APPENDIX A
FIELD MONITORING PROGRAM

A.1 INTRODUCTION

The field monitoring program was designed to provide data to characterize runoff concentrations and to estimate nonpoint source pollutant loads entering the Lower South Bay from Santa Clara County. Monitoring during storm events was conducted to provide data to calibrate and verify the hydrologic and pollutant simulation model. Hydrological and water quality data associated with base dry-weather streamflows were also collected to estimate dry-weather annual pollutant loads. A secondary objective was to obtain initial information on the toxicity of both storm-related and dry-weather flows in streams entering the Bay.

The field monitoring program utilized three types of stations, as follows:

- Land use stations - Small, relatively homogenous land use catchments were selected to represent major land use categories. Data from these catchments were used as input to the loading model.

- Stream stations - Stations that were located in the lower portions of watersheds and which received a composite of storm runoff waters from multiple land use categories. Stream stations were monitored to provide data to verify the loading model.

- Reservoir stations - Stations located immediately below the water supply reservoirs. These were utilized to provide data to establish upstream background water quality conditions and to estimate loads associated with reservoir releases.

R0054359

The field program can be conveniently described in terms of the following elements:

- The hydrology monitoring element consisted of continuously monitoring flows at stream and land use stations at hourly intervals throughout the duration of the monitoring program in order to estimate the hydrological component of the load.

- Water quality monitoring was conducted in three program elements: wet weather, dry weather, and reservoir release. Wet-weather water quality monitoring consisted of monitoring water quality at land use and stream stations for seven storm events. Storm composite samples were collected. The purpose of this sampling was to provide a basis for estimating pollutant loads during winter storm events. In order to estimate loads during winter base flow periods and summer dry-weather periods, dry-weather water quality monitoring was conducted by obtaining grab samples at the stream stations eight times through the program. To provide information on the water quality of water released from reservoirs, one round of reservoir release water quality monitoring was conducted at six stations immediately downstream of reservoirs.

- Bottom sediment sampling was conducted at the four stream stations. This sampling was conducted quarterly throughout the first year of the study. The purpose of this monitoring was to evaluate the role of bottom sediments as both a source and sink of pollutants associated with nonpoint source runoff.

- The bioassay testing program was designed as an initial screening of toxicity exerted by wet-weather samples obtained from land use and stream stations and dry-weather samples from stream stations.

R0054360

In addition to the above, a number of special studies were conducted to address specific concerns. These studies examined: (1) dissolved oxygen concentrations during storm events at selected stream stations, (2) dissolved metal concentrations in runoff, (3) settling rates of suspended particulates in stormwater collected from stream stations, and (4) concentrations of fecal streptococci bacteria in stormwaters.

A.2 SAMPLING STATIONS

The selection of appropriate sites for the field monitoring program was critical to characterize stormwater runoff pollutants. The following sections discuss the selection criteria and the characteristics of the selected catchments and stations.

A.2.1 Selection Criteria

Specific site selection criteria followed the general guidelines provided by Shelley (1979). Criteria used to select specific monitoring sites were (1) catchment characteristics, (2) hydraulic factors, and (3) accessibility and safety.

Catchment characteristics of primary concern in selection of land use stations were representativeness of land use, overall size of the catchment, and uniformity of land use. In practice, the latter two concerns tend to operate in an opposite fashion, thus constraining the suitability of many catchments for siting of monitoring stations. With increasing size of the catchment, it becomes more unlikely that the requirement for uniformity of land use can be met. In the case of stream stations, it was desirable that the stations be located as far downstream in the watershed as possible, yet upstream of any tidal influences that would adversely affect the rating curve.

Hydraulic factors were important considerations in selection of both land use and stream stations. In the case of open-channel stations, it was

VOL 12 2 1061

R0054361

necessary that each be located at a site with an existing stage-discharge rating or at a site where adequate stage-discharge ratings could be established. Similarly, it was essential that manhole stations have suitable hydraulic characteristics for installation (and calibration) of the weirs. Thus, the following hydraulic factors were important considerations in the site selection process:

- Location at a site with an existing stage-discharge rating or at a site having a suitable control where a reliable rating curve could be developed
- Uniform and stable channel conditions for a distance equal to at least six channel widths upstream of the station
- Lack of tidal influence or backwater effects caused by downstream obstructions
- No evidence of surcharging or submergence over the normal range of precipitation (manhole installations)
- Adequate distance from major tributaries in order to allow for complete mixing

Safety and accessibility were important considerations, primarily to avoid accidents and injury, but also to ensure that field crews felt sufficiently safe so they exercised due care in conducting the field effort. Considerations included avoiding heavily trafficked areas or areas where light and/or visibility created conditions conducive to an accident with passing cars or trucks. Choice of station locations was also influenced by accessibility and security, and wherever possible, stations were located on SCVWD right-of-way which was secured.

VOL 12 2 1062

R0054362

A.2.2 Catchment and Station Characteristics

The following describes the catchment and station characteristics for land use and stream stations. For reference, Table A-1 summarizes general information and Table A-2 gives estimates of the land use mix of each catchment.

A.2.2.1 Land Use Catchments. The land use catchments were selected to represent the following major land use categories: light and heavy industry, commercial, single- and multi-family residential, and open.

Station L1 was a light industrial site located on Junction Avenue. The catchment drains a 22-acre industrial park bordered by Charcot Avenue, Dado Avenue, and Coyote Creek (in San Jose). The station was located in a manhole on Junction Avenue near the Southern Pacific Railroad (SPRR) lines. The storm drain diameter was 30 inches, and a sharp-crested weir was placed in the manhole to facilitate flow measurements. Truck traffic on Junction Avenue was often heavy and on one occasion was sufficient to create vibrations that broke the 10-liter glass bottle in the automatic sampler suspended below the manhole.

Station L2 was a heavy-industrial site on a catchment that drains Walsh Avenue between the SPRR lines and Lafayette Street (in Santa Clara). This 28-acre catchment included warehouse distribution centers involving heavy truck traffic, a used-car parts distributor, a commercial carpet cleaning service, a printing shop, and small miscellaneous manufacturing and office facilities. Initially there was an open drum storage area that was associated with a carpet cleaning facility; however, the drums were found to have been removed on a field reconnaissance conducted on December 5, 1988. The station was located in the right-of-way east of the SPRR lines in a manhole with a 20-inch-diameter storm drain. A weir was installed in the manhole for flow measurements. There was evidence of an illicit discharge at this station in August 1988 that was analyzed and shown to be strongly caustic.

[a] Based on county and city general land use plans as compiled by SCVWD (projections generally ranged between 1989 and 2000), field reconnaissances, and aerial photos.

[b] Does not include areas above upland reservoirs.

[c] Definition of low-, medium-, and high-density residential differed amongst municipalities, but generally was as follows: Low--1 to 5 dwelling units/acre; Medium--6 to 12 dwelling units per acre; High--greater than 12 dwelling units per acre.

[d] Light-industrial land use refers to industrial parks and high technology manufacturing. Heavy industry refers to more traditional manufacturing and distribution centers.

R0054367

Station L3 was a manhole station located at the intersection of Frances and Beamer Streets, north of the Sunnyvale Caltrans Station. The 300-acre catchment represented commercial and single-family residential land use and included the Sunnyvale Town Center and the Caltrans station. The drainage area was approximately bounded by the SPRR lines (north), Mathilde Avenue (west), Bayview Avenue (east), and Olive Avenue (south). A weir was also installed at this station.

Station L4 was located on Hale Creek near Magdalena Road. It drains a 1633-acre, low-density (1-2 dwelling units/acre), single-family residential area in Los Altos Hills. The station corresponded to SCVWD gaging station No. 33, which employs a sloping concrete weir as a hydraulic control for flow measurement.

Land use Station L5 was located on Sunnyvale East Channel at Fremont Avenue. It drains a 2080-acre predominantly single-family residential area. The monitoring station, located in a short earthen reach between Fremont Avenue and Ashbourne Drive, was just upstream of a concrete apron and box culvert which pass under Fremont Avenue. The channel was subject to extensive bank and bottom erosion, especially in the area downstream of the box culvert below Ashbourne Drive.

Station L6 was a 85-acre catchment consisting of a multi-family residential area bounded by Passetta, Williams, and Monroe streets, and Deborah Drive, and a single-family residential area located along Sheraton Drive and El Capitan Avenue. This catchment also included a church and school. The station was located in a manhole near the San Tomas Expressway and the SPRR. The second manhole upstream of the station was located at the junction of Passetta and Williams streets. The storm drain in the manhole was 33 inches in diameter. A weir was installed at this station to better estimate flows.

VOL 12 2 1068

R0054368

Station L7 was on Stevens Creek, just upstream of Camp Castanoan Bridge, above Stevens Creek Reservoir. The 8410-acre drainage area consisted primarily of steep, heavily forested land in the Santa Cruz Mountains.

Station L8 was a second open land use catchment (6464 acres in area) located in the Diablo Range and draining primarily open ranchland. The station corresponded to the SCVWD gaging station No. 57 on Packwood Creek, upstream of Anderson Reservoir.

A.2.2.2 Stream Stations. Four stream stations were selected at locations near the Bay, but above the zone of tidal influence. The purpose of the stream stations was to provide a means of making loading estimates from large catchments solely with measured flow and water quality data. Such estimates could then be used as a check by comparing findings with the model predictions (based on the upstream land use characteristics). The following is a description of the stream stations.

Station S1 was located at the SCVWD gaging station No. 26A, located on Calabazas Creek near Wilcox school. The drainage area is 14 square miles and consists of approximately 80 percent residential/commercial and 20 percent open (Table A-2), the latter of which is located mostly in the upland portions of the catchment in the foothills of the Santa Cruz Mountains. The control is a sloping concrete weir.

Station S2 was located on Sunnyvale East Channel, just upstream of Awhanee Avenue (a frontage road along Bayshore Freeway). This catchment has an area of 5.2 square miles and is wholly urbanized, consisting of residential (68 percent) and commercial (32 percent) land use on the valley floor. The station corresponds to the SCVWD gaging station No. 74. The control is a sloping concrete weir.

VOL 12 2 1069

R0054369

VOL 12 2 1070

These two stations were selected to be representative of the smaller more urbanized watersheds on the west side of the Study Area.

Station S3 was the USGS station No. 1119000 on the Guadalupe River, located downstream of the confluence with Los Gatos Creek. This station has a total drainage area of 146 square miles and includes Los Gatos Creek and Lexington Reservoir, Guadalupe Creek and Guadalupe Reservoir, Ross Creek, Alamitos Creek and Almaden Reservoir, and Calero Creek and Calero Reservoir. This station was selected because it drains a large urbanized area that is accurately gaged. The area of the catchment below the reservoirs is approximately 85 square miles. The land use in this area is 30 percent open, 61 percent residential, 5 percent commercial, and 4 percent industrial (Table A-2).

Station S4 was located on Coyote Creek at Montague Expressway at the SCVWD high-flow gaging station No. 2060. This catchment includes Upper Penitencia and Silver and Thompson creeks, and Anderson and Coyote reservoirs. The catchment area below Anderson Reservoir is approximately 120 square miles, 64 percent of which is open ranch land located in the foothills of the Diablo Range. The remaining land use consists of 30 percent residential, 1 percent commercial, and 5 percent industrial (Table A-2). The SCVWD gaging station at this location was designed to record only flood stages, so this station had to be rated for more typical lower storm-event flows.

A.2.2.3 Reservoir Stations. The reservoir stations were located at SCVWD gaging stations below Stevens Creek, Lexington, Guadalupe, Almaden, Calero, and Anderson Reservoirs (Table A-1).

R0054370

VOL 12 2 1071

A.3 SAMPLING AND ANALYSIS PROGRAM

A.3.1 Hydrology

The field study was designed to collect accurate hydrological information at each station to quantify discharges throughout the year and to collect flow-weighted composite samples. Thus, monitoring of stage (water depth) was performed continuously throughout the year, at all stations that had year-round flow.

The majority of open-channel stations were located at sites which had previously-established stage-discharge curves. Two of the open-channel stations (L5 and L7) required establishment of new stage-discharge curves. A third station (S4) required establishment of the low-flow portion of the rating curve.

Flow ratings at all four manhole installations were initially calculated using a standard weir-rating formula. These ratings were later calibrated at manhole installations L2, L3, and L6 using dye-dilution methods.

A.3.2 Water Quality

Water quality constituents included in the field monitoring program were selected based on the following factors:

- Constituents previously identified to be a major concern in Lower South Bay and its tributaries
- Constituents previously identified as prevalent in urban runoff studies conducted as part of EPA's National Urban Runoff Program
- Pollutants expected to be present in surface runoff waters from the Study Area, based upon industrial sources, or other specific local knowledge

R0054371

- Pollutants identified historically in nonpoint source runoff samples collected within the Study Area

The overall approach of the water quality studies was to examine a wide range (or "full suite") of potential pollutants in the early phases of the study and then develop a more refined list (or "reduced suite") of pollutants based upon results of the initial surveys (Table A-3). One analysis, organophosphate pesticides, was added to the reduced suite but was later eliminated, because none were detected.

A.3.3 Sediment Quality

The overall approach and list of sediment quality constituents (Table A-4) were similar to those described for the water quality testing program. The primary difference in the sediment quality program was that the reduced suite of constituents was originally expected to retain the broader scan of organic contaminants provided by the semi-volatile (EPA 625) GC/MS analysis. It was originally expected that a number of priority pollutant compounds would be detected in sediments, due to their low solubilities and their tendency to associate with fine particles. Due to low levels of these compounds detected, the final suite of constituents focused more directly on polynuclear aromatic hydrocarbons (PNA) that are produced as by-products of internal combustion engines.

Organophosphate pesticides were analyzed in the sediments on only one occasion. Since none were detected in the samples, this group of compounds was not included in later analyses.

A.4 SCHEDULE

The field monitoring program was initiated in February 1988 and completed in April 1989. Figure A-1 shows the schedule and Table A-5 gives specific sampling dates. A single survey was conducted to assess the quality of water discharged from six major reservoirs in the Santa Clara

Valley. The reservoir water quality survey was conducted on February 26, 1988, concurrently with the first dry-weather water quality survey.

A total of seven dry-weather water quality surveys were conducted during the 15-month field program. Four of these studies were conducted during winter months, two during the spring, and one in the autumn following a lengthy dry period.

Seven wet-weather (i.e., storm) events were sampled to obtain water quality data. The first and only storm event sampled in the 1987-88 wet-weather season occurred on April 20, 1988. The six remaining storm events that were sampled occurred in the 1988-89 wet-weather season. The first significant rainfall of the 1988-89 wet-weather season was sampled on November 23, 1988. The remaining five storm events monitored were in January, February, and March 1989.

Three wet-weather toxicity tests were conducted in February and March 1989. Dry-weather toxicity testing was coordinated with the December 12, 1988, and the February 1 and April 6, 1989, dry-weather water quality surveys.

The sediment sampling was fully completed during the first year of the study. The final quarterly sediment survey was completed on December 12, 1988.

A number of other program elements classified as "special studies" were completed in association with storm events sampled in early 1989. Detailed monitoring of dissolved-oxygen levels was performed at the four stream stations on February 9. Concentrations of dissolved metals were added to the suite of constituents measured in storm runoff during the March 25 and April 6 storm events. Experiments on settling rates of suspended particulates were conducted on samples collected on May 25. A special survey of concentrations of fecal streptococci bacteria was conducted in association with the January 23 storm event.

A.5 EQUIPMENT

A.5.1 Station Design

Two generalized station designs were employed in the field study. The most common design was for monitoring flow and water quality in open channels. This configuration varied slightly among the several stations, depending upon specific site characteristics. The second type of station was designed for monitoring flow and water quality within storm sewers.

The following design considerations were common to both station configurations:

- Intakes must be protected from large objects transported by the stormwater runoff.
- Intakes must be located in a well mixed area not subject to burial or emergence.
- Water velocity in the intake hose during sampling must be maximized to maintain particulate material in suspension.
- Intake hose material must be appropriate to avoid metals and organic contamination of samples.
- Sample container material must be compatible with holding samples to be analyzed for both trace metals and organic compounds.
- The peristaltic pumps must be capable of delivering consistent sample volumes, regardless of intake hose length and changes in head associated with the rise and fall of stage in the water body being sampled.

R0054378

- Automatic samplers should not exceed a head difference of 20 feet above the water in order to prevent deterioration in water velocities within the intake and decreasing precision in sample volume.

All intakes were placed in cages constructed of quarter-inch stainless rod. These cages were designed to deflect moderate-sized objects around the intakes and the pressure sensors. Coarse stainless steel intake screens were used to reduce the likelihood of blockage within the sample tubing.

In most installations, intakes were positioned between 2 and 4 inches above the bottom, as recommended by Shelley (1979). This range was believed to be a reasonable compromise between avoidance of bedload transport and keeping the intake submerged. When base flow conditions allowed, the intake was positioned higher in the water column. For example, the base stage in Coyote Creek was typically around 3 feet, so the intake at this station was positioned 1.5 feet off the bottom.

The 3/8-inch (i.d.) intake hose was constructed of polyethylene on the outside and Teflon on the inside. The polyethylene provided the required physical strength while the Teflon provided a suitable material for handling samples which would be analyzed for either metals or organic compounds. The bore diameter of the intake hose was selected to maximize the velocity of flow within the hose (in order to prevent settling of suspended solids). An internal diameter of 3/8 inch was calculated to maintain the minimum velocities of 1 to 2 fps at head differences of up to 20 feet.

Consistent sample volumes were obtained over a wide range of head differences by development and use of an algorithm which could compensate for changes in head pressures. This algorithm was part of the specialized software developed to control the automatic samplers. The number of pump

VOL 12 2 1079

R0054379

rotations necessary to obtain a sample volume of 500 ml was calculated as a function of intake hose length and an instantaneous measure of head pressure between the pump and surface of the water. This value could be calibrated in the field to compensate for specific station configurations.

The composite sample containers provided commercially by ISCO were inappropriate for collection of water for analysis of both trace metals and organic compounds. Borosilicate glass provided the best alternative for collection of water to be submitted for metals and organics. Thus 10-liter, borosilicate media bottles were used to replace the standard containers.

Although the open-channel and manhole installations shared common design criteria, the manhole installations were unique in that they required installation of a primary control device to increase accuracy of flow measurements, particularly at lower flows. Rectangular sharp-crested weirs were used, because they were found to be the most cost-effective primary control device to fabricate and install in this application.

A.5.2 Weirs

All weirs utilized in the manhole installations were rectangular weirs made from quarter-inch steel plate. The heights of the weirs were generally about one-half the diameter of each pipe. A rectangular cutout with a width equal to one-quarter of the pipe diameter and a depth equal to one-sixth of the diameter was placed in the center top portion of the weir to facilitate accurate measurement of lower flows (see Figure A-2).

Each weir was secured by stainless steel cable to eyebolts set in the wall of the manhole. This both prevented the weirs from becoming lodged in the pipe if they were to break loose during a storm event, and it allowed for quick removal of the weirs, if upstream flooding were to occur. Hoses were attached to the back of the weirs to aerate the nappe.

A.5.3 Automatic Samplers and Stage Recorders

Automatic samplers and stage recorders were deployed in all of the open-channel and manhole installations. Each system consisted of an ISCO Model 2700 composite sampler, a Campbell Scientific Model CR-10 Data Logger and Control Module, and a pressure sensor. GeoKon Model AVW-1 Vibrating Wire pressure/temperature sensors were initially installed at all stations. These sensors were selected for the study on the basis of their extreme durability and accuracy. Nevertheless, a number of these sensors were observed to drift out of specifications in the early stages of the study. These sensors were then replaced with the newly available Druck Model PDCR-830 titanium pressure sensors. These Druck sensors proved to have both excellent accuracy and stability characteristics under a variety of field conditions.

The ISCO composite samplers were used to pump, cool, and store water samples during storm events. The standard programmable read-only memory (PROM) units which contain the instruction set for the samplers were specially modified to allow full external control via the sampler's flowmeter input data port. All pumping functions could then be controlled externally by the Campbell Scientific CR-10.

A.5.4 Data Logger

Campbell Scientific CR-10s were used at each station to provide overall system control functions and to serve as a central data processor and data storage module. Two types of data, high-resolution storm data and continuous (dry- and wet-weather) hydrology data, were recorded by the data logger. Data were nondestructively retrieved by use of a standard, portable tape deck. The tapes were then read by an IBM-compatible microcomputer with a Campbell Scientific PC-201 card. If the data dump was defective, the station could be revisited and the data retrieved again.

The storm data memory register stored detailed information on the storm events, including the time the storm mode was initiated, the time each

VOL 12 2 1082

R0054382

sample was taken, and the storm runoff volume represented by each sample. After completely filling a 10-liter sample container, 15-minute-averaged values for temperature, stage, and flow were stored in the storm memory register until the station was visited by the field crews to change sample containers.

The continuous hydrology memory register maintained hourly-averaged temperature and stage data. These data were continuously recorded during storm events and base flow conditions.

A.5.5 Software to Initiate and Terminate Flow Composite Sampling

Software installed in each CR-10 was designed to continuously monitor stage at each monitoring station and then automatically initiate flow-weighted composite sampling. Pressure sensors were interrogated every 15 seconds to determine stage. Fifteen-minute averages of the stage data were then stored and later used to evaluate whether storm sampling should be initiated.

The software enabled storm sampling to be initiated, based upon both relative and absolute criteria. At the end of every 15-minute interval, stage or flow data (using stage-discharge equations) were compared to those obtained during the prior 15-minute interval. Storm sampling was initiated, if percentage increases in one of these parameters exceeded a given criterion, typically 20 percent. This criterion could be modified to adjust sensitivity of the "trigger," based upon the specific hydrological characteristics of each station.

In addition to comparing relative increases in either stage or flow, storm sampling could be automatically initiated if the 15-minute average stage measurement exceeded a set value. This trigger was particularly useful for stations that, under certain conditions, did not increase rapidly enough in stage to exceed the relative criteria or where no base flows were present.

VOL 12 2 1083

R0054383

Flow-weighted composite sampling could also be terminated by software control of the system. The data loggers were programmed to terminate the storm sampling mode once the stage dropped below a level 20 percent greater than the storm initiation or trigger stage. Sampling would not terminate automatically without first filling a sample container.

A.5.6 Equipment and Installation

Instrumentation for all open channel installations was contained in custom-built 2-ft x 4-ft x 30-inch steel enclosures mounted on concrete pads. In natural channels, conduits for containment of pressure sensor leads and water intake tubing were installed through the concrete pad and led underground to the channel. In some cases, a short conduit (approximately 0.5 to 1.0 feet) was installed between the instrument enclosure and adjacent stilling wells. The pressure sensor could then be installed in the stilling well where it was well protected from potential vandalism. For installations where both stilling wells and concrete channels existed, both the pressure transducer and intake hose were run into the stilling well. The intake tubing was then fished through the lower communication port and mounted at the bottom of the channel.

Each storm sewer installation was completely contained within the existing manhole chambers. All equipment was suspended by metal cable slings from eyebolts installed in the concrete wall just under the manhole cover. A two-person field crew was required to conduct routine monitoring involving removal of the sampling equipment from the manhole. Data dumps and routine monitoring of station operation could be performed by one person, since the systems communication port was located immediately below the manhole cover.

VOL 12 2 1084

R0054384

A.6 SAMPLING METHODS

A.6.1 Field Procedures and Training

A detailed set of Standard Operating Procedures (SOP) were developed for all phases of the field monitoring program. The SOP contained the following procedural instructions:

- Standard Observations
- Initial setup of the composite samplers
- Storm monitoring station software initiation
- Battery replacement
- Data retrieval
- Sample removal and handling
- Grab sampling
- Sample transfer and tracking

Field training sessions were held prior to each storm season for personnel expected to participate in storm monitoring. The training sessions involved review of the SOP and hands-on experience in interrogating a model storm monitoring station.

Additional training was provided in the field during station maintenance visits. Less experienced field personnel were routinely deployed with key project personnel. This enabled greater dissemination of important station-specific knowledge (e.g., location and special handling needs) and provided an opportunity to practice station interrogation skills that would be needed during the intensive storm monitoring events.

A.6.2 Grab Samples

Grab samples were taken for all water samples that were not appropriate for analysis from the pumped composite sample. Grab samples were necessary for bacteria, volatile organics, pH, and dissolved oxygen.

VOL 12 2 1085

R0054385

Two methods were used to obtain grab samples of water. The primary method involved direct collection of the water sample in the sample container. The open container was attached to a stainless steel rod. This enabled the open container to be fully immersed as near as possible to the centroid of flow and eliminated potential contamination of the sample. This method was applied to samples collected for bacteria, volatile organics, and pH. Van Dorn (1.5-liter) bottle samplers were used for collection of samples for measurement of dissolved oxygen.

The guidelines followed by Kinnetic Laboratories field personnel for grab sampling during storm events calls for collection of samples in the early phase of the storm, certainly during the rising limb of the hydrograph. Most of the grab samples collected in this program were performed in the early phase of the storm.

Sediment grab samples were collected either by use of clean stainless steel scoops or by scraping the sediments directly into the sample containers. Four to five different scrapes were taken to comprise a single sample. A conscious effort was made to sample finer-grained sediments in depositional areas of the stream bed. In several cases, appropriate sediments were difficult to locate. In such cases, professional judgement was used to locate the most appropriate sediments along a given reach.

A.6.3 Automatic Samplers

Sampling of stormwater runoff was accomplished primarily by use of modified ISCO composite samplers. The automatic samplers were designed to take 500-ml aliquots of runoff water at time intervals corresponding to a given volume of water flowing by the monitoring station. The volume of runoff represented by each 500-ml sample was a user-specified value. The default setting for each site was 1/20 of the expected runoff volume for a 0.25-inch storm. The sampling rate at a given station could be altered in the field by increasing or decreasing this value. It was necessary to adjust this variable based upon both sample volume requirements (e.g.,

VOL 12 2 1086

R0054386

VOL 12 2 1087

additional analytical and bioassay water requirements) and anticipated rainfall in excess of 0.25 inches.

The percentage of the total storm represented by each composite sample varied widely among storm events and stations (Table A-6). The precipitation, runoff, and required sample volumes were important factors in determining the percentage of the storm from which flow-weighted composites were attained. After depositing 19 samples (9.5 liters) into the composite sample container, the monitoring system would go into standby mode until visited by the field crew. High sampling rates or brief, intense periods of rainfall occasionally caused the composite samplers to fill too rapidly and enter the standby mode. This would cause loss of storm coverage until the station was revisited by the field crew. Low sampling rates or lower than anticipated rainfall would result in good storm coverage but inadequate sample volumes.

A.6.4 Effects of Partial Storm Capture on Load Estimates

In the field monitoring efforts, it was not always possible to secure samples over the entire runoff period, for use in the flow-weighted composites that were analyzed. In some cases, this was due to the inability of field crews to reach all stations before runoff began. In most cases, it resulted from the sample collection container filling before runoff from the event had terminated. A record was maintained of the fraction of the total runoff volume that was sampled and incorporated in the samples for water quality analysis. This information is summarized in Table A-6 which lists, for each event at each station, the ratio of the sampled volume to the total volume of runoff.

As the listing indicates, the storm fraction sampled varied from event to event at any site, and the pattern was not consistent from site to site for a specific storm event. Fifty-seven (57) of a possible 70 station-events produced composite samples that were analyzed for water quality. Four station-events were missed due to equipment malfunction (SM). The

R0054387

a The ratio of the volume sampled to the total volume of runoff is the percentage of the runoff sampled.

b Samples were not obtained at Station L8 because of lack of runoff; samples were obtained at Station L7, but the rating curve was affected by downstream activities.

c The percent sampled was considered too small for the data to be considered representative.

NS Not sampled (often because of lack of runoff).

SM Sampling equipment malfunctioned.

* Volume sampled did not include the storm peak.

VOL 12 2 1088

R0054388

remaining nine (NS) produced no water quality samples, often due to lack of runoff.

An evaluation of the potential effect of the percentage of an event sampled on the estimate of the site median concentration (SMC) which was used in developing pollutant load estimates was structured on the basis of the following considerations.

- The data set as a whole covers a wide range of sampled fractions, and a significant spread in percent sampled also applies generally to individual stations.
- The quality data exhibit significant variability, with each station having a different mean or median.
- Concentrations of different pollutants have different orders of magnitude.
- Working separately with individual pollutants at individual sites provides too small a sample for reliable analysis.

To evaluate the effect of the fraction of the storm sampled, each EMC (event mean concentration for the site-event for each pollutant) was first normalized by computing the ratio of the individual concentration value to the SMC for the corresponding pollutant and site. Individual EMCs are tabulated in the Volume I Appendix document. The SMC values used are those presented in report Tables 6-2 and 6-3. Pollutants used in this analysis were those for which nearly all measurements were above detection limits. This set included six metals (Cd, Cr, Cu, Pb, Ni and Zn), plus TSS, BOD and Total Hardness (TH), to have several different basic pollutant types represented. The normalization procedure reduced all the data to a common basis, and provides a sample size of about 500 values for analysis.

VOL 12 2 1089

R0054389

A comparison of the normalized pollutant concentrations in relation to the percentage of the storm event that was sampled is displayed by Figure A-3 for the Land Use Sites, and by Figure A-4 for the Stream Stations.

Pollutant concentrations for the Land Use Sites provided the primary basis for the load estimates. A good basis for comparison exists here, because 42 percent of the site-events captured 90 to 100 percent of the runoff (65 percent captured more than 70 percent). The display indicates that the variability in measured concentrations of the nine different pollutants is unrelated to the fraction of total runoff volume captured. There are a small number of individual values that deviate substantially from the median, but the bulk of the results (all pollutants, all sites, all percent captures) fall into a relatively narrow band either side of the site median (Ratio = 1). Note that each SMC reflects a series of events with an appreciable range of percent captures.

On this basis, we conclude that the pollutant site median concentrations, which provided the principal basis for load estimates, are not distorted by the lower percentages of total runoff that were sampled for some events. This situation, therefore, has not influenced the load estimates that were developed.

Results for the Stream Stations are generally similar, but with the difference that less than 10 percent of the values apply to events where more than 90 percent of the runoff was captured. For these stations, 85 percent of the values apply to events which captured between 30 and 70 percent of the storm flow. There is no trend indicated either within this range, or compared with the limited data at 100 percent runoff capture. The single set at 3 percent capture (event 3 at station S-1) would be appropriate to exclude, although this single set of values will not have a significant effect on the overall study results.

R0054390

VOL 12 2 1090

Fig. A-3. Effect of Percentage of Total Storm Sampled on Event Mean Concentration Land Use Sites

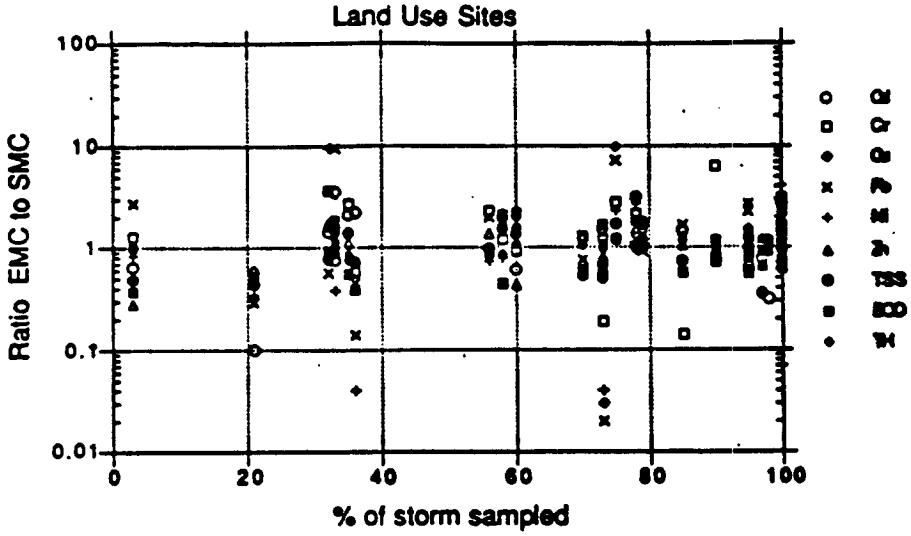

Fig. A-4. Effect of Percentage of Storm Sampled on Event Mean Concentration Stream Stations

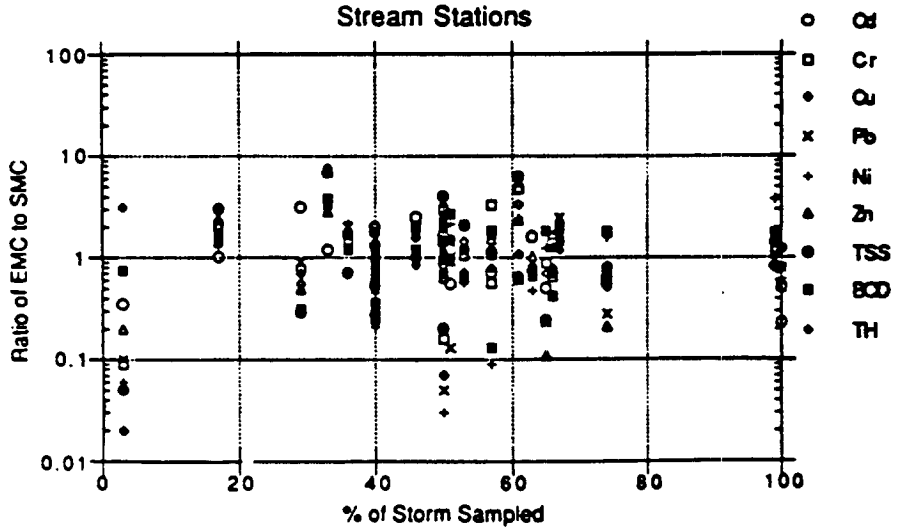

VOL 12 2 1091

R0054391

The stream concentrations were utilized in the study for comparison with projected in-stream concentrations computed from the land use runoff. The differences (measured concentrations were consistently greater than projections based on land runoff) provided the basis for a correction factor. The variation in percent capture of event runoff is not indicated to influence estimates of stream concentrations. However, because the bulk of this data is based on 30 to 70 percent capture of the total event values, there is a somewhat greater uncertainty in the concentration estimates for the Stream Stations, than is the case for the Land Use Sites.

A.6.5 Flow-Rating

Development of new stage-discharge relationships was required at three open channel stations and three manhole stations. In manhole stations, rectangular notched weirs were installed. Flow was then estimated based on the theoretical sharp-crested contracted weir equation (ISCO 1979):

$$Q = 3.33\ (L - 0.2H)H^{1.5}$$

where

Q = flow (cfs)
L = width of the weir crest (ft)
H = stage (feet)

This equation was verified by performing low-flow dye dilution measurements at the manhole stations. These tests indicated that some calibration of the weir equation was required for flow within the weir notch at stations L2 and L3. As a result, the following rating curves were used for low flows in these weirs:

$$Q = 1.73H^{.85} \text{ (Station L2)}$$
$$Q = 1.83H^{1.79} \text{ (Station L3)}$$

VOL 12 2 1092

R0054392

Rating curves for stations L5, L7, and S4 were developed from discharge measurements. Rating curves were developed only for low flows at station S4, since a high flow rating curve had previously been developed by the SCVWD. Figures A-5, A-6, and A-7 show the rating curves for these three stations. Discharge measurements for these stations were generally good. For station S4, the rating curve was developed from 10 flow measurements, and a good fit was obtained to these data. However, the rating curves for stations L5 and L7 are at best of fair quality, given the low number (three) of discharge measurements used at each station.

Current-meter surveys were conducted to develop stage-discharge data at the three open-channel stations. Discharge methods were made using standard USGS methods (USGS 1970). It was desired that at least six discharge measurements be taken over a full range of stages in order to obtain reliable rating information at each site.

Dye-dilution methods were used to verify weir equations at three of the four manhole stations. (At these stations, provisions for a water supply could be arranged with the local water supplier.) Intra-acid Rhodamine WT was used as the tracer. Rhodamine WT is a nontoxic, fluorescent tracer dye that is commonly used in applications such as this. This dye is stable and is not easily adsorbed to particulates.

Flow was established at each station by use of upstream fire hydrants. Dye of a known concentration was injected into the turbulent flow at an upstream manhole by use of FMI constant displacement piston pumps. Stage, temperature, and dye concentration were then measured just upstream of the weir at the subject station. Periodic water samples were obtained for later laboratory verification of dye concentrations in order to provide backup to the field fluorometer and to make certain that concentrations were in the linear response range of the fluorometer. Due to the limited flow capacity of fire hydrants, verification of the theoretical weir equations was only possible for low-flow conditions.

VOL 12 2 1093

VOL 12 2 1095

R0054395

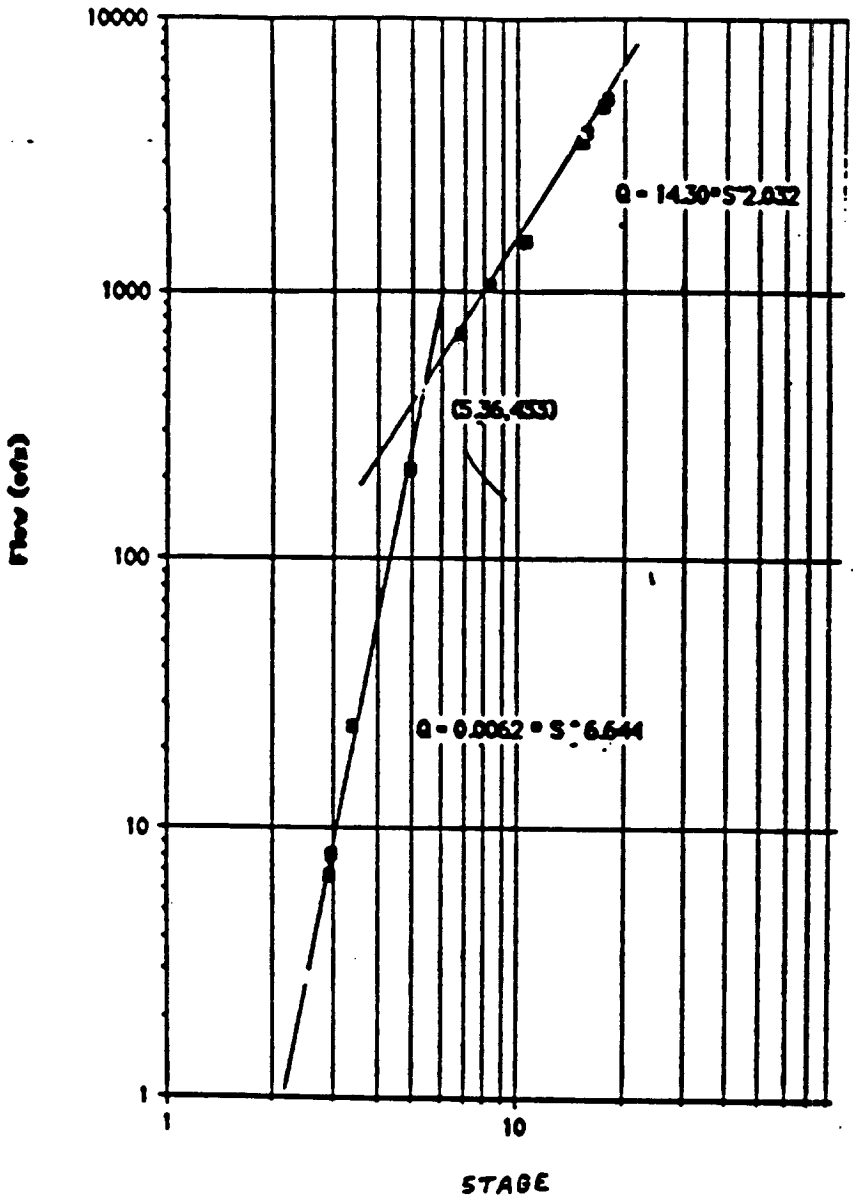

Figure A-7. Rating Curve for Station S4

VOL 12 2 1096

R0054396

A modification of the channel occurred at one station, L7 (Stevens Creek at Camp Castanoan Bridge), midway through the study. That alteration required establishment of a second rating curve. A small rock dam was constructed just below the station in order to enhance the water supply system for Camp Castanoan. This dam was breached during a storm in early March, at which time the initial flow rating was reinstated.

A.6.6 Special Studies - Dissolved Oxygen

Many of the previous studies involving nonpoint source water quality have been concerned about depression of dissolved oxygen levels in the receiving waters. A single intensive study was conducted at each of the four stream stations to measure dissolved oxygen concentrations during and after stormwater discharges.

Dissolved oxygen was measured for a period of approximately 35 hours using duplicate Winkler titrations in lieu of polarographic membrane probe techniques. The titrations provide a much more accurate estimate of dissolved oxygen, particularly in the presence of oil and grease. Polarographic oxygen probes can become rapidly desensitized if contaminated with oil and grease.

Dissolved oxygen results did not show any signs of depression for all four stations studied. The DO results are summarized here and shown in Appendix D.8. For station S-1, DO ranged from 8.9 to 11.8 mg/L, and DO levels ranged from 8.6 to 12.2 for station S-2. The DO concentrations were similar for stations S-3 (9.7 to 10.4 mg/L) and S-4 (8.5 to 9.6 mg/L).

A.6.7 Special Studies - Dissolved Metals

Two sampling rounds were conducted to evaluate the relative contributions of dissolved metals and particulate-associated metals in stormwater runoff. Both dissolved and total metal concentrations were measured in all stormwater samples obtained during each storm event.

VOL 12 2 1097

R0054397

VOL 12 2 1098

Dissolved metal samples were subsampled from the composite storm samples in the same manner as the total metal samples. Prior to fixation, the dissolved metal samples were filtered through 0.45-micron polycarbonate filters. The filtrate was subsequently acidified with HNO_3 to a pH of less than 2.

A.6.8 Special Studies - Settling Column Tests

A preliminary screening of the settling characteristics of particulates present in the NPS discharges from the study area was made by conducting settling tests on samples taken from each of the stream stations (S-1, S-2, S-3, and S-4) during the storm runoff event in March 1989.

This effort was designed to provide information on settleability, for reference and potential use in the consideration of issues such as detention basin controls, sediment accumulation and scour in stream beds, and pollutant accumulations in bay sediments.

Because of the nature of the test procedure and the variability expected of particle size distributions in stormwater runoff, the results obtained should only be considered to provide a general approximation of the settling characteristics of particulates that are introduced to the South San Francisco Bay by nonpoint sources in the study area.

The tests were performed using a settling column constructed from an 8-inch in diameter by 5-foot, 1-inch-long lucite tube. Four sample ports are located at 1-foot intervals.

The column is filled to the top with a sample of the water to be tested, and then stirred to distribute the settleable solids uniformly throughout the column.

R0054398

A sample at time zero is analyzed to establish initial conditions. Total suspended solids (TSS) was selected as the pollutant analyzed for these tests.

Samples are then withdrawn from each port at selected time intervals after the start of the test. They are analyzed to determine the concentration of TSS that remains at the sample location after the elapsed time interval.

The difference between each such concentration and the amount present initially is used to compute a percent removal.

Since each combination of depth to a sample port and elapsed time to the sample reflects a specific distance settled in a specific interval of time, each sample corresponds to a settling velocity (feet per hour). Each such value corresponds to a percent removed value computed from the measured concentration.

The results can be interpreted as the percentage of the TSS in the sample that have settling velocities equal to or greater than the value represented by the port depth and sample time. The results are then plotted to provide an indication of the frequency distribution of pollutant settling velocities in the sample.

Test results are summarized in Table A-7. This table lists both the measured concentration and also the percentage of the initial concentration that each value represents. It also lists the set of settling velocities (in feet per hour) that are computed from the various combinations of depth and sample time. Note that the combinations employed result in multiple measurements for some settling velocities. In the table, the settling velocities are listed in increasing rank order, and for each of these the corresponding removal percentage is tabulated for each of the four samples.

R0054402

Each of the samples shows a difference in particle sizes, reflected by the median settling velocities for the test, which range between 0.15 and 0.45 ft/hr. Because of the variability and the nature of the test, it would be inappropriate at this point to simply observe that the stream samples tested indicate a median settling velocity on the order of approximately 0.25 ft/hr, and having a distribution approximately as shown by Figure A-9.

These results are compared with the results of similar tests reported in other studies in Figure A-10. The principal indication is that the particulates in the Santa Clara wet weather stream samples are appreciably smaller in size (lower settling velocities) than those measured in direct runoff from urban or highway sites. This type of relationship can be expected if one considers that most of the bigger particles will have settled out rapidly in the stream, and as a result do not show up in these samples.

A.6.9 Special Studies - Fecal Streptococci

Analysis of fecal streptococci, together with fecal coliform, provide insight on possible sources of fecal contamination. Ratios of fecal coliform to fecal streptococci provide some indication as to whether the contamination was of human or nonhuman origin. Ratios in excess of 4.1 are sometimes considered to be primarily of human origin, whereas ratios less than 0.7 are considered to be of nonhuman origin. Ratios between 0.7 and 4.1 may be indicative of mixed human and nonhuman fecal contamination (Standard Methods 1980).

A survey of fecal streptococci and coliform bacteria was conducted at the four stream sites in order to assess possible sources of fecal contamination in nonpoint source runoff during storm events. Grab samples were taken at stream sites S1 through S4 during the third Wet-Weather Water Quality event in January 23, 1989. The analyses for both types of bacteria were conducted in accordance with Standard Methods for the Examination of Water and Wastewater (1980).

VOL 12 2 1103

R0054403

VOL 12 2 1104

Results of the fecal streptococci are presented in Appendix D.2-1. Ratios of fecal coliform to fecal streptococci show values ranging from about 1 (S3 and S4) to 10 (S1 and S2).

A.6.10 Subsampling Procedures, Sample Containers, and Preservatives

The 10-liter composite samples collected from the autosamplers during storm events were sealed with Teflon-lined polyethylene caps, packed in ice, and transported to Kinnetic Laboratories, Inc., in Santa Cruz for further processing. When multiple 10-liter bottles were collected for a single station, it was first necessary to thoroughly blend the samples. Blending of the composite samples was accomplished by use of a peristaltic pump and Teflon hose.

The peristaltic pump was also used to draw samples for each set of analyses. Samples for each analyses were placed in prelabeled containers with appropriate preservatives (see Table A-9). Whenever possible, analyses requiring common containers and preservation were placed in the same container in order to minimize sample handling.

Grab samples for analysis of sediment were placed directly into appropriate sample containers (see Table A-10). In most situations, common containers were used for collection and holding of sediments to be analyzed for (1) trace metals and inorganics and (2) volatile and semi-volatile organics. Single containers were utilized for organochlorine pesticides, chlorinated herbicides, and polynuclear aromatic hydrocarbons.

A.6.11 Field QA/QC

Several external or field quality control procedures were used to evaluate potential errors which could have been introduced during sample collection and subsequent analytical procedures. These external quality control checks were performed by blind submission of blanks and duplicates.

Blanks used in the field QA/QC procedures consisted of both field blanks and trip blanks. Field blanks were used to assess errors due to bottle contamination and field sampling procedures. Field blanks were obtained by sampling contaminant-free waters (furnished by the laboratory) using procedures identical to those used for collection of field samples. The field blanks for samples taken from the composite samplers were obtained by pumping contaminant-free waters into sample containers. This same procedure was used to extract field samples from the composite sample. Field blanks for grab samples were obtained by pouring blank water into a sample container. Trip blanks were utilized to assess potential contamination from both sample containers and coolers used for sample transportation. These blanks consisted of contaminant-free water provided in a standard sample container by the laboratory. These blanks remained unopened in the coolers and were returned to the laboratory for analysis.

Field duplicates were utilized to evaluate data precision. Analysis of these types of control samples provide a measure of the variability due to natural factors in the water body, sampling procedures and analytical procedures. Field duplicates were collected in the same manner as the primary samples and submitted blind to the laboratory.

A third quality control check conducted as part of the field program was quarterly analysis of external spike samples. Samples containing certified levels of contaminants were purchased from ERA laboratories in Colorado and the National Bureau of Standards (PNAs only). These samples were received by the project QA/QC officer. The QA/QC officer then removed certification information and submitted the samples to each laboratory under chain-of-custody.

R0054412

A.7.2 Laboratory QA/QC

Laboratory procedures used to monitor bias and precision in analytical measurements included the following:

- Use of full-range internal calibration standards
- Analysis of laboratory blank water for every 10 samples analyzed by each methodology
- Analysis of a laboratory spike for every 10 samples
- Laboratory splits on 10 percent of the field samples submitted to the laboratory

Spikes were intended to evaluate the overall accuracy of the data set. Although spiking of either field samples or contaminant-free blank water was permitted by the project QA/QC plan, all spikes were performed using field samples in order to account for possible matrix interferences.

The laboratory blanks were conducted as part of each participating laboratories quality assurance plans. These blanks provided a measure of potential sources of contamination to the samples.

Laboratory splits were utilized to evaluate the precision of the analytical measurements. The duplicate data were used to calculate relative percent difference (RPD) values for each constituent. Upper and lower control limits based upon 95 percent confidence limits of historical laboratory splits were used to evaluate analytical precision and acceptability of the data.

VOL 12 2 113

R0054413

A.8 DATA MANAGEMENT

Hardcopies of analytical chemistry results received from each contract laboratory were entered into a spreadsheet database using Lotus 1-2-3. Separate spreadsheets were maintained for each major chemical analysis (e.g., PNAs, organochlorine pesticides) or class of analyses (e.g., physical data-TSS, pH).

Each spreadsheet contained information on the type of sample (e.g., dry-weather, wet-weather), station identification, a sequential event number, date of sampling, analytical laboratory sample identifier, and target detection limits for each analyte. Reported values and actual detection limit on the laboratory report were recorded for each analyte.

Copies of the individual laboratory reports (hardcopy), chain-of-custody documents, and the complete Lotus 1-2-3 database were provided to Woodward-Clyde Consultants by Kinnetic Laboratories, Inc.

HYDROLOGIC MODEL CALIBRATION AND VERIFICATION

R0054416

VOL 12 2

APPENDIX B
HYDROLOGIC MODEL CALIBRATION AND VERIFICATION

Stormwater quality loads for 11 watersheds were estimated by first determining the loads from each land use in each watershed, and then summing loads from all land uses to produce loads to the bay. Because land use loads were calculated as the product of flow volume and concentration, this methodology required estimates of 1) the volume of runoff from each land use category, and 2) the average concentration of pollutants from each land use category.

This Appendix describes the procedures used to estimate flow volumes. Section B.1 provides an overview of the Stormwater Management Model (SWMM), the rainfall-runoff model used to estimate flow volumes. Section B.2 describes the model setup for the Santa Clara Valley, Section B.3 discusses model calibration and verification, and Section B.4 presents estimates of stormwater runoff volumes for the Santa Clara Valley.

B.1 OVERVIEW OF SWMM

The review of hydrologic data presented in Section 5.0 provides insight into the historical magnitude and variability of rainfall and runoff in the Santa Clara Valley. However, to estimate nonpoint source loads, knowledge of the sources of storm runoff is required. Runoff from undeveloped areas will differ in terms of water quality from runoff in urban areas on the valley floor, and little can be learned about the apportionment of runoff between developed and undeveloped areas through analysis of existing streamflow records alone. Unless one is willing to install and operate many more stream gages for several years, the preferred way to estimate

R0054417

VOL 12 2 1 1 1 8

runoff from individual land uses and from ungaged areas is by using a rainfall-runoff model.

Rainfall-runoff models use physical and land use information about a catchment to calculate storm runoff from a given rainfall record. Rainfall-runoff models vary in complexity from relatively simple models such as the Rational Method (Linsley et al. 1982), to models which attempt to represent in detail the physical mechanisms through which rainfall is converted to runoff.

In this study, the U.S. EPA Stormwater Management Model Version IV (Huber et al. 1988) was used to estimate runoff volumes from land use areas for loads calculations. This model, referred to as SWMM, contains a detailed mathematical description of the hydrologic cycle, including runoff from impervious and pervious areas, infiltration, percolation to the water table, groundwater flow into channels, losses due to evapotranspiration, interception, and depression storage, and routing of runoff down stream channels. The model also has water quality and treatment components which are useful in evaluating the effects of control measures. Thus, SWMM is sufficiently detailed and general in scope to model the processes which are relevant to the estimation of nonpoint source loads.

SWMM represents a watershed as a set of hydrologic units referred to as subcatchments. Each subcatchment is assumed to have a unique set of runoff properties, including rainfall, area, width, slope, infiltration characteristics, and percent of impervious areas. The model simulates runoff over time using time steps determined by the interval at which rainfall data are available. For accurate simulation of storm hydrographs, this time step is typically on the order of 15 to 60 minutes. At each time step, the model performs a water balance on all subcatchments, as illustrated in Figure B-1. The volume of water available for surface runoff is determined by first subtracting losses for depression storage, infiltration, and evaporation from rainfall. The remaining water is routed

R0054418

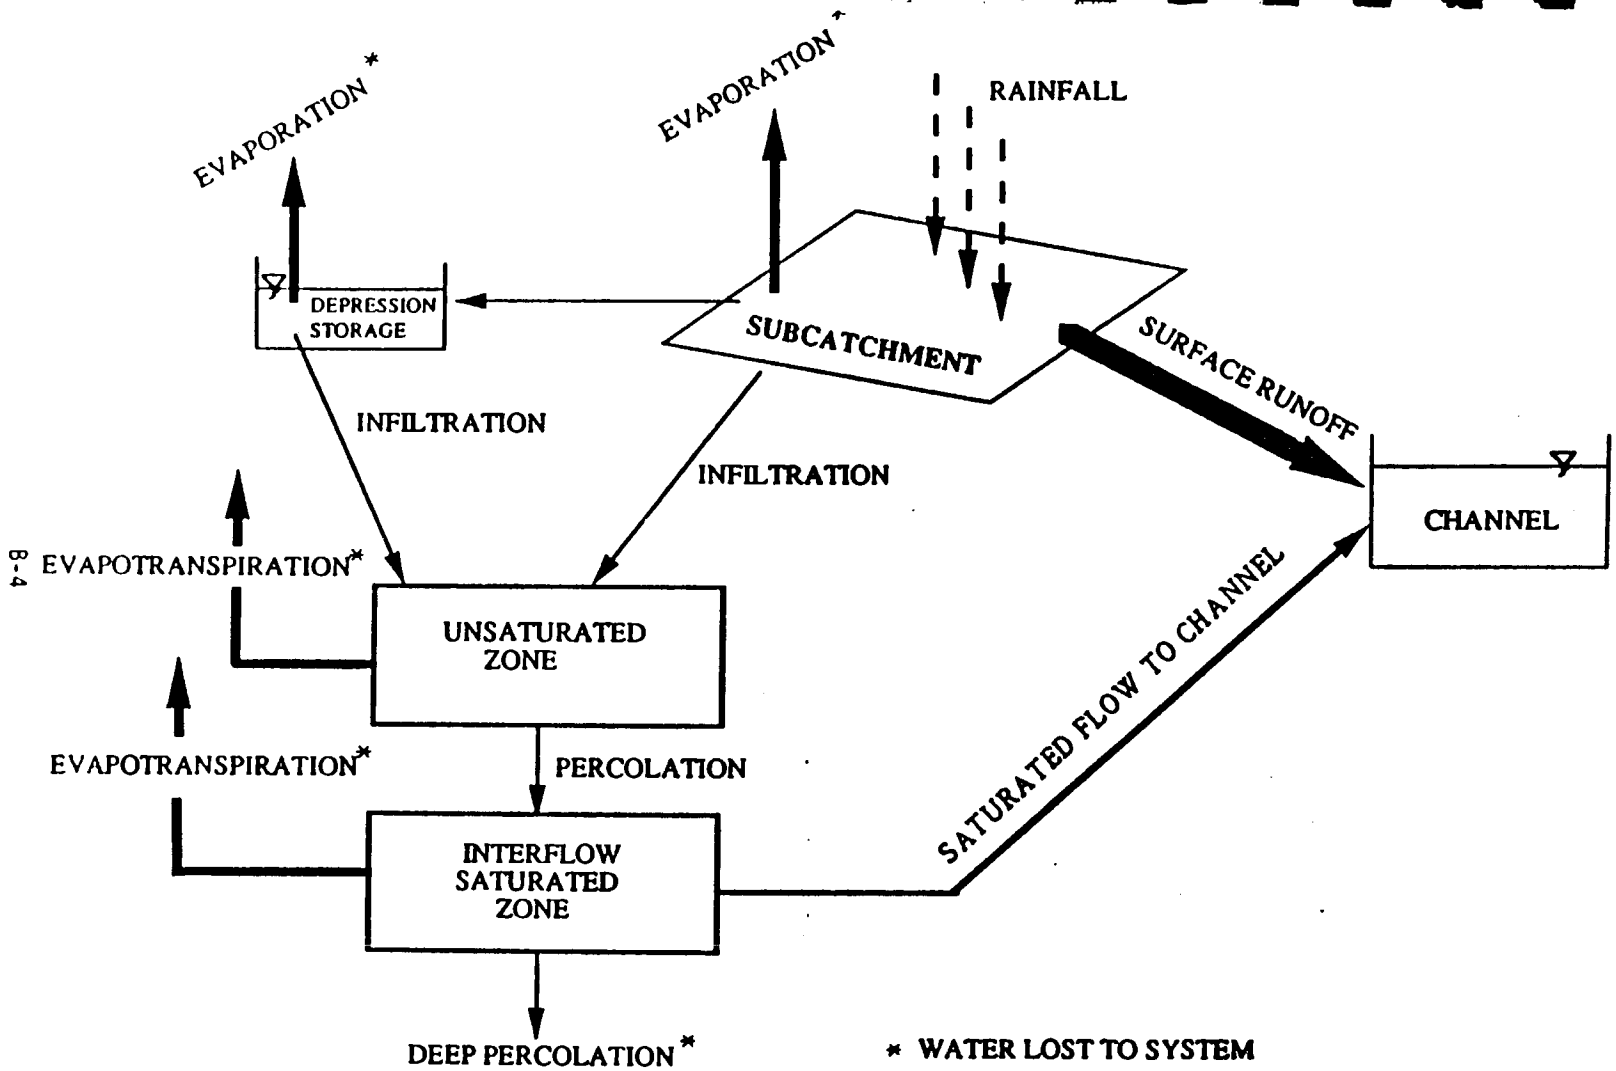

FIGURE B-1. SWMM Water Balance For a Subcatchment

R0054419

VOL 12 2 1120

as runoff from the subcatchments into channels using a non-linear reservoir routing scheme, with the outflow rate determined by Manning's equation. Each subcatchment contains both pervious and impervious areas; runoff is more rapid from impervious areas because rainfall on these areas is not subject to infiltration losses. Water in depression storage, used to simulate storage in depressions on the ground surface, may either infiltrate or evaporate.

The subsurface component of the hydrologic cycle is represented in SWMM by two storage reservoirs, one for the unsaturated zone and one for the saturated zone. The volume of infiltration is determined using either a Horton or a Green-Ampt infiltration model. Infiltrated water then moves into the unsaturated zone, where it may either remain in storage, evapotranspirate, or percolate into the saturated zone. Water in the saturated zone may either remain in storage, flow into channels, or percolate out of the system. Flow from the saturated zone to channels is determined based on the difference in elevation between the water table and the channel water surface; the water table elevation is recalculated each time step based on the current volume of water in the saturated zone and the porosity of the saturated zone.

B.2 MODEL SETUP FOR THE SANTA CLARA VALLEY

The goal of this study was to estimate total nonpoint source loads from the Santa Clara Valley. Thus, SWMM was used to model runoff from the entire valley. For data management and calibration purposes, the valley was subdivided into the 11 major watersheds shown in Figure B-2. Streamflow data for calibration were available at the downstream ends of six of these watersheds; runoff from the remaining watersheds was estimated using SWMM without calibration.

Prior to using SWMM, a conceptual model of the important runoff processes occurring in the valley was developed. Based on the analysis of

Figure B-2. WATERSHEDS IN STUDY AREA

VOL 12 2 1123

VOL 12 2 1124

measured flow and precipitation data presented in Section 5.0, the following concepts were used to guide the application of SWMM to the study area:

1) Orographic effects on rainfall are strong, especially in the Santa Cruz Mountains.

2) Runoff on the valley floor occurs primarily from impervious areas associated with urban development.

3) Runoff from pervious areas occurs primarily in the Santa Cruz Mountains where rainfall intensities are sufficient to exceed soil infiltration capacities.

4) Runoff from pervious areas has a seasonal component, with the strongest runoff response occurring in the late wet season when antecedent soil moisture levels are highest.

5) Storm hydrographs typically have a 2- to 3-day recession component derived from subsurface flow rather than from surface runoff. This subsurface flow is probably interflow through temporarily saturated areas and perched groundwater in the unsaturated zone.

These concepts were used in determining how the SWMM runoff, infiltration, and groundwater algorithms were configured for this study, and will be referred to in terms of specific model parameters in the following sections. Section B.2.1 discusses how watersheds were subdivided into SWMM subcatchments, and Section B.2.2 describes procedures used to estimate model input parameters.

B.2.1 Watershed Discretization

The number and size of subcatchments used by SWMM should be determined by (1) the level of detail required in the model results, and (2) the level

R0054424

VOL 12 2 1125

of detail at which data are available. For this study, complete data were available for relatively small subcatchments used by the Santa Clara Valley Water District (SCVWD) for their flood hydrograph modeling. However, this level of detail, while important for flood modeling, is not necessary for estimating annual-scale runoff and water quality loads. Huber and Dickenson (1988) present data and examples showing that small subcatchments can be lumped into larger SWMM subcatchments with little loss of information, as long as input parameters are scaled appropriately.

Because orographic effects on rainfall are so important in the Study Area, the first step in setting up subcatchments for this study was to divide each watershed into subareas over which rainfall was assumed to be uniformly distributed. The number of subareas were selected such that the variability of rainfall within watersheds was adequately represented. Figure B-3 illustrates the subarea breakdown for the Calabazas Creek watershed. The subareas shown are typical of those used in the smaller watersheds in the western part of the valley, with three subareas representing rainfall on 1) the lower valley floor, 2) the upper valley floor, and 3) the Santa Cruz Mountain foothills. Table B-1 summarizes the rain gages used to model runoff for all of the watersheds in the Study Area.

SWMM performs water balance calculations and estimates flows for areas represented by subcatchments. Thus, to estimate flows from individual land uses each rain gage subarea was divided into subcatchments for up to six land use categories (open, low density residential, medium density residential, high density residential, commercial, and industrial). These land use subcatchments represented "lumped areas" in that all of the areas of a given land use were modeled as a single contiguous subcatchment. In the example shown in Figure B-3, rain gage subarea 100 was subdivided into an open subcatchment, a low residential subcatchment, and a medium residential subcatchment. Because the land use breakdown for the area was 43 percent open, the open subcatchment had an area equal to 43 percent of

R0054425

R0054427

VOL 12 2 1127

the total area represented by rain gage 100. In general, physical properties such as rainfall, subcatchment width, and soil infiltration parameters were identical for all land use subcatchments in a given rain gage subarea. Land use properties such as impervious area were allowed to vary between land use subcatchments to reflect different levels of development.

B.2.2 Model Parameter Estimation

SWMM requires a number of parameters describing meteorology, catchment geometry, and runoff characteristics. The accuracy at which parameters can be estimated without model calibration varies. Thus, parameters can be grouped as follows:

1) Parameters which can be accurately estimated with no calibration (i.e., catchment area)

2) Parameters which can be estimated with reasonable accuracy, but must be refined through calibration (i.e., infiltration parameters)

3) Parameters which can be estimated only through model calibration (i.e., interflow outflow coefficients)

Table B-2 summarizes the important model input parameters and the corresponding estimation procedures; these are discussed in detail in the following paragraphs.

B.2.2.1 Rainfall. Rainfall is the driving force in the model, and is by far the most important input parameter. SWMM in this case was run continuously for multiple-year simulations, and required continuous records of 15-minute or hourly rainfall. Therefore, the continuous rainfall records available for SCVWD and NWS gages in the valley were used as inputs to the model. The SCVWD gages are weighing gages which record at 15-minute intervals with a precision of 0.1 inch. The one NWS gage, located in San

VOL 12 2 1 1 2 8

R0054428

Table B-2. SUMMARY OF SWMM RUNOFF INPUT PARAMETERS

Parameters	Estimation Procedure	Varies by Land Use?	Calibration Parameter?
Rainfall (in.)	NWS hourly and SCVWD 15-minute recording weighing gages (1974-1989). To correct for orographic effects, rainfall records were multiplied by isohyetal correction factors based on the ratio of average annual rainfall for subareas to the average at the gage.		
Potential Evapotranspiration Rate (in./day)	Average monthly pan evaporation data at the Almaden Recharge facilities, multiplied by monthly pan coefficients provided by the SCVWD.		
Area (acres)	Drainage areas were measured from drainage maps provided by the SCVWD.		
Slope (fraction)	Slop s were determined by area-weighting slopes for those SCVWD catchments contained in model subcatchment.	•	
Land Use (%)	Land use percentages were determined by area-weighting values for SCVWD catchments contained within each SWMM subcatchment.	•	
Catchment Width (feet)	Drainage area divided by the maximum length of overland flow.		•
Impervious Area (%)	Derived from calibration of SWMM for monitored land use catchments (Station L1-L7) for the 1988-89 season.	•	•
Surface Roughness	Values for each land use were derived from tables for grassy, paved, and forested surfaces in the SWMM User's Manual.	•	
Depression Storage (in.)	Values for each land use were derived from tables for grassy and paved surfaces in the SWMM User's Manual.	•	•
Infiltration Parameters	Hydrologic soil groups were mapped from Soil Conservation Service (SCS).	•	•
Interflow Parameters	Soil surveys (1941). Typical values for each soil group were then selected from tables in the SWMM User's Manual. The average for a SWMM subarea was determined by area-weighted averaging.		
Unsaturated zone	From typical values tabulated in SWMM user's manual for soil types surveyed by the SCS (1941).		•
Saturated zone	From typical values tabulated in SWMM user's manual for soil types surveyed by the SCS (1941).		•
Outflow coefficients	By calibration to match measured hydrographic recessions.	•	•

R0054429

Jose, is an hourly gage with a precision of 0.01 inch. A detailed description of these data is provided in Section 5.1.

The rainfall record for each subcatchment was selected by first identifying the rain gage located nearest to the centroid of the subcatchment area. The record for this rain gage then became the base rainfall record for the subcatchment. In selecting a base rainfall record, we also compared the elevation of the rain gage to that of the subcatchment (i.e., if the nearest gage were on a high ridge above the subcatchment, another gage at an elevation closer to that of the subcatchment was sometimes selected as a more representative record).

Once a base record was established for the subcatchment, the rainfall record was adjusted for the average difference between rainfall volumes in the subcatchment and at the rain gage. To accomplish this, rainfall records were multiplied by correction factors based on the ratio of average annual precipitation in the subcatchment to average annual precipitation in the rain gage:

$$R_{sc} = R_g * (P_{sc}/P_g) \qquad (B\text{-}1)$$

where

R_{sc} = 15-minute rainfall values used in modeling the sub catchment (in)
R_g = the corresponding 15-minute rainfall in the rain gage (in)
P_{sc} = the mean annual rainfall in the subcatchment (in)
P_g = the mean annual rainfall in the rain gage (in)

The mean annual rainfall for the catchment was estimated from annual average rainfall isohyets. Rainfall isohyets were derived from isohyetal maps provided by the SCVWD.

VOL 12 2 1130

R0054430

VOL 12 2 1 1 3 1

Storm patterns within a year can be highly variable, and this correction of rainfall records based on long-term annual average rainfall totals will certainly not capture all of the spatial variability within an individual storm. However, the method does ensure that, on average, the rainfall record used in modeling runoff will have the correct cumulative volume. This method should therefore be sufficiently accurate for estimating annual flow volumes and loads.

B.2.2.2 Potential Evapotranspiration Rate. The potential evapotranspiration rate determines how much water could be lost to evaporation and transpiration. SWMM uses an average rate for each month of the year; for this study, these rates were estimated using the average monthly pan evaporation rates measured by the SCVWD at the Alamitos Recharge Facility. These pan evaporation rates were corrected by pan coefficients provided by the SCVWD.

B.2.2.3 Catchment Area, Slope, and Land Use. These data were available for catchments used by the SCVWD in their flood modeling. These catchments were smaller than the SWMM subcatchments used in this study. Consequently, model subcatchment areas were determined from the SCVWD catchment maps by summing the areas for the appropriate SCVWD catchments. Similarly, slopes and land use breakdown were determined by area-weighting the values for the SCVWD catchments comprising a SWMM subcatchment.

B.2.2.4 Catchment Width. SWMM represents each subcatchment as a rectangle defined by an area and width; the length of overland flow is then the area divided by the width. Catchment width is therefore an important parameter in determining the timing of runoff. This width is difficult to measure, since the actual shapes of subcatchments are rarely rectangular. As recommended in the SWMM Users Manual (Huber and Dickensen 1988), a first estimate of this parameter was obtained by dividing the subcatchment area by the maximum distance from catchment boundary to the main channel.

R0054431

VOL 12 2 1132

B.2.2.5 Impervious Area. This parameter is defined as the percentage of an area that has no infiltration, i.e., paved areas, rooftops, etc. Impervious areas must also be connected, and paved areas that drain onto pervious areas should not be considered impervious. This parameter could conceivably be measured directly from aerial photos, but this would be extremely costly and of questionable accuracy for an area as large as the Santa Clara Valley.

The approach used here was to determine representative impervious areas for each land use by calibrating SWMM on storm data at the single land use catchments sampled in this study. These values were then adjusted during calibration of the larger watersheds to match observed runoff volumes.

B.2.2.6 Surface Roughness Coefficients and Depression Storages. These were estimated for pervious and impervious areas using values tabulated in the SWMM user's manual for various types of surfaces. Values tabulated for either paved, grassy, or forested surfaces were selected based on land use. Depression storages were also calibrated in forested areas to represent interception on vegetation.

B.2.2.7 Infiltration Parameters. For this study, the Green-Ampt option in SWMM was selected for modeling infiltration during storm events. The Green-Ampt infiltration model, while certainly idealized, is mechanistically rather than empirically based and has input parameters that can easily be related to known soil properties. For infiltration during storms, the model uses three parameters: 1) the saturated hydraulic conductivity, 2) a suction parameter, and 3) the maximum soil moisture deficit. The saturated hydraulic conductivity represents the infiltration rate at saturation. The suction parameter is used to model the effects of capillary suction in the soil. The maximum moisture deficit is analogous to porosity and determines the storage capacity of the soil layer that controls infiltration. Values of these parameters are tabulated for each of the four Soil Conservation Service (SCS) hydrologic soil groups in the SWMM User's Manual. Therefore,

R0054432

VOL 12 2 1133

values for this study were determined by overlaying SCS soil survey maps (SCS 1941) onto maps of the SWMM subcatchments. The area of soils in each SCS hydrologic group were measured, and the average parameters for the watershed were determined by area weighting. The following calculation illustrates the method for the saturated hydraulic conductivity:

$$K = (\%A)(KA) + (\%B)(KB) + (\%C)(KC) + (\%D)(KD) \qquad (B\text{-}2)$$

where:

K = the average saturated hydraulic conductivity for a subcatchment
A, B, C, D = the four SCS hydrologic soil groups
%A = the percentage of the total area that are A soils
KA = the value of saturated hydraulic conductivity for A soils

In general, soils in the area ranged from B to D, where D soils have the lowest infiltration rates.

Between storms, SWMM uses a simple empirical algorithm to determine how dry soils are at the start of the next storm. As previously discussed, the antecedent soil moisture level is an important factor in determining runoff response in the Study Area, especially in the later months of the rainy season. Initial calibration of SWMM indicated that the empirical SWMM soil moisture depletion algorithm was not adequately reproducing the seasonality of soil moisture levels; soils were generally saturating during every storm and then drying out to the maximum moisture deficit within a few days. Thus, the model predicted that storms in February responded the same to rainfall as storms in November. The SWMM soil moisture depletion algorithm was therefore modified so that the depletion rate and storage capacity of the soil layer controlling infiltration could be adjusted during calibration. The depletion rate was defined as a fraction of the potential evapotranspiration rate:

R0054433

$$R_i = (F_d)(PET_i) \qquad (B\text{-}3)$$

where:

R_i = the soil moisture depletion rate for month i
PET_i = the potential evapotranspiration rate for month i
F_d = the soil moisture depletion factor

This modification allowed depletion rates to vary seasonally, and F_d was added as a calibration parameter for the model. To control the storage capacity of the soil, the thickness of the soil layer controlling infiltration was also added as a calibration parameter. This storage parameter could then be adjusted along with the depletion factor to match the observed seasonality in runoff.

B.2.2.8 Interflow Parameters. To model the interflow recession observed in many storm hydrographs in the Study Area, the SWMM groundwater model was configured as shown in Figure B-4. The bottom of the saturated zone was set at a relatively shallow depth (10 to 15 feet) so that the saturated zone rose rapidly during storm events and released stored water into channels within 1 to 7 days. This interflow system was modeled only in steep areas with high rainfall volumes; interflow was generally not observed in valley floor catchments.

