentage of it. Pavement type and condition affect performance more than do differences in equipment. In general, smooth asphalt streets are easier to keep clean than those consisting of loosely bound aggregate in a thick, oily matrix; and the poorer a pavement's condition, the more difficult it is to keep it clean.

Street sweeping has been shown to be an effective but limited method of attacking the source of storm water-related pollution problems. A street sweeping experiment in San Jose, California

R0057717

VOL 12 2 4425

showed that sweeping once or twice per day on smooth asphalt streets can remove up to 50% of the total solids and heavy metal mass loading of urban runoff, whereas typical street sweeping frequencies of once or twice per month remove less than 5% of the total solids and heavy metals per week provided only a very small additional benefit (Motta, 1990).

Effectiveness of Street Flushing

It is possible that under the right conditions street flushing could achieve significant pollutant reductions. Flushing appears to have several advantages over sweeping. A survey of street cleaning personnel from cities around the country identified parked cars as the major deterrent to effective street cleaning (American Public Works Association, 1978). However, flushing can be effective with cars parked at the curbs. In addition, flushing may be more effective than sweeping in moving smaller sediments (less than 43 microns) which are reported to bind a larger proportion of heavy metals than larger sediments. Despite these advantages, flushing fell out of favor in the mid 1970s because its ability to move sediments into catch basins and storm drain inlets was perceived to cause greater storm water pollution (American Public Works Association, 1978). San Francisco's combined sewer system may provide an opportunity to use flushing to push sediments into the collection system where they may be removed either in the catch basins or in the sedimentation chambers at the WPCPs.

IMPLEMENTATION MEASURES

Street cleaning not only affects water quality but has multiple benefits, including the improvement of air quality, aesthetic conditions, and public health. CCSF is already implementing regular street sweeping, at frequencies that vary between one to three times a week. Flushing is conducted on an as needed basis and is not coordinated with sweeping. Since the efficiency of sweeping depends on site-specific variables (sediment loadings, pavement type, equipment type, etc.), existing practices may or may not be adequate to achieve maximum efficiencies for pollutant removal. Given that indiscriminately increasing street cleaning would be costly and labor-intensive, CCSF should first study existing conditions in order to design a site-specific program of street cleaning that will meet CCSF's goal of reducing pollutants of concern. However, since street cleaning alone will probably not ensure that water quality objectives are met, the street cleaning program may need to be incorporated into a coordinated program of best management practices, including catch basin cleaning to remove accumulated sediments.

In addition, San Francisco's combined sewer system may provide an opportunity to use flushing for pollutant removal. CCSF could proactively flush streets in the late summer and early fall when the maximum amount of pollutants have accumulated on the roadways. CCSF would in effect be creating its own wet weather, on its schedule, and at a low enough flow rate to receive secondary treatment at the Water Pollution Control Plants during dry weather.

EXPECTED REDUCTIONS

As is the case for most source controls, the expected reductions in the pollutants of concern from implementing this BMP are difficult to calculate. There is little or no baseline data available on the types and concentrations of pollutants of concern on street sediments in CCSF. Furthermore, little data exists to describe the quantity or chemistry of sediments on the streets under varying conditions. It is not clear if and when sediments act as a secondary source by leaching out

VOL 12
2
4426
R0057718

previously bound pollutants into storm water runoff. If this BMP were chosen for further study, CCSF would gather initial data to establish a baseline, conduct experiments, and then compare subsequent data to document any concentration changes.

The most important measure of street cleaning effectiveness is "pounds of pollutant removed per curb-mile" for a specific protocol. This removal value, in conjunction with the unit curb-mile cost, allows the cost for removing a pound of pollutant for a specific street cleaning protocol to be calculated. Costs of street cleaning around the country have been reported to range from $7.92-$30.61/curb-mile (Moffa, 1990). The wide variation in these costs was attributed to differences in labor rates and equipment costs. As seen in Table 8-9, the cost of San Francisco's current street cleaning program is estimated at $109/curb-mile (Busher, 1992). However, there is no information on the pounds of pollutant removed per curb-mile, so current costs cannot be calculated.

The costs to increase street cleaning depend on a number of undecided factors which make it difficult to calculate the cost of implementing this BMP. These cost factors include:

- Frequency of additional street cleaning,
- Location of additional street cleaning,
- Sediment loading characteristics of streets receiving additional cleaning,
- Type of sediment and debris accumulated,
- Type of equipment (mechanical broom vs. vacuum), and
- Use of flusher trucks (e.g., frequency, number, procedure).

If this BMP were chosen for further study, the data gathered on these cost factors would help determine the actual the cost of implementing this best management practice.

SUMMARY

This section has described the five wet weather BMPs in detail including means of implementation and costs (when available). The annual costs and staffing requirements for those wet weather BMPs for which data is available are presented in Tables 8-10 and 8-11, respectively. One additional BERM staff person would be required to implement these BMPs. The BERM inspector and the BSCUF operator are not expected to be new staff, instead, this staff time would be divided among the existing inspectors and operators. In section 9 this information is used to compare these best management practices against a set of evaluation criteria.

SECTION 9

EVALUATION OF WET WEATHER BMPs

This section describes the evaluation of the five wet weather best management practices (BMPs) using a matrix of evaluation criteria. The evaluation procedure follows that used in evaluating the dry weather BMPs in section 6. The evaluation produces a ranking of the five best management practices. Based on the ranking, a recommendation is made for each of the best management practices to either discontinue consideration, implement, or consider further study of the BMP.

EVALUATION METHODOLOGY

The City developed an evaluation matrix based on 14 criteria. The criteria were grouped into two tiers based on their perceived importance to successful best management practice implementation. The Tier 1 criteria reflect the primary goal of reducing the level of the pollutants of concern in a cost-effective manner. The Tier 2 criteria include issues related to logistics and implementation. In the ranking system described below, the Tier 1 criteria are weighted more heavily than the Tier 2 criteria. The evaluation matrix is designed so that best management practices which address the pollutants of most concern and have the greatest source reduction potential are given the highest priority for implementation.

A ranking system was developed consisting of three possible values: "+", "0", and "-", for each criterion. These values are defined as:

- "+" = Data indicates a positive outcome
- "0" = Insufficient data to determine outcome or criteria not applicable
- "-" = Data indicates a negative outcome

For example, if data indicates that a best management practice is particularly cost-effective, that BMP would be valued a "+" in the evaluation. Converseiy, if data indicated that implementation would be relatively expensive, the best management practice would receive a value of "-". Inconclusive data would yield a value of "0". Values of "+" and "-" were only given when data was relatively conclusive, otherwise a value of "0" was recorded. For ranking purposes, the values were assigned the following numerical scores:

- "+" = 2 points
- "0" = 1 point
- "-" = 0 points

Each BMP was evaluated against each of the criteria and assigned one of the three possible values. The values were then tallied using the numerical scores. Scores on Tier 1 criteria were weighted twice as heavily as Tier 2 criteria scores. After the scoring, best management practices were ranked in order of decreasing final score. The higher the score, the higher priority a BMP is given for implementation.

VOL 12 2 4430

R0057722

Tier 1 Evaluation Criteria

The five Tier 1 evaluation criteria and a definition of the values are listed below:

- Time to achieve results (+ = immediate / - = long-term)
- Compatibility with other CCSF programs (+ = high / - = low)
- Legal changes required (+ = no / - = yes)
- Ability to achieve effluent limits (+ = high / - = low)

Tier 2 Evaluation Criteria

The nine Tier 2 evaluation criteria and a definition of the values are listed below:

- Ease of implementation - CCSF (+ = easy / - = difficult)
- Ease of implementation - affected parties (+ = easy / - = difficult)
- Ability to measure results (+ = easy / - = difficult)
- Public acceptance (+ = high / - = low)
- Promote public awareness (+ = yes / - = no)
- Acceptance by affected parties (+ = high / - = low)
- Environmental impacts (+ = no / - = yes)
- Cross media impacts (+ = no / - = yes)
- Potential to reduce other pollutants (+ = high / - = low)

RANKING OF WET WEATHER BMPs AND RECOMMENDATIONS

Table 9-1 is an evaluation matrix showing the scores assigned to each best management practice for the Tier 1 and Tier 2 criteria. Based on the evaluation, the ranking of the BMPs and a recommendation is presented in Table 9-2. The best management practices are listed in order of decreasing overall benefit.

TOTAL SCORE	5	4.9	3.6	3.4	2.4

Scoring System:
"+" (2)
"0" (1)
"-" (0)

Note: Tier 1 scores are weighted twice as heavily as Tier 2 scores.

VOL 12 2 4 4 3 2

R0057724

TABLE 9-2

RANKING		RECOMMENDATION
1)	P4-Rainfall/Runoff Protection	Implement
2)	R1-Spill Risk Prevention	Implement
3)	P6-Street Cleaning	Consider further study
4)	P2-Catch Basin Cleaning	Consider further study
5)	E1-Leak/Spill Impacts	Discontinue consideration

The scores for best management practices P4 and R1, as well as those for BMPs P6 and P2, were very close. As discussed in section 8, these two pairs of BMPs are closely linked, so it may not be surprising that their scores are similar. The reason for their linkage is that they are designed to achieve the same ends using different but complementary means. Following is a description of why the best management practices achieved the ranking shown above. The BMPs that are linked are discussed together.

BMPs	P4-Rainfall/Runoff Protection / R1-Spill Risk Prevention
Ranking	1 and 2
Purpose	Prevent rainfall or runoff from contacting pollutants of concern

These two best management practices are the most effective because they address the issue of storm water pollution by targeting two major sources:

- industries and commercial businesses, and
- streets and public areas.

BMP R1 uses the City's pretreatment program to regulate industrial dischargers which have been determined to contribute pollutants of concern to runoff. This best management practice is directly linked to Implementation Program BMP R4 (Rainfall/Runoff Protection) and to best management practice P4. While BMP R1 specifically targets industry, best management practice P4 targets all situations in which rainfall and/or runoff may contact pollutants of concern. Both BMP R1 and BMP P4 are linked to Implementation Program best management practices, so that their implementation could be coordinated with ongoing efforts, thus saving resources and increasing the efficiency of the Best Management Practices Program.

R0057725

VOL 12 2 4433

BMPs	P6-Street Cleaning / P2-Catch Basin Cleaning
Purpose	Remove sediments from the collection system

Street and catch basin cleaning have the common function of removing sediments, which may act as secondary sources, from the City's runoff collection system. There is no question that street and catch basin cleaning are effective at removing a large portion of sediments, and that they have other side benefits of improving air quality, aesthetic conditions, and public health. It is not clear however, that street sweeping can effectively remove the very fine sediments, which are believed to adsorb a higher proportion of metals than larger sediments, and whether catch basin cleaning every 1-7 years is sufficient to maintain the optimal effectiveness of the catch basin sumps. Therefore, before best management practices P2 and P6 can be implemented in any meaningful manner, these questions need to be answered through a carefully designed, long-term sampling program.

BMP	E1-Leak/Spill Impacts
Ranking	5
Purpose	Educate the public on the environmental impacts of leaking storage tanks.

As discussed in section 8 and confirmed in the evaluation, BMP E1 is not cost-effective for the following reasons:

- this best management practice was originally targeted at the general public, very few of which own or operate storage tanks in a heavily urbanized and densely populated environment like San Francisco;
- there is limited potential for spills to threaten runoff quality since above ground tanks are required to have secondary containment;
- underground storage tank leaks would not normally contact storm water runoff; and
- leaking underground tanks are adequately addressed through other educational and regulatory programs.

POTENTIAL AREAS OF FURTHER EVALUATION

The City has limited knowledge regarding the concentrations of some of the pollutants of concern as they pass through the City's storm water runoff collection system prior to treatment at the Water Pollution Control Plants (WPCPs) and/or discharge to the Bay and ocean. An important issue to resolve is whether the pollutants of concern that are adsorbed to sediments are a threat to water quality. If much of the pollutants remain attached to sediments, increased cleaning of streets and catch basins may not be cost-effective, especially if most of the sediments travelling through the collection system end up in the grit chambers at the WPCPs and then are disposed of at a landfill. However, if pollutants of concern adsorbed to sediments are later released in significant amounts into runoff because of changing chemical conditions, then

VOL 12 2 4434

R0057726

minimizing the amount and the residence time of sediments in the collection system may be an effective pollution prevention strategy.

and/or catch basin cleaning in reducing the concentrations of the pollutants of concern in the overflow discharges.

In designing a combined street and catch basin cleaning study, the following recommendations should be considered:

- Estimate the effectiveness of current street sweeping practices by selecting two similar areas, sweeping only one of these areas, and comparing the sediment loads leaving the two areas (USEPA, 1985).
- Monitor sediment levels in catch basins over time (keeping in mind the individual capacities of catch basins), and without sweeping, in order to determine the rate at which sediments accumulate in a particular area of the City.
- Coordinate flushing and sweeping to maximize sediment removal by sweeping just prior to flushing (Federal Water Quality Administration, 1971).

SUMMARY

In conclusion, the City recommends the following actions for the wet weather BMPs:

Implement

- P4-Rainfall/Runoff Protection
- R1-Spill Risk Prevention

Consider further study

- P6-Street Cleaning
- P2-Catch Basin Cleaning

Discontinue Consideration

- E1-Leak/Spill Impacts

MEMORANDUM

Pete Wilson
Governor

TO: Regional Water Board
Executive Officers

FROM: William R. Attwater
Chief Counsel
OFFICE OF CHIEF COUNSEL

DATE: NOV 18 1996

SUBJECT: WATER QUALITY LEGISLATION: NOTICES TO COMPLY

At the November 5, 1996 Management Coordinating Committee meeting, there was a short discussion of recently-enacted legislation dealing with the subject matter of minor water quality violations. This memorandum is intended to summarize the legislation.

Overview

Effective January 1, 1997, a new Chapter 5.8 (commencing with section 13399) is added to Division 7 of the Water Code. The purpose of this new law is to provide an expedited approach for dealing with minor violations of the Porter-Cologne Water Quality Control Act. Commonly referred to as the "fix-it ticket" legislation, the new law will require the use of field-issued notices to comply as the sole enforcement option in given situations.

Minor Violations

The notice to comply approach will be limited to minor violations. The term "minor violation" is not defined in the new law. Rather, the State Water Board is required to adopt regulations or state policy to determine the types of violations that are minor violations. In determining what are minor violations, the following factors are to be considered:

* The magnitude, scope, and severity of the violation.
* The degree of risk to human health or the environment.
* The impact of the violation on programs.
* The degree to which the violation hinders other enforcement actions.

Recycled Paper

VOL 12 2 4436

R0057728

VOL 12 SHEET 2

R0057729

The legislation also provides that a minor violation is not:

* Any knowing, willful, or intentional violation.
* A violation which gives an economic benefit or competitive advantage.
* A chronic violation or a violation committed by a recalcitrant violator.
* A violation that cannot be corrected in 30 days.

Notices to Comply

The vehicle for handling minor violations is the notice to comply (NOC). NOCs have certain elements:

* They must be in writing.
* They must state the nature of the alleged minor violation.
* They must state a means to comply.
* They must set a time limit in which to comply, not to exceed 30 days.

Issuance of NOCs

The process for issuing NOCs is as follows:

* NOCs are to be written during the course of an inspection by an authorized representative of the State or Regional Water Board.[1]
* NOCs are to be issued upon detection of a minor violation if the inspector finds that an NOC is warranted. In other words, the inspector has discretion not to issue an NOC.
* The NOC is presented to a representative of the facility being inspected.
* An NOC is not required if there is immediate correction.

---

[1] *As an exception, NOCs may be mailed to the violator if testing is required.*

VOL 12 2 4438

R0057730

* A single NOC is used to cite all minor violations detected during the same inspection.

* The NOC must inform the violator that the facility is subject to reinspection at any time.

Compliance with NOCs

* The violator is required to comply within the time specified for correction.

* The NOC must be signed and returned to the State or Regional Water Board within five working days of achieving compliance.

* The person receiving an NOC may appeal in writing to the State or Regional Water Board.

Other Provisions

* The law contains significant penalties for false statements of compliance.

* A minor violator may be required to submit documentation to support a claim of compliance.

* An NOC is the sole means by which an inspector may cite a minor violator.

* The State or Regional Water Board may take other enforcement actions upon a failure to comply or if necessary to prevent harm to public health or the environment.

* The new law does not limit criminal enforcement nor restrict the State or Regional Water Boards from cooperating in such proceedings.

* Civil penalties may still be assessed for minor violations if warranted or required by federal law.

* On or before January 1, 2000, the State Water Board is required to file a report to the Legislature regarding implementation of the law.

* The law sunsets on January 1, 2001, unless extended by statute.

VOL 12 2 4439

To conclude, the major points of this legislation are as follows:

* The breadth of the NOC approach will be determined by how broadly the term "minor violation" is defined.

* The State and Regional Water Board's enforcement discretion regarding minor violations will be limited.

* If an NOC is violated, there will be a good record for using more severe enforcement options.

A copy of the new legislation is attached. To ensure consistency, a model NOC form will be prepared by this office before the end of the year. If you have any questions, please call your attorney or Craig M. Wilson at 657-2403.

VOL 12

2

4440

(c) Any person discharging hazardous waste, as defined in Section 25117 of the Health and Safety Code, knowingly failing or refusing to furnish technical or monitoring program reports as required by subdivision (b) of Section 13267, or knowingly falsifying any information provided therein, is guilty of a misdemeanor and may be civilly liable in accordance with subdivision (d).

This subdivision shall not be applicable to any waste discharge which is subject to Chapter 5.5 (commencing with Section 13370).

(d) (1) Civil liability may be administratively imposed by a regional board in accordance with Article 2.5 (commencing with Section 13323) of Chapter 5 for a violation of subdivision (c) in an amount which shall not exceed five thousand dollars ($5,000) for each day in which the violation occurs.

(2) Civil liability may be imposed by the superior court in accordance with Article 5 (commencing with Section 13350) and Article 6 (commencing with Section 13360) of Chapter 5 for a violation of subdivision (c) in an amount which shall not exceed twenty-five thousand dollars ($25,000) for each day in which the violation occurs.

SEC. 4. Chapter 5.8 (commencing with Section 13399) is added to Division 7 of the Water Code, to read:

CHAPTER 5.8. MINOR VIOLATIONS

13399. (a) The Legislature hereby finds and declares that the purpose of this chapter is to establish an enforcement policy for violations of this division that the enforcement agency finds are minor when the danger they pose to, or the potential that they have for endangering, human health, safety, or welfare or the environment are taken into account.

(b) It is the intent of the Legislature in enacting this chapter to provide a more resource-efficient enforcement mechanism, faster compliance times, and the creation of a productive and cooperative working relationship between the state board, the regional boards, and the regulated community while maintaining protection of human health and safety and the environment.

(c) This chapter applies solely to the actions of the state board and the regional boards in administering this division and has no application to the administrative enforcement actions of other public agencies.

(d) The state board and each regional board shall implement this chapter by determining the types of violations of this division, or of the regulations, rules, standards, orders, permit conditions, or other requirements adopted pursuant to this division that the state board or the regional board finds are minor violations in accordance with subdivisions (e) and (f). The state board shall implement this chapter through adoption of regulations or state policy for water quality

VOL 12 2 4441

R0057734

control pursuant to Article 3 (commencing with Section 13140) of Chapter 3.

(e) In determining the types of violations that are minor violations, the state board or regional board shall consider all of the following factors:

(1) The magnitude of the violation.

(2) The scope of the violation.

(3) The severity of the violation.

(4) The degree to which a violation puts human health, safety, or welfare or the environment into jeopardy.

(5) The degree to which a violation could contribute to the failure to accomplish an important goal or program objective as established by this division.

(6) The degree to which a violation may make it difficult to determine if the violator is in compliance with other requirements of this division.

(f) For purposes of this chapter, a minor violation of this division shall not include any of the following:

(1) Any knowing, willful, or intentional violation of this division.

(2) Any violation of this division that enables the violator to benefit economically from noncompliance, either by realizing reduced costs or by gaining a competitive advantage.

(3) Any violation that is a chronic violation or that is committed by a recalcitrant violator.

(g) In determining whether a violation is chronic or a violator is recalcitrant, for purposes of paragraph (3) of subdivision (f), the state board or regional board shall consider whether there is evidence indicating that the violator has engaged in a pattern of neglect or disregard with respect to the requirements of this division or the requirements adopted pursuant to this division.

13399.1. For purposes of this chapter, "notice to comply" means a written method of alleging a minor violation that is in compliance with all of the following requirements:

(a) The notice to comply is written in the course of conducting an inspection by an authorized representative of the state board or regional board. If testing is required by the state board or regional board to determine compliance, and the testing cannot be conducted during the course of the inspection, the representative of the state board or regional board shall have a reasonable period of time to conduct the required testing. If, after the test results are available, the representative of the state board or regional board determines that the issuance of a notice to comply is warranted, the representative shall immediately notify the facility owner or operator in writing.

(b) A copy of the notice to comply is presented to a person who is an owner, operator, employee, or representative of the facility being inspected at the time that the notice to comply is written. If offsite testing is required pursuant to subdivision (a), a copy of the

VOL 12 2 4442

R0057735

notice to comply may be mailed to the owner or operator of the facility.

(c) The notice to comply clearly states the nature of the alleged minor violation, a means by which compliance with the requirement cited by the representative of the state board or regional board may be achieved, and a time limit in which to comply, which shall not exceed 30 days.

(d) The notice to comply shall contain the information specified in subdivision (h) of Section 13399.2 with regard to the possible reinspection of the facility.

13399.2. (a) An authorized representative of the state board or regional board, who, in the course of conducting an inspection, detects a minor violation shall issue a notice to comply before leaving the site at which the minor violation is alleged to have occurred if the authorized representative finds that a notice to comply is warranted.

(b) A person who receives a notice to comply pursuant to subdivision (a) shall have the period specified in the notice to comply from the date of receipt of the notice to comply in which to achieve compliance with the requirement cited on the notice to comply. Within five working days of achieving compliance, the person who received the notice to comply shall sign the notice to comply, and return it to the representative of the state board or regional board, stating that the person has complied with the notice to comply. A false statement that compliance has been achieved is a violation of this division pursuant to subdivision (a) of Section 13268, Section 13385, or subdivision (e) of Section 13387.

(c) A single notice to comply shall be issued for all minor violations cited during the same inspection and the notice to comply shall separately list each cited minor violation and the manner in which each minor violation may be brought into compliance.

(d) A notice to comply shall not be issued for any minor violation that is corrected immediately in the presence of the inspector. Immediate compliance in that manner may be noted in the inspection report, but the person shall not be subject to any further action by the representative of the state board or regional board.

(e) Except as otherwise provided in subdivision (g), a notice to comply shall be the only means by which the representative of the state board or regional board shall cite a minor violation. The representative of the state board or regional board shall not take any other enforcement action specified in this division against a person who has received a notice to comply if the person is in compliance with this section.

(f) If a person who receives a notice to comply pursuant to subdivision (a) disagrees with one or more of the alleged violations cited in the notice to comply, the person shall give written notice of appeal to the state board or regional board.

VOL 12 2 4443

R0057736

(g) Notwithstanding any other provision of this section, if a person fails to comply with a notice to comply within the prescribed period, or if the state board or regional board determines that the circumstances surrounding a particular minor violation are such that immediate enforcement is warranted to prevent harm to the public health or safety or to the environment, the state board or regional board may take any needed enforcement action authorized by this division.

(h) A notice to comply issued to a person pursuant to this section shall contain a statement that the inspected facility may be subject to reinspection at any time. Nothing in this section shall be construed as preventing the reinspection of a facility to ensure compliance or to ensure that minor violations cited in a notice to comply have been corrected.

(i) Nothing in this section shall be construed as preventing the state board or regional board, on a case-by-case basis, from requiring a person subject to a notice to comply to submit reasonable and necessary documentation to support a claim of compliance by the person.

(j) Nothing in this section restricts the power of a city attorney, district attorney, county counsel, or the Attorney General to bring, in the name of the people of California, any criminal proceeding otherwise authorized by law. Furthermore, nothing in this section prevents the state board or regional board, or a representative of the state board or regional board, from cooperating with, or participating in, such a proceeding.

(k) Notwithstanding any other provision of this section, if the state board or regional board determines that the circumstances surrounding a particular minor violation are such that the assessment of a civil penalty pursuant to this division is warranted or required by federal law, in addition to issuance of a notice to comply, the state board or regional board shall assess a civil penalty in accordance with this division, if the state board or regional board makes written findings that set forth the basis for the determination of the state board or regional board.

13399.3. (a) On or before January 1, 2000, the state board shall report to the Legislature on actions taken by the state board and the regional boards to implement this chapter and the results of that implementation. Each regional board shall provide the state board with the information that the state board requests to determine the degree to which the purposes described in subdivision (a) of Section 13399 have been achieved.

(b) This chapter shall remain in effect only until January 1, 2001, and as of that date is repealed, unless a later enacted on or statute, which is enacted on or before January 1, 2001, deletes or extends that date.

Title: Thermal Impacts Associated with Urbanization and Stormwater Management Best Management Practices

Date: December, 1990

Author: John Galli, Anacostia Restoration Team
Department of Environmental Programs
Metropolitan Washington Council of Governments

Agency: The Metropolitan Washington Council of Governments is the regional organization of the Washington, D.C. area's major local governments and their governing officials. COG works towards solutions to such regional problems as energy shortages, traffic congestion, inadequate housing, air and water pollution. COG is also the areawide wastewater management agency for the Washington area and is involved with regional policy issues related to provision of adequate wastewater treatment, sludge disposal, nonpoint source pollution control, and municipal water supplies.

Report Abstract:

Study evaluates thermal and dissolved oxygen (DO) impacts to aquatic life associated with urbanization and various representative stormwater management Best Management Practices (BMP's). Continuous water temperature monitoring and grab sampling was performed at six headwater urban streams and four stormwater BMP sites in the Piedmont portion of Maryland's Anacostia River basin. The streams studied spanned the entire watershed imperviousness spectrum and featured undeveloped, as well as, 60 percent impervious sites. The four representative BMP's monitored included: an infiltration facility, artificial wetland, extended detention dry pond, and a wet pond. In addition, a comprehensive literature review was performed to evaluate potential temperature and DO impacts at major levels of the aquatic food chain. Thermal requirement data for 63 species of fish known or expected to occur in Maryland freshwater streams is included among the biological information presented.

Acknowledgements

The author would like to extend his gratitude to a number of individuals whose support, cooperation and patience were instrumental to the completion of the study. In particular the patient assistance of Mr. Brian Clevenger (MDE Project Manager), and Ms. Molly Cannon and Mr. Vince Berg was greatly appreciated. The author would also like to extend his gratitude to Mr. Earl Shaver (formerly of MDE) for helping to make this temperature study possible. In addition, the author is indebted to Ms. Whitney Brown (COG) for her assistance in water temperature data anslysis. Special thanks are also extended to Mr. Robert Dubose for his field sampling and literature review assistance, and Mr. Stan Rosen (NOAA volunteer) for providing invaluable climatological data. Also, I would like to thank Mr. Thomas Schueler (COG) for his valuable insight and constructive suggestions. Others who deserve credit for their assistance were: Mr. Charles Gougeon (Md DNR), Mr. Greg Golden (Md DNR), Mr. Mark Staley (Md DNR), Mr. Ken Yetman (Md DNR), Mr. Mark Kashima (MDE), Ms. Natalie Karouna, Mr. Stephen Kunselman, and Mr. James Watkins (COG), Mr. Nazir Baig (M-NCPPC) and Ms. Candy Bunnag (M-NCPPC). Finally, the author wishes to extend his thanks to Ms. Claudia Thomas (COG) and Mr. Mark Pfoutz (COG) for their tremendous assistance in the preparation of the report.

R0057749

Executive Summary

A two-part study was undertaken in 1989 to evaluate the thermal and dissolved oxygen (DO) impacts to aquatic life associated with urbanization and various representative stormwater management Best Management Practices (BMP's). Part one of the study involved both continuous water temperature monitoring and water quality grab sampling at six headwater streams and four stormwater management BMP sites located in the Piedmont portion of the Anacostia River basin. The urban streams studied spanned the entire watershed imperviousness spectrum, and featured undeveloped, as well as, 60 percent impervious sites. The four representative BMP's monitored in the study included: an infiltration facility, artificial wetland, extended detention dry pond, and a wet pond.

Fourteen paired thermograph thermometers were employed to characterize both BMP inflow-outflow temperature relationships, as well as, spatial variations along streams. In addition, a 55 station grab sampling network was established for the purpose of monitoring DO, streamflow and temperature conditions at discrete longitudinal intervals in and along the streams in the study area.

In the second part of the study a comprehensive literature review was performed to evaluate potential temperature and DO impacts at major levels of the aquatic food chain. Major findings of the study are described in the following five sections.

I. Effect of Meteorological and Watershed Land Use Conditions On Free-Flowing Stream Temperatures

Results from the study indicated that the temperature regime of small, free-flowing headwater Piedmont streams is largely determined by the following interrelated factors:

1. Air Temperature and Other Local Meteorological Conditions.

   - Local air temperature had approximately 90 - 95 percent of the time, a greater influence on stream temperature than did stormflow. Notably, the potential for major stream temperature increases grew dramatically when air temperatures remained at or above 80°F for long periods of time. In general, the critical thermal loading season for the streams studied was late May to late September.

   - The amount and intensity of precipitation was an important, though somewhat smaller factor. During the study, small storms which produced little or no runoff generally had little effect on receiving stream temperatures. Sharp, rapid increases in stream temperature were not observed under steady, light precipitation conditions. They were, however, closely associated with warm air conditions which included heavy shower activity.

VOL 12 2 4457

R0057750

2. Watershed Imperviousness.

- Imperviousness together with local meteorological conditions had the largest influence on urban stream temperatures. In general, the average water temperature of the urban streams increased in a linear fashion with increasing levels of watershed imperviousness. Results indicated that the average rate of increase was 0.14°F per one percent increase in imperviousness.

- Stream temperatures at the undeveloped watershed responded to storm events by becoming slightly cooler. This was largely due to the drop in air temperatures which accompanied most rainfall events. While this was also generally true of urban streams, as the level of watershed imperviousness increased the streams became progressively more responsive to inputs of stormwater runoff. With increasing imperviousness, the storm-size needed to produce large, stream temperature fluctuations decreased. At a 12 percent watershed imperviousness level over 0.7 inches of rainfall was generally required. In contrast, at a 60 percent imperviousness level, less than 0.2 inches of precipitation was needed to produce a comparable temperature change. It should be noted that stormwater inflow generally produced positive stream Delta-T's. In addition, the potential thermal impact of stormwater runoff on receiving streams increased as the runoff (Q_{in}) to receiving stream flow (Q_r) ratio increased.

- Even at the relatively low 12 percent watershed imperviousness level, neither MDE Class III (68.0°F) or IV (75.0°F) temperature standards could be met 100 percent of the time. Both the frequency and magnitude of temperature standards violations increased with increasing levels of watershed imperviousness.

3. Riparian Canopy Coverage.

- Riparian vegetation plays a key role in insulating small streams from the warming effect of solar radiation. Other studies have shown that the removal of riparian vegetation can raise the summer water temperature of small streams by 11 - 20°F, and can lower winter water temperatures by 5 - 7°F. Results from this study revealed an average positive stream Delta-T of 1.5°F per 100 feet of flow through either open or poorly-shaded reaches.

4. Stream Order/Size.

- It is well known that stream temperature naturally increases in a downstream direction with increasing stream order/distance from the source. In urban watersheds a variety of anthropogenic factors, such as the removal of riparian vegetation, micro-climate changes, and reduction of groundwater inflow, add to the so-called "watershed Delta-T" effect. Monitoring results indicated that the watershed Delta-T effect for a 18 percent

NOV 21 2 4959

impervious, urban third order stream system, is on the order of 1 - 2°F per stream mile. In addition, smaller lower-order urban streams are more responsive to this background watershed effect.

II. Effect of Urban Stormwater Management BMP's On Water Temperature

One of the more revealing findings was that none of the four BMP's monitored where thermally neutral. All four BMP types had positive average total Delta-T's and each violated MDE Class III and IV temperature standards some of the time. Temperature standards violations occurred under both baseflow and stormflow conditions. Wet permanent pools, long periods of extended detention, and poorly shaded pilot and outflow channels contributed greatly to the problem. Specific findings for each BMP type are described below and are additionally summarized in Table 1.

1. Infiltration - Dry pond

- Of the four BMP's, this hybrid facility (which had average and maximum BMP Delta-T's of 2.5 and 7.6°F) produced the smallest Delta-T increases. The infiltration trench portion of the BMP, designed for 0.25 inches of street runoff, worked well during small storms. However, large storm events (i.e., $\geq$ 1.0 inches precipitation) and/or 2 - 3 consecutive days of moderate rainfall generally overtaxed the capacity of the infiltration trench system. This often resulted in the ponding of several feet of runoff in the dry pond area. The facility's defacto extended detention control combined with high incoming solar radiation on the unshaded rip-rap pilot channel, storage pool, and outfall area, produced a 4.0°F Delta-T increase.

- From a water temperature standards perspective, this BMP had the lowest frequency of Class III (68.0°F) and IV (75.0°F) violations. Standards violations were more frequently associated with stormflow conditions. Under stormflow conditions, Class III and IV temperature standards were exceeded 18 and 0 percent of the time, respectively. The BMP's single Class IV violation was a product of a large storm and 53 hours of extended detention.

2. Extended Detention Artificial Wetland

- The average and maximum BMP Delta-T's associated with the wetland were 3.2 and 8.7°F, respectively. Delta-T stormflow temperatures at the wetland were typically lower than baseflow Delta-T temperatures. However, approximately two-thirds of the time the difference between baseflow and stormflow Delta-T's was relatively small (i.e., $\leq$ 3.0°F).

- The shallow depth (mean depth is approximately 18 inches) and small permanent pool volume, relative to the 140 acre contributory watershed, made the wetland and its outflow station

VOL 12 2 4460

R0057753

very responsive to air temperature fluctuations. The wetland's small permanent pool did, however, give it a limited ability to moderate outflow temperatures during certain small storm events. In addition, because the wetland's extended detention capability was extremely limited, it had little influence on outflow station temperature behavior.

- Under baseflow conditions, wetland outflow station temperatures exceeded Class III and IV temperature standards 60 and 15 percent of the time, respectively. In contrast, the same standards were violated approximately 57 and 5 percent of the time, respectively under stormflow conditions. Outflow stations were higher than inflow station temperatures 95 percent of the time.

3. Extended Detention Dry Pond

- The average and maximum BMP Delta-T's associated with the ED dry pond were 5.3 and 11.2°F, respectively. The maximum Delta-T produced by this BMP was slightly higher under stormflow conditions (11.2°F) than under baseflow conditions (9.7°F). The higher stormflow Delta-T's were the product of : a) the influx of relatively warm stormwater runoff into the facility, b) the partially shaded pilot channel's heat contribution, and c) additional heating of detained waters via solar radiation. In addition, the highest Delta-T's were noted during hot weather. This BMP's 500 foot long pilot channel produced an average positive stream Delta-T of 3.7°F.

- Under stormflow conditions, the ED dry pond violated Class III and IV temperature standards 48 and 15 percent of the time, respectively.

4. Wet Pond

- The wet pond's large permanent pool served as an effective heat regulator. In general, the pond had a major warming effect on baseflow temperature. However, during most storm events, both pond and outflow station temperatures were depressed. The relatively large permanent pool volume resulted in the pond slowly storing and releasing solar radiation/heat; thus making it slow to respond to air temperature fluctuations. Average summer pond surface water temperatures remained generally over 77°F. Pond waters were noticeably slow to cool-down in late summer/early fall.

- Of the four BMP's, the wet pond had the highest recorded maximum Delta-T (15.1°F). Delta-T baseflow temperatures at the wet pond were higher than stormflow Delta-T's 99 percent of the time. The average baseflow Delta-T (9.7°F) was slightly higher than the average stormflow Delta-T (8.5°F). The pond's rip-rap outflow channel produced an average positive Delta-T increase of 2.0°F.

VOL 12 2 4461

R0057754

- From a water temperature standards perspective, this BMP had the highest frequency of Class III and IV temperature standards violations. Under baseflow conditions, Class III and IV standards were exceeded 77 and 35 percent of the time. In contrast, under stormflow conditions the same standards were violated 64 and 25 percent of the time, respectively.

5. Dissolved Oxygen

Results from the dissolved oxygen monitoring portion of the study revealed the following:

- Baseflow DO levels generally do not appear to be a problem in urban streams; even in those draining highly impervious watersheds
- Some oxygen depletion was noted within the artificial wetland, as well as downstream of both it and the wet pond. However, no anoxia was evident.
- DO levels recovered within relatively short distances of the wet BMP's; generally, within 200 - 500 feet.
- No discernible DO sag was observed during stormflow conditions.

III. Biological Implications

In an effort to identify the potential biological impacts associated with temperature regime modification, COG staff conducted a comprehensive two-part literature survey of the water temperature requirements of freshwater biota known or expected to occur in Maryland streams. Part one examined both the principal environmental factors and various human activities which influence the thermal regime of streams. Part two investigated the general thermal requirements of stream biota as well as the potential biological affects associated with thermal regime modification. Potential biological consequences occurring at all general levels of the aquatic food chain were reached. Over 200 references were collected. Special emphasis was placed on identifying the temperature requirements of Maryland freshwater fish. In addition, because of the general controversy surrounding watershed urbanization and trout streams, a separate subsection on trout was included.

Literature review information together with results from the water temperature monitoring portion of the study were subsequently synthesized. Major findings are presented starting at the bottom of the food chain with algae, and progressing sequentially to fish. In addition, to facilitate reader understanding results have been graphically summarized in Figure 1.

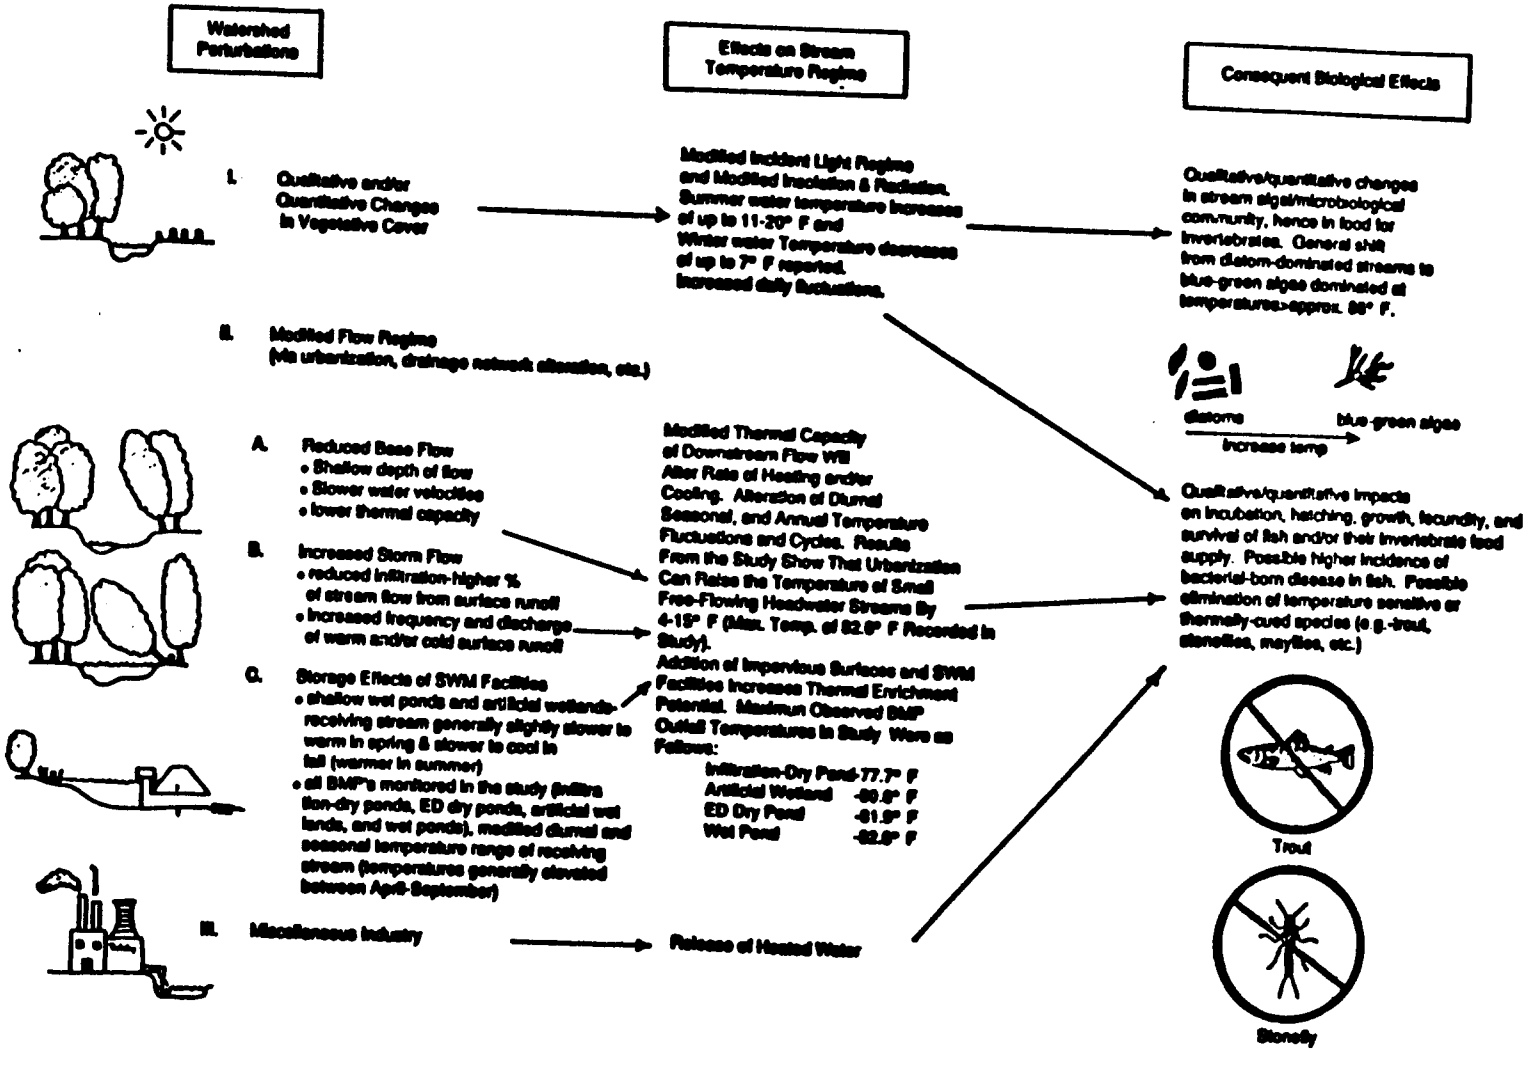
1. Algae.