Model input parameters in the unsaturated zone include storage parameters such as field capacity and wilting point, and parameters describing hydraulic conductivity as a function of soil moisture. These were generally estimated from tables of typical values for the appropriate SCS soil types. Similarly, the saturated zone is defined by storage parameters such as porosity and rate parameters such the saturated zone outflow coefficients. Flow from the saturated zone into the channel was calculated using the following model based on head differences between the channel and the saturated zone:

VOL 12
2
1134
R0054434

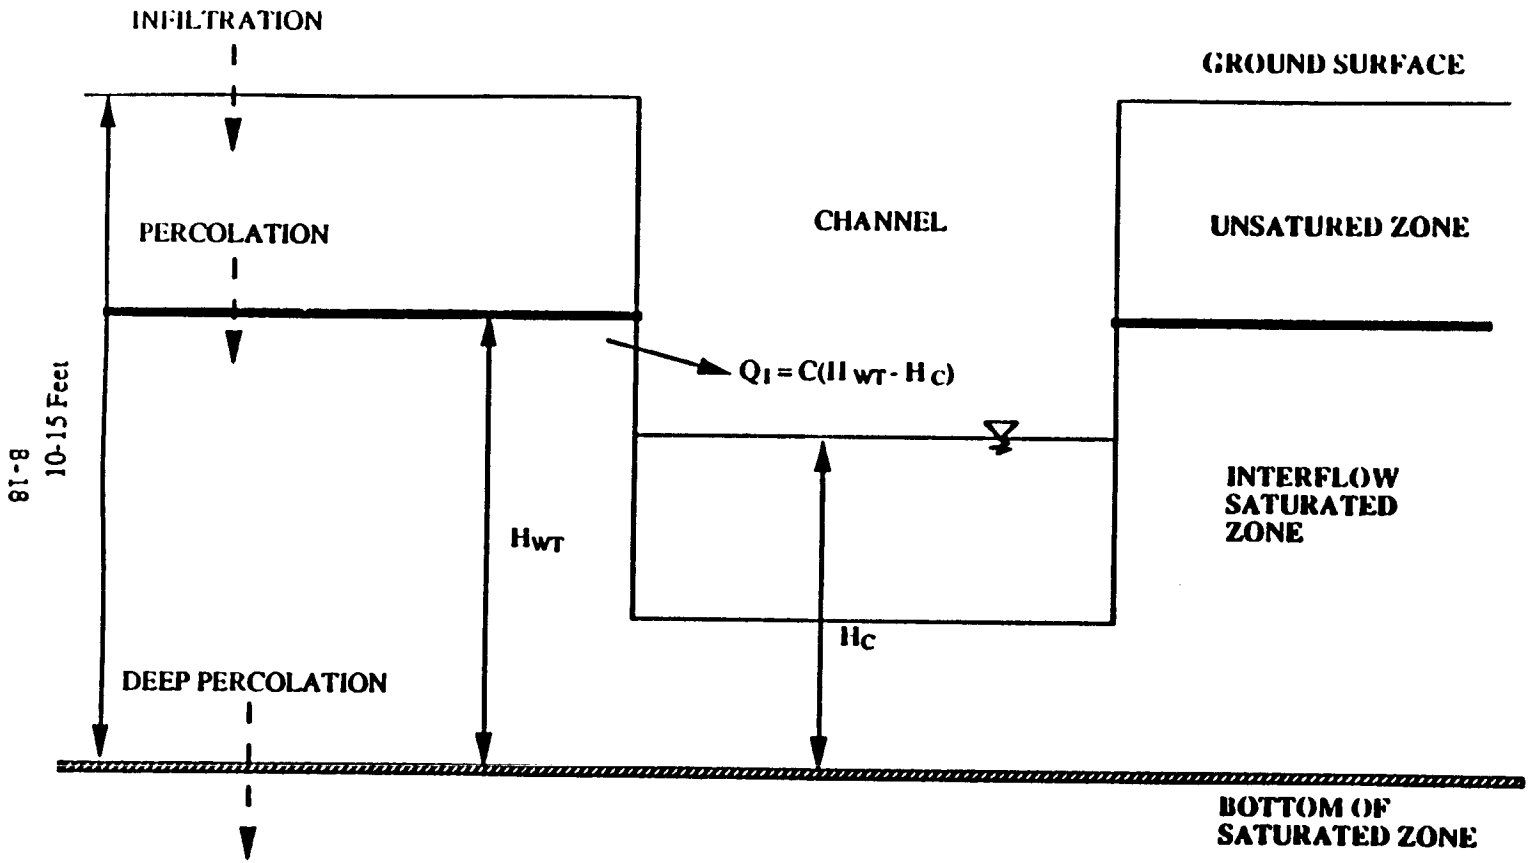

FIGURE B-4. SWMM Interflow Model

R0054435

$$Q_I = C(H_{wt} - H_c) \qquad (B\text{-}4)$$

where:

Q_I = interflow rate into the channel (cfs)
H_{wt} = elevation of the water table (ft)
H_c = elevation of water in the channel (ft)
C = interflow coefficient (ft^2/sec)

The interflow coefficient C is a calibration parameter which was primarily used to determine the magnitude of interflow into the channel. An additional calibration parameter, representing deep percolation out of the saturated zone, was used to steepen predicted hydrograph recessions to match observed recession curves.

B.2.2.9 Channel Data. Runoff and interflow from SWMM subcatchments were routed down channels using the SWMM non-linear routing algorithm. For this study, one channel was defined for each rain gage subarea, and input data were required specifying the slope, Manning's roughness coefficient, and cross section of each channel reach. Cross-sectional data for all streams were provided by the SCVWD in the form of HEC-2 input files used in flood modeling. From these, representative cross sections were selected and approximated as trapezoids for SWMM (defined by a bottom width and two side slopes). Manning's roughness coefficients and slopes were averaged for each channel reach modeled.

B.3 SWMM CALIBRATION AND VERIFICATION

Although SWMM is a state of the art model of rainfall-runoff processes, it, like all runoff models, represents an idealization of the actual processes occurring in a catchment. In addition, the spatial variability of model input parameters is difficult to account for in large catchments with many types of geology and land uses. Therefore, the model must be

VOL 12 2 1136

R0054436

VOL 12 2 1 1 3 7

calibrated against measured streamflow data to produce reliable results. The calibration consists of running the model, comparing model prediction to measured streamflows, and adjusting the model calibration parameters to better match the observed flows. The process is repeated until the comparison between measured and predicted flows is deemed adequate. Calibration is then followed by verification, in which the calibrated model is run and compared to streamflow records for a period not included in the calibration period.

The following sections describe 1) calibration criteria, 2) selection of calibration periods, 3) calibration parameters, and 4) results for individual watersheds.

8.3.1 Calibration Goals and Criteria

To capture the year to year variability of runoff, SWMM was run continuously over several years during calibration and verification. Since the emphasis of this study was on annual loads from storm runoff, the primary goal of calibration was to match measured wet-season total runoff volumes. The runoff volume for a season consists primarily of runoff from relatively few storm events (typically less than 15), and matching wet-season runoff volumes required accurate simulation of individual storm events.

For calibration purposes, predicted flows were compared to measured flows at SCVWD and USGS stream gages. See Section 5.2 for a discussion of stream gages in the Study Area. A number of parameters were calculated to measure the quality of calibration. For comparing predicted versus measured wet-season totals, the following statistics were calculated:

$$RMSE = \frac{100\left(\sum_{i=1}^{n}(P_i - M_i)^2/n\right)^{1/2}}{M} \qquad (B\text{-}5)$$

$$BIAS = 100(P - M)/M \qquad (B\text{-}6)$$

R0054437

VOL 12 2 1 1 3 8

where:

P_1 = predicted wet-season runoff volume for year 1 (in.)
M_1 = measured wet-season runoff volume for year 1 (in.)
n = the number of years in the calibration period.
M = the mean measured wet-season runoff volume (in.)
P = the mean predicted wet-season runoff volume (in.)

The RMSE, or root mean square error, is a measure of the absolute magnitude of calibration errors expressed as a percentage of mean runoff. The BIAS indicates whether the model is on average over- or under-predicting runoff volumes, and is also expressed as a percentage of the mean wet-season runoff volume. The goal of calibration was to minimize both the RMSE and the BIAS.

Results of calibrations performed for comparable studies were consulted to derive specific calibration acceptance criteria. Alley (1986) summarizes calibration results from the USGS rainfall-runoff model DR3M for 37 catchments nationwide. In this study, calibration errors were measured by the mean absolute deviation (MAD) between predicted and observed flow volumes. On average, the MAD was on the order of 20 percent for the 37 simulated catchments. In a modeling study of three small urban catchments, Guay and Smith (1988) calibrated the USGS model DR3M to runoff data for 10 to 13 storms in one season. Prediction errors in total annual runoff volume for these three single land use catchments ranged from 10 to 25 percent. In a study performed on Permanente Creek in Santa Clara County, Nolan and Hill (1989) obtained calibration errors in total annual flow volume of 3 to 33 percent.

These studies indicate that calibration errors are generally on the order of 20 percent, but may range as high as 30 or 40 percent. The studies cited above generally focused on small (less than 100 acre) urban catchments with a single well-defined land use. None of these studies

R0054438

VOL 12 2 1139

calibrated using more than 3 years of flow data. Thus, one would expect that the calibration errors obtained in modeling the large watersheds in the Santa Clara Valley for up to 10 years of flow data would be somewhat higher. Nonetheless, for this study a relatively ambitious calibration goal of 15 percent RMSE was used for annual flow predictions. Given the difficulties inherent in simulating large open areas, this goal was often not achieved. However, the RMSEs summarized in Table B-3 range from 1 to 40 percent, and are consistent with calibration errors obtained in other studies. More importantly, the biases in the model predictions are small, and range from 1 to 16 percent.

Daily predicted flows were compared to measured flows in two ways. First, daily predicted flows and measured flows were plotted together over time and visually compared. These plots were used for detailed analyses of the sources of calibration errors, particularly in terms of matching seasonal runoff patterns and hydrograph recessions. Finally, a Kolmogorov-Smirnov hypothesis test was used to compare the frequency distributions of measured and predicted daily flows. This test first calculates the maximum difference between measured and predicted cumulative probabilities. This difference is then compared to a test statistic based on the number of daily flows and the confidence level. If the maximum difference is less than the test statistic, the hypothesis that the predicted and measured flows are from the same population is accepted. This test, while it does not check that the flow on a given day is accurately predicted, does measure how well the model is reproducing the day to day variability of flows.

B.3.2 Selection of Calibration and Verification Periods

Runoff in the Study Area varies greatly from year to year, and the annual runoff volume for a wet year can be ten times greater than in a dry year. A calibration based on only one dry year would therefore not accurately represent runoff in wet years. Therefore, SWMM was calibrated and verified against as many years of streamflow data as were available,

R0054439

Table B-3. SUMMARY OF STREAM CALIBRATION/VERIFICATION

Watershed	Calibration Period	Verification Period	Calibration			Verification			Combined Calibration and Verification Period		
			Mean Wet-Season Runoff (in.)	RMSE (%)	Bias (%)	Mean Wet-Season Runoff (in.)	RMSE (%)	Bias (%)	Mean Wet-Season Runoff (in.)	RMSE[a] (%)	Bias[b] (%)

[a] RMSE measures the average error in predicted wet-season runoff, as a percentage of the mean wet-season runoff volume.

[b] BIAS measures the average bias (tendency to under- or over-predict) in predicted wet-season runoff, as a percentage of the mean wet-season runoff volume.

R0054440

VOL 12 2 1141

with approximately two thirds of the record used for calibration and one third for verification. As discussed in Section 5.0, concurrent streamflow and rainfall data are generally available for the period 1974 through 1989, with occasional gaps due to gaging errors, data storage problems, and damage to stream gages. Table B-3 summarizes the calibration and verification periods for the various watersheds; calibration periods were typically 4 to 9 years in length, while verification periods were 3 to 5 years long. Both calibration and verification periods were selected to contain a mix of wet, dry, and average years. Note that there was only one year of data available for calibration of the Coyote Creek watershed.

B.3.3 Calibration Parameters

Table B-4 summarizes the values of parameters derived from calibration of SWMM for each watershed. For adjustment of runoff volumes in urban areas, the most important parameters were the percent of impervious area and depression storages. These parameters were especially important in dry years when almost all runoff was from impervious areas; the percent impervious area for each of the various land uses was therefore determined primarily through calibration on dry years. In open and low-residential areas, the most important parameters were the Green-Ampt infiltration and soil depletion parameters. The saturated hydraulic conductivity was used to determine the overall rate of infiltration (and therefore reduction in runoff). The soil moisture depletion parameters L and F_d were used to model the seasonality of infiltration (and runoff) by adjusting the rate at which soils dried out between storms. The interflow coefficient A1 and deep percolation factor DF were used to match hydrograph recessions, while CET, POR, and GRELEV defined the storage characteristics of the saturated zone.

B.3.3.1 Calibration of the Percent Imperviousness. One of the most sensitive model parameters in urban areas is the percent imperviousness. Runoff volumes are often directly proportional to the value of the percent imperviousness, meaning that if this parameter is doubled, runoff volumes

VOL 12 2 1147

will nearly double. This is especially true in urban areas with low rainfall intensities.

Estimation of the percent imperviousness can conceivably be performed by direct measurement from areal photographs. However, this is usually impractical for large areas such as the Santa Clara Valley. The usual practice is therefore to derive general values of this parameter for each land use category. However, even values tabulated in the literature for individual land uses may vary by as much as 100 percent. For instance, Table B-5 compares values tabulated for Santa Clara County by (1) the SCVWD, and (2) the U.S. Geological Survey (1977). In general, the USGS values are considerably lower than the SCVWD values. The USGS data also indicate considerable variability within land use categories, with values ranging from 6 percent in hillside residential areas to 10 percent in valley floor low-density residential areas. An important conclusion that can be drawn from this is that no one value can be realistically used to represent all low-density residential areas, since not all areas within the low-density category are paved or developed to the same extent.

For our calibration of SWMM, we initially used the percent imperviousness values developed by the SCVWD (shown in Table B-5). However, use of these values resulted in consistent overestimation of runoff. That this overestimation was derived from the imperviousness estimate became apparent when examining predicted runoff from small early season storms. Runoff from these storms comes primarily from paved areas, and the model consistently overpredicted runoff from these storms even when infiltration parameters were adjusted to prevent any pervious area runoff from occurring. We therefore adjusted the percent impervious values downward to match storm volumes for these types of events.

Clearly, percent imperviousness is a very sensitive calibration parameter, and should not be adjusted to account for processes that may be better represented by the pervious area infiltration parameters. To ensure

VOL 12 2 1149

that we were not adjusting percent imperviousness when calibration of infiltration parameters would have been more appropriate, calibration of this parameter was performed only to match runoff volumes from small storms where little runoff was occurring from pervious areas. The resulting calibrated percent imperviousness values are shown in Table B-4 for each watershed, and are summarized in Table B-5. As shown in Table B-5, the calibrated values are much lower than the original SCVWD values, but are consistent with percent imperviousness values tabulated by the USGS for Santa Clara County.

8.3.3.2 Sensitivity of the Model to Green-Ampt Infiltration Parameters. An important component of the SWMM rainfall-runoff calibration was the calibration of the Green-Ampt infiltration parameters. These parameters control infiltration of water on pervious surfaces, and thus play a critical role in predicting runoff from open areas. The Green-Ampt infiltration algorithm has three parameters: the saturated hydraulic conductivity, a capillary suction parameter, and the maximum soil moisture deficit. Sensitivity analyses of the model indicated that the controlling infiltration parameter was the saturated hydraulic conductivity, defined as the infiltration rate at saturation. Our calibration efforts therefore focused on this parameter, while leaving the values of the suction parameter and soil moisture deficit constant. As a result, occasionally the final calibrated value of the hydraulic conductivity was not consistent with the values of the suction parameter and maximum soil moisture deficit.

To test whether this inconsistency had a significant effect on the model results, a model run for Calabazas Creek was performed to demonstrate SWMM's insensitivity to the suction parameter and maximum soil moisture deficit. In this run, the values of these two parameters (which formerly corresponded to a moderately permeable "C" soil) were forced to be consistent with the calibrated hydraulic conductivity value (which corresponded to a low permeability "D" soil). Table B-6 summarizes the results of this analysis. In general, annual flow volumes were insensitive

to these parameters. Annual loading results between the new run and the original run differed by as little as .02 percent in 1988-89, and by as much as 4 percent in 1978-79. Total loadings for the 1977-1989 period change by about 3 percent.

B.3.3.3 Sensitivity of the Model to Time Series Potential Evapotranspiration Data. Potential evapotranspiration (PE) was represented in the model by average pan evaporation rates for each month of the year. Evaporation data are used in the model to simulate (1) changes in depression storage between storms and (2) seasonal changes in soil moisture storages. These processes primarily affect the antecedent soil moisture levels before storms, and therefore are most important in nonurban areas. Soil moisture levels change on a monthly or seasonal time scale, indicating that predicted annual runoff volumes are not sensitive to day to day changes in evaporation rates.

Table B-7 summarizes the mean monthly evaporation rates used in the model, and also shows the standard deviation and range of observed monthly values for the period 1976 to 1988. Note that the standard deviation of monthly values is on the order of 20 percent or less of the mean, indicating that monthly evaporation shows little year to year variation. To test the sensitivity of the annual loading predictions to the use of monthly average PE data, a model simulation was performed for Calabazas Creek using time series PE data. Table B-8 compares the resulting flow predictions to those obtained using monthly average evaporation data. Annual loads predicted from the two data sets differed by 1 to 6 percent, while the mean annual load differed by only 1.6 percent. Thus, it is reasonable to conclude that monthly average PE data are adequate for annual loads prediction.

B.3.4 Calibration and Verification Results

Table B-3 summarizes the calibration and verification statistics for all of the watersheds for which flow data were available. Figures B-5

through B-11 plot predicted wet-season volumes against measured volumes. These statistics and plots measure how well the model was able to predict total wet-season runoff volumes. During calibration, RMSEs ranged from 1 to 38 percent, and the BIAS ranged from ±1 to ±12 percent. During verification, RMSEs ranged from 3 to 45 percent, and the BIAS ranged from ±1 to ±16 percent. For the combined period, RMSEs ranged from 1 to 40 percent of mean wet-season runoff, while the BIAS ranged from ±0.1 to ±6 percent. The flow-weighted average RMSEs for the Study Area were 25, 22, and 25 percent for the calibration, verification, and combined periods, respectively. Average BIASes were -4, 5, and -1 percent for these three periods. Details on the calibration and verification process for individual watersheds are presented below.

B.3.4.1 Calabazas Creek. Calabazas Creek originates in the foothills of the Santa Cruz Mountains and drains into Guadalupe Slough. Mean annual rainfall ranges from 12 inches near the Bay to 32 inches in the foothills. For SWMM, the catchment was divided into three rain gage subareas corresponding to SCVWD rain gages 100, 108, and 121. Model calibration was performed primarily against streamflow data for SCVWD streamgage 26a, located on the valley floor and representing about three-fourths of the total watershed area. In addition, streamflow data at SCVWD streamgage 31 were used to refine estimates of pervious runoff parameters in the upper portion of the watershed.

Calibration and verification results for Calabazas Creek, in terms of wet-season runoff, are illustrated in Figure B-5. The calibration for Calabazas Creek was generally accurate and unbiased, with a RMSE for the combined calibration/verification period of 11 percent of the mean volume and a BIAS of 1 percent. The predicted daily flow distribution passed the Kolmogorov-Smirnov distribution test at the 95 percent confidence level. The most important calibration parameters were the Green-Ampt infiltration parameters, used to model seasonal runoff. Matching the seasonal patterns of runoff required an infiltration layer with a thickness of 8 to 10

inches, so that the soil did not saturate until after the first or second major storm of the season.

B.3.4.2 Stevens Creek. Stevens Creek is in the western part of the valley, and extends from the county boundary in the Santa Cruz Mountains down to the Bay. Most of the undeveloped portion of the watershed flows into Stevens Creek Reservoir. This reservoir, while designed to store flows in the winter for release in the summer, does commonly release stormwater during wet years. Mean annual rainfall ranges from 12 inches near the Bay to 24 inches just below the reservoir, and is as high as 60 inches above Stevens Creek Reservoir.

Calibration of SWMM was performed only for the portion of the watershed below Stevens Creek Reservoir; flows out of the reservoir were represented by the record for SCVWD gage 44. Rain gage subareas were designated for SCVWD rain gages 100,48, and 121. The model was calibrated against measured flows at SCVWD gage 35, just north of the Central Expressway. To determine the amount of runoff occurring below the reservoir, flows from gage 44 (immediately below the reservoir) were subtracted from flows at gage 35. Also subtracted from the gage 35 record were diversion flows from Permanente Creek into Stevens Creek (measured by the difference between SCVWD gages 32a and 37). Calibration was limited to the period 1975 to 1983, when the diversion gage 37 was discontinued.

Figure B-6 shows the calibration results for Stevens Creek (areas downstream of Stevens Creek Reservoir). The RMSE for the combined calibration/verification period was 34 percent of the mean annual flow, and the BIAS was 1 percent. The model generally performed well, except in the 1981-82 season, when the model overpredicted runoff by about 60 percent. The predicted daily flow distribution passed the Kolmogorov-Smirnov distribution test at the 95 percent confidence level. Because the area downstream of the reservoir is mostly urbanized, the percent impervious area was the most important calibration parameter, although the Green-Ampt

R0054462

VOL 12 2 1163

infiltration parameters were also important in modeling seasonal effects on runoff.

8.3.4.3 Sunnyvale East Channel. This watershed is a small urban area extending from the City of Cupertino down to the Bay. Mean annual rainfall in the basin ranges from 12 to 16 inches. The entire area was modeled using SCVWD rain gage 48. Calibration and verification were performed for the 1977 to 1989 record at SCVWD streamgage 74.

Calibration results are shown in Figure B-7. The RMSE in this case was 9 percent of the mean wet-season volume, while the BIAS was -1 percent. The predicted daily flow distribution passed the Kolmogorov distribution test at the 95 percent confidence level. The most important calibration parameters in this mostly urban, low rainfall catchment was the percent of impervious area; little or no seasonality was observed in runoff response to rainfall.

8.3.4.4 Saratoga Creek. Saratoga Creek extends from the county boundary in the Santa Cruz Mountains to its confluence with San Tomas Aquinas Creek. Mean annual rainfall ranges from 50 inches in the uplands to 12 inches near the Bay. For SWMM modeling, SCVWD rain gage 77 was used to represent the undeveloped upland areas, while rain gage 108 was used in the urban valley floor areas. Calibration and verification were performed on the record for SCVWD gage 25. The 1984-85 season was not included in the calibration or verification periods because the measured flow data for this year indicated an annual runoff coefficient of 0.95, which is unreasonable for a watershed which includes significant open and low-density residential areas.

Calibration and verification results for Saratoga Creek are shown in Figure B-8. The RMSE for the combined calibration/verification period was 22 percent of the mean wet-season volume, while the BIAS was .1 percent. The calibration of this watershed was complicated due to 1) the strong

R0054463

VOL 12 2 1164

infiltration parameters were also important in modeling seasonal effects on runoff.

B.3.4.3 Sunnyvale East Channel. This watershed is a small urban area extending from the City of Cupertino down to the Bay. Mean annual rainfall in the basin ranges from 12 to 16 inches. The entire area was modeled using SCVWD rain gage 48. Calibration and verification were performed for the 1977 to 1989 record at SCVWD streamgage 74.

Calibration results are shown in Figure B-7. The RMSE in this case was 9 percent of the mean wet-season volume, while the BIAS was -1 percent. The predicted daily flow distribution passed the Kolmogorov distribution test at the 95 percent confidence level. The most important calibration parameters in this mostly urban, low rainfall catchment was the percent of impervious area; little or no seasonality was observed in runoff response to rainfall.

B.3.4.4 Saratoga Creek. Saratoga Creek extends from the county boundary in the Santa Cruz Mountains to its confluence with San Tomas Aquinas Creek. Mean annual rainfall ranges from 50 inches in the uplands to 12 inches near the Bay. For SWMM modeling, SCVWD rain gage 77 was used to represent the undeveloped upland areas, while rain gage 108 was used in the urban valley floor areas. Calibration and verification were performed on the record for SCVWD gage 25. The 1984-85 season was not included in the calibration or verification periods because the measured flow data for this year indicated an annual runoff coefficient of 0.95, which is unreasonable for a watershed which includes significant open and low-density residential areas.

Calibration and verification results for Saratoga Creek are shown in Figure B-8. The RMSE for the combined calibration/verification period was 22 percent of the mean wet-season volume, while the BIAS was .1 percent. The calibration of this watershed was complicated due to 1) the strong

R0054464

interflow recession component observed in many storms, and 2) the extremely strong response to runoff in wet years. To match observed storm response, it was necessary at times to force the model to shut off infiltration through saturation of the soil profile from below. Thus, the important model parameters were 1) the interflow recession constants, and 2) the soil and groundwater storage parameters.

B.3.4.5 San Tomas Aquinas Creek. This watershed is adjacent to Saratoga Creek and extends from the Santa Cruz Mountain foothills to its discharge point into Guadalupe Slough. Rainfall ranges from 12 to 40 inches per year on average. SCVWD rain gage 79 was used to represent the foothills and upper valley, gage 108 was used on the central valley floor, and the San Jose National Weather Service gage was used in the lower valley floor. Calibration was performed primarily at SCVWD streamgage 24, although data at SCVWD streamgage 29 were used to refine estimates of parameters in the upper portion of the catchment.

Calibration and verification results are shown in Figure B-9. The RMSE for wet-season volumes was 21 percent, while the BIAS was -2 percent. San Tomas Aquinas Creek was very similar to Saratoga Creek in terms of runoff, with storm hydrographs exhibiting a very strong interflow recession component and unusually strong response to rainfall. Again, the most important parameters were (1) interflow recession constants, and (2) soil and groundwater storage coefficients. An additional problem encountered here was the very different behavior of runoff between post-1983 and pre-1983 data. Measured flow data at gage 24 generally indicated less response to rainfall (i.e., lower runoff coefficients) after 1983, and we were unable to arrive at a calibration which could match both periods. One possible explanation for this is a change in the rating curve at gage 24 after the floods of the 1982-83 season.

B 3.4.6 Coyote Creek. This is the largest watershed in the valley, and drains the entire eastern side of the valley. Included are large

VOL 12 2 1165

R0054465

VOL 12 2 1 1 6 6

undeveloped areas above Anderson Reservoir, Silver-Thompson Creek, Upper Penitencia Creek, and Berryessa Creek. For SWMM, Coyote Creek was modeled only between SCVWD streamgage 58 (below Anderson Reservoir) and the Bay; most of the area upstream of gage 58 either drain into reservoirs or are undeveloped areas. Storm runoff from these areas was therefore represented by the actual record for streamgage 58. The drainage area below this point is mixed urban and non-urban, with most of the non-urban areas located in the upper portions of Silver-Thompson and Upper Penitencia Creek.

The only streamgage on Coyote Creek below gage 58 is a high-flow gage which records only when stage is above 8.5 feet; the record here is consequently of limited usefulness. However, a continuous stage recorder was installed at this location for the 1988-89 sampling period as part of this study. Thus, Coyote Creek was calibrated for one year only (1988-89). This period was relatively dry, and use of the model for wetter years should be less reliable than if it had been calibrated over a variety of hydrologic conditions. The predicted wet-season volume for this period was 1 percent lower than measured. Because of the dryness of the calibration period, the most important calibration parameter was the percent of impervious area.

B.3.4.7 Berryessa Creek. The Berryessa Creek watershed is located on the eastern side of the valley on the slopes of the Diablo Range, and flows into Coyote Creek near the Bay. Rainfall in this area is much lower than in the Santa Cruz Mountains, and ranges from 14 to 20 inches on average per year. SCVWD rain gage 23 was used to model the upper parts of the catchment, and the San Jose National Weather Service gage was used to model the lower portions of the catchment. Calibration and verification were performed at SCVWD streamgage 64.

Figure B-10 show the calibration and verification results for this watershed. The overall RMSE was 29 percent of the mean annual flow, and the BIAS was 6 percent. The calibration was adequate in most years, with

R0054466

VOL 12 2 1167

most of the RMSE resulting from the 2-inch overprediction of runoff in 1982-83.

B.3.4.8 Guadalupe River. The Guadalupe River is the second largest watershed in the valley, and extends from the Santa Cruz Mountains to the Bay. Major tributaries include Los Gatos Creek, Ross Creek, Calero Creek, Alamitos Creek, and Canoas Creek. Mean annual rainfall in the basin ranges from 12 inches near the Bay to about 50 inches on the Santa Cruz Mountain ridgeline. Rain gages used to model the watershed are shown in Table B-1.

The SCVWD operates an extensive reservoir and recharge system on the Guadalupe River. Most of the areas in the Santa Cruz Mountains drain into Lexington, Guadalupe, Almaden, and Calero reservoirs. Water released from Lexington Reservoir is also stored in Vasona Reservoir. For the most part, these reservoirs are designed to store runoff in the winter and release in the summer for groundwater recharge. However, during wet years the reservoirs do release significant volumes of winter storm runoff. Outflows from each reservoir are measured by stream gages located immediately below the reservoir spillways. Much of the water released by reservoirs during dry weather is diverted downstream into groundwater recharge ponds. Water can also be diverted into the watershed from Coyote Creek through the Coyote-Alamitos Canal.

Calibration and verification of SWMM on the Guadalupe River was performed using the flow record for the U.S. Geological Survey (USGS) gage immediately below the confluence with Los Gatos Creek. This gage is downstream of the recharge ponds, and represents all of the major Guadalupe tributaries. It does not measure runoff from much of the urban San Jose portion of the watershed. Calibration was performed for runoff from areas downstream of reservoirs; runoff above the reservoirs was represented in loads calculations by the actual reservoir release records. To determine the volume of runoff occurring downstream of reservoirs, reservoir releases were subtracted from the USGS gage record using the following rules:

R0054467

VOL 12 2 1168

1) During storms, all of the water released from reservoirs reaches the USGS gage.

2) Between storms, all of the flow recorded by the USGS gage consists of reservoir releases minus diversions to recharge ponds.

These rules basically assume that released water is not diverted during storms, and that dry-weather reservoir releases are much larger than natural baseflow.

Calibration efforts on the Guadalupe River were less successful than at other watersheds, primarily because the Guadalupe River watershed is a highly managed system with numerous storage reservoirs and diversions. Because there were insufficient data to account for all of the stored and diverted water in the watershed, it was difficult to differentiate between storm runoff and water released from other sources. In several years, these data indicated storm runoff coefficients (runoff/rainfall) greater than 1.0 in February and March. As a results, SWMM was calibrated only during periods in which the measured flow data appeared to be reasonable (i.e., had reasonable runoff coefficients). Even focusing on these periods, the calibration/verification resulted in a wet-season RMSE of 40 percent and a BIAS of -2 percent. Calibration and verification results are plotted on Figure B-11. The predicted daily flow distribution passed the Kolmogorov-Smirnov test at the 95 percent confidence level. This calibration could have been improved by using parameter values which were completely inconsistent with those used in other basins. For instance, to match observed dry year totals (when all runoff is from impervious areas), the model would require percent impervious areas ranging from 1 to 20 percent in urban areas. In other similar basins, this parameter generally ranged from 10 to 80 percent. Given the mass balance problems observed in the measured flow data, the final calibration was determined using the best combination of parameters that was consistent with values used on Calabazas, Saratoga, San Tomas Aquinas, and Stevens Creek.

R0054468

VOL 12 2 1169

B.3.4.9 Comparisons of Predictions with Observed Flows for Selected Storms. An important component of any calibration is visual comparison of predicted hydrographs with measured hydrographs. Analysis of calibration statistics alone is not sufficient; visual comparison must also be made to ensure that the model predictions are consistent with our understanding of the relevant physical processes. In this section, selected predicted and measured hydrographs are presented to give the reader some idea of how well we were able to simulate storm hydrographs.

Figures B-12, B-13, and B-14 are examples of the range of hydrograph comparisons we were able to obtain. Figure B-12 shows the measured and predicted daily average flows for February 1980 storms in Calabazas Creek, and is an example of an excellent match between the model and the observed flows. Both the peak and storm recession are accurately predicted by the model. Figure B-13 illustrates a poor match between predicted and observed flows for a December 1977 storm on San Tomas Aquinas Creek. In this case, the model significantly overpredicted the peak flow rate and total storm volume. Figure B-14 shows a perhaps more typical hydrograph comparison for a March 1979 storm on San Tomas Aquinas Creek. Here, the model overpredicts the peak flow rate by about 20 percent, but is able to accurately simulate the total storm volume.

B.4 WATERSHED RUNOFF PREDICTIONS

The goal of the SWMM calibration discussed in the previous section was to produce a model which could 1) estimate runoff in ungaged areas, and 2) estimate the contributions of various land uses to runoff. This section summarizes storm runoff predictions for the Santa Clara Valley. These predictions were made for all watersheds for water years 1977-78 through 1988-89, the period for which rainfall data are available for all catchments.

R0054469

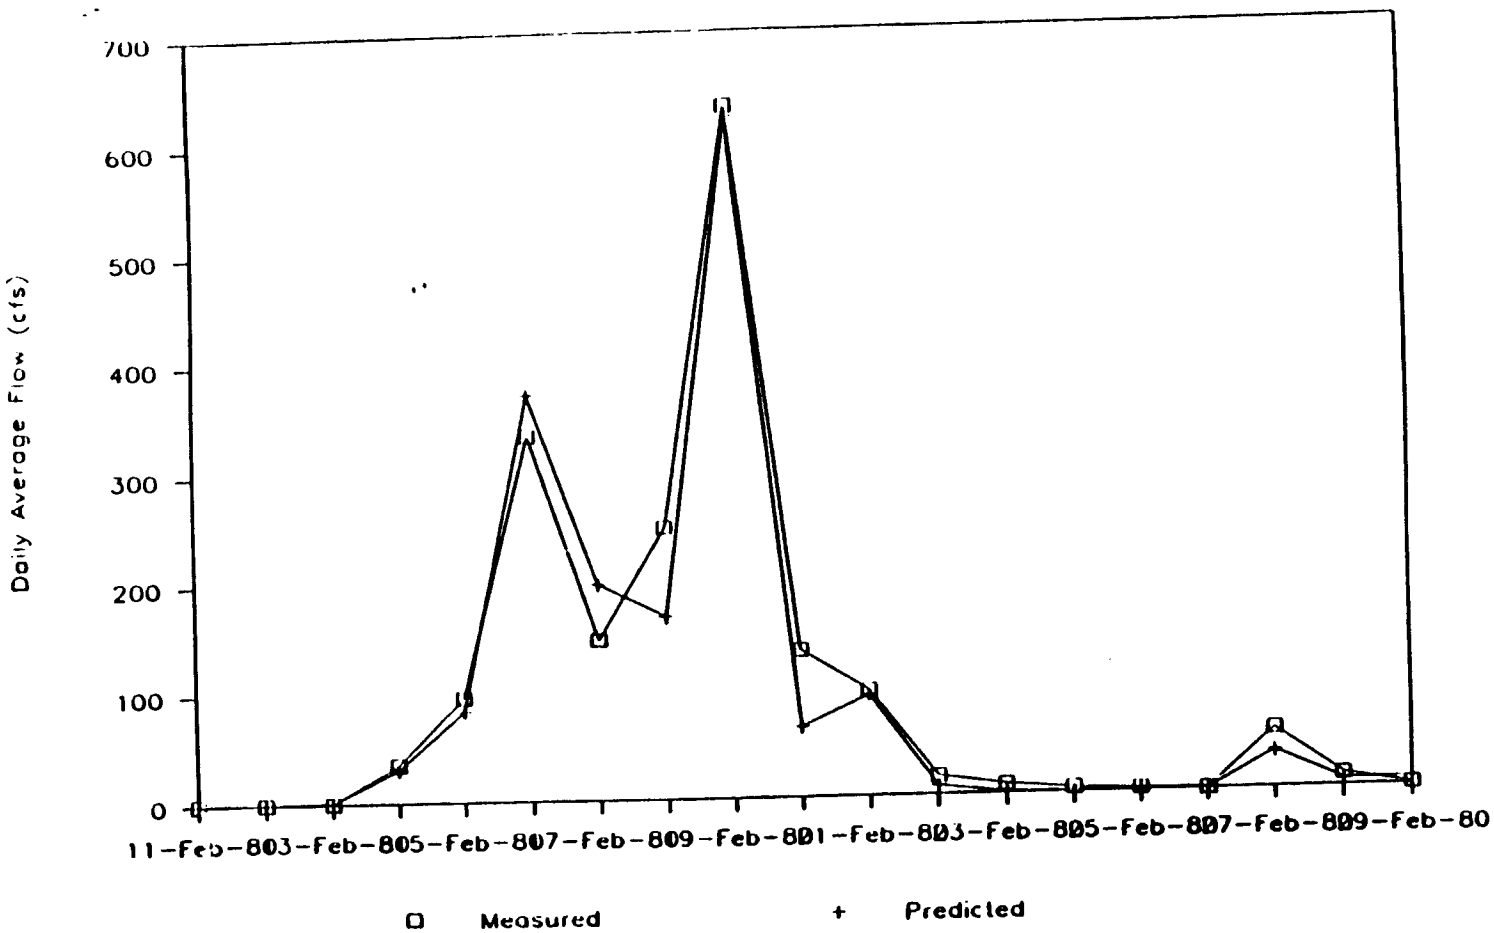

Figure B-12. Comparison of Predicted and Measured Hydrographs for Calabazas Creek, February 1980

R0054471

Figure B-14. Comparison of Predicted and Measured Hydrographs for San Tomas Aquinas Creek, March 1979

R0054472

VOL 12 2 1173

SWMM was used to predict runoff in three types of areas:

1) Areas for which the model was calibrated against measured streamflow data

2) Areas in calibrated watersheds that are downstream of the calibration gage

3) Watersheds for which no flow data are available for calibration

For areas in which the model was calibrated, flow predictions were made by simply running the calibrated version of the model for the projection period. To account for model errors in calibration/verification years, the predicted flows for each land use were then multiplied by the ratio of wet-season measured runoff to predicted runoff for that year. This correction scaled the predicted flows to match measured totals exactly, and assumed that the correction factor was the same for all land uses.

For watersheds with streamflow data for calibration, there were usually uncalibrated urban areas in the lower portions of the watersheds. This applies to the following watersheds: Coyote Creek, Guadalupe River, Calabazas Creek, Saratoga Creek, San Tomas Aquinas Creek, Sunnyvale East Channel, and Stevens Creek. Because Sunnyvale East Channel best represents typical northern valley urban areas, parameters calibrated for this watershed were used in other uncalibrated urban areas. Soils parameters were estimated based on soil type and calibration in areas with similar soils.

Most of the western portion of the valley has little or no flow data for calibration. This includes Permanente Creek, Adobe, Matadero, and Barron creeks, and Sunnyvale West Channel. In addition, as only the portion of the San Francisquito Creek watershed in Santa Clara County was modeled, flow data could not be used for calibration. In these areas, parameters were estimated from similar calibrated watersheds. In urban

R0054473

areas on the lower valley floor, parameters were estimated based on the calibration for Sunnyvale East Channel. In areas on the upper valley floor, parameters were estimated from the calibrations for Stevens Creek and Calabazas Creek. Finally, in upland areas calibration results for Stevens, Calabazas, and San Tomas Aquinas creeks were used to estimate parameters.

Table 8-9 summarizes the predicted annual storm runoff volumes for each watershed in the valley. As would be expected based on the relative drainage areas, 50 percent of storm runoff on average comes from Coyote Creek and the Guadalupe River. The highest runoff volume occurred during the 1982-83 season, while the lowest occurred in the 1988-89 season.

8.5 DETERMINISTIC WATER QUALITY MODELING OF CALABAZAS CREEK

As described in Section 8, loads in this study were derived as the product of annual runoff volume (from SWMM modeling) and annual mean concentration for each constituent and land use. These mean concentrations were obtained from statistical analysis of the water quality data collected at the land use and stream sampling stations. An alternative approach to estimate loads is to use the semi-empirical buildup-washoff models included in SWMM to predict runoff water quality. While these models are highly empirical and largely unverified, they do attempt to represent a number of the physical processes that are thought to determine runoff water quality. To compare this approach to the statistical mean concentration approach used in this study, the SWMM buildup washoff model was applied to estimate annual load from the Calabazas Creek watershed. A description of the model, calibration results, and predicted loads are provided in this section, as well as a comparison of the buildup-washoff load predictions to those derived from the statistical mean concentration model.

8.5.1 Model Description

The SWMM runoff water quality model is based on the concept of pollutant buildup and washoff. The concept behind this model is that a

R0054475

VOL 12 2 1176

supply of constituents builds up on the land surface during dry periods and is subsequently washed off during a storm. Pollutant buildup is assumed to occur as a function of time between storms. During a storm, washoff is assumed to occur as a function of the available mass of pollutants on the land surface and the rate of runoff. While the buildup-washoff concept does explain some of the mechanisms thought to produce runoff water quality, the model itself is highly empirical and requires substantial calibration to produce reasonable results.

Many studies have been conducted to determine rates of buildup on city streets. Sartor and Boyd (1972), among others, found that buildup appears to be non-linear, deveioping rapidly at first and then leveling off to a limit. This form of buildup is implemented in SWMM using an exponential buildup function:

$$P_{Shed} = P_{lim}*(1-\exp(-K_b*t)) \qquad (8-7)$$

where

P_{Shed} = mass of constituent in watershed at time t (lbs/acre)
P_{lim} = upper limit on constituent mass that can accumulate (lbs/acre)
K_b = buildup rate constant ($days^{-1}$)
t = time between storms (days)

Washoff is the process that mobilizes the accumulated constituents into runoff and streamflow. In stream channels and other areas of significant flow, this process is described by sediment transport theory, where flow rate and bottom shear stress are important factors. For thin overland flows (sheet flows) common during storms in urban environments, rainfall energy can also mobilize particles. Therefore, more intense storms are able to washoff more of a constituent than a less intense storm. Whatever mechanisms are involved, it is obvious that as rainfall and washoff continue the amount of constituen. remaining in the watershed diminishes.

R0054476

VOL 12 2 1178

This observation, combined with the results of several empirical studies leads to the washoff formula used in SWMM:

$$Poff(t) = K_w * r^c * P_{shed} \qquad (B\text{-}8)$$

where

Poff = amount washed off at time t (lbs/acre)
K_w = washoff coefficient
r = runoff rate (in/hr)
c = empirical washoff exponent

Thus, the model has four input parameters: the limiting buildup rate (P_{lim}), the buildup rate constant (K_b), the washoff coefficient (K_w), and the washoff exponent (c). The buildup limit sets an upper limit on the availability of the constituents, and has a linear effect on the total mass load. The buildup rate constant sets the time scale of buildup between storms and thus attempts to capture the effects of "antecedent conditions." It can therefore be used to match observed water quality variations between sequential storm events. The washoff coefficient has a linear effect on the total mass that washes off during a storm. The washoff exponent primarily controls how load varies with time during a storm.

B.5.2 Model Calibration

None of the buildup-washoff model parameters can be measured directly, and all must be estimated by calibrating the model against measured water quality data. Few data on initial estimates of the buildup parameters are available in the literature for the types of constituents of concern in this study, although there are data on buildup rates of "dust and dirt" on parking lots and streets. The SWMM manual suggests an initial estimate of the washoff coefficient K_w of 4.6 in_{-1}, although other studies have used values ranging from .052 to 6.6 in_{-1}. The washoff exponent is suggested to range from 1.0 to 2.0, with a median value of 1.5.

R0054478

VOL 12 2 1179

8.5.2.1 Data Used for Calibration. The buildup washoff model was calibrated against water quality data collected at the Calabazas Creek monitoring station (S1) for five storms in the 1988-89 season. The available water quality data consisted of Event Mean Concentrations (EMCs) derived from composite samples; no data on the time-dependence of concentrations within a storm were available. Three constituents, Total Suspended Solids (TSS), copper and lead, were chosen for this test of the water quality model portion of SWMM. Measured EMCs used in calibration are listed in Table B-10.

8.5.2.2 Calibration Methods. The goal of calibration was to match to the extent possible the observed EMCs for the five storms for each constituent. Calibration was performed by systematically changing the values of the four buildup washoff parameters to minimize the difference between the simulated and observed EMCs. A number of parameters were used to measure the accuracy of the calibration. The root mean square error (RMSE) of predicted vs. observed EMCs was used to quantify the magnitude of model calibration errors. This was reported as a percentage of the mean measured concentration. The BIAS, or sum of errors, was used to indicate if the model was systematically under or overpredicting EMCs. To verify that the model was reproducing the statistics of the measured data, the predicted mean and coefficient of variation of the EMCs for the five storms were compared to the mean and coefficient of variation of the observed data. Finally, the data for each storm were tabulated and plotted as a function of time to verify whether or not the model was reproducing the observed trends in the data.

8.5.2.3 Calibration Results. Table B-10 compares the calibrated model to the measured data, and lists the calibration statistics for each constituent. Final calibrated values of the model input parameters are shown in Table B-11. RMSEs for the calibrations ranged from 19 percent for copper to 25 percent for TSS, and were relatively unbiased. The model was able to accurately reproduce the means of the observed data, but consistently underestimated the coefficient of variation of the data.

VOL 12 2 1182

Figure B-15 compares the predicted and observed EMCs as a function of time for Copper. The model was able to reproduce the relatively high concentrations observed in the first November storm, but was unable to simulate the low concentrations found in the January and February storms. Much of the rainfall in 1988-89 occurred in the last week of December 1988, and the low concentrations observed in January may be a result of heavy washoff of constituents from street surfaces in December. However, the model did not reproduce this effect. The model also could not reproduce the rapid drop in concentration that was measured in the second of the two March storms. Overall, although the model was on average able to match observed concentrations with an RMSE of about 20 percent, it was not particularly successful at matching the observed sequence and timing of storm concentrations.

B.5.3 Comparison of Annual Load Estimates for Deterministic and Constant Concentration Water Quality Models

The calibrated water quality model was used to estimate annual loads for the 12 year simulation period (water years 1977-78 to 1988-89). Table B-12 compares these results to the annual load predictions obtained from the statistical mean concentration model. In dry years such as the 1988-89 calibration period the two models give comparable estimates of annual load. However, the deterministic water quality model predicts loads that are 2-3 times lower in wet years such as 1982-83. Overall, the deterministic water quality model predicts significantly lower concentrations than does the mean concentration model.

The reasons behind this difference between the two methods lie primarily in the assumptions behind the buildup-washoff model. During wet years, the buildup-washoff model assumes that the increased number of storms will reduce the mass of pollutant available on the street surfaces for washoff. Thus, although flow volumes may be an order of magnitude higher in wet years than in dry years, predicted concentrations in runoff are lower due to this source limitation effect. On the other hand, the

VOL 12 2 1184

R0054484

mean concentration method assumes no difference in average water quality between wet and dry years. There is of course no direct evidence that the "dilution" effect predicted by the buildup-washoff model actually occurs. In this study, little or no correlation was found between the time between storms and runoff concentration, implying that the number of storms in a year should have little effect on water quality concentrations.

In summary, the deterministic water quality model predicts significantly lower loads and concentrations in wet years. The model does account for a number of mechanisms that one would intuitively believe to occur during and between storms. However, the model requires substantial calibration, and was not able to accurately simulate observed patterns in water quality during the 1988-89 monitoring period. The mean concentration model used in loads estimation in the remainder of this study makes direct use of the observed water quality data, and requires little calibration. The mean concentration model, however, is unable to account for possible differences in water quality during wet and dry years. Currently, there are no data available to determine which (if either) of these models is best able to simulate water quality in wet years.

APPENDIX C
SUMMARY OF LABORATORY QA/QC

VOL 12 2 1187

R0054487

VOL 12 2 1/18/88

APPENDIX C
SUMMARY OF LABORATORY QA/QC

Evaluation of the quality of the analytical data included:

1) Precision of laboratory duplicates (Table C.1)
2) Precision of field duplicates (Table C.2)
3) Precision of matrix spike and matrix spike duplicate recoveries (Table C.3)
4) Potential contamination of field and laboratory (method or reagent) blanks (Table C.4)
5) Laboratories performance on Environmental Resources Associates (ERA) quality control samples (Table C.5)

C.1 WATER SAMPLES

C.1.1 Laboratory Duplicates

Laboratory duplicates were routinely performed by the laboratory for a reduced suite of parameters. The only exception was for dry-weather 3 (May 12, 1989) and wet-weather 1 sampling events (May 5, 1989), where laboratory duplicate analyses were not generated. Results of laboratory duplicate analyses are presented in Tables C.1-1 to C.1-12. The precision of the laboratory duplicates is an indication of the variability in the extraction and analytical procedures in the laboratory. This precision is commonly expressed as a relative percent difference (RPD). The RPD was calculated by the following equation:

$$|\text{Conc (A)} - \text{Conc (B)}|/[[\text{Conc (A)} + \text{Conc (B)}]/2]$$

R0054488

VOL 12 2 1 1 89

where

Conc (A) = Concentration of primary duplicate sample
Conc (B) = Concentration of secondary duplicate sample
|Conc (A) - Conc (B)| = Difference between concentrations of primary and secondary duplicates expressed as absolute values

For the dry-weather sampling events 1, 2, 4, 5, 6, and 7, the RPD ranged from 0 to 29%, with a mean value of 6%. The RPDs for all wet-weather sampling events (2 to 7) were between 0 to 40% (mean of 16%), with the exception of two elevated RPDs for lead (55%) and mercury (100%) analyses for wet-weather 2 duplicate samples. Thus the reported RPDs for both dry and wet-weather samples are considered to be within laboratory acceptable limits.

C.1.2 Field Duplicates

Results of field duplicate samples are an indication of overall field variability, precision of field sampling and laboratory analyses. As such, the results of field duplicates have more variability than laboratory duplicates, which measure only laboratory performance. Field duplicate samples were collected and analyzed for a reduced parameter suite for all dry and wet-weather sampling events, with the exception of wet-weather 1 (May 5, 1989). The results of field duplicate analyses are presented in Tables C.2-1 to C.2-13. For all dry-weather field duplicate samples, the RPD ranged from 0 to 100%, with a mean of 23%. The RPD ranged from 0 to 94% for all wet-weather field duplicate samples; the mean value was 31%. These mean field duplicate RPDs are higher than the laboratory duplicate RPDs by about a factor of two to three, and likely represent the additional variability from field sampling.

C.1.3 Matrix Spike and Matrix Spike Duplicates

Matrix spike (MS) and matrix spike duplicate (MSD) recovery data are performed to evaluate accuracy and precision of each individual analytical

R0054489

VOL 12 2 1 1 90

method. The results of MS and MSD recoveries and also the RPD of these matrix spikes are summarized in Tables C.3-1 to C.3-10. Matrix spike recoveries for specific compounds analyzed under each method evaluated in this program were within acceptable limits according to the current EPA guidance for laboratory analyses (EPA, Test Methods for Evaluating Solid Waste, SW846, Third Edition). The RPD between MS and MSD recoveries were generally less than 30%, and therefore considered to be within EPA acceptable limits.

C.1.4 Laboratory (Method or Reagent) and Field Blanks

The purpose of laboratory and field blank analysis is to detect potential contamination from the laboratory and/or field sampling. All laboratory method blanks and field blanks were generally free of contaminants, with the exception of the detections of some organic compounds and metals.

C.1.4.1 Metals. It is important to note that the collection of field blanks in this sampling program was different for the dry- and wet-weather sampling events. Field blanks were obtained using procedures identical to those for collection of field samples. Dry-weather samples were collected by dipping sample containers in the sampling stream. Correspondingly, field blanks were collected by pouring laboratory reagent water (Milli-Q purified) into sample containers at each sampling station. Wet-weather composite samples were collected in the ISCO samplers in 10-liter borosilicate bottles, which were then taken to the laboratory. In the laboratory, a peristaltic pump with Teflon hose was used to fill individual sample bottles required for the various analyses (e.g., metals, pesticides, etc.). The Teflon hose was flushed with laboratory reagent water every time a new 10-liter sample bottle from each of the sampling stations was to be drained. At the end of this process, the Teflon hose was flushed and then laboratory reagent water was used to fill sample bottles for the blank analysis. This method of blank collection is commonly known as an

R0054490

VOL 12 2 1191

equipment blank. Hereinafter, all "field blanks" collected in the wet-weather period will be referred to as equipment blanks.

For the dry-weather samples, field blanks showed low levels of zinc contamination in dry-weather 4 (0.011 mg/L), dry-weather 5 (0.014 mg/L), dry-weather 6 (0.010 mg/L), and dry-weather 7 (0.006 mg/L). These levels of zinc were generally equal to or lower than the actual zinc levels found in the stream samples (Stations S1 to S4). No zinc contamination was found in the method blank analyses for the above-listed dry-weather sampling rounds. Because the method blanks were free of contamination, the source of the zinc contamination in the field blank is not the laboratory reagent water or the acid-preservative.

In addition, mercury and lead were detected at 0.0003 mg/L and 0.003 mg/L in dry-weather 4 and 6, respectively. The impact of mercury and lead contamination on the actual concentrations found in water samples is minimal because of the following reasons:

1) Mercury and lead were not detected in method blanks.

2) Mercury and lead concentrations in the field blank are close to the detection limit of 0.0001 mg/L and 0.001 mg/L, respectively.

3) Mercury levels detected in actual water samples are about 10 times higher than those found in the field blank.

4) Lead was not detected in actual water samples except for a lead concentration of 0.004 mg/L detected in one stream sample.

For the wet-weather samples, low levels of some metals were detected in the equipment blanks from wet-weather 2 (Table C.4-8), wet-weather 3 (Table C.4-10), wet-weather 5 (Table C.4-12), and wet-weather 7 (Table C.4-14). The source of contamination is potentially from carryover

R0054491

VOL 12 2 1192

of residual metals found in the hose used with the peristaltic pump. The concentrations found in the actual water samples were not corrected for these metal contaminants because all method blanks were generally free of metal contamination for the above-listed wet-weather sampling events with the exception of wet-weather 2, in which cadmium was detected in the method blank at the detection limit of 0.0002 mg/L.

For wet-weather 6, five metals--chromium (0.052 mg/L), copper (0.011 mg/L), lead (0.001 mg/L), nickel (0.06 mg/L), and zinc (0.018 mg/L)--were detected in the equipment blank. The source of these elevated metals is probably from the laboratory water. Because the Milli-Q purification system was broken during this sampling event, laboratory water was obtained from the solar still, which probably contained the elevated metals. Although the equipment blank was contaminated, the metals results for the actual water samples should not be affected because the samples did not come in contact with the solar still water except perhaps for a very small volume that may have adhered to the tubing from the flushing operation. The method blank analysis generally did not detect any metals concentrations that were comparable to those found in the equipment blank. For wet-weather 6, the only metal detected above the detection limit in the method blank was chromium. Chromium was detected at 0.002 mg/L in the first method blank and at a lower level of 0.001 mg/L in the second method blank.

C.1.4.2 Organics. Two volatile organics, methylene chloride and acetone, were detected in method blanks. Methylene chloride was detected at 6, 11, and 7 µg/L in method blanks for dry-weather 1 and 2, and wet-weather 1, respectively. Acetone was detected twice at 27 and 20 µg/L for dry-weather 2 and wet-weather 1, respectively. These volatile organics are commonly used solvents in the laboratory for sample extractions. Therefore, the detections of methylene chloride and acetone in storm runoff samples during dry-weather 1 and 2, and wet-weather 2, are suspect and most probably due to laboratory contamination.

R0054492

A semi-volatile organic, bis(2-ethylhexyl)phthalate (BEHP), was detected in method blanks from dry-weather 1 and 2, and wet-weather 1 and 2. The concentrations of BEHP ranged from 11 to 800 µg/L. The presence of BEHP is common in plastic material such as gloves and tubing. According to the current guidance from EPA on evaluation of phthalate data (EPA 1988), phthalates are common laboratory contaminants at levels of less than 100 µg/L. Based on evidence of BEHP contamination in the laboratory and EPA's current position on phthalate compounds, the detections of BEHP in storm runoff samples from L1, L2, and L6 are therefore suspect and most probably due to laboratory contamination.

A detection of 4,4'-DDE at 0.077 µg/L was found in a field blank from wet-weather 3. Since this organochlorine compound, 4,4'-DDE, was not detected in any of the storm runoff samples for wet-weather 3, this one-time detection of 4,4'-DDE in a field blank is likely due to field or laboratory contamination, and does not impact the results of organochlorine analyses of water samples collected from wet-weather 3.

C.2 SEDIMENT SAMPLES

Results of QC analyses for sediment samples are presented in Tables C.1-13, C.2-14 to C.2-16, and C.3-11 to C.3-14. Generally, the RPDs for laboratory and field duplicates were similar to those reported for the water samples. Matrix spike recoveries and RPDs of these matrix spike recoveries were also within acceptable limits.

As with the water samples, BEHP was detected in method blanks in the second and third sampling rounds. BEHP concentrations ranged from 940 to 2400 µg/kg The ubiquitous presence of BEHP in both laboratory and field environments is discussed earlier in Section C.1.4. Detections of BEHP in actual sediment samples from sampling events 2 and 3 are therefore suspect and likely due to laboratory artifacts.

C.3 EXTERNAL REFERENCE SAMPLES

External reference samples were submitted to the laboratories by the Project Quality Control Officer. These samples were supplied by Environmental Resource Associates (ERA), Arvada, Colorado, with certified analyses of target parameters. External reference samples were selected by the project quality control officer to match specific method analyses, expected concentration ranges, and sample matrices as closely as possible. The analytical results supplied with the reference samples were not disclosed to the individual laboratories. Samples were submitted a total of five times on a quarterly basis throughout the study. A summary of the results of comparisons between laboratory performance and ERA results for selected constituents is presented in Table C.5.1. Results of each quarter are presented in Tables C.5.2 through C.5.6.

C.3.1 First Quarter ERA Quality Control Samples, 1988

All laboratory reported concentrations were within the advisory ranges of the external reference samples except for arsenic, semi-volatiles (1,2,3-trichlorobenzene), and pesticides (gamma-BHC and PCBs, Aroclor 1242). The advisory range is the range of values that an experienced laboratory can expect to attain using the most precise methods and equipment. In determining advisory ranges, ERA considers both the parameter and the most commonly used method of analysis for the parameter. The arsenic value was outside the advisory range, but was determined to be an acceptable level of performance by the individual laboratory. True and advisory values for ERA organic quality control samples (volatiles, semi-volatiles, pesticides and PCBs, and herbicides) are based on analytical results from applicable EPA reference methods. True values represent 100% recoveries for the analyses. Since many organic analytical methods do not yield 100% recoveries, ERA advisory ranges reflect typical recoveries from water samples for the applicable EPA methodologies. The semi-volatile and pesticides and PCBs values were within an acceptable level of performance by the laboratory.

R0054494

VOL 12 2 1195

C.3.2 Second Quarter ERA Quality Control Samples

Laboratory reported values were within the advisory ranges except for the conventional constituents (BOD and TKN), and organic quality control samples such as volatiles (chloroform) and semi-volatiles (acenaphthene, benzo(a)pyrene, 2-chloronaphthalene, 1,3-dichlorobenzene and hexachlorobutadiene). The conventional constituent values were within acceptable levels of performance. The organic sample values were low due to laboratory contamination problems experienced during sample preparation.

C.3.3 Third Quarter ERA Quality Control Samples

Laboratory reported values outside the advisory ranges were for conventional constituents (TKN, ammonia, and phosphate) and organic quality control samples including:

1) Semi-volatiles (hexachloroethane, 1,2,4-trichlorobenzene, 2-chloronaphthalene, acenaphthylene)
2) Pesticides (aldrin and heptachlor epoxide)
3) PCBs (Aroclor 1242)

The pesticides and PCBs true values were near or below the detection limits for the laboratory, which caused recovery values to be unattainable by the laboratory.

C.3.4 Fourth Quarter ERA Quality Control Samples

Laboratory reported values were within the advisory ranges except for trace metals (arsenic, mercury, selenium, and silver), conventional constituents (ammonia, nitrate, phosphate), and organic quality control samples including semi-volatiles (1,4-dichlorobenzene and bis(2-chloroisopropyl)ether), PCBs (Aroclor 1221), and herbicides (2,4-D and 2,4,5-TP). The true values for PCBs and herbicides were below the detection limits for the laboratory and recovery values were unattainable. The herbicides ERA sample was no longer analyzed because the

R0054495

concentration levels of the analyte were always below laboratory detection limits. Due to complications during sample preparation for the metals analysis, low recoveries were reported by the laboratory. The conventional constituent values were acceptable levels of performance.

C.3.5 First Quarter ERA Quality Control Samples, 1989

Laboratory reported values were within the advisory ranges except for trace metals (lead and cadmium), and the organic quality control samples: pesticides (endrin aldehyde) and PCBs (Aroclor 1221). The concentration of endrin aldehyde and Aroclor 1221 were below the laboratory detection limits. The conventional constituent values and the trace metal values were acceptable levels of performance.

C.4 CONCLUSIONS

In summary, the QA/QC data are of acceptable quality according to the current EPA guidelines for laboratory analyses. Based on this QA/QC evaluation, the chemical data (water and sediment) collected in this program are therefore considered of good and reliable quality.

The precision of the data, represented by the relative percent difference (RPD), was evaluated for both field and laboratory duplicates. For field duplicates collected during wet and dry weather periods, the RPD ranged from 0 to 100 percent with an associated mean of 27 percent. For laboratory duplicates, the RPD ranged from 0 to 29 percent (mean of 6 percent) for dry weather samples, and 0 to 40 percent (mean of 16 percent) for wet weather samples. Results of field duplicate samples are an indication of overall field variability, and precision of field sampling techniques and laboratory analyses. As such, the results of field duplicates show more variability than laboratory duplicates, which measure only the precision of laboratory methods.

VOL 12 2 1/1/96

R0054496

The accuracy of the data is represented by the results of (1) matrix spike recoveries, and (2) external reference standards. Matrix spike recoveries for all constituents were within acceptable limits. Based on the results of five rounds of external reference standards, most of the metals concentrations (arsenic, cadmium, chromium, copper, lead, mercury, nickel, and zinc) and other conventional pollutants (TKN, nitrate, phosphate, BOD, and total suspended solids) were within the "true" concentrations, therefore indicating that they are reliable values. It is important to note that cadmium, chromium, copper, lead, nickel, and zinc are the five metals used for estimates of metals loads to the Bay. For selenium and silver, however, the actual measured concentrations appear to underestimate the "true" concentrations by about 10 to 30 percent. These two metals were not used in the loading estimates, and were consistently found at low levels with a few values above the detection limit.

VOL 12 2 1278

APPENDIX D
SANTA CLARA NONPOINT SOURCE WATER AND SEDIMENT QUALITY DATA

The following section presents the water and sediment quality data collected for the Santa Clara Valley Nonpoint Source study. The data are organized by parameter type (e.g., metals, conventional, etc.) and are titled D.1 through D.7. Under each parameter type the data are further subdivided into water samples and sediment samples. In addition, the metals include subgroups for total and dissolved concentrations in the water column. Following is a list of the parameter types and the corresponding appendix section:

D.1 Metals
- D.1-1 Total metals in water column
- D.1-2 Dissolved metals in water column
- D.1-3 Total metals in sediment

D.2 Conventional parameters
- D.2-1 Conventional parameters in water column
- D.2-2 Conventional parameters in sediment

D.3 Organochlorine pesticides
- D.3-1 Organochlorine pesticides in water column
- D.3-2 Organochlorine pesticides in sediment

D.4 Chlorinated herbicides
- D.4-1 Chlorinated herbicides and TOX in water column
- D.4-2 Chlorinated herbicides in sediment

D.5 Organophosphate pesticides
- D.5-1 Organophosphate pesticides in water column
- D.5-2 Organophosphate pesticides in sediment

R0054578

D.6 Polynuclear aromatic hydrocarbons
- D.6-1 Polynuclear aromatic hydrocarbons in water column
- D.6-2 Polynuclear aromatic hydrocarbons in sediment

D.7 Volatiles and semi-volatiles
- D.7-1 Volatiles and semi-volatiles in water column
- D.7-2 Volatiles and semi-volatiles in sediment

D.8 Dissolved oxygen data from stream stations and settling data

Within each parameter subgroup, the data are further organized by sample I.D. along rows and with the parameters sampled along columns. The sample I.D. corresponds to the sampling station identification number (e.g., L1 through L7 for land use stations, S1 through S4 for stream stations, and R1 through R6 for reservoir release stations). Under each sample I.D. the data are again subdivided into samples collected during dry (DRY) and wet (WET) weather, when appropriate. Also shown under sample I.D. are field duplicate (FD), lab replicates (LR), and field blanks (FB).

Under each parameter type are the measured concentrations (or ND if non-detected) and the value of the detection limit for the sample collected. Blanks in the data set mean that an analysis was not performed for certain parameters (such as hexavalent chromium) during a particular sampling event.

ORGANOCHLORINE PESTICIDES

Abbreviated Name	Actual Name
6CL-CHX-A	Alpha-BHC (hexachlorocyclohexane
6CL-CHX-B	Beta-BHC (hexachlorocyclohexane)
6CL-CHX-D	Delta-BHC (hexachlorocyclohexane)
6CL-CHX-G	Gamma-BHC (hexachlorocyclohexane)
G-CHLORDANE	Gamma-chlordane
ENDOSULFAN-A	Endosulfan I
ENDOSULFAN-B	Endosulfan II
ENDOSULFAN-S	Endosulfan sulfate
ENDRIN-ALD	Endrin aldehyde
HEPCL EPOX	Heptachlor epoxide
METHOXYCL	Methoxychlor
tPCB	Total polychlorinated biphenyls
DDD	4,4'-DDD
DDE	4,4'-DDE
DDT	4,4'-DDT

D.6 Polynuclear Aromatic Hydrocarbons

VOL 12 2 1356

R0054656

POLYNUCLEAR AROMATIC HYDROCARBONS

Abbreviated Name	Actual Name
ACENAPE	Acenaphthene
ACENAPTYLE	Acenapthylene
BAA	Benzo(a)anthracene
BAP	Benzo(a)pyrene
BBF	Benzo(b)fluoranthene
BGHIP	Benzo(ghi)perylene
BKF	Benzo(k)fluoranthene
DBAHA	Dibenzo(a,h)anthracene
FLUORANTHN	Fluoranthene
ICDP	Indeno(1,2,3-cd)pyrene
PHENANTHRN	Phenanthrene

square root transformed weight data. There was no significant decrease in mean larval weight in samples L-4 and L-7 when compared with the weight of laboratory water controls. There was significantly decreased larval weight in samples S1, S2 and L5.

Environmental monitoring data for fathead minnow larvae are summarized in Table 6.

Selenastrum

Growth and environmental monitoring data are summarized in Table 7.

Because of the large number of samples, the test was run in two batches. Run #1 included samples L3, L4, L5, L6 and L7. Run #2 included samples S1, S2, S3, L1 and L2. Each sample set had its own control.

For Run #1, cell number data were normally distributed (Shapiro-Wilkes) and homogeneous (Bartletts B = 3.653 vs tabled X^2 value at p=0.01 and 5 d.f. = 15.09). ANOVA and Dunnetts analyses were done on the untransformed data. There was no significant decrease in mean cell numbers in samples L3 and L4 when compared with growth in lab water controls. There were significantly decreased cell numbers in sample L5, L6 and L7.

For Run #2, cell number data were normally distributed (Shapiro-Wilkes), but were not homogeneous. Square root transformation corrected the homogeneity (Bartlett's B = 14.88 vs tabled critical value for p=0.01 and df=5 of 15.09). ANOVA and Dunnett's tests were done on the square root-transformed data. There was no significant decrease in mean cell numbers in samples S1, S2 and S3 when compared with growth in lab water controls. There were significantly decreased cell numbers in samples L1 and L2.

All algal counts were made manually with a hemacytometer and microscope. Treatment groups and controls were set up with a minimum of three replicates. Testing was conducted in an environmental chamber with continuous illumination of 400 ft/candles at 24 ± 2°C for 96 hours. All test flasks were innoculated with approximately 1×10^4 cells/ml from a 4 day old stock culture. Cultures were shaken twice daily by hand. Upon conclusion of testing, statistical analyses were made of final cell densities to determine EC50 concentrations using the Probit Method. Bartlett's test was used to confirm homogeneity of variance after which Dunnett's test was used.

VOL 12 2 1391

R0054697

Results and Conclusions

Ceriodaphnia

On 14 February, testing was initiated on all samples. Within 8 hours, all daphnids in samples S1, S2, S3, L2, L3, L4, L5 and L6 had died. Ten percent dilutions of those samples were prepared using laboratory water, and the entire test was re-started on 15 February. The reproduction and survival data summarized in Tables 1 and 2 are the results of testing 100% concentrations of samples L1 and L7, and 10% concentrations of the samples listed above. Data were statistically analyzed using the laboratory water controls as the comparative data.

Analysis of survival data by Fisher's Exact Test showed that samples S1, L1 and L3 produced statisticelly significant mortality when compared with laboratory water controls. Following protocol guidelines, reproduction data for those samples was excluded from subsequent statistical analysis.

Reproduction data were found to be non-homogeneous, with a Bartlett's B value of 19.86 (tabled Bartletts value at P = 0.01 for 7 df = 18.48). This non-homogeneity could not be corrected by data transformation (square root, log, arcsin), and subsequent analysis was done by Steel's Many-One Rank Test. The tabulated critical rank sum value for n= 10 and K=8 at P=0.05 is 73. Rank sums for samples S-2 (55) and L3 (55) were less than 73, indicating that reproduction in these samples was significantly lower than in the laboratory control water.

Environmental monitoring data are tabulated and presented in Table 3.

Fathead Minnow Larvae

Survival and growth (dry weight) data are summarized in Table 4, and data for individual replicate test containers are presented in Table 5.

Mortality in samples L1 and L2 was significantly higher than in control water, and these data were excluded from further statistical analysis.

Larval weight data were normally distributed (Shapiro-Wilkes) but were not homogeneous (Bartletts B = 22.42). Data transformation (square root, log, arcsin) did not correct the non-homogeneity. Protocol guidance suggests that Steel's Many-One Rank Test be used to analyze growth data, but Steel's cannot be used when there are less than 4 replicates. Telephone guidance from EPA Cincinnati directed us to transform the data to produce the Bartletts B value closest to the critical number, and use that transformed data set to perform Dunnett's test. Square root transformation produced a Bartlett's B value of 17.64, compared with a critical B at 0.05 with 5 df of 15.09. Dunnett's analysis was done on the

VOL 12 2 1398

R0054698

Introduction

As part of the Santa Clara Valley Non-Point Source Program, toxicity testing must be carried out on water samples collected during both dry weather (four times) and wet weather (three times). Dry weather tests require daily collection of water samples at the four stream stations (S1-S4). Wet weather tests are conducted using a single composite sample of runoff water for the daily renewals. This test is the first of three wet weather tests. Three toxicity tests are conducted, utilizing Ceriodaphnia dubia (invertebrate), Pimephales promelas (fish) and Selenastrum capricornutum (plant).

The Ceriodaphnia and Pimephales tests are seven days in duration, and are static-renewal protocols, requiring daily replacement of test solutions. Collections of runoff water are made by MBL personnel and stored at 4°C. Aliquots of this stored water are used for daily renewals.

The three bioassays were performed concurrently. Daphnids and fish were run on 15-21 February, 1989. Algae were tested in two batches, 14-18 February and 15-19 February, 1989. Methods, results and data are presented in the following pages.

The samples were collected and delivered to MBL by Kinnetic Laboratories Inc. personnel. The experimental design called testing only undiluted (100%) stream water. A lab water control (EPA moderately-hard) was run to provide quality assurance data. The lab water results were also used as the comparative data for statistical comparisons.

Most of the runoff samples proved to be acutely toxic to Ceriodaphnia, producing 100% mortality within 8 hours of test initiation. Those acutely toxic samples were S1, S2, S3, L2, L3, L4, L5 AND L6. After consultation with our client, we prepared 1:10 dilutions of each of those samples and started the Ceriodaphnia test again using 10% concentrations.

Fathead minnow and Selenastrum bioassays were done with undiluted runoff samples.

VOL 12 2 1399

Methods

Ceriodaphnia

Test organisms were neonates derived from in-house cultures. Original broodstock was from EPA Duluth, received 11 May, 1988 and cultured in EPA moderately hard water prepared with Milli-Q water. Samples of stream test water were collected daily during the test, and lab control water was EPA moderately hard (Milli-Q).

The test was initiated with 4-8 hour old neonates derived from third broods of individually maintained broodstock. Testing was conducted with 10 individuals per treatment, each in individual plastic cups containing 15 ml of test solution. Test temperature was 25 ± 1°C and photoperiod was 16 hour light:8 hour dark. Test solutions were renewed daily, concurrent with transfers, water quality measurements and assessment of survival and reproduction. At each daily transfer, new media were inoculated with food (2 drops of Ceriodaphnia chow and 1 drop of Selenastrum culture, density approximately 2.5 X 10^6 cells/ml). Following the 7-day test period, survival data was statistically evaluated using the probit method to calculate the 96-hour LC50. Reproductive data was evaluated using ANOVA and Dunnett's Test after confirming data homogeneity by Bartlett's Test. Test conditions and organism data are summarized in Appendix Table A-1.