- Water temperature monitoring results suggest that subtle shifts in the periphyton (attached algae) community species composition would have been expected to have occurred in some of the urban

VOL 12 2 4462
R0057755

Figure 1

Summary: General Impacts of Human Activities on Stream Temperature and Biota



R0057756

streams studied. At all developed watershed and BMP sites, diatoms would have continued to remain the dominant overall algal group. However, certain coldwater and/or light sensitive species may have either declined in numbers and/or been replaced by other, more temperature or light-tolerant species. The scenario would have occurred most likely in stream reaches where considerable thermal enrichment and/or removal of riparian vegetation took place (e.g., wet pond outflow, ED wetland outflow, highly developed urban stream site, and ED dry pond outflow station). In addition, it is probable that green and blue-green algal species would have been represented in greater numbers in the warmer, open-lit sections of these streams.

- While some temperature-related shifts in algal community species composition undoubtedly occurred, it is unlikely that they would have in themselves had a major effect on either the resident macroinvertebrate or fish communities of these urban streams.

2. Macroinvertebrates - Aquatic Insects.

- Results indicate that the thermal enrichment effects produced either through urbanization and/or associated BMP's, would severely effect coldwater aquatic insects. It is most likely that sensitive groups, such as stoneflies, would either be eliminated or severely restricted (for much of the year) at temperature levels comparable to those observed at the moderately and highly developed watershed sites and at the wet pond, ED wetland, and ED dry pond outflow stations. While collectively more temperature tolerant, many mayfly and caddisfly species would similarly be eliminated, severely restricted and/or stressed at the preceding temperature levels.

- Restructuring of the macroinvertebrate community would also occur, with intolerant species and/or groups of insects being replaced by thermally-tolerant ones. It would be expected that tolerant groups such as Diptera (flies & midges) would gain greater dominance in these stream systems. In addition, non-insect species would probably become more abundant. The preceding changes could, if particularly extensive, have a negative impact on the resident fish community.

3. Fish

- Results show that the vast majority of resident fish species would not be affected by the temperature increases produced either through urbanization and/or construction of BMP's. However, coldwater species such as trout would not be expected to survive at temperature levels observed at either the moderately or highly developed watershed sites or at any of the four BMP outfall locations. While generally regarded as being slightly more temperature tolerant than trout, sculpins would only be expected to survive at temperature levels observed at either the lightly developed watershed sites, or below the infiltration -

VOL 12 2 4464

R0057757

dry pond. The findings from this study underscore the point that moderate levels of watershed imperviousness and/or the improper introduction of associated BMP's, can have a devastating impact on sensitive coldwater streams and the fish communities which they support.

- All trout species are extremely sensitive to thermal pollution/stress. Sustained elevated water temperatures over 70° F are generally considered to be stressful, while those at or above 77°F are usually lethal. Water temperature monitoring results from the 12 percent impervious Gum Springs tributary indicate that baseflow water temperatures remain safely below levels considered to be stressful to trout. However, under stormflow conditions water temperature exceeds 70°F. The frequency and magnitude of these stress-producing episodes were more severe in Lower Gum Springs, where the temperature regime is negatively affected by the stormwater discharge from the Oak Springs ED wetland. Results further indicate that the thermal regime of Lower Gum Springs may, under stormflow conditions, be approaching the trout supporting temperature threshold for young-of-year and juvenile trout.

IV. Land Use Control Program Implications

Through the process of urbanization, vegetation is removed from watersheds, formerly pervious surfaces are converted to hard, impermeable ones such as rooftops, streets and parking lots, and natural drainage networks are modified to convey runoff more efficiently. These processes act together to alter the thermal regime of urban, headwater streams.

Among the more enlightening results of the study, was the finding that the level of watershed development had the single, greatest anthropogenic influence on the temperature regime of urban, headwater streams. This, as well as other land use control program implications, are briefly described below.

1. Watershed Imperviousness Factor

For urban headwater streams, the level of watershed imperviousness largely determines the magnitude of change from the pre-development thermal regime. As previously noted, results from this study show that mean, summer stream temperatures increase linearly with increasing watershed imperviousness. Importantly, watershed imperviousness has a negative influence on stream temperatures under both baseflow and stormflow conditions.

As seen in Table 2, the frequency of MDE temperature standards violations generally increases with increasing levels of imperviousness. This phenomenon occurs regardless of whether watershed stormwater management controls are present or absent. Reduction of groundwater flows, the urban heat island effect, removal of riparian vegetation, and drainage network alteration are primary causes of the problem.

2. Conflicting Stream Protection and Watershed Development Goals

VOL 12 2 4465

R0057758

Table 2. Summary: MDE Water Temperature Standards Violations Versus Watershed Imperviousness

Watershed Development Level	Percent Imperviousness (%)	Percent of Time MDE Temperature Std. Violated (%)			
		Class III (68°F)		Class IV (75°F)	
		Baseflow	Stormflow	Baseflow	Stormflow
Light	12.0	10	5	0	1
Moderate	30.0	25	1	25	1
High	60.0	67	57	12	10

VOL 12 2 4466

R0057759

All too often the goal of stream protection conflicts with land use development. Many of the environmental problems caused by urbanization, stream warming for one, cannot be completely mitigated by engineering means. Thus, far greater emphasis on land use control measures is required in sensitive streams.

Results from this study show that stream temperature regime changes occur at relatively low levels of watershed imperviousness (i.e., $\leq$ 12 percent). They also strongly suggest that trout and other coldwater biota will most likely be lost when watershed imperviousness exceeds 12 - 15 percent.

3. Thermal Regime Protection Strategy

It is clear that the long-term protection of thermally sensitive streams requires a holistic watershed management approach which includes, at a minimum, the following water temperature protection elements:

- Land use controls (which govern type, density and location of development within a watershed);
- Riparian/stream buffer requirements;
- Employment of temperature sensitive BMP's and stormwater conveyance systems.
- Long-term water temperature and biological monitoring at strategic stream locations within the watershed; and
- Routine long-term maintenance of BMP's and other associated infrastructure.

Not surprisingly, extraordinary land use, riparian management and stormwater management controls are needed to properly protect the resident aquatic life of MDE Class III streams. The same watershed protection approach is also generally needed, on a case-by-case basis for thermally sensitive Class I and IV stream areas. This stream protection strategy requires that many difficult, and potentially costly, land use decisions be made.

V. Implications for Stormwater Management Programs

Aquatic community species composition and activity in freshwater stream systems is largely regulated by water temperature. In urban streams, the composition and structure of the aquatic community is generally affected by thermal regime modification, as well as, by flow regime, water quality and physical/structural habitat changes.

The results of the water temperature monitoring study have several major implications with regard to current stormwater management practice selecion, design and policy. These implications are outlined below.

1. Stormwater Management Practice Selection

VOL 12 2 4467

R0057760

The four BMP's tested were, in ranked order of both Delta-T and outflow temperatures standards performance: 1.) infiltration-dry pond, 2.) artificial wetland, 3.) extended detention dry pond, and 4.) wet pond. By a wide margin the infiltration facility outperformed all other BMP types. The preceding findings strongly support the current MDE stormwater management practice prioritization policy. Clearly, infiltration generally remains the best BMP choice in thermally sensitive watershed areas. At low levels of watershed imperviousness, improper BMP selection can have a major negative effect on the water temperature regime of small, headwater Piedmont streams. This is particularly the case in coldwater stream systems, where the selection of conventional wet and/or extended detention BMP's could conceivably eliminate temperature sensitive species such as trout.

However, results from the study also show that at moderate levels of watershed imperviousness the potentially negative influence of BMP's on the receiving stream's temperature regimes is reduced. This is due to the fact that the temperature regimes of these streams have been (or will be modified by the background level of urbanization. Consequently, temperature sensitive biota will, even in the absence of BMP's, most likely be reduced and/or eliminated from these streams. At high levels of watershed imperviousness, the general impact of BMP's on the receiving stream temperature regime is minimal. In these streams, the need for providing high levels of water quality and stream channel erosion control may outweigh temperature concerns. In MDE Class III watershed areas, both extraordinary land use and stormwater management controls are necessary to protect resident stream biota. A similar watershed protection strategy is also generally needed, on a case-by-case basis, for thermally sensitive Class I and IV stream areas. It is also understood that the absence of water temperature and biologicl data, together with the lack of rapid assessment guidelines often makes the BMP selection process difficult in these areas.

2. BMP Design Feature Considerations

- The thermal performance of the infiltration - dry pond could have been improved had its infiltration design treatment capacity been sized to handle more than 0.25 inches of runoff from roadway areas. Although infiltration systems which are to be located in thermally sensitive watersheds should, as a general rule, be intentionally over-sized there is a finite storm-size which can be treated in this manner. Because of the high probability of large storms and/or several consecutive days of precipitation overtaxing infiltration system design capacity, it is extremely unlikely that 100 percent compliance with MDE Class III standars can be achieved in the field.

- Results from the study revealed that unshaded (and/or poorly shaded) pilot and rip-rap outflow channels produced maximum positive Delta-T's of 8.5°F. Shading of these structures via landscaping, or other means, would have improved the overall performance of every BMP type tested in the study. In addition,

VOL 12 2 4468

R0057761

results further indicated that the practice of employing long, wide rip-rap outflow channels should be seriously re-examined. Whenever possible, outflow channels should be heavily shaded. They should also include a deep, narrow baseflow channel to quickly return this water back to the natural stream channel.

- One of the more revealing findings was that long periods of extended detention control can produce BMP Delta-T increases on the order of 4 - 12.0°F. For this reason, the use of extended detention BMP's in thermally sensitive areas should be carefully evaluated. It is further recommended that a 6 - 12 hour detention period limit be established for these areas and that shading of the storage pool area be required.

3. Ability of Current MDE Class I Temperature standards to Protect Aquatic Life

- Results from the literature review portion of the study indicate that the 90°F MDE Class I discharge temperature standard is inadequate to protect a large portion of the biota normally present in headwater Piedmont streams. At the 90°F level, wholesale changes at all levels of the aquatic food chain would be expected to occur. Therefore, it is strongly recommended that new criteria be developed to better protect the aquatic life of Class I streams.

4. Future Research Needs

- The current water temperature class designations are not a reliable guide to the existing or future thermal regime status of headwater Piedmont streams. This is particularly the case for urban streams. Consequently, there is a strong need to develop holistic guidelines and stream assessment procedures for defining appropriate stormwater management options within any Maryland watershed area.

- Water temperature monitoring of parallel pipe and baseflow diversion systems, multiple-port release wet ponds, sand filters, and other promising thermally sensitive conveyance/stormwater management practices is urgently needed.

Introduction

The growing concern over the potential thermal impacts to Maryland's freshwater streams, from both urban stormwater runoff and the various Best Management Practices (BMP's) employed for its control, led the Maryland Sediment and Stormwater Administration to contract the Metropolitan Washington Council of Governments to perform a comprehensive evaluation. As a result, a two-part study was undertaken in 1989 to evaluate the thermal and dissolved oxygen (DO) impacts to aquatic life associated with both urbanization and representative stormwater management BMP's.

Part one of the study involved both continuous water temperature monitoring and water quality grab sampling at six headwater streams and four stormwater management BMP sites located in the Piedmont portion of the Anacostia River basin. The urban streams studied spanned the entire watershed imperviousness spectrum, and featured undeveloped, as well as, 60 percent impervious sites. The four representative BMP's monitored in the study included: an infiltration facility, artificial wetland, extended detention dry pond, and a wet pond. In the second part of the study a comprehensive literature review was performed to evaluate potential temperature and DO impacts at major levels of the aquatic food chain.

For organizational purposes this report has been divided into four main chapters. Chapter one describes study, design, and methodology. The second chapter examines the general thermal effects associated with watershed urbanization, removal of riparian vegetation, increase in stream order/stream size and stormwater management BMP's. In addition to providing detailed information on the thermal characteristics and performance of each

VOL 12 2 4471

R0057764

of the four BMP's, the chapter provides supplemental information on: thermal loading as a function of flow ratio, stormwater management features which increase water temperature, and results from the dissolved oxygen grab sampling monitoring. In the third chapter, both water temperature monitoring results and literature review findings are synthesized in a comprehensive evaluation of potential biological impacts. The fourth and final chapter, discusses the implications of the study's findings on both stormwater management and land use control programs.

VOL 12 2 4472

R0057765

Chapter I. Study Design and Methodology

The study was designed to evaluate potential thermal and dissolved oxygen (DO) impacts associated with representative stormwater management BMP's currently in use throughout the state (i.e., wet ponds, artificial wetlands, extended detention dry ponds, and infiltration). In addition, the general effects of both the level of watershed urbanization and riparian management practices on stream temperature were investigated, together with potential biological implications.

In order to meet the preceding objectives, a study design featuring three major elements, or tasks, was developed. Under the first task, a continuous water temperature monitoring network was created to provide necessary baseline data. Second, a water quality grab sampling network was established to provide baseline dissolved oxygen, stream flow, and air/water temperature data. Last, a comprehensive literature search was performed to identify water temperature requirements of freshwater biota, at all general levels of the food chain, and relate them to water temperature monitoring results.

The following sections describe in greater detail the study design, sampling techniques, and calculations employed in the study.

VOL 12 2 4473

R0057766

Development of a Comprehensive Field Monitoring Network

A. Site Selection

Metropolitan Washington Council of Governments staff (COG) in consultation with MDE, MdDNR, and local agency staff identified the following six representative study categories for monitoring:

1. Wet pond;

2. Artificial wetland;

3. Extended detention dry pond;

4. An innovative stormwater management facility which incorporates temperature mitigation features;

5. An urban stream draining a small, highly impervious and uncontrolled watershed; and

6. A reference stream draining a small undeveloped watershed.

An inventory of possible candidate sites for each of the preceding six categories was conducted within the Maryland portion of the Anacostia River basin. Each candidate site was carefully screened and ranked according to the following criteria: MDE water use class designation, drainage area,

VOL 12 2 4474

R0057767

watershed land uses, stream discharge, stormwater and stormdrain conveyance system, and representativeness and access. After consultation with MDE, COG staff selected a total of six sites from the inventory for subsequent continuous water temperature monitoring and water quality grab sampling. Study area locations are shown in Figure 2, and the general characteristics of each site are summarized in Table 3. Additional information on each BMP site can be found in Appendix A. A brief description of each study site is provided as follows:

1. Lakemont tributary. This reference Piedmont stream is located in the headwaters of Northwest Branch, an MDE Class IV recreational trout stream area. The Lakemont tributary drains an undeveloped watershed area of approximately 400 acres. During the late 1970's much of the subwatershed was used as a sludge trenching area. However, since 1978 the disturbed portions of the watershed have remained fallow. Forest and old abandoned fields are now the predominant land uses in the study area. The Lakemont tributary, which is approximately 8-9 feet wide is heavily shaded by the mixed-age hardwood forest through which it flows. Average stream baseflow during the study period was 0.9 cfs.

2. Oaksprings/Gum Springs tributaries. The Oaksprings tributary is a small feeder branch of the Gum Springs tributary. Both streams are designated by MDE as Class III natural trout waters. The Oaksprings tributary, which flows through a mixed-age hardwood forest, drains a developed 140 acre watershed. Principal land uses in the catchment include 0.25-0.5 acre lot single family residential development and

R0057770

townhouses. In addition, two SWM facilities, which are separated by a distance of approximately 1800 ft., are located on the stream. The upper Oaksprings pond is an old farm pond that has a surface area of approximately 0.5 acres. The lower Oaksprings pond which was monitored in the study, is a 1.0 acre artificial wetland with extended detention control. A notched wooden weir - flashboard system provides approximately 1.0 acre-foot of extended detention storage. The Oaksprings wetland, which was constructed in 1986, supports a diverse wetland plant community and includes numerous emergent and submerged species. This wetland is located approximately 500 feet upstream of the confluence with the Gum Springs tributary. The Oaksprings tributary enters Gum Springs approximately 1900 feet upstream from the Gum Springs/Paint Branch confluence.

Gum Springs, which drains a 620 acre watershed area, is well-known for its ability to support a natural self-sustaining brown trout population. Principal land uses in this subwatershed include 0.25 - 0.5 acre lot single family residential development, townhouses, old abandoned fields, and mixed-age hardwood forest. Overall watershed imperviousness is approximately 12.0 percent. The stream, which has an average baseflow of approximately 1.0 cfs, is well-shaded along its entire length.

VOL 12 2 4478

R0057771

3. **Countryside Wet Pond.** The Countryside wet pond drains a 165 acre MDE Class III watershed area consisting of large residential estates, 0.25 - 0.5 acre single family residential development, mixed-age hardwood forest, and a small commercial shopping area. Watershed imperviousness is approximately 12.0 percent. The pond, which has a surface area of approximately 1.5 acres, underwent a major retrofit in 1988. Retrofit work included the replacement of the original rusted-out metal riser and barrel with a concrete structure, dredging, and establishment of fringe marsh habitat. It should be noted that pond waters are released approximately 2.5 feet below the normal pool elevation via a reverse sloping 8 inch diameter pipe. Baseflow to the pond is approximately 0.25 cfs. The Countryside tributary is well-shaded both upstream and downstream of the pond. Waters discharged from the pond flow through approximately 1200 feet of mixed-age hardwood forest before entering Paint Branch.

4. **Tanglewood Extended Detention Dry Pond.** Constructed in 1983, the Tanglewood SWM facility is a 3.0 acre, extended detention dry pond serving a 195 acre MDE Class I watershed area. Principal land uses in the catchment include townhouses, 0.25 - 0.5 acre single family residential development, office park development, pasture/old fields, and mature hardwood forest. Watershed imperviousness is approximately 30 percent. The Tanglewood tributary is well-shaded both upstream and downstream of the SWM facility. The stream, which has an average baseflow of approximately 0.26 cfs, is a tributary of the Little Paint Branch.

VOL 12 2 4479

R0057772

5. Fairland Ridge Stormwater Management Facility. This innovative dry SWM facility, which became operational in 1987, provides both water quantity and quality control for a 25 acre, MDE Class III watershed area. Water quality control for the existing 0.25 - 0.5 acre lot residential development is provided through a series of stilling basins, grass swales, and infiltration trenches located in the terraced side slopes of the pond. The three infiltration trenches present in the pond were sized to treat the first 0.25 inches of runoff from the street portion of the development.

During the course of the study it became obvious that one of the three infiltration areas present was incapable of infiltrating any runoff. In fact, this bowl-shaped infiltration area was observed to pond water for months at a time. A second observation made during the study was that the pond provides, via its 8 inch diameter low-flow orifice, defacto extended detention storage for the larger storm events which exceeded the infiltration trench system's capacity.

The Fairland Ridge SWM facility also includes a spring, bearing the same name, which originates in the vicinity of the pond's lowflow orifice. Waters form the spring flow approximately 600 feet whereupon they join the Good Hope tributary of Paint Branch. The small 2 - 3 foot wide spring meanders through a partially forested riparian area. Baseflow produced by the spring is a relatively constant 0.05 cfs.

VOL 12 2 4480

R0057773

6. White Oak Tributary. This severely degraded, urban stream drains an intensively developed 225 acre MDE Class III watershed. Principal land uses in the contributory drainage basin include a major commercial shopping center area, garden apartments, and mature hardwood forest. For all intents and purposes this watershed area has no SWM controls. Although the headwaters of the fall-line stream have been piped, approximately 2500 feet of open stream channel remain. The majority of the remaining lower open section of stream flows through a mature hardwood forest. In character with fall-line streams, the White Oak tributary is boulder-strewn and contains numerous rock outcroppings and ledges. Stream width averages 8 - 12 feet and baseflow is approximately 0.35 cfs.

B. Continuous Water Temperature Monitoring

Characterization of the thermal regime of each of the six study areas was accomplished via the systematic employment of paired Ryan TempMentor recording thermograph thermometers. COG staff, with assistance from MdDNR Freshwater Fisheries, developed a continuous water temperature monitoring network consisting of 14 thermograph thermometer stations. The stations were strategically located so as to measure inflow-outflow temperature conditions, at the four BMP study sites, and identify spatial temperature variations along the streams. The general location of the 14 continuous temperature monitoring stations is shown in Figure 3.

VOL 12 2 4481

R0057774

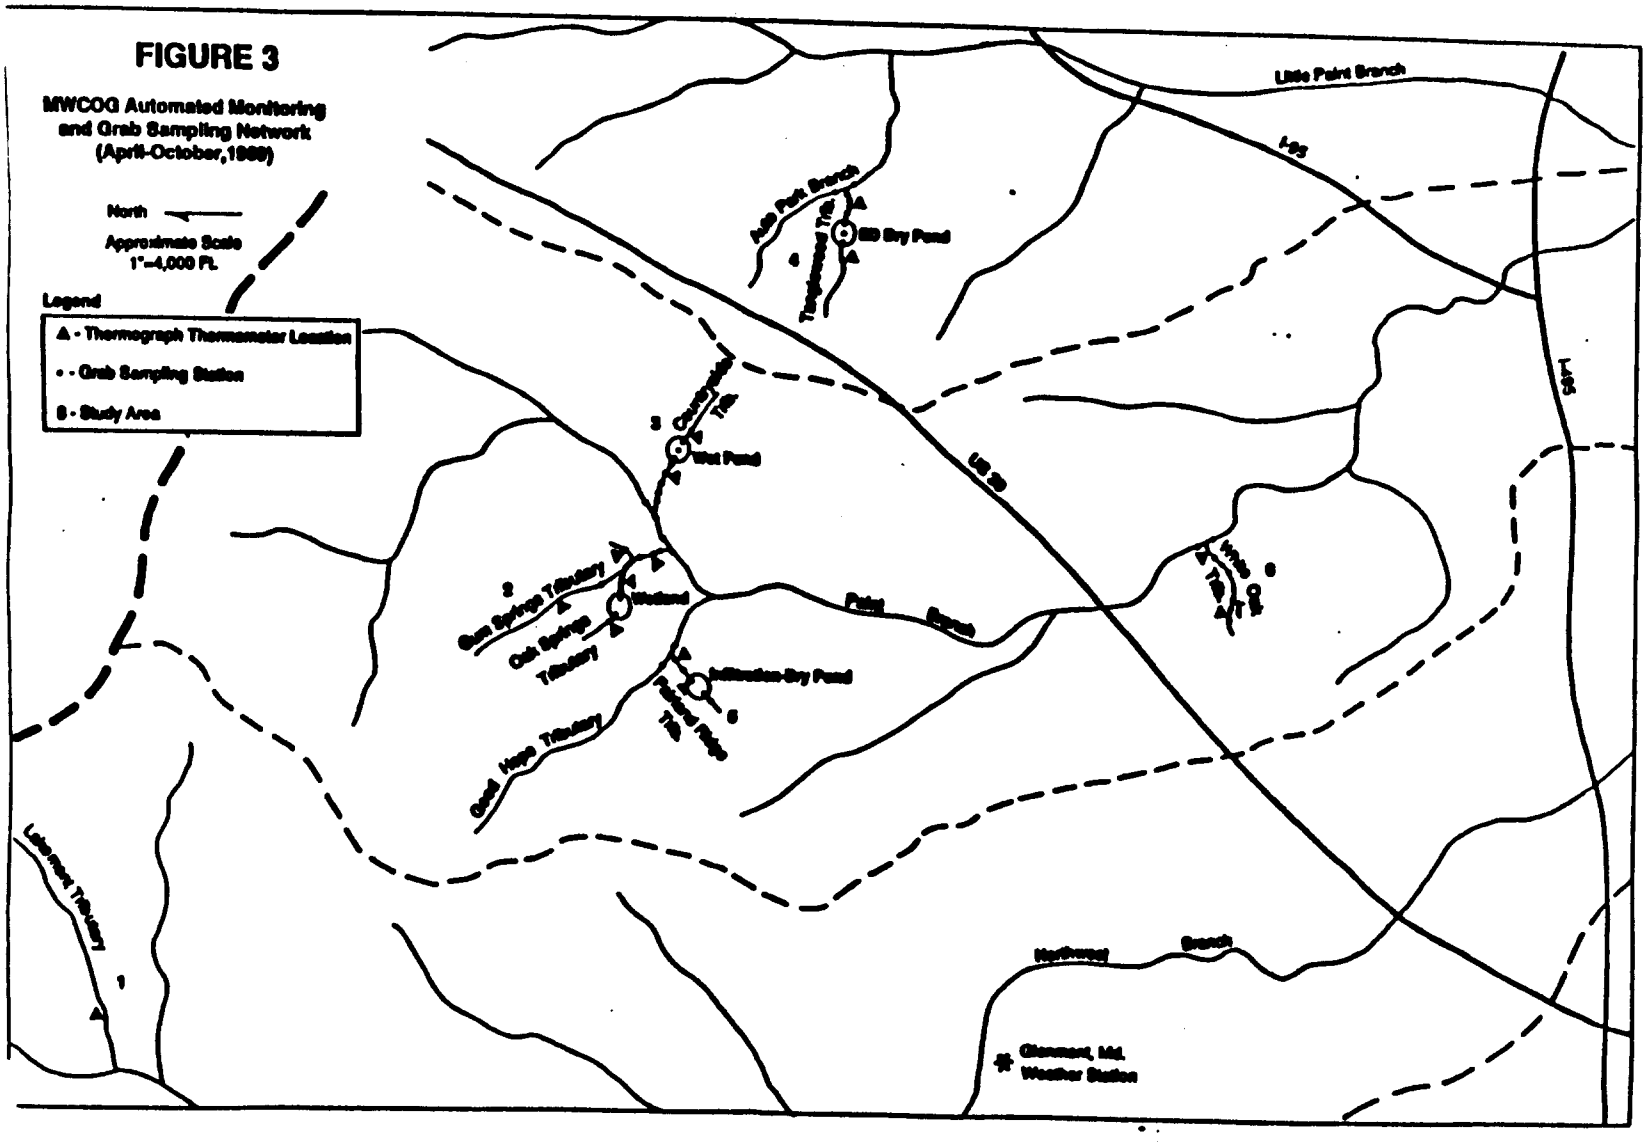

FIGURE 3

MWCOG Automated Monitoring and Grab Sampling Network (April-October, 1989)

R0057775

VOL 12 2 4482

Monitoring Period

All 14 thermograph thermometers were installed and operated, by COG staff, for the April 25 through September 20, 1989 period. Each unit was programmed to record water temperatures on a 20 minute time interval. This time interval was selected so as to measure and characterize stream temperature responses to small storm events in a uniform manner. Units were allowed to remain in the field for as long as 64 days before being removed. Stored temperature data was retrieved from each unit via downloading into an IBM compatible personal computer. The 14 thermograph thermometers were subsequently redeployed and returned to their original field locations within 48 hours. This process was repeated for each of the three deployment periods used in the study. Specific information for each of the three deployment periods is contained in Appendix B.

Equipment Selection and Field Installation

Ryan thermograph thermometers were selected for use in the study on the basis of the following attributes: 1.) the units feature an easily programmable sampling time interval ranging from one second to two hours, 2.) the units may be left unattended in the field for months at a time, and 3.) stored data can be quickly downloaded from the unit into a computer for further processing and analysis.

VOL 12 2 4483

R0057776

Each thermograph thermometer was placed into a silicone-sealed, screw-top Lexan plastic jar, then tightly sealed in two or more plastic garbage bags. The units were carefully buried, 4 - 6 inches below ground level, in an overbank area so as to reduce the risk of damage or loss from flooding and/or vandalism. Actual stream water temperature readings were made via an associated 15 foot long sensor cable that extended from the buried unit into the stream. The buried sensor cables were attached to steel rebars driven into the stream bottom. All cables were located in well-shaded undercut bank areas of the stream, where depth of flow was sufficient to keep the sensor tip completely submerged at all times. The basic sampling configuration used during the study is depicted in Figure 4. Each site was inspected by COG staff on a weekly basis.

C. Climatological Information System and Data Summary

Due to budgetary constraints rainfall, air temperature, and other pertinent climatological data was obtained from the National Oceanic and Atmospheric Administration (NOAA) Independent Weather Station Network. After careful review of existing NOAA stations in the vicinity of the six study areas, COG staff selected the Glenmont, Md. station as its primary reference weather station (Figure 3.). This decision was based upon the following: 1.) of the 14 stations examined, the Glenmont station's location was closest to the center of the six study areas, 2.) the station has provided comprehensive and reliable meteorological data for over 10-years, and 3.) the physical setting of the station, i.e., elevation and stream valley location, is similar to those of the study sites. Furthermore, it should be noted that meteorolgical data for a select group of storm events

VOL 12 2 4484

R0057777

FIGURE 4

THERMOGRAPH THERMOMETER SAMPLING CONFIGURATION

was obtained from one or more of the neighboring, 13 sister stations.

April - October, 1989 Climatological Summary

A comparative summary of climatological conditions, April - October 1989, at both the Glenmont station and Washington National Airport (DCA) is presented in Table 4. Included for reference in the table are 30-year historical levels for DCA. Additional climatological information may be found in Appendix D.

VOL 12 2 4486

R0057779

Table 4. Summary: 1989 Climatological Data

Parameter	Month						
	April	May	June	July	Aug.	Sept.	Oct.

R0057782

From a historical perspective, the April-July portion of the study was notably cooler and wetter than normal. In particular, the month of May was exceptionally wet with 10.93 inches of rain recorded at the Glenmont Station. Of this total amount, 4.6 inches of rain fell during one 24-hour period (May 6-7). Runoff from this near 10-year frequency storm event resulted in severe flooding of both study area and local streams. Flood waters severely damaged one of the 14 thermograph thermometers, requiring replacement of the unit. The storm also damaged two other thermographs thermometers resulting in the loss of stored water temperature data.

While the spring and early summer months were wetter than normal, extremely dry and cloudy conditions occurred in August. Precipitation in August totalled only 0.89 inches at Glenmont. This amount was 3.51 inches below reported 30-year historical averages for the WMA. Precipitation, temperature, and cloudiness were generally higher than normal in September. As seen in Table 4, monthly average temperatures, precipitation, and the number of clear days in October were also above 30-year historical averages for the WMA.

D. Water Quality Sampling

Under this task, COG staff developed and operated a 55 station water quality grab sampling network (Figure 3). The network was specifically designed to measure DO, stream flow, and air and water temperature conditions at discrete longitudinal intervals in and along the streams in the study area. Grab sampling was conducted, on a weekly basis, during the June 16 - October 20, 1989 period. In addition, limited stormflow monitoring was

VOL 12 2 4490
R0057783

performed during the same period.

DO measurements were made in the field via the employment of a YSI-57 (Yellow Springs Instrument) dissolved oxygen meter. Instrument accuracy was maintained during the four month sampling period through weekly calibration and spot checks against Winkler-titration sampling results.

Stream discharge was determined via the Embody Float Method (Embody, 1927). This technique uses the following equation for calculating flow:

$$\text{Discharge } (Q) = \frac{W \times D \times a \times T}{L}$$

where:

W = stream width (ft.)
D = stream depth (ft.)
a = roughness coefficient for stream bed (0.9 rough bottom, 0.8 smooth bottom)

T = travel time of float (sec.)
L = distance travelled by float (5 ft.)

Twelve flow measuring stations, each having a standard five foot flow length were established. Station locations were selected on the basis of representativeness of stream flow condition, ease of access, and ability to maintain relatively uniform cross-sectional areas. At each station, nine or more depth measurements, three wetted perimeter measurements, and three timed-floats were made per stream flow calculation. Because of the similarity in stream bed roughness, an 'a' value of 0.9 was used at all stations throughout the study.

VOL 12 2 4491

R0057784

E. Delta-T Water Temperature Analysis and Calculation

In order to quantify the degree of change in water temperature resulting from either the passage of stormwater runoff through a BMP, or from an undeveloped reference stream to a highly urbanized stream, a uniform comparative approach was required. Since these site specific changes may be expressed as a Delta-T value, water temperature analyses in the study were performed using this approach. The Delta-T method features direct comparisons of observed temperatures between a subject station(s) and some known reference at specific points in time.

For reasons already stated, the Lakemont tributary was chosen as the standard reference station against which all other study stations were compared. In addition, in order to quantify the inflow-outflow temperature relationships for a particular BMP, a second series of Delta-T comparisons was required. This second series involved the establishment of the SWM inflow station as the reference station. An example of the possible water temperature comparisons under the study's Delta-T approach is illustrated in Figure 5.

Delta-T Calculation

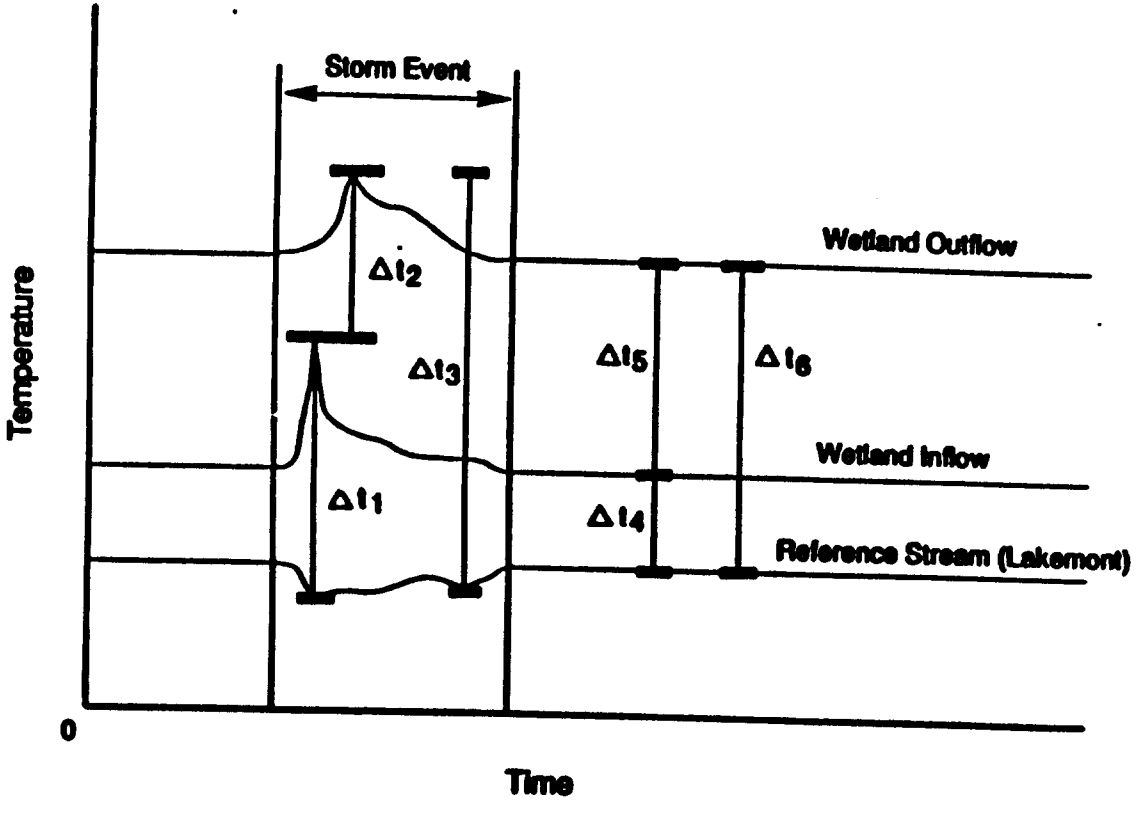
The Delta-T temperature, which can be either positive or negative, was calculated by taking the mean hourly temperature for both the subject and reference stations, then subtracting the reference station temperature from that of the subject station. An example of a standard one-hour Delta-T

VOL 12 2 4492

R0057785

FIGURE 5

Δt SCENARIOS FOR OAKSPRINGS ARTIFICIAL WETLAND



R0057786

calculation for the Countryside Inflow station is presented below:

Station	20 Minute Temperature Readings (°F)	Mean Hourly Temp. (°F)	Difference Btwn. Reference & Subj. Station (°F)
Lakemont (Reference)	64, 65, 66	65	+ 4.0
Countryside Inflow (Subject)	68, 69, 70	69	

The one-hour Delta-T for the Countryside Inflow station is positive 4.0 °F.

A minimum of 24 hourly Delta-T's, per day, were calculated for each subject station. Where possible, efforts were made to relate Delta-T values to environmental conditions such as rainfall, air temperatures, and stream discharge.

F. Percent of Time Plots

In addition to the Delta-T analyses, data from each continuous monitoring station were statistically analyzed and graphically depicted to show the percent of time water temperatures remained at, above, or below some particular temperature of interest (e.g., 68 °F MDE Class III temperature standard). Percent of time plots were generated for baseflow, stormflow, BMP performance, and climatological influence scenarios. These plots, along with the Delta-T analyses, served as the analytical backbone of the study.

VOL 12 2 4494

R0057787

G. Data Manipulation - SAS Architecture

The Statistical Analysis System (SAS), which is a mainframe computer system for data analysis, was used to statistically analyze and graphically depict water temperature and climatological data. A series of SAS programs was specifically written to accomplish the following general objectives:

1. Organize data by date, time, sampling station location, station type, and stream system;

2. Develop, through the integration of water temperature and precipitation data, baseflow and streamflow water temperature data sets;

3. Compute BMP and stream Delta-T's under baseflow, stormflow, and/or total flow conditions;

4. Statistically analyze, via the PROC UNIVARIATE (procedure analysis package), water temperature data sets; and

5. Graphically depict data.

H. Literature Review of Water Temperature Stress and Aquatic Communities

In an effort to identify the potential biological impacts associated with

VOL 12 2 4495

R0057788

temperature regime modification, COG staff conducted a comprehensive literature survey of the water temperature requirements of freshwater biota known or expected to occur in Maryland streams. Over 200 references, in one or more of the following categories, were collected:

- The thermal regime of natural streams - their general characteristics and the environmental factors which influence them;
- The general impact of human activities, particularly urbanization, on the temperature regime of streams; and
- Potential water temperature-related effects on the aquatic food chain of streams.

Special emphasis was placed on identifying the temperature requirements of Maryland freshwater fish. One of the major accomplishments of this subtask was the gathering and summarizing of water temperature-related findings for 63 fish species. The major findings of this overall effort are included in Appendix C. of the report.

VOL 12 2 4496

R0057789

Chapter II. Monitoring Results

A. General Effects of Watershed Urbanization, Riparian Cover, Stream Order, and Stormwater Management BMP's

Water temperature in natural streams is greatly influenced by factors such as climate, riparian vegetation, hydrology, topography, and stream order/distance from source. Development within natural watersheds sharply increases average stream temperatures in summer and depresses them in winter (Gray & Eddington, 1969; Hewlett & Forston, 1982). Concurrent temperature differences between sites along urban streams have been shown to vary by as much as 14 - 20°F on hot, sunny summer days (Pluhowski, 1970). These large temperature differences have been attributed to a wide variety of urban factors, including the removal of vegetation from stream banks, reduction in the amount of groundwater input to streams, construction of lakes and ponds, increased stormwater runoff to streams, and micro-climate changes associated with increased levels of impervious surfaces such as streets, parking lots, and roof tops (Klein, 1979; Pluhowski, 1970).