Fathead Minnow Larvae

Test organisms were larvae, less than 24 hours old, obtained from in-house culture. All larvae were from the same spawning substrate, but probably from multiple spawns. Original broodstock was purchased from Thomas Fish Farms, San Rafael, California, approximately March of 1988. Stream test water samples were collected fresh each day. Control water was EPA moderately hard (Milli-Q). Ten larvae were used in each test container and there were three replicate containers per concentration. Each larval container was fed three times daily with 750-1000 newly-hatched Artemia nauplii. Test temperature was 25 ± 1°C, and photoperiod was 16:8. Daily renewal of 80% of the test volume coincided with daily environmental monitoring and assessment of survival. After seven days of exposure, the test was terminated by addition of formalin to each container. Surviving larvae were dried and weighed, and weight data were statistically evaluated using Bartlett's Test followed by ANOVA and Dunnett's Test. Probit analysis of survival data was used to calculate the 96-hour LC_1. Test conditions and organism data are summarized in appendix Table A-2.

Selenastrum

Algal assays were conducted in sterile 250 ml Erlenmeyer flasks. Preparation of the nutrient medium followed guidelines set forth in EPA-600/9-78-018.

Introduction

As part of the Santa Clara Valley Non-Point Source Program, toxicity testing must be carried out on water samples collected during both dry weather (four times) and wet weather (three times). Dry weather tests require daily collection of water samples at the four stream stations (S1-S4). Wet weather tests are conducted using a single composite sample of runoff water for the daily renewals. This test is the second of three wet weather tests. Three toxicity tests are conducted, utilizing Ceriodaphnia dubia (invertebrate), Pimephales promelas (fish) and Selenastrum capricornutum (plant).

The Ceriodaphnia and Pimephales tests are seven days in duration, and are static-renewal protocols, requiring daily replacement of test solutions. Collections of runoff water are made by MBL personnel and stored at 4°C. Aliquots of this stored water are used for daily renewals.

The three bioassays were performed concurrently. Daphnids and fish were run on 14-21 March, 1989. Algae were tested in two batches, 11-15 March and 12-16 March, 1989. Methods, results and data are presented in the following pages.

The samples were collected and delivered to MBL by Kinnetic Laboratories Inc. personnel. The experimental design called for testing only undiluted (100%) stream water. A lab water control (EPA moderately-hard) was run to provide quality assurance data. The lab water results were also used as the comparative data for statistical comparisons.

Some of the runoff samples proved to be acutely toxic to Ceriodaphnia, producing 100% mortality within 8 hours of test initiation. Those acutely toxic samples were S1, S2, L5 and L6. We prepared dilutions of each of those samples and started the Ceriodaphnia test again using 25% or 50% concentrations.

Fathead minnow and Selenastrum bioassays were done with undiluted runoff samples.

R0054711

Methods

Ceriodaphnia

Test organisms were neonates derived from in-house cultures. Original broodstock was from EPA Duluth, received 11 May, 1988 and cultured in EPA moderately hard water prepared with Milli-Q water. Samples of stream test water were collected daily during the test, and lab control water was EPA moderately hard (Milli-Q).

The test was initiated with 4-8 hour old neonates derived from third broods of individually maintained broodstock. Testing was conducted with 10 individuals per treatment, each in individual plastic cups containing 15 ml of test solution. Test temperature was 25 ± 1°C and photoperiod was 16 hour light:8 hour dark. Test solutions were renewed daily, concurrent with transfers, water quality measurements and assessment of survival and reproduction. At each daily transfer, new media were inoculated with food (2 drops of Ceriodaphnia chow and 1 drop of Selenastrum culture, density approximately 2.5 X 10^6 cells/ml). Following the 7-day test period, survival data was statistically evaluated using the probit method to calculate the 96-hour LC50. Reproductive data was evaluated using ANOVA and Dunnett's Test after confirming data homogeneity by Bartlett's Test. Test conditions and organism data are summarized in Appendix Table A-1.

Fathead Minnow Larvae

Test organisms were larvae, less than 24 hours old, obtained from in-house culture. All larvae were from the same spawning substrate, but probably from multiple spawns. Original broodstock was purchased from Thomas Fish Farms, San Rafael, California, approximately March of 1988. Stream test water samples were collected fresh each day. Control water was EPA moderately hard (Milli-Q). Ten larvae were used in each test container and there were three replicate containers per concentration. Each larval container was fed three times daily with 750-1000 newly-hatched Artemia nauplii. Test temperature was 25 ± 1°C, and photoperiod was 16:8. Daily renewal of 80% of the test volume coincided with daily environmental monitoring and assessment of survival. After seven days of exposure, the test was terminated by addition of formalin to each container. Surviving larvae were dried and weighed, and weight data were statistically evaluated using Bartlett's Test followed by ANOVA and Dunnett's Test. Probit analysis of survival data was used to calculate the 96-hour LC_1. Test conditions and organism data are summarized in appendix Table A-2.

VOL 12 2 1412

Selenastrum

Algal assays were conducted in sterile 250 ml Erlenmeyer flasks. Preparation of the nutrient medium followed guidelines set forth in EPA-600/9-78-018.

All algal counts were made manually with a hemacytometer and microscope. Treatment groups and controls were set up with a minimum of three replicates. Testing was conducted in an environmental chamber with continuous illumination of 400 ft/candles at 24 ± 2°C for 96 hours. All test flasks were innoculated with approximately $\bar{1} \times 10^4$ cells/ml from a 4 day old stock culture. Cultures were shaken twice daily by hand. Upon conclusion of testing, statistical analyses were made of final cell densities to determine EC50 concentrations using the Probit Method. Bartlett's test was used to confirm homogeneity of variance after which Dunnett's test was used.

2

1413

Results and Conclusions

Ceriodaphnia

On 13 March, rangefinder acute testing was initiated on all samples. Within 8 hours, all daphnids in samples S1, S2, L5 and L6 had died. Dilutions of those samples were prepared using laboratory water, and the entire test was re-started on 14 February. The reproduction and survival data summarized in Tables 1 and 2 are the results of testing 100% concentrations of samples L1, L3, L4 and L7, 50% concentrations of samples S1 and L5 and 25% concentrations of samples S2 and L6. Data were statistically analyzed using the laboratory water controls as the comparative data.

Analysis of survival data by Fisher's Exact Test showed that all samples except L7 produced statistically significant mortality when compared with laboratory water controls. Following protocol guidelines, reproduction data for those samples was excluded from subsequent statistical analysis.

Mean young production for Sample L7 was higher (25.8 per adult) than laboratory water controls (17.3 per adult). No statistical analysis was necessary to determine that Sample L7 did not inhibit reproduction when compared with controls.

Environmental monitoring data are tabulated and presented in Table 3.

Fathead Minnow Larvae

Survival and growth (dry weight) data are summarized in Table 4, and data for individual replicate test containers are presented in Table 5.

Mortality in sample L1 was significantly higher than in control water, and these data were excluded from further statistical analysis.

Larval weight data were normally distributed (Shapiro-Wilkes) and homogeneous (Bartletts B = 7.324). Dunnett's analysis was done on the untransformed weight data. There was no significant decrease in mean larval weight in samples S1, S2, L5, and L7 when compared with the weight of laboratory water controls.

Environmental monitoring data for fathead minnow larvae are summarized in Table 6.

VOL 12 2 1 4 1 4

Selenastrum

Growth and environmental monitoring data are summarized in Table 7.

Because of the large number of samples, the test was run in two batches. Run #1 included samples S1, S2, S3, S4 and L1. Run #2 included samples L3, L4, L5, L6 and L7. Each sample set had its own control.

For Run #1, cell number data were normally distributed (Shapiro-Wilkes) and homogeneous (Bartletts B = 8.606 vs tabled X^2 value at p=0.01 and 4 d.f. = 13.28). There were no visible cells in sample L1 after four days of incubation, so these data were excluded from further statistical analysis. There were significantly decreased cell numbers in sample S1, S2, S3 and S4 when compared with growth in lab water controls.

For Run #2, cell number data were normally distributed (Shapiro-Wilkes) and homogeneous. (Bartlett's B = 9.736 vs tabled critical value for p=0.01 and df=5 of 15.09). ANOVA and Dunnett's tests were done on the untransformed data. There was no significant decrease in mean cell numbers in samples L3, L6 and L7 when compared with growth in lab water controls. There were significantly decreased cell numbers in samples L4 and L5.

Introduction

As part of the Santa Clara Valley Non-Point Source Program, toxicity testing must be carried out on water samples collected during both dry weather (four times) and wet weather (three times). Dry weather tests require daily collection of water samples at the four stream stations (S1-S4). Wet weather tests are conducted using a single composite sample of runoff water for the daily renewals. This test is the third of three wet weather tests. Three toxicity tests are conducted, utilizing Ceriodaphnia dubia (invertebrate), Pimephales promelas (fish) and Selenastrum capricornutum (plant).

The Ceriodaphnia and Pimephales tests are seven days in duration, and are static-renewal protocols, requiring daily replacement of test solutions. Collections of runoff water are made by MBL personnel and stored at 4°C. Aliquots of this stored water are used for daily renewals.

The three bioassays were performed concurrently. Daphnids and fish were run on 28 March - 4 April, 1989. Algae were tested in two batches, both run on 30 March - 4 April, 1989. Methods, results and data are presented in the following pages.

The samples were collected and delivered to MBL by Kinnetic Laboratories Inc. personnel. The experimental design called for testing only undiluted (100%) stream water. A lab water control (EPA moderately-hard) was run to provide quality assurance data. The lab water results were also used as the comparative data for statistical comparisons.

Based upon previous wet weather test results, we expected many of the runoff samples to produce rapid and complete mortality in Ceriodaphnia tests. After one day of exposure in this test, however, most Ceriodaphnia were still alive, so we did not prepare dilutions of any of the test samples. All species were tested with undiluted runoff samples.

VOL 12 2 1434

Methods

Ceriodaphnia

Test organisms were neonates derived from in-house cultures. Original broodstock was from EPA Duluth, received 11 May, 1988 and cultured in EPA moderately hard water prepared with Milli-Q water. Samples of stream test water were collected daily during the test, and lab control water was EPA moderately hard (Milli-Q).

The test was initiated with 4-8 hour old neonates derived from third broods of individually maintained broodstock. Testing was conducted with 10 individuals per treatment, each in individual plastic cups containing 15 ml of test solution. Test temperature was 25 ± 1°C and photoperiod was 16 hour light:8 hour dark. Test solutions were renewed daily, concurrent with transfers, water quality measurements and assessment of survival and reproduction. At each daily transfer, new media were inoculated with food (2 drops of *Ceriodaphnia* chov and 1 drop of *Selenastrum* culture, density approximately 2.5 X 10^6 cells/ml). Following the 7-day test period, survival data was statistically evaluated using the probit method to calculate the 96-hour LC50. Reproductive data was evaluated using ANOVA and Dunnett's Test after confirming data homogeneity by Bartlett's Test. Test conditions and organism data are summarized in Appendix Table A-1.

Fathead Minnow Larvae

Test organisms were larvae, less than 24 hours old, obtained from in-house culture. All larvae were from the same spawning substrate, but probably from multiple spawns. Original broodstock was purchased from Thomas Fish Farms, San Rafael, California, approximately March of 1988. Stream test water samples were collected fresh each day. Control water was EPA moderately hard (Milli-Q). Ten larvae were used in each test container and there were three replicate containers per concentration. Each larval container was fed three times daily with 750-1000 newly-hatched *Artemia* nauplii. Test temperature was 25 ± 1°C, and photoperiod was 16:8. Daily renewal of 80% of the test volume coincided with daily environmental monitoring and assessment of survival. After seven days of exposure, the test was terminated by addition of formalin to each container. Surviving larvae were dried and weighed, and weight data were statistically evaluated using Bartlett's Test followed by ANOVA and Dunnett's Test. Probit analysis of survival data was used to calculate the 96-hour LC_1. Test conditions and organism data are summarized in appendix Table A-2.

VOL 12 2 1435

Selenastrum

Algal assays were conducted in sterile 250 ml Erlenmeyer flasks. Preparation of the nutrient medium followed guidelines set forth in EPA-600/9-78-018.

All algal counts were made manually with a hemacytometer and microscope. Treatment groups and controls were set up with a minimum of three replicates. Testing was conducted in an environmental chamber with continuous illumination of 400 ft/candles at 24 ± 2°C for 96 hours. All test flasks were innoculated with approximately 1×10^4 cells/ml from a 4 day old stock culture. Cultures were shaken twice daily by hand. Upon conclusion of testing, statistical analyses were made of final cell densities to determine EC50 concentrations using the Probit method. Bartlett's test was used to confirm homogeneity of variance after which Dunnett's test was used.

VOL 12 2 1436

R0054736

Results and Conclusions

Ceriodaphnia

Testing was initiated on 28 March, 1989. Reproduction and survival data are summarized in Table 1 and are presented in full in Table 2. Data was statistically analysed using the laboratory water as the comparitive dictum ("control").

Analysis of survival data by Fisher's Exact Test showed that all samples except L-2 and L-7 produced statistically significant mortality when compared with laboratory water controls. Following protocol guidelines, reproduction data for those samples was excluded from subsequent statistical analysis.

Reproduction data for control, L-2 and L-7 samples were found to be normally distributed (Shapiro-Wilkes test) and homogeneous (Bartlett's B = 2.760). Subsequent ANOVA and Dunnett's tests showed that there was significantly decreased young production in sample L-2 when compared with lab water controls. Sample L-7 was not significantly diferent from controls.

Environmental monitoring data are tabulated and presented in Table 3.

Fathead Minnow Larvae

Survival and growth (dry weight) data are summarized in Table 4, and data for individual replicate test containers are presented in Table 5.

Larval weight data were normally distributed (Shapiro-Wilkes) and homogeneous (Bartletts B = 11.89). Dunnett's analysis was done on the untransformed weight data. Mean larval weight in all samples tested was significantly decreased in comparison with larval weight of laboratory controls. For this data set, the minimum significant difference was 0.145 grams, representing a 17.9% reduction in larval weight from the control.

Environmental monitoring data for fathead minnow larvae are summarized in Table 6.

VOL 12 2 1437

Selenastrum

Growth and environmental monitoring data are summarized in Table 7.

Because of the large number of samples, the test was run in two batches. Run #1 included samples L4, L5, L6 and L7. Run #2 included samples S1,S2,S4,L2,and L3. Each sample set had its own control.

For Run #1, cell number data were normally distributed (Shapiro-Wilkes) and homogeneous (Bartletts B = 8.941 vs tabled X^2 value at p=0.01 and 4 d.f. = 13.28). There were significantly decreased cell numbers in samples L4, L5, L6 and L7 when compared with growth in lab water controls.

For Run #2, cell number data were normally distributed (Shapiro-Wilkes) but were not homogeneous (Bartletts B = 16.84). Data transformation (square root, log, arcsin) did not correct the non-homogenity. Protocol guidance suggests that Steel's Many-One Rank Test be used to analyze growth data, but Steel's cannot be used when there are less than 4 replicates. Telephone guidance from EPA Cincinnati directed us to transform the data to produce the Bartletts B value closest to the critical number, and use that transformed data set to perform Dunnett's test. Square root transformation produced a Bartlett's B value of 15.58, compared with a critical B at 0.05 with a 5df of 15.09. Dunnett's analysis was done on the square root trasformed data. There was no significant decrease in cell number in samples S1, S2, and L3 when compared with laboratory water controls. There were significantly decreased cell numbers in samples S4 and L2.

APPENDIX A

Summary of Test Conditions

R0054744

TABLE A-1

Ceriodaphnia Bioassay

Test Type:	Static Daily Renewal
Test Endpoints:	Survival, Reproduction
Test Duration:	7 days - 168 hours
Temperature:	25 ± 1°C
Photoperiod:	16 L: 8 D
Start:	12 December, 1988, 14:30 hours
Finish:	19 December, 1988, 14:30 hours
Test Containers:	1 oz plastic cups
Test Volume:	15 ml
Dilution Water:	Not Applicable
Test Material:	Santa Clara Valley NPS - Dry Weather #1
Test Concentrations:	100%, controls
# Replicates:	10
Organisms per replicate:	1
Test Species:	Ceriodaphnia dubia
Source:	in-house culture
Age:	4-8 hours
Acclimation/Culture Water:	EPA Moderately Hard (Milli-Q)
Diet:	Selenastrum, Ceriodaphnia chov

VOL 12 2 1445

TABLE A-2

Fathead Minnow Bioassay

Test Type:	Static Daily Renewal
Test Endpoints:	Survival, Growth
Test Duration:	7 days - 168 hours
Temperature:	25 ± 1°C
Photoperiod:	16 L: 8 D
Start:	12 December, 1988, 11:00 hours
Finish:	19 December, 1988, 11:00 hours
Test Containers:	1 liter glass jars
Test Volume:	500 ml
Dilution Water:	Not Applicable
Test Material:	Santa Clara Valley NPS - Dry Weather #1
Test Concentrations:	100%, control
# Replicates:	3
Organisms per replicate:	10
Test Species:	Pimephales promelas (Fathead minnow)
Source:	in-house culture
Age:	<24 hours
Culture Water:	Dechlorinated Tap
Diet:	Artemia nauplii

VOL 12 2 1446

R0054746

TABLE A-3

Selenastrum Bioassay

Test Type:	Static
Test Endpoints:	Growth, (cell number)
Test Duration:	4 days, 96 hours
Temperature:	24 ± 2°C
Photoperiod:	Continuous light
Light Intensity:	400 ± 40 FC
Start:	13 December, 1988, 16:00 hours
Finish:	17 December, 1988, 16:00 hours
Test Containers:	250 ml Erlenmeyer flasks
Test Volume:	100 ml
Dilution Water:	Not Applicable
Test Material:	Santa Clara Valley NPS - Dry Weather #1
Test Concentrations:	100%, Control
# Replicates:	3
Organisms per replicate:	10,000/ml innoculated
Test Species:	*Selenastrum capricornutum*
Source:	In-house culture
Age:	4 days
Culture Water:	EPA Moderately Hard

R0054761

Introduction

As part of the Santa Clara Valley Non-Point Source Program, toxicity testing must be carried out on water samples collected during both dry weather (four times) and wet weather (twice). Dry weather tests require daily collection of water samples at the four stream stations (S1-S4). Wet weather tests will be conducted using a single composite sample of runoff water for the daily renewals. This test is the first of four dry weather tests. Three toxicity tests are conducted, utilizing Ceriodaphnia dubia (invertebrate), Pimephales promelas (fish) and Selenastrum capricornutum (plant).

The Ceriodaphnia and Pimephales tests are seven days in duration, and are static-renewal protocols, requiring daily replacement of test solutions with newly-collected test water samples. Daily collections of stream water are made by MBL personnel.

The three bioassays were performed concurrently. Daphnids and fish were run on 13-20 December,1988 while algae were tested on 13-17 December, 1988. Methods, results and data are presented in the following pages.

The samples were collected and delivered to MBL by MBL personnel. The experimental design called testing only undiluted (100%) stream water. A lab water control (EPA moderately-hard) was run to provide quality assurance data. The lab water results were also used as the comparative data for statistical comparisons.

VOL 12 2 1462

R0054762

Methods

Ceriodaphnia

Test organisms were neonates derived from in-house cultures. Original broodstock was from EPA Duluth, received 11 May, 1988 and cultured in EPA moderately hard water prepared with Milli-Q water. Samples of stream test water were collected daily during the test, and lab control water was EPA moderately hard (Milli-Q).

The test was initiated with 4-8 hour old neonates derived from third broods of individually maintained broodstock. Testing was conducted with 10 individuals per treatment, each in individual plastic cups containing 15 ml of test solution. Test temperature was 25 ± 1°C and photoperiod was 16 hour light:8 hour dark. Test solutions were renewed daily, concurrent with transfers, water quality measurements and assessment of survival and reproduction. At each daily transfer, new media were inoculated with food (2 drops of Ceriodaphnia chow and 1 drop of Selenastrum culture, density approximately 2.5 X 10^6 cells/ml). Following the 7-day test period, survival data was statistically evaluated using the probit method to calculate the 96-hour LC50. Reproductive data was evaluated using ANOVA and Dunnett's Test after confirming data homogeneity by Bartlett's Test. Test conditions and organism data are summarized in Appendix Table A-1.

Fathead Minnow Larvae

Test organisms were larvae, less than 24 hours old, obtained from in-house culture. All larvae were from the same spawning substrate, but probably from multiple spawns. Original broodstock was purchased from Thomas Fish Farms, San Rafael, California, approximately March of 1988. Stream test water samples were collected fresh each day. Control water was EPA moderately hard (Milli-Q). Ten larvae were used in each test container and there were three replicate containers per concentration. Each larval container was fed three times daily with 750-1000 newly-hatched Artemia nauplii. Test temperature was 25 ± 1°C, and photoperiod was 16:8. Daily renewal of 80% of the test volume coincided with daily environmental monitoring and assessment of survival. After seven days of exposure, the test was terminated by addition of formalin to each container. Surviving larvae were dried and weighed, and weight data were statistically evaluated using Bartlett's Test followed by ANOVA and Dunnett's Test. Probit analysis of survival data was used to calculate the 96-hour LC_1. Test conditions and organism data are summarized in appendix Table A-2.

Selenastrum

Algal assays were conducted in sterile 250 ml Erlenmeyer flasks. Preparation of the nutrient medium followed guidelines set forth in EPA-600/9-78-018.

VOL 12 2 1463

All algal counts were made manually with a hemacytometer and microscope. Treatment groups and controls were set up with a minimum of three replicates. Testing was conducted in an environmental chamber with continuous illumination of 400 ft/candles at 24 ± 2°C for 96 hours. All test flasks were innoculated with approximately $\bar{1}$ X 10^4 cells/ml from a 4 day old stock culture. Cultures were shaken twice daily by hand. Upon conclusion of testing, statistical analyses were made of final cell densities to determine EC50 concentrations using the Probit Method. Bartlett's test was used to confirm homogeneity of variance after which Dunnett's test was used.

VOL 12 2 1464

Results and Conclusions

Ceriodaphnia

Reproduction and survival data for Ceriodaphnia are summarized in Table 1, and are presented in full in Table 2. Data were statistically analyzed using the laboratory water as the comparative datum ("control").

No stream sample produced ≥ 50% mortality of Ceriodaphnia after 96 hours exposure. The 96-hour LC_{50} for Ceriodaphnia is >100% for all samples.

Reproduction data were determined to be homogeneous by Bartlett's test, with a B value of 0.5476. Tabled X^2 value for 4 d.f. at $p=0.05$ was 9.488. ANOVA and Dunnett's test were performed on the untransformed reproduction data. For these data, the minimum significant difference is 8.15 young per adult, representing a 45.3% reduction of mean young production from control levels. There was no significant reduction in young produced between any stream water and the lab water controls.

Environmental monitoring data are tabulated and presented in Table 3.

Fathead Minnow Larvae

Survival and growth (dry weight) data are summarized in Table 4, and data for individual replicate test containers are presented in Table 5.

There was no effluent concentration tested in which survival was less than 83%. The 96-hour LC_{50} values, therefore, are >100% for all samples.

Larval weight data were determined to be homogeneous, with a Bartlett's B value of 4.674. The tabled X^2 value for 4 d.f. at $p=0.05$ is 9.488. Subsequent ANOVA and Dunnetts analyses were done on the untransformed weight data. There was no significant decrease in mean larval weight in samples S-1, S-2 and S-3 when compared with the weight of dilution water controls. There was significantly decreased larval weight in the S-4 sample.

Environmental monitoring data for fathead minnow larvae are summarized in Table 6.

Selenastrum

Growth and environmental monitoring data are summarized in Table 7.

The lab water growth (cell number) data were set equal to 100% growth, and cell numbers in each stream sample were transformed to

VOL 12 2 1465

percentage of the lab water values. The 96-hour EC_{50} was calculated to be >100% of all stream samples.

Cell number data were homogeneous (Bartletts B = 0.9274 vs tabled X^2 value at p=0.05 and 4 d.f. = 9.488). ANOVA and Dunnetts analyses were done on the untransformed data. There was no signficant decrease in mean cell numbers in any of the stream samples when compared with growth in lab water controls.

All algal counts were made manually with a hemacytometer and microscope. Treatment groups and controls were set up with a minimum of three replicates. Testing was conducted in an environmental chamber with continuous illumination of 400 ft/candles at 24 ± 2°C for 96 hours. All test flasks were innoculated with approximately 1×10^4 cells/ml from a 4 day old stock culture. Cultures were shaken twice daily by hand. Upon conclusion of testing, statistical analyses were made of final cell densities to determine EC50 concentrations using the Probit Method. Bartlett's test was used to confirm homogeneity of variance after which Dunnett's test was used.

VOL 12 2 1478

R0054778

Results and Conclusions

Ceriodaphnia

Reproduction and survival data for Ceriodaphnia are summarized in Table 1, and are presented in full in Table 2. Data were statistically analyzed using the laboratory water as the comparative datum ("control").

Analysis of mortality data by Fisher's Exact Test showed that sample S-2 produced statistically significant mortality when compared with laboratory water controls (Fishers b value = 3). Following protocol guidance, reproduction data from S-2 were not included in subsequent statistical analyses.

Reproduction data were found to be not normally distributed (D'Agostino's D value = 0.2397). Critical D values are 0.2655 to 0.2874. Data could not be normalized by any transformation (Square root, log, or arcsin $\sqrt{x}$), and subsequent analysis was done by the non-parametric Steel's Many-One Rank Test. The tabulated critical rank sum value for n=10 and k=4 is 76. Rank sums for S-1, S-3, S-4 and S-5 all exceeded 76, indicating that reproduction in these samples was not significantly lower than in the laboratory control water.

Environmental monitoring data are tabulated and presented in Table 3.

Fathead Minnow Larvae

Survival and growth (dry weight) data are summarized in Table 4, and data for individual replicate test containers are presented in Table 5. There was not enough sample from S-5 to do the fathead minnow bioassay, and only S-1 through S-4 were included.

Larval weight data were determined to be normally distributed (Shpiro-Wilkes test), and homogeneous, with a Bartlett's B value of 0.979. The tabled X^2 value for 4 d.f. at p=0.01 is 13.28. Subsequent ANOVA and Dunnetts analyses were done on the untransformed weight data. There was no significant decrease in mean larval weight in samples S-1, S-2, S-3 and S-4 when compared with the weight of dilution water controls.

Environmental monitoring data for fathead minnow larvae are summarized in Table 6.

Selenastrum

Growth and environmental monitoring data are summarized in Table 7.

Cell number data were normally distributed (Shapiro-Wilkes) and homogeneous (Bartletts B = 0.9274 vs tabled X^2 value at p=0.01 and 5 d.f.

VOL 12 2 1479

Introduction

As part of the Santa Clara Valley Non-Point Source Program, toxicity testing must be carried out on water samples collected during both dry weather (four times) and wet weather (twice). Dry weather tests require daily collection of water samples at stream stations. Wet weather tests will be conducted using a single composite sample of runoff water for the daily renewals. This test is the second of four dry weather tests. Three toxicity tests are conducted, utilizing Ceriodaphnia dubia (invertebrate), Pimephales promelas (fish) and Selenastrum capricornutum (plant).

The Ceriodaphnia and Pimephales tests are seven days in duration, and are static-renewal protocols, requiring daily replacement of test solutions with newly-collected test water samples. Daily collections of stream water were made only during the first two days of the test period. On the second day it became clear that an unexpected rainstorm was imminent, and the inclusion of storm runoff in our "dry weather" samples was not appropriate in terms of the study objectives. The decision was made, therefore, to collect enough sample on Day 2 (our last dry day) to perform daily renewals for the remainder of the 7-day test period. In summary, water collections were made only on Days 1 and 2 of the test period. Water collected on Day 2 was stored at 4°C for the remainder of the 7-day test period, and daily renewals on days 2-7 were done using this stored water.

The three bioassays were performed concurrently. Daphnids and fish were run on 3-10 February, 1989 while algae were tested on 3-7 February, 1989. Methods, results and data are presented in the following pages.

The samples were collected and delivered to MBL by MBL personnel. The experimental design called testing only undiluted (100%) stream water. A lab water control (EPA moderately-hard) was run to provide quality assurance data. The lab water results were also used as the comparative data for statistical comparisons.

VOL 12 2 1480

Methods

Ceriodaphnia

Test organisms were neonates derived from in-house cultures. Original broodstock was from EPA Duluth, received 11 May, 1988 and cultured in EPA moderately hard water prepared with Milli-Q water. Samples of stream test water were collected daily during the test, and lab control water was EPA moderately hard (Milli-Q).

The test was initiated with 4-8 hour old neonates derived from third broods of individually maintained broodstock. Testing was conducted with 10 individuals per treatment, each in individual plastic cups containing 15 ml of test solution. Test temperature was 25 ± 1°C and photoperiod was 16 hour light:8 hour dark. Test solutions were renewed daily, concurrent with transfers, water quality measurements and assessment of survival and reproduction. At each daily transfer, new media were inoculated with food (2 drops of Ceriodaphnia chow and 1 drop of Selenastrum culture, density approximately 2.5 X 10^6 cells/ml). Following the 7-day test period, survival data was statistically evaluated using the probit method to calculate the 96-hour LC50. Reproductive data was evaluated using ANOVA and Dunnett's Test after confirming data homogeneity by Bartlett's Test. Test conditions and organism data are summarized in Appendix Table A-1.

Fathead Minnow Larvae

Test organisms were larvae, less than 24 hours old, obtained from in-house culture. All larvae were from the same spawning substrate, but probably from multiple spawns. Original broodstock was purchased from Thomas Fish Farms, San Rafael, California, approximately March of 1988. Stream test water samples were collected fresh each day. Control water was EPA moderately hard (Milli-Q). Ten larvae were used in each test container and there were three replicate containers per concentration. Each larval container was fed three times daily with 750-1000 newly-hatched Artemia nauplii. Test temperature was 25 ± 1°C, and photoperiod was 16:8. Daily renewal of 80% of the test volume coincided with daily environmental monitoring and assessment of survival. After seven days of exposure, the test was terminated by addition of formalin to each container. Surviving larvae were dried and weighed, and weight data were statistically evaluated using Bartlett's Test followed by ANOVA and Dunnett's Test. Probit analysis of survival data was used to calculate the 96-hour LC_1. Test conditions and organism data are summarized in appendix Table A-2.

Selenastrum

Algal assays were conducted in sterile 250 ml Erlenmeyer flasks. Preparation of the nutrient medium followed guidelines set forth in EPA-600/9-78-018.

Introduction

As part of the Santa Clara Valley Non-Point Source Program, toxicity testing must be carried out on water samples collected during both dry weather (four times) and wet weather (twice). Dry weather tests require daily collection of water samples at stream stations. Wet weather tests will be conducted using a single composite sample of runoff water for the daily renewals. This test is the third of four dry weather tests. Three toxicity tests are conducted, utilizing Ceriodaphnia dubia (invertebrate), Pimephales promelas (fish) and Selenastrum capricornutum (plant).

The Ceriodaphnia and Pimephales tests are seven days in duration, and are static-renewal protocols, requiring daily replacement of test solutions with newly-collected test water samples. Daily collections of stream water were made by Kinnetic Laboratories (KLI) personnel.

The three bioassays were performed concurrently. Daphnids and fish were run on 9-16 April, 1989 while algae were tested on 8-12 April, 1989. Methods, results and data are presented in the following pages.

The experimental design called for testing only undiluted (100%) stream water. A lab water control (EPA moderately-hard) was run to provide quality assurance data. The lab water results were also used as the comparative data for statistical comparisons.

VOL 12 2 1496

R0054796

Methods

Ceriodaphnia

Test organisms were neonates derived from in-house cultures. Original broodstock was from EPA Duluth, received 11 May, 1988 and cultured in EPA moderately hard water prepared with Milli-Q water. Samples of stream test water were collected daily during the test, and lab control water was EPA moderately hard (Milli-Q).

The test was initiated with 4-8 hour old neonates derived from third broods of individually maintained broodstock. Testing was conducted with 10 individuals per treatment, each in individual plastic cups containing 15 ml of test solution. Test temperature was 25 ± 1°C and photoperiod was 16 hour light:8 hour dark. Test solutions were renewed daily, concurrent with transfers, water quality measurements and assessment of survival and reproduction. At each daily transfer, new media were inoculated with food (2 drops of Ceriodaphnia chow and 1 drop of Selenastrum culture, density approximately 2.5×10^6 cells/ml). Following the 7-day test period, survival data was statistically evaluated using the probit method to calculate the 96-hour LC50. Reproductive data was evaluated using ANOVA and Dunnett's Test after confirming data homogeneity by Bartlett's Test. Test conditions and organism data are summarized in Appendix Table A-1.

Fathead Minnow Larvae

Test organisms were larvae, less than 24 hours old, obtained from in-house culture. All larvae were from the same spawning substrate, but probably from multiple spawns. Original broodstock was purchased from Thomas Fish Farms, San Rafael, California, approximately March of 1988. Stream test water samples were collected fresh each day. Control water was EPA moderately hard (Milli-Q). Ten larvae were used in each test container and there were three replicate containers per concentration. Each larval container was fed three times daily with 750-1000 newly-hatched Artemia nauplii. Test temperature was 25 ± 1°C, and photoperiod was 16:8. Daily renewal of 80% of the test volume coincided with daily environmental monitoring and assessment of survival. After seven days of exposure, the test was terminated by addition of formalin to each container. Surviving larvae were dried and weighed, and weight data were statistically evaluated using Bartlett's Test followed by ANOVA and Dunnett's Test. Probit analysis of survival data was used to calculate the 96-hour LC_1. Test conditions and organism data are summarized in appendix Table A-2.

Selenastrum

Algal assays were conducted in sterile 250 ml Erlenmeyer flasks. Preparation of the nutrient medium followed guidelines set forth in EPA-600/9-78-018.

All algal counts were made manually with a hemacytometer and microscope. Treatment groups and controls were set up with a minimum of three replicates. Testing was conducted in an environmental chamber with continuous illumination of 400 ft/candles at 24 $\pm$ 2°C for 96 hours. All test flasks were innoculated with approximately 1×10^4 cells/ml from a 4 day old stock culture. Cultures were shaken twice daily by hand. Upon conclusion of testing, statistical analyses were made of final cell densities to determine EC50 concentrations using the Probit Method. Bartlett's test was used to confirm homogeneity of variance after which Dunnett's test was used.

Testing was conducted in an environmental chamber with continuous illumination of 400 ft/candles at 24 ± 2°C for 96 hours. All test flasks were innoculated with approximately $\bar{1}$ X 10^4 cells/ml from a 4 day old stock culture. Cultures were shaken twice daily by hand. Upon conclusion of testing, statistical analyses were made of final cell densities to determine EC50 concentrations using the Probit Method. Bartlett's test was used to confirm homogeneity of variance after which Dunnett's test was used.

VOL 12 2 150 1

Results and Conclusions

Ceriodaphnia

Reproduction and survival data for Ceriodaphnia are summarized in Table 1, and are presented in full in Table 2. Data were statistically analyzed using the laboratory water as the comparative datum ("control").

Analysis of mortality data by Fisher's Exact Test showed that sample S-4 produced statistically significant mortality when compared with laboratory water controls (Fishers b value = 3). Following protocol guidance, reproduction data from S-4 were not included in subsequent statistical analyses.

Reproduction data were found to be normally distributed (D'Agostino's D test) and homogeneous (Bartlett's B = 9.81).

None of the samples produced significantly decreased young production when compared with laboratory water controls.

Environmental monitoring data are tabulated and presented in Table 3.

Fathead Minnow Larvae

Survival and growth (dry weight) data are summarized in Table 4, and data for individual replicate test containers are presented in Table 5. There was not enough sample from S-5 to do the fathead minnow bioassay, and only S-1 through S-4 were included.

Larval weight data were determined to be normally distributed (Shapiro-Wilkes test), and homogeneous, with a Bartlett's B value of 3.85. The tabled X^2 value for 4 d.f. at p=0.01 is 13.28. Subsequent ANOVA and Dunnetts analyses were done on the untransformed weight data. There was no significant decrease in mean larval weight in samples S-1, S-2, and S-4 when compared with the weight of dilution water controls. There was significantly decreased larval weight in sample S-3.

Environmental monitoring data for fathead minnow larvae are summarized in Table 6.

Selenastrum

Growth and environmental monitoring data are summarized in Table 7.

Cell number data were normally distributed (Shapiro-Wilkes) and homogeneous (Bartletts B = 5.86 vs tabled X^2 value at p=0.01 and 4 d.f. = 13.28). ANOVA and Dunnetts analyses were done on the untransformed data. There was no signficant decrease in mean cell numbers in samples S1, S2 and S3 when compared with growth in lab water controls. There were significantly decreased cell numbers in sample S-4.

APPENDIX A

Summary of Test Conditions

R0054812

TABLE A-1

Ceriodaphnia Bioassay

Test Type:	Static Daily Renewal
Test Endpoints:	Survival, Reproduction
Test Duration:	7 days - 168 hours
Temperature:	25 ± 1°C
Photoperiod:	16 L: 8 D
Start:	9 April, 1989, 11:00 hours
Finish:	16 April, 1989, 11:00 hours
Test Containers:	1 oz plastic cups
Test Volume:	15 ml
Dilution Water:	Not Applicable
Test Material:	Santa Clara Valley NPS - Dry Weather #3
Test Concentrations:	100%, controls
# Replicates:	10
Organisms per replicate:	1
Test Species:	Ceriodaphnia dubia
Source:	in-house culture
Age:	4-8 hours
Acclimation/Culture Water:	EPA Moderately Hard (Milli-Q)
Diet:	Selenastrum, Ceriodaphnia chow

VOL 12 2 1513

R0054813

TABLE A-2

Fathead Minnow Bioassay

Test Type:	Static Daily Renewal
Test Endpoints:	Survival, Growth
Test Duration:	7 days - 168 hours
Temperature:	25 ± 1°C
Photoperiod:	16 L: 8 D
Start:	9 April, 1989, 12:00 hours
Finish:	16 April, 1989, 12:00 hours
Test Containers:	1 liter glass jars
Test Volume:	500 ml
Dilution Water:	Not Applicable
Test Material:	Santa Clara Valley NPS - Dry Weather #3
Test Concentrations:	100%, control
# Replicates:	3
Organisms per replicate:	10
Test Species:	Pimephales promelas (Fathead minnow)
Source:	in-house culture
Age:	<24 hours
Culture Water:	Dechlorinated Tap
Diet:	Artemia nauplii

VOL 12 2 1514

R0054814

TABLE A-3

Selenastrum Bioassay

Test Type:	Static
Test Endpoints:	Growth, (cell number)
Test Duration:	4 days, 96 hours
Temperature:	24 ± 2°C
Photoperiod:	Continuous light
Light Intensity:	400 ± 40 FC
Start:	8 April, 1989, 13:00 hours
Finish:	12 April, 1989, 13:00 hours
Test Containers:	250 ml Erlenmeyer flasks
Test Volume:	100 ml
Dilution Water:	Not Applicable
Test Material:	Santa Clara Valley NPS - Dry Weather #3
Test Concentrations:	100%, Control
# Replicates:	3
Organisms per replicate:	10,000/ml innoculated
Test Species:	Selenastrum capricornutum
Source:	In-house culture
Age:	4 days
Culture Water:	EPA Moderately Hard

APPENDIX G
POINT SOURCE LOADS

G.1 WASTEWATER TREATMENT PLANT LOADS

Annual loads were estimated for the three Lower South Bay wastewater treatment plants (San Jose/Santa Clara, Sunnyvale, Palo Alto) based on self-monitoring data provided by the Regional Board for 1987 and 1988. The data, shown in Table G-1, give for each year the number of samples, the number of samples below the detection limit, the average concentration, and the load for each plant. The total annual load is then computed in the right-hand column. Loads were estimated using synoptic rather than average flow measurements. The mean annual flows for each treatment plant are also provided at the top of each table.

When the majority of samples are below detection, the estimated load is uncertain and conservative because the concentration was assumed to equal the detection limit, whereas the actual concentration is between zero and the detection limit. Comparisons with nonpoint source loads were made only for those constituents which were consistently measured at levels well above detection limits.

G.2 OTHER POINT SOURCES

There are a number of point source discharges to the area streams, operating under NPDES Permits. These are facilities which pump contaminated groundwater from the aquifer, subject it to treatment to remove contaminants, and then discharge to a stream, often via a storm drain. All of the identified discharges are upstream of the stream

monitoring stations used in the study, and would therefore influence the conditions at the station, primarily during dry weather periods.

As part of their permit requirements, these plants submit regular reports providing information on discharge quantity and quality. For this study, WCC obtained and reviewed these reports for each of the facilities which discharge, covering a substantial portion of 1987. This source was useful in establishing the approximate rate and total volume of discharge by these point sources. There are usually a large number of flow observations reported, and the degree of fluctuation between observations is nominal, so that the average that was computed for use in the load estimates is considered to provide a suitable indicator of the quantity of treated groundwater discharged to the streams.

Characterization of the quality of these discharges is a different matter. The principal constraint imposed by the data in the Permit reports is that the laboratory analyses performed examined only organic compounds (the pollutants of concern at these sites), and, following treatment, all concentrations reported (with isolated occasional exceptions) were below detection levels.

To address this limitation, the RWQCB requested the facilities involved to conduct a special supplementary survey to provide information on heavy metal levels in the discharge. Heavy metals are a normal component of urban runoff and this information would provide a common element to use for comparisons of sources. Results from the single sample analyzed by these special studies were reviewed, and the concentrations observed were combined with the discharge flows from the more comprehensive flow records, to compute estimates of the pollutant loads from the point sources.

These results are summarized by Table G-2. Facilities are organized by stream, and the discharge rate and concentrations of observed pollutants are listed. Copper and zinc are selected for load computations because

they are the only metals that appear to be present often enough to include in a watershed summary. Coyote Creek is a partial exception, in that nickel, rather than copper is present. Zinc appears to be the only heavy metal that is observed in most of the discharges.

The flows are assumed to be uniform throughout the year, and the mass loads computed from the listed flows and concentrations are shown for the wet and dry seasons. These results are presented for each discharge, as is the total for all the discharges upstream of each stream monitoring station. The concentrations shown for the PS total for the watershed are the flow weighted concentrations for the composite point source discharges above each station, which could be compared with the measured concentrations at the station. Chapter 8 of the report discusses the influence of the presence of pollutants from upstream point sources on the projections of loads from watersheds that do not contain such facilities.

VOL 12 2 1620

APPENDIX H
ANALYSIS OF UNCERTAINTY IN LOAD ESTIMATES

The annual nonpoint source load estimates presented in Section 8 were derived from simulated flows and measured concentration data. Because the exact values of flows and concentrations are not known, annual load estimates have some degree of uncertainty associated with them. In this appendix we describe and quantify this uncertainty, so that future decisions and analyses can be based on both the loads estimates and their associated confidence levels.

The sources of uncertainty in loads estimates are summarized and discussed in Section H.1. Section H.2 then presents the procedures used to quantify uncertainty. Section H.3 discusses the results of the quantitative uncertainty analysis in terms of confidence bounds on annual load estimates for the entire valley.

H.1 SOURCES OF UNCERTAINTY

For the purposes of this study, annual loads are estimated as the product of annual flow volume and mean concentrations for each land use. Thus, uncertainty in the load arises from (1) uncertainty in the estimate of flow from each watershed and land use, and (2) uncertainty in the estimate of mean concentrations for each land use.

H.1.1 Uncertainty in Flow Estimates

Storm runoff flow volumes were estimated in this study using the rainfall-runoff model SWMM, as described in Appendix B. In watersheds where flow data were available, the model was calibrated to match observed

R0054920

VOL 12 2 1621

flow volumes. In watersheds where no flow data were available, the model was applied using input data from similar calibrated watersheds. The following factors contribute to uncertainty in flow estimates:

1. Model input parameters are not known exactly,

2. The model itself is an inexact representation of the actual hydrologic processes,

3. The measured flows used in calibration of the model are not exact.

Calibration of the model against observed flows attempts to minimize the first two components of flow uncertainty. However, as described in Appendix B it is not possible to arrive at a perfect calibration for any one watershed. Root Mean Square Errors (RMSEs) in annual load estimates generally ranged from 15 to 25 percent, but were as high as 40 percent in some watersheds. Errors in uncalibrated watersheds would be expected to be higher.

Even if the calibration resulted in a perfect match with observed flows, there would be some uncertainty associated with errors in flow measurements. The magnitude of these errors is currently unknown, but is assumed to be small relative to calibration errors in most watersheds. A possible exception to this is the Guadalupe River, where flow measurements were found to be inconsistent with reservoir release data (see Section 5.3.2 for a detailed discussion).

H.1.2 Uncertainty in the Mean Concentration

The annual mean concentrations for each land use and constituent were estimated from the sampling data collected during the 1987-88 and 1988-89 monitoring periods. The following factors contribute to the uncertainty in the estimated mean concentrations:

R0054921

1. Mean concentrations for each land use were estimated from a finite number of water quality samples (generally less than 25). Statistically, the degree of uncertainty in the mean decreases with large samples sizes, and increases as the sample variance increases. For industrial and open land uses, mean concentrations were estimated based on 5 or fewer samples.

2. Measured concentrations are subject to laboratory and field sampling errors. As discussed in Section C.4, laboratory QA/QC data indicated the data collected in this study are of good and reliable quality. Relative percent differences (RPDs) between field duplicates were on average 29 percent, and ranged from 0 to 100 percent. For laboratory duplicates, relative percent differences were on average 16 percent, and ranged from 0 to 40 percent.

3. Data collected during the 1987-88 and 1988-89 monitoring periods may not be representative of other years with higher rainfall. The monitoring period for this study unfortunately coincided with several years of drought in California. Thus, there is the concern that water quality in wet and normal years might differ significantly from data collected during dry years. As discussed in Section 8.6.4, dry years differ from wet years primarily in terms of the number of storms, not the volume of storms. Data collected during the monitoring period suggest little relationship between runoff volume, storm frequency, and concentration. However, buildup-washoff, water quality modeling results for Calabazas Creek (Appendix B) suggest that water quality is significantly different in wet years such as 1982-83 than in dry years such as the monitoring period. This component of uncertainty cannot be quantified until monitoring data are collected in wet years.

4. Land use concentrations were corrected by loads correction factors to compensate for differences between land use and stream station concentrations. As discussed in Section 8.6.2, the processes that might be explained by these loads correction factors are currently unknown. We

VOL 12 2 1622

R0054922

believe that these factors probably account for processes occurring within the stream bed. This component of uncertainty cannot be quantified until more data are collected on stream processes and stream bed water quality.

H.2 PROCEDURES USED TO QUANTIFY UNCERTAINTY

For this analysis, uncertainty is quantified by deriving confidence bounds on annual loads estimates, given the uncertainty in flow and concentration. A first-order, second moment approach is used, assuming that the distribution of load estimates for a given year can be described completely by the mean and variance of the estimates. Alternative methods for uncertainty analysis (e.g., Monte Carlo simulation) can give a more precise evaluation of uncertainty, but generally require more data and computational time than is practical for a modeling study of this scale.

The following sections describe the procedures and equations used in the analysis. Key assumptions include:

- Flow and concentration are assumed to be independent of each other.
- Uncertainty due to differences between water quality during the dry monitoring period and wetter years is not quantified, due to the lack of data. This component of uncertainty should be evaluated when wet-year water quality data are collected.
- Uncertainty due to stream bed processes is not evaluated, again due to lack of quantitative data on the effects of these processes.
- The mean and variance in flow estimates can be quantified using the model calibration errors, expressed as the ratio of observed to predicted annual flow volumes.

VOL 12 2 1623

R0054923

87

- The distribution of load estimates can be described completely by the mean estimate and the variance in estimates.

- In deriving confidence bounds, the distribution of errors in loads estimates is assumed to be Log Normal.

H.2.1 Uncertainty in Loads from a Single Land Use in a Watershed

The estimate of annual load from a single land use within a watershed is computed from the following model:

$$L_{ij} = Q_{ij} \bar{C}_j \qquad \text{(H-1)}$$

where

L_{ij} = the estimated load for a given year from watershed i, land use j

Q_{ij} = the estimated flow volume from watershed i, land use j

$\bar{C}_j$ = the estimated mean concentration for land use j

Because Q_{ij} and Cm_j are not precisely known, the expected value (or mean estimate) of L_{ij} is estimated by correcting the estimated flow by the mean calibration error:

$$E[L_{ij}] = E[Q_{ij}]\, E[C_j] = (Q_{ij}\bar{e}_i)\bar{C}_j \qquad \text{(H-2)}$$

where

$E[\,]$ = expected value (or mean) of $[\,]$

$\bar{e}_i$ = the mean flow model calibration error for watershed i, expressed as the mean ratio of observed to predicted flows

VOL 12 2 1624

R0054924

The variance of load estimates about this mean has two components. The first component, referred to as the intrinsic variance, accounts for the variability of flow and concentration estimates, assuming that the mean estimates of flow and concentration are known exactly:

$$\mathrm{Var}[L_{ij}]_{int} = (Q_{ij}\bar{e}_i)^2\mathrm{Var}[C_j] + \bar{C}_j^2\mathrm{Var}[Q_{ij}] + \mathrm{Var}[Q_{ij}]\mathrm{Var}[C_j] \quad \text{(H-3)}$$

where

$$\mathrm{Var}[\,] = \text{variance of } [\,] \quad \text{(H-4)}$$

The variance in C_j is simply the variance in the measured water quality samples for land use j, and accounts for both natural storm to storm variability and variability due to measurement (QA/QC) errors. The variance in Q_{ij} can be derived from the model calibration errors as follows:

$$\mathrm{Var}[Q_{ij}] = Q_{ij}^2\,\mathrm{Var}[e_i] \quad \text{(H-5)}$$

where e_i is the ratio of observed to predicted flows for watershed i.

The second component of the uncertainty in load estimates is the parametric variance. The parametric variance accounts for the fact that the mean estimates of flow and concentration are derived from limited data sets, and are therefore uncertain:

$$\mathrm{Var}[L_{ij}]_{par} = \mathrm{Var}[\,E[Q_{ij}]\,E[C_j]\,] \quad \text{(H-6)}$$

$$= (Q_{ij}\bar{e}_i)^2\mathrm{Var}[C_j]/n_c + \bar{C}m_j^2Q_{ij}^2\mathrm{Var}[e_i]/n_e + Q_{ij}^2\mathrm{Var}[e_i]\,\mathrm{Var}[C_j]/(n_e n_c)$$

R0054925

VOL 12 2 1625

where

n_c = number of concentration data
n_e = number of years of data used to estimate the mean model error

The total variance in load estimates for a given year is then given by the sum of the intrinsic and parametric variances:

$$Var[L_{ij}] = Var[L_{ij}]_{int} + Var[L_{ij}]_{par} \quad \text{(H-7)}$$

H.2.2 Uncertainty in Annual Loads Estimates for the Entire Study Area

The expected value of annual load estimates for the study area in year t is the sum of the mean load estimates for each watershed and land use in year t:

$$E[L_t] = \Sigma_i \Sigma_j E[L_{ij}] \quad \text{(H-8)}$$

where

$E[L_t]$ = the expected value of the load estimate for the study area in year t

Similarly, the variance in the estimate of the total annual load is the sum of the variances of load from each watershed and land use:

$$Var[L_t] = \Sigma_i \Sigma_j Var[L_{ij}] \quad \text{(H-9)}$$

H.2.3 Uncertainty in the Mean Annual Load Estimate

The mean annual load is the mean of the annual loads for the 12 year simulation period, and is estimated as follows:

$$E[L] = \Sigma_t E[L_t] / n_t \quad \text{(H-10)}$$

where

R0054926

VOL 12 2 1626

n_t = the number of years in the simulation period

The estimated mean is uncertain due to (1) the limited number of years of data used to estimate E[L], and (2) the parametric uncertainty in the mean estimates of flow and concentration. As a result, the variance in the mean annual load estimate is the sum of the sample variance of annual loads and the parametric variance:

$$Var[\ E[L]\ ] = \Sigma_t[(L_t - E[L])^2/(n_t-1) + Var[L_t]_{par}]/n_t \qquad (H\text{-}11)$$

H.2.4 Estimation of Confidence Bounds

The equations given above allow for the estimation of the mean estimate and the variance in estimates for (1) study area loads for any year t, and (2) the mean annual study area load. The next step in the analysis is to derive confidence bounds by assuming a distribution of estimates about the mean estimate. For this study, a log normal distribution of loads estimates was assumed. While there is no direct evidence that load estimates should be log normally distributed, this distribution is commonly observed in environmental data, and has the advantage of being bound by zero. Log normal distributions are described completely by the mean and variance.

H.2.5 Data Used in the Uncertainty Analysis

The uncertainty analysis described above requires (1) estimates of the flow model calibration errors, and (2) estimates of the mean and variance of concentrations for each land use and constituent.

Table H-1 summarizes the mean and variance of the model calibration error ratios (e_i) for each calibrated watershed. These were derived directly as the ratio of observed to predicted annual flow volumes for each calibration period. To quantify error ratios for uncalibrated watersheds, simulation experiments were conducted in which data from one calibrated

R0054927

VOL 12 2 1627

Table H-1. SUMMARY OF FLOW CALIBRATION ERROR RATIOS FOR EACH WATERSHED

Watershed	Mean Error (em_1)	Variance of Errors	Number of Values
Coyote Creek	1.01	0.20*	6*
Guadalupe River	1.22	1.11	9
San Tomas Aq. Cr.	1.20	0.09	12

Sunnyvale East Ch.	1.10	0.03	11
Stevens Creek**	1.28	0.27	8
Ungaged Areas**	1.19	0.28	22

*Since only 1 year of calibration was available for Coyote Creek, the variance in error was estimated as the mean of the variances from the 6 other calibrated watersheds.

**Derived from simulation experiments on Sunnyvale East and San Tomas Aquinas Creek.

VOL 12 2 1628

R0054928

watershed were used to simulate runoff from a second calibrated watershed. Thus, the second watershed was treated as if it were uncalibrated. For these experiments, Sunnyvale East Channel was simulated using Calabazas Creek model data, and San Tomas Aquinas Creek was simulated using Saratoga Creek data. The resulting error ratios are summarized in Table H-1.

The means and variances of concentrations for each land use were obtained from statistical analysis of the sampling data, as described in Section 6. Table H-2 summarizes these for each land use and constituent.

H.3 RESULTS OF THE UNCERTAINTY ANALYSIS

Results of the uncertainty analysis for total loads from the study area are presented here as confidence bounds about the estimated load. Confidence bounds define the region in which one believes the true estimate of load lies, at a given level of confidence. Thus, 90 percent confidence bounds define the bounds between which one is 90 percent certain that the true value lies. Narrow confidence bounds imply a low level of uncertainty in an estimate, while wide confidence bounds imply high uncertainty.

Table H-3 summarizes the 90 percent confidence bounds for the mean annual total load estimate for each chemical parameter. In general, the 90 percent bounds are about plus or minus 50 to 60 percent away from the mean estimate. The relative widths of the bounds vary little among the different chemical parameters.

Note that these confidence bounds account only for uncertainty in flow estimates and in mean concentration estimates for land uses. They do not account for possible differences in water quality between wet and dry years, nor do they account for possible stream bed processes.

VOL 12 2 1632

R0054932

As an example of how this information can be interpreted, the estimated mean annual copper loading is 14,600 lbs. Uncertainty results indicate that we can be 50 percent certain the actual mean annual load is between 11,500 and 17,600 lbs. We can be 90 percent certain the actual mean annual load is between 8400 and 24,000 lbs.

As an indication of how uncertainty varies year to year, Figure H-1 presents the confidence bounds about the estimated annual copper load for each of the twelve simulated years. As would be expected, confidence bounds tend to be wider for individual years than they are for the mean (i.e., we are more certain about the mean of the 12 annual load estimates than we are of any one year's load). 90 percent bounds are about plus or minus 95 percent away from the estimated value.

A COOPERATIVE PROJECT OF THE ORANGE COUNTY FLOOD CONTROL DISTRICT, THE COUNTY OF ORANGE, AND ITS TWENTY-NINE INCORPORATED CITIES

VOL 12 2 1638

R0054938

Executive Summary

The following report was prepared in response to the requirements contained in Stormwater and Urban Runoff Permits issued to the County of Orange and its incorporated cities. These permits, prepared by the Santa Ana and San Diego Regional Water Quality Control Boards, require that proposals for water quality monitoring programs be submitted to the Boards by November 30, 1990.

The proposed monitoring program for storm channels and receiving waters consists of field screening (channels only); dry-weather, flow-composite, sampling; and storm sampling.

Field screening will be used to detect gross contamination which may be indicative of illegal disposal of pollutants. Monitoring locations were sited on channels which have drainage areas greater then one square mile or which have industrial (manufacturing) land uses in the drainage areas. Reports exhibiting elevated concentrations of field-screened constituents will be referred to the EMA Water Pollution Section for further investigation.

Data from dry-weather and storm sampling will be used to estimate the total annual volume of contaminants discharged by each monitored channel. These monitoring locations will be in channels which are identified in the permits as "Waters of the State", or will be in major tributaries to "Waters of the State".

Storm monitoring of channels will also be used to evaluate the level of contamination during and after storm events. Samples will be analyzed from the first 3 hours of the storm (first flush), the next 21 hours, and from two consecutive 36 hour periods (after the first day). These data will be used to compute four-day average, contaminent concentrations.

The receiving water monitoring program includes stations in the Huntington Harbour; Sunset, Anaheim, and Bolsa Bays; Upper and Lower Newport Bays; and Dana Point Harbor. These stations will also be monitored during and subsequent to storms for the same contaminents as in the channel monitoring program.

In the channel and receiving water monitoring programs semiannual sampling of bed sediment will also be conducted to determine the chronic effects of stormwater runoff.

The permits are renewable and have a term of five years. They were issued in July of 1990. The water quality monitoring programs will be initiated in January of 1991. The FY 1990/91 labor requirement will be 3432 hours ($88,200). Equipment expenditures will be $33,000 and analytical costs will be $100,300. Total first year costs are estimated at $221,500. Annual costs in the four subsequent years (adjusted for cost of living) will include 5424 labor hours ($146,900 - $170,000), averages of $65,100 for equipment and $255,900 for analytical services. Annual totals are projected to be between $436,800 and $516,100.

R0054942

3.0 Introduction

To comply with Order Nos. 90-71 (NPDES No. CA 8000180) and 90-38 (NPDES No. CA 0108740), Stormwater and Urban Runoff Management Permits issued by the Santa Ana and San Diego California Regional Water Quality Control Boards (RWQCB), the following water quality monitoring program is proposed.

The water quality monitoring will be conducted by the County of Orange Environmental Management Agency (EMA) by the authority granted by California Assembly Bill No. 3664 which amended the Orange County Flood Control Act. The ammended Act gives EMA (formerly the Orange County Flood Control District) the legal authority to "carry on technical and other investigations, examinations, or tests of all kinds, making measurements, collecting data, and making analyses, studies, and inspections pertaining to water supply, control of floods, use of water, water quality, nuisance, pollution, waste, and contamination of water both within and without the District."

The monitoring program will be funded through a cooperative agreement (Stormwater Permit Implementation Agreement) between the County and its incorporated cities.

This program was prepared with the following considerations:

1. Program objectives established in the permit;
2. Funding available for personnel, equipment and analytical services;
3. Present and proposed equipment and staffing;
4. Safety during storm monitoring;
5. Existing data;
6. Historical annual frequency of representative storms; and
7. Tidal influences on the collection of representative samples.

The proposals for Receiving Water and Stormwater System Monitoring Programs have been combined in this document.

A description of the present, channel and receiving water monitoring programs maintained by EMA is included in Appendix 1.

4.0 Objectives

The objectives of the monitoring program as stated in the Santa Ana RWQCB Permit are:

a. To define the type, magnitude (concentration and mass load*) and sources of pollutants in the stormwater system discharges within each permittees respective jurisdiction so that appropriate pollution prevention and correction measures can be identified;

b. To evaluate the effectiveness of pollution prevention and correction measures; and

VOL 12 2 1643

R0054943

c. To evaluate the compliance with water quality objectives established for the stormwater system or its components.

In addition, it is proposed that the program assess the impacts of selected, permitted, NPDES discharges on the discharges of the Municipal Separate Storm Sewer System. These NPDES discharges include the runoff from nurseries in the San Diego Creek watershed. Information gathered during the life of the permit (FYs 90-95) will be used in developing future monitoring programs.

4.1 Discussion

Objective a.

To define the mass load of pollutants from the stormwater system will be a substantial undertaking. The degree of accuracy in determining this quantity will be a function of the available equipment, manpower and funds (for analytical services). The program will concentrate on the major regional* facilities which discharge directly to large receiving water bodies (Pacific Ocean; Huntington Harbour/Sunset, Anaheim and Bolsa Bays; Upper Newport Bay; Dana Point Harbor; Santa Ana and San Gabriel Rivers; and San Juan Creek).

To calculate the mass load from major regional facilities will require a representative sampling of these outfalls throughout the year. This representative sampling entails flow-weighted* automatic sample collection during storms and the dry season. Equipment required includes automatic wastewater samplers with toxics (synthetic organic compounds) sampling capabilities and continuous water discharge recorders. The proposed monitoring program reflects the current and proposed availability of this required equipment.

To assist in the development of the appropriate pollution prevention and correction measures (generally water pollution enforcement activities) a field screening program is proposed. This program will detect gross contamination by illegal/illicit* connections.

Objective b.

To assume that the water quality benefit from each Best Management Practice (BMP) could be measured by water quality monitoring is very presumptuous. The only BMPs which may result in any statistically significant change in water quality would be water quality structures (eg. basins; water quality benefit would be determined by monitoring the quality of inflow and outflow) or the elimination (through enforcement activities) of a significant (high mass load relative to ambient) illegal/illicit connection. The San Diego Creek Sediment Monitoring Program, a cooperative project of the County of Orange, the Irvine Company and the cities of Irvine, Tustin and Newport Beach, assesses the sediment trapping efficiency of in-channel basins in San Diego Creek. Much of the contaminants found in stormwater discharge are adsorbed onto the finer sediments.

Assessing the effectiveness of some BMP programs can be conducted by monitoring the volume of collected material (recycled oil, street sweepings etc.) which may have otherwise entered the storm sewer system. This

* terms marked with an asterisk are defined in Section 13.0

VOL 12 2 1644

R0054944

assessment approach will be developed in subsequent compliance program documents.

The proposed water quality monitoring program is designed to identify trends in the receiving water quality which result from the entire BMP program.

Objective c.

Both Regional Boards have adopted as a general objective, the State Water Resources Control Board Resolution No. 68-16, the policy of nondegradation of the waters of the state of California. In this resolution it is stated, "WHEREAS the California Legislature has declared that it is the policy of the State that the granting of permits and licenses for unappropriated water and the disposal of wastes into the waters of the state shall be so regulated as to achieve highest water quality consistent with maximum benefit to the people of the State and shall be controlled so as to promote the peace, health, safety and welfare of the people of the State; and ..."

Water quality objectives (limiting concentrations) have been adopted by each RWQCB, in their respective Basin Plans, to protect the waters with specific beneficial uses. Most of these objectives are applicable only to waters designated as Municipal Water Supply (MUN) and would not be appropriate for channels which are primarily stormwater conveyances. Other objectives were developed to protect freshwater and marine habitats.

The monitoring program for the Stormwater Permit should only evaluate the types of contamination which significantly effect the existing or intended beneficial uses of the receiving waters*. The following is a list of chemical characteristics which were considered in developing the monitoring programs.

1. Biostimulatory substances (compounds of nitrogen and phosphorus) can lead to nuisance growths of plants and algae.

2. The illegal introduction of acidic or alkaline substances to the stormdrain system can alter the pH and create chronic or acute toxicity problems for the indigenous biota.

3. Discharges of waters with high temperature can be harmful or lethal to aquatic life in the receiving water.

4. Unionized ammonia* can be toxic to aquatic life. The concentration of this contaminent is a function of the pH and the temperature.

5. Depressed dissolved oxygen levels can result from inputs of substances which impart a high biochemical (BOD) or chemical (COD) oxygen demand on the receiving waters. Stormwaters typically have elevated BODs and CODs.

6. Trace elements* at high concentrations can be toxic to aquatic life. These can be introduced into the system by illegal discharges from plating or integrated circuit board companies.

7. The toxicity of trace elements is inversely proportional to the hardness*.

8. PCBs, organochlorine pesticides and herbicides (PHP)* are toxic to aquatic life and have been detected in several channels and receiving

VOL 12 2 1645

R0054945

waters in the the Toxic Substance Monitoring Program (TSMP) and the State Mussel Watch Program (SMW).

9. Many organic and inorganic contaminants are adsorbed onto settleable and suspended solids. Settleable solids can deposit in the receiving waters reducing circulation and impacting navigation. Contaminated settleable solids introduce toxics at the bottom of the food chain. These toxic compounds can be concentrated at higher levels of the food chain.

5.0 Equipment Inventory

The County's Environmental Resources Division currently maintains a large inventory of water quality and hydrographic monitoring equipment. These include automatic wastewater samplers, portable and laboratory diagnostic equipment, fluvial* and bed sediment samplers, streamgages, a fleet of vehicles, and a boat. Table 1a is a list of the laboratory and transportable field equipment. Table 1b is a list of the equipment currently in the field at streamgaging stations near the proposed sampling locations. This hydrographic monitoring equipment includes water level sensors (mechanical floats or manometers), graphic analog recorders, and transmitting dataloggers. The information is transmitted (by radio frequency) to the County's ALERT Flood Warning System. The system is capable of converting the water level information into discharge rates so that flow compositing of discrete samples can be conducted in the laboratory.

Flow-weighting* of composite samples will be dependent on the availability of necessary equipment and the desired analyses. To collect samples for full-spectrum analyses (organic and inorganic), the wetted components of the automatic sampler must be composed of inert materials. Presently EMA has two such samplers (ISCO 2700) and will order three more (ISCO 3700) in FY 1990/91. These new samplers will be used to replace the oldest samplers in the current inventory. The Model 3700 allows a more accurate flow compositing (when integrated with a flowmeter) because it is capable of mainteining a uniform sample volume whereas the model 2700 (operates on a timed collection cycle; sample volume is influenced by the level of water in the channel) does not.

The current sampler inventory also includes seven older model ISCO samplers (1680) which have only inorganic sampling capabilities (nutrients and trace elements). These also can be integrated with a flowmeter to obtain a reasonable, flow-weighted sample. A Manning Model 4500T automatic sampler is also available. This unit can collect representative samples which are high in suspended or settleable solids. Its vacuum collection system (versus ISCO's peristaltic* pump) provides a higher sample transport velocity with less settling of solids in the collection line. The model 4500T also can ensure uniform sample volumes but does not have toxics (organic) monitoring capability. In order to collect flow-weighted composites, it will require a compatible flowmeter or it will be utilized in channels with continuous water level recorders.

Future equipment purchases will include automatic samplers (with full spectrum sampling capability) and compatible flowmeters. Ten samplers with flowmeters will be ordered during FY 91/92. Five additional samplers with compatible flowmeters will be ordered in FY 92/93 to replace the remaining ISCO model 1680s.

2A-35 - Leopold Stevens dual pen, continuous water level stripchart recorder
ATB - ALERT tipping bucket raingage
AT - ALERT transmitter
ATDL - ALERT transmitter with datalogger

6.0 Field Screening Program

This program is designed to detect gross contamination of regional flood control facilities by illegal/illicit discharges. It will consist of 1 dry season (2 samplings at least 4 hours apart) and one storm sampling of the facilities listed in Table 2. A map with these locations can be found in the Appendices. The criteria for channel selection were drainage area size and/or presence of industrial land uses in the corresponding watershed. Those channels with drainage areas greater than one square mile, and smaller conduits with industrialized watersheds are included. Also included are retention/detention basins with detention times greater than 24 hours.

The monitoring parameters will be those listed on the attached Field Screening Information sheet (Figure 1). This information includes channel configuration, discharge rate (measured if pollution observed; otherwise estimated), instrumental determinations of physical conditions, visual and olafectory observations, and field chemical analyses. This list of information was developed from the draft federal regulations. The chemical analyses will be used as indicators of swimming pool (chlorine residual), illegal construction dewatering (total suspended and settleable solids), printed circuit board (copper), plating (chromium, cyanides), plastics manufacturing and sewer line (phenols) discharges.

A sample for Chemical Oxygen Demand (COD) will be collected and analyzed at the Environmental Resources Laboratory. Samples will also be collected for "laboratory" analyses if high silt-clay turbidity or foam is observed.

The in-situ chemical analyses will be performed with a field uv-visible spectrophotometer* and pre-packaged, single analysis reagents. Samples will be vacuum filtered through a 0.45 micron glass fiber filter before analyses.

Information which indicates pollution will be referred to the Water Pollution Section of the Environmental Resources Division. If the source is determined to be continuous and non-point, followup sampling will be performed to assess the mass loading. Identified point sources will be issued a discharge permit by the Regional Board or be eliminated through enforcement.

The stations in the field screening program will be monitored each year according to the procedure outlined above. Additional channels will be added to the list if the land uses in the watersheds become industrial.

7.0 Channel Monitoring Program

The proposed channel monitoring program includes the streamcourses also identified in the permits as receiving waters. In addition to these receiving water channels, five stations in the Huntington Harbour watershed, five stations in the Upper Newport Bay watershed and two quality control stations are included in the program. Table 3 is a list of the proposed locations. The sites can also be found on the map in the Appendices.

7.1 Monitoring Locations

The rationale for selection of these monitoring locations included the existence of prior monitoring data; the proximity of existing, continuous discharge monitoring locations; and general compliance to the lists of "Waters of the State" in the permits. The additional stations were chosen because they

A-F Stations are not identified in Table 2 (See Location Map)

are tributary to "Waters of the State" and, in some instances (Lane and Serrance Channels), have exhibited (in the current monitoring program) higher than system average concentrations of heavy metals.

Two quality control stations (upper San Juan Creek and Silverado Creek) will also be monitored to establish "no or limited urban impact" conditions to which the urban channels can be compared. These channels have also been designated as "Waters of the State" in the Stormwater Permits.

7.2 Monitoring Parameters

The selection of monitoring parameters was based on the analyses of past data from EMA, the RWQCB-SAR Toxic Substance Monitoring Program (TSMP) for Huntington Beach Channels and the State Mussel Watch Program (SMW).

A voluminous amount of data has been collected during dry weather conditions. Both the TSMP and EMA data show that aqueous concentrations of organochlorine pesticides and trace metals (except for rare instances) have been low or below the detection limits of the laboratory. Sediment samples collected from the channel bottoms have exhibited higher relative concentrations of these contaminants. This is a logical observation since these contaminants tend to be adsorbed onto silt and clay particles which deposit onto the channel bottom when water velocities decrease after storms. Shellfish collected in the SMW have also shown bioaccumulation of these substances.

7.2.1 Dry-weather

The constituents monitored during dry weather conditions will include biostimulatory substances (nutrients*) which tend to be found in the dissolved form. This nutrient sampling will be conducted in channels which have historically produced high (>20 ppm as NO3) mean nitrate concentrations or are directly tributary to major waters of the state (Pacific Ocean, Sunset/Bolsa Bay, and Upper Newport Bay). These stations include those in the upper San Diego Creek watershed, San Juan Creek, Aliso Creek, Prima Deschecha, Segunda Deschecha, Bolsa Chica and East Garden Grove-Wintersburg Channels.

Stations which have exhibited high (relative to system average) dry-weather trace element concentrations, such as Lane and Serrance Channels in the San Diego Creek watershed, will be sampled for these contaminants.

Bed sediment sampling of channels, designated as waters of the state, will be used to assess the magnitude of pollutent (trace elements, PHP, Polynuclear Aromatic Hydrocarbons* [PAH]) deposition. PAHs include the byproducts of combustion (automotive emissions) and are washed into the system during storms. This sampling will also be conducted in Lane and Serrance Channels to evaluate the potential for pollutant discharges to San Diego Creek during high water velocities (scouring). Samples will be collected in specially prepared glass containers with teflon caps. The bed material will be sampled as close to midchannel as possible. This type of sampling however, will not be conducted in channels which are concrete-lined.

7.2.2 Storms

Storm monitoring will include collection of samples for nutrients and trace metals. The mean values of the storm data will be assumed representative of all storms for that channel. These mean values will be used in computing the

VOL 12 2 1655

R0054955

annual mass pollutant load from those channels. During the first 24 hours of each monitored storm samples will be collected for both nutrients and trace metals.

Two additional samples from the subsequent 72 hour period will also be analyzed. The additional samples will be collected at channels (except upper San Juan Creek and Silverado Creek) which are designated as "Waters of the State".

Some storm samples will also be analyzed for particle size distribution to correlate the level of contamination to the concentrations of transported silts and clays. If a significant correlation can be developed between silt/clay and pollutant concentrations, the former analyses can be used to supplement the chemical concentration data used in mass load calculations.

These particle size distribution analyses are much less expensive than chemical analyses. They can be performed in the Environmental Resources Laboratory. Grab samples of fluvial (transported) sediment can be collected during storm sampling with equipment currently available.

Initially this correlation analysis will be attempted for stations which are presently monitored in the San Diego Creek sediment transport study. If a significant correlation is identified, the sampling will be expanded to other stations.

7.3 Monitoring Frequency

The frequency must be developed so that the program is cost effective and produces data which can be used to address the program objectives. An initial frequency will be proposed and modified according to analysis of the collected data.

For example, if after 2 years of representative storm sampling (5-10 storms) no (below detection limit) trace element contamination is detected, the monitoring frequency for those parameters will be reduced. If the standard deviation of the mean concentration is low the same reduction will be implemented. If however, a mean concentration of a contaminant exceeds a water quality standard but the standard deviation of that mean is high, the sampling frequency for that contaminant will be increased to more accurately assess the mass loading.

Before implementation, modifications (changes in sampling location, parameters monitored, sampling and analytical procedures, or monitoring frequency) must first be approved by the Executive Officers of the Regional Boards.