The following sections examine in varying detail the general influence of watershed urbanization, riparian cover, stream order and stormwater management BMP's on the temperature of small, headwater streams (stream order 1 - 3).

VOL 12 2 4497

R0057790

1. Influence of Watershed Imperviousness

The water temperature of small, heavily shaded, free-flowing Piedmont streams generally increases with increasing percentages of watershed imperviousness. As seen in Figure 6, no violation of MDE Class I, III, or IV temperature standards occurred at the undeveloped Lakemont station during the course of this study. However, both the frequency and magnitude of Class III and IV violations increased directly with corresponding increases in watershed imperviousness. Figure 6 also provides several other interesting insights into the relationship between imperviousness and stream temperature.

- The consistently cold water temperatures reported at the undeveloped Lakemont tributary station strongly suggest that, from a historical perspective, most headwater Piedmont streams in Maryland were once cold enough to support naturally reproducing trout populations and/or their associated support organisms.

- The impact of watershed development on stream temperatures was still evident in lightly developed watersheds. Even at the relatively low 12 percent watershed imperviousness level (Countryside inflow station), neither MDE Class III or IV temperature standards could be met 100 percent of the time (Class III and IV violations occurred 10 and 1 percent of the time, respectively). As previously noted, the frequency and magnitude of Class III and IV violations rose steadily with associated increases in the level of imperviousness. For

VOL 12 2 4498

R0057791

FIGURE 6

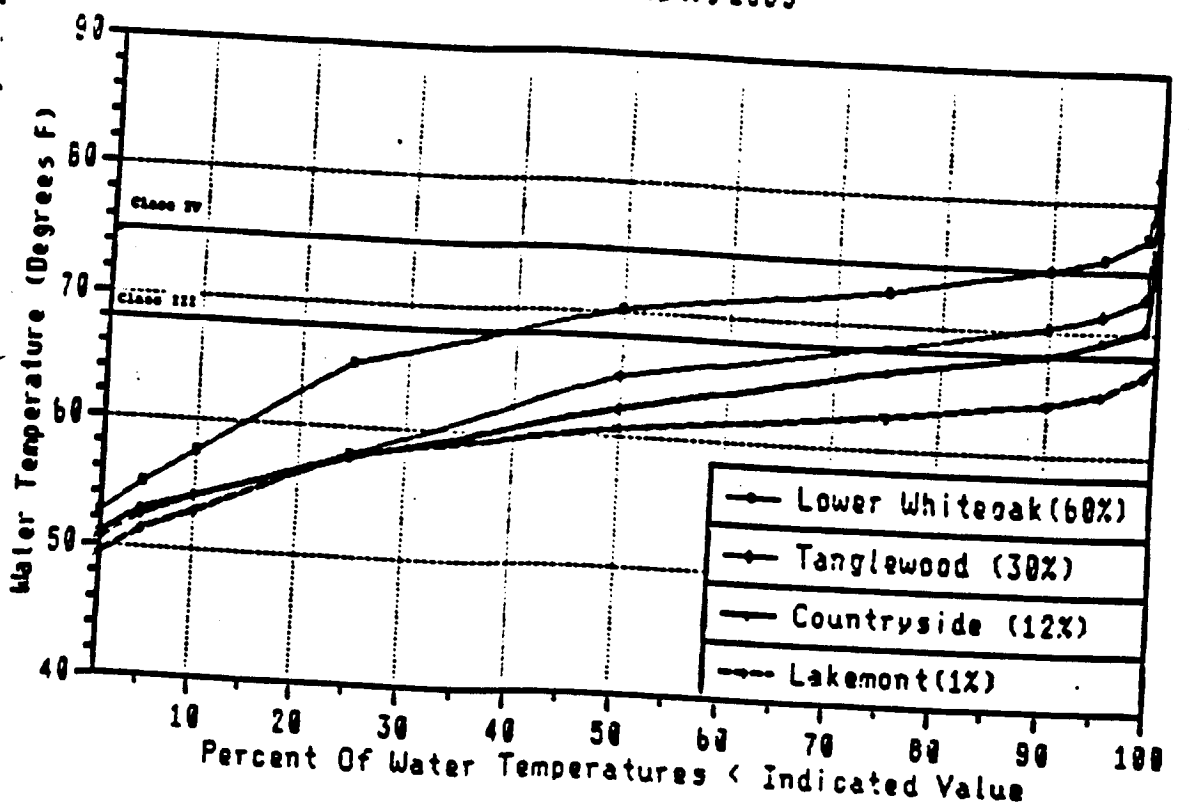
April-Sept., 1989



VOL 12 2 4499

R0057792

example, at the moderately developed, 30 percent impervious Tanglewood inflow station the frequency of Class III and IV violations occurred 25 and 1 percent of the time, respectively. However, at the heavily developed 60 percent impervious level (Lower White Oak tributary) Class III and IV standards were violated 60 and 10 percent of the time, respectively. The preceding findings bolster Klein's (1979) contention that sensitive coldwater fish, such as trout, may be negatively affected when watershed imperviousness exceeds 10 percent.

- Only about one percent of all recorded water temperatures at the Tanglewood inflow and Lower White Oak stations equalled or exceeded 80°F. Although representing only a very small percentage of all recorded temperatures, these temperatures are significant in that they exceed the temperature tolerance of most coldwater organisms.

- No violation of the 90°F MDE Class I water temperature standard was reported, at any stations during the study. However, a recently completed study of the urban Anacostia River basin (Kumble, 1990) indicates that this temperature standard is frequently violated by large streams during summer months.

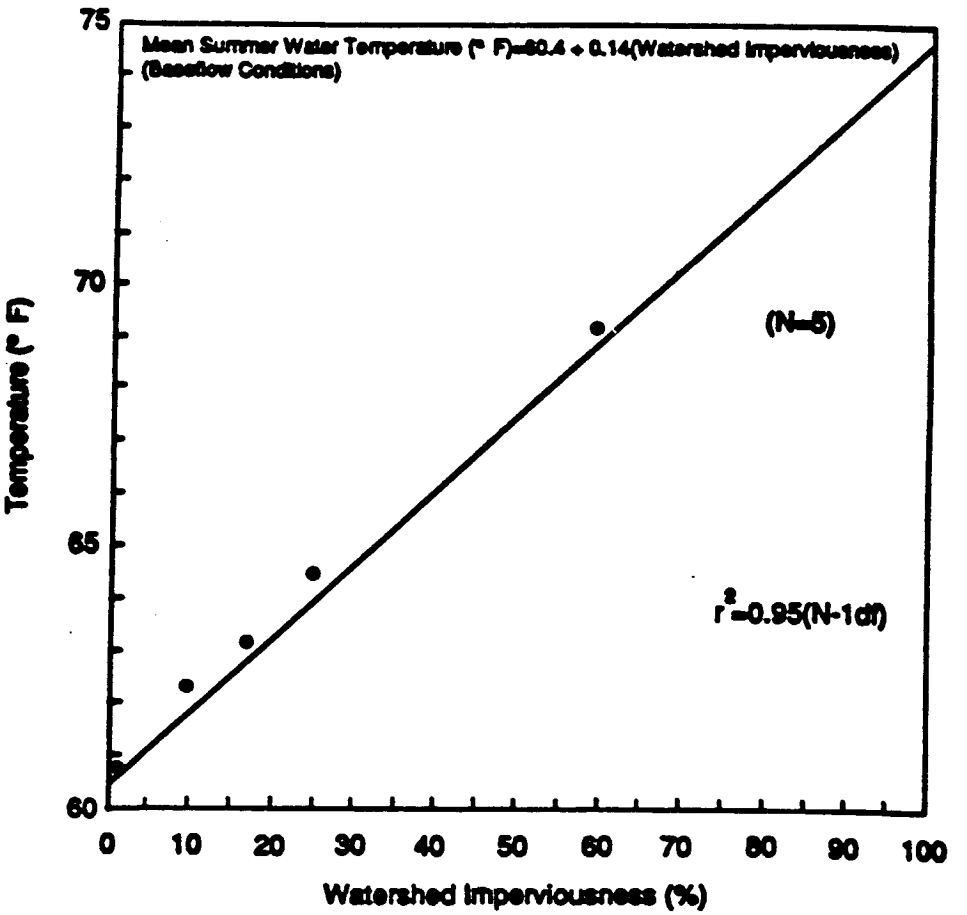
Further analysis of the data revealed a strong linear relationship between mean late spring-summer water temperatures and watershed imperviousness. As seen in Figure 7, an estimate of the mean, late spring-summer water temperature of small, heavily shaded, headwater Piedmont streams was derived from the following equation:

VOL 12 2 4500

R0057793

FIGURE 7

RELATIONSHIP BETWEEN WATERSHED IMPERVIOUSNESS AND WATER TEMPERATURE



VOL 12 2 4501

R0057794

Mean Water Temperature (^{o}F) = 60.4 + 0.136 (percent watershed imperviousness)

This least squares linear regression yields a correlation coefficient (r2), adjusted for degrees of freedom, of 0.95; indicating a strong general relationship between water temperature and watershed imperviousness.

The preceding equation indicates that for each one percent increase in watershed imperviousness there is a corresponding stream Delta-T increase of about $0.14^{o}F$. It is further noted that this equation pertains to streams in the study area under a slightly cooler than normal air temperature scenario.

Results supported the findings of Pluhowski (1970) that urbanization can markedly increase the average summer temperature of small streams. For example, closer examination of the Lower White Oak versus Lakemont water temperature distributions (Figure 8) revealed that Lower White Oak was typically 4 - 15 ^{o}F warmer than the undeveloped, forested Lakemont tributary. The average Delta-T increase for this highly urbanized stream was 8.6 ^{o}F. Maximum daily instantaneous water temperatures at the Lower White Oak station reached a high of $82.6^{o}F$. This represented the highest recorded free-flowing stream temperature in the study. In contrast, the highest maximum daily instantaneous water temperature at the Lakemont station was $67.8^{o}F$.

As expected, maximum daily water temperatures for all monitoring stations were recorded in July and August, the warmest months during the study. Figure 9, provides an interesting examination of the relationship between

VOL 12 2 4502

VOL 12 2 4504

R0057797

water temperature and climatological conditions at the Lakemont and Lower White Oak stations during the July period. Major findings are as follows:

- Both sites exhibited similar daily (or diurnal) stream Delta-T temperature fluctuations of between 2 and 8°F. The daily range in water temperatures generally followed the late afternoon (maximum) and early morning (minimum) pattern common to most North American streams.

- High maximum daily Delta-T stream temperatures at both stations, corresponded closely to periods of high maximum daily air temperatures. MDE Class IV temperature standard violations at the Lower White Oak tributary occurred on a regular basis during periods of sustained high air temperature (i.e., air temperatures $\geq$ 85 °F). Water temperatures in the mid to upper 70's were common at the White Oak tributary station during these high air temperature periods.

- In general, the stream temperatures were more responsive to daily air temperature fluctuations than to rainfall-runoff events.

- Approximately one percent of all storms produced major daily Delta-T increases at the heavily developed White Oak tributary. The highest water temperature recorded at this site (82.6°F) was the result of a brief, intense local shower which dropped 0.17 inches of rain. Delta-T stream temperatures responded to the influx of warm stormwater runoff by increasing 5.8°F in 20 minutes (Figure 9).

VOL 12 2 4505

R0057798

Interestingly, the maximum instantaneous water temperature of 82.6°F was reached at 10:00 p.m. (some 35 minutes after the start of the storm).

VOL 12 2 4506

R0057799

2. Baseflow versus Stormflow Conditions

In order to determine what general effect(s) rainfall-runoff events had on free-flowing streams draining watershed areas of different background levels of imperviousness, a series of simplified baseflow versus stormflow plots were made for the Lakemont, Countryside inflow, Tanglewood inflow, and Lower White Oak stations. For the purposes of the study, baseflow conditions were simply defined as dates in which no rainfall fell at the Glenmont, MD weather station. All other non-baseflow dates were considered to be, to some extent, under the varying influence of stormflow conditions (i.e., precipitation, cooler air temperatures, and/or increased cloud cover). Stormflow days were further defined as dates in which $\geq$ 0.01 inches of precipitation fell at the Glenmont, MD station. During the study, stormflow and baseflow dates respectively comprised 48.5 and 51.5 percent of the record. Results from this portion of the study are graphically presented as Figures 10 - 13. Major findings are summarized below:

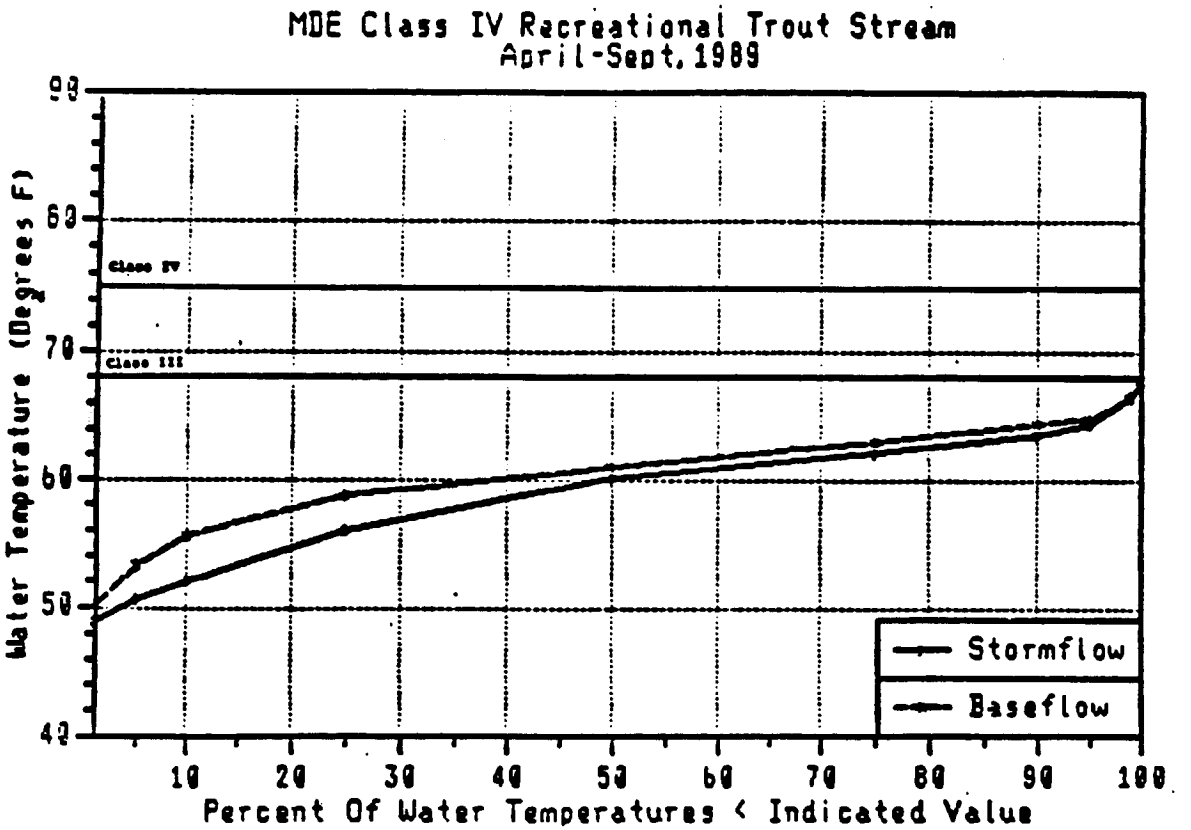
- During the entire study period, baseflow and stormflow water temperatures in the undeveloped watershed (Figure 10) were within four degrees Fahrenheit of one another. Stormflow water temperatures never exceeded baseflow temperatures, and in fact were cooler approximately 95 percent of the time. This finding strongly suggests that the increased cloud cover and cooler air temperatures associated with most rainy day - stormflow conditions generally depress the water temperature of small, heavily-shaded headwater streams. In addition, an increase in groundwater inflow, from

VOL 12 2 4507

R0057800

FIGURE 10

EFFECT OF STORMFLOW ON UNDEVELOPED LAKEMONT TRIBUTARY STREAM TEMPERATURES



VOL 12 2 4508
R0057801

infiltration of rainfall, may also contribute to overall stream temperature reduction.

- Results from both the lightly developed watershed (12 percent impervious) and moderately developed (30 percent impervious) watersheds stations were generally similar to those from the undeveloped Lakemont tributary. Countryside stormflow temperatures (Figure 11) were cooler than baseflow temperatures approximately 94 percent of the time. As seen in Figure 11, approximately 5 percent of the stormflow temperatures at this lightly developed watershed site exceeded the 68°F Class III standard; whereas, only 1 percent exceeded the 75°F Class IV standard. In contrast, Countryside baseflow temperatures exceeded the Class III and IV standards 10 and 0 percent of the time, respectively. At the moderately developed Tanglewood site (Figure 12), both stormflow and baseflow temperatures exceeded the Class III and IV standards 25 and 1 percent of the time, respectively.

- Although we expected stormflow temperatures at the highly developed watershed site to be much higher than baseflow temperatures and to exhibit large temperature spikes, this was generally not the case. In fact, stormflow temperatures at the Lower White Oak station (Figure 13) were equal to or cooler than baseflow temperatures 99 percent of the time. Air temperature seemed to be a more important factor than storms, about 90 - 95 percent of the time. Under stormflow conditions, Class III and IV standards were violated 57 and 10 percent of the time, respectively. Baseflow water temperature

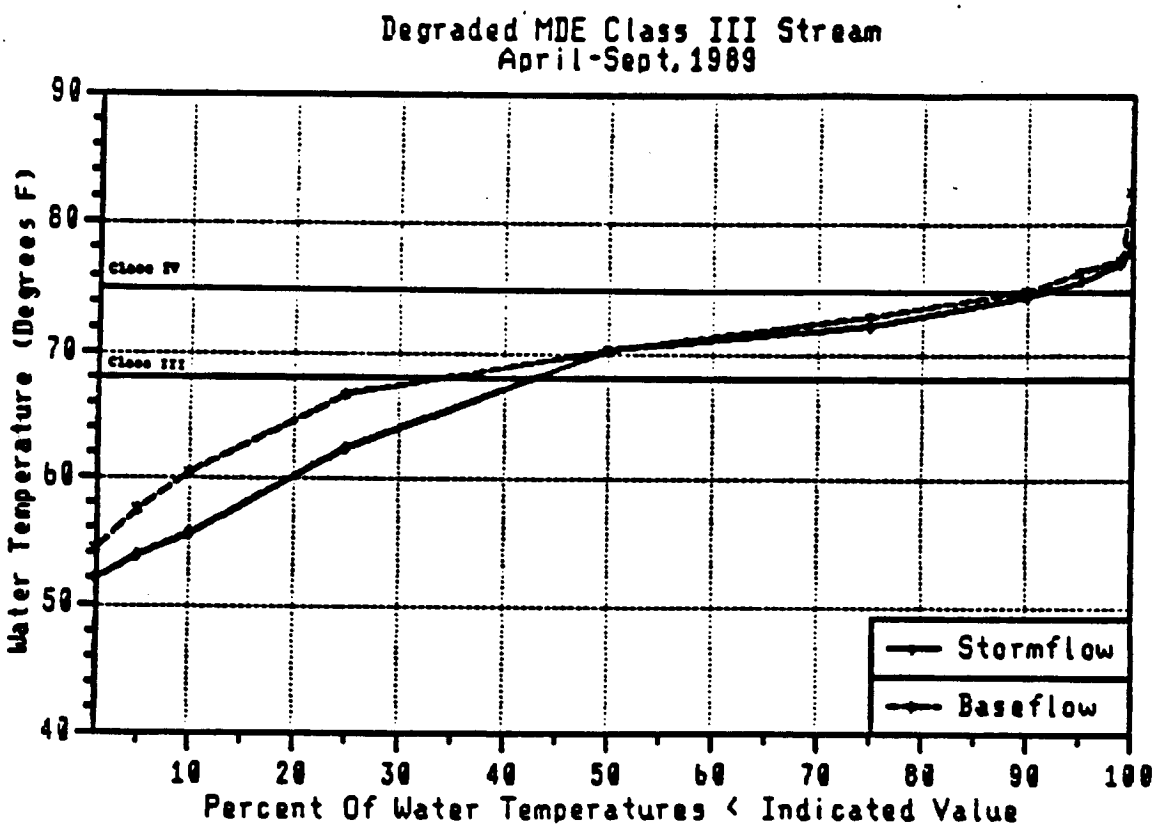
EFFECT OF STORMFLOW ON HIGHLY DEVELOPED LOWER WHITE OAK STREAM TEMPERATURES



R0057805

VOL 12 2 4512

violated the preceding standards 67 and 12 percent of the time, respectively.

In summary, results show that stormflow temperatures are generally cooler than baseflow temperatures. However, in developed watersheds stormflow temperatures will be higher, roughly 1-5 percent of the time, when certain conditions are met. The three principal conditions are:

1. The storm event occurs during a high air temperature period, or date;

2. Precipitation occurs mainly as the result of heavy shower activity; and

3. The amount of precipitation is sufficient to generate significant runoff. In highly developed watersheds the amount of rainfall needed to generate significant volumes of runoff can be as little as 0.1 inches.

The preceding conditions or factors explain the rapid, "J-"shaped curve increase evident in the upper right hand corner of the plots for the developed watersheds (Figures 11, 12, and 13). They do not, however, adequately explain the flatter temperature curve response observed at the Lakemont site (Figure 10).

VOL 12 2 4513

R0057806

3. Role of Riparian Vegetation

Studies have shown that the partial and/or complete removal of stream-side vegetation can raise summer stream temperatures by as much as 11 - 20°F and can reduce winter water temperatures by up to 5 - 7 °F (Gray and Edington, 1969; Hewlett and Forston, 1982; Lynch et al., 1980). The importance of riparian vegetation as a thermal insulator of small, headwater streams cannot be overemphasized. In particular, during summer months, an umbrella of dense vegetation typically shields natural streams from solar radiation; thereby reducing daily temperature fluctuations. Unfortunately, the common practice of removing riparian vegetation can greatly alter the temperature regime of small streams. Even relatively short open, or partially shaded stream reaches can produce a major elevation of downstream water temperatures.

Limited instantaneous grab sampling results from both the White Oak and Tanglewood tributaries revealed a maximum stream Delta-T increase of 8.5°F after the streams flowed through 150 foot long unshaded reaches (Figure 14). On average, a Delta-T increase of 3.5 - 3.7°F occurred when water flowed through relatively short (approximately 150 - 300 feet long), open or partially-shaded stream reaches. Although stream depth, current velocities, and discharge were comparable in both tributaries, the White Oak tributary had the highest observed temperature increase.

Physical factors such as stream channel width, depth of flow, current velocity, and volume of flow are known to play key roles in determining to what extent exposed stream reaches will be warmed by increased solar

VOL 12 2 4514

R0057807

Figure 14

Influence of Canopy Coverage on Mean Baseflow Temperature (° F) [1/] June-August, 1989

VOL 12 2 4515

R0057808

radiation. In general, the smaller the discharge, and the greater the amount of exposed stream surface area and travel time, the higher the potential temperature increase. Given that the 12 foot wide White Oak tributary is 2 to 3 times wider than the Tanglewood tributary, it appears that the greater amount of exposed surface area per unit volume of flow was primarily responsible for the observed higher temperature increases.

As seen in Figure 15, once elevated by the addition of warm water from the Oaksprings tributary, Gum Springs tributary baseflow temperatures did not demonstrably cool-down within the 1200 foot long test reach. In fact, temperatures remained elevated all the way downstream to the confluence with Paint Branch (a distance of approximately 1900 feet). While initially experiencing a stream Delta-T increase of 11.4°F after flowing through the Countryside wet pond, the smaller Countryside tributary did cool down slightly over a similar distance. However, the stream still posted a net stream Delta-T increase of 8.3°F. Since both test stream reaches were heavily shaded and air temperature along each respective tributary was constant, factors other than riparian canopy coverage apparently were responsible for the 3.1°F cooling-effect observed at the Countryside site.

Research has demonstrated that the temperature of small streams can be significantly reduced upon passage through heavily shaded reaches (Klein, 1979; Karr and Schlosser, 1977). However, it is widely acknowledged that as stream flow increases, the influence of riparian vegetation on stream temperature decreases. Once warmed, considerable energy must be expended to cool-down streams. Whether or not the small observed decrease in Countryside

VOL 12 2 4517

R0057810

water temperature was attributable to the influence of groundwater inputs, greater conduction of heat to the streambed and banks, higher convection rates, or some other means of thermal energy reduction remains unclear.

The preceding results show that on hot, sunny days the water temperature of small, poorly shaded streams can experience Delta-T increases on the order of 1.0 - 3.0°F per 100 feet of open or lightly-shaded channel length. Results also indicated that even after flowing through 1000 or more feet of forested stream buffer, stream temperatures are likely to remain elevated. This is particularly the case for larger-sized streams.

VOL 12 2 4518

R0057811

4. Stream Temperature As a Function of Stream Order

Macan (1958) reported that the temperature of small headwater streams warmed up and reached equilibrium within relatively short distances from their source. This is primarily attributed to the response of small streams to both air temperature variations and riparian canopy coverage. In addition, stream temperatures generally increase in a downstream direction with increasing stream order and/or distance from the source.

The premise that a temperature continuum normally exists within urban stream systems is supported by findings from the grab sampling portion of the study. As illustrated in Figure 16, stream temperatures along the mainstem of Paint Branch (a third-order stream) increased in a downstream direction. Over the course of approximately 4.3 stream miles, an average mainstem stream Delta-T increase of 5.0°F occurred. However, when compared to cooler first-order tributary areas such as the Upper Gum Springs, the average Lower Paint Branch increase was actually 14.0°F.

The observed 14.0°F stream continuum temperature increase, which represents the "watershed Delta-T effect," is the result of a combination of natural phenomena and anthropogenic factors. In the case of the urban Paint Branch, the watershed's Delta-T effect produces a 1.0 - 2.0°F baseflow temperature increase per stream mile. Results further suggest that smaller, low-order urban streams are most sensitive to this watershed Delta-T effect.

5. Effect of Stormwater Management BMP's on Water Temperature Distribution: MDE Water Temperature Standard Performance Series

None of the four urban BMP sites were thermally neutral. While no violation of MDE Class I temperature standards were recorded during the study, outflow from all four of the monitored stormwater management BMP sites violated either Class III or IV standards some of the time. As seen in Figure 17, the Fairland Ridge infiltration - dry pond facility had the lowest recorded BMP outflow temperatures. This hybrid BMP site violated Class III and IV standards 8 and 1 percent of the time, respectively. The highest outflow station temperatures were recorded at the Countryside wet pond. This BMP violated Class III and IV standards 75 and 50 percent of the time, respectively. Temperatures at the Countryside pond outflow station were, in comparison to the other three BMP sites, higher 75 percent of the time. Major findings are presented below. In addition, the BMP Delta-T performance for each site is summarized in Table 5 and described in greater detail in the following sections.

- All four BMP's increased receiving stream temperatures during baseflow conditions. The average BMP baseflow Delta-T increase ranged from a low of 2.6°F at the infiltration-dry pond site, to a high of 9.7°F at the wet pond (Table 5).

- During stormflow conditions, all four BMP's raised downstream water temperatures. Once again, the infiltration-dry pond produced the

smallest average BMP Delta-T increase (2.3°F). The wet pond had the largest average Delta-T increase (8.5°F). In addition, all four BMP's raised stormflow temperatures in the "J" section of the temperature curve.

- BMP Delta-T's were sufficient to dramatically increase the frequency and magnitude of temperature standards violations, and in some cases, were high enough to have severely impacted downstream coldwater organisms (had they been present).

- Outflow from the Tanglewood extended detention (ED) dry pond violated Class III and IV temperatures standards 50 and 10 percent of the time, respectively. This station had the second highest percentage of Class IV violations recorded (by any station) in the entire study.

- The Oaksprings ED wetland outflow station violated Class III and IV standards 58 and 10 percent of the time, respectively.

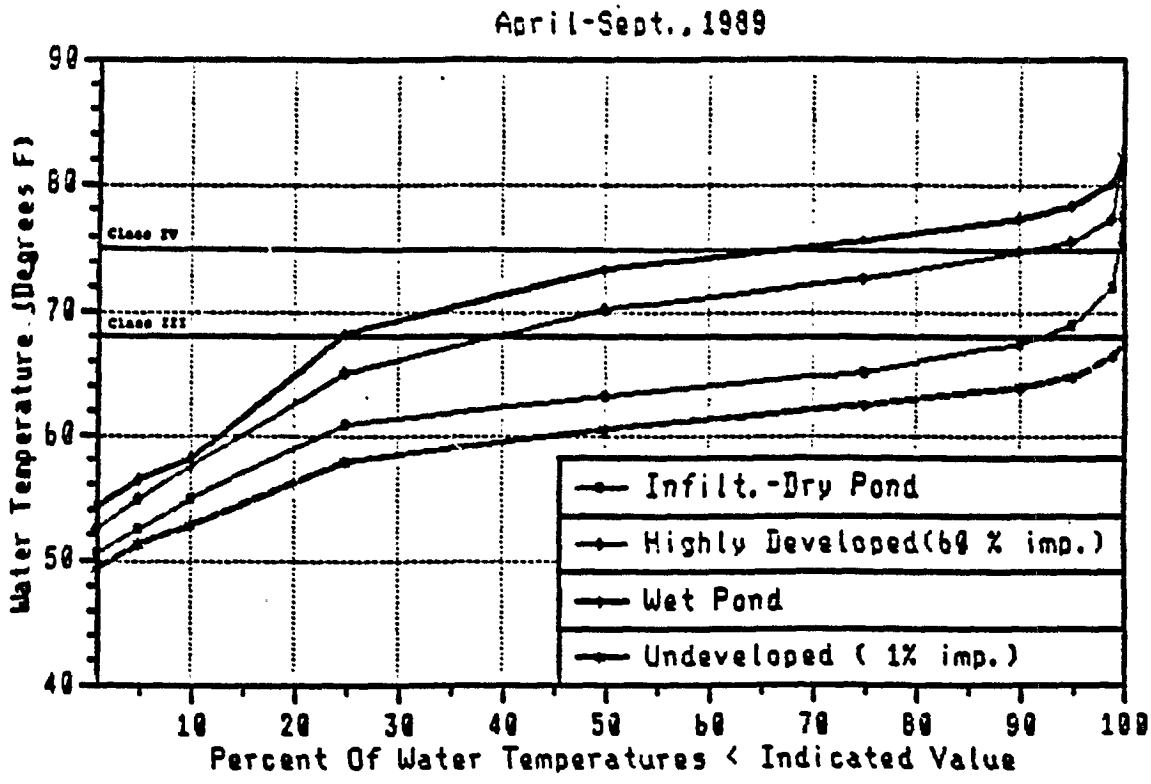
Figure 18 provides additional comparative information on the influence of both stormwater management BMP's and background levels of watershed imperviousness on receiving stream temperatures. Not surprisingly, high levels of watershed imperviousness and/or introduction of BMP's into headwater stream areas can produce average total stream Delta-T increases of 2.5 - 9.1°F. Closer examination of the data indicated that the average total stream Delta-T increase was 9.1°F for the wet pond, versus 8.6°F for the highly developed watershed. In addition, both scenarios reported identical

VOL 12 2 4524

R0057817

FIGURE 18

COMPARITIVE THERMAL IMPACTS OF URBANIZATION AND STORMWATER MANAGEMENT BMP'S: UNDEVELOPED, HIGHLY DEVELOPED, INFILTRATION-DRY POND AND WET POND



VOL 12 2 4525

R0057818

highly developed watershed produced an average total Delta-T increase which was 6.1°F higher than the infiltration - dry pond BMP.

A comparison of both the highly developed watershed and ED wetland outflow stream temperatures (Figure 19) reveals that the thermal regime of the two sites are virtually identical. The preceding results provide compelling evidence that at high levels of watershed imperviousness, the thermal impacts to the receiving stream system closely resemble those produced by wet and/or extended detention stormwater management BMP's.

Summary

Results from the study indicate that the temperature regime of small, urban headwater streams is greatly influenced by the five following factors:

1. Degree of watershed urbanization. Imperviousness, together with local meteorological conditions, generally had the largest influence on urban stream temperatures. Results from the study indicate that the average water temperature of urban streams increases on the order of 0.14°F per one percent increase in watershed imperviousness. When compared against the undeveloped watershed, the average total stream Delta-T increase at the 12 percent impervious watershed was 1.9°F, versus 8.6°F at the 60 percent impervious one. In addition, a general inverse relationship exists between watershed imperviousness and storm-size needed to produce large, rapid stream temperature increases.

2. Meteorological conditions. During the study the observation was made that air temperature was a more important factor than storms approximately 90 - 95 percent of the time. It was further noted that forested, undeveloped headwater streams such as the Lakemont tributary generally respond to storm events by becoming slightly cooler. This is largely due to the drop in air temperatures which accompanies most rainfall events. While this is also normally true of small urban streams, as the level of watershed imperviousness increases these streams become progressively more responsive to

VOL 12 2 4528

R0057821

inputs of stormwater runoff. In addition, the potential for large stream temperature increases is greatest during prolonged, hot weather periods which include heavy shower activity.

3. Riparian canopy coverage. Riparian vegetation plays a key role in insulating small streams from the warming effect of solar radiation. Results show that stream Delta-T's can increase an additional 1 - 3°F per 100 feet of flow through either open or poorly-shaded stream reaches.

4. Stream order. It is well known that stream temperature naturally increases in a downstream direction with increasing stream order/distance from the source. In urban watersheds a variety of anthropogenic factors, such as the removal of riparian vegetation, micro-climate changes, and reduction of groundwater inflow, add to the so-called "watershed Delta-T" effect. Monitoring results indicate that the watershed Delta-T effect for the urban, third order, Paint Branch stream system is on the order of 1 - 2 °F per stream mile. In addition, lower-order urban streams are, because of their generally smaller volume of flow, more sensitive to this background watershed effect.

5. Urban BMP's. As previously noted, all four types of stormwater management practices monitored in the study imparted additional heat to the receiving stream. The average total BMP Delta-T increase ranged from 2.5°F for the infiltration - dry pond to 9.1°F for the wet pond. Out of the four BMP's studied, the wet pond produced the

VOL 12 2 4529

R0057822

highest maximum BMP Delta-T increase.

B. Factors Influencing Stormwater Management Facility Temperature Performance

From a water temperature perspective, the performance of stormwater management wet ponds, artificial marshes, ED dry ponds, and infiltration facilities is strongly influenced by a large number of interrelated variables. These factors include, but are not limited to, the following: BMP surface area, volume and mean depth of the permanent pool, release depth (which changes relative to the facility's water surface elevation), hydraulic residence time, design storm storage capacity, infiltrative capacity of underlying soils, size and frequency of storm events, type and condition of stormwater conveyance system, BMP outfall design, watershed imperviousness, and baseflow/stormflow water temperatures. While it is beyond the scope of the study to examine each of these factors, a comprehensive examination of associated water temperatures under baseflow and stormflow conditions was performed to characterize general temperature relationships and BMP performances under field conditions.

The following sections examine baseflow-stormflow water temperature relationships, BMP baseflow-stormflow Delta-T's, thermal loading as a function of flow ratio, and stormwater management design features which contribute to thermal loading.

VOL 12 2 4530
R0057823

1. Stormwater Management BMP Performance Under Baseflow and Stormflow Conditions

Fairland Ridge Infiltration - Dry Pond

Results from the preceding section demonstrated that the Fairland Ridge infiltration - dry pond Delta-T water temperatures were the lowest of the four BMP-types monitored. The general performance of this BMP under both baseflow-stormflow and inflow versus outflow conditions is shown in Figures 20 and 23. Major findings are presented below and summarized in Tables 6 and 7.

1. As previously noted, all four BMP's had positive average total Delta-T's. However, Fairland Ridge, which had an average total BMP Delta-T increase of 2.5°F, produced the smallest Delta-T increase.

2. On one occasion, Fairland Ridge outflow station temperatures were actually slightly lower than inflow station temperatures. This occurred during a cool, small storm event. The unexpected result suggests the possibility of: a) higher associated stormflow conduction and/or convection rates downstream of the BMP, and/or b) an increase in groundwater inflow downstream of the facility.

VOL 12 2 4531

R0057824

3. Larger storms (i.e., $\geq$ 1.5 inches precipitation) raised downstream temperatures considerably. The lengthy detention of stormwater runoff, together with high solar radiation levels associated with the unshaded storage pool, rip-rap pilot channel and outfall areas, were co-contributors. The maximum recorded outflow temperature of this BMP site (77.7°F) was attributed to the preceding factors.

4. The thermal behavior at Fairland Ridge was unique. No other BMP monitored during the study displayed such well-pronounced extended detention effects. During large storms, this facility was capable of maintaining elevated outflow station temperatures for over 48 continuous hours.

Baseflow Versus Stormflow Delta-T's

As seen in both Figure 20 and Table 6, under baseflow conditions this BMP raised outflow station temperatures an average 2.6°F. It should be noted that the maximum observed Delta-T increase of 7.6°F was the combined product of stormwater runoff from 1.5 inches of rainfall and the BMP facility's defacto extended detention control. Therefore, a more realistic baseflow maximum Delta-T was probably on the order of 5.0 - 6.0°F.

With regard to stormflow Delta-T conditions, the infiltration dry pond raised outflow station temperatures an average 2.3°F. The maximum stormflow Delta-T for this BMP was 5.0°F. Approximately 65 percent of the time the

VOL 12 2 4534

R0057827

Delta-T difference between baseflow and stormflow conditions was less than 1.0°F (Table 6). Eighty-two percent of the time the positive Delta-T effect produced by this BMP was insufficient to cause a violation of the 68.0°F Class III standard. Exceedance of Class III standards was generally associated with periods of high rainfall. Only one violation of the Class IV standard was noted at this BMP site during the study.

Temperature Standard Performance

Monitoring results indicated that approximately one-fifth of all stormflow discharges from this BMP produced an increase in downstream water temperatures. They also revealed that Class III temperature standards were violated under both baseflow and stormflow scenarios, but that a 10 percent higher violation rate existed under stormflow conditions.

Under stormflow conditions (Figure 21) outflow temperatures exceeded the Class III and IV temperature standards 18 and 0 percent of the time, respectively. In contrast, baseflow outflow temperatures violated the same standards 8 and 1 percent of the time, respectively. As seen in both Figure 22 and Table 7, under stormflow conditions outflow station temperatures were slightly higher than inflow temperatures 100 percent of the time. Short, open and partially shaded reaches below this facility were primarily responsible for the slight stormflow temperature increase.

Example of Extended Detention Effect

One of the study's more interesting findings was that the infiltration-dry pond was the only BMP observed to produce a distinct extended detention temperature effect. Although this effect occurred infrequently and was clearly associated with large precipitation events (i.e., those dropping ≥ 1.5 inches of rainfall), it resulted in markedly higher downstream water temperatures.

Described below is the chronology of events for the July 20, 1989 storm; which was responsible for Fairland Ridge's maximum recorded outflow station water temperature of 77.7°F.

- As seen in Figure 23, Fairland Ridge inflow-outflow temperatures rose steadily in response to the 1.5 inches of precipitation which fell between 12:30 - 5:00 a.m., July 20, 1989. Within approximately three hours after the start of the storm, both inflow and outflow station water temperatures began to rise. The increase was caused by the large influx of stormwater runoff which had overwhelmed the 0.25 inch design capacity of the infiltration trenches. By the end of the storm, several feet of runoff had been impounded in the dry pond portion of the facility.