The proposed initial frequency is outlined in Table 3a.

7.3.1 Dry-weather

The proposed initial frequency for dry weather monitoring for nutrients and trace elements (at locations identified in 7.2.1) is monthly. This is based on the present equipment, staffing, the analytical services budget, and the past observed seasonal variations in concentrations and water discharges. Nutrient monitoring will be conducted using the entire inventory of automatic samplers. Sites without continuous water level recorders will be sampled with automatic samplers and compatible flowmeters. Field determinations of

dissolved oxygen, electrical conductance*, pH and temperature will be made at the time of sampler collection.

Semiannual sediment sampling will be conducted before the storm season to assess the magnitude of dry season, pollutant deposition and after the storm season to assess the deposition and/or removal (due to channel scouring) as a result of storms.

7.3.2 Storms

The period designated as the official storm season by EMA is October 15 to April 15 of each year. This period was established from storm frequency analysis.

The automatic sampling equipment will be left in the field (on storm activation mode) during this period and will be serviced weekly (battery changes, sample line/strainer inspection and operation checks). Since the number of storm samplings is a function of the number of representative storms*, the available staff and equipment, an annual frequency can only be estimated. Two storm samplings per station will be attempted during the 1990-91 season. During subsequent seasons 3-5 samplings will be attempted.

The data from storm sampling will be used to characterize the distribution of pollutants during and after storm events. An automatic sampler will be programmed to activate when the water level in the channel is indicative of a storm. The level of activation will be above the maximum, observed (from discharge hydrograph analysis) diurnal water surface elevation. Once activated, 24 discrete, hourly samples will be collected. The time of activation can be determined from the the memory on the sampler or remotely from the ALERT system computer (from the water level at activation).

Samples collected in the first three hours (first flush) will be flow-composited in the laboratory (using hydrographic information from the ALERT system or from flowmeter records) and sent out for analysis. The remaining 21 samples will also be flow-composited and analyzed. Field measurements will also be made at the time of sampler collection.

A 72-hour sampling (24 discrete samples: one collected every three hours) will be initiated within 12 hours of cessation of the first 24-hour sampling. The first 12 samples will be flow-composited and sent to the laboratory for analyses; the remaining 12 samples will be processed similarly. In addition to determining the degree of contamination during and after the storm, the data will be used to determine 4-day average concentrations of the monitored substances.

In the first year of the program, the five, newer model (ISCO 2700 and 3700), automatic samplers will be used for storm sampling. The remaining sampler inventory will be used to conduct the monthly sampling. The samplers used for storm monitoring will be dedicated to one watershed per month. If at least two representative storms are sampled during the month in that watershed, the samplers will be moved to another watershed.

The Upper Newport Bay watershed is comprised of more tributaries than available samplers. The most important monitoring sites are those which are located on direct tributaries to the Upper Newport Bay. Bonita Canyon Channel, although not a direct tributary, is listed as a "Water of the State",

VOL 12 2 1658

R0054958

has exhibited high trace element concentrations in storm effluent, and is downstream of the San Diego Creek monitoring station. The following monitoring priority has been established.

1. San Diego Creek at Campus Drive
2. Santa Ana Delhi-Channel at Irvine Avenue
3. Big Canyon Wash at Back Bay Drive
4. Costa Mesa Channel at Highland Avenue
5. Bonita Canyon Channel at San Diego Creek confluence
6. Santa Isebella Channel at Irvine Avenue
7. Lane Channel at Jamboree Road
8. Peters Canyon Wash at Barranca Parkway
9. Barranca Channel at Jamboree Road
10. San Diego Creek at Culver Drive
11. All other channels

8.0 Receiving Water Program

8.1 Monitoring Locations

The waterbodies that will be monitored in the Receiving Water Program include the Huntington Harbour/Anaheim, Sunset, Bolsa Bay complex; the Upper and Lower Newport Bay; Dana Point Harbor; the Santa Ana River; San Diego and San Juan Creeks. The last three waterbodies are included in the Channel Monitoring Program as are many of the other channels designated as "Waters of the State" (See Section 8).

The monitoring locations were chosen on the basis of the existence of past data and the proximity of tributary inputs. The locations are listed in Table 4 and maps are in the appendices. As in the Channel Monitoring Program, quality control (assumed to be limitedly affected) stations at the Harbor entrances will also be monitored.

8.2 Monitoring Parameters

8.2.1 Dry-weather

Dry season sampling will include semiannual sediment analyses for organic and trace element concentrations as well as nutrient evaluations of the water.

8.2.2 Storms

These locations will be sampled during storms, for the same contaminants monitored in the channel program (storms). Samples representative of the entire water column will be collected with a USGS depth integrating sampler which has been coated with trace metal (epoxy) paint. The depth of the fresh water lens" will also be noted. Field readings of dissolved oxygen, electrical conductivity, pH and temperature will be made throughout the water column at the time of sampling. The Hydrolab with datalogger enables the operator to make these measurements quickly.

8.3 Monitoring Frequency

The proposed frequencies for Harbor/Bay monitoring are outlined in Table 4b.

m - monthly; semi - semiannual; st - storm; f - 96 hr followup

VOL 12 2 1661

R0054961

8.3.1 Dry-weather

Dry weather monitoring will be conducted monthly (to monitor the influences of tributary inflows and tidal flushing) in the Upper Newport Bay and semiannually (pre and post storm season) at other locations (unless designated storm only in Table 4). Monthly nutrient sampling will be conducted in the Upper Newport Bay on the days during which the automatic samplers are collected in the watershed. The nutrient content of the tributary discharges are assumed to be seasonally influenced; monthly sampling will allow three determinations per season. This should be adequate to develop a cause and effect relationship between the tributary inputs and the quality of the water in the Upper Bay.

Control stations at the Harbor entrances will only be sampled during storms (if safe to do so); problems with rapid currents, depth to bottom, and boat traffic make semiannual benthic sediment sampling impractical at these sites.

8.3.2 Storms

The storm monitoring frequency will be dependent on the weather and will be limited by the amount of equipment (one boat) and available manpower. Monitoring of storms greater than 0.5 inches in magnitude will be attempted. This volume of rainfall should be great enough for these receiving waters to exhibit a fresh water influence. Two followup samplings, 48 and 96 hours from the initial storm sampling, will also be conducted to assess the chronic and acute influences of the runoff on the receiving waters.

As in the channel monitoring program, the frequency will be modified according to the analyses of the data.

9.0 Database Management

The water quality monitoring data will be entered into the USEPA's national water quality database, located in Triangle Park, North Caroline. This database management system is known as STORET, an acronym meaning storage/retrieval. The data storage and retrieval process is performed by PC communication, via modem, with the system mainframe.

Chemical data from the contractor laboratory and field data collected by Enviromental Resources staff are tranformed into the proper computer format and are transmitted to the National Computer Center. After the transmitted data is integrated into the STORET database, the information is rechecked and edited, if necessary.

Retrievals of information can be in various forms including raw data, statistics, graphical displays and maps. These retrievals are also performed with the PC/modem link.

10.0 Quality Assurance

All methods of analyses employed by the contractor laboratory shall be from 40 CFR Part 136, "Guidelines for Establishing Test Procedures for the Analyses of Pollutants Under the Clean Water Act". Included are the APHA-AWWA-WPCF Standard Methods for the Examination of Water and Wastewater, 18th Edition. Field, chemical test methods shall be EPA approved (if available).

VOL 12 2 1662

R0054962

Quality assurance of chemical analyses performed by the contractor laboratory will be conducted by the contractor laboratory through its internal quality control program and by a blind, check-sample submittal program conducted by the County.

With every batch of samples submitted to the contractor laboratory, at least one synthetically prepared, spiked or replicate sample for each ten samples will be included. The synthetic or spiked samples containing trace elements or organic compounds will be prepared using aliquots of commercially or EPA prepared stock solutions. Quality assurance samples containing nutrients will be prepared from aliquots of stock solutions prepared in the Environmental Resources laboratory. Replicate samples will be splits of well-mixed samples. Both fractions will be sent to the laboratory to evaluate the precision of analyses.

The accuracy of analyses will be evaluated from the results of the synthetic and spiked sample submittals. A deviation from the contract (Attachment 3) limits of error will result in a request to reanalyze the batch of samples containing the QC sample. Only that constituent which exhibits the discrepancy will be reanalyzed in each sample.

The quality of the field screening analyses will be maintained by performing analyses on chemical standards from the spectrophotometer vendor. These analyses will be conducted at the beginning of each week in which field screening is scheduled.

11.0 Program Costs

The costs for the sampling programs will include manpower, equipment and contracted analytical services. Manpower includes sample collection / preparation, hydrographic monitoring and calculations, equipment maintenance, employee training, laboratory contract administration including quality control, database management and report preparation.

11.1 Labor

11.1.1 Sampling/Water Quality Monitoring

A team of two persons is required to conduct the water quality field sampling. This sampling includes field screening and channel/receiving water monitoring (storm and dry-weather). The time required includes transportation, sample collection, automatic sampler deployment, sample preparation (labeling, preservation, logging, laboratory submittal) and equipment maintenance. The required manpower is summarized in Table 5.

11.1.2 Hydrographic Monitoring

EMA conducts hydrographic monitoring to support its Public Works/Flood Control Design and Field Operations Divisions. Hydrographic monitoring for the Stormwater Program which exceeds these requirements will be charged to the Program. This monitoring will include maintenance, stage-discharge calibration and preparation of annual discharge summaries for stations on receiving water channels which presently do not have (or were not previously scheduled to have) continuous water level recorders. Each new gaging station will require 120 manhours annually. Calculations of precipitation intensities for stations in excess of the number in the present program will also be

charged to the program. These calculations will require 40 hours annually to complete.

11.1.3 Analytical Services Contract Administration

Contract administration includes quality control sample preperation, analytical report evaluation, and invoice processing. This will require approximately 20 hours per month or 240 hours annually.

11.1.4 Database Management

Database management as described in Section 10.0 will require approximately 20 hours monthly or 240 hours annually.

11.1.5 Report Writing

Compilation of data and report writing will require approximately 400 hours annually. The reports will include rainfall intensities at 23 existing EMA precipitation gages, discharge summaries for streamgeges near water quality stations, calculations of the annual pollutent load from each monitored channel and a summary of the impacts of those discharged pollutants on the the water and bed sediment quality of each receiving water. The results of the monitoring will also be used in the modification of existing BMPs or the implementation of new BMPs.

The report will be reviewed by the Orange County City Engineers Stormwater Committee before submittal to the Regional Water Quality Control Boards.

11.1.6 Compilation of Existing Data

This activity will be conducted only in the first year. It entails compiling all water quality and hydrographic information gathered since 1980. This information will include (as outlined in the permit) the following:

a. Analytical and flow data for stormwater samples collected from the stormwater conveyance system outfalls, and within any waters of the United States;

b. Precipitation data from the precipitation stations and the duration of storm events (if available);

c. Discharge data from the stormwater conveyance systems as determined from gaging stations;

d. Analysis of the data and the major pollutants identified in the stormwater discharges from each drainage area to each receiving water and a determination whether the identified pollutants came from non-point or point-source discharges.

Approximately 320 hours will be required to complete this process.

11.1.7 Training

Training must be completed by all staff throughout the life of the permit. This training will include OSHA-required hazardous material handling;

VOL 12 2 1665

R0054965

equipment operation; new employee orientation; and computer software usage (STORET). Approximately 240 hours annually will be devoted to training.

11.1.8 Labor Summary

The total annual manpower requirement will be approximately 5424 hours. Most of the work will be performed by Environmental Resources Specialist IIs who are presently compensated at an hourly rate (including overhead) of $23.79. The 5424 hours will compute to approximately $129,000. Approximately half of the storm sampling however, will be conducted during non-working (overtime) hours. The total number of overtime hours required annually is 910. This computes to an additional $10,800 or a total of $139,900. With an annual cost of living adjustment of 5% the labor costs will be $146,900 in FY 91/92.

Since the program will be initiated after the midpoint of the first budget year, the corresponding first year costs will be lower. Of the costs outlined in Section 12, only those for equipment and field screening will be uneffected by the starting date for the program. The esteblishment of additional gaging stations in FY 91/92 will result in an additional manpower requirement (960 hrs) in that and subsequent years. The number of storms which will be sampled after the first year will also increase as additional sampling equipment will be available. Table 6 reflects the differences in the first yeer and annual totals for analytical services and labor. The value for labor includes 550 hours of overtime. Table 6a outlines the annual labor requirements (regular and overtime hours) for the the program.

11.2 Analytical Services

The costs for analytical services were derived from the 1989-90 fee schedule from the current analytical services vendor, Brown and Caldwell Analytical Laboratories. The costs per analysis and the total annual costs are also outlined in Table 5. Prices for analyses can be expected to increase 10% per year to compensate for the increases in the cost of living and disposal costs for completed samples.

11.3 Equipment Costs

Equipment which will be required to supplement the existing inventory of EMA includes automatic samplers; flowmeters; field, diagnostic equipment and analytical reagents; and continuous, water level, recording gages.

Three automatic samplers (@ $3500), five compatible flowmeters (@ $3000), and a field, uv-visible spectrophotometer (@ $1600) w/reagents ($800) will be ordered during the 1990-91 Budget Year. This will cost approximately $28,000.

Ten additional samplers with compatible flowmeters, another spectrophotometer with reagents, and two temperature compensating conductivity meters (@$1300) will be ordered during FY 91/92.

Continuous water level recording gages will be installed at the urban channels which are identified as "Waters of the State" and currently lack this equipment. Eight stations currently fit this criteria. They are Serrano Creek; Segunda Deschecha, Prima Deschecha, Sand Canyon, and Bee Canyon Channels; and Rattlesnake Canyon, Hicks Canyon and Agua Chinon Washes. The cost of the equipment per station is approximately $7500. This equipment will also be purchased in FY 91/92.

Four vehicles will be used in the sampling program. Two of these will be replaced FY 92/93 at a cost of $20,000 each.

Miscellaneous equipment expenditures (analytical reagents; automatic sampler, repair parts; field sampling equipment; etc) will be approximately $5000 annually. Table 7 presents the proposed annual equipment expenditures by fiscal year.

11.4 Cost Summary

The first year costs will be approximately $221,500, which includes 3432 hours (550 overtime hours), $32,800 in equipment, and $100,300 in analytical services. Starting in FY 91/92, total costs will increase because the monitoring period will be an entire year, additional equipment purchases will allow more sampling and analytical costs will consequentially rise. Table 8 summarizes the total costs (manpower, equipment, and analytical services) of the water quality monitoring programs for channels and receiving waters. Cost of living adjustments are also included. An annual increase of 10% is projected for equipment and analytical services; salaries for staff can be expected to increase by 5% annually.

12.0 Definition of Terms

Beneficial Uses - Categories into which specific Waters of the State have been assigned by the Regional Water Quality Control Board. A listing of the present and intended beneficial uses of each Water of the State can be found in the respective Regional Water Quality Control Board Basin Plans.

Best Management Practices (BMPs) - Programs, procedures, or structural devices intended to reduce the impact of non-point source urban runoff on the receiving waters.

electrical conductance - also known as specific conductance or electrical conductivity. It is the numerical expression of ability of a solution to carry an electric current. It is proportional to the concentration of dissolved ionic solids.

flow-weighted sampling - Samples are collected in proportion to the volume of water passing the sampling point. The composite of all samples collected is representative of the entire period of collection.

fluvial - That sediment which is transported when water velocity increases as during storms.

freshwater lens - The layer of freshwater will flows over the more dense salt water layer. This situation occurs when the magnitude of the tributary discharge into the saline receiving water is great, as in a storm.

hardness - The amount of calcium carbonate dissolved in water.

illegal/illicit - When referring to discharges an illicit connection is an undocumented or unpermitted conduit. An illegal discharge is one which is in direct violation of an ordinance.

mass load - The annual total mass (pounds or tons) discharged from a tributary stream into a receiving water.

nutrients - The physical or chemical characteristics from the following list.

- nitrate + nitrite
- ammonia
- Total Kjeldahl Nitrogen (TKN)
- total phosphate
- total suspended solids (TSS)
- volatile suspended solids (VSS)
- pH
- dissolved oxygen
- specific conductance
- turbidity

Polynuclear Aromatic Hydrocarbons (PAHs) - Those organic compounds from the following list.

- Acenaphthene
- Acenaphthylene
- Anthracene
- Benzo(a)anthracene
- Benzo(a)pyrene
- Benzo(b)fluoranthene
- Benzo(ghi)perylene
- Benzo(k)flouranthene
- Chrysene
- Dibenzo(a,h)anthracene
- Fluoranthene
- Fluorene
- Indeno(1,2,3-cd)pyrene
- Naphthalene
- Phenanthrene
- Pyrene

VOL 12 2 1671

R0054971

PCB - Polychlorinated biphenyls. Those analyzed by EMA include:

Aroclor 1016	Aroclor 1221	Aroclor 1232
Aroclor 1242	Aroclor 1248	Aroclor 1254
Aroclor 1260	Aroclor 1262	

peristaltic - When describing a pump, it is fluid transport in a tubing when a rotating pinch roller assembly compresses the tubing in the pump housing. The fluid moves in the direction of rotation.

PHP - Pesticides, herbicides and PCBs.

Aldrin	2,4-D
Chlordane	2,4,5-TP Silvex
Dieldrin	Malethion
Endosulfan I	Methoxychlor
Endosulfan II	Ethyl Parathion
Endosulfan sulfate	Perthane
Endrin	Simazine
Heptachlor epoxide	p,p' DDD
Heptachlor	p,p' DDE
alphe BHC	p,p' DDT
beta BHC	Toxephene
delte BHC	PCBs from above
gamma BHC (lindane)	

regional facilities - Flood control channels with drainage areas greater than one square mile. Designated by a letter followed by two numeric characters (e.g. C02 - Boise Chice Channel).

representative storms - Those storm events during which at least 0.1 inch of rain falls and which were preceded by at least 96 hours of dryness.

spectrophotometer - An instrument used in colorometric analysis. A solution containing an unknown concentration of a substance is treated with reagents to form a colorometric complex. The intensity of the color of this complex is measured against that of a complexed solution of known concentration.

stormwater - as defined by the EPA means storm water runoff, snow melt runoff, surface runoff, street cleaning or maintenance, runoff from fire fighting, infiltration (other than infiltration contaminated by seepage from sanitary sewers or by other discharges) and drainage. Included is runoff from residential car washing and irrigation.

trace elements - Those elements from the following list:

copper	lead	zinc	nickel
chromium	cadmium	silver	

unionized ammonia - Dissolved gaseous ammonia.

APPENDIX 1

PRESENT WATER QUALITY MONITORING PROGRAM FOR THE ORANGE COUNTY ENVIRONMENTAL MANAGEMENT AGENCY'S FLOOD CONTROL DRAINAGE FACILITIES AND THEIR RESPECTIVE RECEIVING WATERS

2 1674

R0054974

Overview

From 1973 to 1990, the Environmental Resources Division of the County of Orange Environmental Management Agency conducted routine water quality monitoring on drainage facilities which are tributary to water bodies identified as waters of the state by the San Diego and Santa Ana Regional Water Quality Control Boards. The receiving waters were also monitored routinely to assess the chronic effects on established (by the Regional Boards) beneficial uses.

The data collected from in-situ monitoring and laboratory analyses of the samples were compiled in the EPA's STORET, national water quality database. An alpha-numeric designation was assigned to each station in the monitoring network. The first two or three letters usually are an abbreviation of the channel name (e.g. EGUC05-East Garden Grove-Wintersburg Channel) and the last three alphanumeric characters represent the drainage basin and facility number (e.g. EGUC05-channel 05 in drainage basin C). The receiving waters are identified by a three or four alphabetic designation for the harbor or bay complex followed by two or three characters which represent the location (e.g. LNBRIN-Lower Newport Bay in the Rhine Channel).

The storm channel sampling stations were grouped into three separate watershed or drainage area monitoring programs. These drainage areas impact (1) Huntington Harbour / Anaheim, Sunset, Bolsa Bays; (2) Upper and Lower Newport Bays; and (3) South County, Dana Point Harbor. The sites were selected to assess the contributions from the upstream drainage areas associated with each facility. A specific land use or combination of land uses has been identified for each drainage area. Table 1 is a list of the storm channel monitoring stations. Table 2 is a list of the locations monitored in the receiving water program.

Monitoring Parameters/Frequencies

When the storm channel monitoring program was initiated in 1973, monthly nutrient and trace element sampling was performed at several locations. Additional constituents were evaluated semiannually to address impacts on the sediment (contaminant deposition, adsorption) and public concerns on controversial issues (Mercury, Selenium, DDT,PCBs, radioactivity). The monitored constituents are listed in Table 3. Some of these stations were deleted (lack of relevent data) and others have been added (to better identify sources of pollution) during the term of the program.

The receiving water program was initiated in 1976. The monitoring frequency was established as monthly with each Harbor or Bay complex sampled on the day subsequent to the sampling of the corresponding watershed. The monitoring parameters are similar to those of the storm channels. However, storm sampling was performed only in the Newport Bay (twice). Depth monitoring at 1 meter intervals (pH, conductivity, dissolved oxygen, and temperature) was also conducted to assess gross differences in chemical character from surface to bottom. These differences are typically found near the mouths of tributary channels with high flowrates (during storms). When field monitoring identifies this stratification, samples from the surface and bottom layers were collected.

Storm sampling of channels consisted of collecting grab samples and conducting

VOL 12 2 1675

R0054975

in-situ measurements . selected stations in each . ershed. The chemical analyses included, in addition to nutrients and trace elements, total coliforms, oil and grease and Methylene Blue Active Substances (MBAS). As the program expanded, automatic samplers were used to collect 24-hr composite samples during dry weather and storm conditions. Stations for which storm run-off sampling data are available are included in Table 4.

For routine (dry-weather) channel monitoring samples were generally collected using an automatic sampler which collects one sample per hour for a 24-hour period. The composite sample was then used as a representative mean for the entire period. This composite sampling technique was employed at the following sites.

Huntington	Newport	South County
BCC02	SABF01	ACJ01
ABCC03	SDHF05	SJCL01
WMCC04	LANF08	TCOL02
EGWC05	SRCF09	OSOL03

The channel monitoring program was modified in the mid 1980's so that the normal, dry-weather, frequency of sampling for each watershed was bimonthly. Storm sampling was limited to the Newport Bay Watershed and some of these stations were only sampled during periods of significant storm run-off (>0.5 inches of rainfall in the watershed). Other locations in the Newport Bay Watershed were modified for only nitrate assessment. Excessive levels of this constituent have been identified as having an adverse impact on the beneficial uses of the Upper Newport Bay. Stations with sampling requirements different from the standard program are included in Table 5.

The Receiving Water Program was modified to a similar bimonthly sampling frequency.

Supplemental Information

Some of the monitoring stations are located near continuous water level recording gages from which discharge rates can be obtained. This information can be used to compute loading values for each constituent. The County also maintains a system of recording/non-recording raingages some of which have data transmitting capabilities.

Chemical Analysis Program

All analyses were performed using procedures outlined in 40 CFR Part 136, "Guidelines for Establishing Test Procedures of Pollutants Under the Clean Water Act". These analytical methods include those outlined in "Standard Methods for the Examination of Water and Wastewater", a joint publication of the American Water Works Association, the American Public Health Association and the Water Pollution Control Federation. From 1983 to 1990 analyses for trace elements in fresh water samples were conducted at the Environmental Resources Division Laboratory; all others were performed by a contracted laboratory certified by the Calif. Dept. of Health Services.

Executive Summary

The Palo Alto Regional Water Quality Control Plant (RWQCP) treats wastewater generated in East Palo Alto, Los Altos, Los Altos Hills, Mountain View, Palo Alto, and Stanford. In order to meet stricter effluent limits for discharge to San Francisco Bay, the RWQCP is targeting specific business types to reduce their metals loading to the RWQCP. One of the targeted business types is vehicle service facilities.

As part of the effort to reduce pollution from vehicle service facilities, the RWQCP and Uribe & Associates (U&A) developed the Vehicle Service Facility Waste Minimization Program. Implementation of this program began in 1992. This report summarizes the results of the second year of the Vehicle Service Facility Waste Minimization Program.

The program scope is multi-media, pollutants entering both the storm and sanitary sewer systems are targeted for reduction. The program approach combines increased regulation, education, and positive incentives to encourage waste minimization. The two major elements of this approach are **on-site visits**, and a **positive incentive program**.

On-site visits provided technical assistance to 375 vehicle service facilities in 1993. Besides providing information and assistance, shop visits were used to determine compliance with vehicle-related ordinance requirements. The number of shops in compliance with the sewer use ordinance is steadily increasing. At the beginning of the program in 1992, only 12 shops (4%) were in full compliance with the 15 requirements after their initial visit. By the end of the first year, 48% of the shops (156) were in compliance. After the visits in 1993, 179 (54%) shops were in compliance with these requirements.

Some of the most significant results of the 1993 visits include:

- From 1992 to 1993, the number of retail vehicle service shops with direct discharges to storm drains decreased from 56 to 2 (96% reduction). Elimination of these last two discharges is pending.
- From 1992 to 1993, the number of violations of the sewer use ordinance was reduced by 66%. The violations of some of the requirements were reduced by as much as 100%.

VOL 12 2 1689

R0054989

- There was little reduction in violations caused primarily by poor employee training. This result indicates that shops may need more help with training and that more rigorous enforcement of the training requirement may be needed.

As a positive incentive, "Clean Bay Business" recognition was given to shops that met established criteria. The criteria included complying with all of the requirements of the revised sewer use ordinance. In the fall of 1992, the first group of 131 shops was recognized as Clean Bay Businesses. In the spring of 1993, an additional 25 shops were recognized for having met the criteria. In the fall of 1993, the total number of Clean Bay Businesses recognized reached 179.

In addition to on-site visits and the positive incentive program, there were three additional components to the program in 1993, permitting and monitoring, a fleet outreach program, and a car wash coupon program.

The first of these components was permitting and monitoring of shops with sanitary sewer discharges. The revised sewer use ordinance requires that any discharges of parts wash water or vehicle wash water to the sanitary sewer be permitted by an industrial waste discharge permit. The first visits to the shops in 1992 identified 125 discharges that required a permit. The outreach efforts that year resulted in about one-half of these shops eliminating their discharges (i.e., zero discharge). In 1993, almost all of the rest of the shops with sanitary sewer discharges were issued industrial waste discharge permits. At the end of 1993, permits for the last two shops were pending.

A fleet outreach program was implemented to further reduce pollutants generated from vehicle servicing. A survey was conducted to identify businesses maintaining fleets of vehicles in the service area. Those companies maintaining greater than five vehicles on-site were visited to provide information on water quality protection and to determine the status of the facility's compliance with the sewer use ordinance. The results of this program include:

- Of the 328 companies contacted, 128 (39%) had fleets of more than five vehicles.
- Seventy-five companies (23%) were found maintaining more than five vehicles on-site and in the service area, and were therefore included in the program.

VOL 12 2 1690

R0054990

- Vehicle washing is the primary activity conducted by fleets with the potential to damage surface water quality.
- Over one-half of the fleets visited this year were washing their vehicles in areas draining to storm drains. Half of these fleets were using mobile washing companies.
- Seven (17%) of the fleets visited had wash racks connected to the sanitary sewer.
- Leaking vehicles parked on the company property also created storm water quality problems.

A car wash coupon program was also initiated to encourage the public to use commercial car washes in order to reduce pollutant discharges to the storm drain system from residential car washing. Coupons were distributed giving the public a financial incentive for using commercial car washes.

1.0 Introduction

The Palo Alto Regional Water Quality Control Plant (RWQCP) treats wastewater generated in East Palo Alto, Los Altos, Los Altos Hills, Mountain View, Palo Alto, and Stanford. In order to meet stricter effluent limits for discharge to San Francisco Bay, the RWQCP is targeting specific business types to reduce their metals loading to the RWQCP. One of the targeted business types is vehicle service facilities.

As part of the effort to reduce pollution from vehicle service facilities, the RWQCP and Uribe & Associates (U&A) developed the Vehicle Service Facility Waste Minimization Program. Implementation of this program began in 1992. In the first year, 318 facilities were visited and provided with information about revisions to the sewer use ordinance and about best management practices (BMPs), which are shop practices designed to reduce pollutant discharges. In 1993, after the addition of fleet operations to the program, 375 shops were visited. For information on the first year of the program see the *1992 Summary Report for the Vehicle Service Facility Waste Minimization Program* (Uribe & Associates, 1993a). This report summarizes the results of the second year of the Vehicle Service Facility Waste Minimization Program.

2.0 Program Scope and Approach

The program scope is multi-media, pollutants entering both the storm and sanitary sewer systems are targeted for reduction. The program approach combines increased regulation, education, and positive incentives to encourage waste minimization. The two major elements of the positive approach are:

- **On-site visits** of vehicle service facilities to help them reduce the pollutants they generate. In the first year of the program, shop "visits" and shop information packages were used to help the shops learn how to meet the new requirements. These information packages included best management practices and lists of product/service vendors. In 1993, shops were revisited to provide further outreach and to assess their compliance status.

- **A positive incentive program** encourages pollutant reduction by extending incentives and recognition to facilities that make efforts to prevent pollution. In both years of the program, shops that met the criteria were recognized as "Clean Bay Businesses." The shops received free publicity in

VOL 12 2 1694

R0054994

local newspapers via full page ads, and recognition items such as decals and patches to publicize their status.

Three additional components of the program in 1993 were:

- **Permitting and monitoring** was completed for shops with sanitary sewer discharges. Of the 375 open shops in the service area, only 61 still have discharges or open floor drains. In 1993, 59 of these shops were permitted and samples collected of their discharges. Permits for the other two shops are pending.

- **A fleet outreach** program was implemented to identify businesses maintaining fleets of vehicles in the service area and to help them prevent pollution and comply with the ordinance requirements for vehicle service facilities.

- **A car wash coupon program** was initiated to encourage the public to use commercial car washes in order to reduce pollutant discharges to the storm drain system from residential car washing. The commercial car washes that participated in this program all discharge through a pretreatment system to the RWQCP. This program combined pubic education with a financial incentive to wash cars at a participating commercial car wash in the service area.

3.0 Shop Visits - Methods

This year, as last year, inspectors visited each of the 334 retail automotive shops in the service area. Also, visits were conducted at the 41 new fleet operations identified this year (see Section 7.0). The method of conducting visits in 1993 was similar to the method used in 1992, except for the following differences:

- In the first year, the initial visits to all shops in the service area were made by Uribe and Associates. This year, the City of Mountain View Environmental Safety Division conducted all the visits within Mountain View.

- At the outset of the program, appointments were made with the shops for visits. Later, it became clear that making shop visits unannounced saves considerable telephone and travel time. In 1993, all visits were made unannounced except to the new fleets in the program (see Section 7.0).

VOL 12 2 1695

R0054995

- In 1992, all shops were given a period of time to correct problems and then notify the RWQCP. If a shop notified the RWQCP that problems were corrected, they were revisited to confirm that they met Clean Bay Business criteria. In 1993, all shops were notified of any problems but only the Clean Bay Businesses from 1992 that had minor problems were given the opportunity for a revisit.

- In 1993, the *Shop Information Package* (Uribe & Associates, 1993b) was only given to new shops or shops that had changed management. A *Fleet Operations Information Package* (Uribe & Associates, 1993c) was developed and given to all new fleets (see Section 7.0).

- One fact sheet was revised prior to the 1993 visits and was distributed during the visits of all the shops. This fact sheet covers requirement 11 of the ordinance which regulates the discharge of materials to the storm and sanitary sewer from shop cleaning activities. The fact sheet was modified to ensure that shops understood that this requirement covers not only the cleaning of indoor surfaces but also of outside paved areas.

- Inspection checklists were simplified this year. A copy of the inspection checklist used is attached as Appendix A. The second page is a form used to notify the facilities of the requirements they did not meet.

- In the first year, samples were collected from a few shops for background information. This year, samples were taken from all shops with permitted waste discharges to ascertain their compliance with the discharge limits.

4.0 Shop Visits - Results

4.1 Introduction

There are currently 375 open and regulated vehicle service facilities in the RWQCP's Source Control Management (SCM) database. The vast majority of these facilities are retail shops (334) and the rest are fleets (41). In the first year of the program, 1992, there were 326 facilities in the SCM database.

VOL 12 2 1696

R0054996

4.2 Database - 1993 Numbers

Changes to the RWQCP's SCM database include:

- 22 facilities have closed or moved from the service area,
- 24 new retail facilities have opened, and
- 41 businesses maintaining fleets were added (see Section 7.0).

4.3 Compliance with Vehicle Service Facility Requirements

The number of shops in compliance with the sewer use ordinance is steadily increasing. At the beginning of the program in 1992, only 12 shops (4%) were in full compliance with the 15 requirements after their initial visit. By the end of the first year, 48% of the shops (156) were in compliance. After the visits in 1993, 179 (54%) shops were in compliance with the requirements. For a detailed discussion of the specific requirements, see the 1992 Summary Report (Uribe & Assoc., 1993a). The ordinance requirements are provided in Appendix B.

From 1992 to 1993, there was a significant decrease in the rate of noncompliance for each requirement (see Figures 4-1 and 4-2, data is for all cities except Mountain View). Overall, there was a 66% decrease in the number of violations.

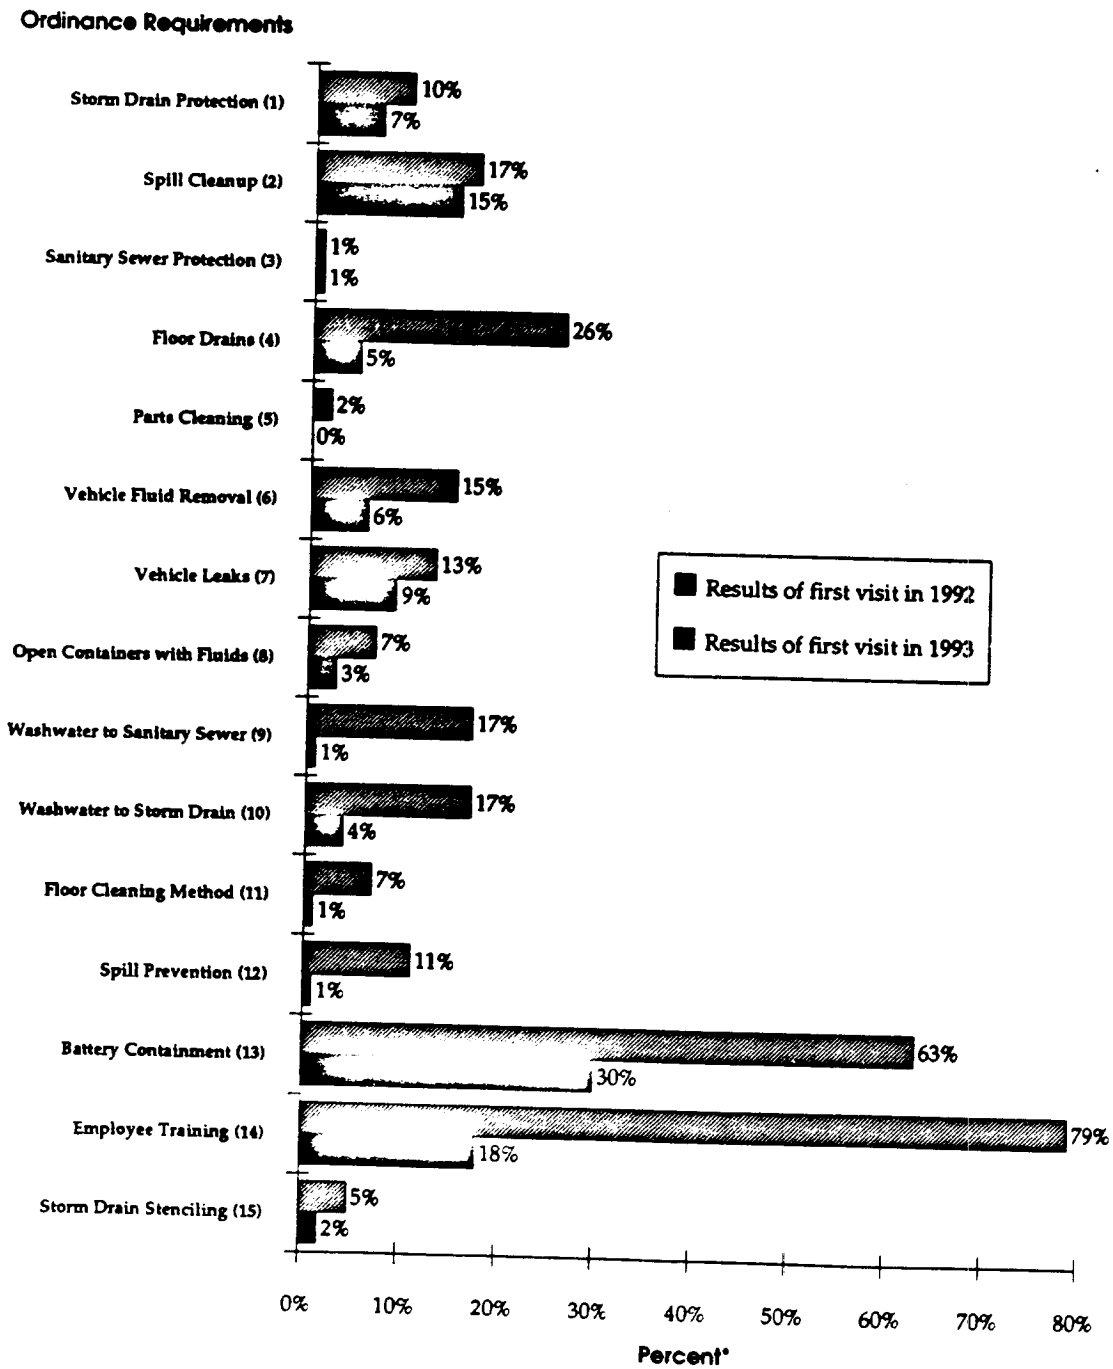
Figure 4-1 shows the decrease in noncompliance rates for each ordinance requirement. There was a significant reduction in the number of violations of most requirements. For example, violations of the two vehicle washing requirements were reduced by 96% (#9, wash water to sanitary sewer) and 80% (#10, wash water to storm drain). The smallest reduction in violations included a 12% reduction in violations of the spill cleanup requirement (#2), and a 35% reduction in leak containment (requirement #7) violations. Both these types of violations could be reduced further if employee training were improved. An effort should be made in the next year of the program to provide more assistance in training and to enforce the training requirement more rigorously.

Figure 4-2 shows the number of violations in each year, grouped by type of requirement. This figure shows that there was a 87% reduction in violations specific to sanitary sewer protection and a 55% reduction in violations specific to storm drain protection. There was also a 65% reduction in violations of requirements that protect both the sanitary sewer and the storm drain. These requirements include employee training, spill prevention, and cleanup.

VOL 12 2 1697

R0054997

Figure 4-1 Reduction in Noncompliance Rates



*Data for all cities except Mountain View

VOL 12 2 1698

R0054998

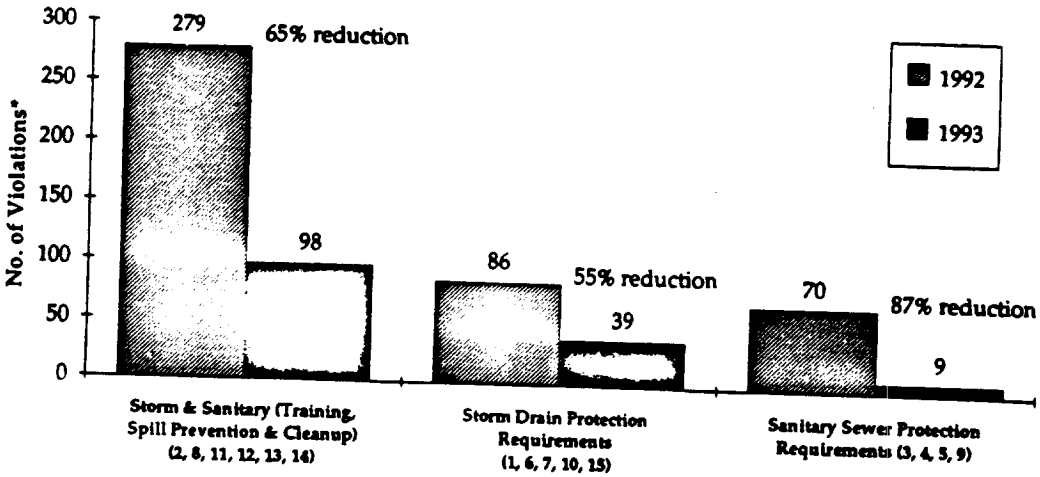


Figure 4-2 Reduction in Sanitary and Storm Sewer Violations
*Note: Data for all cities except Mountain View

Sanitary sewer-related violations were reduced most significantly because these discharges are distinct and therefore relatively easy to identify and address. All of these violations were resolved by plugging floor drains or obtaining permits for sanitary discharges. While the number of direct discharges to the storm drain was reduced drastically (see below), other storm water-related violations are more difficult to resolve. These include providing secondary containment for vehicle fluid removal, vehicle washing, and containing vehicle leaks.

Some of the most significant improvements made from 1992 to 1993 include (data for all cities):

- A reduction in the number of direct discharges from retail facilities to storm drains from 56 to only 2 (96% reduction). Elimination of these last two discharges is pending. The corrected discharges were mostly from vehicle washing but also included parking lot cleaning, wet sanding of vehicles, and in one case, the use of an outdoor sink.

- At the end of 1992, 68 shops in the service area had unpermitted open sumps and floor drains, down from 125 at the beginning of the year. By the time of the 1993 visits, only two unpermitted sumps or floor drains were found, a 97% reduction. Permits for these remaining discharges are pending. The rest of these discharges had either been discontinued by plugging the drain or permitted by the RWQCP.

VOL 12
2
1699

R0054999

- Six automotive machine shops were found discharging parts cleaning wastewater into the sanitary sewer in 1992 without an industrial waste discharge permit. This year they are all in compliance. Two shops have industrial waste discharge permits and four shops became zero dischargers.

5.0 Permitting and Monitoring

5.1 Introduction

The 1992 amendments to the sewer use ordinance require that any discharge of parts wash water or vehicle wash water to the sanitary sewer be permitted by an industrial waste discharge permit. Shops with open sumps or floor drains are also required to obtain permits or permanently plug these drains.

The first visits to the shops in 1992 identified 125 discharges that required a permit. The outreach efforts that year resulted in about one-half of these shops eliminating their discharges. In 1993, almost all of the rest of the shops with sanitary sewer discharges were issued industrial waste discharge permits. At the end of 1993, permits for the last two shops were pending. About 84% of the facilities are "zero dischargers" to the sanitary sewer.

5.2 Permitting

Fifty-seven permits were issued to vehicle service facilities this year. The RWQCP issued permits to 23 shops in Palo Alto, two in East Palo Alto, and one each in Los Altos and Los Altos Hills. The City of Mountain View Environmental Safety Division issued 30 permits to shops located in Mountain View. There are a total of 59 permitted vehicle service facilities in the service area (16% of all vehicle service facilities), including two permits issued prior to the implementation of this program. These 59 permitted facilities include:

- 14 fleets (e.g., garbage cos., transportation cos., school district)
- 12 general repair shops,
- 11 car washes,
- 9 gas stations,
- 6 rental car agencies,
- 4 body shops,
- 2 automotive machine shops, and
- 1 radiator repair shop.

VOL 12 2 1700

R0055000

Vehicle wash water is the primary discharge from these facilities. The sources of the wash water include:

- cleaning both vehicle exteriors and engines (28 of the permitted shops (47%)),
- cleaning vehicle exteriors only (19 shops (32%)),
- cleaning engines only (2 shops),
- sumps for general use (e.g., floor cleaning wastes) (5 shops),
- parts cleaning (3 shops), and
- radiator cleaning (1 shop).

A RWQCP permit includes the following conditions:

- Self-monitoring on a monthly or quarterly basis depending on discharge flow rate. The shops are required to analyze each sample for two metals (copper and lead), or more depending on the type of activity generating the waste.
- Conducting weekly visual inspections of any treatment systems (generally oil/water separators).
- Cleaning the treatment system at least quarterly.
- Logging inspection results and cleaning events.
- Submitting an annual report, reporting violations within 24 hours, and reporting spills immediately. Beginning in 1994, permitted shops will be required to submit sampling results quarterly.

A sample permit for a Palo Alto facility is included in Appendix C.

5.3 Sampling of Permitted Facilities

U&A collected samples of each permitted facility. For most facilities, this was the first sample taken of their wastewater. Most samples were collected from the last chamber of a two or three chambered sump. An Isco sampler was used to pump wastewater from the exit point of the sump into a sample container. Figure 5-1 is a photograph of this sampling activity. In some cases, samples were collected from a sewer clean-out downstream of the permitted discharge prior to dilution with other discharges.

VOL 12 2 1701

R0055001

U&A measured the samples for pH in the field. The samples were put into containers with nitric acid as a preservative. U&A then labeled and logged the samples on a Chain of Custody form and delivered them to the RWQCP, who later delivered them to the lab for metals analyses.

5.4 Sampling Results

The quality of water in these initial samples varied significantly. It was apparent from the color of some samples that they contained large quantities of oil and grease. Figure 5-2 is a photograph showing six of the most interesting sample colors.

The analytical results of the samples collected are summarized in Table 5-1 and Table 5-2 below. It should be noted that the results are based on the collection of only one sample at each permitted shop.

Tables 5-1 and 5-2 summarize the data for all but one of the samples, wash water from a paving company. This fleet operation's sample had metal concentrations one order of magnitude higher than the next highest results. These extremely high levels in one sample increased the mean and standard deviation of the pooled data inordinately and therefore the results of this one sample were treated as an outlier and were not used in calculations.

Table 5-1 lists the range and mean for each metal by primary business activity. The results in this table show:

- Eighteen shops (32%) exceeded their discharge limits for one or more metals.
- By city, the number and percent of sampled shops with a discharge limit violation was one (50%) in East Palo Alto, one (100%) in Los Altos Hills, nine (30%) in Mountain View, and seven (30%) in Palo Alto.
- General repair shops, gas stations, and the one radiator repair shop exceeded the metals limits most severely and frequently.
- The highest lead concentration (aside from the one paving company) was from a gas station with 32 mg/L.
- A gas station also had the lowest lead level reported -- 0.008 mg/L, well below the local limit of 0.5 mg/L.

VOL 12 2 1702

R0055002

Figure 5.1 Sump Sampling by U&A

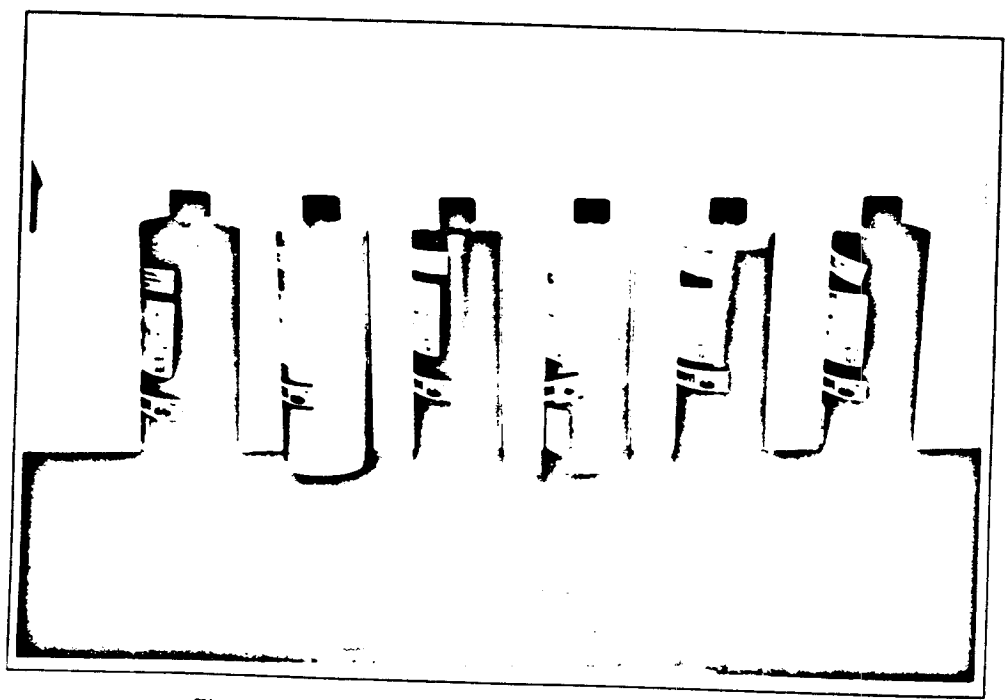

Figure 5.2 Sample Bottles Showing Variation in Color

(As a comparison, the wastewater in the third sample bottle from the right appeared to be relatively clear water)

VOL 12 2 1103

R0055003

- The limits most often exceeded were copper (14% of sampled shops), lead (18%), and zinc (29%), with 8, 10 and 16 exceedances respectively. Almost all of the shops with exceedances (16 of the 18 shops or 89%) violated the zinc limit (2.0 mg/L).

- The cadmium limit was exceeded twice, and chromium and nickel limits were each exceeded once.

- There are only two radiator repair shops in the service area. One is closed-loop and has no discharge. The other shop exceeded the limits for copper (3 times the limit), lead (36 times the limit), and zinc (5 times the limit).

- Although a number of the vehicle washing discharges violated metals limits, none of these violations were at commercial car washes.

Table 5-2 lists the same figures calculated for waste generating activity, rather than business type, since there is not a direct correlation between type of business and waste generating activities. For instance, a general repair shop may discharge wastewater from parts cleaning, floor cleaning, or vehicle exterior cleaning. Some car washes clean only vehicle exteriors and others clean engines as well. The data in Table 5-2 show:

- Wastewater from sumps used for general cleaning (e.g., floor cleaning) most consistently exceeded metals limits. Five shops with this type of discharge were sampled. Three (60%) of these shops violated one or more of the permit limits.

- Twenty-eight shops were sampled that clean both engines and vehicle exteriors. Surprisingly, only three of these shops exceeded the lead limit and five exceeded the zinc limit.

- Of the nineteen shops washing only vehicle exteriors, two exceeded the lead limits, one by 60 times the limit. The zinc limit was exceeded by six shops (32%).

- One of the two shops conducting parts cleaning exceeded the lead limit, the other was in compliance.

VOL 12 2 1706

R0055006

The range of results for each metal and waste generating activity was very large (often three orders of magnitude). This large range in data shows that other factors, besides the activity performed, play a big role in determining metals concentration. These factors include implementation of best management practices, regularity of sump cleaning, and the time interval between sump cleaning and sampling.

6.0 Positive Incentive Program

6.1 Introduction

The second major element to the program's approach is a positive incentive program. Shops meeting the criteria described below are formally recognized by the RWQCP as "Clean Bay Businesses." Positive incentives are in the form of publicity in the local media, and decals and customer brochures at the shop to advertise its Clean Bay Business status.

6.2 Criteria

The program has three criteria for recognition:

- **Shop visit completed** - The shop must be visited by RWQCP staff or its representatives.

- **Compliance with ordinance requirements** - Based on the inspection checklist results, the shop must be in compliance with the fifteen ordinance requirements. Shops that were Clean Bay Businesses last year were given the opportunity to correct minor violations within a limited period of time in order to maintain their Clean Bay Business standing. Shops with permitted discharges must meet local limits.

- **No significant violations related to surface water** - The names of those shops meeting the first two criteria are circulated to other environmental regulatory agencies (e.g., County Health Department, City Fire Department) to receive their concurrence that the shop has no significant violations pending of which the RWQCP may not be aware. The violations must be related to surface water. Groundwater, air quality, noise, aesthetics, and other potential issues were not considered.

VOL 12 2 1707

R0055007

6.3 Clean Bay Businesses

At the beginning of the program in 1992, only 12 shops (4%) were in full compliance with the 15 requirements after their initial visit. In the fall of 1992, the first group of 131 shops were recognized as Clean Bay Businesses. In the spring of 1993, an additional 25 shops were recognized for having met the criteria. In the fall of 1993, at the end of the second year of the program, the total number of Clean Bay Businesses recognized reached 179. Figure 6-1 shows the increase in Clean Bay Businesses for the first two years of the program.

In addition to the 179 Clean Bay Businesses recognized this year, eleven shops that were in compliance with all 15 vehicle service facility requirements were not recognized as Clean Bay Businesses. This was because ten of these shops had sample results exceeding one or more permit limits. One shop was kept off the list due to violations of hazardous materials requirements that threatened surface water quality.

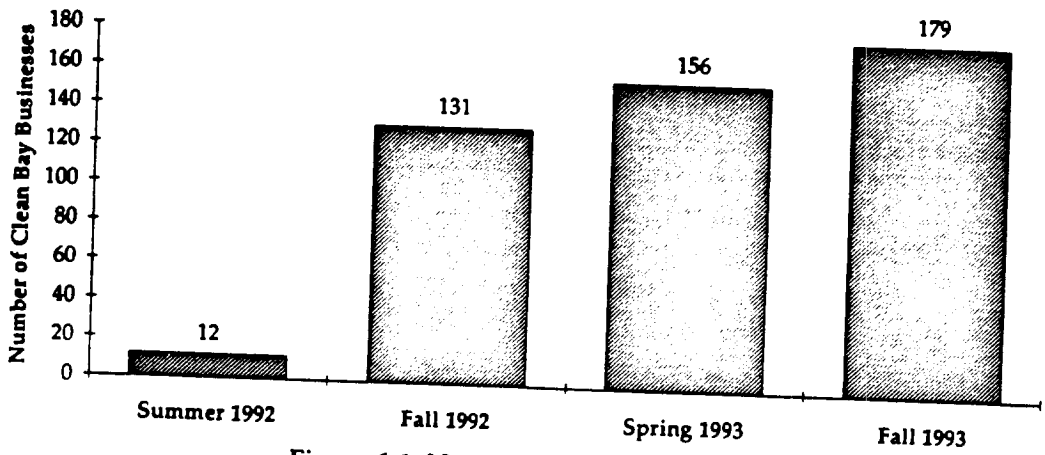

Figure 6-1 Number of Clean Bay Businesses

Twenty-nine shops (19%) that were Clean Bay Businesses in 1992 were not recognized in 1993. Of these twenty-nine shops, fourteen (9% of the 1992 list) were not recognized because of ordinance violations. Five of these shops were in violation of one or more of the 15 requirements and nine shops were not recognized due to discharge limit violations. The other sixteen shops were not recognized for a variety of reasons including: six closed their business, two were fleets and no longer eligible to be Clean Bay Businesses, four were no longer subject to the ordinance because they did not conduct regulated activities, and

VOL 12 2 1708

R0055008

three shops were removed from the list for violations of their Conditional Use Permit issued by the Mountain View Planning and Community Development Department.

6.4 Recognition Items

Each of the Clean Bay Businesses received a recognition packet (Appendix D) containing the following items:

- Decals - for display in shop windows, walls, or display counters;
- Brochures - for distribution to customers; and
- Camera-ready "tear strips" - for use in display ads (e.g., newspaper, phone book), business cards, stationery, etc.

The Clean Bay Business decal was changed slightly this year to distinguish the 1994 recognition items from the 1992-93 items. The year on the decal was changed and the background color on the decals was changed from blue to green. In addition to the recognition items provided directly to the shops, the RWQCP purchased full page ads (also included in Appendix D) in three local newspapers (San Jose Mercury News, Palo Alto Weekly, and The View) announcing the Clean Bay Business recognition and listing all 179 shops by name and location.

7.0 Fleet Outreach Program

7.1 Introduction

In 1992, during the first year of the program, only city maintenance yards or those fleet operations whose main business activity involved vehicle use were visited. These categories of fleets included schools, transportation (bus) companies, moving services, trucking companies, garbage collection companies, and rental car companies.

In 1993, additional fleet maintenance operations were targeted in an effort to further reduce pollutants generated from vehicle servicing. Examples of the other types of businesses with fleets include large corporations, golf courses, and service companies (e.g., landscaping/gardening, painting, carpet cleaning). The identified fleets were visited to provide information on water quality protection and to determine the status of the fleet's compliance with the sewer

VOL 12 2 1709

R0055009

use ordinance. Information from the visits was added to the RWQCP's Source Control Management database and follow-up visits were made.

7.2 Regulation of Fleet Maintenance Facilities

The sewer use ordinance developed for vehicle service facilities applies to all facilities that conduct at least one vehicle maintenance activity. Maintenance activities include: repair, fueling, fluid replacement, parts cleaning, salvaging, and washing. For the purposes of the ordinance, a fleet was defined as follows:

- Consists of more than five vehicles in one location,
- Located within the RWQCP service area, and
- Conducts at least one vehicle maintenance activity on-site.

Some companies with large fleets conduct many vehicle maintenance activities, however the primary maintenance activity conducted on-site at fleet yards is vehicle washing. The vehicle washing requirements in the sewer use ordinance include requirement 9, which states that vehicle wash water may not enter the sanitary sewer unless it is discharged in accordance with an industrial wastewater discharge permit. Requirement 10 prohibits the discharge of wash water to a storm drain if it contains soap, or if it results from routine washing of dirty vehicles in a fleet washing operation. These ordinance requirements apply to vehicle washing whether it is done at a wash rack or by a mobile cleaner.

7.3 Survey of Fleet Maintenance Facilities

In 1993, an extensive telephone survey was conducted of businesses in the service area to search for and identify fleets not visited in 1992. A list of approximately 300 businesses in 55 different categories was generated from phone book listings. The survey was designed to determine how many of the potential fleets were "fleets" as defined by the ordinance. A copy of the survey worksheet is attached in Appendix E. Questions included:

- Does your company own more than 5 vehicles?
- Are they kept in one location?
- Is that location in the RWQCP service area?
- Are the vehicles serviced on-site?
- If so, which activities are performed?

VOL 12 2 1710

R0055010

Information was gathered about off-site maintenance practices and about mobile vehicle maintenance businesses that provided services to the fleet owner. During the phone calls, visits were scheduled with the companies that maintain more than five vehicles on-site and in the service area.

7.4 Findings of Fleet Survey

Of the total 328 companies contacted, 128 (39%) had fleets of greater than five vehicles, 178 (54%) had a fleet of five or fewer vehicles, and 22 companies were no longer in business. Of the 128 companies with fleets of greater than five vehicles, 32 (25%) housed their fleet outside the service area, and 21 (16%) had all of the maintenance done at retail service facilities, many of which were already visited as part of this program. The remaining 75 companies (23%) were conducting maintenance on more than five vehicles on-site and in the service area, and were therefore included in the program. These 75 companies were visited, 34 in 1992, and 41 after the survey in 1993.

Table 7-1 summarizes the status of the 328 companies contacted in the first two years of the program. The distribution of visited fleets in the various business categories is shown in Figure 7-1. These figures are given as an indication of the number of fleets other cities might find amongst businesses in their service area.

Table 7-1 lists 33 of the 55 categories of businesses contacted. The first column lists the total number of businesses contacted in each category. The second column lists the number of businesses that have more than five vehicles that are serviced on-site and in the service area. These are the businesses that were visited. Also listed in this column, is the percentage of the total number of fleets visited in each category of business. For example, 16% (or 12 of the 75 fleets visited) are car or truck rental companies.

The third column of Table 7-1 gives the number of businesses that have more than five vehicles (regardless of whether they are serviced on-site or in the service area) and the percent of the total number contacted in the category. For example, 10 pest control companies were contacted. Forty percent of these had fleets of greater than five vehicles. However, none of these four businesses kept the vehicles in the service area or serviced them on-site, so none were visited.

VOL 12 2

R0055011

As can be seen from Table 7-1, 100% of the businesses in certain categories were maintaining five vehicles on-site and were therefore visited as fleets. These categories included car rental agencies, bus companies, and post offices.

Table 7-1 Summary of Fleet Survey Results

Type of Business	# Visited fleets with >5 vehicles, serviced on-site (% of fleets visited)	Total # of fleets with >5 vehicles (% of # contacted)	Total number of businesses contacted

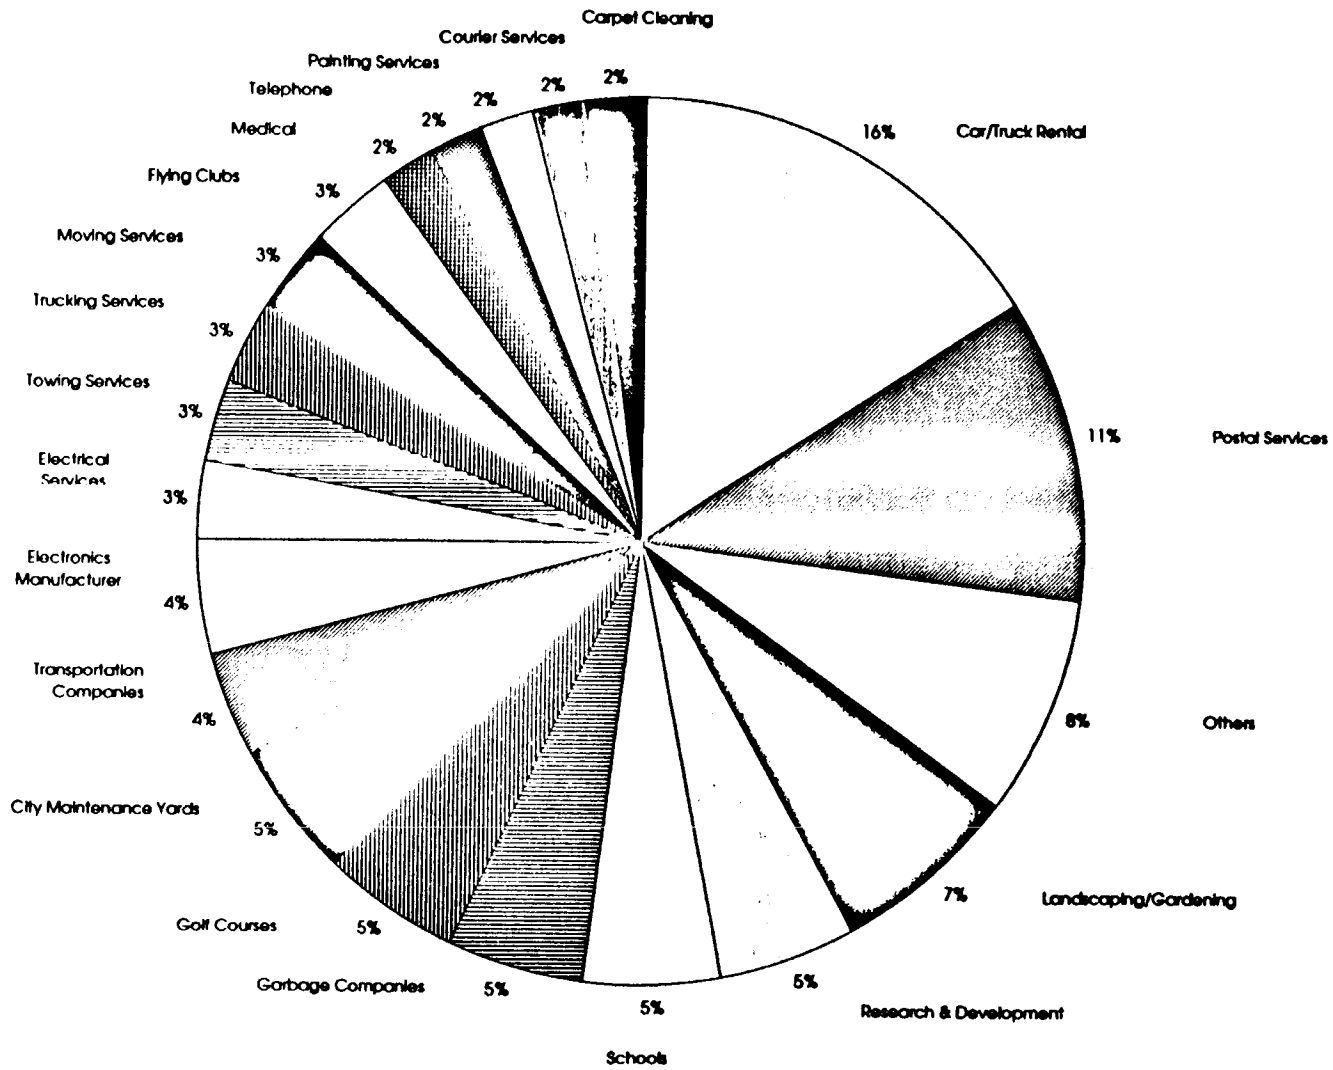
VOL 12

2

1712

R0055012

Figure 7-1 Distribution of Businesses Regulated as Fleets



R0055013

However, in other categories our survey showed little correlation between type of business and size of fleet. For example, seemingly similar large corporations have fleets ranging in size from zero to over fifty vehicles. Most service industries (electrical, painting, cleaning, gardening, etc.) were found to have zero to eight vehicles, but one electrical servicing company we visited had close to 100 vehicles.

Appendix F presents the complete results of the fleet survey.

7.5 Fleet Visits

Visits were conducted between June and August 1993. The visits were similar to those conducted at retail facilities. A *Fleet Operations Information Package* (Uribe & Associates, 1993c) was given to each fleet manager. This package contained the same information as the *Shop Information Package* (Uribe & Associates, 1992) supplied to retail facilities, except that it did not contain information on the Clean Bay Business program. Clean Bay Business recognition was not offered to fleets whose primary business activity was not related to vehicle service (e.g., U.S. Postal Service).

7.6 Findings of Fleet Visits

Vehicle Washing Activities

The primary activity conducted by fleets with the potential to damage surface water quality is washing vehicles in areas draining to storm drains. Twenty-two of the 41 fleets (54%) visited this year were washing their vehicles in areas draining to storm drains. Of the remaining fleets, seven (17%) had wash racks connected to the sanitary sewer, five (12%) washed vehicles in areas that allowed the wastewater to soak into the ground, six (15%) had the vehicles washed off-site, and one cleaned vehicles with rags only. Eleven of the twenty-two fleets (50%) washed in areas that drain to storm drains were washed by mobile cleaning services. None of these discharges was routed to the sanitary sewer. The RWQCP is working on guidelines for mobile cleaning to eliminate these non-storm water discharges.

The volume of contaminated wastewater entering storm drains from fleet washing can be significant. For example, two fleets were washing over 100

VOL 12 2 1714

R0055014

vehicles in parking lots draining to storm drains. One of these is a U.S. Postal Office and the other is a large electrical servicing company.

There are a variety of methods to comply with the requirement prohibiting wash water discharge to storm drains. Companies can construct a wash rack with an oil/water separator and discharge to the sanitary sewer. They can also take their vehicles to commercial car washes with permitted discharges to the sanitary sewer. A few companies with small fleets have unpaved areas that can be used to wash vehicles allowing all of the wastewater to percolate or evaporate, rather than running off into storm drains. One car rental agency is complying by cleaning vehicles with wet rags only.

Most of the companies with a small number of vehicles plan to comply by taking their vehicles to a commercial washing facility. Many fleet managers felt they could not afford the expense of the commercial car wash nor the time to deliver the cars to the car wash. However, we found that even some companies with large fleets are using commercial car washes. Most commercial car washes offer corporate rates for fleets and the companies reduce the time commitment by having the driver of the vehicle stop at the car wash during their business travel. Another concern expressed by a tree service company is the difficulty in finding a commercial facility equipped to handle large vehicles.

One potential socioeconomic impact of moving fleet washing operations to commercial car washes is the closing of mobile cleaning companies. In order for these companies to stay in business and to operate in a way that protects surface water quality, methods and products are needed to contain the wastewater and redirect it or transport it to a sanitary sewer. Methods and products that are currently used by mobile cleaners in other parts of the state and country include:

- Plugging the storm drain and pumping out the wash water, and
- Employing a temporary boom to collect and vacuum up the wash water before it reaches a storm drain.

The RWQCP has met with some of the mobile cleaners to agree to acceptable methods of protecting storm drains. For example at the Palo Alto Airport, mobile cleaners are using rags to clean the dirtiest portions of the airplanes. Then, a fine mist of water is applied to rinse off dust from the upper surfaces of

VOL 12 2 1715

R0055015

the plane. This reduces the quantity and improves the quality of the water discharged.

A regional effort to control discharges from mobile cleaners is currently being planned. Efforts will include investigating alternative methods and products to reduce and control pollutants generated by mobile cleaning.

Other Fleet Findings

Other findings of the fleet visits include:

- Leaking vehicles parked on company property created storm water quality problems. This is particularly true for large transportation and garbage companies. Diesel engines in trucks and buses tend to leak more than gasoline engines. Garbage trucks use hydraulic fluid in several places in order to operate the various lifts, making it difficult to contain a leak and identify its source. Most fleet managers are hesitant, if not completely resistant, to placing drip pans under every vehicle with a tendency to drip oil, for fear of the pans being driven over and the contents, if any, spilled.
- Some fleets operations clean their parking lots and flush not only leaked fluids but also soaps into the storm drains.
- Some fleet operations dispense fuel. Often the fuel pumps are located close to and upgradient of storm drains, increasing the potential for spills to contaminate storm water.

8.0 Car Wash Coupon Program

This year, a pilot car wash coupon program was developed and implemented. The purpose of this program was to educate the public about the pollution of storm water resulting from cleaning cars at home and the benefits of using commercial car washes that treat the wastewater and send it to the RWQCP for further treatment before discharge to the bay. The program also provided a $2 off coupon as a positive incentive for using commercial car washes.

Commercial car washes were contacted for input on the program. All of the car washes in the service area were enthusiastic about participating. The RWQCP reimbursed them $2 for each coupon they received. The coupon was printed on a flier featuring Flo, the Storm Drain Program's mascot raccoon, and the name

VOL 12 2 1716

R0055016

and address of each commercial car wash in the area. A copy of the coupon is included in Appendix G.

A total of 3,000 coupons were distributed. The number of coupons distributed was limited by the budget set aside for reimbursing the car washes and by the uncertainty of the return rate. An adult-sized Flo the raccoon handed out coupons at local schools. Some coupons were distributed at the Stanford University Earth Day fair. However, the number distributed was fewer than expected because of rainy weather that held down attendance. Other coupons were available at distribution points around town, including libraries, the recycling center, and City Hall.

The number of coupons actually used was disappointingly few. The total number of coupons used was only 40, all from one car wash facility. One reason for the poor rate of return may have been that the largest car washes in the area have very aggressive coupon programs already. One of these car washes regularly offers $5 off their standard price. Although it was stated on the coupon that the $2 off applied to the "regular or discounted price" of the car wash, it may not have been understood that the coupon could be used together with other coupons. Another reason for the poor usage rate may have been that the coupon did not look like a coupon. It looked more like an educational piece and as a result probably did not catch people's attention.

The RWQCP is considering revising the coupon and redistributing them this year. Last year the coupons were distributed in the spring when it was still raining regularly. This year the program may be more successful if coupons are distributed in the middle of summer when the rains have stopped.

9.0 Program Effectiveness

This section summarizes program effectiveness information presented elsewhere in this report.

9.1 Retail Facilities

- The number of shops in compliance with the sewer use ordinance is steadily increasing. At the beginning of the program in 1992, only 12 shops (4%) were in full compliance with the 15 requirements after their initial visit. By the end of the first year, 48% of the shops (156) were in compliance. After

VOL 12 2 1717

R0055017

the visits in 1993, 179 (54%) shops were in compliance with these requirements.

- From 1992 to 1993, the number of violations of the sewer use ordinance was reduced by 66%. The violations of some of the requirements were reduced by as much as 100%.

- There was little reduction in violations caused primarily by poor employee training. This result indicates that shops may need more help with training and that more rigorous enforcement of the training requirement may be needed.

- There was a significant reduction in the number of direct discharges from retail facilities to storm drains from 56 to only 2 (96% reduction). Elimination of these last two discharges is pending. The corrected discharges were mostly from vehicle washing but also included parking lot cleaning, wet sanding of vehicles, and in one case, the use of an outdoor sink.

- About 84% of the vehicle service facilities in the service area are "zero dischargers" to the sanitary sewer.

- At the end of 1992, 68 shops in the service area had unpermitted open sumps and floor drains, down from 125 at the beginning of the year. By the time of the 1993 visits, only two unpermitted sumps or floor drains were found, a 97% reduction. Permits for these remaining discharges are pending. The rest of these discharges had either been discontinued by plugging the drain or permitted by the RWQCP.

- Six automotive machine shops were found discharging parts cleaning wastewater into the sanitary sewer in 1992 without an industrial waste discharge permit. This year they are all in compliance. Two have industrial waste discharge permits and four became zero dischargers.

- In the fall of 1992, the first group of 131 shops was recognized as Clean Bay Businesses. In the spring of 1993, an additional 25 shops were recognized for having met the criteria. In the fall of 1993, the total number of Clean Bay Businesses recognized reached 179.

VOL 12 2 1 7 1 8

R0055018

9.2 Fleet Operations

- Forty-one fleet operations, not previously identified because their primary business activity is not vehicle service or transportation, were found by the fleet survey and are now part of the vehicle service facility waste minimization program. Their addition represents a 12% increase in the number of facilities in the program.

9.3 Car Wash Coupon Program

- Approximately 3,000 fliers with coupons were distributed to the public this year. These fliers educated the public about storm water impacts from car washing at home and gave an incentive to use commercial car washes. Although only 40 coupons were actually used, future public education effort should reduce the amount of vehicle wash water entering storm drains.