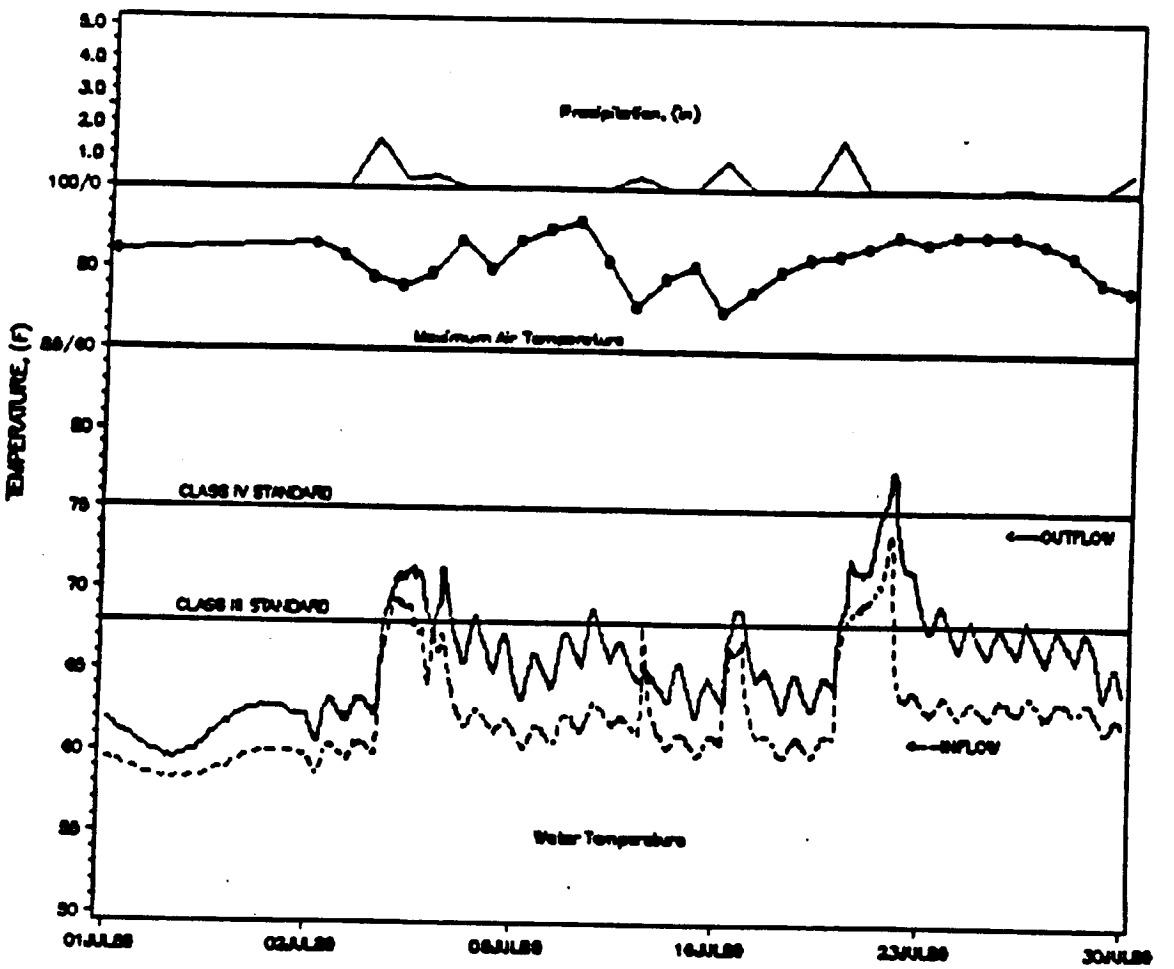
- The facility's 8 inch diameter low flow orifice, which provided the

VOL 12 2 4539

R0057832

FIGURE 23

GENERAL RELATIONSHIP BETWEEN MAXIMUM AIR TEMPERATURE, PRECIPITATION AND WATER TEMPERATURE: FAIRLAND RIDGE INFILTRATION-DRY POND, JULY, 1989



VOL 12 2 4540
R0057833

defacto extended detention control, stored and slowly released this stormwater over a two-day period. In response to both the detention of relatively warm stormwater runoff and solar radiation, the July 20, 1989 inflow station posted a 4.0°F Delta-T increase (water temperature increased to 69.3°F). It is further noted that during the approximate 53 hour detention period, maximum daily air temperatures of 86 and 89°F were recorded.

- The combination of high daily maximum and minimum air temperatures, lack of shade, large rip-rap pilot channel and relatively shallow depth of stored runoff, raised July 21-22, 1989 inflow station temperatures some 4.5°F (to a high of 73.8°F). Results also showed that an additional 3.9°F Delta-T increase occurred between the lowflow orifice area and the downstream outflow station. Much of this increase is believed to have been caused by flow through warmer, open or partially shaded areas below the BMP facility. Surprisingly, the maximum outflow temperature of 77.7°F was recorded at approximately 11:40 p.m. on July 21, 1990. Inflow and outflow station temperatures both returned to normal around 5:00 a.m., July 22, 1989; some 53 hours after the start of the storm. The net Delta-T increase associated with the subject storm was 12.4°F.

VOL 12 2 4541

R0057834

Oaksprings ED Artificial Wetland

The general performance of the Oaksprings wetland under both baseflow-stormflow and inflow versus outflow conditions is graphically illustrated in Figures 24 - 27. Major results are described below and summarized in Tables 8 and 9.

1. The shallow depth (mean depth is approximately 18 inches) and small permanent pool volume, relative to the 140 acre contributory watershed, made the Oaksprings wetland and outflow station very responsive to air temperature fluctuations. The wetland's small permanent pool did, however, give it a limited ability to moderate outflow temperatures during certain small storm events.

2. Both inflow and outflow stations exhibited similar diurnal Delta-T temperature fluctuations of between 3 and 8°F. In addition, the similarity in diurnal temperature profile response during and after rainfall events suggests that the wetland's limited extended detention capability generally had little effect on outflow station temperature behavior.

3. Delta-T stormflow temperatures at the Oaksprings wetland were typically lower than Delta-T baseflow temperatures. However, approximately 65 percent of the time the difference between baseflow and stormflow Delta-T's was relatively small (i.e., $\leq 3.0^{\circ}F$).

VOL 12 2 4542

R0057835

4. Inflow station temperatures were negatively affected by the Upper Oaksprings wet pond. Warm water released from the upper pond site, located approximately 1700 feet upstream, frequently produced periods of extended temperature elevation at the Oaksprings inflow station.

5. The average June - August grab sampling surface water temperature (measured approximately one foot below the surface) for the Oaksprings wetland was 74.2°F.

Baseflow Versus Stormflow Delta-T's

During baseflow conditions the Oaksprings wetland had both an average and maximum positive Delta-T effect of 3.9 and 8.7°F, respectively. As seen in Figure 24, maximum baseflow Delta-T's speaked in early June, and gradualy declined thereafter. Results indicated that seasonal trends in Oaksprings BMP Delta-T performance, under both baseflow and stormflow conditions, generally paralleled seasonal air temperature fluctuations. Approximately one percent of the time, the artificial wetland had a small negative Delta-T effect.

As seen in both Figure 24 and Table 8, stormflow Delta-T's were generally smaller than baseflow Delta-T's. Average and maximum stormflow Delta-T's for the BMP were 3.2 and 7.8°F, respectively. In addition, nearly 100 percent of all stormflow Delta-T temperatures were cooler than baseflow Delta-T's. The preceding findings indicate that the artificial wetland has a limited capacity to moderate outflow station temperatures during small storm events.

R0057838

Because of the wetland's small permanent pool volume, this moderating ability was highest for smaller storm events occurring during cool air temperature periods. It is further noted that the -6.0°F stormflow Delta-T recorded in the second week of May was the result of unseasonably cool, wet weather during that period.

Temperature Standard Performance

As seen in Figure 25, trends in maximum daily inflow-outflow station water temperature generally paralleled those of maximum air temperature. The same figure also shows that inflow station temperatures were more responsive to inputs of stormwater runoff than were outflow station temperatures.

Under baseflow conditions, outflow station temperatures (Figure 26) exceeded Class III and IV temperature standards 60 and 15 percent of the time, respectively. In contrast, the same standards were violated approximately 57 and 5 percent of the time, respectively under stormflow conditions.

Outflow station temperatures were higher than inflow station temperatures 95 percent of the time (Figure 26). While the stormflow Delta-T temperature difference between the two stations was generally less than 3.0°F, outflow temperatures during the warmest month of the study (July) were as much as 7.8°F higher than inflow station temperatures.

During stormflow conditions, inflow station temperatures violated Class III and IV temperature standards approximately 35 and 4 percent of the time,

Tanglewood ED Dry Pond

As previously noted, the Tanglewood ED dry pond had both high maximum Delta-T temperatures and a high percentage of MDE Class III temperature standard violations. In addition, maximum outflow water temperatures associated with this facility were second only to those of the Countryside wet pond. The general performance of this BMP under both baseflow-stormflow and inflow versus outflow scenarios are presented in Figures 28-31. Major findings are described below and are additionally summarized in Tables 10 and 11.

1. The maximum Delta-T produced by this BMP was higher under stormflow conditions (11.2°F) than under baseflow conditions (9.7°F). The higher stormflow Delta-T's were the product of: a) the inflow of relatively warm stormwater runoff into the facility, b) pilot channel heat contributions, and c) additional heating of detained waters via solar radiation. In addition, the highest Delta-T's were noted during warm weather.

2. The Tanglewood outflow station had large daily Delta-T temperature swings, which were amplified by the BMP. Over the course of the monitoring period, average diurnal Delta-T temperature fluctuations at the inflow and outflow stations were, respectively, 3.6°F and 5.6°F. The generally wider daily Delta-T temperature range observed at the outfall station was largely the result of water being heated

VOL 12 2 4552

R0057845

by its passage through the pond's partially shaded pilot channel. It should also be noted that, of the four BMP outflow stations monitored, the Tanglewood station's diurnal temperature flux was consistently the highest.

3. During the study COG staff observed, on three separate occasions, evidence of impounded stormwater within the Tanglewood facility. However, it appeared that runoff from most small storm events either was not detained, or detained for only very brief periods of time. Examination of the outflow station diurnal temperature response during and after storm events, did not reveal obvious extended detention effects.

4. Under baseflow conditions, this BMP's partially shaded pilot channel had an average positive stream Delta-T effect of 3.7°F.

Baseflow Versus Stormflow Delta-T's

Under baseflow conditions, the Tanglewood ED dry pond had both an average and maximum positive Delta-T effect of 5.5 and 9.7°F, respectively. In general, maximum baseflow and stormflow Delta-T's coincided with warm air periods (Figure 28).

Stormflow Delta-T's were generally higher than baseflow Delta-T's approximately 25 percent of the time (Table 10). Average and maximum stormflow Delta-T's for the ED dry pond were 5.2 and 11.2°F, respectively. The 11.2 °F maximum stormflow Delta-T observed at this BMP site occurred

during a warm air period which included 0.52 inches of precipitation.

Temperature Standard Performance

Outflow station temperatures (Figure 29 and Table 11) were, under stormflow conditions, slightly higher than baseflow temperatures 20 percent of the time. In addition, the frequency of MDE Class III and IV water temperature standard violations was similar under both flow scenarios. Stormflow outfall temperatures violated Class III and IV standards 48 and 15 percent of the time, respectively. The same standards, under baseflow conditions were exceeded 50 and 10 percent of the time, respectively.

Among the more revealing findings (Figure 30) was that 99 percent of all Tanglewood outflow station temperatures were, under stormflow conditions, warmer than inflow station temperatures. Examination of these two stations, under baseflow conditions, yielded similar results. As seen in Table 11, stormflow outflow station temperatures ranged from 0.0 - 5.8°F higher than inflow temperatures.

A comparison of inflow versus outflow station temperatures, under stormflow conditions (Figure 30), revealed that inflow temperatures violated Class III and IV temperature standards 25 and 1 percent of the time. In contrast, Tanglewood outflow station temperatures violated the same standards 50 and 10 percent of the time, respectively. Outflow station temperature profiles did not exhibit signs of artificially produced periods of prolonged temperature elevation, reduction, or stasis. In fact, outflow temperature profiles closely paralleled those of the inflow station. The

Countryside Wet Pond

Shallow, surface release impoundments are often credited with raising, especially during the warmer months of the year, the water temperature of small receiving streams. During summer months it is not unusual to see the surface water temperature of lakes and ponds in the Middle-Atlantic States occasionally hovering near the 90°F mark. This is particularly the case during extended hot weather periods and/or for small, shallow ponds which are heavily sheltered from the mixing-effect of the wind.

While much of the study period was cooler than normal, the Countryside outflow station proved to be the warmest of the four BMP outflow stations monitored. The general performance of this eight foot-deep, surface release wet pond under both baseflow-stormflow and inflow versus outflow conditions is graphically summarized in Figures 32-35. Significant findings from both the grab sampling and automated monitoring portions of the study are discussed below and additionally summarized in Tables 12-14.

1. The wet pond's large permanent pool served as an effective heat regulator. In general, the pond had a major warming effect on baseflow temperatures. However, during most storm events, the pond depressed the already elevated outflow station temperatures.

2. Delta-T baseflow temperatures at the Countryside wet pond were higher than stormflow Delta-T's 99 percent of the time. The average

VOL 12 2 4562

R0057855

baseflow Delta-T (9.7°F) was slightly higher than the average stormflow Delta-T (8.5°F). As previously noted, the pond's rip-rap outflow channel produced an average positive Delta-T increase of 2.0°F.

3. The average June - August, 1989 grab sampling surface water temperature in the Countryside pond was 77.8°F. This temperature was 3.6°F higher than the average temperature recorded, during the same period, in the Oaksprings wetland. The higher summer water temperatures associated with the wet pond are primarily a function of its larger permanent pool volume. The larger volume of water resulted in the Countryside pond storing and releasing heat from solar radiation more slowly; thus making it less responsive to air temperature fluctuations. Consequently, wet pond water temperatures remained generally higher throughout the summer (Table 12). In addition, the larger permanent pool volume resulted in the pond being noticeably slower to cool-down in late summer/early fall.

4. The maximum Countryside outflow station temperature, under stormflow conditions was 82.6°F. This temperature was only 1.3°F higher than the maximum outflow temperature recorded under base flow conditions (81.3°F). It should also be noted that the maximum surface water temperature observed in the pond during the grab sampling portion of the study was 86.9°F.

R0057857

Baseflow Versus Stormflow Delta-T's

As seen in both Figure 32 and Table 13, under baseflow conditions the wet pond raised outflow station temperatures an average 9.7°F. Not surprisingly, the maximum baseflow Delta-T (15.1°F) occurred during one of the warmest periods of the study (i.e., late June - early July). By the end of the automated monitoring period (September 20, 1989), maximum baseflow Delta-T's had declined to around 8.0°F.

Both baseflow and stormflow Delta-T's were always positive during the study. However, stormflow Delta-T's were smaller than baseflow Delta-T's approximately 99 percent of the time. This indicates that most storm events lowered both pond and outflow station temperatures. Most likely, the temperature reductions were caused by cool air temperatures and/or an influx of stormwater runoff (whose temperature was lower than ambient pond temperatures). The average and maximum stormflow Delta-T's during the study were 8.5 and 14.0°F, respectively.

Temperature Standard Performance

Under stormflow conditions (Figure 33), Countryside outflow station temperatures were typically 0.5 - 5.9°F lower than under baseflow conditions. In addition, both MDE Class III and IV temperature standards were more frequently exceeded under baseflow conditions. Outflow station temperatures violated Class III and IV temperature standards (under baseflow and stormflow conditions) 77 and 35 percent, and 64 and 25 percent of the time, respectively.

Outflow station temperatures (under stormflow conditions) were higher than inflow station temperatures 100 percent of the time. As seen in Figure 34, the much cooler Countryside inflow station (under stormflow conditions) violated Class III and IV temperature standards 10 and 1 percent of the time, respectively. The median outflow station temperature under both baseflow and stormflow conditions (Table 14) was approximately 11.0°F higher than the median inflow station temperatures.

Examination of the water temperature data also revealed that the maximum stormflow outflow station temperature occurred on a date (August 6, 1989) in which a maximum of only 0.05 inches of rain fell in the vicinity of the Countryside pond. Additional review of air temperature data indicated that this maximum outflow water temperature coincided with a warm to hot air temperature period.

During this warm air period, maximum air temperatures ranged between 86

R0057864

and 92°F for four straight days. Therefore, in all likelihood the 82.6°F outflow station temperatures was the result of high air temperatures raising pond water temperatures, rather than a discharge of warm stormwater runoff-pond spillover.

2. Example of Summer Thunderstorm Effect

Thermograph thermometer results indicated that the Countryside inflow station exceeded the 75°F Class IV temperature standard on only one occasion. The violation, which occurred on July 26, 1989 (Figure 35), coincided with an intense afternoon thunderstorm. During this storm event, water temperatures at the inflow station rose 9.0°F within two hours, to a high of 77.9°F. The principal factors which are thought to have contributed to this high stream temperature are briefly outlined below:

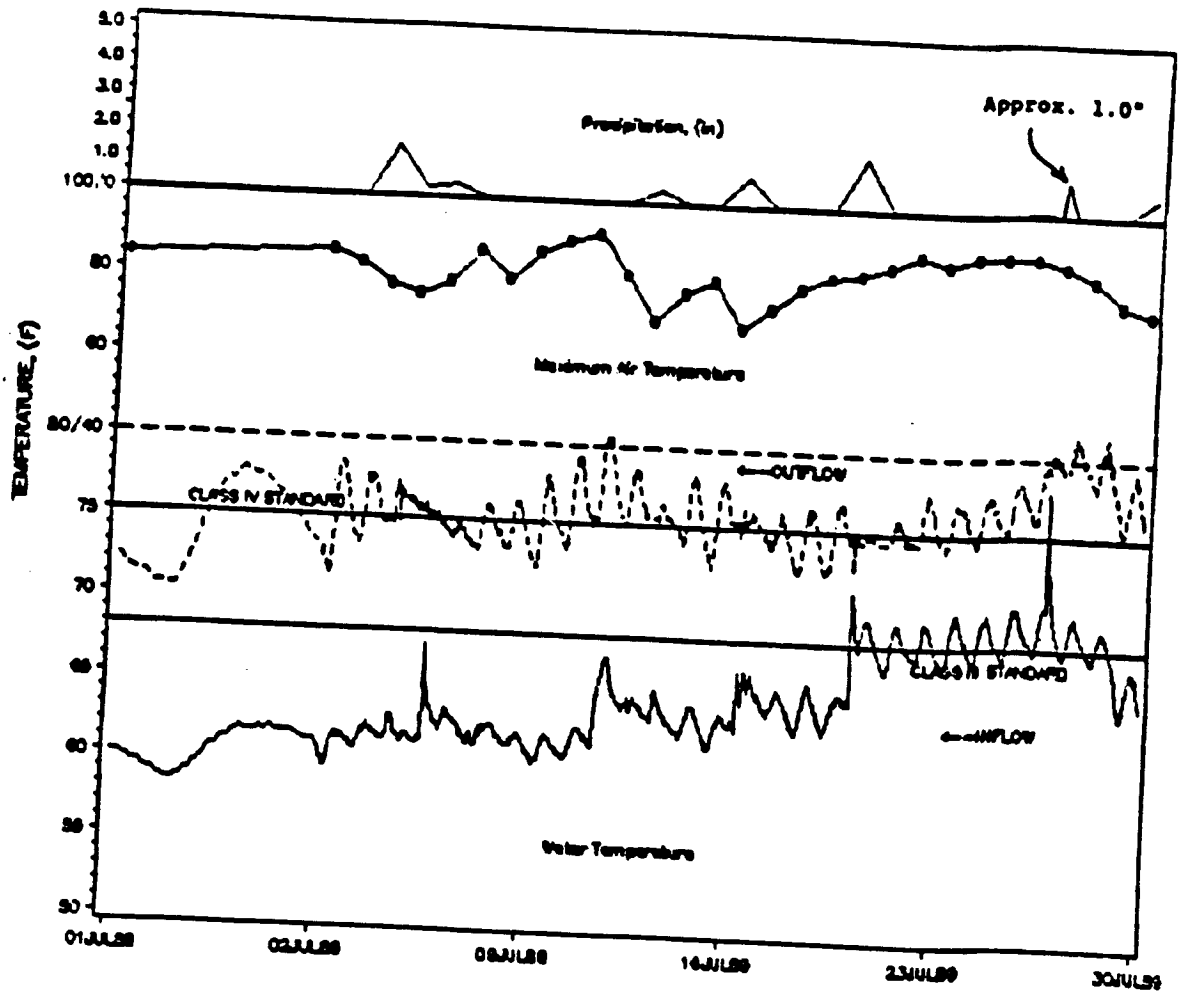
- The high stream temperature occurred on a date in which the air temperature in the study area was a hot, 91°F. In addition, five consecutive warm days and nights preceded the storm date. Average daily high and low air temperatures during this five-day period were 88.0 and 72.2°F, respectively. As seen in Figure 35, stream temperatures during the same period responded to the warm air temperatures by also becoming warmer. It is also quite probable that ground temperatures responded in an analogous fashion.

- While only a trace amount of rainfall was reported at the Glenmont, MD weather station, intense local thunderstorms were reported in the

VOL 12 2 4572
R0057865

FIGURE 35

GENERAL RELATIONSHIP BETWEEN MAXIMUM AIR TEMPERATURE, PRECIPITATION AND WATER TEMPERATURE: COUNTRYSIDE WET POND, JULY, 1989



VOL 12 2 4573

R0057866

vicinity of the Countryside pond. Reports from Messrs. Friedman and Swanson, two independent NOAA weather reporters whose stations are both located approximately 1.5 miles from the pond site, indicated that between 0.70 and 1.28 inches of precipitation was associated with this 5:00 - 7:00 p.m. storm. Thus, significant volumes of stormwater runoff were quickly generated from the 12 percent impervious catchment area.