10.0 Recommendations

The following are recommendations for continued improvement in the program:

In terms of the decrease in noncompliance rates for each ordinance requirement, the smallest reduction in violations included a 12% reduction in violations of the spill cleanup requirement (#2), and a 35% reduction in leak containment (requirement #7) violations. Both these types of violations could be reduced further if employee training were improved. An effort should be made in the next year of the program to provide more assistance in training and to enforce the training requirement more rigorously.

The sampling results this year indicate that factors, other than the type of activity performed, play a big role in determining metals concentration. These factors include implementation of best management practices, regularity of sump cleaning, and the time interval between sump cleaning and sampling. As more data is collected on these maintenance activities and on wastewater quality, more conclusions can be drawn. These conclusions should be used to help noncomplying shops to achieve compliance.

Over one-half of the fleets visited this year were washing vehicles in areas draining to storm drains. Half of these are using mobile washing companies. Efforts should be continued to address these mobile businesses on a regional basis.

VOL 12 2 1719

R0055019

The RWQCP is considering revising the car wash coupon and redistributing them this year. Last year the coupons were distributed in the spring when it was still raining regularly. This year the program may be more successful if coupons are distributed in the middle of summer after the rains have stopped.

TEXT OF ORDINANCE REQUIREMENTS

Excerpt from the Revised
REGIONAL WATER QUALITY CONTROL PLANT
1992 SEWER USE ORDINANCE
affecting
VEHICLE SERVICE FACILITIES

16.09.010 Definitions.

(19) "Pretreatment system" means a treatment system at an industrial or commercial facility that is designed to treat water prior to entering the city's sewer system.

(21) "Secondary containment" means and shall have the meaning specified by Title 17 of this code.

16.09.110 Standards. (Partial list)

Instantaneous Concentration Allowable

Parameter	*Maximum*	*Minimum*
Oil grease **	20 mg/liter	–
Oil grease (total)	200 mg/liter	–
Cadmium	0.1 mg/liter	–
Chromium, Hexavalent	1.0 mg/liter	–
Chromium (total)	2.0 mg/liter	–
Copper	2.0 mg/liter	–
Lead	0.5 mg/liter	–
Nickel	1.0 mg/liter	–
Zinc	2.0 mg/liter	–
pH	11.0 units	5.5 units
Total Toxic Organics (TTO)	1.0 mg/liter	–
Any Single Toxic Organic	.75 mg/liter	–

** Gravity separation at a temperature of 20° C and a pH of 4.5

16.09.113 Requirements for vehicle service facilities.

(a) Definitions. For the purposes of this section the following words and phrases shall be as defined herein.

(1) "Commercial vehicle washing facility" means a commercial facility where vehicle washing is a primary business activity. Commercial vehicle washing facilities include, but are not limited to, mobile washing rigs.

(2) "Fleet washing facility" means a facility for washing vehicles, at a location where a business maintains six or more vehicles.

(3) "Ground surfaces" means and includes dirt, gravel, or other unpaved surfaces.

(4) "Vehicle" means a mode of transporting people or things. Vehicles include, but are not limited to, automobiles, trucks, recreational vehicles, tractors, airplanes and boats.

(5) "Vehicle fluid" means a liquid used in or drained from a motor vehicle. Vehicle fluids include, but are not limited to, gasoline, diesel fuel, motor oil, brake fluid, radiator fluid, hydraulic fluid, transmission fluid, and coolant.

(continued on back)

NOTE: Paragraph numbering corresponds to the Palo Alto Municipal Code. Numbering systems used for the other cities in the service area (East Palo Alto, Los Altos, Los Altos Hills, and Mountain View) will vary.

VOL 12 2 1727

(continued from inside back cover)

(6) "Vehicle service facility" means a commercial or industrial facility that conducts one or more of the following operations with respect to vehicles or components of vehicles: vehicle repair, fuel dispensing, vehicle fluid replacement, engine and parts cleaning, body repair, vehicle salvage and wrecking, or vehicle washing.

(b) All vehicle service facilities shall be operated, on and after October 1, 1992, in accordance with the following standards:

(1) No person shall dispose of, nor permit the disposal, directly or indirectly, of vehicle fluids, hazardous materials, or rinsewater from parts cleaning operations into storm drains.

(2) All owners and operators of vehicle service facilities shall ensure that any vehicle fluid, hazardous material, or rinsewater from parts cleaning operations that comes into contact with any floor, pavement or ground surface is cleaned up immediately from such surface.

(3) No person shall dispose of vehicle fluids or rinsewater from parts cleaning operations into the sanitary sewer system except pursuant to an industrial waste discharge permit obtained in accordance with this chapter.

(4) No vehicle service facilities shall contain floor drains, excepting only such floor drains as are connected to wastewater pretreatment systems for which an industrial waste discharge permit has been obtained in accordance with this chapter.

(5) No tanks, containers or sinks used for parts cleaning or rinsing shall be connected to the storm drain system, or to the sanitary sewer system except pursuant to an industrial waste discharge permit obtained in accordance with this chapter.

(6) No person shall perform vehicle fluid removal outside a building, nor on asphalt or ground surfaces, whether inside or outside a building, except in such a manner as to ensure that any spilled fluid will be in an area of secondary containment.

(7) Leaking vehicle fluids shall be contained or drained immediately.

(8) No person shall leave unattended drip pans or other open containers containing vehicle fluid, unless such containers are in use or in an area of secondary containment.

(9) No person shall discharge wastewater from vehicle washing operations or wash racks to the sanitary sewer system except pursuant to an industrial waste discharge permit obtained in accordance with this chapter. Nothing in this subsection shall be construed to prohibit the proper reuse of wastewater.

(10) No person shall discharge into the storm drain water from vehicle washing operations, except from rinsing of vehicle exterior surfaces, with water only, for appearance purposes. This exception does not apply to commercial vehicle washing facilities or fleet washing facilities.

(11) Vehicle service facilities shall be cleaned using only those methods of cleaning that ensure that no materials are discharged to the storm drain or to the sanitary sewer system, except for wastewater which is discharged to the sanitary sewer system pursuant to an industrial waste discharge permit obtained in accordance with this chapter; provided, however, that a permit shall not be required for facilities that use the following three-step sequence for cleaning floors:

(i) Clean up spills with rags or other absorbent materials.

(ii) Sweep floor using dry absorbent material.

(iii) Mop floor. Mop water must be discharged to the sanitary sewer via a toilet or sink.

(12) All owners and operators of vehicle service facilities shall ensure that spill prevention and clean-up equipment and absorbent materials are kept in stock at all times and are readily available for use.

(13) No acid-containing batteries shall be stored except within secondary containment.

(14) All owners and operators of vehicle service facilities shall ensure that all employees of such facilities are trained, upon hiring and annually thereafter, regarding best management practices in accordance with guidelines issued and published by the superintendent.

(15) All owners and operators of vehicle service facilities shall post or cause to be posted signs on all storm drains located on the property of the facility notifying persons that the discharge of wastes into the storm drain is illegal.

In the case of any conflict between the provisions of this section and other provisions of this chapter, this section will apply.

SAMPLE PERMIT

R0055029

VEHICLE SERVICE FACILITY DISCHARGE PERMIT

Discharger:
Facility Address:

Permit Number:

This Vehicle Service Discharge Permit is granted to the above facility to discharge treated vehicle service wastewater and domestic waste to the City of Palo Alto sewer collection system in compliance with the City of Palo Alto Sewer Use Ordinance Chapter 16.09, any applicable provisions of Federal or State law and regulations, and in accordance with all provisions set forth herein. In addition to the Specific Permit Conditions (Attachment 1), the discharger's attention is specifically directed to Attachment 2 (Standard Permit Conditions) of this permit, which refers to certain provisions of City of Palo Alto Municipal Code, Chapter 16.09. Violation of the conditions set forth herein may result in civil and criminal penalties as described in Chapter 16.09.140, but not limited to civil liability of $6,000 per day.

This permit is issued to in accordance with the application filed on February 4, 1993 with the Palo Alto Regional Water Quality Control Plant (RWQCP) and in conformity with plans, specifications, and other data submitted in support of the above application. This permit is not transferrable without submission of a new discharge permit application and written consent of the superintendent.

Effective Date: May 27, 1993
Expiration Date: May 27, 1996

5. Inspection/Maintenance Log Form

VOL 12 2 1730

R0055030

Attachment 1

SPECIFIC PERMIT CONDITIONS

Part A. Discharge Conditions

1. Discharge Rate

The discharge rate from this facility shall not exceed a maximum process flow rate of 22,000 gallons per month and a total flow rate of 22,000 gallons per month. Any increase in either discharge rate from this facility requires the prior approval of the Palo Alto Regional Water Quality Control Plant (RWQCP).

Part B. Sampling Location

The designated sampling point is after the treatment system and prior to discharge to the sanitary sewer. The designated sampling point is labelled Sampling Point "1" on the attached sampling point diagram (Attachment 4).

Part C. Effluent Limitations

During the term of this permit, the discharge from this facility shall not exceed the following effluent limitations at sampling point "1":

Applicable Effluent Limits*

PARAMETER	INSTANTANEOUS MAXIMUM	PARAMETER	INSTANTANEOUS MAXIMUM
Arsenic	0.01	Silver	0.25
Beryllium	1.00	Zinc	2.00
Cadmium	0.10	Fluoride	65.0
Chromium (total)	2.00	Formaldehyde	5.00
Copper	2.00	Oil & Grease	200.0
Cyanide	1.00	Phenols	1.00
Lead	0.50	TTO**	1.00
Mercury	0.05	pH	5.5-11.0
Nickel	1.00	Susp. Solids	6,000
Selenium	2.00		

*All limits are given in mg/L except for pH.
**TTO=Total Toxic Organics

vsf:template permit

VOL 12

2

1731

R0055031

Part D. **Monitoring and Maintenance**

1. Sampling Frequency

The facility operator shall conduct sampling according to the schedule provided in the following table:

PARAMETER	SAMPLING FREQUENCY
Copper	quarterly
Lead	quarterly

Revisions to the sampling frequency may be considered based on performance.

Part E. **Treatment System**

1. Treatment System

The facility operator shall operate and maintain the two-stage oil/water separator specified in the permit application.

2. Visual Inspection

The facility operator shall conduct a visual inspection of the oil/water separator a minimum of once per week to ensure that the system is operating properly and to determine if cleaning is necessary. A written log/record of the inspections shall be kept on the attached Inspection/Maintenance Log Form, Attachment #5. Inspection dates, observations, and any actions or cleaning required shall be logged.

3. Cleaning/Maintenance

The facility operator shall clean and maintain the oil/water separator a minimum of once per month, or more frequently if suggested by a visual inspection. A written log/record of the cleaning/maintenance events shall be kept on the attached Inspection/Maintenance Log Form, Attachment #5. Cleaning/maintenance dates, observations, and any further actions required shall be logged.

VOL 12 2 1 7 3 2

R0055032

Part F. **Reporting**

1. Annual Report of Continued Compliance

The facility operator shall submit an Annual Report of Continued Compliance (ARCC) to the RWQCP by January 15th of each calendar year. The report shall contain all the changes that may have affected the quantity and the quality of the effluent during the past twelve month reporting period. The report shall also contain the analytical results from all sampling events required by Part D of this permit. In addition, a copy of the log (Attachment #5) of treatment system visual inspections and cleaning/maintenance events, as specified in Part E, shall also be submitted. The ARCC shall be completed according to the guidelines provided by the RWQCP.

2. Noncompliance Reporting

If the results of any sampling analysis indicates that the discharge has exceeded the allowable limits, the facility operator must:

i. Verbally inform the RWQCP of the violation within 24 hours of the dischargers knowledge of the violation.

ii. Submit a written report to the RWQCP, within fifteen working days of the discharger's knowledge of the noncompliance, explaining the following: the nature, volume, and duration of the violation; and mitigation measures taken to correct the noncompliance and prevent reoccurrence.

3. Spill Reporting

The facility operator shall immediately notify the RWQCP by phone, at 415-329-2598 (24 hour number), in the event of a spill and discharge to either the storm or sanitary sewer system. In addition, the facility operator shall submit a written report to the RWQCP, within fifteen days of the discharger's knowledge of the noncompliance, explaining the following: the nature, volume, and duration of the violation; and mitigation measures to correct the noncompliance and prevent reoccurrence.

It's important for residents to know that washing or working on cars at home can pose severe hazards for the environment.

- ❑ If you wash your car with soap, do it on a grassy area where soapy water will not run into the street, and dispose of the bucket of suds into a sink or toilet.
- ❑ Take care to catch drips when you change vehicle fluids.
- ❑ Recycle used motor oil and antifreeze.
- ❑ If you cannot take these precautions, consider having a ***Clean Bay Business*** take care of your car.

Los Altos, Los Altos Hills, Mountain View,
Palo Alto, and Stanford University

January 19, 1994

Jim Kuhl
Paragon Automotive Service Center
249 Evelyn Avenue, West
Mountain View, CA 94041

Dear Jim Kuhl:

CONGRATULATIONS! You have met the Regional Water Quality Control Plant's (RWQCP) criteria for recognition as a Clean Bay Business for 1994. We commend you for your efforts to keep pollutants out of local creeks and San Francisco Bay (via the storm drain and sanitary sewer systems). We greatly appreciate the time, energy, and expense that you have invested in becoming an environmentally proactive business.

We are enclosing a variety of materials for your use including: decals, camera-ready tear strips, and brochures. The decals are for your shop windows, walls, or display counters. Please note that they may not be used for vehicle windows because of CHP size restrictions. The tear strips are provided so that you may use the Clean Bay Business logo in your advertising or on business cards or stationery. The brochures are for you to hand out to your customers at the counter. Please let us know if you need additional brochures through out the year.

We'd also like to let you know that we will be running ads in the local newspapers during the week of January 17 announcing the Clean Bay Business program. All businesses receiving the 1994 recognition will be listed. The advertisement will be placed in the San Jose Mercury News, the Palo Alto Weekly, and The View.

Lastly, we will be placing in ad in the automotive repair section of the yellow pages in the telephone book. The ad will feature the Clean Bay Business logo and a brief message. The message suggests that people ask their favorite auto repair shop if it is a Clean Bay Business. It also explains that Clean Bay Businesses have made extra efforts to reduce pollution and protect our creeks and Bay.

Thank you again for your pollution prevention efforts! Please fill out the enclosed "response card" and include any program suggestions or comments that you may have. Please call Suzanne Healy, at 415-329-2117, if you have any questions.

Sincerely,

Margaret Bitle

If you really must wash your car at home, Flo hopes you ll

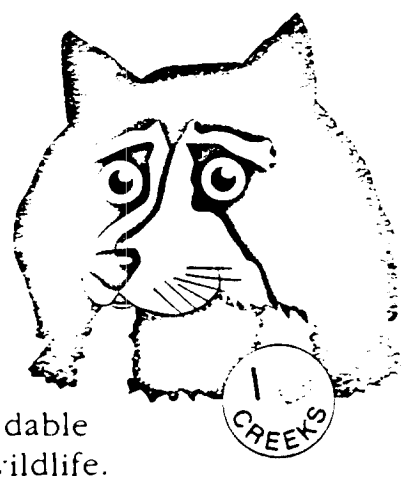
- ✓ *Always use a bucket for soapy water, and pour it down the sink or toilet when you re done.*
- ✓ *Wash the car on a lawn or grassy area where soap and water will not run off into the street.*
- ✓ *Use only water if you can.*
- ✓ *Conserve water by using a hose with an automatic shutoff attachment.*

Flo s friends at the Regional Water Quality Control Plant and the storm drain programs of East Palo Alto, Los Altos, Los Altos Hills, Mountain View, and Palo Alto are sponsoring this car wash discount program to help you protect wildlife and the Bay.

Keep pollution away from storm drains!

The Regional Water Quality Control Plant is operated by the City of Palo Alto for the communities of East Palo Alto, Los Altos, Los Altos Hills, Mountain View, Palo Alto, and Stanford.

Flo says, "Protect the Bay! Take that car to a car wash!"



Commercial car washes are good because they send soap and greasy water to the sewer, NOT to storm drains, creeks, and Bay. Even biodegradable soaps contain ingredients that are harmful to wildlife.

ABSTRACT

Title:	Analysis of Urban BMP Performance and Longevity In Prince George's County, Maryland
Date:	August, 1992
Author:	John Galli, Anacostia Restoration Team Department of Environmental Programs Metropolitan Washington Council of Governments
Agency:	The Metropolitan Washington Council of Governments is the regional organization of the Washington, D.C. area's major local governments and their governing officials. COG works towards solutions to such regional problems as energy shortages, traffic congestion, inadequate housing, air and water pollution. COG is also the areawide wastewater management agency for the Washington area and is involved with regional policy issues related to provision of adequate wastewater treatment, sludge disposal, nonpoint source pollution control, and municipal water supplies.
Report Abstract:	Study examined the performance and longevity of 11 types of water quality and quantity BMP's in use in Prince George's County, Maryland since 1984. BMP types which were field surveyed included infiltration trenches and basins, dry wells, porous pavement, grassed swales, ED dry ponds, wet ponds artificial marshes, pocket wetlands, oil/grit separators and dry ponds. Background literature survey information on the fundamental design, performance capability and limitations of currently employed or proposed BMP systems was integrated with findings from the field survey portion of the study. Design strengths and weaknesses, maintenance aspects, structural-related problems and environmental attributes for 156 BMP sites inspected during the study are critically assessed. Study recommendations include both generic and specific criteria and techniques for improving BMP water quality and quantity performance, system longevity, maintenance, public safety, and environmental and aesthetic quality.
Report Price:	$20.00

Acknowledgements

The author would like to thank a number of individuals whose support, cooperation and patience were instrumental to the completion of this study. In particular, the patient assistance of Ms. Jennifer Smith (PGDER Project Manager) and Mr. Stan Wildesen was greatly appreciated. The author would also like to extend his gratitude to the following BMP Task Force Committee members for their valuable insight: Mr. Dave Bourdon (PGSCD), Mr. Felix Guadalupe, Mr. Chai Chowgrjank, Mr. Derek Winogradoff and Dr. Mow-Sun Cheng (all PGDER), Mr. Stephen Lotspeich (M-NCPPC) and Mr. Bud Dombrowski (PGDPW). Special thanks are also extended to both Mr. James Brown and Ms. Karen Moreland (PGDER) for sharing their site inspection expertise. In addition, the author is indebted to Mr. Desmond Cole, Mr. Stephen Kunselman, Mr. Dave Shepp, Ms. Maureen Heraty, Mr. Peter Kumble and Ms. Vetoria Alston (all COG) for their help. Also, I would like to thank Mr. Thomas Schueler (COG) for his constructive suggestions. Last, the author wishes to extend his many thanks to Ms. Daphne Okeh, Ms. Giselle Bernstein, Ms. Claudia Thomas and Mr. Mark P. Pfoutz (all COG) for their tremendous assistance in the preparation of the report.

Executive Summary

The purpose of this study was three-fold: 1.) evaluate the overall effectiveness of stormwater management BMP's presently in use in Prince George's County, MD, 2.) provide, via an independent urban SWM task force, a forum for review and comment on both study findings and existing SWM design criteria, and 3.) where appropriate (or warranted) make recommendations to improve performance, maintenance and/or the environmental value of these BMP systems. In order to accomplish the preceding objectives, COG staff reviewed over 200 as-built stormwater management plans, conducted a field evaluation survey of 156 different BMP sites in the County, performed a comprehensive literature review of recent BMP monitoring studies and associated environmental findings, and both presented findings and solicited input from Prince George's County SWM task force members.

A general summary assessment of the 11 BMP types field surveyed in the study is graphically presented in Figure 1. As seen in Figure 1, considerable variation exists in both the relative ability and long-term reliability of BMP's to meet various performance and environmental objectives. Based on the results from this study, several important conclusions and recommendations regarding present generation BMP design and use can be made:

General BMP Performance Capability and Reliability

It is important to recognize that no single BMP type is ideally suited for every situation and that each brings with it various performance, maintenance and environmental advantages and disadvantages.

1. BMP's which can consistently achieve moderate to high levels of removal for both particulate and soluble pollutants include: wet ponds, artificial marshes, sand filters (not field surveyed in this study) and infiltration trenches. Of the preceding BMP types, only wet ponds and artificial marshes have demonstrated a general ability to continue to function as designed for relatively long periods of time without routine maintenance.

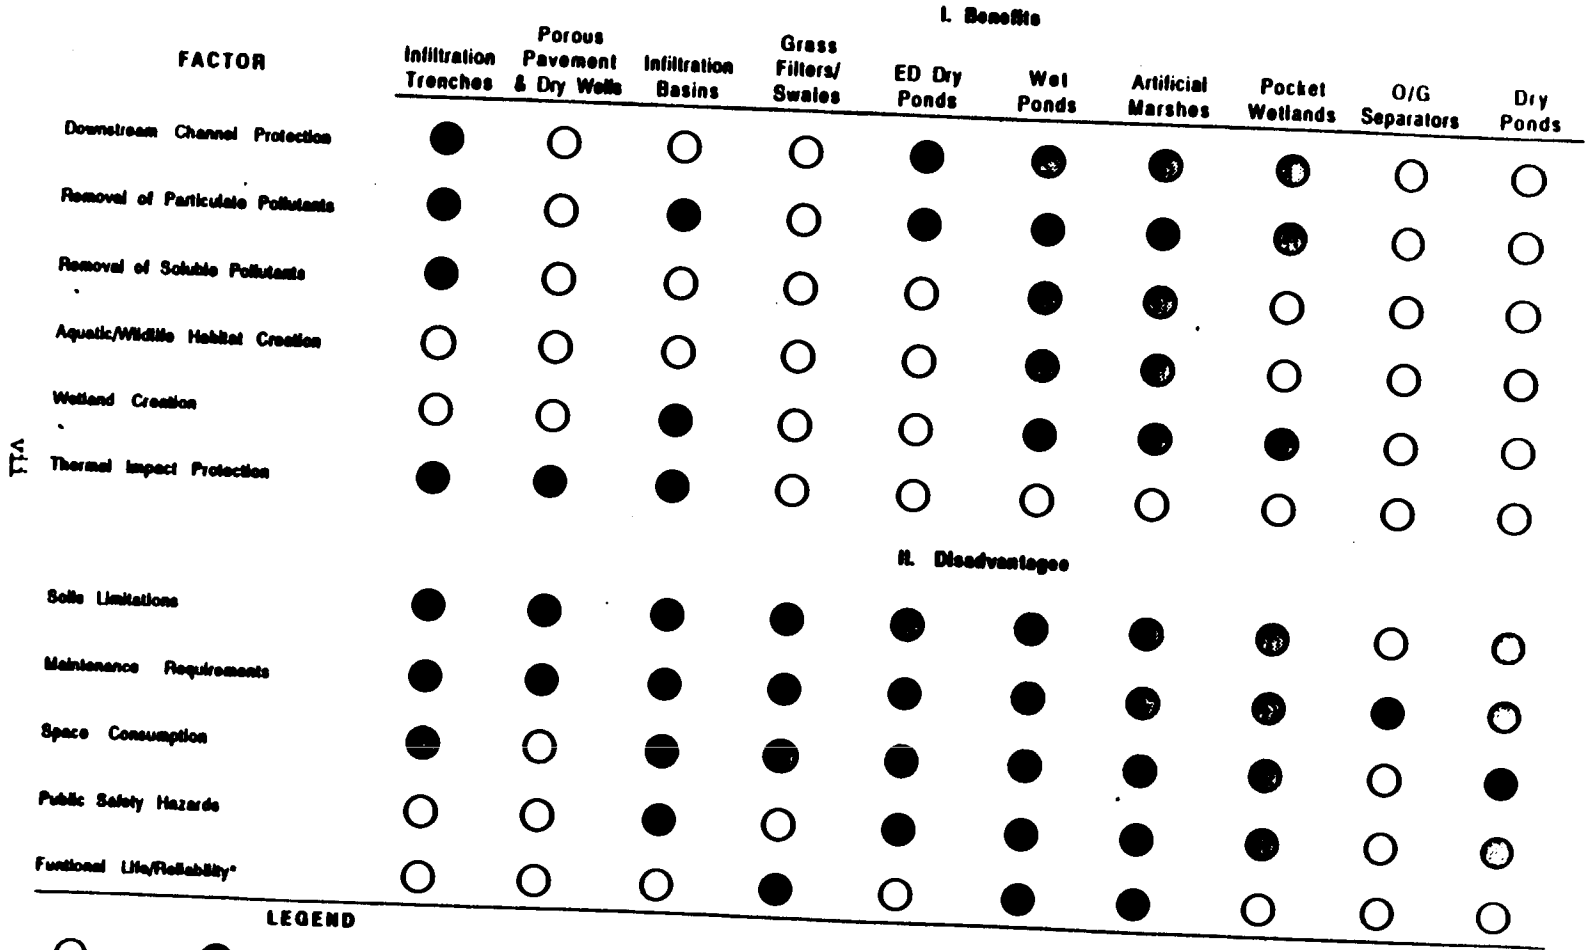
2. BMP's which are generally incapable of providing reliable pollution reduction until their fundamental design is improved or modified include: infiltration basins, porous pavement, grass filters and swales, smaller so-called 'pocket' wetlands, extended detention (ED) dry ponds, and oil/grit separators. The redesign of porous pavement systems does not, at this time, appear feasible. Furthermore, because of the inability to provide pre-treatment control for porous pavement and the system's high maintenance requirement and failure rate, the future use of this BMP in the WMA is not

VOL 12 2 1769

R0055069

FIGURE 1

SUMMARY: GENERAL ATTRIBUTES OF BMP SYSTEMS FIELD SURVEYED



R0055070

recommended. It should be noted that the PGDER Watershed Protection Branch has recently disallowed the use of porous pavement.

3. As a group, infiltration BMP's are extremely fragile systems with characteristically high failure rates. Results from this study revealed that many existing infiltration facilities failed or were not working as designed due to poor initial site selection, lack of proper maintenance, or both.

4. Given both the susceptibility of infiltration basins to clogging problems and their extremely high failure rate, water quality and quantity control can generally be achieved more reliably with other BMP's. The employment of present generation infiltration basin systems is no longer permitted by PGDER. Future design modifications which could significantly enhance both basin reliability and system longevity include:

   a.) the incorporation of adequate pre-treatment control,

   b.) limiting the maximum ponding depth to approximately two feet so as to reduce the risk of post-construction soil compaction problems, and

   c). intentionally oversizing water quality storage volumes to account for eventual loss of infiltration capacity.

5. The PGDER Watershed Protection Branch has recently required that all future oil/grit separators be constructed as off-line facilities. While this step should help to improve overall performance, considerable uncertainty still remains about the pollutant removal capability and maintenance requirements of present generation oil/grit separators. Pending monitoring results from both off-line and prototype second generation oil/grit separators, the continued employment of oil/grit separators is strongly discouraged. As an alternative, the Watershed Protection Branch should seriously entertain the use of off-line sand filters. It is further recommended that the employment of sand filters be considered for all development sites having an associated catchment area of 10 acres or less.

6. Results from this study confirm that dry ponds are unable to provide water quality control benefits, offer little in the way of either stream channel erosion protection or environmental amenities, and require a high level of maintenance. For all of these reasons, the future employment of dry ponds is not recommended. Alternative BMP's include artificial marshes, wet ponds and ED dry ponds. It is further recommended that the majority of the existing dry ponds in the County be gradually converted over into one of the three preceding BMP types.

VOL 12 2 1771

R0055071

Pond Location

7. With regard to on-stream versus off-stream pond siting, off-stream wet ponds, marshes and ED dry ponds appear to perform their water quantity and quality control duties as well as those located on-stream. Each choice of location has both environmental and water quality trade-offs. Where the treatment of both baseflow and stormflow is desired and where wetlands/receiving stream-related issues (such as thermal regime alteration) are not critical, the preferred approach is generally an on-stream system.

Wet Pond/Artificial Marsh Design

8. Both wet ponds and artificial marshes should withdraw water from at or near their surface. Mid-level or bottom release locations are generally discouraged because of the strong possibility of discharging water with low dissolved oxygen concentrations/poor water quality characteristics downstream.

9. The current minimum permanent pool storage volume requirement for wet ponds should be increased so as to provide higher levels of water quality control. It is recommended that: 1.) the minimum permanent pool volume for wet ponds be increased from 0.5 to 1.0 inches per impervious acre and 2.) a multiplier, land use intensity/watershed imperviousness level coefficient be employed to account for anticipated increases in pollutant loadings. A similar multiplier approach is further recommended for artificial marsh systems.

10. Results from this study indicated that a large percentage of both wet ponds and artificial marshes were designed as marsh/pond 'hybrids'. In other words, they were both too shallow to generally support adult gamefish populations year-round, and too deep to permit the establishment of emergent vegetation. It is strongly recommended that all future wet ponds and artificial marshes feature variable microtopography, so as to provide a proper balance between shallow water, mid-depth and deep water areas.

11. Field survey results revealed that short internal flow length was partially responsible for suboptimal water quality performance at several wet pond, artificial marsh and ED dry pond sites. It is strongly recommended that a minimum 1:1 internal flow path length be required.

VOL 12 2 1772

R0055072

Extended Detention Control

12. Stream channel erosion protection is generally best achieved through the employment of ED-type controls. Because of practical ED orifice sizing constraints, the employment of ED dry ponds, marshes and/or wet ponds is generally not feasible for catchment areas of 10 acres or less.

13. Results form this study revealed that only about 50 percent of the ED stormwater management facilities surveyed were capable of generally meeting their target ED times. In fact, survey results indicated that the runoff produced from smaller, less intense rainfall events often flowed through the majority of these facilities with little or no detention. What appears to be needed, is an improved ED approach which can more reliably provide a minimum of 6-12 hours of detention over a broader range of both storm size and rainfall intensity conditions. Possible design improvements include a greater use of gate valves or the employment of a proportioning weir outlet system.

Inspection and Maintenance

14. Without routine inspection and proper maintenance, BMP performance and functional life will ultimately be greatly reduced. The PGDER Watershed Protection Branch is to be strongly commended for its recent implementation of a comprehensive stormwater management inspection program. In order to provide maximum long-term protection of County water resources, this critical program element will require both adequate funding and staffing for the foreseeable future.

Landscaping and Mowing

15. The majority of the pond BMP systems surveyed would have benefitted, from both an aesthetic and wildlife habitat perspective, from greater pond landscaping treatment. Greater adherence to existing PGDER stormwater management aquatic and terrestrial landscaping criteria is strongly recommended. Where wildlife habitat creation is an objective, both grass mowing height and frequency should be adjusted to better meet target species requirements. Consultation with local wildlife biology experts and SWM maintenance personnel is strongly recommended.

Signage and Safety Features

16. It is strongly recommended that future wet ponds and artificial marshes be posted with appropriate information/warning and environmental

VOL 12 2 1113

R0055073

education signage. In addition, the incorporation of pond safety features such as safety benches and aquatic shelves should largely eliminate the need for pond fencing.

Future Research Needs

17. During the course of the study, it became evident that additional BMP research is needed in at least two major areas: a.) comprehensive performance monitoring of oil/grit separators (to provide information necessary for the formulation of second generation design improvements, possible retrofit modification of existing structures, and enhanced maintenance and residual material disposal practices) and b.) development of improved ED calculation/methodology and control systems (which can provide greater ED control over a broader spectrum of storm scenarios)

VOL 12 2 1774

R0055074

For organizational purposes this report has been divided into five chapters. Chapter one briefly describes study design and methodology. The second chapter provides the reader with background information on the fundamental design, performance capability and limitations of currently employed or proposed BMP systems. In the third chapter, a brief overview of the major physical and hydraulic factors which affect the performance of wet ponds and artificial marshes is presented. Chapter four provides detailed information on the results from the field survey portion of the study. Included in this chapter are: background findings from as-built file review, observations on general BMP performance and system longevity, description of BMP type-specific performance, maintenance and/or structural problems, and the identification of environmental attributes. In the fifth and final chapter, both generic and specific criteria and techniques were identified to improve the following: 1.) BMP water quality and quantity control performance, 2.) system longevity, 3.) maintenance, 4.) public safety and 5.) environmental and aesthetic features. In addition, both alternative BMP practices and future research needs are discussed. Last, a list of possible BMP retrofit candidate sites identified through the field survey was developed and included in the final section.

R0055075

Introduction

Since the inception of its 1984 stormwater management (SWM) ordinance, the Prince George's County SWM program has become a model throughout the State of Maryland. In the ensuing years, both the number and type of SWM facilities have proliferated throughout the County. As expected, this has raised a number of concerns from the engineering, development and environmental communities regarding the long-term performance, pollutant removal capability, longevity, maintenance burden, hydrologic performance and environmental attributes of these urban Best Management Practices (BMP's).

In response, the Prince George's County Department of Environmental Resources (PGDER) Watershed Protection Branch concurred that an independent and in-depth assessment of the general performance and reliability of urban SWM practices within the County was needed. Subsequently, the Watershed Protection Branch contracted the Metropolitan Washington Council of Governments (COG) to perform a comprehensive evaluation. As a result, a study was undertaken in 1991 to accomplish the following objectives:

1. Evaluate a representative sub-population of urban BMP's installed since 1984 with respect to performance, longevity and maintenance. This would entail a comprehensive field review under both wet and dry weather conditions, and would focus on isolating both critical design factors and procedures.

2. Provide, with respect to current SWM design specifications for urban BMP's, a forum for independent review and input. This objective was to be met through the creation of an urban SWM task force, composed of prominent individuals selected by the Manager of the Watershed Protection Branch.

3. Prepare a comprehensive report on specific design recommendations which would serve to improve water quality/quantity performance, reduce maintenance burdens and increase the overall environmental value of urban SWM practices.

In order to accomplish the preceding objectives a three-part study was required. Part one of the study consisted of the review of SWM as built-engineering drawings and computations for the complete range of BMP types presently in operation. BMP types included: infiltration trenches, infiltration basins, dry wells, porous pavement, grass filters/swale systems, extended detention dry ponds, wet ponds, artificial marshes, oil/grit separators and dry ponds. In the second part of the study, actual BMP field performance was evaluated by COG staff. Part three of the study featured a comprehensive literature review to identify expected BMP pollutant removal efficiency and potential environmental amenities/impacts.

VOL 12 2 1776

Chapter 1. Prince George's County BMP Field Evaluation Study Design and Methodology

As previously stated, the purpose of this study was three-fold: 1.) comprehensively assess current Prince George's County stormwater management (SWM) water quality and quantity control design criteria; 2.) perform both a thorough field evaluation of a representative sub-population of BMP's presently in operation in the County, as well as, conduct a literature survey on the present status of BMP monitoring studies and technologies; and 3.) develop a series of both generic and BMP specific recommendations to further improve BMP performance, facilitate SWM maintenance operations, and enhance the aesthetic value and environmental opportunities associated with BMP's.

In order to meet the preceding objectives, a study design featuring three major tasks, or elements was formulated. Under the first task, COG Staff screened over 250 as-built files both to identify potential BMP design strengths and weaknesses and to check for general compliance with existing County SWM design criteria. Next, approximately 200 as-built plans representing the full array of BMP types in use were comprehensively reviewed. Pertinent information obtained from these plans, such as age, drainage area, land uses controlled, etc., was combined with field survey findings to form the data base backbone of the study. In addition, COG staff performed a literature survey of over 60 recent SWM monitoring studies from across the country. Last, as-built file review data, field survey results and literature review findings were synthesized to formulate specific study recommendations.

The following sections briefly describe the site selection process, field survey methodologies and calculations employed in the study.

A. Site Selection

With the assistance of PGDER staff, as-built files were obtained for each BMP type. Subsequently, an inventory of candidate BMP inspection sites was conducted. General background information, such as site name, P.G. County file number, street map book location, watershed area, catchment size, land use and age, was complied for nearly 200 existing BMP sites (Appendix A). On the basis of general BMP type representativeness and site accessibility, 156 sites were selected and subsequently field surveyed by COG staff. As seen by the BMP site distribution in Figure 1, a concerted effort was made to survey BMP sites representative of soil, watershed location, and land use conditions prevalent throughout the County.

VOL 12 2 1778

R0055078

B. General Field Survey Protocols

Survey Forms

In order to properly integrate both pertinent as-built file information and field survey data, COG staff developed a series of BMP evaluation forms (Appendix B). Background information such as BMP design features, ownership, maintenance responsibilities, associated site imperviousness, etc., was recorded, along with both BMP site inspection performance findings and receiving stream survey results. In addition, two to four representative black and white photographs were taken per survey site, so as to: a.) document existing conditions and b.) provide a reference base for future site inspections by local government personnel. All of the preceding information was incorporated in logbook form. It should be noted that the evaluation survey forms used in this study were partially based on forms currently in use by the Maryland Department of the Environment (MDE).

Development of a Relative Index System

In an effort to further standardize field investigation reporting, a qualitative index measuring system was developed for each of the following physical/biological parameters: A. floatable materials and visible, oily residual material (present in oil/grit separators and infiltration sump pits); B. degree of substrate fouling (fouling defined as the presence or absence of patinas of silt/fine organic material and/or algal growth on the surface of stones, as well as, the presence or absence of slime coatings on the underside of stones); and C. general aquatic/wildlife habitat value. Both of the first two indices (A. and B.) employed the same, 1 - 5 descriptive scale system. Under this system, a value of one indicated either no visible oil, floatable material or substrate fouling; whereas, a value of five signified a heavy presence. Similarly, the aquatic-wildlife habitat index was based on a descriptive scale of 1 - 3; with a value of one representing a low habitat value condition and a value of three signifying excellent site conditions. For a more detailed description of the preceding indices the reader is referred to Appendix B.

Physical Measurements

Field measurements of channel width, bank height, water depth, etc., were made with either a 100 foot fiberglass tape measure or collapsible 12 foot long wooden rod. Stream channel measurements were taken at approximately 100 foot intervals. The wooden rod was used extensively for measuring both permanent pool and sediment depth. It should be noted that 1/8 inch diameter holes were drilled at one inch intervals over the first foot to better determine sediment depths in both oil/grit separators and infiltration sump pits.

Residual material present in both oil/grit separators and infiltration sump pits was sampled with a custom-made scoop. The 'scooper' featured a nine foot long PVC

VOL 12 2 1779

R0055079

handle attached at a 90-degree angle to a 50 cubic inch capacity sediment bucket. Five sediment samples per water-holding chamber were taken. The five samples were composited in the field to create one composite sediment sample per chamber. The residual material was then qualitatively categorized as to the general percent coarse-grained, fine-grained and coarse organic material present. This was achieved by both feel (rubbing the material between the fingers) and visual comparison against known reference particle size material. The color, odor, and amount of oil present were also qualitatively described.

Stream discharge was calculated via the Embody Float Method (Embody, 1927). Substrate composition was visually determined.

C. Water Quality Grab Sampling

The following water quality parameters were measured, under both dry and wet weather conditions, during the study:

- Secchi depth,
- temperature,
- dissolved oxygen (DO)
- pH,
- alkalinity,
- carbon dioxide (CO_2), and
- total dissolved solids (TDS)

Secchi depth, which is an indication of water transparency or clarity, was measured with a standard 20 centimeter diameter secchi disk. From these secchi depth measurements the general trophic status (a measure of the relative productiveness of a body of water) was determined using the Carlson (1977) secchi disk trophic state index system.

Temperature was measured via a Hach model No. 4450 temperature meter. DO, pH, alkalinity and carbon dioxide levels were measured with a Hach kit (model No. FF-2). This kit employs the Winkler-titration method for measuring DO concentrations. TDS levels were determined with a Hach TDS meter (model No. 44400). It should be noted that water samples from observation wells, oil/grit separators and infiltration sump pits were obtained with a hand-operated pump (Black and Decker - 'jackrabbit' pump).

D. Sediment Trapping Rate Calculations

The sediment trapping rate for oil/grit separators and infiltration sump pits was estimated via the following approach: 1.) the average depth of sediment was first converted both to total volume and weight (using an assumed average weight of 60 lbs/cubic foot), and 2.) sediment weights were divided by the catchment area and age

VOL 12 2 1780

R0055080

of the structure (or age class) to obtain an average estimated sediment trapping rate expressed in lbs/ac/year.

E. Data Manipulation - SAS Architecture

The Statistical Analysis System (SAS), which is a mainframe computer system for data analysis, was employed to statistically analyze field survey data. A series of SAS programs were specifically written to meet the three following objectives:

1. Convert and reformat Lotus 1-2-3 field survey data into a series of data fields for each BMP type;

2. Statistically analyze, via the PROC UNIVARIATE (procedure analysis package), field survey data sets; and

3. Test for the general strength of association between various BMP design elements and field survey results, through a series of Pearson's rank correlation analyses.

F. Literature Review

COG staff conducted a comprehensive literature review of over 80 recent BMP performance and environmentally-related studies. One of the major accomplishments of this subtask was the compilation of study findings into a comprehensive tabular format. This information is included as Tables 1 and 2 of the report.

VOL 12 2 1781

R0055081

Chapter 2. Background BMP Capsule Summaries

This chapter provides general background information on the fundamental designs, performance capabilities and limitations of 11 currently employed or proposed urban BMP systems in the Washington Metropolitan Area (WMA). Major findings for each BMP type appear in a capsule summary format and are presented in the following order:

- infiltration trenches;
- dry wells;
- infiltration basins;
- grass/filters/grass swale systems;
- porous pavement;
- extended detention dry ponds;
- artificial marshes;
- wet ponds;
- sand filters;
- peat-sand filters; and
- oil/grit separators;

It should be noted that each capsule summary represents a synthesis of findings from both available published data and the Prince George's County BMP field evaluation portion of the study. As previously stated, a summary assessment of the general overall effectiveness of current BMP's is included as Table 1. Actual reported pollutant removal efficiency data for nearly 60 wet pond and wetland systems is summarized in Table 2. Reference sketches for each of the preceding BMP types are provided in Appendix D.

TABLE I

A COMPARATIVE ASSESSMENT OF THE EFFECTIVENESS OF CURRENT URBAN BEST MANAGEMENT PRACTICES (MWCOG, 1992)

URBAN BMP OPTIONS*	RELIABILITY FOR POLLUTANT REMOVAL	LONGEVITY*	APPLICABLE TO MOST DEVELOPMENTS	WILDLIFE HABITAT POTENTIAL	ENVIRONMENTAL CONCERNS	COMPARATIVE COST	SPECIAL CONSIDERATIONS
STORMWATER WETLANDS	Moderate to High depending on design	20+ years expected	Applicable to most sites if land is available.	High.	Stream warming; natural wetland alteration.	Marginally higher than wet ponds.	Recommended with design improvements and with the use of macropools and wetlands
EXTENDED DETENTION PONDS	Moderate, but not always reliable	20+ years, but frequent clogging and short detention common.	Widely applicable, but requires at least 10 acres of drainage area.	Moderate.	Possible stream warming and habitat destruction.	Lowest cost alternative in size range	Recommended with design improvements and with the use of macropools and wetlands
WET PONDS	Moderate to high	20+ years	Widely applicable, but requires drainage area of greater than 2 acres.	Moderate to high.	Possible stream warming, trophic shifts, habitat	Moderate to high compared to conventional	Recommended, with careful site evaluation
MULTIPLE POND SYSTEMS	Moderate to high; redundancy increases reliability.	20+ years	Widely applicable.	Moderate to high.	Selection of appropriate pond option minimizes overall environmental impact.	Most expensive pond option	Recommended
INFILTRATION TRENCHES	Presumed moderate	50 % failure rate within five years.	Highly restricted (soils, ground water, slope, area, sediment input).	Low.	Slight risk of ground water contamination.	Cost-effective on smaller Rehab costs can be considerable.	Recommended with pretreatment and geotechnical evaluation.
INFILTRATION BASINS	Presumed moderate, if working	40 - 100 % failure within five years.	Highly restricted (see infiltration trench).	Low to moderate.	Slight risk of ground water contamination.	Construction cost moderate, but rehab cost high.	Not widely recommended until longevity is improved
POROUS PAVEMENT	High (if working)	75 % failure within five years.	Extremely restricted (karstic, soils, ground water, slope, area, sediment input).	Low.	Possible ground water impacts; uncontrolled runoff.	Cost-effective compared to conventional asphalt when working properly.	Recommended in highly restricted applications with careful construction and effective maintenance.
SAND FILTERS	Moderate to high	20+ years	Applicable (for smaller developments).	Low.	Minor.	Comparatively high construction costs and frequent maintenance.	Recommended, with local demonstration
GRASSED SWALES	Low to moderate, but unreliable.	20+ years	Low density development and roads.	Low.	Minor.	Low compared to curb and gutter.	Recommended, with checkdams, as one element of a BMP system
FILTER STRIPS	Unreliable in urban settings.	Unknown, but may be limited.	Restricted to low density areas.	Moderate if forested.	Minor.	Low.	Recommended as one element of a BMP system
WATER QUALITY INLETS	Presumed low	20+ years	Small, highly impervious catchments (< 2 acres).	Low.	Decomposition of hydrocarbon loadings. Disposal of hydrocarbon and toxic residuals.	High, compared to trenches and sand filters.	Not currently recommended as a primary BMP option

*based on current designs and prevailing maintenance practices

TABLE 2

THE POLLUTANT REMOVAL CAPABILITY OF POND AND WETLAND SYSTEMS: A REVIEW (MWCOG, 1992)

NOTE: The table below provides summary data on the pollutant removal capability of nearly sixty stormwater pond and wetland systems. Each study differs with respect to pond design, number of storms monitored, pollutant removal calculation technique, and monitoring technique, so exact comparisons between studies are not appropriate.

R0055088

I. Infiltration Trenches

Infiltration trenches are shallow, excavated trenches which are backfilled with clean, 1.0-3.0 inch diameter stone to provide temporary underground storage of stormwater. In general, the first 0.5 inches of runoff from the impervious portion of the catchment is directed into the trench, whereupon it gradually percolates into the underlying soil. All infiltration trench systems include either a pre-treatment grass filter strip or wet sump pit/water quality inlet for reducing incoming loads of suspended solids, oils and grease. Newer infiltration trenches also feature a six inch thick sand layer underneath the stone reservoir to both enhance drainage and reduce the risk of soil compaction during trench construction.

Infiltration trenches are commonly used to provide first flush water quality control for drainage areas less than 10 acres in size. Because of their relatively high pollutant removal efficiency, low number of associated secondary environmental impacts, and ability to closely replicate pre-development hydrology they along with infiltration basins and other infiltration-type practices have received preferred BMP status by MDE. As with all infiltration BMP systems, pollutant removal is accomplished by physical filtration, adsorption, and microbial decomposition in the underlying subsoil, as well as via the trapping of particulate matter within the pre-treatment portion of the system.

Capsule Summary

Pollutant Removal Capability: Although performance data on conventional infiltration trenches is rare, trenches are believed to have high capability to remove particulate pollutants and a moderate capability to remove most soluble pollutants. It should be noted that certain soluble pollutants such as nitrates, chlorides and various hydrocarbon-based products can effectively migrate through the underlying soil.

Longevity: Theoretically, the life expectancy of infiltration trenches should be approximately equal to that of septic fields (i.e., - 15-30 years). However, conventional infiltration trenches have thus far generally proven to have much shorter life spans. Slightly over half partially or totally fail within the first five years of construction. Longevity could be improved through more rigorous site-specific geotechnical evaluation, regular inspection and maintenance, and enhanced pre-treatment control.

Feasibility: The application of trenches, like other infiltration practices, is severely restricted by soils, water table, slope and contributing drainage area conditions. These conditions must be carefully investigated in the field before proceeding with design.

VOL 12

2 1 7 8 9

R0055089

Environmental Concerns: Concerns persist about the possibility of groundwater contamination by trenches. Studies to date do not indicate a major risk, but have noted migration of nitrate and chlorides.

Environmental Benefits: The widespread use of infiltration trenches in a watershed could help to replicate pre-development hydrology, increase dry-weather baseflow, and reduce bankfull flooding frequency. Unfortunately, this benefit is often not realized in practice given the short lifetimes of conventional trenches. In addition, because infiltration trenches can be located under parking lots (not recommended) or in lawn areas, they can help preserve more on-site natural area.

Costs: While infiltration trenches are more costly than pond systems in terms of cost per unit of runoff treated, they are a cost-effective option for smaller sites where ponds cannot be applied.

Adaptability: Because of practical volume of storage limitations, infiltration trenches typically cannot treat large amounts of stormwater runoff. As such, they are generally restricted to smaller development sites where water quality control is the primary management objective.

Maintenance Burden: To enhance longevity and maintain performance, trenches and associated pre-treatment systems do require significant maintenance. Most conventional trenches do not appear to be regularly maintained in the field and thus many will require costly rehabilitation or replacement to maintain their function.

II. Dry Wells

Dry wells are small infiltration trench systems generally employed to capture and treat the first 0.5 inches of roof runoff from either small, individual commercial buildings or single family residences. From a design standpoint, they differ from infiltration trench systems in that they rarely, if ever, include any pre-treatment feature. In general, roof runoff is delivered via a roof leader/perforated dry well inlet pipe into the upper portion of the stone reservoir. The stone reservoir, which is typically buried one foot below ground level, includes an observation well for routine inspection. Runoff which exceeds the infiltration capacity of the system is discharged to the surface, via an overflow pipe located within the roof leader.

The pollutant removal efficiency, longevity, feasibility, maintenance burdens and environmental benefits and concerns associated with dry wells are comparable to those previously described for conventional infiltration trench systems. However, it should be noted that dry wells are generally longer-lived. In a recent MDE study (Lindsey et al., 1991) reported that 72 percent of the dry well systems surveyed were still working

VOL 12 2 1790

R0055090

after five years. This represents the highest working rate for any infiltration BMP system presently in use in the WMA. More than likely, reduced sediment and particulate organic material loads are responsible for the higher dry well working rate.

III. Infiltration Basins

Infiltration basins are typically sump-like, grass-lined dry ponds where incoming stormwater runoff is temporarily stored until it gradually percolates through the soil of the basin floor. In general, infiltration basins are designed to capture and treat the first 0.5 inches of runoff from the impervious portion of drainage areas less than 50 acres in size. Unlike infiltration trench systems, conventional infiltration basins do not include stone reservoir storage areas, observation wells, or any dedicated pre-treatment system. The vast majority of the basins inspected in the field survey portion of this study featured both a concrete barrel and riser control structure, and had associated catchment areas of less than 10 acres.

Capsule Summary

Pollutant Removal Capability: Performance data unavailable. However, like infiltration trenches they are presumed to have high pollutant removal efficiency rates for particulate pollutants ($\geq$ 75 percent removal) and moderate removal for most soluble pollutants ($\geq$ 45 percent removal).

Longevity: Infiltration basins are relatively short-lived. Lindsey (et al., 1991) reported that only 38 percent of the basins surveyed were still capable of infiltrating runoff after five years . Major design refinement, better construction practices and additional site investigation work will be required to improve longevity.

Feasibility: The application of basins is restricted by numerous site factors (soils, slope, water table and contributing watershed area).

Environmental Concerns: The greatest environmental concern relative to infiltration basins is the fact that their water quality benefits may not be realized due to widespread failure. Groundwater contamination is frequently cited as a risk, yet studies to date indicate that pollutant migration is very localized in scope.

Environmental Benefits: When infiltration basins work, they can replicate pre-development hydrology more closely than other BMP options. Basins also provide more habitat value than other infiltration systems. Not surprisingly, the vast majority of basins which do fail become defacto artificial marsh systems. Although significant storage volume is typically lost, many basins are still capable of providing partial water

VOL 12 2 1791 1

R0055091

quality control, as well as, environmental benefits generally associated with small artificial marsh systems.

Costs: An attractive feature of infiltration basins is their cost-effectiveness. They are projected to cost only ten to twenty percent more than dry detention ponds; however, the cost of an improved infiltration basin may be much higher.

Adaptability: Infiltration basins consume a considerable amount of space, often making them poorly suited for smaller development sites. In addition, because of their high susceptibility to clogging they are not recommended for sites which generate high amounts of suspended solids.

Maintenance Burden: Regular maintenance activities apparently cannot prevent rapid clogging and compaction of infiltration basins. Once clogged and/or compacted it has been very difficult to restore their original function; thus, many have been converted to wet ponds or artificial marshes.

IV. Grass Filter Strips/Grass Swales

Conventional grass filter strips and swales are long, relatively flat sloping earthen conveyance systems in which pollutants are removed from urban runoff principally through physical filtration through the grass cover crop, and secondarily via infiltration through the underlying soil. Enhanced grassed swale systems feature a series of low height check dams which provide temporary detention storage; thereby, improving the gravitational settling and infiltration characteristics of the system.

Both grass filter strips and grassed swales are commonly designed to safely convey large infrequent storm flows, such as the 10-year frequency storm, from the contributory drainage area. Unfortunately, comprehensive water quality design criteria for grass filters and other vegetative filtration systems are presently unavailable.

Capsule Summary

Pollutant Removal Capability: Conventional grass filter and swale designs have achieved mixed performance in removing particulate pollutants such as suspended solids and soluble nutrients. Vegetative filters that increase detention, infiltration and physical filtration have the potential to substantially improve removal rates.

Longevity: Conventional filters and swales can last an indefinite period of time if properly designed, periodically mowed, and if sediment deposits are removed as necessary.

VOL 12 2 1792

R0055092

Feasibility: Grass filter strips and swale systems are typically restricted to: 1) small, flat development sites less than 2-3 acres in size where runoff velocities, soils and/or high water table problems are not limiting, and 2) within road right-of-way (ROW) areas where similar slope, soils, and runoff volume/velocity conditions are not restrictive.

Environmental Concerns: Direct over-fertilization and herbicide use together with leaching from culverts and wash-off from lawn areas may, under certain conditions, increase the presence of trace metals, nutrients and toxics.

Environmental Benefits: Grass swales eliminate curbs and gutters along roads and parking lots, thereby slightly decreasing overall site imperviousness levels. Because grass filter systems are typically maintained as lawn area and are often directly adjacent to areas with high automobile traffic, their wildlife habitat value is relatively low.

Costs: Swales are usually less expensive to construct than curb and gutter but may require more land.

Adaptability: Swale performance diminishes sharply in larger highly urbanized settings. Also, swales should generally not receive construction stage runoff.

Maintenance Burden: Mowing, periodic rill and gully repair, and reseeding of bare spots are the primary maintenance activities.

V. Porous Pavement

Porous pavement systems consist of an underground, filter cloth-lined stone reservoir area overlain by a two to four inch thick layer of specially mixed asphalt, in which much of the fine aggregate material has been intentionally left out. The asphalt layer, which has both a high void ratio and rough surface texture, is often referred to as "popcorn" asphalt. Like most infiltration BMP systems, porous pavement can effectively remove both fine particulate and soluble pollutants present in urban runoff. In addition, it can provide partial water quantity control, as well as, groundwater recharge benefits. Its use is generally restricted to flat, small to medium size parking lot areas where only light to moderate automobile parking and traffic occurs.

Because of its high failure rate, porous pavement is rarely used any more in the WMA. Additional background information is presented in the following capsule summary.

VOL 12 2 1193

R0055093

Capsule Summary

Pollutant Removal Capability: Porous pavement systems have been shown to have high removal rates for both particulate ($\geq$ 80 percent removal) and soluble pollutants ($\geq$ 65 percent removal). The majority of the removal is a function of the exfiltration of runoff into the subsoil, and subsequent physical filtration, adsorption and microbial decomposition/transformation of pollutants.

Longevity: Porous pavement sites generally have one of the highest BMP failure rates (75% have reportedly failed within the first five years). Failure is due to partial or total clogging of the facility that occurs:

- Immediately after construction;
- Over time, when porous asphalt is clogged by sediment and oil; and
- When pavement is resurfaced with non-porous asphalt.

Feasibility: The use of porous pavement is highly constrained, requiring deep and permeable soils, restricted traffic (automobile traffic only), and suitable adjacent land uses.

Environmental Concerns: Concerns range from possible groundwater contamination (exacerbated by leaching of asphalt materials and hydro-carbons) to the loss of benefits due to premature failure.

Environmental Benefits: When operating properly, porous pavement can replicate pre-development hydrology, increase groundwater recharge, and provide excellent pollutant removal. Because the treatment area is physically located beneath the parking lot, the employment of porous pavement can help preserve more natural on-site area.

Costs: Porous pavement can be a very cost-effective BMP in the commercial areas where it can be applied. While the asphalt is more expensive than conventional pavement, porous pavement may (in some cases) eliminate the need for conventional on-site storm drainage systems.

Adaptability: Use of porous pavement may be restricted in regions with harsh winters, arid regions or regions with high atmospheric deposition rates, and in areas of sole-source aquifers.

Maintenance Burden: Quarterly vacuum sweeping and/or jet hosing is needed to maintain porosity. Field data, however, indicate that this routine maintenance practice is generally not followed.

VOL 12 2 1794

R0055094

VI. Extended Detention Dry Ponds

Extended detention dry ponds (ED dry ponds), differ from conventional dry ponds in that they are intentionally designed to capture and slowly release stormwater runoff from smaller, more frequent storms. Review of local ED dry pond design criteria revealed high variability both in ED design storm size and ED period. In the WMA, ED dry ponds have been designed to provide 6 to 40 hours of ED control for 0.25 inches of runoff per impervious acre all the way upto the full two-year frequency storm.

ED dry ponds rely almost exclusively on gravitational settling to remove pollutants. Depending upon the volume and length of time runoff is detained, ED dry ponds can achieve moderate to high removal efficiencies for particulate pollutants. They are also one of the more effective BMP's in reducing downstream channel erosion problems. Because of practical orifice sizing constraints, ED dry ponds are generally employed to control runoff from contributory drainage areas of 10 acres or greater.

Capsule Summary

Pollutant Removal Capability: Conventional ED dry ponds provide moderate yet highly variable removal of particulate pollutants, such as sediment, phosphorus and organic carbon, but provide negligible removal of soluble pollutants. They are also highly susceptible to resuspension problems, particularly if routine maintenance is neglected.

Longevity: While few conventional ED dry ponds built to date have totally failed, many do not operate as designed, some are clogged and have become defacto wet ponds, and a majority are not achieving target detention times.

Feasibility: The enhanced ED dry pond can be utilized in most low visibility development situations, as a retrofit practice, or in combination with wetlands or permanent pools. ED dry ponds can be located either on or off-stream and can be designed to treat runoff over a broad drainage area size range.

Environmental Concerns: Poorly-maintained ED dry ponds may create nuisances and are not popular with nearby residents. If improperly designed and located, ED dry ponds can degrade forests, wetlands and other natural habitat areas, and can contribute to downstream thermal loading problems.

Environmental Benefits: Enhanced ED dry ponds can provide both excellent downstream channel erosion protection and valuable wetland and wet meadow habitat.

VOL 12 2 1795

R0055095

Costs: ED dry ponds are generally the least costly stormwater quality ponds to construct, but also have the greatest regular maintenance burden of any stormwater pond system.

Adaptability: ED dry ponds are an adaptable BMP that can be applied to most, if not all, parts of the WMA.

Maintenance Burden: Conventional ED dry pond designs exhibit chronic clogging and are often difficult to mow. Debris and sand deposits quickly accumulate. This is particularly the case for ED dry ponds which are located directly on streams.

VII. Artificial Marshes

Artificial marshes are retention ponds predominantly comprised of large, shallow-depth water areas ideally suited for the establishment and growth of wetland plant species. These stormwater wetlands are designed to maximize pollutant removal through gravitational settling, dilution, filtration, and biological uptake and retention mechanisms. Artificial marshes may be located either on or off-stream and generally provide both water quality and quantity control for a wide array of drainage area and land use conditions.

Enhanced artificial marshes are designed for more effective pollutant removal and greater wetland plant species diversity and aquatic/wildlife habitat. They generally feature design elements such as extended detention control, a sediment forebay, complex microtopography, and extensive pond and terrestrial landscaping with native aquatic plants, shrubs and trees. Few stormwater wetlands are capable of replicating all of the varied ecological functions and attributes of natural wetland systems.

Capsule Summary

Pollutant Removal Capability: In general, conventional artificial marshes have a high pollutant removal capability that is roughly comparable to that of conventional wet ponds. Sediment removal can be greater in well-designed stormwater wetlands, but phosphorus removal is variable.

Longevity: Larger well-designed conventional artificial marshes should generally function for approximately 10 years before requiring major sediment removal or other rehabilitation work.

Feasibility: Enhanced artificial marshes can be applied to most development situations where sufficient baseflow, groundwater and/or contributory drainage area is available to maintain normal pool elevations.

VOL 12 2 1796

R0055096

Environmental Concerns: If located improperly, the construction of artificial marshes may impact existing forests and natural wetlands, and can also contribute to downstream thermal loading problems.

Environmental Benefits: With careful design and siting, enhanced artificial marshes can create unique and valuable habitat for waterfowl and wildlife.

Costs: Construction costs for artificial marshes have not been systematically analyzed, but are expected to be similar to those for wet ponds. Maintenance costs may average three to five percent of construction costs annually.

Adaptability: Enhanced artificial marshes can be adapted for most parts of the WMA. Their use in coldwater stream areas, however, may often be inappropriate due to temperature-related concerns.

Maintenance Burden: Artificial marshes require greater maintenance in the first one to three years to properly establish wetland vegetation. Thereafter, the maintenance burden is similar to other pond systems.

VIII. Wet Ponds

Wet ponds differ from artificial marshes in that they feature a large, deep permanent pool area which is generally over four feet deep. Most conventional wet ponds have traditionally been graded with 3:1 underwater slopes, so as to intentionally discourage the establishment of cattails and other emergent plants. More recently, however, an increasing number of wet ponds are being designed with shallow underwater benches or shelves around their perimeter. These aquatic benches are typically less than one foot deep and provide both an added safety feature, as well as, a suitable area for the creation of fringe marsh habitat. Wet pond permanent pools are generally sized on a volumetric basis; with the permanent pool volume corresponding to all (or some major portion) of the design water quality storm runoff volume.

Wet ponds, along with artificial marshes, are among the top BMP's in terms of providing water quality and quantity control benefits over a broad range of storm frequency/size, drainage area and land use scenarios. They may be constructed either on or off-stream. Typically, wet ponds are restricted to catchment areas of 10 acres or greater.

Enhanced wet ponds are designed to provide higher levels of water quality control, downstream channel erosion protection, and wildlife and aquatic habitat amentities. They typically feature design elements such as extended detention control, a sediment forebay area, aquatic benches to support emergent wetland plants, multiple-

VOL 12 2 1 7 9 7

R0055097

cells, and extensive pond and terrestrial landscaping with a variety of native aquatic plants, shrubs and trees.

Capsule Summary

Pollutant Removal Capability: Conventional wet ponds provide moderate to high removal of both particulate and soluble urban stormwater pollutants. Reliable removal rates can be achieved with permanent pool volumes ranging from 0-.5 to 1.0 inches of runoff per impervious acre.

Longevity: Well-designed wet ponds can function for twenty years or more and very few conventional ponds have ever failed to provide some water quality benefit. Performance will decline over time, however, unless regular sediment cleanout is undertaken.

Feasibility: Wet ponds can be utilized in both low and high visibility development situations if the contributing watershed area is greater than ten acres and/or a reliable source of baseflow exists.

Environmental Concerns: If located improperly, wet ponds can have several adverse environmental impacts, including downstream warming, trophic shifts, and a slight risk of poor quality pond effluent during dry weather. Local impacts include possible wetland and forest destruction, and slight risks of sediment and/or groundwater contamination. For larger wet ponds, sacrifice of upstream channels together with the possible creation of fish barriers are concerns.

Environmental Benefits: An enhanced wet pond can be an attractive landscape and community feature, and can create a warm-water fishery, waterfowl habitat and wetlands in urbanized areas.

Costs: Wet pond costs are twenty-five to forty percent greater than those reported for conventional stormwater detention. Maintenance costs range from three to five percent of construction costs annually.

Adaptability: Enjoys wide spread use. Permanent pool size needs to reflect contributory drainage area acreage, type and source of water supply and local runoff frequency. Pond performance may decline slightly during ice and snowmelt runoff conditions.

Maintenance Burden: Wet ponds have a modest maintenance burden, consisting primarily of inspections, mowing of the embankment and buffers, and removal of sediment, trash and debris from the permanent pool.

VOL 12 2 1/19/98

R0055098

IX. Sand Filters

Sand has been employed successfully in sewage trickling filter installations in the United States since around the turn of the century. Its ability to remove effectively suspended solids and other pollutants, as well as, its general low cost and availability makes sand an ideal filtering medium for the treatment of urban stormwater runoff.

Nationally, sand filters have been used as an urban stormwater management BMP for about 10-years. While numerous variations exist, the most wide-spread stormwater sand filter systems feature the following basic design elements:

- off-line locations;
- sized to capture and treat first flush runoff volume;
- pre-treatment sediment basin or sump pit;
- sand filter basin with 18 inch layer of fine to medium grain sand;
- perforated PVC underdrain system; and
- emergency, over-spill system.

Other noteworthy sand filter BMP systems include the parking lot sand-trench system and the underground sand filter (which is presently in use in the District of Columbia).

Capsule Summary

Pollutant Removal Capability: Sand filter removal rates are high for sediment and trace metals, and moderate for nutrients, BOD and fecal coliform.

Longevity: Sand filters appear to have excellent longevity due to their off-line design and the high porosity of sand as a filtering media; however, relatively simple but frequent maintenance is generally required to maintain long-term performance.

Feasibility: Because sand filters are a man-made soil system, they can be applied to most development sites and have few constraining factors. Most sand filters have been used to treat small drainage areas of less than 50 acres. Their flexible design allows them to be used in both surface and underground applications.

VOL 12 2 1799

R0055099

Environmental Concerns: Sand filters have very few environmental-related problems. Surface sand filters can be an eyesore; hence, they may enjoy limited community acceptance in some regions.

Environmental Benefits: Particularly useful for groundwater protection. Little or no wildlife habitat value is provided.

Costs: For small sites, sand filters are generally more costly than infiltration trenches (by a factor of two or three), but have lower regular maintenance/rehab costs.

Adaptability: To date, sand filters have only been widely applied in one region of the country, and some localities may experience some initial problems in importing the technology. This BMP appears to be well-suited for most parts of the WMA.

Maintenance Burden: Sand filters generally require annual maintenance. This usually involves surface sediment removal, removal of trash, debris and leaf litter, and filter cloth replacement.

X. Peat-Sand Filters

Peat-sand filters (PSF) are made-soil, filtration systems which were first developed as alternative wastewater treatment systems. Their high phosphorus (P), biochemical oxygen demand (BOD), and pathogen removal capabilities, coupled with their simple design, low-maintenance and affordability make them an attractive alternative to many conventional treatment systems. PSF systems combine the many attributes of peat with a nutrient removing grass cover crop and a subsurface sand layer to achieve high overall pollutant removal efficiency within a single, relatively compact unit. These attributes make them very attractive as potential urban stormwater BMP's.

Prototype stormwater management peat sand filters generally feature three basic components: a small pre-treatment wet pool, a flow splitting weir/diversion box, and an off-line peat-sand filter bed basin area. Runoff is generally applied to the peat basin surface via gravitational flow/surface flooding. The system is designed to reduce nonpoint source pollutant loadings by capturing and treating first flush runoff from the impervious portion of the contributory watershed. Surface and subsurface storage and detention within the PSF system also provides partial flow attenuation for smaller, high frequency storms; thereby, reducing the frequency of stream channel scouring events.

Capsule Summary

Pollutant Removal Capability: Removal rates for the untested peat-sand filter system are projected to be very high for particulate pollutants and moderate to high for most soluble pollutants.

VOL 12 2 1800

R0055100

Longevity: The general life expectancy of the peat layer is 10-25 years. The remainder of the system should have longevity comparable to that of pond systems.

Feasibility: Peat-sand filters are man-made soil systems which may be applied to most development sites. While they may be used to treat first flush runoff from both small to large-sized catchments, they are essentially restricted to watershed areas which are fully developed. In addition, the ability of peat-sand filter systems to operate fully during colder, winter months is unknown.

Environmental Concerns: Peat-sand filters have very few associated environmental problems.

Environmental Benefits: Well-suited for urban stormwater retrofit application. Grassed peat basin and pre-treatment wet pool provide some wildlife habitat value.

Costs: Peat-sand filters are projected to cost significantly more than conventional pond systems. Their regular maintenance and rehabilitation costs, however, are approximately the same.

Adaptability: Year-round use in colder climates unknown. Selection of proper peat material is critical to system success. Limited by cost and availability of fibric/hemic peat. Construction of system requires expertise unfamiliar to many localities.

Maintenance Burden: Requires mowing one to three times per year and collection and disposal of grass clippings. Also, sediment and trash removal from the pre-treatment wet pool.

XI. Oil/Grit Separators

Oil/grit separators, also known as water quality inlets, are modified versions of rectangular gravitational settling tanks long used by the petroleum refining industry for the separation of oily wastes from water. The primary objective behind the employment of oil/grit separators is to reduce the quantity of nonpoint source pollutants associated with the settleable solids portion of the first flush of urban runoff; particularly, automotive-derived petroleum products. Most oil/grit separators feature two underground water-holding chambers plus a third, dry outlet chamber. In general, oil/grit separator permanent pools are sized so as to provide a minimum 200-400 cubic feet of dead storage volume per impervious acre of drainage.

Capsule Summary

Pollutant Removal Capability: Current designs of oil/grit separators generally have limited pollutant removal capability and appear to mostly trap coarse-grained sediments

VOL 12 2 1801

R0055101

and some hydrocarbons. Removal of silt, clay, soluble nutrients, trace metals, oily emulsions and organic matter is generally expected to be slight. Re-suspension also appears to limit long-term removal. Actual removal only occurs when oil/grit separators are cleaned out. Currently, a lack of effective disposal methods hampers the recommended quarterly clean-out of trapped residuals.

Longevity: Longevity of oil/grit separators is high. Over ninety-five percent of all separators are operating as designed in their first five years of operation.

Feasibility: Oil/grit separators are most commonly employed to treat runoff from small developments of two acres or less (such as gas stations, parking lots, fast food outlets, and convenience stores).

Environmental Concerns: The greatest concern is the pollutant toxicity of trapped residuals and oily waters, and how the toxicity influences the ultimate disposal of the residuals. A secondary concern is the possibility of pulse loadings of the trapped residuals during larger storm events (due to re-suspension). This is particularly the case for oil/grit separators which are located on-line.

Environmental Benefits: Oil/grit separators show some capacity to trap trash, debris, and other floatables, thereby preventing their discharge to receiving waters.

Costs: The cost of pre-cast oil/grit separators averages about $8,000 per structure. The separators are costly on a runoff volume treated basis, averaging three to four times the unit cost of trenches or sand filters.

Adaptability: Oil/grit separators can be adapted to all regions of the country.

Maintenance Burden: Oil/grit separators require quarterly clean-outs. However, few acceptable clean-out and disposal techniques currently exist, often making maintenance difficult.

VOL 12 2 1802

R0055102

Chapter 3. Retention Pond Performance - An Overview of Physical and Hydraulic Factors

Background

In general, artificial lakes, ponds and marshes located on-stream produce (in varying degree) the following physical, chemical and biological changes in the natural downstream condition: 1.) dampening and moderation of peak flow discharges, 2.) temperature regime alteration, 3.) reduction in downstream sediment transport, 4.) modification in the type and supply of organic material and food available to the biological community and, 5) shifts in both species composition and trophic structure in the aquatic community 6.) water chemistry changes related to concentrations of dissolved oxygen (DO), nutrients and reduced compounds. The extent of these modifications is dependent on conditions both upstream, and within the retention facility (e.g., - inflow pollutant loads, age, trophic state, presence of density currents, degree of thermal stratification, hydraulic residence time, and withdrawal depth and volume of discharge (Wright, 1967; Petts, 1984; Galli, 1990; Walburg, et al., 1981).

Among the more important interrelated physical and hydraulic design factors influencing the water quality performance of SWM wet ponds and artificial marshes are release depth (e.g., - surface, mid-level, bottom, etc.), hydraulic residence time, permanent pool volume and depth, and surface area. While it is beyond the scope of this study to examine each of these factors in detail, the following sections provide a brief summary of major literature survey findings.

Release Depth

It is generally understood that both the chemical properties and temperature of water downstream of retention facilities are heavily dependent upon the water quality and temperature within the facility at the release depth. Typically, water quality in these facilities is best at or very near the surface (Galli, 1988; Redfield, 1983)[1/]. Under normal dry weather conditions, total dissolved solids, phosphorous and nitrogen concentrations generally decrease in the upper portions of the water column through physical settling and algal and bacterial assimilation. Adsorption to clay and organic particles and subsequent flocculation/gravitational settling may further reduce surface concentrations of these and other pollutants. Functionally, surface release facilities closely resemble

1/ Downstream water quality can also be modified by groundwater inflow, stormwater inputs, riparian vegetation and climatological conditions.

VOL 12 2 1803

R0055103

natural water bodies in that they continuously discharge warmer surface waters; thereby dissipating heat brought in by both the inflow and that which accumulates at or near the surface from solar heating (Wright, 1967).

In contrast, subsurface release facilities can (depending on permanent pool volume size, stratification patterns and withdrawal depth conditions) produce several unnatural modifications in both the diurnal and seasonal temperature regime (Walburg, et al., 1981). These changes to the receiving streams thermal regime generally fall into one or more of the following five categories: increased diurnal constancy, increased seasonal constancy, spring/summer temperature depression, fall/winter temperature elevation and thermal pattern changes. In addition, subsurface withdrawal facilities (particularly bottom and/or deep release) generally release water with higher nutrient and suspended solids levels and lower dissolved oxygen concentrations than do surface release facilities (Galli, 1988; Petts, 1984; Walburg et al., 1981). It is also important to note that release depth changes relative to the retention facility's water surface elevation.

Hydraulic Residence Time

Numerous studies have shown that, typically, the longer the hydraulic residence time the better the overall pollutant removal performance (Kulzer, 1989; Driscoll, 1983). Hydraulic residence time, which is generally calculated by dividing the permanent pool volume by the average outflow discharge rate, is normally greater in SWM ponds and marshes having large associated permanent pool volumes. In general, a mean annual hydraulic residence time of 14-30 days has been recommended for achieving high total phosphorous removal rates (Driscoll, 1988; Kulzer, 1989; Schueler, 1987). Longer hydraulic residence times usually improve the biological treatment, chemical transformation and gravitational/physical settling of pollutants present in stormwater runoff.

With regard to gravitational settling, laboratory settling column studies (Whipple and Hunter, 1981; Randal et al., 1982, OWML, 1983) have shown that approximately 30 to 70 percent of the particulate pollutant load present in urban runoff settles out in the first six to twelve hours. Thereafter, removal of smaller diameter particles, such as fine silt and clay-sized material, occurs incrementally over a much longer time frame (usually days or weeks). Because of the slow settling velocity of smaller-sized particles (Table 3), the selection of the pond release depth(s) greatly influences its overall pollutant removal efficiency. It is further noted that: 1.) silt and clay-sized particles comprise the greater portion of the suspended solids fraction, 2) totally quiescent conditions are rarely encountered in most wet pond and artificial marsh systems, and 3.) ED control can increase both stormflow residence time and overall sediment trapping performance.

VOL 12 2 1804

R0055104

Table 3. Typical Settling Velocities Under Quiescent Conditions (modified from MDE, 1987a)

	Particle Size	Diameter (microns)	Average Settling Velocity (ft/hr)
Sand	V. Coarse	1000-2000	1170-2370
	Coarse	500-1000	630-1170
	Medium	125-250	300-630
	Fine	62-125	30-120
Silt	Coarse	31-62	9-30
	Medium	16-31	2-9
	Fine	8-16	0.5-2.0
	V. Fine	4-8	0.1-0.5
Clay		<4	0.1

Permanent Pool Volume and Depth

The pollutant removal efficiency of wet ponds and artificial marshes often increases with increasing permanent pool volume/treatment volume. Although this relationship is hardly linear, a larger permanent pool volume generally serves to improve both hydraulic residence times and pollutant dilution capabilities. While permanent pool sizing rules are imprecise, a minimum permanent pool volume equal to the mean annual runoff volume is often cited (Kulzer, 1989).

Permanent pool depth is also an important factor in that it: 1.) largely determines where both emergent and submerged aquatic plants may grow, 2.) influences both particle settling dynamics and sediment trapping efficiency, 3.) affects internal nutrient cycling and retention dynamics, as well as, dissolved oxygen distributions, and 4.) greatly influences thermodynamic conditions. In general, shallow water bodies less than three feet deep which are not well protected from the mixing effect of either wind or turbulent flow, are often prone to sediment resuspension problems.

Surface Area

Typically, wet ponds and marshes with large surface areas have correspondingly greater permanent pool volumes, as well as, more area for the support of both higher and lower forms of aquatic plant life (e.g., - emergent and submerged aquatic plants, phytoplankton, and periphyton). These, as well as other factors, tend to enhance both their overall pollutant removal performance and aquatic/wildlife habitat value. Once

VOL 12 2 1805

R0055105

again, no hard and fast surface area sizing rule exists. However, both computer modelling and field studies suggest that a minimum surface area to catchment ratio of between one and three percent should result in improved pollutant removal performance (Kulzer, 1989; Driscoll, 1988).

Chapter 4. Prince George's County BMP Field Survey Results

From May through December, 1991 COG staff field surveyed over 150 stormwater management BMP sites located throughout Prince George's County, Md.. BMP sites, which were carefully pre-screened on the basis of the availability of as-built engineering plans and overall BMP type representativeness, were inspected under wet and dry weather conditions. At all sites, an effort was made to : 1.) determine whether or not the BMP was providing water quality and/or quantity benefits as designed, 2.) isolate design elements and procedures which work (or do not work) in the field, 4.) quantify physical, chemical and/or biological differences in the upstream versus downstream condition, 5.) assess existing and/or potential aquatic/wildlife habitat value, and 6.) where warranted, identify possible BMP retrofit opportunities. A breakdown of the number of facilities surveyed, by both BMP type and area of maintenance responsibility, is included as Table 4). As seen in Table 4, maintenance responsibility for approximately 27 percent of the BMP sites surveyed resided within the public domain.

The following six sections summarize the major field survey study findings for each BMP system type. Additional information is provided in Appendix D.

I. Infiltration Systems

A. Infiltration Trenches

Background

Representing almost 42 percent of the 500- plus water quality control facilities constructed between 1985-91, infiltration trenches are currently the most widely used BMP in Prince George's County (Figure 3). Under the field survey portion of the study, COG staff inspected a total of 38 infiltration trench facilities. Classification of surveyed infiltration trench systems by pre-treatment type revealed that 31 (82 percent) employed sump-pits; whereas, seven (18 percent) featured grass filter strips. As-built plan review also identified 18 trenches (47.4 percent) which specified a six inch thick bottom layer of sand. With regard to aggregate material used for the stone reservoir portion of the system, washed bankrun gravel was specified 42.1 percent of the time. All 38 infiltration trenches employed the MDE recommended filter cloth lining approach of lining the top and sides, only.

A review of Prince George's County stormwater management files revealed that infiltration trenches are being employed to treat runoff from the full spectrum of land uses. Results from the field survey show that they are most often associated with small commercial developments of less than 2.0 acres. The vast majority of the infiltration

VOL 12 2 1809

R0055109

trench systems surveyed were sized to treat the first 0.5 inches of runoff from the impervious portion of the site. Infiltration trench systems had an average age of 2.5 years. Trenches with sump pits were generally older than their vegetative filter counterparts.

Additional background survey highlights are listed below and graphically summarized in Figures 4 and 5.

- Age Range (yrs): 0.5 - 5.1 (avg.-2.4)
- D.A. to Structure Range (ac): 0.2-5.0 (avg.-1.3)
- Range of Water Quality Runoff Volumes Controlled: 0.5 in/imp. ac - 0.5 in/ac
- Sump Pit Permanent Pool Depth Range (ft): 0.0-7.4 (avg.-3.2)
- No. of Sump Pits with Feeder Pipe Elbow: 22 out of 31 (71.0%)
- Grass Filter Strip Length Range (ft): 3.0-50.0 (avg.-23.9)
- Average Height of Grass (in): 2.0-12.0 (avg.-4.1)
- Trench Soil Textural Class Range: Urban Land Use Complex, Silt Loam, Sandy Loam, Gravel Loam, Gravel-Sandy Loam, Sandy Loam, Loam, Silty Clay Sand, Loam Sand, and Mixed Alluvial
- General Availability of Soil Boring Information: 32 out of 38 sites
- Land Uses Controlled: Single Family Residential, Townhouses, Garden Apartments and Commercial

General Performance and System Longevity

Results (Table 5) show that slightly less than half of all the inspected infiltration trenches were working as designed (i.e., - either not infiltrating water, exhibiting signs of slow infiltration, short-circuiting of runoff, etc.).

VOL 12 2 1810

R0055110

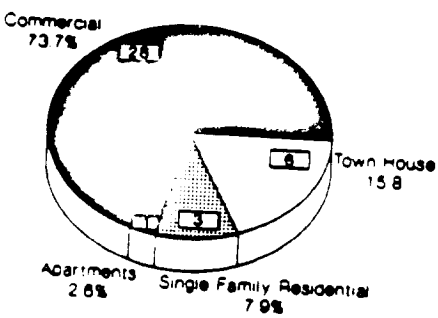
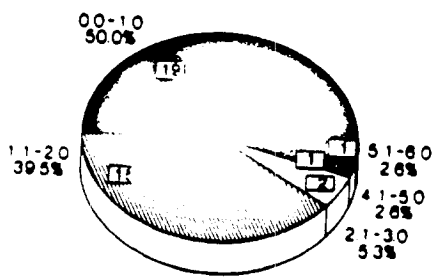
Vegetative Filter (N=7)

Age of System (yrs)



Land Uses Controlled (N=38)

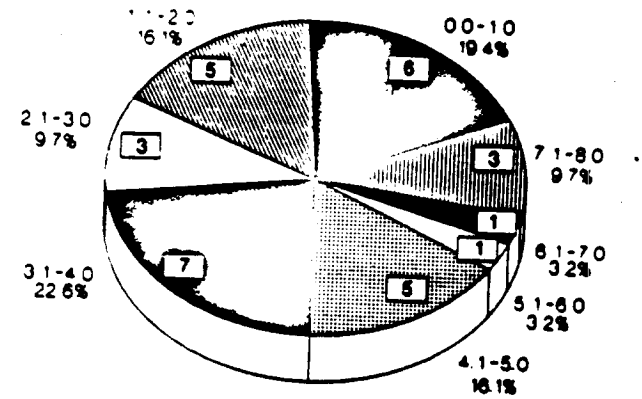


Drainage Area to Trench (ac) (N=38)

VOL 12 2 18 11

R0055111

Figure 5. Infiltration Sump Pit: Permanent Pool Depth and Volume (N=31)



R0055112

Table 5. General Infiltration Trench Performance (N=38)

No. and Percent Working As Designed

Pre-Treatment Type	Yes	No	Unknown
Sump Pit	15 (48.4%)	13 (42.0%)	3 (9.6%)
Grass Filter	3 (42.9%)	4 (57.1%)	- - -
Total	18 (47.4%)	17 (44.7%)	3 (7.9%)

Not surprisingly, the general performance of both infiltration trench types declined over time (Figure 6). System failure was more pronounced for the grass pre-treatment type, in which no trench over two years old was working as designed. Sump pit systems were markedly less fragile. In fact, several trenches were still functioning after almost five years of service. Results further showed that the percentages of infiltration trenches either with or without a bottom sand layer, which were working as designed, were nearly identical (55.6% versus 55.0%).

Performance, Maintenance and/or Structural Problems

The major performance, site selection, maintenance and/or structural problems identified by the field survey are graphically shown in Figure 7. As seen in Figure 7, slow infiltration was the leading problem in approximately 40 percent of the systems surveyed. Almost one-third of the infiltration trenches had standing water present in their observation well(s) more than 48 hours after a storm event.

Partial and/or total loss of infiltration capacity was often abetted by either questionable site selection, design shortcomings, inadequate construction practices, lack of routine maintenance; or combinations thereof. For example, survey results revealed that seven infiltration trenches were located in areas having a relatively high water table (water encountered 5-7 feet below the ground surface). Nearly one-fifth of the trenches were constructed in questionable soils. In addition, three out of the seven pre-treatment grass filter strips (42.9 percent) were shorter than the required 20 foot length.

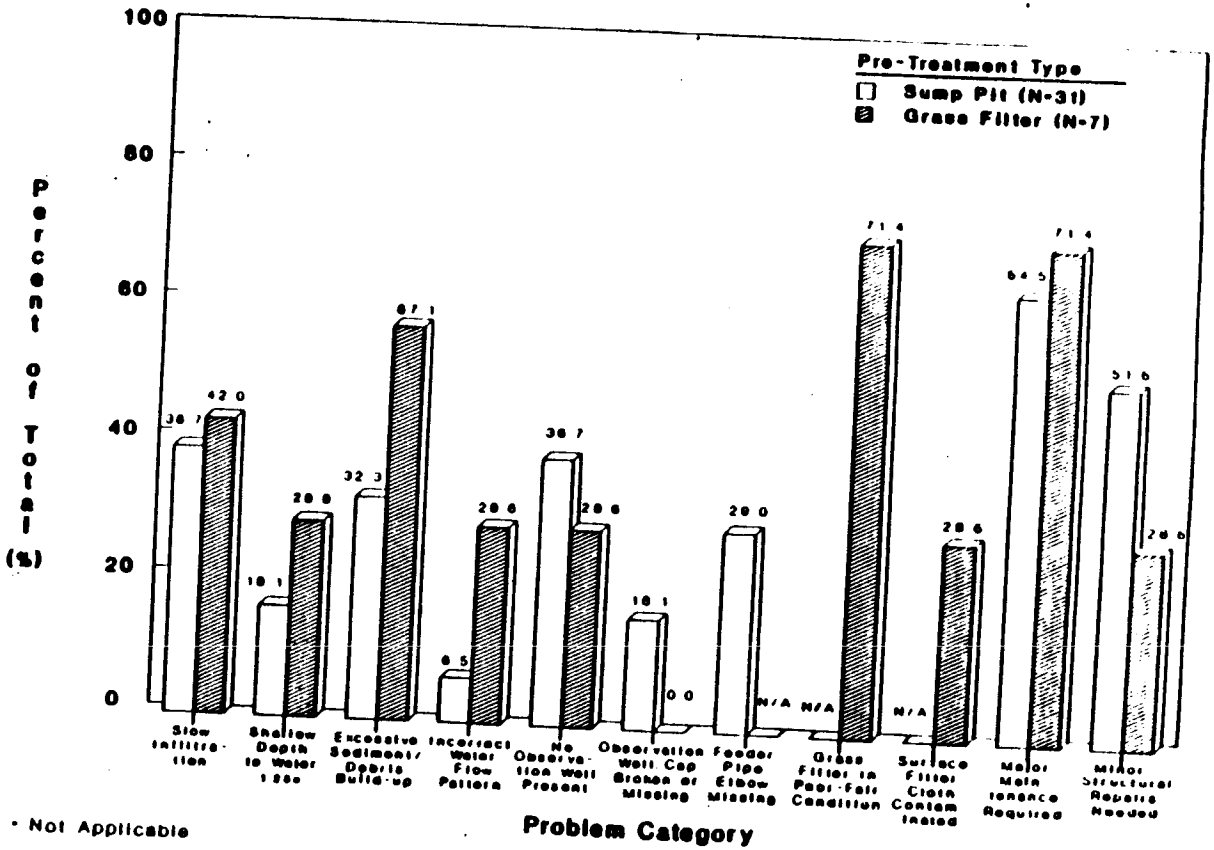
Figure 7. Infiltration Trenches: Typical Performance, Maintenance and/or Structural-Related Problems 1/



1/ N/A - Not Applicable

R0055115

5--8--2 NOV 21

With the exception of routine mowing of the grass filter strips, none of the infiltration trenches surveyed appeared to have ever had regular maintenance performed. Overall maintenance condition was rated as follows (no. out of 38 facilities indicated):

Poor	-	11 (29.0%)
Fair	-	13 (34.2%)
Good	-	10 (26.3%)
Very Good	-	4 (10.5%)

It should also be noted that routine observation well inspection was made more difficult by the high diversity of observation well caps encountered.

Structurally, 18 out of the 38 infiltration facilities (47.4 percent) required some minor amount of repair work. The number and type of observed structural problems were as follows (no. out of 38 facilities indicated):

- 2 - brick sump pits not holding any water
- 2 - no observation wells present
- 5 - observation well caps broken or missing
- 9 - elbow on feeder pipe missing

Environmental Attributes

Unlike most BMP systems, infiltration trenches can be located under either parking lot or lawn area; thereby, increasing the possibility of preserving a larger amount of natural on-site area. As expected, no meaningful wildlife habitat value was directly associated with either infiltration trench system types. It should be noted that infiltration sump pits do not appear to support any life.

Infiltration Sump Pits

Because of the heavy reliance on sump pits for pre-treatment control and their functional similarity to oil/grit separators, COG staff felt that a more comprehensive evaluation of the sediment trapping performance of these systems was warranted. Major findings on the general nature of the residual material present, volume of sediment trapped, and average sediment trapping rate are graphically summarized in Figures 8-10.

VOL 12 2 1816

R0055116

As seen in Figure 8, coarse-grained inorganic sediment (fine sand grain size or larger) constituted the major portion of the residual material present in the sump pits. Fine inorganic material (smaller than fine sand) typically accounted for 25 percent of the residual material. The remaining portion was generally comprised of larger organic material such as leaves, twigs, etc.

Further examination of sump pit sediment deposits (Figure 8) revealed that over half of the sump pits contained little or no visible oily materials. However, approximately 30 percent had moderate to high amounts of oil present.

Based on sediment depth readings, COG staff was able to estimate the volume of sediment present in each sump pit. Results show that a rather broad range exists in the quantity of residual material present (Figure 9). From both a performance and maintenance standpoint, nearly 22 percent of the sump pits had managed to trap a rather considerable volume of sediment (i.e., - one cubic yard / 27 cubic feet or greater). Taking this information one step further, the sediment trapping rate (on a lbs/ac/year basis) was calculated for each sump pit age class. As seen in Figure 10, the mean sump pit sediment trapping rate for the entire population was 280.6 lbs/ac/year. More importantly, however, is the finding that sump pit sediment retentiveness generally decreased over time. This was most likely caused by stormflow scouring and resuspension problems within the structure. Additional infiltration sump pit findings are included in Appendix D.

B. Dry Wells and Porous Pavement

A total of two dry well facilities and two porous pavement sites were comprehensively inspected by COG staff (a third dry well facility was also casually surveyed). Field survey results for both BMP types are summarized in Table 6.

As seen in Table 6, all three dry wells had considerable amounts of standing water present in their observation wells, indicating loss of all or most of their infiltration capacity. Results also revealed that none of the dry well systems surveyed had gutter guards or any other type of pre-treatment control.

With regard to porous pavement, repeated water pour tests at four separate locations within the J. and L. Valve Corp. porous pavement parking lot area revealed that the major portion of the system was still functioning as designed. However, pavement areas with higher vehicular traffic, such as driveway areas, had lost virtually all infiltration capacity. It should be noted that the parking lot was not posted to alert one of the presence of porous pavement. Also, it did not appear that the porous pavement lot had ever been maintained.

C. Infiltration Basins

Background

A total of 12 infiltration basins, representing slightly over half of the total constructed in the County since 1985, were inspected by COG staff. As seen in Figure 11, the majority of the infiltration basins were between two and three years old. Two-thirds of the surveyed sites were associated with small commercial developments having catchment areas of between one and four acres. The majority of the basins surveyed were relatively small; averaging just under one-tenth of an acre in size. Seventy five percent of the facilities had concrete riser-barrel outlet structures. None of the basins surveyed had any formal type of pre-treatment system. Additional background findings are listed below.

- Age Range (yrs): 0.5-5.1 (avg.-2.8)
- D.A. to Structure Range (ac): 0.8-9.3 (med.-1.8)
- Range of Water Quality Runoff Volumes Controlled: 0.5 in/imp. ac to runoff volume generated from a one-inch rainfall event
- Basin Surface Area Range (ac): 0.01-0.18 (med.-0.10)
- Percent Excavated Basin - 100%
- Basin Soil Textural Class Range: Urban Land Use Complex, Silt Loam, Sandy Loam, and Gravel-Sandy Loam
- General Availability of Soil Boring Information: 7 out of 12 sites
- Land Uses Controlled: Single Family Residential, Institutional Commercial and Industrial

General Performance and System Longevity

Unfortunately, not one of the 12 infiltration basins surveyed was working as designed. In fact, all 12 facilities exhibited either surface ponding or saturated soil conditions. Although none of the basins were capable of infiltrating any runoff, seven facilities (58.3 percent) had enough available storage to provide at least some partial water quality control.

Over the years, infiltration basins have earned the reputation of being extremely fragile BMP's with characteristically high failure rates. Although this reputation is

VOL 12 2 1822

Outlet Structure Type

VOL 12 2 1823

R0055123

generally well-deserved, examination of as-built file information revealed that poor initial site selection may have contributed to several system failures. For example, one of the surveyed basins was constructed in an area where the depth to the seasonally high water table was less than four feet. Two others were built on sites in which the depth to the water table was questionable. In addition, seven of the 12 basins appear to have been constructed on soils with generally less than ideal soil textural classifications (i.e., - Beltsville silt loam and urban land complex designations).

Importantly, results strongly suggest that the majority of infiltration basins are likely to fail within their first year due to either clogging and/or compaction of the soil surface, unsuitable site conditions or combinations thereof. It should be noted that gradual sealing of the soil surface may occur, after construction, through the lawnroller-like effect of repeatedly flooding a basin with several feet of standing, silt-ladened water.

Performance, Maintenance and/or Structural Problems

As seen in Figure 12, the principal basin performance problem was total loss of infiltration capacity. Both internal and external sediment loadings contributed to this problem. Three of the 12 basins (25.0 percent) had excessive sediment/debris build-up. Other maintenance-related problems included erosion at both inflow and outflow locations, poorly stabilized side slopes, and partial clogging of the outlet structure. None of the basins required any structural type repairs. This was largely due to both the employment of concrete risers and barrels and extremely simple design of the basins. It should be noted that the only apparent regular maintenance performed at any of the 12 sites was grass mowing of non-flooded areas. Overall maintenance ratings for the infiltration basins were as follows (no. out of 12 facilities indicated).

Poor	-	3 (25%)
Fair	-	6 (50%)
Good	-	3 (25%)
Very Good	-	0 (0%)

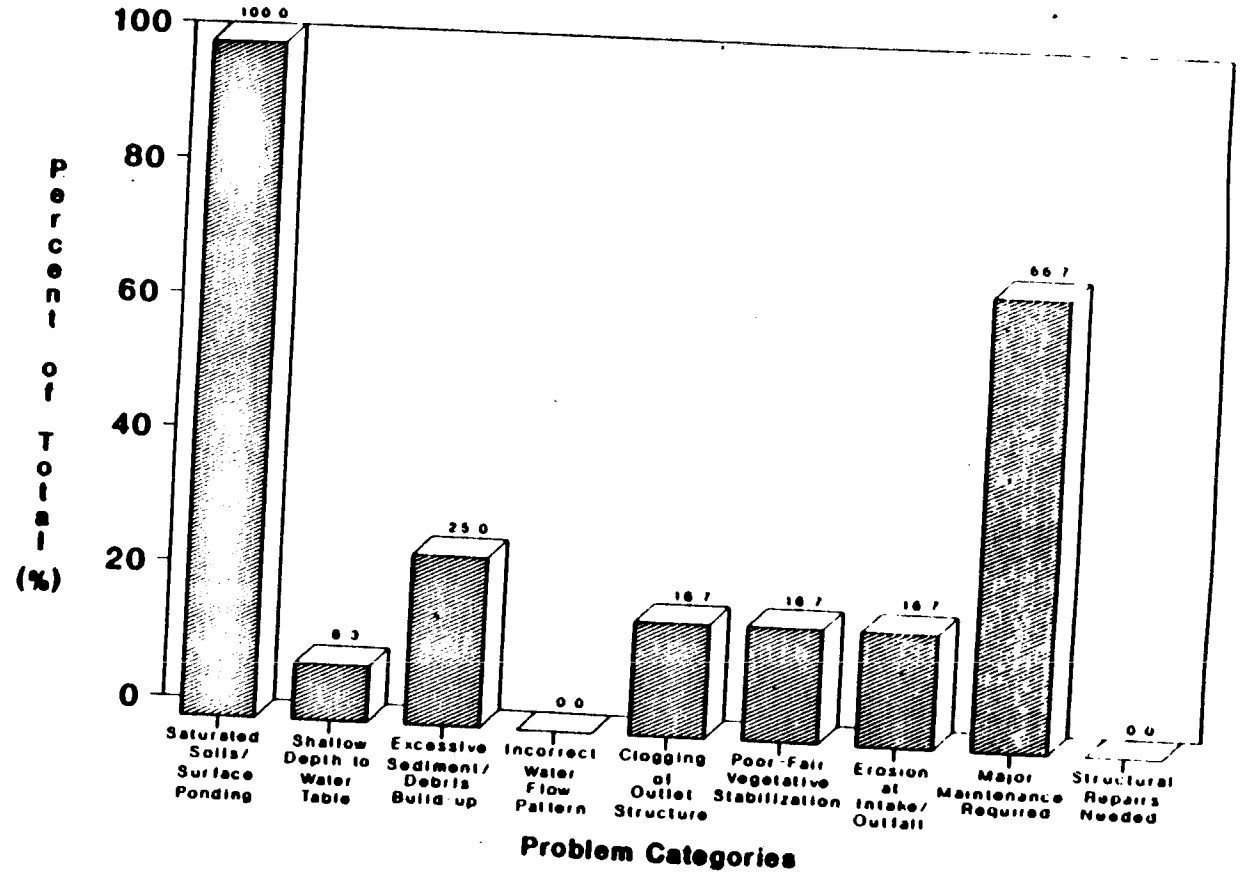
Environmental Attributes

With only one exception, all of the infiltration basins surveyed had permanent pools with well-developed stands of emergent wetland vegetation. Both the permanent pool characteristics and environmental attributes of these defacto artificial marsh systems are graphically summarized in Figure 13. As seen in Figure 13, the average maximum depth of standing water was one foot. The maximum July - August, 1991 basin surface water temperature was a warm, 86.0 °F. Typically, the areal extent of floating algal mats was inversely proportional to the amount of emergent aquatic vegetation present.

VOL 12 2 1824

R0055124

Figure 12. Infiltration Basins: Typical Performance, Maintenance and/or Structural Problems (N-12)



R0055125

Based on the COG aquatic/wildlife habitat value index system, the average infiltration basin score was 1.3 (low value rating). In general, the highest habitat scores were associated with larger facilities that had a good mix between stands of emergent vegetation and open water, and were relatively isolated from automobile and pedestrian traffic areas. Submerged aquatic vegetation, including wild celery (Valisneria americana) was observed growing at three sites. Both frogs and toads were abundant at 50 percent of the basins inspected. Mosquito larvae were observed at only one relatively young site. It appears that the abundant supply of natural predators such as dragon fly and damselfly larvae help to generally keep the mosquito problem in check.

R0055127

II. Grass Filter Strip/Grass Swale Systems

All of the grass filter systems surveyed were, at a minimum, designed to safely convey runoff (at non-erosive velocities) from the 10-year frequency storm. While these systems were constructed in the absence of specific water quality design criteria, it was assumed that first flush water quality benefits would occur via filtration through the grass cover crop. With this as background, COG staff set out to comprehensively examine both the filtering capability of the grass cover crop, as well as, the system's apparent ability to safely convey larger stormflows.

Background

Six grass filter systems, three conventional grass swales without checkdams and three enhanced swales with checkdams, were field inspected by COG staff. As seen in Figure 14, all of the systems surveyed were between two and four years old. Associated land uses were equally split between institutional uses, such as recreational centers, and small commercial developments. Two-thirds of the catchment areas were between one and two acres; with the remainder, less than one acre in size. All of the surveyed sites were extremely flat. Additional background survey highlights are summarized as follows.

- Age Range (yrs): 1.3-2.6 (avg.-2.2)
- Checkdam Material Type: No.2 bluestone, surge stone (WSSC Class I rip-rap), and earth berm
- Checkdam Height Range (in): 4-12 (avg. 9.0)
- Grass Filter System Length Range (ft): 230-500.0 (avg.-417.0)
- Grass Filter Bottom Width Range (ft): 3.0-20.0 (avg.-11.3)
- Grass Filter Slope Range (%): 1.0-3.0 (avg.-1.7)
- Range in Height of Grass (in): 1.0-5.0(avg.-3.0)
- Relative Density of Grass Range (Index: 1-3): 1-3 (low-to high), avg.-2.3 (moderate)
- No. with Partial Shade: 2 (33.3%)
- System Soil Textural Class Range: Silt Loam, Loamy Sand, Gravelly Loamy Sand

VOL 12 2 1829

R0055129

- Land Uses Controlled: Institutional, Commercial (Fast Food) and Commercial (Office Bldg.)

General Performance and System Longevity

Because of severe runoff filtering limitations associated with both short grass height and low to moderate grass densities, only one out of the three conventional grass swales was judged capable of providing any first flush water quality control benefits. Conversely, two out of the three grass swales with checkdams appeared to be capable of both physically filtering and partially infiltrating runoff from small, low intensity storm events. Results confirmed the value of using enhanced grassed swales with checkdams. As stated earlier, checkdams provide temporary detention storage and lengthened contact time, thereby, improving the gravitational settling and infiltration characteristics of the system.

With regard to large stormflow conveyance, all six grass filter sites appeared to still be working as designed. However, all six sites were showing some evidence of gradual system deterioration, partially related to high runoff velocities. Without some additional corrective and/or preventative maintenance work, it is extremely doubtful that any of these systems will continue to be working as designed in another two or three years.

Performance, Maintenance and/or Structural Problems

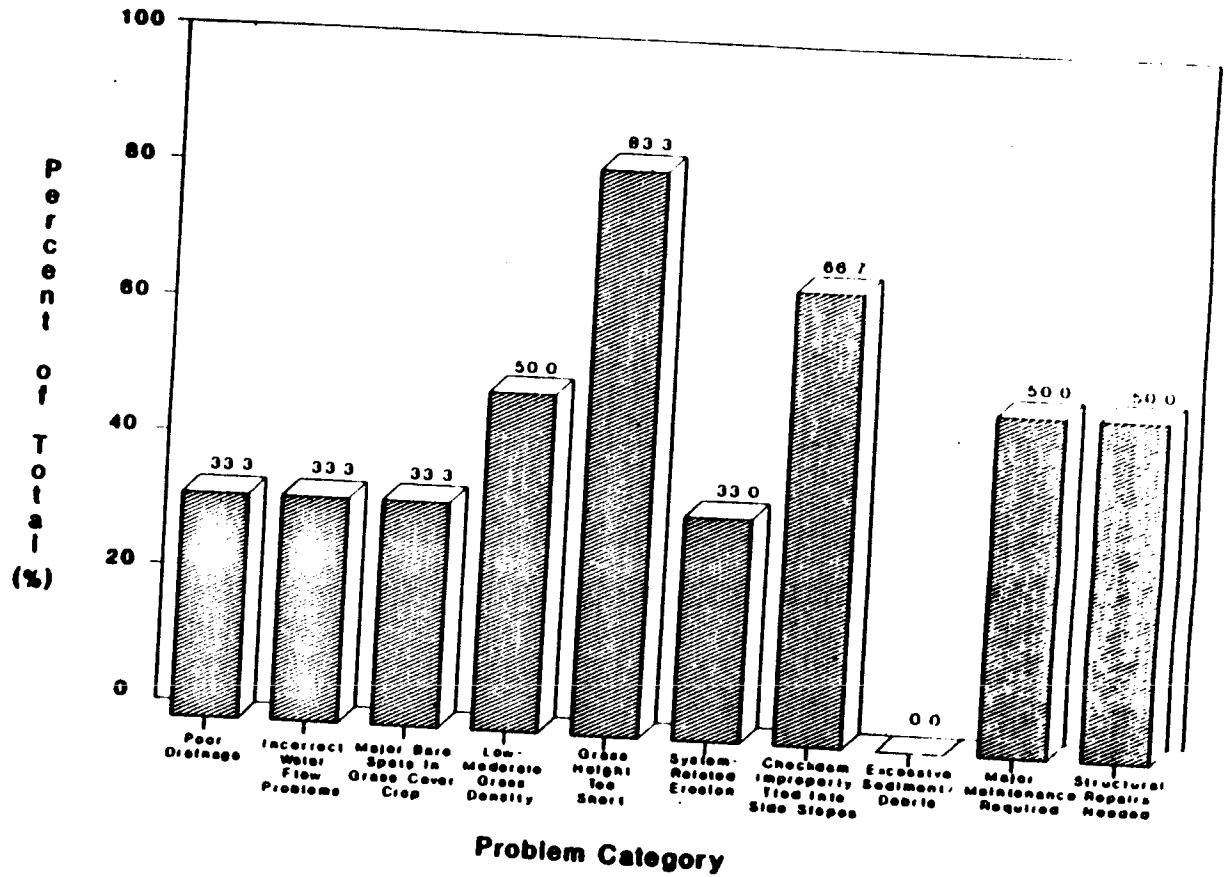
Without question, the leading cause of poor performance was low grass height. As seen in Figure 15, over 80 percent of the grass filters surveyed were identified as being mowed too close to the ground (i.e., - grass height of $\leq$ 3 inches). Bare spots, poor drainage (localized sump areas with saturated soil conditions), and internal short-circuiting problems (around checkdams) were additionally noted at one-third of the sites. None of the grass filter systems exhibited any sign of either excessive sediment build-up or oil contamination. Sand deposition was observed in only the first five to ten feet of the grass filter; with the majority of this material being retained at the pavement - grass interface.

Tall fescue, Kentucky bluegrass, and crabgrass were the dominant grasses present in these systems. Invasive annual grasses and weeds, such as crabgrass, can reduce overall system filtering ability (particularly during the colder months of the year) when they experience seasonal die-back. As seen in Figure 15, 50 percent of the sites required major maintenance such as reseeding of bare spots, stabilization of rill erosion areas and regrading of low spots. In addition, structural repair work on one-half of the checkdams was warranted (i.e., - repair eroding areas and replace dislodged stone).

VOL 12 2 1830

R0055130

Figure 15. Grass Filter Strip / Grass Swale Systems:
Typical Performance, Maintenance and/or Structural Problems (N=6)



R0055131

Environmental Attributes

Given that all of the grass filter systems inspected were maintained as lawn area, their wildlife habitat value was extremely limited. However, allowing the grass cover crop to grow one foot tall or higher between mowings would provide greater habitat opportunities for both small mammals, as well as, for many song birds. Alternatively, wildlife habitat could be improved by incorporating a minimum 10-12 foot wide, no-mow buffer strip into the design.

VOL 12 2 1832

R0055132

III. Extended Detention Dry Ponds

Background

Twelve ED dry ponds, representing almost 71 percent of the total number in operation in the County since 1985, were field surveyed by COG staff. As seen in Figure 16, all of the inspected ED facilities were less than four years old; with the majority being under one year in age. ED dry ponds were associated with both the entire spectrum of land uses and catchment area size range. Review of as-built file information revealed that the drainage areas controlled by these facilities ranged from as small as 0.8 acres all the way up to 1164.8 acres. In addition, a rather broad range in both ED period and range in the runoff volume controlled was further noted. The average ED period and design ED runoff volume were 15.8 hours and 0.5 inches of runoff/impervious acre, respectively. Not surprisingly, ED dry ponds were constructed in both on and off-stream locations. Additional background highlights are listed below and graphically summarized in Figure 17.

- Age Range (yrs): 0.1-3.6 (avg.-1.9)
- D.A. to Structure Range (ac): 0.8-1164.8 (med.-21.1)
- Design ED Period Range (hrs): 6-40 (med.-10.0)
- Range of Runoff Volumes Controlled by ED: 0.25-1.0 in./imp. ac; 0.5 in/ac., runoff from full 2-yr storm
- No. with Micropools: 3 (25%)
- No. with Gate Valve ED Control: 1 (8.3%)
- No. with Pond Drain: 1 (8.3%)
- Range in Minimum Flowpath Length (ft): 18-approx. 1200 (med.-140)

General Performance and System Longevity

Performance

In abstract terms, the concept of gradually releasing stormwater runoff over a pre-determined period of time (i.e., -ED control) appears quite simple. However, in practice, the goal of consistently achieving design ED times and release rates over

VOL 12 2 1833

VOL 12 2 1835
R0055135

anything other than a narrow range of stormflow conditions is very difficult to achieve. Results from this study show that only about 50 percent of the ED dry ponds were able to generally meet their target ED times. A second major finding was that the runoff produced by smaller, less intense rainfall events generally flowed through these facilities subject to little or no ED control. This was particularly the case for older ED dry ponds which were intentionally designed to provide water quality control for larger, less frequent storm events. In addition, a review of the as-built files showed that the majority of the ED release rates were calculated using the rather crude 'Kerplunk' method (i.e., - dividing the design storm runoff volume by the target ED period). This approach may also have been a factor in the generally poor control of smaller storms.

Because most of the off-stream located ED dry ponds had no upstream/ downstream channel network, a full assessment of their effect on downstream areas was generally not possible. Consequently, only on-stream facilities were comprehensively evaluated. Major findings from the stream survey portion of the study are summarized in Figure 18.

Although no major difference in upstream versus downstream channel stability was noted, all of the ED dry ponds surveyed (including off-stream ponds) appeared to have generally had a positive, downstream stabilizing influence. Among the more positive effects observed, was the significant reduction in the amount of sand and silt-sized inorganic sediment present in downstream reaches. As expected, these facilities are trapping and retaining large volumes of this material within the upstream channel network. In two cases, heavy in-channel sediment deposition was still evident nearly 300 feet upstream of the control structure. Little if any overbank deposition was observed at any of the five in-stream facilities inspected.

Limited wet weather monitoring confirmed the general inability of ED dry ponds to remove either clay-sized particles or dissolved pollutants commonly present in urban stormwater runoff. Additional secondary evidence of this shortcoming was provided via the examination of the degree of substrate fouling present (i.e., - presence or absence of surface patinas of silt/fine organic material and/or algal growth, and slime coatings on the underside of stones. As seen in Figure 18, the relative level of downstream substrate fouling was generally slightly higher than that observed upstream of the major stormwater inflow point(s).

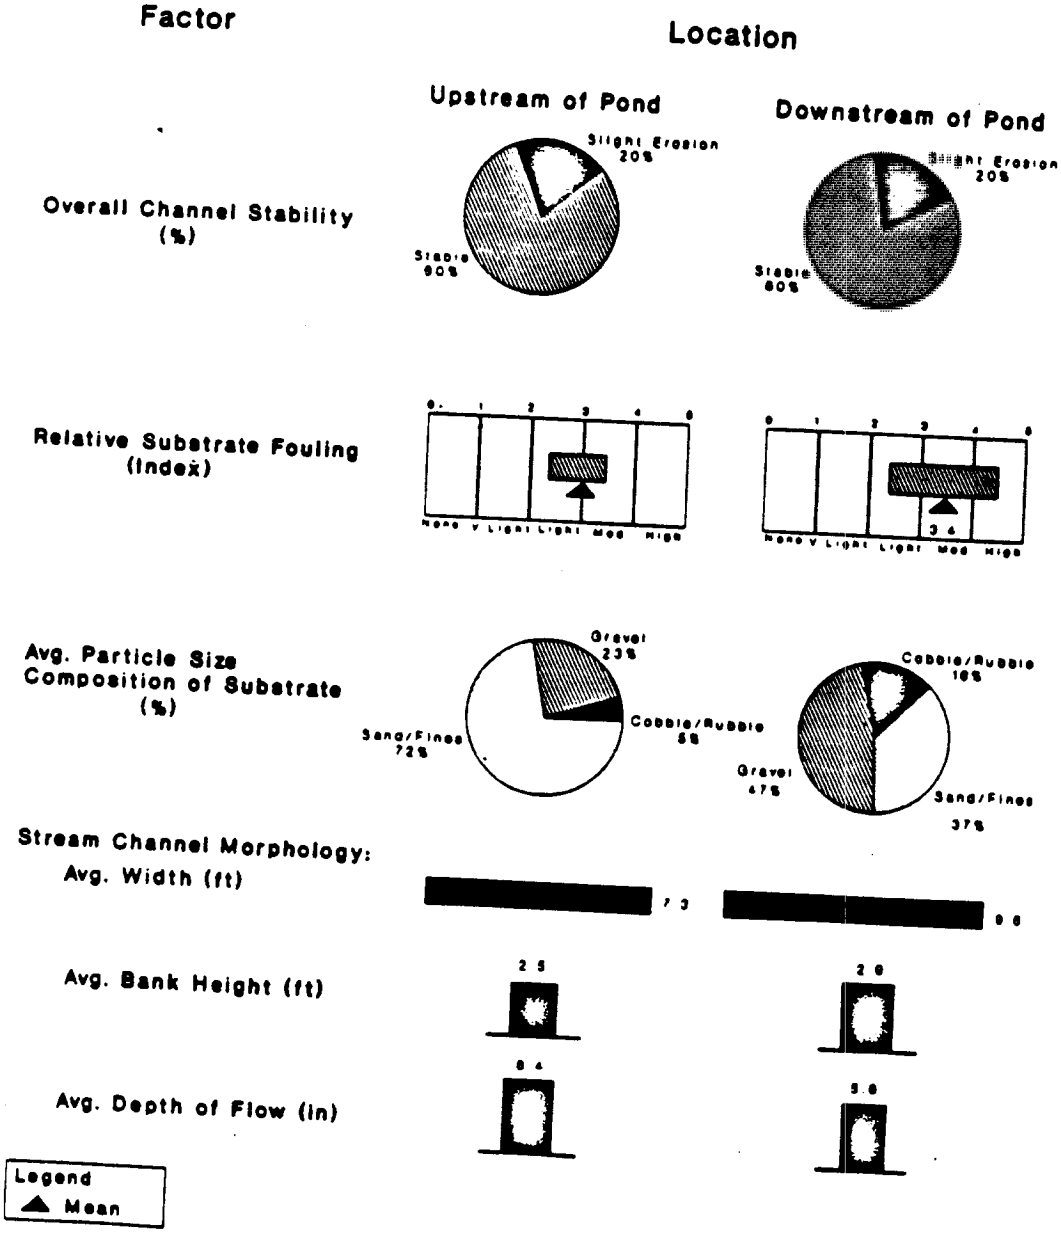
System Longevity

By the nature of their design, ED dry ponds are particularly susceptible to clogging problems. Field survey results revealed that, because of clogging, two of the twelve pond sites were functioning as defacto retention ponds. Present design criteria stipulate that the minimum acceptable ED size opening shall be two inches in diameter. Field inspection results confirmed that a two inch opening is capable of working for

VOL 12 2 1836

R0055136

Figure 18. ED Dry Ponds: Receiving Stream Survey Results (N=5)



VOL 12 2 1837

R0055137

relatively long periods of time with out clogging, provided that a very effective trash rack/anti-clogging system is employed.

Based on field observations, the horizontal perforated PVC pipe with gravel jacket proved to be the least effective anti-clogging system. Far more effective were the vertical stand pipe and trash rack systems, and the use of a micropool with a vertical hood extending well into the permanent pool. In addition, the minimum acceptable perforation size opening appeared to be 0.75-1.0 inches diameter. In COG staff's opinion, without the regular removal of accumulated sediment and debris it is highly unlikely that most ED dry ponds would remain 'dry' for more than two or three years.

Performance Maintenance and/or Structural Problems

Many of the above-referenced problems have already been discussed. As seen in Figure 19, clogging problems were endemic to 25 percent of the ED dry ponds surveyed. Other maintenance-related problems included poor vegetative stabilization of side slopes and embankment areas, excessive sediment/debris build-up, and displacement of rip-rap at both inflow and outflow locations. The overall maintenance condition for the twelve ED dry ponds surveyed are summarized below (no. out of 12 facilities indicated).

Poor	-	3 (25%)
Fair	-	4 (33.3%)
Good	-	4 (33.3%)
Very Good	-	1 (8.3%)

From a structural standpoint, all of the facilities surveyed appeared to be well-constructed. Seventy-five percent were problem-free. Structural problems, which warranted repair work were identified as follows:

No. of Facilities	Problem
1	seepage/leak in brick riser
1	leak in gabion weir wall
1	poor grout work around concrete barrel

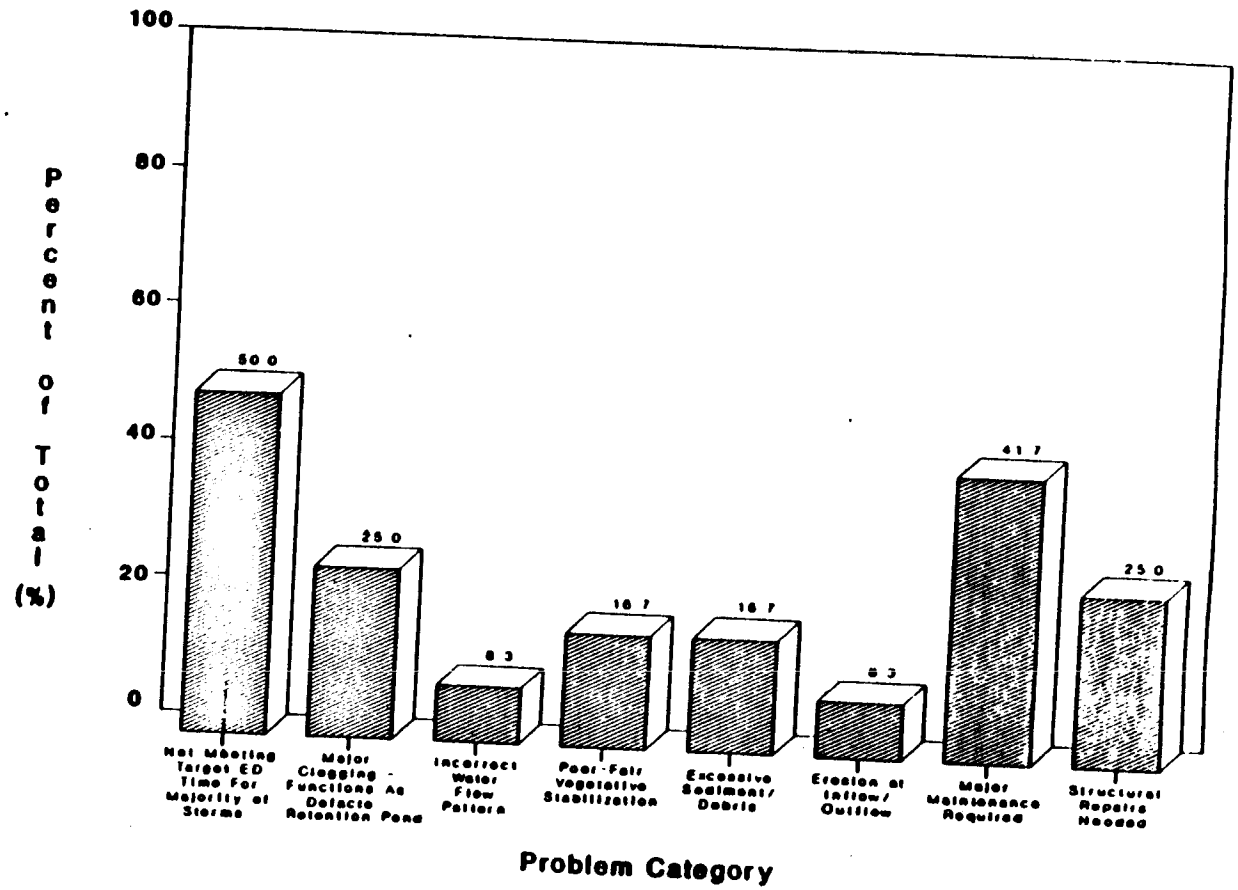
Environmental Attributes

Several of the on-stream ED dry ponds provided some secondary wetland/wildlife habitat benefit. In general, the highest habitat scores (Figure 17) were associated with the larger facilities which featured a good supply of food, cover and water; capable of supporting a diverse faunal community. As for aquatic habitat benefits, four out of the five downstream reaches surveyed showed some slight improvement over upstream conditions (one showed no change). These improvements

VOL 12 2 1838

R0055138

Figure 19. ED Dry Ponds: Typical Performance, Maintenance and/or Structural Problems (N-12)



R0055139

were primarily associated with both the greater stability of the flow regime and a reduction in the percentage of sand/fines present in the substrate.

VOL 12 2 1840

IV. Wet Ponds

Background

A total of 12 wet ponds were field surveyed in the study. As seen in Figure 20, 75 percent of the ponds were between one and three years old. Slightly more than one-half of the ponds were located on flowing streams. Associated catchment area size ranged from 4.0 to 338.2 acres with a median drainage area of 54.6 acres. The majority of the surveyed ponds had permanent pool surface areas of 0.5 acres, or less. Permanent pool storage volumes also varied considerably between pond sites; ranging from between 0.25 to 5.0 inches per impervious acre (Table 7). All 12 wet ponds featured a surface release design without ED control.

Only three ponds incorporated sediment forebays into their design. The majority of the ponds surveyed had a maintenance bench along at least one side of the pond. Fewer than one-half of the wet ponds employed either an aquatic bench or a pond drain. The large percentage of ponds without a drain feature was largely a function of excavation depth. Maximum and mean pond depths ranged from 3-5 - 7.0 feet and 2.5 - 4.5 feet, respectively (Figure 21).

Additional background information is both listed below and included in Appendix D.

- Age Range (yrs.) 1.5 - 1.4 (avg. - 99.3)
- D.A. to Structure Range (ac): 4.0 - 332.2 (avg. - 99.3)
- Range of Permanent Pool Storage Provided (in./impervious ac.): 0.25 - 5.0 (med. - 1.08)
- No. with Multiple Cells - 0
- Range in Pond Length/Width Ratio: 0.9 - 11.5 (med. - 2.3)
- Range in Minimum Internal Flow Path Length (ft): 20 - 535 (med. - 82.5)
- Range in Associated Watershed Imperviousness (%): 15-85 (med. - 50)
- Pond Surface Area Range (ac): 0.15 - 4.9 (med. - 0.48)
- Pond Surface Area to Catchment Area Ratio (%): 0.5 - 3.8 (med. - 1.0)

Water Quality Grab Sampling Results

Major pond water quality grab sampling results are graphically depicted in Figures 22 and 23. Additional information is found in Appendix D. From an overall water quality standpoint, three out of the top four rated ponds were located off-stream.

VOL 12 2 1847

R0055147

As seen in Figure 22, little difference in trophic category status was observed between on and off-stream pond systems. All of the wet ponds surveyed were either eutrophic or mesotrophic.

One-third of the pond sites had highly turbid, sediment-ladened water. High average depth of sediment was recorded at two sites. Both of these ponds were older, on-stream types with relatively large upstream drainage areas and active construction in the watershed.

No violation of the 5.0 mg/L MDE Class I DO standard was observed at any pond site. Total dissolved solids, carbon dioxide (CO_2), and pH levels were all within the range expected for eutrophic bodies of water. Not surprisingly, surface water temperatures during the late August to early October sampling period were generally warm (median - 77.0°F).

General Performance and System Longevity

Performance

Field survey results strongly suggested that all 12 wet ponds were generally providing both water quantity and quality control as designed. Partial supporting evidence of this is provided in Figure 24. As seen in Figure 24, varying levels of downstream improvement were recorded in several major categories. These included: 1.) a slight increase in overall channel stability, 2.) a slight decrease in the level of substrate fouling, 3.) improved morphological characteristics such as reduced channel width and bank height and increased depth of flow, and 4.) reduction in total dissolved solids. In addition, casual macroinvertebrate sampling results indicated a general improvement in downstream aquatic habitat/stream quality conditions. As expected, the only negative result was an average downstream water temperature increase of 7.7°F.

Based on field observations, wet ponds with permanent pool volumes over 1.0 inches/impervious acre appeared to outperform those having smaller volumes. No significant correlation was noted between the amount of rooted aquatic vegetation present and the areal extent of floating algal mats.

On the basis of sediment depth measurements, COG staff was able to estimate the average annual sediment deposition rate for both the wet ponds and artificial marsh systems surveyed. As seen in Figure 25, off-stream wet ponds and marshes had an average sediment deposition rate of approximately 0.8 yds^3 per acre of drainage area per year. This rate was almost 2.2 times higher than the rate for on-stream retention systems (which was 0.37 yds^3/ac/year). While these preliminary results should be viewed cautiously, they suggest that off-stream facilities may be more efficient sediment traps.

R0055150

System Longevity

All of the wet ponds surveyed employed both long-lived concrete risers and barrels. With the exception of the two on-stream ponds which had excessive amounts of sediment deposition, the majority of the ponds surveyed appeared to have lost very little, if any, permanent pool volume. Invariably, the greatest depth of sediment was associated with the pond inlet area. As previously indicated, only 33 percent of the ponds employed a sediment forebay in their design. While forebays generally do not extend the sediment removal interval, they would appear to greatly facilitate dredging operations by confining most of the larger grained sediment to one location within the pond. As such, forebays should help extend the life span of other potentially valuable deep water areas.

Performance, Maintenance and/or Structural Problems

As a group, overall pond water quality performance was rated as being good. However, both poor internal flowpath length and large sediment deposits are thought to have reduced the individual performance of several pond sites. With regard to the former, one-third of the ponds featured major storm drain outfalls located within 50 feet of the outlet structure. In most of these cases, little if any intervening emergent vegetation was present to slow down and filter runoff before it exited the pond. Thus, it would be expected that these ponds would experience short-circuiting problems during most storm events. It is further noted that 50 percent of the pond sites had relatively short internal flowpath lengths of less than 100 feet. Sediment deposits, which appeared highly susceptible to resuspension during large stormflow conditions, were observed at one-quarter of the ponds.

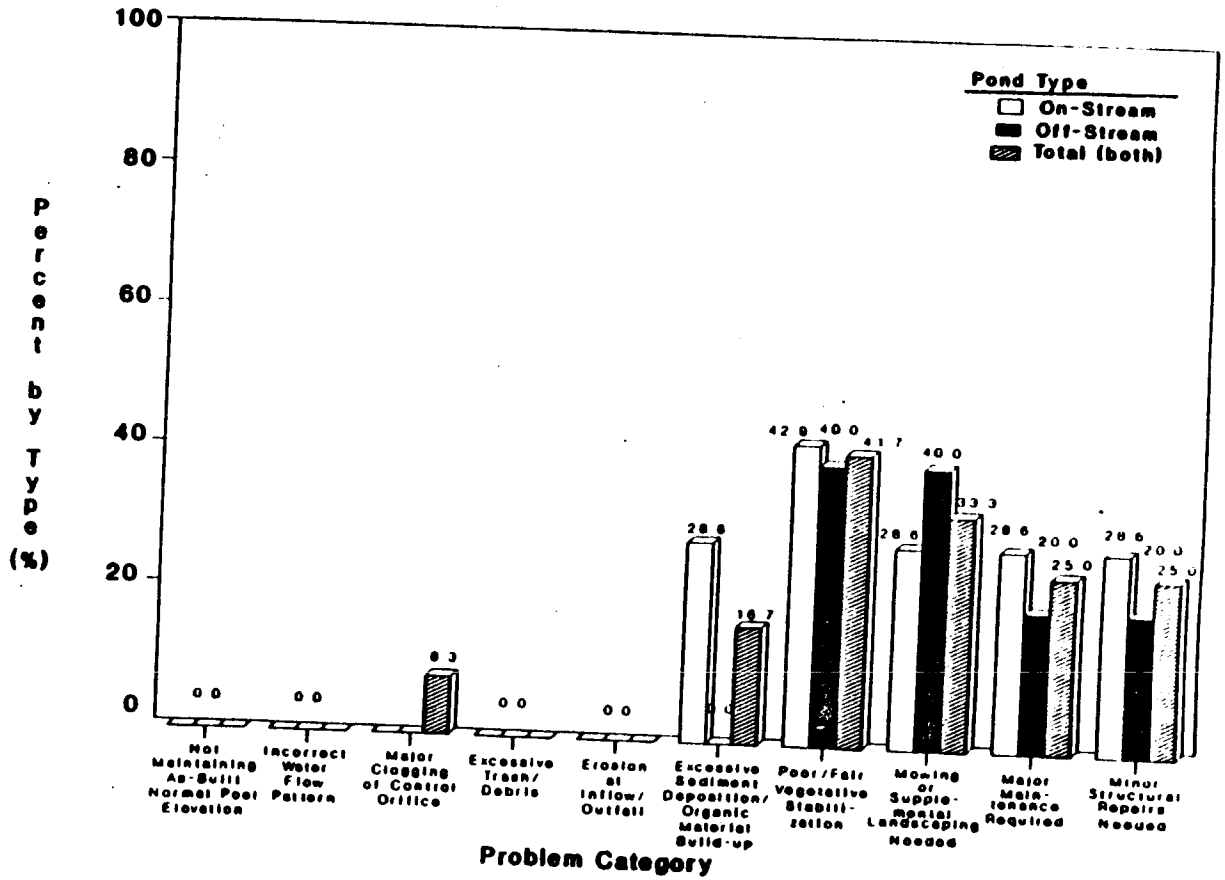
One of the more interesting study findings regarded the amount of trash present. In general, the quantity of floatable trash and debris was relatively light and well-defined trash lines were observed infrequently. Given both the high percentage (58%) of commercial and industrial land uses in the contributory watersheds and generally suspect pond maintenance, a higher amount of floatable material would have been expected. These findings strongly suggest that a substantial portion of the smaller-sized floatable material is washed out during successive storm events. Contributing to the overall problem was the exclusive reliance upon bar-type trash tracks with large on-center spacing. None of the ponds surveyed employed the more retentive hooded trash rack or reverse sloping pipe outlet design. As seen in Figure 26, few clogging problems were reported.

The majority of the ponds surveyed appeared to be regularly mowed. Relatively few maintenance problems, other than vegetative stabilization and sediment removal were observed. From an aesthetic standpoint, one-third of the pond sites would have benefitted from additional landscaping treatment. Also, three of the ponds were totally enclosed by a five foot high chain link fence; thereby, creating a very unnatural looking pondscape. Maintenance access to seven of the ponds was rated as excellent, courtesy

VOL 12 2 1851

R0055151

Figure 26. Wet Ponds: Typical Performance, Maintenance and/or Structural Problems (N=12)



R0055152

2582

of their maintenance bench design features. Overall wet pond maintenance condition was rated as follows (No. of ponds indicated).

Poor	-	1	(8.3%)
Fair	-	3	(25.0%)
Good	-	6	(50.0%)
Very Good	-	2	(16.7%)

Eight of the pond sites (66.7%) were judged to have adequate space for future on-site sediment dewatering operations. However, only two out of 12 sites appeared to have enough flat area(s) for permanent on-site sediment disposal. Also, none of the as-built plans identified potential sediment disposal sites.

Structurally, all of the ponds appeared to be in generally good condition. The only problems observed were poor grout work around the barrel/riser joint of two ponds and one pond whose damaged trash rack was barely hanging on the face of the riser. It should be noted that this trash rack was made out of heavy concrete reinforcing wire instead of larger diameter, welded rebar or smooth bar.

Environmental Attributes

As expected, the highest aquatic/wildlife habitat index scores were recorded at the larger, older, on-stream ponds which featured: large stands of emergent aquatic vegetation, adjacent mature forest area, and a good mix between shallow and deeper open water (> 4 ft. deep). Overall, the average habitat index score, Figure 27, was 1.7 (low to moderate range).

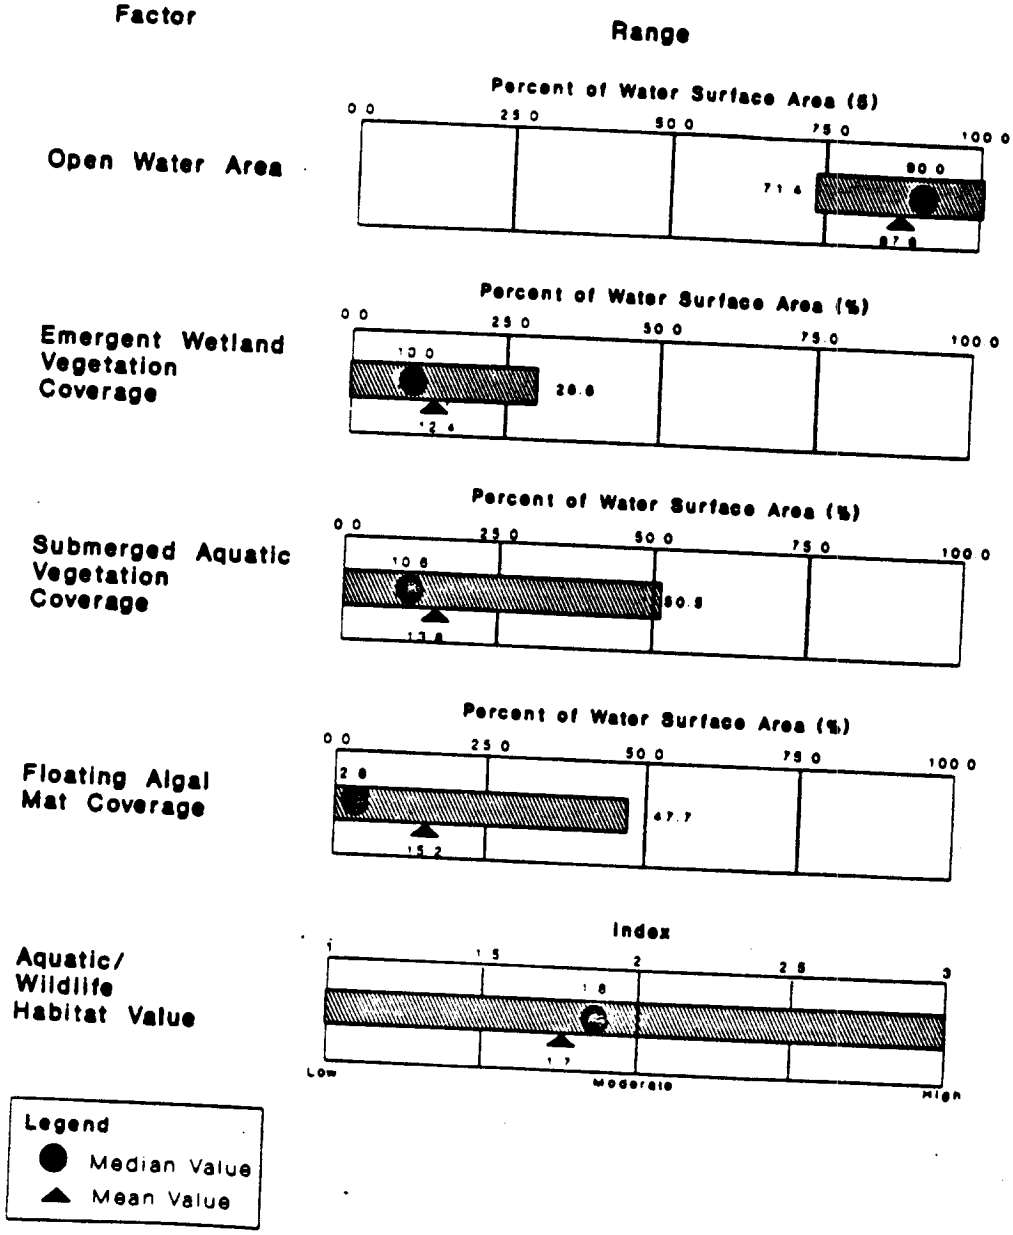
With the exception of one relatively young pond, all of the sites supported emergent aquatic vegetation around their perimeter. Emergent wetland vegetation coverage ranged from 0 - 28.6 percent of the pond surface; with a mean coverage of 12.4 percent. Field survey results also indicted that cattails (Typha latifolia) were the dominant emergent wetland plant species at 9 out of the 12 pond sites. Other dominant and co-dominant species observed were American three-square (Scirpus americanus), spike rush (Eleocharis sp.), soft-stem bulrush (Scirpus validus) and arrowhead (Sagittaria latifolia). Review of the as-built files indicated that only one pond was the recipient of intentional emergent aquatic plantings. However, only one species, arrowhead, was introduced there.

Somewhat to COG staff's surprise, two-thirds of the pond sites supported varying amounts of submerged aquatic vegetation. As seen in Figure 27, as much as 50.5 percent of the pond bottom area was covered with this vegetation. Observed species included Hydrilla verticillata, coontail (Ceratophyllum demersum), and eurasian millfoil (Myriophyllum spicatum). From a warmwater fisheries standpoint, 10 - 50 percent bottom coverage is generally considered beneficial (Gougeon, 1992). The presence of this vegetation is also significant in that it provides additional filtration and removal of both suspended solids and nutrients present in the water column.

VOL 12 2 1853

R0055153

Figure 27. Wet Ponds: Environmental Attributes (N=12)



VOL 12 2 1854

R0055154

With regard to wildlife, green (Rana clamitans) and/or pickeral frogs (Rana palustris) were observed at eight out of the 12 wet ponds inspected. Painted (Chysemys picta), spotted (Clemmys guttata) and/or snapping turtles (Chelydra serpentina) were also observed at two pond sites. Native minnow species were present at one site and sunfish and largemouth bass were seen at two others. Several of the ponds supported ducks and geese. No mosquito larvae were observed.

Depth-Area/Depth-Volume Distributions

In an effort to better assess each pond's potential ability to support rooted aquatic plants and gamefish, the approximate percentage of the permanent pool area and volume associated with each of the three following depth zones were calculated:

I.	Shallow Water Zone	-	Depth, 0.0 - 1.5 feet. Zone most commonly associated with emergent aquatic plant communities. Both plant diversity and densities are typically greatest in those areas which are less than one foot deep. Emergent vegetation in this zone generally provides food and cover for a variety of wildlife, including juvenile gamefish.
II.	Mid-depth Zone	-	Depth, 1.6 - 4.0 feet. Zone in which the majority of submerged aquatic plants are found in SWM ponds.
III.	Deep Water Zone	-	Depth, over 4.0 feet. Provides deeper water habitat required by adult gamefish populations on a year-round basis.

While the preceding depth zones are somewhat arbitrary, results (Figure 28) indicated that one-third of the pond sites were designed as marsh/pond 'hybrids.' In other words, they were both too shallow to generally support a healthy adult gamefish population year-round, and too deep to meet MDE (1987) recommended wetland design guidelines of approximately 75 percent emergent vegetation coverage.

As for submerged aquatic plants, the availability of light in the water column is generally considered to be the principal factor limiting their depth distribution. Generally, the maximum depth for growth is very closely associated with the maximum secchi depth (which in this study was approximately four feet).

In COG staff's opinion, site R-11 (which featured both a sediment forebay and an extensive aquatic shelf area around the entire pond perimeter) would serve as a relatively good model for general wet pond depth-area/depth-volume distribution design. It is further noted that this pond had a maximum depth of approximately 7.0 feet.

V. Artificial Marshes

Background

Nine artificial marsh systems, five conventional marshes and three enhanced marshes, were field surveyed in the study. All of the marsh facilities surveyed were less than four years old; with slightly more than half being under two years in age. As seen in Figure 29, artificial marshes were most frequently associated with small commercial development sites. Although the drainage area size range ran from 0.6 to 221.0 acres, two-thirds of the catchment were less than 20 acres in size. Given the relatively small drainage areas controlled, all of the marshes (except for one) were located off-stream. Marsh surface areas ranged from 0.03 to 0.75 acres. Roughly half of the marshes surveyed were the aptly named pocket wetland variety (i.e., - surface area $\leq$ 0.1 acres).

Permanent pool storage volumes ranged from 0.17 to 2.30 inches per impervious acre. All of the marshes surveyed were of the surface release type. Only two facilities provided ED control (both had a design 24-hr. ED period). The majority of the marshes were classified as being hypereutrophic (i.e., - indicative of undesirable, highly productive and nutrient-rich water). Maximum and mean marsh depth ranged from 1.3 - 5.0 feet and 0.3 - 3.5 feet, respectively (Figure 30). Other background highlights are both listed below and presented in Appendix D.

- Age Range (yrs.): 1.4 - 3.8 (avg. - 2.4)
- D.A. to Structure Range: 0.6 - 221.0 (med. - 2.8)
- Range of Permanent pool Storage Provided (in/imperviousness acre): 0.17-2.30 (med. - 0.50)
- No. with Multiple Cells - 1
- Range in Marsh Pond Length/Width Ratio: 1.4 - 5.4 (avg - 3.1)
- Range in Minimum Internal Flowpath Length (ft): 20 - 140 (med.-70)
- Marsh Surface Area Range (ac): 0.02 - 0.75 (avg. - 0.21)
- Marsh surface Area to Catchment Area Ratio (%): 0.3 - 7.1 (avg. - 2.3)
- No. of Marshes Fenced - 6 (66.7%)

Water Quality Grab Sampling

The major findings from both the artificial marsh and wet pond grab sampling portions of the study are presented in Table 8. As seen in Table 8, several obvious water

R0055162

quality differences were recorded between the two BMP systems. Among these were: 1.) the surveyed marshes were predominantly hypereutrophic; 2.) wet ponds tended to be both considerably warmer and better oxygenated . One-third of the artificial marshes failed to meet the 5.0 mg/L DO standard for Class I waters. No apparent correlation was noted between marsh DO concentration and the amount of emergent vegetation present, 3.) CO_2 levels were higher in the artificial marshes, suggesting higher respiration and decomposition rates in these systems, and 4.) the percentage of the permanent pool area covered by floating algal mats was much lower in the marsh systems. This may have been partially due to the proportionately higher amount of emergent aquatic vegetation generally present in the marshes.

While none of the artificial marshes surveyed appeared to be anoxic, the lowest DO readings were recorded at the pocket wetland sites. This finding suggests that some of these systems are being pushed to their limit to breakdown both external and internal organic loads. The high CO_2 readings also observed at the pocket wetland sites partially supports this line of reasoning.

General Performance and System Longevity

Performance

Field survey results revealed that three out of the nine artificial marsh systems were not working as designed. Two of the problem marshes were unable to maintain their design normal pool elevations because of pond drain leakage problems. Conversely, the third marsh experienced major clogging problems with its ED orifice, resulting in a four foot increase in the normal pool elevation. It should be noted that the rebar trash rack employed at this site provided little protection for the two-inch diameter ED orifice.

Another major leading performance-related problem associated with permanent pool depth was the highly variable amount of emergent aquatic vegetation present. As seen in Table 9, not one of the nine marshes surveyed met the MDE 75 percent emergent vegetation coverage guideline. Close examination of marsh depth/volume distributions (Figure 31) revealed that at least four of the marshes were far too deep to permit the establishment of even modest (40 - 50 percent) emergent vegetation coverage.

Based on MDE wetland design guidelines, approximately 25 percent of the marsh should have maximum depths ranging from two to three feet. However, as seen in both Figure 31 and Table 9, one-third of the marsh sites had maximum depths of 18 inches or less. This resulted in almost complete emergent vegetation coverage with little or no open water area provided. From both a biofiltration/water quality performance and wildlife habitat standpoint, a proper balance between open water and emergent vegetation area is critical.

As previously indicated, the majority of the artificial systems inspected were constructed off-stream. Even though much of the survey period was drier than normal,

[1/]Site No R-14 was the only marsh site where submerged aquatic vegetation was observed.

the off-stream locations did not appear to have any real effect on design normal pool elevations. It should be noted that at least three out of the eight off-stream marshes received some groundwater inflow. Also, the larger marsh sites seemed to generally provide both better water quality control and far greater environmental amenities.

With regard to ED control, only one of the two ED marshes appeared to be providing any real ED. However, because the marsh had its ED orifice partially plugged, it was providing far more than the 24 hours of ED control for which it was designed. In addition, most of the design storm storage in the marsh was lost due to a major increase in normal pool height.

The age of the marsh system also strongly influences performance. For example, it normally takes at least two or more growing seasons to naturally develop extensive, dense beds of emergent aquatic vegetation; hence, plant densities may not provide optimal stormflow velocity dissipation, biofiltration and pollutant uptake and wildlife habitat opportunities during this initial start-up period. Both the start-up period and the threat of creating undesirable plant monoculture systems can be reduced through the artificial introduction of a variety of native wetland plant species. Based on both field surveys and review of as-built file information, it appears that no wetland plantings were made at any of the nine marsh sites surveyed.

VOL 12 2 1865

R0055165

Overall, emergent aquatic plant diversity at the marshes was relatively poor. Cattails were the dominant volunteer species present, typically comprising 70 - 90 percent of the emergent plant community. Phragmites was not observed at any site.

System Longevity

Results showed that four of the marshes had lost considerable permanent pool storage via sediment and/or organic detritus build-up. It should be noted that the two most severe cases were shallow pocket wetlands. Given their relatively small size, without regular sediment/debris removal and routine inspection and maintenance of the outlet control structure, few pocket wetlands would be expected to function as designed for more than four or five years. Not surprisingly, a strong positive correlation $r = 0.755$ ($p < 0.05$), was recorded between average sediment depth and the age of the marsh.

In general, the incorporation of both a two- to three-foot deep sediment forebay at the marsh inlet and a similarly deep area at the control structure would improve marsh longevity and reduce the need for frequent and highly disruptive sediment removal from the entire marsh bottom. Alternatively, the use of a two-cell wetland design (such as the R-18 marsh site) should accomplish the same objectives.