- In a recent study of a small, urban Maryland stream system, Galli (1988), reported that the temperature of stormwater runoff during hot weather periods can exceed 84°F. The study also noted that even after 55 minutes of steady rain from a 1.0 inch storm the temperature of stormwater runoff did not decrease substantially. As such, large quantities of warm stormwater runoff would have been expected to have been generated from the residential and commercial portions of the Countryside subwatershed.

- Baseflow at the Countryside inflow station was, on July 25th, only 0.16 cfs. This flow, which was approximately one-third below the station's average discharge of 0.25 cfs, would have comprised a minor portion of the total stream flow during the July 26th storm event.

Although a large number of the storm events which took place during the study had an overall cooling effect on stream temperatures, the preceding result demonstrates that moderately-sized rainfall events which occur during hot weather periods are capable of markedly increasing the temperature of small, lightly developed urban streams.

VOL 12 2 4574
R0057867

3. Thermal Loading As A Function of Flow Ratio

It has already been shown that the introduction of large quantities of stormwater runoff into small, urban headwater streams, can under certain meteorological conditions, sharply alter normal diurnal stream temperature patterns. For instance, the mixing of relatively large quantities of stormwater runoff with baseflow on July 26 and 27, 1989, quickly raised stream temperatures 9.0°F and 5.8°F, respectively, at the Countryside inflow and Lower White Oak stations. According to Pluhowski (1970), the impact of stormwater runoff on receiving stream temperature patterns increases as the ratio of runoff to total streamflow increases.

To test the validity of this theory, COG staff examined the effect of thermal discharges from the Oaksprings artificial wetland on the Delta-T temperature response of the Gum Springs tributary. Water temperature and stream discharge grab sampling data collected from the Lower Oaksprings, Upper Gum Springs, and Gum Springs stations, were used to perform a simple linear regression of thermal loading versus flow ratio. In this test, the Upper Gum Springs station served as the reference station against which Delta-T temperature responses at the more downstream Gum Springs station were calculated. Data from a total of 10 separate sampling dates, collected between June - October, 1989 were used in the regression calculation. It is further noted that seven of these sampling dates were under the influence of stormwater discharge from the Oaksprings wetland.

Results from the analysis revealed that a distinct linear relationship exists between the Delta-T temperature response of the Gum Springs tributary

VOL 12 2 4575

R0057868

and the flow ratio of the two streams. An approximation of the thermal response of the Gum Springs tributary to different Oaksprings tributary outflow conditions can be made from the following equation:

Gum Springs Delta-T(^{o}F) = 0.27 + 2.81(Flow Ratio)(between Gum Springs & Oaksprings tributary)
(thermal response)

The least squares linear regression yielded a correlation coefficient (r2), adjusted for degrees of freedom, of 0.63; indicating a moderately strong general relationship between water temperature response and flow ratio. Although the predicted Delta-T temperature increases were somewhat lower than observed Gum Springs values, both supported the previously stated findings of Pluhowski, (1970).

As seen in Figure 36, when the Oaksprings-Gum Springs tributary flow ratio is 1:1, a 3.0^{o}F Gum Springs Delta-T increase would be expected. At a 2:1 flow ratio, the expected Delta-T increase is doubled to 6.0^{o}F. The preceding results demonstrate that the potential thermal impact of stormwater runoff on receiving streams increases as the runoff (Q_{in}) to receiving stream flow (Q_{r}) ratio increases.

4. Stormwater Management Design Elements Which Add To Thermal Load

During the grab sampling portion of the study it became very clear that basic BMP facility design elements, such an inflow - outflow channels can add measurably to downstream thermal loading. This is particularly the case when these conveyance channels are unshaded, heavily rip-rapped, or both. Major findings from two BMP test sites, Tanglewood ED dry pond and Countryside wet pond, are described in detail in the following sections.

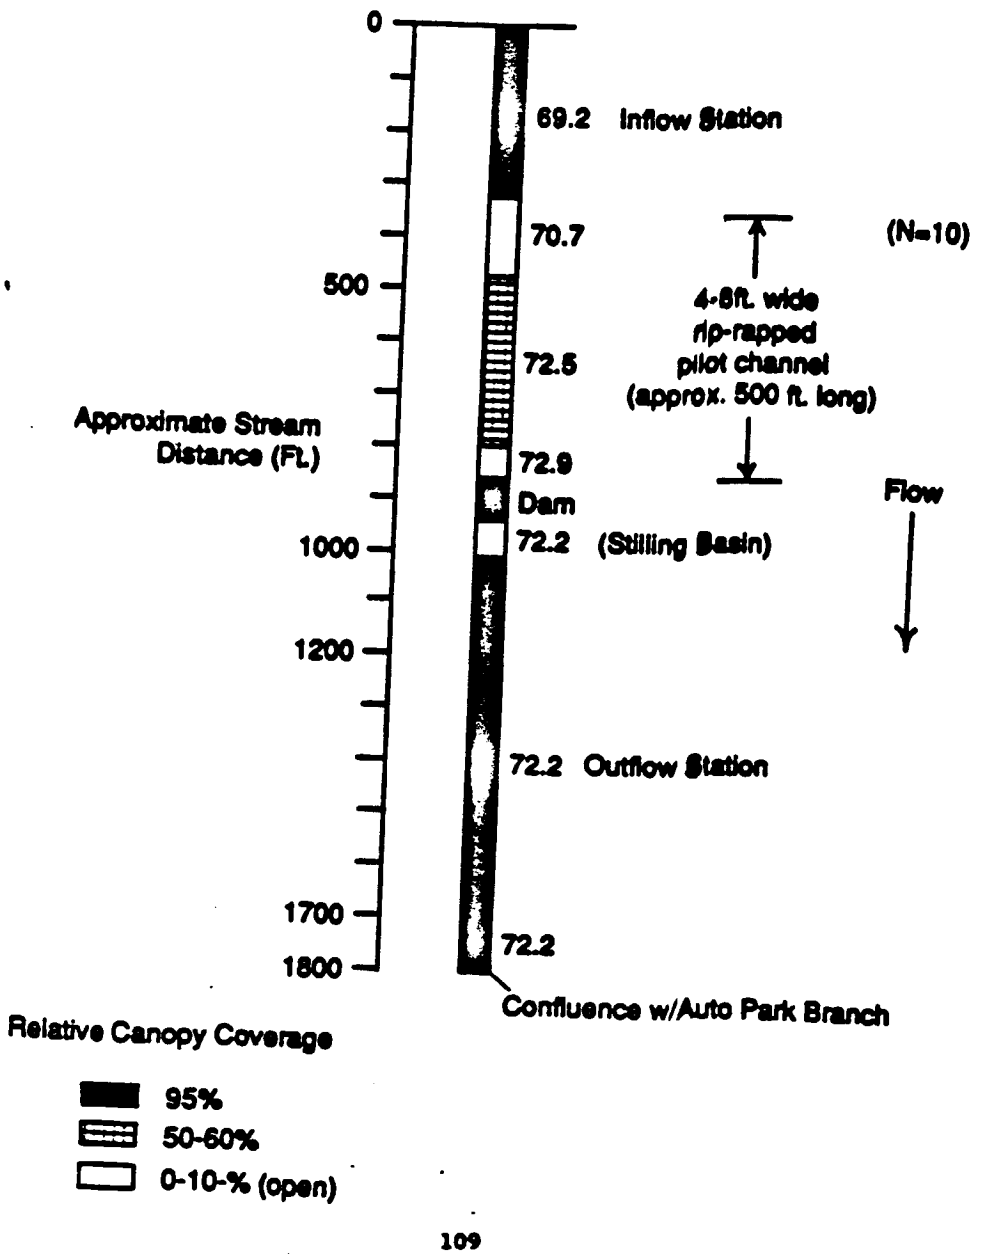
Tanglewood Pilot Channel

One of the noteworthy features of the Tanglewood facility is its rather long, flat pilot channel. Both base and storm flows are carried by the 4 - 8 foot wide x 500 foot long rip-rapped channel. As depicted in Figure 37, the pilot channel is partially shaded along its length by a narrow strip of 8 - 12 foot high black willow (Salix nigra) trees. Approximately 175 feet of the channel is open and only marginally shaded by herbaceous vegetation. The lack of adequate shading along the channel results in a net mean baseflow Delta-T increase of almost 4.0°F at the riser. Although a slight decrease in mean baseflow temperature occurred as water flowed through the 60 foot long, 48 inch diameter RCP barrel, lower Tanglewood tributary baseflow temperatures remained elevated (even after flowing through 800 feet of forested buffer).

VOL 12 2 4578
R0057871

Figure 37

Effect of Partially Shaded Pilot Channel on Tanglewood ED Dry Pond Mean Baseflow Temperature(° F) (June-August, 1989)



VOL 12 2 4579

R0057872

Countryside Barrel - Outflow Channel Temperature Relationship

The Countryside wet pond features a 60 foot long, 72 inch diameter RCP barrel which discharges into a 75 foot long by 30 foot wide rip-rap outflow channel. This unshaded, trapezoidal shaped channel has a bottom width of approximately 12 feet. Under normal conditions, baseflow completely fills the bottom of the rock strewn channel. The average depth of flow, under baseflow conditions, is approximately 1 - 3 inches.

Both the length and unshaded nature of the outflow channel raised COG staff's suspicions that it may have been additionally increasing downstream water temperatures. Grab sampling results (Table 15) revealed that mean baseflow temperatures were raised as much as 8.5°F after flowing through the outflow channel. On average, a 2.0°F Delta-T increase was produced by the combination of lack of shade, shallow depth of flow, and presence of large, heat absorbing rip-rap associated with this channel.

It should also be noted that, on one occasion, a Delta-T decrease of 9.9°F was observed between pond waters (at the dam) and flow at the end of the barrel. The average Delta-T temperature difference between these two locations was a negative 3.3°F. Based on limited sampling results, it appears that the 10 foot fall of water between the pond's eight inch diameter pipe outlet and invert of the riser, together with cool barrel and air temperatures in these structures, were responsible (through convection and conduction forces) for the temperature decrease.

R0057874

Summary

Results from the study indicated that all four of the BMP facilities had positive average total Delta-T's and each violated MDE Class III and IV temperature standards some of the time. Wet permanent pools, long periods of extended detention, and poorly shaded pilot and outflow channels contributed greatly to the problem. The thermal performance of each BMP is summarized in Table 16. Specific findings are presented below.

1. Infiltration-Dry pond

- Of the four BMP's, the infiltration-dry pond produced the smallest Delta-T increases (Table 16). The infiltration trench portion of the BMP, designed for 0.25 inches of street runoff, worked well during small storms. However, large storm events (i.e., $\geq$ 1.0 inches precipitation) and/or 2 - 3 consecutive days of moderate rainfall generally overtaxed the capacity of the infiltration trench system. This often resulted in the ponding of several feet of runoff in the dry pond area. The facility's defacto extended detention control combined with high incoming solar radiation on the unshaded rip-rap pilot channel, storage pool, and outfall area, produced a 4.0°F Delta-T increase.

- From a water temperature standards perspective, this BMP had the lowest frequency of Class III (68.0°F) and IV (75.0°F) violations (Table 16). Standards violations were more frequently associated with stormflow conditions. The BMP's single Class IV violation was

R0057876

VOL 12 2 4583

a product of a large storm and 53 hours of extended detention.

- The thermal performance of the infiltration - dry pond could have been improved had its infiltration design treatment capacity been sized to handle more than 0.25 inches of runoff from roadway areas. For thermally sensitive watersheds, such as those which support naturally reproducing trout populations, infiltration systems should be intentionally oversized. Results also showed that the infiltration-dry pond's lengthy extended detention control was a major thermal loading factor. For this reason, the use of extended detention BMP's in thermally sensitive areas should be carefully evaluated. It is further recommended that a maximum 6-12 hour detention period limit be established for these areas and that shading of the storage pool area be required.

2. Extended Detention Artificial Wetland

- The average and maximum BMP Delta-T's associated with the wetland were 3.2 and 8.7°F, respectively. As seen in Table 16, Delta-T stormflow temperatures at the wetland were typically lower than baseflow Delta-T temperatures. However, approximately two-thirds of the time the difference between baseflow and stormflow Delta-T's was relatively small (i.e., $\leq 3.0^{\circ}F$).

- The shallow depth (mean depth is approximately 18 inches) and small permanent pool volume, relative to the 140 acre contributory

VOL 12 2 4584

R0057877

watershed, made the wetland and its outflow station very responsive to air temperature fluctuations. The wetland's small permanent pool did, however, give it a limited ability to moderate outflow temperatures during certain small storm events.

In addition, because the wetland's extended detention capacity was extremely limited, it had little influence on outflow station temperature behavior.

- Under baseflow conditions, wetland outflow station temperatures exceeded Class III and IV temperature standards 60 to 15 percent of the time, respectively. In contrast, the same standards were violated approximately 57 and 5 percent of the time, respectively under stormflow conditions. Outflow stations were higher than inflow station temperatures 95 percent of the time.

3. Extended detention Dry Pond

- Surprisingly, the ED dry pond had the second highest recorded Delta-T's (Table 16). The maximum Delta-T produced by this BMP was slightly higher under stormflow conditions (11.2°F) than under baseflow conditions (9.7°F). Higher stormflow Delta-T's were the product of: a) the influx of relatively warm stormwater runoff into the facility, b) the partially shaded pilot channel's heat contribution, and c) additional heating of detained waters via solar radiation. In addition, the highest stormflow Delta-T's were

VOL 12 2 4585

R0057878

noted during hot weather. This BMP's 500 foot long pilot channel produced an average positive stream Delta-T of 3.7°F.

- Under stormflow conditions, the ED dry pond violated Class III and IV temperature standards 48 and 15 percent of the time, respectively.

4. Wet Pond

- The wet pond's large permanent pool served as an effective heat regulator. In general, the pond had a major warming effect on baseflow temperature. However, during most storm events, both pond and outflow station temperatures were depressed. The relatively large permanent pool volume resulted in the pond slowly storing and releasing solar radiation/heat; thus making it slow to respond to air temperature fluctuations. Average summer pond surface water temperatures remained generally over 77°F. Pond waters were noticeably slow to cool-down in late summer/early fall.

- Delta-T baseflow temperatures at the wet pond were higher than stormflow Delta-T's 99 percent of the time. The average baseflow Delta-T (9.7°F) was slightly higher than the average stormflow Delta-T (8.5°F). The pond's rip-rap outflow channel produced an average positive Delta-T increase of 2.0°F.

- From a water temperature standards perspective, this BMP had the highest

VOL 12 2 4586
R0057879

frequency of Class III and IV temperature standards violations. As seen in Table 16, violations were more frequent under baseflow conditions.

5. Storm-Size/Watershed Imperviousness Factor

- Results indicated that with increasing levels of watershed imperviousness, the storm-size needed to produce large stream temperature fluctuations decreased. At a 12 percent watershed imperviousness level over 0.7 inches of rainfall was generally required. In contrast, at a 60 percent imperviouness level less than 0.2 inches of precipitation was needed to produce a comparable temperature change. It should be noted that stormwater inflow generally produced positive stream Delta-T's.

6. Thermal Loading As A Function of Flow Ratio

Results revealed that a linear relationship exists between the positive Delta-T response of the receiving stream and the runoff (Q_{in}) to streamflow (Q_r) ratio. The potential thermal impact of stormwater runoff on receiving streams increased as the ratio of runoff (Q_{in}) to receiving stream flow (Q_r) increased. Not surprisingly, small headwater streams with low baseflow rates are at greatest risk from large inputs of stormwater runoff.

VOL 12 2 4587

R0057880

C. Dissolved Oxygen Monitoring Results

The two-fold purpose of the dissolved oxygen (DO) monitoring portion of the study was to: 1.) determine whether or not the four BMP's and/or their associated discharges were violating MDE water quality standards, and 2.) quantify any "downstream effect" if they in fact existed. As part of its water quality grab sampling effort, COG staff took (at its 55 station network) nearly 800 DO readings. Dissolved oxygen measurements were taken at discrete longitudinal intervals both upstream and downstream of BMP sites, as well as, within each BMP facility. While the majority of these readings were taken during baseflow conditions, approximately 100 were made under the influence of stormwater discharge. Dissolved oxygen monitoring results are summarized in Table 17. A brief general description of the major findings are presented below.

General Findings

Dissolved oxygen concentrations at the 55 sampling stations were normally well-above the state standard for their respective water use class. In general, cold well-aerated streams, such as the Lakemont tributary, had the highest DO concentrations. During the study, the DO levels in these stream areas were frequently at or above 10.0 mg/L. Even relatively warm, heavily urbanized stream reaches such as the Lower White Oak tributary remained well-oxygenated. Much of this is attributable to the excellent aeration/mechanical turbulence associated with the stream's high gradient character. Not surprisingly, DO levels were generally lower below wet BMP

VOL 12 2 4588

R0057881

facilities. This was due to a combination of higher associated water temperatures and higher biochemical oxygen demand (BOD). Average surface DO levels in the Countryside wet pond were an excellent 10.9 mg/L. In addition, because of the generally larger volume of flow, hence higher stream velocity and aeration, no reduction in DO levels were observed under stormflow discharge conditions.

Out of a total of 781 measurements taken, 14 readings (1.8 percent) violated the 6.0 mg/L MDE Class III/IV dissolved oxygen standard. Another 11 readings (representing 1.4 percent of the total) violated the 5.0 mg/L MDE Class I dissolved oxygen standard. As seen in Table 17, 13 out of the 14 Class III/IV violations and 10 out of the 11 Class I violations occurred within the Oaksprings wetland-tributary system. The only other observed MDE Class III/IV violation occurred downstream of the Countryside pond. One MDE Class I violation (DO concentration of 4.2 mg/L) was also recorded immediately upstream of the Tanglewood ED pond's riser.

Oaksprings

Almost half of the observed DO standard violations (12) occurred within the Oaksprings wetland. In addition, the study's lowest DO concentration (3.9 mg/L) was recorded a short distance upstream of the wetland's riser. Throughout the monitoring period, the wetland's average DO levels were consistently lower than those recorded at other sites. The principal causal factor behind this appears to have been the large amount of decaying organic material trapped within the wetland's extensive emergent and submerged aquatic plant beds.

Table 17 Summary: Dissolved Oxygen Monitoring Results
June-October, 1989

LOCATION	STATION NUMBER	MDE Water Use Class	DO(mg/l) MAX	MIN	MEAN	Sample Size	No. of Violations Cl.I std (5.0mg/l)	Cl.III&IV (4.0mg/l)
1)Lakemont Trib.	1	IV	11.8	9.5	10.8	14	0	0
2)a)Oaksprings Inflow	1	III	10.4	4.9	8.5	20	1	1
ED wetland	all	III	12.5	3.9	7.2	48	6	6
outflow	1	III	10.0	5.3	7.6	19	0	2
	2	III	9.5	4.8	7.2	19	1	2
	3	III	8.9	6.8	7.4	20	0	1
	4	III	9.8	3.8	7.4	19	2	1
b)Upper Gum Springs	1A	III	11.8	9.8	10.3	20	0	0
c)Gum Springs	1B	III	13.0	8.9	10.3	20	0	0
	2B	III	11.6	8.2	9.7	13	0	0
	3B	III	11.8	9.1	10.3	19	0	0
	4B	III	11.8	8.1	9.8	19	0	0
	5B	III	11.8	8.7	10.1	19	0	0
d)Lower Gum Springs	1C	III	12.2	8.4	10.3	20	0	0
	2C	III	11.8	9.5	10.5	13	0	0
e)Paint Branch above Gum Springs	3C	III	11.9	9.1	10.4	13	0	0
below Gum Springs	4C	III	12.8	9.3	10.3	13	0	0
3)a)Countryside inflow	1	III	10.8	6.8	9.2	19	0	0
pond	all	III	20.8	6.5	10.9	56	0	0
outflow	1	III	13.5	7.1	9.4	18	0	0
	2	III	9.5	8.2	7.9	17	0	0
	3	III	10.4	5.5	8.1	19	0	1
	4	III	10.4	6.5	8.1	13	0	0
	5	III	11.4	7.1	8.3	13	0	0
	6	III	10.6	6.8	8.6	13	0	0
b)Paint Branch above Countryside	7	III	12.0	9.4	10.2	13	0	0
below Countryside	8	III	11.4	9.1	10.0	13	0	0