Performance, Maintenance and/or Structural Problems

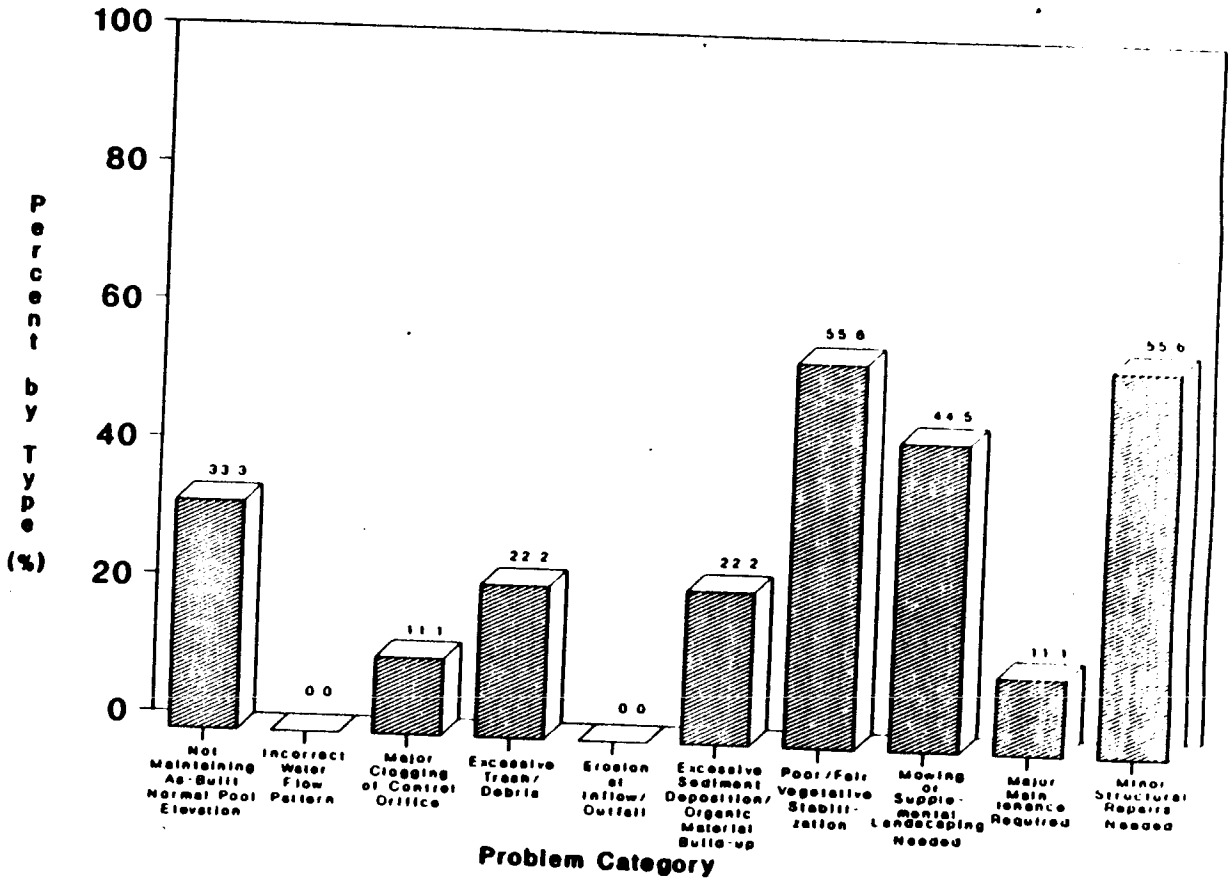
As seen in Figure 32, over half of the marshes surveyed required some additional vegetative stabilization of side slope and/or embankment areas. Although current Prince George's County design criteria require that an additional one foot of depth be provided for sediment storage, the majority of the marshes did not meet this criterion. Other findings are listed below.

- On a volumetric basis, the amount of permanent pool storage provided was the same for all land use categories;
- While the average length/width ratio of the surveyed marshes was slightly over 3:1, minimum internal flowpath lengths were generally very short (median ~70 linear feet). This was particularly the case for the pocket wetland sites;
- Only three of the nine marshes inspected included a maintenance bench in their design;
- Three out of nine control orifices lacked a protective trash rack. Of the six control structures which had trash racks, five employed the rebar variety and one used a perforated, vertical pvc pipe; and
- Four out of the nine marsh sites lacked adequate areas for future sediment dewatering operations. None of the as-built plans identified potential on-site sediment disposal areas;

VOL 12 2 1866

R0055166

Figure 32. Artificial Marshes:Typical Performace, Maintenance and/or Structural Problems (N=9)



R0055167

Overall, artificial marsh maintenance condition was rated as follows (No. out of 9 sites indicated).

Poor	-	1	(11.1%)
Fair	-	4	(44.5%)
Good	-	3	(33.3%)
Very Good	-	1	(11.1%)

Environmental Attributes

As seen in Figure 33, the average aquatic/wildlife habitat index score was 1.4 (low overall habitat rating). The relatively poor habitat scores were attributed to four major limiting factors: 1.) small marsh size - the median surface area of the systems surveyed was 0.10 acres, 2.) poor environmental location - six out of nine marshes were located either directly adjacent to high traffic paved areas, or in mowed open space, 3.) high mean permanent pool depth - four out of nine sites had average depths $\geq$ 2 feet. These depths effectively restricted the pond bottom area available for the support of emergent aquatic vegetation, and 4.) off-stream location - eight out of nine marshes were hydraulically remote from open receiving streams.

With regard to wildlife, amphibians (frogs and toads) were observed at five out of nine marshes. Native minnow species were present at two sites. Goldfish and Koi were also observed at one marsh location. No mosquito larvae were observed at any of the marshes.

VI. Oil/Grit Separators

Background

Fifty-three oil/grit separators, representing approximately 29 percent of the total constructed in the County since 1985, were inspected by COG staff. As seen in Figure 34, nearly three-quarters of the structures surveyed were less than two years old. Oil/grit separators were most frequently employed to treat parking lot runoff from small commercial drainage areas of less than one acre. Based on the number of water holding chambers present, oil/grit separators were placed into one of the following categories: 1.) Type I - single wet chamber and 2.) Type II - two wet chambers. It should be noted that the Type I separator is the older design type and under current SWM design criteria is no longer allowed. Over 90 percent of the separators surveyed were Type II's.

All of the oil/grit separators were of the poured-in-place variety (i.e., no pre-cast structures used). Current sizing criteria requires that a minimum permanent pool volume of 200 ft.^{3}/impervious acre of drainage be provided. Review of as-built file information revealed that 33 of the 53 oil/grit separators provided more than the minimum amount of permanent pool storage (Table 10).

Additional background information is presented below and included in Appendix D.

- Age Range 0.7 - 4.9 (avg. - 1.7)
- D.A. to Structure Range (ac): 0.3 - 11.3 (avg. - 1.4)
- Water Quality Runoff Volume Controlled: 0.5 in/imp.ac (assuming clean-out of 4x - 5x/yr)
- Permanent Pool Depth Range: 2.0 - 6.8 (avg. - 4.7)
- Permanent Pool volume Range (cuft):

  Grit Chamber - 27.2 - 780.0 (avg. - 204.2)
  Oil Chamber - 31.5 - 393.3 (avg. - 110.5)

- Avg. Storage Volume above Permanent Pool (cuft): 218.7
- Total Length/Width Ratio Range: 1.9 - 5.6 (avg. - 2.9)

General Performance and System Longevity

Performance

Fifty-one (96.2 percent) of the oil/grit separators surveyed were working as designed. When compared against all of the other BMP systems surveyed, only wet ponds proved to be less trouble-free than oil/grit separators. Much of this success is attributed to both the simple design and rugged construction of oil/grit separators.

Although oil/grit separators were essentially problem-free, their long-term ability to both trap and retain sediment, oils and grease and other pollutants was quite limited. As seen in Figure 35, neither the Type I or II oil/grit separator (nor the infiltration sump pit) were particularly retentive of sediment over time. The relatively poor long-term trapping efficiencies were greatly assisted by the practice of locating these structures on-line. In fact, all of the structures surveyed were located directly on-line, where they are subject up to full 10-year frequency storm flow-through. Under turbulent flow-through conditions, residual materials may be effectively resuspended and transported out of the facility. It is also important to note that none of the oil/grit separators have ever been maintained.

Results also showed that both the single wet chamber (Type I) oil/grit separator and infiltration sump pit (also one wet chamber) were more retentive of fine-grained residual material than the Type II separator (Figure 36). Conversely, the Type II separator was somewhat more efficient at both trapping and retaining oily sediments and floatable trash and debris.

Preliminary results suggest that sediment trapping performance may be more strongly influenced by internal design features such as port and elbow intake end locations than by permanent pool volume size or chamber geometry. For example, correlation analyses revealed that a significant negative relationship, $r = -0.609$ ($p < 0.05$), exists between the percentage of fine sediment found in grit chambers and weir wall port invert location (i.e., the higher off the bottom the less fine sediment). In addition it appears that extending the elbow intake end more than one to two feet below the permanent pool may actually promote the undesirable concentration and siphoning-off of smaller diameter sediment particles. As expected, oil chambers generally contained a higher percentage of fine sediment than did grit chambers.

All of the oil/grit separators had relatively high amounts of organic colloidal material present in suspension in each chamber. Stormflow monitoring results indicated that a large portion of this material is flushed out of the structure. In addition, relatively large quantities of emulsified oil were also observed in the discharge.

Limited stormflow monitoring of total dissolved solids (TDS) revealed no difference between inflow and outflow concentrations. These results confirm that oil/grit separators are generally ineffective at removing dissolved pollutants. In addi-

R0055175

tion, dye test results revealed that, under light rainfall intensity conditions, the minimum pollutant residence time in oil/grit separators is generally less than 26 minutes. Higher intensity rainfall would be expected to significantly reduce this residence time.

Concurrent dye test and stormwater discharge rate monitoring results also indicated that oil/grit separators do contain quiescent areas where very slow, non-uniform water mixing and turnover occurs. In fact, under light to moderate intermittent rainfall conditions some 30 - 50 percent of the dye was still visible within the structure after 2.5 hours.

System Longevity

As previously indicated, because of their all-concrete construction and rugged design, oil/grit separators are structurally long-lived. However, data clearly shows that without routine sediment and trash removal, this BMP rapidly loses its effectiveness over time. In fact, results indicated that, without maintenance, performance drops precipitously after the first year. Again, the practice of locating these structures on-line is thought to contribute greatly to both the resuspension and scour of residual material.

Performance, Maintenance and/or Structural Problems

With the exception of some minor trash-rack related clogging problems, all of the maintenance-related problems centered around the removal of sediment and floatable items such as plastic cups and wrappers. In order to reduce the loss of residual material, a sediment clean-out frequency of at least four times per year is strongly recommended for all on-line oil/grit separators.

Environmental Attributes

None. As expected, results from the field investigation revealed that oil/grit separators do not support any aquatic life. No aquatic worms, mosquito, or midge fly larvae were observed in either the water column or in the sediment. It is thought that the presence of oil sheens, which cover the surface of the permanent pools, plus oil contamination of the sediment effectively preclude their presence.

If properly maintained, oil/grit separators do demonstrate some ability to trap oil adsorbed to particulate material, sediment, leaves and a variety of floatable objects; thereby preventing their discharge to local streams.

Chapter 5. Study Recommendations

The recommendations which appear in this chapter represent a synthesis of findings derived from the three main study tasks, plus guidance obtained from consultation with both local and national SWM and natural resource experts. Both general and specific criteria and techniques were identified to improve the following: 1.) BMP water quality / quantity control performance, 2.) system longevity, 3.) maintenance, 4.) public safety, and 5.) environmental and aesthetic features. Second, both new possible BMP practices and future research needs are discussed. Last, a list of possible BMP retrofit candidate sites identified through the field survey has been included.

For organizational purposes, the chapter has been arranged as follows: I. Recommendations for Present BMP Systems, II. New BMP Practices and Future Research Needs, and III. BMP Retrofit Opportunities.

I. Recommendations for Present BMP Systems

A. General Infiltration System Recommendations

1.) **Site Analysis.** Per current PGDER criteria, a very rigorous site suitability study which, at a minimum, includes BMP site specific soil borings and laboratory testing of soil infiltration/permeability characteristics and depth to the seasonal high water table, is required. Results from this study revealed that many existing infiltration facilities either failed or were not working as designed due to poor initial site selection. In COG staff's opinion, any proposed infiltration site where groundwater is encountered within 15 feet of existing grade is highly suspect, and is therefore not recommended for such use. Also, where infiltration basins are proposed, the soils analysis should determine the maximum allowable surface ponding depth which will not contribute to premature soil surface compaction.

2.) **Soil Borings.** The practice of generally requiring only one soil boring per infiltration site needs to be re-examined. In COG staffs opinion, one boring should be required for every 50 feet of infiltration system length.

3.) **Pre-Treatment.**

- Because of their high susceptibility to clogging, greater pre-treatment controls are needed for all infiltration systems. It is therefore recommended that extraordinary and redundant pre-treatment

VOL 12 2 1871

R0055177

control measures be required. The use of a small, sump pit-sand filter system for pre-treatment control should be seriously considered.

- Pre-treatment control(s) for dry wells, such as gutter guards and/or sump pits, should be mandatory.

- The premise that infiltration basins do not require pre-treatment measures, because of the suspended solids filtration provided by their grassed surface, is flawed. Without adequate pre-treatment control the bottom area of most basins will rapidly seal, resulting in loss of infiltration capacity. Therefore, the incorporation of pre-treatment control measures such as a large grass filter strip, gravel/sand filter, etc., is strongly recommended.

4.) **Construction Practices.** In order to reduce the likelihood of either internal or external sediment contamination problems, infiltration trench systems with grass filter strips and infiltration basins should not receive any stormwater runoff until a full, dense turf has been established. It is further recommended that the exposed stone reservoir portion of infiltration trenches be sealed with 4 mil plastic sheeting throughout the turf establishment period.

5.) **Inspection/Maintenance.** Given the highly fragile nature of infiltration systems, routine inspection and maintenance is extremely critical. It is recommended that these systems be inspected at least two to four times per year, and preferably after a significant rainfall event.

6.) **Observation Well Cap.** Observation well cap specifications should be standardized and the maximum number of types allowed should be restricted to no more than two or three. Whenever possible, observation wells should not be located in high traffic areas of parking lots, sidewalks, or private driveways.

B. Infiltration Trenches

1.) **Stone Reservoir Location.** The current practice of allowing infiltration trenches to be located beneath paved surfaces, such as parking lots, should be seriously re-examined. To reduce the potential for costly maintenance and/or system reconstruction, it is strongly recommended that the stone reservoir portion be located in

VOL 12 2 1878

R0055178

a lawn-type area and as close to the ground surface as possible (i.e.,- bottom should be within 8 feet of the surface)

2.) **Stone Type.** To reduce the possibility of self-contamination from residual stone dust, it is recommended that only washed bank run gravel be permitted for the stone reservoir portion of these systems (i.e., - double-washed bluestone gravel is not recommended).

3.) **Construction Practices.** During construction, the bottom of the infiltration trench should generally be roto-tilled so as to reduce the probability of initial soil compaction (caused by excavation with large, heavy equipment).

4.) **Bottom Sand Layer Feature.** A six inch deep bottom sand layer is mandatory for all trenches so as to both promote better drainage and reduce the risk of soil compaction (when the trench is backfilled with stone) Strict compliance with this existing design criteria is recommended.

5.) **Off-Line Design.** In order to reduce both the frequency of turbulent flow-through and the associated scour/resuspension of residual material, all future infiltration trenches with sump pits should have the sump pit area located off-line.

6.) **Sump Pit Feeder Pipe Elbow.** The sump pit feeder pipe elbow intake end should extend down approximately one foot below the normal pool elevation. This withdrawal depth appears to represent the best compromise for reducing the amount of suspended solids, oil and floatable materials siphoned-off into the feeder pipe/stone reservoir.

7.) **Inspection/Maintenance.** Because of their functional similarity to oil/grit separators, all sump pits which are located on-line should be inspected and, if warranted, cleaned-out four times per year.

8.) **Permanent Pool Depth.** The recommend permanent pool depth for sump pits is four feet.

9.) **Grass Filter Design.** For infiltration trench systems with pre-treatment grass filter strips the following grass filter design and maintenance criteria are recommended:

a.) The slope of the filter strip should be approximately one percent along its entire length and zero percent across its width;

VOL 12
2 1879
R0055179

b.) The presently required 20 foot minimum filter length needs to be increased, particularly, for those areas receiving high suspended solids loads. A minimum 50 foot filter length is recommended for all sites.

c.) Ideally, the mowed height of the grass should be 2-4 inches taller than the maximum flow depth of the design water quality storm; and

d.) The grass filter should be located in a sunny area.

10.) **Pre-treatment Control Selection.** Because of their lower overall maintenance requirements, sump pits are generally preferred over grass filter strips.

C. Infiltration Basins

1.) **Recommended Design Changes.** Because of the fragile nature of infiltration basins and their extremely high failure rate, water quality and quantity control can generally be achieved more reliably with other BMP's. Given the present infiltration basin performance shortcomings, the following design changes appear warranted:

a.) Future basins should include adequate pre-treatment control, a stone infiltration trench area for basin dewatering, and observation wells (See Figure 37);

b.) Ponding depth should not be so great as to contribute to the compaction of the soil surface. A maximum ponding depth of two feet is generally recommended; and

c.) Basin water quality storage volumes should be intentionally oversized to account for the eventual total loss of infiltration capability. In addition, both a riser/barrel control structure and pond drain feature are recommended.

D. Porous Pavement

1. Because of the inability to provide pre-treatment control for porous pavement, and the system's high maintenance requirement and failure rate, the future employment of this BMP is not recommended.

VOL 12 2 1880

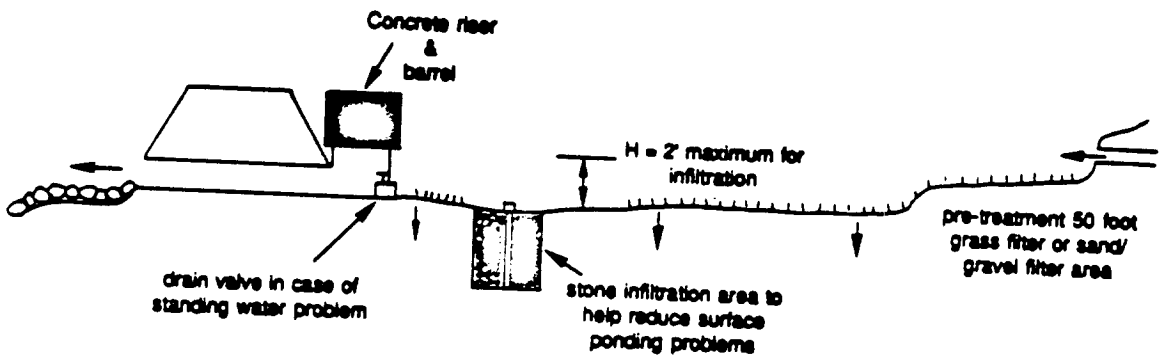
PROFILE



VOL 12 2 1881

R0055181

E. Grass Filter Strip/Grass Swale Systems

1.) **Alternative BMP's.** Because of their limited ability to remove dissolved pollutants, conventional grass filter systems should be viewed as pre-treatment systems. In general, grass filter systems are most effective when: 1) they are used in combination with other BMP's and 2) their use is restricted to relatively small, flat sites where runoff volumes are not large.

2.) **Site Analysis.** A rigorous site suitability analysis, which includes laboratory testing of soil infiltration/permeability characteristics and suitability for the intended grass cover crop, is recommended.

3.) **Grass Selection.** Grasses used in water quality filter strips/swale systems should have the following characteristics:

- high stem density, well-branched top growth, and a root system which is very resistant to temporary inundation/flooding;
- grass stems should exhibit a high resistance to being 'flattened' by the design storm;
- should be an aggressive grower, tolerant of both periodic drought and runoff carrying varying concentrations of road salts; and
- should form dense sod. Avoid bunch-type grasses.

Recommended grasses include, but are not limited to, the following:

Ky-31 tall fescue, reed canary grass, redtop, and roughstalked blue grass. Note, the preceding grasses can be mixed.

4.) **General Design Criteria.** In order to maximize the removal of nonpoint source pollutants the following design criteria are recommended:

- underlying soils should have a high infiltration rate. An fc of $\geq$ 1.0 inches/ hour is recommended. It is further recommended that the soils be tilled before the

VOL 12 2 1882

R0055182

grass cover crop is established to restore infiltration capacity lost during previous grading operations;

- grass filter systems should be constructed in sunny locations;
- the filter strip should, at a minimum, be as long as the contributing impervious area;
- the slope of grass filter/swale systems should be nearly flat (i.e., - one percent bottom slope along its entire length and zero percent slope across its width). Note, an underdrain system may, in some cases, be desirable;
- for swale systems, relatively broad, minimum bottom channel width to channel depth ratio of 3:1 is recommended;
- maximum water quality design storm flow velocities through the filter must be kept well below 1 fps. It is further recommended that the maximum allowable Q10 velocity be less than 3 fps.
- the mowed height of the grass should be 2-4 inches taller than the maximum flow depth of the design water quality storm. For Ky-31 tall fescue, reed canary grass, redtop, and/or roughstalked bluegrass a minimum mow height of 6 inches is generally recommended. Note, this would most likely require the use of a sickle bar-type mower.

5.) **Swale Systems.**

- In order to improve the performance of swale systems, a series of notched or ported low head checkdams (≤ 12 inches high) should be incorporated into their design. Note, the maximum recommended ponding time of runoff backed up behind the checkdams is 12 hours. Also, the area around each checkdam needs to be properly armored with stone.
- For both maintenance and long-term system design performance reasons, earth and/or stone checkdams should generally be avoided.

VOL 12 2 1803

R0055183

- Designers should seriously consider integrating redundant pollutant removal enhancement features, such as stilling basins, stone infiltration trenches, and/or checkdams, into their swale systems.

6.) **Inspection/Maintenance.** It is recommended that grass filter strips/swale systems be carefully inspected seasonally and preferably after a significant rainfall event.

- Routine maintenance should include: the immediate repair of newly formed channels or gullies, reseeding/sodding of bare spots, removal of trash, leaves and/or accumulated sediment, and the control of woody or other undesirable vegetation. In addition, the filter strip may require periodic mechanical aeration to restore infiltration capacity. Routine fertilization and/or use of pesticides is strongly discouraged.

7.) **Signage.** The grass filter/swale system should have proper signage so that it can be readily distinguished from other lawn-type areas.

8.) **Wildlife Habitat.** In order to increase the wildlife habitat potential of these systems it is recommended that an additional, minimum 10-12 foot wide buffer strip be incorporated into their design. This buffer strip could be planted with a variety of food producing grasses/small shrubs and/or native wildflowers.

9.) **Miscellaneous.** As-built plans should include certification of the type of grass cover crop used.

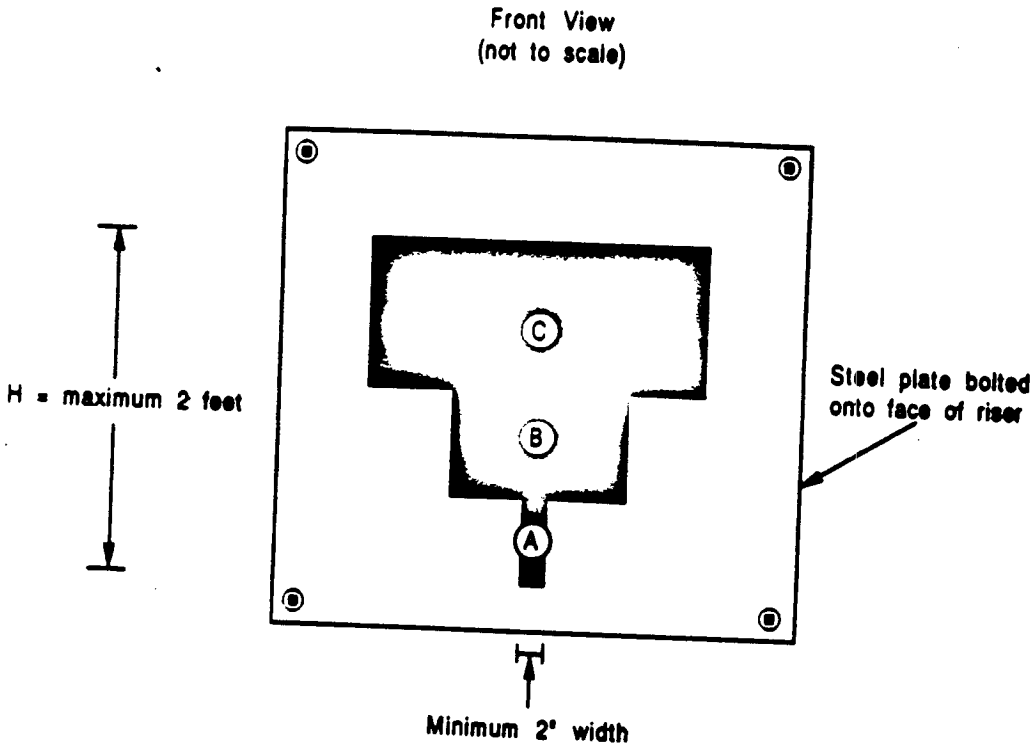
F. Extended Detention Dry Ponds

1.) **Basic ED Design.** Results from this study revealed that a large percentage of ED dry ponds failed to meet their design ED period. What is badly needed is a new ED control system which is truly capable of providing a minimum of 6 - 12 hours detention over a broad range of storm-size and rainfall intensity conditions. One possible design improvement is the employment of a proportioning weir-type system (Figure 38). A second alternative is the greater use of gate valves, which

VOL 12 2 1884

R0055184

Figure 38. ED Control Orifice: Conceptual Proportioning Weir Outlet System



A - Bottom slot control - small-sized, low intensity rainfall/storms

B - Middle and bottom slots - for medium-sized, moderate intensity rainfall/storms

C - Full slot control - for larger, less frequent storm events or high intensity rainfall storms

VOL 12 2 1 8 8 5

R0055185

provide greater operational flexibility in adjusting ED times. However, even these control improvement features cannot completely compensate for a release rate based on a single size storm event.

2.) **ED Calculations.** Although the present one-year 24-hour frequency storm inflow/outflow centroid method for calculating ED time is an improvement over the old 'Kerplunk' method, it too is deficient in that it is unable to accurately estimate the volume of runoff produced by storms of smaller size or different intensity levels. Further research in this area is needed.

3.) **On-Stream Locations.** For on-stream ED dry ponds which serve large drainage areas, design consideration needs to be given to the removal of sediment deposited within the upstream channel network. Without proper design and maintenance, there exists a strong probability that an eroding, braided channel network could develop. Good vehicular access to these areas is essential.

4.) **Micropools.** Micropools should be sized on the basis of both expected annual sediment deposition rates and design sediment-removal frequency.

5.) **Pond Drain.** Because of the high probability of clogging and hence ponding, ED dry pond design should include a pond drain feature.

6.) **Trash Racks.** The horizontal perforated PVC pipe and gravel jacket system should be dropped in favor of a vertical slotted/perforated standpipe or vertical perforated half-round CMP-type trash rack. However, whenever possible, a micropool/mini-wetland system with either a partially submerged hood or reverse slope pipe is the preferred approach.

7.) **Maintenance Access.** Good vehicular access to key ED dry pond component areas, such as the trash rack/micropool and pilot channel(s), is absolutely essential.

8.) **Inspection.** ED dry ponds which control high trash/debris and/or sediment-producing land uses should be inspected on a monthly basis (or after each major storm event).

VOL 12 2 1886

R0055186

9.) **Perforation Size.** The minimum acceptable perforation size opening for trash rack/anti-clogging systems should be 0.75 - 1.0 inches diameter.

10.) **Minimum Orifice Size.** The existing PGDER minimum two-inch diameter ED orifice sizing criterion works in the field and should therefore not be changed.

11.) **Internal Flowpath Length.** ED dry pond systems should feature a design which maximizes the flowpath length between the stormwater inflow point(s) and the outlet/control structure. A minimum 3:1 pond length/width ratio is further recommended.

12.) **Minimum D.A. Requirements.** Because of the generally small orifice diameter/cross-sectional area required to achieve ED control, conventional ED dry ponds are not recommended for sites having drainage areas of less than 10 acres.

13.) **Shading.** To reduce potential downstream thermal problems, both pilot and outfall channels should be shaded to the greatest extent possible.

14.) **Forested Locations.** When an ED pond is proposed to be located in a forested area, the existing forest must be evaluated for flood tolerance. In general, priority forest retention areas should be avoided.

15.) **Landscaping.** To improve both wildlife habitat value and aesthetics, ED dry ponds should generally be landscaped with native tree and shrub species.

16.) **Ergonomics** - Place valves, manhole covers, steps, platforms, etc., within safe and easy reach. Reduce vandalism potential by properly limiting access to the control structure and its appurtenances (i.e., lock up).

VOL 12 2 1887

R0055187

G. Wet Ponds and Artificial Marshes

Wet Ponds

1.) **Permanent Pool Volume.** The present 0.5 inches of permanent pool storage per impervious acre sizing requirement should be increased and modified to include a multiplier, land use intensity/imperviousness level coefficient to account for anticipated increases in pollutant loadings. It is recommended that the minimum permanent pool storage requirement for all wet ponds be set at 1.0 inch/impervious acre.

2.) **Permanent Pool Depth.** Approximately 10-20 percent of the permanent pool area should be less than 18 inches deep, and should include a minimum 10 foot wide by zero to 12 inch deep aquatic bench system. All wet ponds should generally have a maximum depth of between 4-8 feet. However, where game fish are planned to be introduced, the maximum pond depth should be at least six feet.

3.) **Surface Area.** The minimum wet pond surface area to catchment area ratio should be one percent (50.0 percent of the ponds surveyed had a surface area ratio of $\leq$1.0%).

4.) **Extended Detention Control.** It is strongly recommended that wet ponds serving larger sites, approximately 50 acres or greater, include a minimum of 6-12 hours of ED storage volume (for 0.25-0.50 inches of runoff/impervious acre) above the permanent pool. A maximum ED ponding depth of two feet is generally recommended.

5.) **Pond Configuration.** A minimum 3:1 pond length/width ratio is recommended. In order to reduce potential short-circuiting problems, storm drain outfalls should be strategically located so as to maximize flowpath length within the pond. Internal flowpath length can often be maximized through the employment of earthen berms or baffles located within the permanent pool. In addition, the use of a multiple-celled pond configuration should be considered as an option for reducing both potential short-circuiting and turbulent flow problems.

VOL 12 2 1 8 8 8

R0055188

6.) **Release Depth.** As a rule, wet ponds should withdraw water at or within 18 inches of the surface. Mid-level and bottom release locations are generally discouraged because of the strong possibility of discharging water with poor DO/water quality characteristics downstream.

7.) **Sediment Storage and Removal.** Sediment storage volume sizing should be based on both expected annual sediment deposition rates and design sediment-removal frequency. The employment of a sediment forebay area or alternatively, a multiple-cell configuration is recommended. In addition, whenever possible, future wet ponds should include adequate on-site sediment dewatering and disposal areas.

8.) **Maintenance Access.** A 10-12 foot wide maintenance bench should be provided so as to allow full vehicular access to both the outlet/control structure area and to at least one other side of the pond. Maintenance access road(s) should have a grade of less than 12 percent.

9.) **Trash Rack/Clogging Reduction Systems.** Field survey results indicated that both the partially submerged vertical hood and the submerged, reverse sloping ED pipe-type systems were far superior to the rebar design trash rack and should be the required approach.

10.) **Aquatic and Terrestrial Plantings.** Both aquatic and wildlife habitat and pond aesthetics could be significantly enhanced through the systematic introduction of native plant materials. Pond plantings are strongly encouraged so as to reduce the potential for the creation of monotypic cattail stands.

11.) **Longevity of Control Structures.** The use of concrete risers and barrels is the correct approach and should be a requirement for all future wet pond and artificial marsh systems.

12.) **Pond Location.** Off-stream ponds and marshes appear to perform their water quantity and quality control duties as well as those located on-stream. Each choice of location has both environmental and water quality trade-offs. Where the treatment of both baseflow and stormflow is desired and where wetlands/receiving stream-related issues (such as thermal regime alteration) are not critical, the preferred approach is an on-stream system.

VOL 12 2 1889

R0055189

13.) **Signage.** Both wet ponds and artificial marshes should be posted with an information/warning sign prohibiting swimming, ice skating, diving and/or other activities considered inappropriate or dangerous. It is further recommended that the posting of a small, companion environmental education sign also be considered.

14.) **Fencing.** The use of fences around wet ponds and marshes is generally not recommended. However, where deemed necessary, a wooden split-rail fence with a dark colored chain link backing is preferred over the traditional five foot high, galvanized chain link fence.

15.) **Safety Features.** To lessen the risk of accidentally falling into deep water areas, all retention pond systems should be designed with both wide aquatic shelves and safety/maintenance bench features.

16.) **Forested Locations.** When a wet pond or artificial marsh is proposed to be located in a forested area, the existing forest must be evaluated for flood tolerance. In general, priority forest retention areas should be avoided.

17.) **Shading.** To reduce potential downstream thermal problems, both inflow and outflow channels should be shaded to the greatest extent possible.

18.) **Ergonomics.** Place valves, manhole covers, steps, platforms, etc., within safe and easy reach. Reduce vandalism potential by properly limiting access to the control structure and its appurtenances (i.e., lock up).

Artificial Marshes

1.) **Surface Area.** The minimum marsh surface area to catchment area ratio should be two percent (Note, 55.6% of the marshes surveyed had a surface area ratio of (≤2%). A larger marsh surface area ratio is recommended for high nonpoint source pollution generating land use areas (e.g., - large commercial and/or industrial sites).

2.) **Permanent Pool Volume.** The present 0.5 inches of permanent pool storage per impervious acre sizing

VOL 12 2 1890

R0055190

requirement should be modified to include a multiplier, land use intensity/imperviousness level coefficient. As currently envisioned, the proposed minimum permanent pool storage volume would increase incrementally with increasing levels of site imperviousness/pollutant loads.

3.) **Permanent Pool Depth.** Approximately 50-70 percent of the permanent pool area should be less than 12 inches deep, and should include a minimum 12 foot wide by zero to six inch deep aquatic bench system. Shallow, variable depths are required for the establishment of a well-balanced emergent plant community. The remainder of the permanent pool area should be less than 5 feet deep. A large pocket of deeper water (between 2-5 feet deep) is recommended for both marsh inlet and outlet areas.

4.) **Extended Detention Control.** It is strongly recommended that artificial marshes serving larger sites, approximately 10 acres or greater, include a minimum of 6-12 hours of ED storage volume (for 0.25-0.5 inches of runoff/impervious acre) above the permanent pool. A maximum ED ponding depth of two feet is generally recommended. In addition, either a gate valve or proportioning-type weir should be employed.

5.) **Marsh Configuration.** A minimum 3:1 pond length/width ratio is recommended. In order to reduce potential short-circuiting problems, storm drain outfalls should be strategically located so as to maximize flow path length within the marsh. As previously indicated, internal flowpath length can often be maximized through the employment of earthen berms or baffles located within the permanent pool. In addition, the use of a two-celled marsh configuration should be considered as an option for reducing both potential short-circuiting and turbulent flow problems.

6.) **Release Depth.** A surface release design is generally recommended for all artificial marsh systems.

7.) **Sediment Storage and Removal.** Sediment storage volume sizing should be based on both expected annual sediment deposition rates and design sediment-removal frequency. Field survey results suggest that for most marsh systems, the presently required one foot sediment storage volume may be filled within the space of 5-7 years. Where possible, a 10-year sediment removal schedule is encouraged. For all marsh systems, a sediment forebay or a two-wet celled configuration

VOL 12 2 1891

R0055191

is strongly recommended. In addition, whenever possible, all future marsh systems should include adequate on-site sediment dewatering and disposal areas.

8.) **Maintenance Access.** A 10-12 foot wide maintenance bench should be provided so as to allow full vehicular access to both the outlet/control structure area and to at least one other side of the marsh.

9.) **Trash Rack/Clogging Reduction System.** Field survey results indicated that both the partially submerged vertical hood and the submerged, reverse sloping ED pipe-type systems were far superior to the rebar design trash rack and should be the required approach.

10.) **Aquatic and Terrestrial Plantings.** Both aquatic and wildlife habitat could be significantly enhanced through the systematic introduction of native plant materials. Marsh plantings with 7-10 native emergent species is strongly recommended.

H. Oil/Grit Separators

1.) **Alternative BMP's.** Given their limited pollutant removal capability and need for frequent costly maintenance, the employment of oil/grit separators is generally not recommended. As an alternative, the PGDER Watershed Protection Branch should seriously entertain the use of sand filters.

2.) **Off-Line Location.** All of the structures surveyed were located directly on-line, where they are subject up to full 10-year frequency storm flow-through. Under turbulent flow conditions, residual material may be effectively resuspended and transported out of the facility. Per recent PGDER criteria, all future oil/grit separators must be located off-line.

3.) **Inspection/Maintenance.** None of the oil/grit separators inspected in the study have ever been maintained. In order to reduce the loss of residual material, a sediment clean-out frequency of at least four times per year is strongly recommended for all on-line oil/grit separators.

VOL 12 2 1892

R0055192

4.) **Reduction of High Flow - Through Rate.** The relatively short pollutant residence times in these passive gravitational settling systems is generally insufficient for the removal of most silt-sized particles. In order to settle the major portion of this material, a minimum 45-60 minute residence time (under quiescent conditions) would be required. Unfortunately, this would be difficult to achieve without both significantly increasing storage capacity and reducing discharge rate/outlet orifice size.

5.) **Internal Location of Ports and Elbow Intake End.** Results indicate that the invert locations of both weir wall ports and the elbow intake end strongly influence sediment settling/retention dynamics. It appears that extending the elbow intake end more than 1-2 feet below the permanent pool may actually promote the undesirable concentration and siphoning-off of smaller diameter sediment particles. Therefore, a one foot withdrawal depth is recommended.

6.) **Suspended Solids Particle Size, Colloidal Material and Emulsified Oil.** The present oil/grit separator design operates under the assumption that oil floats at or near the water surface and that an inverted elbow extending three feet below the normal pool will trap and retain most of this material. Both field and literature survey results indicate that a large portion of the oil in urban runoff is quickly adsorbed onto fine sediment. Furthermore, oil which is in an emulsified state tends to remain in suspension and is not effectively trapped by an inverted elbow. Importantly, overall oil/grit separator performance is additionally hampered by the fact that much of the suspended solids are comprised of silt and clay-sized inorganic particles, as well as, colloidal organic material. Removal of the preceding materials through conventional gravitational settling is difficult, if not impossible to achieve. Thus, the next improved generation of oil/grit separators will need to include some type of additional filtering component, such as a sand filter element, in its design.

7.) **Coalescing Plates.** Given their high cost and high associated maintenance, the use of internal coalescing plates for improving oil/grit separator performance is not recommended.

VOL 12 2 1893

R0055193

8.) **Monitoring Needs.** Additional performance monitoring of oil/grit separators is needed to better quantify pollutant removal efficiencies and to provide information necessary for the formulation of possible design improvements and retrofit changes.

I. Dry Ponds

1.) **Alternative BMP's.** Because of their inability to provide water quality benefits, limited stream channel protection capability, and high maintenance requirements, the future employment of dry ponds is not recommended. Alternative replacement BMP's include: artificial marshes, wet ponds and ED dry ponds. It is further recommended that the majority of the existing dry ponds in the County be gradually converted over into one of the three preceding BMP types.

VOL 12 2 1894

R0055194

II. Alternative BMP's and Future Research Needs

Alternative BMP's - Sand Filters

Given both performance and reliability shortcomings of current oil/grit separators and infiltration BMP's, the employment of alternative SWM practices merits serious consideration. This is particularly the case for small catchment areas of less than 10 acres in size; where the employment of more traditional BMP's, such as wet ponds, artificial marshes, and/or ED dry ponds, is often neither feasible nor desirable.

Having carefully evaluated several possible alternative BMP systems, it is COG staff's opinion that sand filters represent the most flexible, reliable and affordable alternative. This conclusion is based on the following facts: 1.) sand filters have been successfully employed for several years in both surface and underground SWM applications, 2.) they have a proven ability to provide water quality control for small to medium size drainage areas, 3.) the pollutant removal efficiency of these systems is generally moderate to high for most stormwater constituents, 4.) vis-a-vis infiltration trenches or basins, sand filters are generally both far more resistant to clogging, and in the event of system failure, easier and cheaper to rehabilitate, 5.) sand filters can be coupled with either dry surface detention or underground pipe storage to provide full stormwater management control, 6.) on a volume-of-runoff treated basis, sand filters can be more economical to construct than either infiltration trenches or oil/grit separators, 7.) the removal and disposal of accumulated surface scum and contaminated sand does not require elaborate and/or costly procedures or disposal sites and 8.) sand filters pose no groundwater contamination threat. For all of the above reasons, it is strongly recommended that sand filters, along with infiltration trenches, be considered as the preferred BMP for small development sites with catchment areas of 10 acres or less.

Future Research Needs

During the course of the study, it became evident that additional BMP research is needed in at least two major areas: a.) comprehensive performance monitoring of oil/grit separators (to provide information necessary for the formulation of second generation design improvements, possible retrofit modifications of existing structures, and enhanced maintenance and residual material disposal practices) and b.) development of improved ED calculation/methodology and control systems (which can provide greater ED control over a broader spectrum of storm scenarios).

VOL 12 2 1895

R0055195

III. BMP Retrofit Opportunities

Based on field survey findings, COG staff has identified several existing BMP sites which appear to be likely candidates for future retrofit work. Presented below, in tabular format, are preliminary retrofit recommendations for 15 sites.

Table 11. Candidate BMP Retrofit Sites

Site No.	Name	BMP Type	Preliminary Recommendations
I-43	Tick Tock Plaza	Infiltration Basin	• Excavate to convert to artificial marsh. • Stabilize side slopes with combination of grass and shrub vegetation.
I-44	Park Virginia Manor	Infiltration Basin	• Excavate to convert to artificial marsh. • Add concrete riser to ex. barrel.
G-10	Decatur Heights	Oil/Grit Separator	• On an experimental basis, add a small sand filter component to the third chamber (outfall chamber).
R-16	Stanallen Estates	ED Artificial Marsh	• Replace ex. rebar trash rack with either a vertical hood or reverse sloping pipe system.

VOL 12 2 1896

R0055196

Table 11. Cont'd

Site No.	Name	BMP Type	Preliminary Recommendations
R-18	Tantallon Square	Artificial Marsh	• Regrade shoreline areas so as to create aquatic benches. • Perform aquatic and terrestrial pond-scaping.
R-22	Dontrine Pond #2	Wet Pond	• Add ED control feature. • Replace ex. wire mesh trash rack.
R-24	Montpelier Hills	Wet Pond	• Remove sediment deposit/excavate to maximum 6 ft. depth. • Add ED control feature. • Landscape Pond.
E-3	Den Lee Park	ED Dry Pond	• Convert to ED artificial marsh via excavation.
E-6	Lowes of Bowie	ED Dry Pond	• ditto
E-12	Inglewood Business	ED dry Pond	• Add gate valve to provide greater ED control. • Add micropool feature. • Replace ex. bar-type trash rack with a vertical hood.

VOL 12 2 1897

R0055197

Table 11. Cont'd

Site No.	Name	BMP Type	Preliminary Recommendations

VOL 12 2 1898

R0055198

Glossary of Terms

Aquatic Bench - A ten to fifteen foot bench around the inside perimeter of a permanent pool that is approximately one foot deep. Normally vegetated with emergent plants, the bench augments pollutant removal, provides habitat, conceals trash and water level drops, and enhances safety.

Biochemical Oxygen Demand - the quantity of oxygen utilized in the breakdown of pollutants via bacterial, fungal, algal, and/or other biologically driven processes, as well as, through chemical oxidation.

Eutrophication - the process through which bodies of water generally become more nutrient-rich and biologically productive.

Exfiltration - The downward movement of runoff through the bottom of an infiltration BMP into the subsoil.

Extended Detention - A stormwater design feature that generally provides for the gradual release of a volume of water (0.25 - 1.0 inches per impervious acre) over a 6 - 40 hour period to increase settling of urban pollutants, and protect channels from scouring flows.

Macroinvertebrates - animals without backbones that are large enough to be retained on a U.S. Standard No. 30 sieve, 0.595 mm openings.

Secchi Disk - a 20 cm diameter disk with four equal-sized, alternating white and black colored areas used for the approximate evaluation of the transparency or clarity of water.

Sump Pit - A single-chamber oil/grit separator used to pretreat runoff before it enters an infiltration trench.

Trophic State - refers to the productivity/nutrient status of a water body. In general, marshes, ponds and lakes are placed into one of four categories based on the following characteristics:

- oligotrophic (low nutrient loads and/or biological productivity)
- mesotroplic (moderate nutrient loads and/or biological productivity)
- eutrophic (high nutrient loads and/or biological productivity; generally viewed as being an undesirable condition)
- hypereutrophic (excessively high and undesirable nutrient loads and/or biological productivity.

VOL 12 2 1919

R0055219

A. Floatables and Oily Residual Material Indices

A qualitative index measuring system, based on visual estimates of both the amount of floatable materials (plastic cups, wrappers, etc) and oil-in-sediment present in both oil/grit separators and infiltration sump pits, was used to standardize field observations. The indices featured a 1-5 descriptive scale system. General observed field conditions and corresponding index values are described below.

I. Floatables

Percent of Permanent Pool Area Covered	Verbal Description	Point Value
0-5	None	1.0
6-20	Very Light	2.0
21-35	Light	3.0
36-50	Moderate	4.0
≥51	Heavy	5.0

II. Oil-in-Sediment

Residual Material Characteristics	Verbal Description	Point Value
• No oily discharge, no oily smell, does not leave oil stain on hands	None	1.0
• Very light oily discharge, little odor, generally does not stain	Very Light	2.0
• Light oily discharge when disturbed, faint oily odor, generally stains	Light	3.0
• Moderate oily discharge (oozes out freely), distinct odor, stains	Moderate	4.0
• Heavy oily discharge (free-flowing), very strong odor, stains	Heavy	5.0

VOL 12 2 1920

R0055220

B. **Substrate Fouling**

In order to qualitatively assess organic carbon, nutrient and sediment loadings, COG staff visually examined the stream substrate for evidence of the following: a.) patinas of silt/fine organic material and/or algal growth on the surface of stones and b.) slime coatings on the underside of stones. The stream assessment protocol employed in the study involved the inspection of 10 rocks (large gravel or larger sized material) per riffle. In general, three or more riffles were examined per BMP/receiving stream site.

A relative substrate fouling index based on a 1-5 descriptive scale was employed. Under this system, the 10 stones were composited into one sample so that a single riffle score could be assigned. Scoring was determined as follows:

Approximate % of Underside Surface Area 'Fouled'	Verbal Description	Point Value
0-5	None	1.0
6-15	Very Light	2.0
16-25	Light	3.0
26-50	Moderate	4.0
≥ 51	Heavy	5.0

Individual riffle scores were later averaged to produce one receiving stream substrate fouling score per BMP site.

VOL 12 2 1921

R0055221

C. Aquatic/Wildlife Habitat

A relative aquatic/wildlife habitat index system, which was based on a descriptive scale of 1-3, was employed in the study. As previously stated, under this system a value of one represented a low habitat value condition and a value of three indicated excellent site conditions. Factors used in assessing existing habitat conditions included, but were not limited to, the following:

- size of BMP site/pond area;
- extent of human presence and traffic (e.g., - proximity to roads; mowed areas, houses, etc.);
- size of water body/water source and amount of open water;
- type, size and age of surrounding forested area;
- water depth distribution;
- percent of pond bottom area supporting submerged aquatic vegetation (SAV) and emergent aquatic plants;
- observed vegetational community diversity, quality and quantity;
- presence or absence of downed trees, snags or other habitat features;
- water quality conditions; and
- observed faunal diversity

In general, the highest habitat scores were associated with older, large BMP pond sites which featured: surrounding mature deciduous forest; a large permanent pool size; near equal distribution between shallow water, mid-depth and deep water areas; 10-50% SAV coverage; large no-mow zones around the pond perimeter; and were physically connected to a larger, natural riparian corridor area.

Gravel 20% Sand 60% Silt ____ Other ____
Downstream: Gravel - 7.5%, Cobble - 17%, Sand - 12%, Silt - 5%

36. Degree of Embeddedness/Sediment Load: 1) Upstream: High amount of embedding and transport of sand. Approx. 0.5" of sand deposits along ~~toes~~ banks.
2) Downstream - low embedding, low sediment transport

37. Degree of Substrate "Fouling": 1) Upstream - high. Rocks & wood coated w/brown, floc-type material; 2) Downstream - mod.-low fouling.

38. General Aquatic/Riparian Habitat Condition(s):
1) Upstream - fair. Stream has few riffles, mostly series of pools & runs. Several pools over 2' deep. Stream has high sand load
2) Downstream - good. Stable banks w/veg. growing down to water. Good balance ~~between~~ pools and riffles. One pool approx. 2' deep.

39. Miscellaneous: 1) Observed no fish or crayfish upstream (only frogs).
2) Observed fish immediately downstream of 12" barrels.

40. Preliminary Stream Quality Rating: 1) Upstream - Fair. Macroinvert. diversity is relatively depauperate, water quality appears to be in fair range.
2) Downstream - good. Macroinvert. diversity is fairly good, water quality better than upstream.

Field Protocol For Oil/Grit Separators

1. Remove manhole covers and visually inspect for: a.)presence of oil sheen, b.)type and quantity of floatable materials present, and c.)height(in.) and quantity of oil coatings on side walls.

2. Verify: a.) type of trash rack and b.)diameter (in.) and type of elbow(s) present.

3. Measure Secchi Depth(in.) in both grit and oil chambers.

4. Measure depth(ft.) of permanent pool in both grit and oil chambers.

5. Determine average depth(in.) of sediment in both grit and oil chambers (avg. of 4 measurements per chamber).

6. Take 5 sediment "scoop" samples per chamber to form two composite samples (one composite sample per water holding chamber). Categorize residual material present in samples as to percent coarse grain, fine grain, and organic material. Qualitatively describe color, odor and amount of oil present.

7. Visually inspect condition of storm drain structure(s) draining to the oil/grit separator. Record presence or absence of blockages, flow by-pass/short-circuiting, andoverall operating condition of the system.

8. Take 2-4 photos per oil/grit separator and record photo no. and description on data sheet.

9. Replace manhole covers.

VOL 12 2 1933

R0055233

FIELD PROTOCOL FOR INFILTRATION TRENCH SYSTEMS WITH PRE-TREATMENT SUMP PITS/O-G SEPARATORS

1.) Remove manhole covers and observation well cap(s).

2.) Measure depth of standing water (in.) present in bottom of observation well(s). Calculate average depth (in.). If water is present, take sample from both well(s) and sump pit and qualitatively determine water clarity.

3.) Inspect sump pit for: a.) presence of oil sheen, b.) type and quantity of floatable materials present, and c.) height (in.) and quantity of oil coatings on side walls.

4.) Measure secchi depth (in.) in sump pit.

5.) Measure depth (ft.) of permanent pool in sump pit.

6.) Determine average depth (in.) of sediment in sump pit (avg. of 4 measurements per chamber).

7.) Take 5 sediment "scoop" samples from sump pit to form one composite sample. Categorize residual material present in sample as to percent fine grain, coarse grain and organic material.

8.) Replace manhole covers and observation well cap(s).

VOL 12 2 1934

R0055234

Appendix C:

Synopsis of Current Prince George's County SWM Design Criteria

VOL 12 2 1935

R0055235

I. Priority of Water Quality Measures to be Utilized

Where water quality measures are to be implemented onsite, the order of preference shall be as follows:

a) Infiltration practices
b) Retention facilities
c) Extended detention facilities
d) Oil/grit separators (commercial/industrial sites only) 200 cf/acre of impervious area.
e) A combination of other measures (i.e. tree preservation, grass swales, level spreaders, vegetated filter strips, check dams, etc...)

The concept approval letter requires the utilization of one of the measures listed above unless site constraints prove the measure infeasible, then generally the next measure down on the list must be selected and a revised concept approval must be obtained. If the quality measures required by the Concept letter cannot be implemented a revised concept approval must be obtained.

Infiltration Planning Considerations

Infiltration practices shall be designed for the 1/2" of runnoff from impervious surfaces, including rooftops. Infiltration practices may be waived if the conditions exist:

a) Soils are determined to have infiltration rates less than 0.5 inches per hour based on actual soils data boring. (Refer to Appendix 3-3 for Suitable Soils Listing and Appendix 3-4 for Unsuitable Soils Listing as a general guide.)

b) The area is determined to have a high water table (including seasonally high water tables). The minimum depth to the water table is 2 feet from the infiltration bed.

c) The site is located upgrade of and in close proximity to an unstable soils stratum, such as Marlboro Clay. (Refer to the Prince George's County map book delineation for Marlboro Clay outcrops and refer to Appendix 4-4).

d) The site is on existing slopes of 20% or greater.

Soil borings may be required in cases where a determination of infiltration feasibility is critical, e.g. where the development as proposed offers little opportunity for alternative water quality practices. Otherwise, available soils/water table data may be used at the concept approval stage.

In those cases where infiltration is determined to be infeasible, retention of the first 1/2 inch of runoff from the impervious area shall be considered.

VOL 12 2 1936

R0055236

II. General Guidelines for Water Quality Control

a) For Public facility measures:

- Retention (wet basins) - The perranent pool storage will be sized to hold 1/2 inch of runoff for all impervious areas within the area of development. For regional facilities, ultimate development of the total drainage area according to zoning maps shall be used. For all basins an additional 1-foot depth shall be provided for sedimentation.

- Extended Detention - The one-year 24-hour frequency storm will be detained temporarily for an additional 12 hours. This interval shall be measured by determining the time interval between the time of mass inflow centroid and the time of the mass outflow centroid. The extended detention volume may not be incorporated within the 2-year pool volume requirement.

- The most preferred extended detention design includes a shallow permanent pool. By designing a facility with a permanent pool, the pollutant removal is enhanced by allowing greater settling time. Settling column experiments have shown that suspended sediments will settle 70% within 6 hours under testing conditions (based on data presented in the "Controlling Urban Runoff" by C.O.G., 1986). Twelve (12) hours was selected to allow for less than ideal conditions as well as for capturing additional settling quantities.

- In order to ensure the expected settling, the design of the facility should be such that the flow length from the inflow point to the discharge point is maximized.

The release opening shall be no smaller than a 2-inch diameter orifice. The orifice must be protected by a trash rack or hood which is capable of preventing the orifice from blocking. Generally, a low flow-pipe discharging to the riser structure protected by a gravel blanket and slotted standpipe is sufficient. The preferred designs acceptable in Prince George's County are shown in detail in C.O.G.'s "Controlling Urban Runoff Manual, July, 1987.

b) Private On-Site and Off-Site Facility Measures:

- Retention Systems (Wet Basins) - These facilities will store the first 1/2 inch of runoff for the impervious area of the site. Underground storage retention is not permitted.

- Extended Detention - These facilities will store 1/2 inch of runoff for the impervious area of the site and release this volume over a period of 24-hours. The detention time may be reduced to 10 hours for a drainage area less than the following:

VOL 12 2 1937

R0055237

Type	Approximate % of Imperviousness	Acreage
Low Density Residential (RE, RR, R80, R55)	20	50
Med Density Residential (R35, RT, R20, R30, R18)	50	20
High Density Residential (R-H, R10, R-10A), and Industrial (I1, I2, I3, I4)	80	10
Commercial (C1, CO, CA, CC, CG, etc.)	90	10

Other developments not listed may reduce the detention time to 10 hours when the total volume of 1/2 inch of runoff for the impervious area is less than 18,000 cubic feet.

III. General Design Considerations

a) Riser structures must be reinforced concrete (Appendix 4-24 E). Outfall pipes must be round, reinforced concrete pipe with rubber gasket joints and anti-seep collars as per ASTM C-361 and SCS MD378 (Appendix 4-27). Outflow pipes require a low concrete cradle within the embankment area. Provide a concrete cradle detail (Appendix4-24 D).

b) Sodded embankment and side slopes are to be 3 feet horizontal to 1 foot vertical maximum (3:1).

c) All dams require a minimum of a 5' deep core trench below the existing ground. Note: Where necessary or as determined by the soils engineer, the core trench may need to be extended to reach suitable material as determined in the MD378.

d) For dry basins passing a continuous stream flow, the vegetated floor is to have a 2 percent minimum slope to direct the flow toward the riser area. A rip-rap pilot channel is to be provided to prevent erosion of the facility. Appropriate vegetation is to be provided along the pilot channel to allow for temperature reduction.

e) Soil boring locations are to be shown on the plan view, profile and cross-section of the center line of dam.

f) If the design includes a permanent pool, a pond drain capable of draining the pond within a 24 hour time period shall be provided.

VOL 12 2 1938

R0055238

g) For all basins, the assumed phreatic line shall be drawn at a four horizontal to one vertical slope from the intersection of the 10 year W.S.E.L. and the embankment to the invert of the outflow pipe, unless specified (100 year W.S.E.L.) by WPB.

h) Stormwater management riser structure openings shall be protected from clogging by trash racks:

- The dimensions of the trash rack openings shall be no larger than three-quarters the dimension of the opening to be protected. The minimum dimension will be not less than 6 inches unless otherwise directed by WPB.

- The trash rack on the primary outflow shall have 6 times the cross-sectional area of the outflow protected opening. Computations must indicate that the criteria is met.

- Vertical bars shall be located outside of horizontal bars and spaced 9 inches maximum on center.

- The trash rack shall project out a minimum of 6" from the riser wall.

- The reinforcing bars used in the fabrication of a trash rack shall be sized according to the design. However, in no case bars less than 1/2" (#4) shall be utilized. All trash racks shall be painted with battleship gray paint to prevent corrosion.

i) For basins with permanent pools, provide a hood or inverted elbow over the orifice opening to prevent oils and other floatable objects from leaving the pond. The hood should extend at least 12 inches below the surface of the permanent pool. Be sure that adequate clearance is provided below the inverted elbow to avoid blockage (minimum 1').

j) If it can be incorporated into the design, the elbow or hood should draw from the bottom 1/3 of the permanent pool to provide a cooler discharge and to minimize the effects of thermal pollution.

k) Show all physical improvements and existing conditions. Provide 1' or 2' contour intervals to define surface features.

l) Show all storm drainage inflow and outflow improvements and provide adequate rip-rap protection extending into wet pool areas or into pilot channels in dry pool areas.

m) Provide sections, details and profiles of the SWM embankment, with pertinent supporting information.

n) Risers designs will require structural review if nonstandard design.

VOL 12 2 1939

R0055239

o) Outfall protection shall be based on the 10-year discharge from the facility. The outfall should be protected as per SCS outfall protection charts and rip-rap shall be sized accordingly. (Appendix 4-10)

p) For basins with maintenance benches, all storm drain outfalls must be located beyond the bench and next to the permanent pool W.S.E.L. The bench may be slightly elevated to allow for the pipe crossing with a 1-foot minimum cover for the pipe crossing.

q) The riser/barrel connection shall be water-tight and sealed by using proper water stops.

r) Construction specifications notes should be provided on the stormwater management plan as per Appendix 4-12.

Infiltration Devices

General

Infiltration systems shall be designed in accordance with the current WRA "Standards and Specifications for Infiltration Practices." The manual is available through the State of Maryland, MDE. Infiltration facilities shall also meet the following guidelines and criteria:

1) Field Investigation

a) To be done by boring or open excavation.

b) Soil description to include all soil horizons.

c) Soil texture to be identified according to USDA soil classification.

d) Soil boring depth shall extend a sufficient distance below the bottom of the proposed trench to determine groundwater conditions. The required water table buffer (seasonally variable; see appendix 4-24A) or at least 2' below the bottom of the trench, whichever is greater.

e) Ground water elevation to be recorded at time of boring and after 24 hours. Based on this information, the seasonal high ground water table shall be determined.

2) Detailed Laboratory and Field Tests

a) Grain-size sieve analysis and hydrometer tests where appropriate are required to determine USDA classification.

b) Insitu infiltration tests may be used to determine infiltration rate by one of the following methods if desired:

- Health Department Constant Test (perc. test)

- Flooding basin

VOL 12 2 1940

R0055240

- Cylinder Infiltrometer

- Air entry permeator

c) Soil boring locations to correspond to location of proposed infiltration trenches.

d) A minimum of one boring for every 50' length of infiltration trench.

e) Soil boring location stakes to be left in the field for inspection purposes.

f) Soils investigation to be performed by licensed soils or geotechnical engineer.

3) Infiltration trench not permitted in Marlboro Clays. Check geological information for presence of Marlboro Clays.

Trench Design Criteria

1) Infiltration systems shall be located at least 25 feet, horizontal distance, from basement walls.

2) Special consideration should be made for excessive depth of infiltration trenches.

3) Infiltration systems designed to handle runoff from commercial or industrial impervious parking areas shall be a minimum of 100 feet from any water supply well.

4) An observation well is required for each trench.

5) Infiltration systems shall not receive runoff until the entire contributory drainage area to the infiltration system is permanently stabilized.

6) Soil borings must indicate depth to seasonal high water table and bedrock, if any. Minimum distance acceptable from bottom of trench and water table is 2.0'.

7) Generally, soil borings shall be located within the infiltration facility boundary and shown on the SWM plan view sheet. In addition, soil suitability shall be field-verified at the time of installation.

8) Notes shall be provided indicating infiltration construction specifications. See Appendix 4-9 for notes.

9) Appropriate ROWs are to be provided in accordance with the easement and rights-of-way chapter for public systems.

VOL 12 2 1941

R0055241

10) Provide a 6" layer of clean, washed sand in place of filter fabric on the bottom of the trench; (Note: This area is not to be included in the trench volume computations.)

11) All dimensions of the trench shall be shown on the detail sheet. Provide adequate information, inverts, elevations and dimensions as necessary for all pipes and trenches.

12) Provide approved filter cloth on top and sides of trench.

13) A minimum of 5' horizontal distance shall be maintained between a utility line and infiltration trench. No utility line should be placed over, under or within infiltration trench.

14) The infiltration trench shall not be placed in fill area.

15) The infiltration trench shall not be placed on slopes greater then 20%. When the trench is placed on a slope, the trench should be a minimum of 25' away from the proposed grade.

16) No more then 1/2 acre of impervious area for residential development and 1 acre impervious area for commercial should drain to an infiltration trench for each inlet. Also Tc for impervious area should not be more than 5 minutes.

17) The infiltration trench should not be provided at a location which could cause water problems in down grade properties.

18) Trenches shall be filled with 1 1/2" to 3" washed bank-run gravel or Md. #2 or #3 washed crushed bluestone. Bluestone must be obtained from an approved supplier.

19) Minimum allowable void ratio is .35.

20) Infiltration structures shall not be placed upstream of Marlboro Clay outcrops.

21) Locations of trenches shall be shown on plan view and profile of the storm drain plans.

22) Maximum trench depth should be such that it will drain within 72 hours.

23) The surface drainage systems require a minimum of a 20-foot grass buffer filter prior to runoff entering the trench.

24) Infiltration trenches shall not be utilized as an integral part of the main conveyance system. If the trench runoff is received via a storm drainage system, the trench must be located "off-line". An off-line trench shall be connected to an inlet structure that has a sump chamber with minimum depth of 3' below the trench inlet pipe. (Appendix 4-9 for sample detail)

VOL 12 2 1942

R0055242

25) The invert of the outfall discharge pipe shall be higher than the invert of the infiltration feeder pipe by the head plus 1/2 pipe diameter of feeder pipe required for the peak inflow into the infiltration trench.

26) Plans should specify the perforation spacing and sizing with the minimum total area > 5x the cross-sectional area of the feeder pipe in the trench.

27) The minimum allowable infiltration rate 0.50 inches/hour.

Oil and Grit Separators

General

Oil-grit separators may be used if approved by the Stormwater Concept Section to enhance water quality from small commercial areas when the preferred water quality measures have been proven infeasible. Oil-grit separators are applicable in areas where heavy automobile traffic and/or parking lots contribute large loads of oil, grit and trash to runoff water. (Appendix 4-11 for sample detail)

Design Procedures

1) Size the structure horizontally by computing the volume of storage needed for the oil. Provide 200 cubic-feet of storage per acre of impervious parking area directed to the structure. The depth of the oil storage shall be a minimum of 3 feet measured from the normal pool surface down to the intake end of the 90-degree elbow pipe. The depth of grit storage shall be 1.5 feet minimum under the oil storage.

   a) The first two chambers are for storage and the third chamber is for controlling the discharge and does not contribute to the storage volume.

   b) The minimum acceptable width of the chambers is 3 feet.

   c) Oil storage volume should be calculated as the total length of the 1st and 2nd chambers x width x length of drawdown pipe.

   d) The minimum depth from the normal pool surface to bottom of the structure shall be 4.5'.

   e) Size the structure vertically by first establishing the inverts of the inflow and outflow pipes. The invert of the inflow pipe shall not be lower than the normal pool elevation. The invert of the outflow pipe should allow enough head to pass the 10-year storm discharge.

   f) The trash rack protecting the orifices shall have an area 3 x the combined area of the orifices.

VOL 12 2 1943

R0055243

g) Determine the size of 90-degree elbow pipe that could pass the 10-year storm discharge through the structure allowing for 1-foot of freeboard.

2. Show the hydraulic gradient through each chamber of the structure based on the 10-year storm. Assume that the velocity head is zero and the gradient will be at the water surface. The hydraulic gradient shall not be higher than the proposed grade. Provide one foot of freeboard from the HGL to the top slab.

IV. Stormwater Management Quantity Requirements

Generally all developments will be required to attenuate the 2-year and 10-year storms using the following control structures (listed in preferred order):

a) Regional Stormwater Management Facility
b) Onsite facility
c) Infiltration combined with "b" above when no other quantity management option is available.

Required water quality measures may be incorporated with the stormwater attenuation facilities or installed separately. 100 year storm attenuation will generally be required only in cases where potential for flooding of downgrade developed properties exist.

2 = Moderate (basin size, size of perm pool, vegetation and/or BMP location mod. limiting to fauna)
3 = High (basin size, size of perm pool, vegetation and/or BMP location capable of supporting diverse faunal community)

1/ = Except for I-29 str. 11, Secchi Depth = Max. water depth.

2/ = Percent of basin surface area covered with emergent plants (e.g. - cattails).

3/ = Basin has 90ft. long veg. filt. for pretreatment.

Date: 10/17/91
Observer: John Galli (MWCOG)

Stormflow Monitoring Chronology for Decatur Heights Oil/Grit Separator (G-10)

Time	Observation/Measurement
1440 Hrs.	• Secchi Depth - 22cm grit chamber, 22 cm oil chamber TDS - 40 mg/L grit ch., 40 mg/L oil ch. Water depth - 4'-9" grit ch., 4'-9" oil ch.;
* 1453 Hrs.	• Released dye capsule #1 into stormwater runoff flowing along curb (approx. 8 ft. from throat inlet)
	• Dye immediately mixed with runoff and flowed into grit chamber;
1457 Hrs.	• Green dye observed covering surface of grit chamber (which contained moderate amount of floatables);
	• No dye observed in oil chamber;
	• Dye strength in girt chamber is generally weak;
1500 Hrs.	• Released 2nd dye capsule along curb;
* 1512 Hrs.	• Green dye observed in oil chamber - covers approx. 15% of surface area (concentrated in front, right hand corner near M.H. Steps).
1515 Hrs.	• Discharge from elbow into outfall chamber is 13.6 gal/min.. Rainfall intensity is light;
	• Photo ref. #12 = green dye in grit chamber;
* 1518 Hrs.	• Rainfall intensity increased to moderate level;
	• Water in grit chamber slightly more turbulent at point of inflow, oil chamber - quiescent;
** 1519 Hrs.	• Light trace of green dye observed flowing into outfall chamber (chamber # 3);
	• Photo ref. # 15 = white bucket with green dye water taken from outfall chamber;

R0055282

VOL 12 2 1982

10/17 Field Monitoring of G10 Cont'd.

Time	Observation/Measurement
	• Photo ref. # 16 = green dye flowing out of elbow;
1524 Hrs.	• All three chambers bright green (ie - full strength), complete mixing/stasis appears to have been achieved;
	• Photo ref. # 17 = bright green dye in oil chamber;
1530 Hrs.	• Discharge from elbow into outfall chamber is now 60.0 gal./min (discharge rate basically unchanged from 1520 Hrs.);
1532 Hrs.	• Photo ref. # 19 = green dye in outfall chamber
1539 Hrs.	• Permanent Pool/Water depth: grit chamber - 4'-10", oil chamber 4'-9", outfall chamber - 12"; Note, 1 in. head difference between grit and oil chambers;
	• Avg. sediment depth: (based on 4 measurements) grit chamber - 3.0" oil chamber - 0.5"
1545 Hrs.	• Rainfall intensity has slacked-off to very light drizzle;
1550 Hrs.	• Discharge from elbow into outfall chamber is 15.0 gal/min.;
1600 Hrs.	• All chambers still bright green;
1600 - 1620 Hrs.	• Rain stopped. Little runoff entering O/G separator;
1620 - 1720 Hrs.	• Rainfall intensity moderate;
1720 Hrs.	• Green dye still visible in grit chamber, but strength greatly reduced (approx. 30% of maximum);
	• Oil chamber is still green. Dye strength is approx. 40-50% of maximum;
	• Light trace of dye still visible in discharge from elbow into outfall chamber.
	• Discharge from elbow approx. the same as that of 1530 hrs.
1730 Hrs.	• Closed all manhole covers.

VOL 12 2 1983

R0055283

10/17 Field Monitoring of G10 Cont'd.

Miscellaneous:

- Dye used is marine distress type;
- Approx. 0.25 in of rain fell between 1440 and 1730 Hrs.;
- 1 Liter water sample collected from each chamber prior to release of dye;
- All three chambers contained significant oil sheens. Discharge from oil chamber to outfall chamber relatively clear, low to mod. amt. of suspended solids with oil globules noted;
- Normal permanent pool depth for G-10 is 4'-7";
- Sediment depths on 10/17 almost identical to those recorded on 5/13;
- 3 ft. deep sink hole has developed approx. 12' downslope of the outfall chamber. Green dye observed flowing through bottom of sink hole.
- Rescued small snapping turtle swimming in grit chamber.

January 3, 1995

Mr. Gerard J. Thibeault
Santa Ana Regional Water
Quality Control Board
2010 Iowa Avenue, Suite 100
Riverside, CA 92507-2409

Dear Mr. Thibeault: Re: NPDES Permit Application

On behalf of the Riverside County Flood Control District and the Cities and Countyof Riverside County within the Santa Ana drainage area, we are submitting the enclosed application for the renewal of our NPDES municipal stormwater permit. Our existing NPDES permit (Order 90-104), which expires on July 1, 1995, requires us to submit for renewal 180 days before expiration.

This application addresses the requirements listed in the our existing NPDES permit and also addresses the October 11, 1994 "Municipal Stormwater Resources Management Plan Components" guidance prepared by the Regional and State Board staffs. A similar application for permit renewal for the Santa Margarita area of Riverside County will be submitted to the San Diego Regional Water Quality Control Board (RWQCB) by January 17, 1995.

There are three items presented in the application that I would like to note to you in this letter as follows:

1. The area currently covered by the existing permit includes all of Riverside County within the jurisdiction of the Santa Ana RQWCB. We have, of course, been concentrating our efforts in the cities and urbanized areas of the County. We wish to continue to focus our resources on these 'municipal areas of greatest concern'. To address this objective, a set of criteria was developed which denotes areas not within the jurisdiction of the permittees (Federal and State facilities), excluded from coverage under the stormwater program (agricultural operations), or not within the intent of the municipal program (open space and vacant undeveloped properties). Our application proposes that the new permit include a reference to these three criteria stating that our programs need not apply to them.

2. We have included in the application a proposed permit for your consideration. The proposed permit is written to reference the plans and documents that we have already developed during the current permit period. This proposed permit (modified for that area) will be presented to the San Diego RWQCB in order to promote consistency between the two permit areas.

January 3, 1995

Mr. Gerard J. Thibeault
Santa Ana Regional Water
Quality Control Board
2010 Iowa Avenue, Suite 100
Riverside, CA 92507-2409

Dear Mr. Thibeault:

Re: NPDES Permit Application

On behalf of the Riverside County Flood Control District and the Cities and Countyof Riverside County within the Santa Ana drainage area, we are submitting the enclosed application for the renewal of our NPDES municipal stormwater permit. Our existing NPDES permit (Order 90-104), which expires on July 1, 1995, requires us to submit for renewal 180 days before expiration.

This application addresses the requirements listed in the our existing NPDES permit and also addresses the October 11, 1994 "Municipal Stormwater Resources Management Plan Components" guidance prepared by the Regional and State Board staffs. A similar application for permit renewal for the Santa Margarita area of Riverside County will be submitted to the San Diego Regional Water Quality Control Board (RWQCB) by January 17, 1995.

There are three items presented in the application that I would like to note to you in this letter as follows:

1. The area currently covered by the existing permit includes all of Riverside County within the jurisdiction of the Santa Ana RQWCB. We have, of course, been concentrating our efforts in the cities and urbanized areas of the County. We wish to continue to focus our resources on these 'municipal areas of greatest concern'. To address this objective, a set of criteria was developed which denotes areas not within the jurisdiction of the permittees (Federal and State facilities), excluded from coverage under the stormwater program (agricultural operations), or not within the intent of the municipal program (open space and vacant undeveloped properties). Our application proposes that the new permit include a reference to these three criteria stating that our programs need not apply to them.

2. We have included in the application a proposed permit for your consideration. The proposed permit is written to reference the plans and documents that we have already developed during the current permit period. This proposed permit (modified for that area) will be presented to the San Diego RWQCB in order to promote consistency between the two permit areas.

VOL 12 2 1989

3. Opportunities for coordinating some municipal stormwater programs on a regional, State-wide and national level are currently under consideration and may become available during the next permit period. These opportunities currently include public education and stormwater sampling. The application and the proposed permit provide the flexibility for modifying compliance programs in order to join the coordinating efforts as they become available.

As noted in our discussions with Ms. Pavlova Vitale of your office, additional implementation assistance will be needed for the permittees. Following submittal of this application, we will begin preparation of individual implementation matrices for each of the permittees. Two types of matrices will be provided. The first matrix will identify all of the compliance best management practices (BMPs), department(s) responsible for implementation, references for program requirements, schedule and man-hour requirements. The second type of matrix will be similar to the first; however, it will identify for each department, all of the BMPs for which they have implementation responsibility and the other information provided in the first matrix. We believe that these matrices will facilitate understanding and implementation of the permit requirements and the municipal stormwater program.

Based on our conversations with Ms. Vitale, we understand that the specific provisions of the application will be open to discussion and comment through May of 1995. During that time we will provide any additional information requested.

I would like to thank you and your staff for your continued cooperation and support which you have provided to us and the other permittees in this program. We look forward to working with you in the development and implementation of the permit programs. If you have any questions, please call me at 909/275-1250 or Jason Christie at 909/275-1273.

Very truly yours,

Kenneth L. Edwards

SECTION 1

R0055301

1.1 MUNICIPAL STORMWATER NPDES PERMIT PROGRAM

1.1.1 Federal NPDES Stormwater Regulations

In 1987 Congress enacted the Water Quality Act (WQA) which amended portions of the Clean Water Act (CWA) and set requirements for permitting stormwater runoff. Section 402(p) of the CWA required that the United States Environmental Protection Agency (USEPA) establish regulations setting forth a program for National Pollutant Discharge Elimination System (NPDES) applications and corresponding permits for discharges from municipal and industrial separate storm drain systems. USEPA published its draft regulations in December 1989 for review and comment.

The Final Rule for NPDES Permit Application Regulations for Storm Water Discharges was published on November 16, 1990. The Final Rule specifies who is covered by the regulations; prescribes a variety of required information-gathering, planning, and reporting activities; and sets forth a schedule for compliance with the two-part permit application requirements. The Final Rule also sets forth specific application requirements for identified industries.

1.1.2 Stormwater NPDES Permitting in California

In most states, including California, the NPDES permitting program is administered at the state level, rather than by USEPA. California's Porter-Cologne Water Quality Control Act established the State Water Resources Control Board (SWRCB) and the system of nine Regional Water Quality Control Boards (RWQCBs) (Section 13000, "Water Quality," et seq., of the California Water Code). The SWRCB sets statewide policy and, together with the RWQCBs, implements state and federal laws and regulations, including the NPDES program.

VOL 12 2 2002

R0055302

1.1.2.1 Municipal Stormwater NPDES Permitting

Prior to publishing of the Final Rule, representatives from USEPA's Region IX office and the SWRCB worked with many local municipal agencies (especially in Southern California) and encouraged them to seek "early" NPDES stormwater permits before the final regulations were promulgated. The objective was to give the municipal agencies (as permittees) and the respective RWQCBs the flexibility to tailor the permit requirements to conditions in California while meeting the statutory requirements of the CWA. It was also viewed as a means of facilitating prompt implementation of municipal stormwater management programs, rather than waiting for two or more years for the two-step permitting process.

1.1.2.2 Industrial Stormwater NPDES Permitting

To implement the industry-related provisions of the federal stormwater regulations, the SWRCB adopted the General Industrial Activities Stormwater Permit (Industrial Permit). The Industrial Permit mandates that regulated industries must file for coverage, prepare and implement a stormwater pollution prevention plan (SWPPP) and a monitoring program, and report annually. The monitoring program requires dry-weather observations, wet-weather observations, and stormwater sampling. Industrial facilities that discharge stormwater to a municipal storm drain system must also comply with additional stormwater requirements established by the municipality where the facility is located.

1.1.2.3 Construction Stormwater NPDES Permitting

To implement the construction-related provisions of the federal stormwater regulations, the SWRCB adopted the General Construction Activities Stormwater Permit (Construction Stormwater Permit). The Construction Stormwater Permit currently applies to projects which disturb five or more acres of land area. In the future, in response to a lawsuit by the National Resources Defense Council and a decision by the Ninth Circuit Court of Appeals, the USEPA is expected to issue new regulations which may reduce the five-acre threshold.

The Construction Stormwater Permit mandates that regulated projects file for coverage and prepare a SWPPP and a monitoring program. Unlike the Industrial Permit, the Construction Stormwater Permit does not require stormwater sampling. However,

VOL 12 2 2003

R0055303

dischargers are required to conduct regular visual inspections of the construction site to assess if the stormwater quality controls identified in the SWPPP are functioning properly and if additional controls are needed. As with the Industrial Permit, construction sites that discharge stormwater to a municipal storm drain system must also comply with additional stormwater requirements established by the municipality where the construction site is located. Since most construction is primarily regulated at the local level, the SWRCB strongly encourages management programs associated with municipal stormwater NPDES permits to require construction projects to comply with the provisions of the Construction Stormwater Permit and to develop and enforce local policies and ordinances that address stormwater quality from construction sites.

1.2 RIVERSIDE COUNTY MUNICIPAL STORMWATER NPDES PERMITS

Portions of Riverside County fall under the jurisdiction of three RWQCBs. Roughly, the northwest quarter of the county falls under the jurisdiction of the Santa Ana RWQCB; the southwest quarter falls under the San Diego RWQCB; and the eastern half falls under the Colorado River Basin RWQCB.

In May 1990, the Riverside County Flood Control and Water Conservation District (RCFC&WCD) and the County of Riverside (County) joined with the cities of Beaumont, Corona, Hemet, Lake Elsinore, Moreno Valley, Norco, Perris, Riverside, and San Jacinto to prepare and submit an application for an NPDES municipal stormwater discharge permit for the Santa Ana region of the county. An "early" permit was issued in July 1990 by the Santa Ana RWQCB (Board Order 90-104). That permit is referred to throughout this document as the Santa Ana Permit. On July 10, 1992, the newly incorporated cities of Calimesa and Canyon Lake were added to the Santa Ana Permit. The RCFC&WCD is the Principal Permittee, and the remaining 11 municipalities and the County are considered Co-Permittees. The Principal Permittee and the Co-Permittees are referred to collectively as the Permittees. A copy of the Santa Ana Permit is included as Appendix A.

In June 1990, the RCFC&WCD and the County joined with the City of Temecula to prepare and submit an NPDES permit application for an area-wide stormwater discharge permit for the Santa Margarita region of the county. An "early" permit for this area was issued in July 1990 by the San Diego RWQCB (Board Order 90-46). On May 18, 1992, the

VOL 12 2 2004

R0055304

City of Murrieta was added to that permit. The RCFC&WCD is the Principal Permittee, and the two municipalities and the County are considered Co-Permittees.

On May 16, 1994, a Part II Municipal Permit Application for compliance with the federal NPDES municipal stormwater regulations was submitted to the Colorado River Basin RWQCB for the eastern areas of Riverside County. The co-applicants included the RCFC&WCD, the County, and the cities of Banning, Cathedral City, Coachella, Desert Hot Springs, Indian Wells, Indio, La Quinta, Palm Desert, Palm Springs, Rancho Mirage, and the Coachella Valley Water District. As of this writing, no response to this application has been received from the Colorado River Basin RWQCB.

1.3 MISSION STATEMENT

The Permittees of the Riverside County municipal stormwater NPDES permits are committed to a cooperative program of pollution control measure activities which reduce or eliminate pollutants in stormwater to the maximum extent practicable. This program minimizes the impact on public and private resources and maximizes the benefits to the community by improving the environment. The program emphasizes pollution prevention, control measure activities, utilization of existing resources and programs, and coordination with regional and state compliance activities.

1.4 ORGANIZATION OF PERMIT APPLICATION

This municipal stormwater NPDES application for permit renewal (Permit Application) addresses the Report of Waste Discharge requirements for permit renewal as described in Section 2.3 of this report. In addition, information described in the "Municipal Stormwater Management Plan Components" guidance document dated October 11, 1994, which was prepared by the SWRCB in consultation with the RWQCBs, is generally addressed. In discussions with Santa Ana RWQCB staff, this guidance document has been described as only advisory since it has not been officially adopted by either the SWRCB or the RWQCBs.

To effectively communicate the interests and concerns of the Permittees and to facilitate coordination with the information provided in this Permit Application, a draft permit has been prepared for consideration by the Santa Ana RWQCB and is presented in Section 11.0.

VOL 12 2 2005

R0055305

VOL 12

2

2006

SECTION 2

R0055306

2.1 SANTA ANA DRAINAGE AREA

Approximately one-quarter of Riverside County drains into water bodies within the Santa Ana RWQCB area. About 1,360 square miles of the Santa Ana RWQCB area is under the jurisdiction of the RCFC&WCD. This area has a population of approximately 930,000. Stormwater discharges from urbanized areas within the Santa Ana RWQCB area consist mainly of surface runoff from residential, commercial, and industrial development. The RCFC&WCD's storm drain system includes an estimated 200 miles of drainage facilities. The Co-Permittee's storm drain systems include an estimated 57 miles of drainage facilities. Maps of the existing storm drain facilities are included as Appendix B, which is bound as a separate volume of this Application.

The surface water bodies (or portions thereof) in Riverside County within the Santa Ana RWQCB area are:

Rivers and Streams

- Santa Ana River, Reaches 3 and 4
- Tributary to South Bank of Santa Ana River
  - Tequesquite Arroyo (Sycamore Creek)
  - Temescal Creek, Reaches 1, 2, 3, 4, 5, and 6
  - tributaries to Temescal Creek
    - Coldwater Canyon Creek
    - Bedford Canyon Creek
  - other tributaries to these creeks
- Tributary to North Bank of Santa Ana River
  - Day Creek
  - San Sevaine Creek

VOL 12
2
2007
R0055307

- San Jacinto River Basin
  - San Jacinto River, Reaches 1, 2, 3, 4, 5, 6, and 7
  - Bautista Creek, headwaters to Debris Dam
  - Strawberry Creek
  - San Jacinto River, North Fork
  - Fuller Mill Creek
  - Stone Creek
  - Salt Creek
  - other tributaries: Indian, Hurkey, Poppet, and Potrero Creeks
- San Timoteo Creek Area Streams
  - San Timoteo Creek, Reaches 3 and 4
  - Little San Gorgonio Creek
  - other tributaries to these creeks, both mountain and valley reaches

Lakes and Reservoirs

- Lake Evans
- Lake Mathews
- Canyon Lake
- Lake Fulmor
- Lake Perris
- Lee Lake
- Mockingbird Reservoir
- Lake Elsinore
- Lake Hemet

The beneficial uses of these surface water bodies include: municipal and domestic supply, agricultural supply, industrial service supply, industrial process supply, groundwater recharge, water contact recreation, non-contact water recreation, warm freshwater habitat, cold freshwater habitat, wildlife habitat, and preservation of rare and endangered species.

The major topographic features in the area inciude the Santa Ana, San Jacinto, San Bernardino, and Little San Bernardino Mountains. The Santa Ana Mountain range trends southeasterly along the western border of Riverside County and forms a barrier between the Pacific Ocean and the inland valleys of Riverside County. However, the major orographic barrier in the region lies approximately 50 miles to the east. It is comprised of the San Bernardino and San Jacinto Mountain ranges, which also trend southeasterly across Riverside County. Between the Santa Ana and the San Bernardino-San Jacinto barriers lies an area of broken topography including valleys, plateaus, and minor mountain ranges. Most of the mountainous regions of Riverside County lie either in the Cleveland or San Bernardino National Forests.

VOL 12 2 2008

R0055308

Historically, the inland valleys have been devoted primarily to agriculture. Land uses within the county currently range from residential and commercial to mining and agriculture. Agricultural land uses include citrus and fruit orchards; row crops, such as sugar beets and potatoes; and pasture land, both irrigated and dry; dairies; and stockyards. However, over the past 15 years, urbanization has steadily increased, and development has occurred at an unprecedented pace in many areas of Riverside County.

2.2 SANTA ANA REGIONAL DRAINAGE AREA MANAGEMENT PLAN

The Santa Ana Permit required the development of a drainage area management program. The Permittees submitted the Santa Ana Regional Drainage Area Management Plan (DAMP) to the Santa Ana RWQCB in February 1993. The DAMP was approved by the Santa Ana RWQCB on January 18, 1994. The DAMP is included in this Permit Application by reference.

The DAMP describes 34 best management practices (BMPs) to be developed and implemented: 13 regulatory BMPs, 3 solid waste BMPs, 6 operation and maintenance BMPs, and 12 educational BMPs. Specific actions necessary to implement the BMPs and a schedule for BMP implementation are also presented in the DAMP.

Progress reports on the implementation of the DAMP were submitted to the Santa Ana RWQCB in 1993 and 1994. The Permittees will revise the DAMP by July 31, 1997. An annual progress report on implementation of the DAMP will be submitted to the Santa Ana RWQCB by September 30 of each year during the permit period.

2.3 APPLICATION REQUIREMENTS OF SANTA ANA RWQCB ORDER 90-104

Santa Ana RWQCB Order 90-104 expires on July 1, 1995. In accordance with Title 23, Chapter 3, Subchapter 9 of the California Code of Regulations, a Report of Waste Discharge must be filed no later than 180 days before the expiration date as an application for a new waste discharge permit. The Santa Ana Permit requires that the Report of Waste

VOL 12 2 2009

R0055309

Discharge "shall include, but is not limited to, the following:

a. Summary of the results of the monitoring program.

b. Summary of the BMPs implemented and evaluations of their effectiveness.

c. Summary of the procedures implemented to detect, identify, and eliminate illegal discharges and illicit disposal practices and an evaluation of their effectiveness.

d. Summary of enforcement procedures and actions taken to require stormwater dischargers to comply with the approved stormwater management programs.

e. Summary of measures implemented to control pollutants in surface runoff from construction sites and an evaluation of their effectiveness.

f. Evaluation of the need for additional BMPs, source control, and/or structural control measures.

g. Proposed plan of stormwater/urban runoff quality management activities that will be undertaken during the term of the next permit.

h. Any significant changes to the storm drain systems, outfall locations, detention/retention basins, and structural/nonstructural controls."

In addition to these requirements, the Santa Ana RWQCB staff has endorsed the "Municipal Stormwater Management Plan Components" guidance document dated October 11, 1994. Although it is not a regulatory requirement, this Permit Application generally follows this guidance document.

2.4 AREA COVERED UNDER THE PERMIT APPLICATION

Currently, all of that portion of Riverside County within the jurisdiction of the Santa Ana RWQCB is included under the Santa Ana Permit. However, that permitted area includes large areas to which the municipal stormwater NPDES regulations were not intended to apply and areas not under the jurisdiction of the Permittees. The municipal stormwater NPDES regulations are intended to address stormwater discharges from urbanized areas (i.e., areas with commercial, industrial, or residential land uses) which discharge to municipal separate storm sewers.

VOL 12

2

2010

R0055310

To allow the Permittees to focus their resources on managing stormwater from municipal areas under their respective jurisdictions, this Permit Application proposes to exclude from coverage under the new permit the following areas, for the reasons described:

- national parks and monuments - these areas are not under the jurisdiction of the Permittees or within the intent of the stormwater provisions of the Clean Water Act;
- state and federal facilities - these facilities are not under the jurisdiction of the Permittees;
- Native American tribal lands - these areas are not under the jurisdiction of the state or the Permittees and are regulated directly by the USEPA (i.e., not through the California SWRCB or the RWQCBs);
- Caltrans facilities - Caltrans facilities and operations are not under the jurisdiction of the Permittees and are being permitted separately by the RWQCB;
- open space and rural (non-urbanized) areas - these areas are not within the intent of the stormwater provisions of the Clean Water Act. For the purposes of this application, these areas have been identified as those census tract areas: 1) with a population density of less than 200 per square mile; 2) with a density of 100 parcels per square mile; and 3) with a density of 50 parcels with structures per square mile;
- agricultural areas - these activities are specifically excluded under the provisions of the Clean Water Act; and
- utilities and special districts - these facilities and operations are not under the jurisdiction of the Permittees (e.g., Lake Mathews, University of California - Riverside, public schools, etc.).

As a partial illustration, Figure 2-1 generally depicts state and federal lands in Riverside County within the jurisdiction of the Santa Ana RWQCB for which coverage under a municipal stormwater NPDES permit is not requested. As presently non-urbanized areas become developed, they will be added to the permitted area. For example, as areas are proposed for development, standard conditions of approval will be applied and compliance with local stormwater and construction/grading ordinances will be required, as will compliance with the Construction Stormwater Permit. In addition, the Santa Ana RWQCB

VOL 12 2 2011

R0055311

may add state agencies, special districts, federal agencies, or other entities to the new permit. The Permittees will rely on the Santa Ana RWQCB to regulate the compliance of state and federal agencies with the stormwater requirements as it has sole jurisdiction for their compliance with NPDES.

R0055316

3.1 PROGRAM STRUCTURE AND ORGANIZATION

3.1.1 Administrative Organization

The RCFC&WCD is designated as the Principal Permittee in the Santa Ana Permit. The County of Riverside and the following cities are Co-Permittees in the Santa Ana Permit:

- Beaumont
- Canyon Lake
- Hemet
- Morena Valley
- Perris
- San Jacinto
- Calimesa
- Corona
- Lake Elsinore
- Norco
- Riverside

A list of Permittee contacts for the municipal stormwater NPDES program is provided in Appendix C.

The RCFC&WCD and the Co-Permittees are co-applicants for this Permit Application. Copies of letters of intent to participate in the Riverside County municipal stormwater NPDES program are included in Appendix D.

The relationship between the Principal Permittee and the Co-Permittees and the committees is depicted in the organization chart, which is included as Figure 3-1. To facilitate coordination of the Riverside County stormwater compliance activities, the Santa Margarita Advisory Committee has been combined with the Santa Ana Advisory Committee and sub-committees.

The responsibilities of the Principal Permittee and the Co-Permittees are defined in the Santa Ana Permit and the Implementation Agreement. The responsibilities of the Principal

VOL 12 2 2017

R0055317

Permittee are:

- coordinate compliance activities with the Co-Permittees;
- prepare operating budgets for the RCFC&WCD activities;
- prepare plans for and monitor the implementation programs;
- coordinate and submit reports to the Santa Ana RWQCB;
- conduct inspections of the RCFC&WCD's storm drain system;
- conduct the stormwater monitoring program; and
- conduct the public education program.

The responsibilities of the Co-Permittees are:

- develop site-specific compliance requirements;
- perform compliance monitoring and inspections;
- submit storm drain maps and compliance reports;
- exercise enforcement authority for achieving compliance;
- review and implement stormwater management programs;
- prepare individual budget or report on its stormwater program compliance activities; and
- prepare an internal implementation plan and schedule for site specific BMPs.

3.1.2 Committees

To assist in guiding the direction of the Riverside County Stormwater/Cleanwater Program, two committees were established, the Advisory Committee and the Construction and New Development Sub-Committee. A third committee, the Industrial and Commercial Stormwater Sub-Committee, will be formed in 1995 to assist the Advisory Committee.

VOL 12 2 2018

R0055318

3.1.2.1 Advisory Committee

The purpose of the Advisory Committee is to assist the Principal Permittee in interpreting the requirements of the Santa Ana Permit and planning the implementation of the BMPs outlined in the Santa Ana Regional DAMP. This committee includes representatives of each of the Co-Permittees and meets several times annually on an ad-hoc basis. The decisions of this committee are based on a consensus of the participating representatives.

3.1.2.2 Construction and New Development Sub-Committee

The Construction and New Development Sub-Committee assisted the Advisory Committee in developing BMPs intended to reduce pollutants in stormwater discharge from new development. The sub-committee included representatives from the Co-Permittees, the RCFC&WCD, the RWQCBs, and the development community. In addition, the meetings were informally open to participation by various interest groups which may be affected by the construction and new development requirements. Several industry representatives were invited to make presentations on issues affecting their operations. It was determined that the recommended BMPs for new development should be incorporated into the Santa Ana Regional DAMP as a supplement. The Construction and New Development Sub-Committee has completed its task and was disbanded in December 1994.

3.1.2.3 Industrial and Commercial Stormwater Sub-Committee

An Industrial and Commercial Stormwater Sub-Committee will be formed in 1995. Members of this sub-committee will be representatives of the Permittees, local regulatory agencies or districts, and the industrial and commercial sector. The Industrial and Commercial Sub-Committee will assist the Advisory Committee in establishing priorities and providing guidance for the industrial and commercial facility inspection programs that will be developed and implemented by the Co-Permittees. This sub-committee and the Public Education Coordinator for the Stormwater/Cleanwater Protection Program will work together to develop the "clean business" incentive program.

VOL 12 2 2019

R0055319

3.2 IMPLEMENTATION AGREEMENT

On November 19, 1991 the RCFC&WCD, the County, and the cities of Beaumont, Corona, Hemet, Lake Elsinore, Moreno Valley, Norco, Perris, Riverside, and San Jacinto entered into a NPDES Stormwater Discharge Permit Implementation Agreement (Implementation Agreement). In an amendment dated January 12, 1993, the cities of Calimesa and Canyon Lake also became parties to the Implementation Agreement. This Implementation Agreement resulted from a cooperative effort which began in 1990 between the RCFC&WCD, the County, and the cities to establish a coordinated and cost-effective means to comply with the municipal stormwater NPDES permit program.

The purposes of the Implementation Agreement are to:

- develop an integrated stormwater discharge management program designed to improve water quality in the County and in the region;
- establish a cooperative and coordinated municipal stormwater NPDES compliance program;
- identify the responsibilities of the Principal Permittee and the Co-Permittees; and
- establish funding responsibilities and a mechanism for the cost-sharing of county-wide compliance activities, including:
  - developing a stormwater management plan (DAMP);
  - implementing stormwater management programs;
  - stormwater monitoring;
  - administering the program; and
  - paying the annual municipal stormwater NPDES permit renewal fees.

The Implementation Agreement was developed with the full participation of the Permittees. The term of the Implementation Agreement is "indefinite or as long as required for compliance with the CWA." However, it will be necessary to revise the agreement following adoption of the new permit. A copy of the Implementation Agreement is included as Appendix E.

VOL 12 2 2020

R0055320

3.3 INTERAGENCY AGREEMENTS

3.3.1 Hazardous Materials Emergency Response

The County's Fire Department staffs and maintains a Hazardous Materials Emergency Response Team. To help ensure the existence and level of activity of this team and to meet the requirements of the municipal stormwater NPDES permits, the RCFC&WCD has entered into an agreement with the County whereby the RCFC&WCD contributes to the funding of the County Fire Department's Hazardous Materials Emergency Response Team. The RCFC&WCD contributes $450,000 each year (subject to an escalation clause) toward salaries, equipment, and maintenance of the County's Hazardous Materials Emergency Response Team. In January of each year, the County submits a report to the RCFC&WCD on the activities, responses, and cases performed or conducted during the preceding year. The report contains a narrative description of the team, its operations, and any major spills. The report also includes categorical information regarding responses inside and outside the RCFC&WCD's jurisdiction, traffic-related responses, construction-related responses, drug enforcement responses, etc. A current budget and revenue sources for the Hazardous Materials Emergency Response Team is also provided in the report. A copy of this agreement is included as Appendix F.

3.3.2 Household Hazardous Waste Collection Program

To increase household hazardous waste collection program activities within the County and to meet the requirements of the municipal stormwater NPDES permits, the RCFC&WCD has entered into an agreement with the County's Department of Environmental Health, whereby the RCFC&WCD contributes to the funding of the County's household hazardous waste collection program. The RCFC&WCD contributes $450,000 each year (subject to an escalation clause) toward salaries, equipment, waste disposal, and maintenance of the County's household hazardous waste collection program. The remaining operating funds (approximately $900,000) are provided from tipping fees collected by the Waste Resources Management District. Under the agreement the County conducts up to 15 regularly scheduled household hazardous waste collection events during each year, and each collection event must include two Saturdays. Each month, the County must advertise the annual schedule for the household hazardous waste collection events in a local newspaper. In

VOL 12 2 2021

R0055321

January of each year, the County submits a report to the RCFC&WCD on the prior year's program. The report contains a narrative summary of the household hazardous waste collection program and the collection events. The report also includes information regarding materials collected, waste disposal cost, labor cost, materials cost, and a current budget and revenue sources for the program. A copy of this agreement is included as Appendix F.

3.3.3 Interagency Inspection and Enforcement Options

The Hazardous Materials Management Division of the County's Department of Environmental Health conducts inspection and enforcement activities related to the management of hazardous materials at commercial and industrial facilities. The Hazardous Materials Management Division has indicated that they would be willing to expand their inspection and enforcement activities to include municipal stormwater NPDES permit requirements or stormwater ordinance compliance for the Co-Permittees on a reimbursable basis. Other options may also exist, such as using wastewater pre-treatment inspectors, fire department inspectors, or other existing commercial and industrial facility inspection programs. These options for interagency agreements to perform inspection and enforcement for municipal stormwater programs will continue to be investigated. As workable, cost-effective arrangements are identified, these options will be presented to the Co-Permittees as alternatives to developing their own inspection and enforcement programs.

3.3.4 Education

A position has been established to provide education and outreach in support of the Stormwater/Cleanwater Protection Program. The activities of this county-wide program are described in Section 8.0. The Public Education Coordinator is funded 85 percent by the RCFC&WCD and 15 percent by the County, based on the population within and outside of the jurisdiction of the RCFC&WCD. Day-to-day guidance and direction is provided by the RCFC&WCD with overall guidance provided by the Advisory Committee.

VOL 12 2 2022

R0055322

3.4 FISCAL RESOURCES

3.4.1 Benefit Assessment

The RCFC&WCD's funding source for the municipal stormwater NPDES program is a benefit assessment that covers the entire Santa Ana regional drainage area, including county and city jurisdictions. Property owners are assessed for the benefit derived from the development and implementation of the municipal stormwater NPDES program by the RCFC&WCD. Predominantly remote mountainous areas have been exempted from the assessments, since little or no urban pollution of stormwater is generated in those areas. Undeveloped vacant parcels and agricultural parcels are also exempted from the benefit assessment. The assessment is calculated using the County Tax Assessor's data for each parcel. The amount of the assessment is based on proportionate stormwater runoff, which is related to the size and land use of the parcel.

Since the benefit assessment covers urban areas throughout the jurisdiction of the RCFC&WCD, activities that are considered common and of equal benefit to all are financed in whole or in part by the funds generated through this benefit assessment. These "umbrella" activities include the stormwater monitoring program, support of the County's Hazardous Materials Emergency Response Team, support of the County's household hazardous waste collection program, and support of the stormwater education program.

3.4.2 County Service Area 152

The County formed County Service Area (CSA) 152 in December 1991 to provide partial funding for compliance activities associated with the municipal stormwater NPDES permits. Originally, CSA 152 assessment was collected through property tax bills as an annual ten-dollar charge per parcel in the unincorporated portion of the county. For fiscal year 1993-94, the County adopted the same method for assessment calculation as the RCFC&WCD, and calculations for CSA 152 are now performed by the RCFC&WCD.

The County has refined their assessment method for fiscal year 1994-95. Two sub-zones of the unincorporated areas of the County were formed. The sub-zones represent areas of higher service and lower service (i.e., high or low relative stormwater quality impact). The

VOL 12 2 2023

R0055323

rates for each zone are based on the level and type of services received by the property owners in these areas. The sub-zones were determined by a statistical assessment methodology for CSA 152 that is based upon three criteria: 1) population per square mile, 2) parcels per square mile, and 3) parcels with structures per square mile.

Local jurisdictions besides the County may belong to a CSA. Under the laws that govern CSA's, sub-areas may be established within one CSA with different assessment rates in each sub-area. The cities of Corona, Moreno Valley, Norco, and Riverside have joined CSA 152. These cities set their individual rates and decide how to allocate these funds.

3.4.3 Other Funding Sources

The City of Hemet funds their municipal stormwater NPDES program through an increased utility charge. The charge is added to monthly utility bills by the City of Hemet, the Lake Hemet Water District, or the Eastern Municipal Water District in their respective billing/service areas within the city. As with other programs, the level of funding for the NPDES stormwater compliance program indirectly reflects the level of public support. Increases in program activities may exceed funding currently available. As public understanding and support for stormwater quality control increases, support for increased funding levels for the compliance program may also be expected.

The cities of Calimesa, Canyon Lake, Lake Elsinore, Perris, and San Jacinto finance their municipal stormwater NPDES programs through their general funds. Due to the small size of these cities and the limited extent of their storm drain systems, these cities believe use of their general funds is an adequate funding mechanism at this time.

3.4.4 Budget for 5-Year Permit Period

Fiscal Analysis reports, which presented expenditure, budget, and funding information for the municipal stormwater NPDES program, were submitted to the Santa Ana RWQCB in 1991, 1992, 1993, and 1994. Table 3-1 presents expenditure data for fiscal year 1993-94 and budget data for fiscal year 1994-95 for each Permittee. Table 3-2 presents budget data for 1994-95 by category of expenditure.

VOL 12 2 2024

R0055324

Detailed budget information for 1995-96 is not available at this time. Since some of the municipal stormwater NPDES programs are not developed completely or are yet to be developed, it is difficult to estimate the budget for those programs. Additionally, as more experience is gained in implementing the stormwater programs and as program coordination efforts improve, cost-savings should be achieved. An annual Fiscal Analysis report will be submitted to the Santa Ana RWQCB by September 30 of each year during the permit period.

3.5 LEGAL AUTHORITY

3.5.1 Porter-Cologne Act

The CWA allows the USEPA to delegate its NPDES permitting authority to states with approved environmental regulatory programs. The State of California has an approved environmental regulatory program and has been delegated authority to implement the NPDES program. California's Porter-Cologne Water Quality Control Act established the SWRCB and the system of nine RWQCBs (Section 13000, "Water Quality," et seq., of the California Water Code). The SWRCB and the RWQCBs are responsible for the protection and, where possible, the enhancement of the quality of California's waters. The SWRCB sets statewide policy, and together with the RWQCBs, implements state and federal laws and regulations, including the NPDES program.

Although local governments may have ordinances designed to protect or enhance water quality, these ordinances are only complementary to the NPDES program, and the SWRCB and the RWQCBs have primary and ultimate responsibility for enforcement of the NPDES program.

3.5.2 Local Government Authority

The federal stormwater regulations require permittees to demonstrate adequate legal authority to implement the stormwater NPDES program, including controls on industry and construction. The DAMP contains a detailed evaluation of the legal authority of the Permittees. Both the police power and the "home rule" power enunciated in the California constitution confer broad authority on local government to regulate public health, safety, and

VOL 12 2 2025

R0055325

welfare. However, these ordinances were enacted to address concerns such as zoning, flood control, nuisance litter control, or blockage of storm drains, and were not enacted for the purposes of regulating stormwater quality. As a result, the Co-Permittees's various ordinances tend to differ in scope and focus from the municipal stormwater NPDES program. This is particularly true with respect to the inspection and monitoring requirements of the federal stormwater regulations. In order to close gaps in the local regulatory scheme and to create uniformity in ordinances, the Co-Permittees will adopt essentially the same model ordinances for stormwater/urban runoff management and discharge control and for grading and erosion control. It expected that the Co-Permittees will have these ordinances adopted by December 31, 1995.

Local government authority is limited by the state and federal constitutions and statutes. Therefore, the following facilities and activities are not within the jurisdiction of the Permittees:

- state and federal facilities and activities;
- agricultural operations;
- utilities and special districts; and
- Native American tribal lands.

In this Permit Application, the Permittees propose to exclude these areas from coverage under the new permit (see Section 2.4).

3.5.2.1 Stormwater/Urban Runoff Management and Discharge Ordinance

The County of Riverside has developed a proposed stormwater/urban runoff management and discharge controls ordinance. A copy of the proposed ordinance is included as Appendix G. The proposed ordinance has been submitted to the other Co-Permittees and the Santa Ana RWQCB for review. The proposed ordinance would provide the authority to:

- prohibit disposal of wastes (potential pollutants) to any street, alley, sidewalk, storm drain, inlet, catch basin, etc.;

VOL 12 2 2026

R0055326

- prohibit the storage or use of equipment or hazardous materials in such as manner that hazardous substances may be discharged to the storm drain system;
- require BMPs for construction sites;
- require (with discretion) new development or redevelopment to take measures to control the volume and rate of stormwater runoff;
- prohibit illicit connections and discharges to the storm drain system;
- prohibit any discharge that would result in a violation of the municipal stormwater NPDES permit;
- require (with discretion) proof of compliance with the Industrial Permit, Construction Stormwater Permit, and/or the Dewatering General Permit for issuance of grading, building, or occupancy permits;
- require property owners to maintain good housekeeping practices; and
- inspect property for compliance with the ordinance and issue notices of violation for failure to comply.

Each Co-Permittee will pursue adoption of the proposed stormwater ordinance by their respective City Councils or Board of Supervisors. However, the County of Riverside will not proceed with adoption of the proposed stormwater ordinance until the Santa Ana Regional DAMP has completed the California Environmental Quality Act review process. It is unlikely that the other Co-Permittees will adopt the proposed stormwater ordinance prior to adoption by the County.

3.5.2.2 Grading and Erosion Control Ordinance

The Co-Permittees have existing ordinances for grading and erosion control at construction sites. The County is in the process of developing an improved ordinance and is consulting its own agencies and the Santa Ana RWQCB for review and comment. The other Co-Permittees are in the process of reviewing their ordinances, but will not pursue revision of their ordinances until the County has finalized its proposed ordinance, which will be used as a model.

VOL 12 2 2032

4.0 ILLICIT CONNECTIONS AND ILLEGAL DISCHARGES

The elimination of illicit connections and illegal discharges to storm drain systems is a major component of this program, which is intended to improve or protect the quality of stormwater/urban runoff and the affected receiving waters.

4.1 RECONNAISSANCE SURVEY PROGRAM

In accordance with the Santa Ana Permit, reconnaissance surveys were conducted to identify illicit and undocumented connections and illegal discharges to the storm drain systems. It was assumed that undocumented connections resulted in illegal discharges until determined otherwise. Further, the Permittees are required to "effectively eliminate all identified illegal discharges/illicit connections in the shortest time practicable, and in no case later than July 1, 1995."

The reconnaissance surveys of the storm drain systems were limited to underground storm drains of 36-inch diameter or larger and open channels. The majority of the Permittees utilized television camera video taping of their storm drain systems. Some of the Permittees, including Moreno Valley, inspected their storm drain systems manually, since their systems were not very extensive. Each undocumented connection to a storm drain system was traced back to its origin. Almost 200 undocumented connections to the underground storm drain systems were found. *With the inspections and investigations almost complete, none of the connections have been determined to be illegal connections with regard to stormwater NPDES program.*

Numerous undocumented connections to the RCFC&WCD's open channels were also discovered. Most of these connections appear to be either landscape or pool drains originating from residences. Table 4-1 presents a summary of the reconnaissance surveys conducted by the Permittees. The most recent Annual Progress Report on the Reconnaissance Survey Program for Storm Drain Facilities was submitted to the Santa Ana RWQCB in September 1994. The Reconnaissance Survey Plan and subsequent progress reports to the Santa Ana RWQCB are incorporated in this Permit Application by reference.

R0055332

The Permittees are continuing to investigate the remaining undocumented connections to their storm drain systems. Once the origin of the connection has been determined, where appropriate, the connections will be permitted by the owner or operator of the discharging facility. If the connection is determined to be unacceptable under the municipal stormwater NPDES regulations, the Permittees will take action to have the illicit connection or illegal discharge eliminated or permitted by the RWQCB. The Permittees expect that illicit connections and illegal discharges to their storm drain systems will be eliminated by July 1, 1995, barring lengthy enforcement actions.

Training of field personnel to identify and report illegal discharges is described in Section 7.6.3. In addition, the following implementation protocols will be developed to facilitate these efforts:

- procedures for conducting the storm drain system inspection;
- guidance materials and standardized checklists and reporting forms for performing and documenting storm drain system inspections;
- identification of personnel responsible for reviewing field reports and coordinating enforcement;
- procedures to coordinate with agency(s) with authority to enforce local stormwater ordinances (i.e., code enforcement, County Environmental Health, etc.); and
- procedures to coordinate enforcement with the RWQCB and other agencies.

4.2 CONTROL MEASURES

The Santa Ana Regional DAMP describes the BMPs (control measures), implementation responsibilities, and time frame for BMP implementation. Some of those BMPs pertain to eliminating illicit connections and illegal discharges. The more important measures related to illicit connections and illegal discharges are discussed in Sections 4.2.1 and 4.2.2.

VOL 12 2 2033

R0055333

4.2.1 Illicit Connections

The Permittees will implement an ongoing program for detecting illicit connections to storm drain systems. Investigations for potential illicit connections will be conducted when that possibility is indicated by the monitoring program, citizen complaints, or public employee reports. Storm drain channels will be inspected for illicit connections again during 1997-98. The underground storm drains will not be inspected during the next permit period (1995-2000) for the following reasons:

1) the current reconnaissance survey of underground storm drains has yet to identify any illicit connections;

2) the underground storm drain systems are predominantly inaccessible (under streets and roads); and

3) inspection of underground storm drains is a relatively expensive component of the municipal stormwater NPDES program. These resources will be more effectively applied to other NPDES program activities.

It is believed that an inspection of underground storm drain systems once every ten years would be appropriate. However, where monitoring or inspection activities identify evidence of an illegal discharge to an underground storm drain, efforts will be made to identify the source.

4.2.2 Illegal Discharges

The three primary types of pollutant discharges (or illegal dumping) that must be controlled or eliminated are caused by:

- individuals who do not know that their action is illegal (or harmful);
- individuals who know that their action is illegal; and
- accidental spills.

To address the problem of individuals who do not know their actions are illegal, two steps were taken. The first step was the implementation of an education and outreach program to inform the public of the impact of illegal discharges on surface water quality. The second step was the implementation of a program to inform the public of the household hazardous

VOL 12 2 2034

R0055334

waste collection program operated by the County's Department of Environmental Health as an alternative to illegal dumping. The household hazardous waste collection program will reduce the amount of material illegally disposed to the municipal storm drain system. This program was expanded with an initial contribution of $300,000 (presently $450,000). By providing two weekend collection events instead of one, increasing the total number of annual events, and increasing the publicity of the events, the program was able to increase the awareness and convenience of proper disposal.

The education and outreach program and municipal employees will be used to prevent and/or identify individuals who know their actions are illegal. The Stormwater/Cleanwater Education and Outreach Program being developed and implemented will increase public awareness, promote proper disposal of household hazardous waste, and encourage reporting of suspected illegal discharges. An "800" telephone number for toll-free reporting of illegal or improper pollution activities and for requesting information was established in October 1994. By calling 800/506-2555, the caller is connected to an operator who will provide the name and telephone number of the appropriate municipal staff to help the caller. The municipal staff can assist callers with information regarding recycling, disposal of waste, reporting of dumping, street and catch basin maintenance, and other information or services. Reports of discharges are referred to the appropriate agencies for response. In addition, public employees will receive training to recognize and report suspected illegal discharges observed during the course of their work (see Section 7.6.3).

For several years the County's Fire Department has maintained a Hazardous Materials Emergency Response Team. This team responds to accidental spills and dumping of hazardous materials, and supports other agencies encountering hazardous materials (e.g., police during drug lab raids). This includes coordinating containment and cleanup of spills which may impact the storm drain system. Three years ago, with the County facing financial problems, the team was almost permanently disbanded. The RCFC&WCD, on behalf of the Permittees, contributed $300,000 to help ensure that the team remained intact. Since then, the team has responded to over 360 incidents annually. The continued support of the County's Hazardous Materials Emergency Response Team will help ensure that hazardous materials from spills or dumping have minimal impact on storm drain systems and receiving waters.

VOL 12 2 2035

R0055335

4.3 ENFORCEMENT PROCEDURES

Presently, the Co-Permittees must utilize existing regulations to manage stormwater quality (e.g., nuisance laws, littering ordinances, public health regulations, etc.). The Co-Permittees plan to adopt a comprehensive stormwater ordinance during 1995. A copy of the Stormwater/Urban Runoff Management and Discharge Controls ordinance is provided in Appendix G. This ordinance will prohibit:

- disposal of wastes (potential pollutants) to any street, alley, sidewalk, storm drain, inlet, catch basin, etc.;
- illicit connections and discharges to the storm drain system; and
- any discharge that would result in a violation of the municipal stormwater NPDES permit.

Enforcement actions may include citations, notice of violation, cease and desist notices, and, in some cases, arrest depending on the nature and intent of the discharge and the number of previous violations.

4.4 COORDINATION WITH OTHER NPDES PERMITS

4.4.1 Non-Stormwater Permits

The Co-Permittees will notify the Santa Ana RWQCB of detected non-storm water discharges to their storm drain systems. In addition, the RCFC&WCD will request the opportunity to review and comment on proposed point source discharge permits for discharges to surface waters in Riverside County. The Permittees oppose permitting of point source discharges which may impair their ability to meet the requirements of the Riverside County municipal stormwater NPDES permits. Proposed point source discharge permits will be reviewed and comments may be provided by the RCFC&WCD to the RWQCB. If the RWQCB were to issue permits for discharges that are not acceptable to the Permittees, the Permittees may refuse to accept the discharge into their storm drain systems.

VOL 12 2 2036

R0055336

4.4.2 Construction Stormwater Permit

The Permittees will continue to require private construction projects to demonstrate compliance with the Construction Stormwater Permit prior to the issuance of local construction and grading permits. In addition, building and grading inspectors will be provided training on construction BMPs using the California Stormwater Best Management Practice Handbook - Construction Activities. The Permittees will notify the RWQCB of construction activities not in compliance with the Construction Stormwater Permit when additional enforcement support is needed. Enforcement actions and investigations related to stormwater control from construction activities will be summarized in the annual report to the RWQCB.

4.4.3 Industrial Permit

When identified, the Permittees will notify the RWQCB of industrial facilities which are not in compliance with the requirements of the Industrial Permit. The Permittees will develop a commercial and industrial facilities inspection program as described in Section 6.3.

4.5 REPORTING TO THE SANTA ANA RWQCB

An annual report will be submitted by the Principal Permittee to the RWQCB summarizing the information related to the illicit connection and illegal discharge elimination program. The Reconnaissance Survey Implementation Plan will be replaced with an Illegal Discharge Control Plan which will be submitted to the Santa Ana RWQCB in mid-1996 for review and approval.

VOL 12 2 2038

VOL 12

2

2039

SECTION 5

R0055339

The Construction and New Development Sub-Committee prepared a supplement (Supplement A) to the Santa Ana Regional DAMP which requires implementation of site-specific BMPs intended to reduce pollutants in stormwater discharge from new development and redevelopment projects. Supplement A is included as Appendix H to this Permit Application. The Construction and New Development Sub-Committee has placed emphasis on building upon existing programs and achieving uniformity of implementation by the Permittees. Proposed measures will apply to both private- and public-sector development projects and both structural and non-structural control measures have been included.

5.1 PLANNING PROCESS FOR DEVELOPMENT AND REDEVELOPMENT

5.1.1 Watershed Protection Policies

The Permittees will monitor and coordinate with watershed protection programs which may be implemented by the RWQCB, the Santa Ana Watershed Planning Agency (SAWPA) and others during the next permit period. Applicable policies related to construction and new development developed in these efforts will be incorporated into the DAMP.

5.1.2 Coordination with CEQA

The Permittees will adopt policies (some already have) that will include evaluation of construction-period and post-construction stormwater impacts during staff review of California Environmental Quality Act (CEQA) and National Environmental Policy Act (NEPA) documents. Where appropriate, measures to mitigate anticipated stormwater quality impacts will be incorporated into environmental documents and incorporated into standard conditions of approval for proposed development and redevelopment projects.

VOL 12 2 2040

R0055340

5.1.3 Site Planning Practices

The requirement for a post-construction stormwater quality BMPs will be specified in each Permittee's standard conditions of approval. The standard conditions of approval will require project proponents to include in their plans BMPs that will be incorporated into the project to control nonpoint source pollutants after construction. Supplement A will be adopted by the Permittees and uniformly implemented by to promote consistency.

5.1.4 General Plans and Master Plans

The California General Plan Law and the CEQA provide a basis for municipalities to review and comment on proposed projects within their jurisdiction. Under the General Plan Law, municipalities are required to develop policies and regulations that guide development within the municipality. Each development project is then reviewed for conformance with these policies. Under CEQA, projects are also subject to review and comment for adverse impacts the projects may have on the environment, including impacts from stormwater discharges. As the Permittees revise their General Plans or Master Plans, the management of stormwater quantity and quality will be addressed, and the measures identified in Supplement A will be incorporated into those plans.

5.1.5 Planning/Public Works Interface

Construction inspectors will monitor projects for implementation of stormwater quality control measures incorporated as conditions of approval by Planning. Where the conditions are not implemented, inspectors will take appropriate follow-up actions, including enforcement where appropriate, to ensure that the stormwater quality control measures are implemented.

5.1.6 Implementation Procedures

Each Permittee will take the following actions:

- Train personnel responsible for permitting or development plan review regarding the new development BMPs included in Supplement A. Personnel training is described in Section 7.6 of this Permit Application.

VOL 12 2 2041

R0055341

- Make Supplement A available to development or permit applicants at the earliest possible time in the application/permit process.

- Notify applicants of known water quality problems which may affect the proposed development at the earliest possible opportunity.

- Modify procedures for approval of grading, building, and similar permits to include applicable BMPs from Supplement A. Permits will not be issued until conditions of approval related to stormwater quality management are satisfied.

5.2 CONTROL MEASURES FOR CONSTRUCTION SITES

Section IV.1.c of the Santa Ana Permit requires the DAMP to include "a full range of structural and non-structural BMPs" that shall be required at new construction sites. "All industrial or commercial construction operations that result in a disturbance of one acre or more of total land area (or smaller parcel of land which is a part of a larger common development) and residential construction sites that result in a disturbance of five acres or more of total land area (or a smaller parcel of land which is a part of a larger common development) shall be required to develop and implement BMPs, including a long-term funding mechanism and commitment to support required maintenance of the BMPs, to control erosion/siltation and contaminated runoff from the construction sites."

The Co-Permittees have existing ordinances for grading and erosion control at construction sites. The County is in the process of developing an improved ordinance and is consulting its own agencies and the Santa Ana RWQCB for review and comment. A copy of the County's proposed grading and erosion control ordinance is included as Appendix I. The other Co-Permittees are in the process of reviewing their ordinances, but will not pursue revision of their ordinances until the County has finalized its proposed ordinance, which will be used as a model. By December 1995, the Co-Permittees should have revised grading and erosion control ordinances in place.

5.2.1 Permits

The model grading and erosion control ordinance will include a requirement that an erosion control plan be submitted for review and approval by the appropriate municipal department prior to the issuance of a grading and/or building permits. Also, if the construction site is

VOL 12 2 2042

R0055342

subject to the Construction Stormwater Permit, the applicant will have to show proof of compliance with the Construction Stormwater Permit prior to the issuance of the local grading and/or building permits.

5.2.2 Bonding

Bonding is a mechanism used by municipalities to ensure that various conditions of approval and items specified in plans, including stormwater quality control measures, are implemented in private-sector development projects. Bonding involves the deposit of cash or the purchase of a policy from a bonding firm by the developer for a specific development project. The amount of the bond is based on the anticipated cost of the required improvement. If the conditions of approval are not met, the municipality may use the deposited funds or may cash-in the bond policy to complete the work. As stormwater quality control measures are written into plans or included as conditions of approval, they are being covered by the bonding mechanism.

5.2.3 Inspections

The County has developed a one-day training program for construction inspectors. This training program has been made available to the other Permittees for a nominal charge. This training program will be conducted on an as-needed basis to train new inspectors and to provide refresher training. This training program addresses soil erosion, construction pollution control measures, and the requirements of the Construction Stormwater Permit. Reporting and follow-up procedures, including enforcement alternatives, will also be addressed at this training program.

Construction inspectors will specifically inspect the construction site for compliance with the erosion control plan or with the SWPPP prepared for the Construction Stormwater Permit. A summary of the activities of this program will be incorporated into the annual report submitted to the RWQCB (Section 10.3.4).

5.3 CONTROL MEASURES FOR NEW DEVELOPMENT AND REDEVELOPMENT

It is generally understood that, as development progresses, the percentage of paved surface

VOL 12 2 2043

R0055343

increases, the discharge rate and volume of runoff increases, and the amount of pollutants in stormwater runoff also increases. Section IV.1.c of the Santa Ana Permit requires the DAMP to include provisions that "all new developments and existing facilities with significant redevelopment, irrespective of their size, must develop individual, comprehensive, long-term, post-construction stormwater management plans, incorporating structural and non-structural BMPs. These management plans shall include a long-term funding mechanism and commitment to support required maintenance of the BMPs."

Supplement A to the DAMP specifies structural and non-structural BMPs that will become "standard" practices for new development or redevelopment. Each new development will be required to implement appropriate non-structural BMPs in keeping with the size and type of development and the potential for stormwater pollution. Each new development will also be required to implement appropriate "routine" structural BMPs. "Routine" structural BMPs are economical, practicable, small-scale measures, which can be feasibly applied at the smallest unit of development.

5.4 ENFORCEMENT

Construction inspectors have received training in the available enforcement alternatives. Enforcement actions may include cease and desist orders, fines, and stop work orders.

5.5 COORDINATION WITH CONSTRUCTION STORMWATER PERMIT

As stated previously, where applicable, grading and/or building permits will not be issued without proof of compliance with the Construction Stormwater Permit. The Permittees will develop procedures such that the Santa Ana RWQCB will be notified when non-compliance with the Construction Stormwater Permit is suspected.

VOL 12 2 2044

R0055344

VOL 12

2 2345

R0055345

SECTION 6

6.1 IDENTIFICATION OF SOURCES

In prior years, "specific industrial sources" (including name, location, and Standard Industrial Code) discharging stormwater to Permittee municipal storm drain systems were identified and reported to the Santa Ana RWQCB to satisfy requirement IV.2.d of the Santa Ana Permit. The identification of industrial and commercial facilities will help the Permittees in developing appropriate stormwater quality programs and will be useful in prioritizing the implementation of control measures pertaining to industrial and commercial facilities.

6.2 CONTROL MEASURES

The DAMP established a number of BMPs specifically applicable to industrial or commercial facilities. A few of the more significant BMPs that will be implemented by the Permittees are:

- evaluate the need to establish local regulations giving municipalities the authority to require oil and grease controls in areas which may be significant sources of oil and grease to stormwater (e.g., retail gasoline stations, automotive shops, parking areas, food service establishments)
- develop, implement, and enforce regulations requiring landowners and/or tenants to provide covers (roofs, tarps) to keep rain off of areas which contain potential pollutants (storage areas) and to keep stormwater runoff from draining through areas which contain potential pollutants
- educate/inform on impacts from gasoline, fuel oil, and oil and grease - effective use of good housekeeping practices, oil/grease traps, and the proper use of absorbents and cleaning compounds by industrial and commercial facilities

The proposed stormwater/urban runoff ordinance to be adopted by the Co-Permittees during 1995 contains provisions that prohibit the storage of "grease, oil, motor vehicles, machine parts, or other objects that may leak grease, oil, or other hazardous substances such

VOL 12 2 2046
R0055346

that these substance are discharged into any street, alley, sidewalk, storm drain, inlet, catch basin, conduit, or other drainage structure." The proposed ordinance also requires that "where BMP guidelines or requirements have been identified by any federal, State of California, regional, and/or county agency, for any activity, operation, or facility which may cause or contribute to stormwater pollution or contamination, ... , every person undertaking such activity or operation, or owning or operating such facility shall comply with such guidelines or requirements." Compliance with additional BMPs identified by the municipality would also be required by the proposed ordinance.

The education and outreach program has components directed at industrial and commercial facilities. Research and evaluation of educational materials and outreach programs targeted for industries and commercial activities has begun and will continue during 1995. During 1996 a "clean business" incentive program will be initiated. The education and outreach program is discussed in more detail in Section 8.0.

6.3 INSPECTIONS

The purpose for inspecting industrial and commercial facilities is to identify compliance or non-compliance with local stormwater ordinances and regulations and to ensure that BMPs are being implemented to manage discharges to municipal storm drain systems. Inspections of commercial and industrial facilities will also be a component of the "clean business" incentive program.

A sub-committee (Industrial/Commercial Stormwater Sub-Committee) will be formed with representatives of the Permittees, local regulatory agencies or districts, and the industrial and commercial sector. This sub-committee will assist the Advisory Committee in establishing priorities and providing guidance for the industrial and commercial facility inspection programs that will be developed and implemented by the Co-Permittees. The Industrial/Commercial Stormwater Sub-Committee and the Public Education Coordinator for the Stormwater/Cleanwater Protection Program will work together to develop the "clean business" incentive program.

Local programs exist for inspection of industrial and commercial facilities on a regular basis. Such programs may address environmental or public health, fire prevention and safety,

VOL 12 2 2047

R0055347

hazardous materials management, industrial and commercial waste management (solid), and wastewater pretreatment. By July 1, 1996, each Co-Permittee will elect to have inspections related to their stormwater ordinances and regulations and/or the "clean business" incentive program incorporated into existing inspection programs or will develop a separate inspection program depending upon the needs and resources of the Co-Permittee. The inspection programs developed will include:

- identification of the person responsible for overseeing the inspection programs;
- procedures for conducting the inspection, including reporting, follow-up, and enforcement;
- a standardized checklist and inspection report form for use during inspections;
- training of personnel to conduct inspections;
- frequency of inspection based upon the type of industrial or commercial facility; and
- coordination with the applicable Regional Water Quality Control Boards and other jurisdictional agencies.

6.4 COORDINATION WITH INDUSTRIAL PERMIT

The Permittees will develop procedures which will include notification to the Santa Ana RWQCB when non-compliance with the Industrial Permit is suspected. The Santa Ana RWQCB will also be notified regarding the identification of illegal discharges from commercial or industrial facilities to the municipal storm drain system. Other findings from the commercial or industrial facility inspections may also be communicated to the Santa Ana RWQCB. The Santa Ana RWQCB will implement investigations and enforcement actions, as appropriate, in response to these notifications.

VOL 12 2 2048

R0055348

VOL 12

2

2049

SECTION 7

R0055349

All of the Permittees perform functions that may have an impact of stormwater quality, including construction and maintenance of storm drain and flood control systems, construction and maintenance of streets and roads, maintenance of vehicles and/or heavy equipment, operation and maintenance of wastewater collection systems, collection and disposal of solid waste, landscape maintenance, and weed control.

7.1 STORM DRAIN SYSTEM AND FLOOD CONTROL

The Permittees will continue to evaluate existing programs for catch basin, inlet, and storm drain cleaning and maintenance of open channels. As additions to storm drain systems or as capital improvements of existing storm drain systems are planned, the Permittees will consider designs and retro-fit options that will enhance stormwater quality.

7.2 STREETS AND ROADS

The Co-Permittees have ongoing programs for street and road maintenance, including street sweeping and pavement management. The DAMP identified two BMPs specific to these activities.

Most of the Co-Permittees have regular schedules for street sweeping in areas where streets are constructed with curbs and gutters. A few of the Co-Permittees have modified their street sweeping schedules such that streets in commercial, business, and industrial areas are swept weekly. The Co-Permittees will continue to prioritize and evaluate problem areas which may benefit from a more frequent street sweeping schedule. As additional streets within the Co-Permittees jurisdictions have curb and gutter installed, those streets will be included in the street sweeping program.

VOL 12 2 2050

R0055350

The County has initiated a street sweeping pilot study of one area, which was selected based upon :

- streets and roads passing through particular land use areas;
- streets and roads not within city limits; and
- road segments with curb and gutter.

The pilot study route (approximately 300 centerline miles) will be swept once per month for 12 months beginning in the spring of 1995. Records will be kept for number of miles swept, amount of debris removed, field inspection of the route after sweeping, and evaluation of the pilot study. The RCFC&WCD will collect samples of the runoff and material collected by the street sweepers for analysis. The information gained from this street sweeping pilot study will be used to:

- identify other areas within the County for sweeping;
- prepare County budget for street sweeping;
- evaluate and refine street sweeping programs of the other Co-Permittees; and
- determine the effectiveness of alternative methods.

By December 31, 1995, the Co-Permittees will evaluate their pavement management programs, and where appropriate, revise their program to protect stormwater quality. The Co-Permittees will consider measures such as:

- regular repair of potholes and worn pavement to reduce sediment load in stormwater runoff;
- avoiding paving work during wet weather;
- implementing BMPs for concrete (storage, mixing, pouring, and cleanup); and
- covering catch basins, inlets, and manholes during application of seal coat, tack coat, etc.

7.3 CORPORATION YARDS

Corporation yards include areas or facilities that are regularly used for vehicle maintenance or washing, other maintenance, chemical storage or use (such as a painting facility), waste management, or supportive activities for field crews. These are essentially industrial

VOL 12 2 2051

R0055351

activities being performed at municipal corporation yards. To the extent that corporation yards do not perform vehicle maintenance activities, municipalities are generally not required to obtain an Industrial Permit for their corporation yards. The Permittees do not intend to prepare stormwater pollution prevention plans, per se, for their corporation yards unless (or until) they are required by regulation. However, the Permittees will assess their facilities and operations and implement BMPs needed to reduce exposure of stormwater to potential pollutants.

7.4 PUBLIC FACILITIES

Municipalities manage a variety of public facilities, including parks and recreation areas, swimming pools, golf courses, schools, civic or community centers, and parking lots. Managing such facilities often requires the storage and use of chemicals (e.g., fertilizers, herbicides, pesticides, chlorine), discharges of non-storm water, and management of waste.

The Permittees will evaluate their existing programs or procedures for managing public facilities. BMPs will be implemented, as appropriate, to minimize the exposure of stormwater to potential pollutants. The control measures may include:

- developing a list of approved herbicides and pesticides and the respective uses;
- periodic training in chemical storage and use;
- storage of equipment, materials, or chemicals indoors, under roofs, or covered by tarps;
- training in the proper disposal of wash waters, swimming pool water, or fountain water; and
- regular sweeping of parking lots and use of absorbents to cleanup automobile fluid leaks.

7.5 SEWAGE SYSTEMS

The Riverside County Department of Environmental Health, RWQCB, and sanitation agencies in Riverside County will be contacted to document existing procedures for

VOL 12 2 2052

R0055352

responding to sewage spills. These procedures will be reviewed, and recommendations for containment and disposal to reduce the amount of sewage discharged to the storm drain system will be recommended.

7.6 EMPLOYEE TRAINING

7.6.1 Permitting and Plan Review

The Permittees will train personnel responsible for permitting or development plan review regarding the new development BMPs included in Supplement A. This will include a review of the California Stormwater Best Management Practice Handbook - Construction Activities.

7.6.2 Construction Inspection

Building and grading inspectors not previously trained will be provided training on construction BMPs using the California Stormwater Best Management Practice Handbook - Construction Activities. This program was initiated in 1993 for County employees and made available to city and other interested parties in December, 1994.

7.6.3 Storm Drain Inspection

City, County, and the RCFC&WCD maintenance, inspection and other field personnel will be trained to recognize evidence of illegal discharges and dumping (e.g., stains, materials in or discoloration of water, stressed vegetation, etc.). In addition, they will receive instructions on reporting and documentation procedures.

7.6.4 Operations

City, County, the RCFC&WCD and other public agency personnel will be provided training to increase awareness of procedures to reduce pollution related to their job activities.

VOL 12 2 2053

R0055353

7.7 COMPLIANCE WITH INDUSTRIAL PERMIT AND CONSTRUCTION STORMWATER PERMIT

The Permittees operate facilities and conduct activities which are within the intent of the Industrial and Construction Stormwater Permits. Additional facilities and activities may be included in the USEPA Phase II regulations which may be promulgated during the next permit period. The Permittees will comply with the Industrial Permit and the Construction Stormwater Permit in operating municipal facilities and conducting operations. This may include submitting Notices of Intent (NOI) to comply with the general permits, preparing and implementing storm water pollution prevention plans, conducting monitoring and submitting annual reports to the RWQCB. To the extent of their legal authority, the Permittees will require and encourage other public agencies (e.g., Caltrans, special districts, public utilities) to comply with the Construction Stormwater Permit for construction projects within the Permittee's jurisdiction.

2055

SECTION 8

R0055355

VOL 12 2 2056

8.0
EDUCATION AND OUTREACH

Education and outreach are seen by the Permittees as the keystone to municipal stormwater management. The primary focus of the education and outreach program is to keep pollutants out of the storm drain system rather than treating stormwater at the "end of the pipe." Because source reduction means controlling human activity and encouraging behavioral change, education about the effects of stormwater pollution and fostering broad participation in pollution prevention and control are critical to the success of the education and outreach program.

8.1 PROGRAM TO DATE

The RCFC&WCD and the County of Riverside established a full-time Public Education/Information Coordinator position to assist the Permittees in performing the education and outreach component of the municipal stormwater NPDES program. The Public Education/Information Coordinator develops and implements the stormwater education and outreach program for the Permittees. Materials and products produced for the education and outreach program are routinely submitted for comment and approval to the Permittees, Riverside County Waste Resources Management District, the County's Department of Environmental Health, and the County's Public Information Officer.

Coordination with other existing pollution prevention programs is ongoing. Staff from the County of Riverside Administrative Office, the County's Department of Environmental Health, and the Riverside County Waste Resources Management District meet regularly to coordinate similar pollution prevention program efforts. In addition there is coordination with programs such as the Riverside-Corona Resource Conservation District, the Coachella Valley Association of Governments' (CVAG) Illegal Dumping Task Force and the Western Riverside Council of Governments. Participation in a joint outreach program with the Southern California Coalition for Pollution Prevention (an industry-backed group) may also be pursued.

R0055356

8.1.1 General Outreach

General outreach provides information and materials to the general public about stormwater pollution prevention. The general outreach activities of the Stormwater/Cleanwater Protection Program which have been implemented to date include:

- The Riverside County education and outreach program commenced with the development of a program name/theme/message:

StormWater CleanWater PROTECTION PROGRAM

Stormwater should be
Cleanwater only . . .
Help keep our water clean!

- An information brochure was developed to introduce the assessment fee associated with the municipal stormwater NPDES program and mailed to over 150,000 property owners. The brochure informed residents of FACTS about the Stormwater/Cleanwater Protection Program and ACTIONS . . . what they can do to help protect their water. The brochure is also available in Spanish.

- Two half-page Sunday advertisements were printed to accompany the information brochure. Advertisements appeared county-wide through the Press Enterprise (all zones), the Desert Sun and the Californian daily newspapers.

- Public information presentations were conducted in eleven cities to introduce the Stormwater/Cleanwater Protection Program to city residents. The presentations included overhead transparencies, photos, and a question and answer forum.

- The Stormwater/Cleanwater Protection Program's toll-free number (800/506-2555) was established. It was determined that the establishment of one central number for all residents in Riverside County would make distribution of collateral material less complicated by alleviating the need to list 23 city phone numbers. The toll-free number is monitored by an answering service which refers calls to the appropriate agency based on the callers questions and their location. The toll-free number serves all cities within Riverside County, excluding Blythe (which is exempt from NPDES stormwater regulations).

- The brochure "Stormwater Pollution . . . What You Should Know" was developed. The toll-free number is listed in the brochure. The brochure introduces the problem of stormwater pollution, its effects on the environment

VOL 12 2 20571

R0055357

and informs residents of primary things they can do to help prevent it. The brochure is also available in Spanish. Each city in Riverside County is supplied with brochures for distribution.

- The brochure "20 Ways to Protect Your Water" was developed. The toll-free number is referenced in the brochure. This brochures provides 20 specific examples of how residents can help protect their water by activities in their home, their yard, their auto, and their neighborhood. The brochure is also available in Spanish. Each city in Riverside County is supplied with brochures for distribution.

- The Stormwater/Cleanwater Protection Program display booth was constructed and made its debut at the 1994 Lake Perris Farmer's Fair. Over 800 packets of information were handed out at the fair via the display booth.

- A Stormwater/Cleanwater Protection Program magnet in the shape of a water drop was developed. The magnet relays the program message of "Help Keep Our Water Clean." It also references the toll-free number for information: on how to protect our water; for proper disposal of household hazardous waste; how to recycle motor oil; and how to report illegal dumping.

- Coordination with other agencies, such as Riverside-Corona Resource Conservation District and CVAG's Illegal Dumping Task Force, has created a cooperative arrangement to share resources and outreach opportunities. Riverside-Corona Resource Conservation District publishes stormwater pollution information and promotes the County's household hazardous waste collection events. CVAG has agreed to promote the Stormwater/Cleanwater Protection Program's toll-free telephone number.

8.1.2 Focused Outreach

Focused outreach provides information and materials pertinent to a specific aspect of stormwater pollution prevention or to a specific group of people, businesses, or industries. The focused outreach activities which have been implemented by the Stormwater/Cleanwater Protection Program to date include:

- Five utility inserts have been developed. Two specifically address stormwater pollution from motor oil. The Stormwater/Cleanwater Protection Program produced 105,000 utility inserts for the City of Riverside to be distributed in the their November 1994 utility bill. Coordination with various water districts and utility agencies is ongoing to schedule mailing of inserts.

VOL 12 2 2058

R0055358

- Research and evaluation of existing educational materials for focus groups such as construction and industry are ongoing. A "clean business" incentive program will be modelled after the Bellevue, Washington program, "Business Partners for Clean Waters," which includes manuals on BMPs for construction, industry, and automotive businesses.

8.1.3 Education Programs

Stormwater education programs include components directed toward children in school systems or developed for municipal employee training. The stormwater education activities which have been implemented by the Stormwater/Cleanwater Protection Program to date include:

- Research and evaluation of existing educational materials for school grades K-12 are ongoing. A preliminary cartoon character has been selected: "Water Warrior" pollution prevention warriors who protect our water. Various reference materials will be developed such as: book covers and markers, pencils and coloring books.

- The HAZMAN coloring book from the Riverside County Environmental Health Department and the "Solution to Pollution Is You" pamphlet from the Riverside-Corona Resource Conservation District was provided to children as part of the information packet the Stormwater/Cleanwater display booth distributed at the Farmer's Fair. We will continue to distribute these items pending full development of the "Water Warriors" program for the Stormwater/Cleanwater Protection Program.

- Riverside County's Building and Safety Department staff has provided soil erosion and sediment control training to over 100 County employees including planners; engineers; road, grading, and building inspectors; equipment operators; and other field personnel.

- The Riverside County's employee newsletter, Network, published a special edition on various pollution prevention programs within the County. The six-page newsletter informed over 10,000 employees of the various programs and informed them about how to actively participate in pollution prevention.

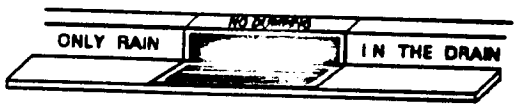
VOL 12 2 2059

R0055359

8.1.4 Citizen Participation

Components of the Stormwater/Cleanwater Protection Program have been developed to actively involve citizens in protecting stormwater quality. The citizen participation activities which have been implemented by the Stormwater/Cleanwater Protection Program to date include:

- The theme for the storm drain stencil campaign has been selected and will be:



- Each Permittee in Riverside County will be provided with a supply of stencils and a stencil program instructional kit. The Permittees, with assistance from the Public Education/Information Coordinator, will coordinate with local volunteer groups for stenciling days/activities.

- The toll-free phone number is designed to refer callers' questions to the appropriate agency. If a caller wants to report a full catch basin, or report illegal dumping, the answering service will refer the call to the appropriate agency. The operator will also advise the caller that if they were unable to reach the referenced agency/individual, or were dissatisfied with the help they received, they should call the toll-free number again and the operator will refer their call directly to the Stormwater/Cleanwater Public Education Coordinator. All cities within Riverside County have provided the Stormwater/Cleanwater referral service with a list of contact names for various agencies and programs.

8.2 FIVE-YEAR PLAN: 1995-2000

Education and outreach will be continued as a fundamental element of the Stormwater/Cleanwater Protection Program during the next permit period. This will include continuation and further development of the programs implemented during the current permit period as described in the following sections.

8.2.1 General Outreach

Written, audio, and video products for general outreach will be developed during the next

VOL 12 2 2060

R0055360

permit period. A supply of the brochures and reference products developed will be provided to all cities within Riverside County for distribution at information counters, special meetings, etc. Some of the products contemplated are:

Written Materials

- periodic media kit – media kits will be distributed to local daily and weekly newspapers (Permit years 1-3);
- a brochure on the Stormwater/Cleanwater Protection Program with a theme "a partnership with your local government"; brochure will be distributed through a direct mailing campaign (Permit years 1-2);
- reference products, such as bags, pens, pencils, posters (Permit years 1-2);
- information packet to be distributed at the County's household hazardous waste collection events conducted throughout the County; packet will include stormwater pollution brochures, handouts, magnets, as well as, the County's Department of Environmental Health household hazardous waste recycling information (Permit years 1-2);
- bus stop shelter billboards – will require coordination with Riverside Transit Authority (RTA) for western Riverside County and the Sun Bus for the desert area (Permit years 2-4);
- tabletop and floor stand brochure display for distribution at public libraries and for city public information counters (Permit year 2);
- half-page and quarter-page newspaper advertisements to continue to increase public awareness (Permit years 1-5);

Audio Materials

- several public service announcements – coordinate production with the County of Riverside, Health Services Agency Media Production Center (Permit years 1-2);
- paid advertisement versus public service announcements – requires assessment of budget feasibility (Permit years 1-5);

VOL 12 2 2061

R0055361

Video Materials

- an educational video and a 60-90 second public service announcement, film will show various locations throughout Riverside County (i.e. eastern desert area and western Riverside areas) - coordinate development and production with the County of Riverside, Health Services Agency Media Production Center (Permit years 1-2);
- air video on local cable station (Permit years 2-5); and
- copies of video to schools accompanying grades K-12 educational material (Permit years 2-5).

The Stormwater/Cleanwater display booth will be scheduled for various fairs throughout Riverside County including fairs for Earth Week and Pollution Prevention and Water Awareness Week. Brochures and reference products will also be distributed at these events.

8.2.2 Focused Outreach

The focused outreach information and materials to be developed during the next permit period are:

- a brochure on alternatives to toxic or hazardous household products (Permit years 1-2);
- a brochure on less toxic pest control methods (Permit years 1-2);
- additional utility inserts focusing on potential pollutants such as pesticides, fertilizers and illegal dumping; continuing coordination with water districts and utility agencies for scheduled mailing of inserts (Permit years 1-3);
- a series of BMP manuals for construction, industry, and automotive businesses for the "clean business" incentive program; contact businesses and seek partnership in the program; reference products to be developed will include: posters describing good housekeeping practices for various industries, "clean business" posters for displays, and "clean business" decals to affix to windows at participating businesses (Permit years 2-4);
- a series of workshops to introduce developers to the NPDES Guidelines for New Development (Permit years 2-4); and

VOL 12 2 2062

R0055362

- a kick-off event coordinated with the County's Department of Environmental Health for the opening of two permanent battery, oil, and anti-freeze collection centers in Riverside County; kick-off activities, information packets and media opportunities will be coordinated (Permit year 2).

8.2.3 Education Programs

Stormwater education programs developed during the next permit period will expand upon topics and materials used in school curriculums. Development of training programs for municipal employees regarding stormwater pollution prevention and compliance and enforcement of stormwater regulations will also be emphasized. Education programs or activities contemplated are:

- A graphic artist will be retained to develop "Water Warriors" characters and drawings. (Permit year 1-2)
- The County will utilize the services of the Riverside-Corona Resource Conservation District for the development of:
  - stormwater protection curriculum and activity books with the "Water Warriors" theme for elementary schools;
  - teacher workshops to introduce school curriculum and activity books; and
  - school assembly presentations. (Permit years 1-2)
- Additional workshops for soil erosion and sediment control will be developed in coordination with the Riverside-Corona Resource Conservation District and the San Diego RWQCB. (Permit years 1-2)
- A workshop will be developed for the County's Automotive Fleet Services Division and various County road and maintenance facilities, to present BMPs for automotive servicing. (Permit years 2-3)
- A workshop will be developed for the County's Building Services Division on proper storage and disposal of hazardous materials and hazardous wastes. (Permit years 2-3)

VOL 12 2 2063

R0055363

- A workshop will be developed to introduce the County's Stormwater/Urban Runoff Management and Discharge Controls Ordinance to County Planning and Development staff. (Permit year 2)

8.2.4 Citizen Participation

Components of the Stormwater/Cleanwater Protection Program will continue to promote the active involvement of citizens in protecting stormwater quality. These efforts may include the following:

- Although each city will be working with volunteer groups for storm drain stenciling, the County will conduct annual county-wide "Catch Basin Stenciling Days." Kick-off events will be coordinated with media opportunities. The events will coincide with Earth Week and/or Pollution Prevention Week activities. (Permit years 1-5)

- Community services groups such as the Kiwanis Club, Lions Club, and Rotary Club and environmental groups, will be contacted to coordinate stormwater education presentations. (Permit years 1-5)

- Organize "Clean-Up" day activities. Coordinate with volunteers to target specific areas in Riverside County for community clean-ups. Coordinate with the CVAG Illegal Dumping Task Force to participate in their "Clean-Sweep" program. Kick-off events and media opportunities will be coordinated. (Permit years 1-5)

- Coordinate and participate in special community activities associated with Earth Week, Pollution Prevention Week, and Water Awareness Week. (Permit years 1-5)

VOL 12 2 2066

9.0 CONSOLIDATED PROGRAM FOR WATER QUALITY MONITORING

A monitoring program plan was submitted to the Santa Ana RWQCB in 1991 for the portion of Riverside County under their jurisdiction. In March 1993, a second monitoring program plan was submitted to the San Diego RWQCB for the portion of Riverside County under their jurisdiction. In 1994, a third monitoring program was proposed in the permit application for the area of Riverside County under the jurisdiction of the Colorado River Basin RWQCB. To coordinate these three monitoring programs, the RCFC&WCD and the other Co-Permittees in Riverside County decided to pursue a county-wide monitoring program. A Consolidated Program for Water Quality Monitoring (Monitoring Program) was submitted to the three RWQCBs in October 1994 and is included as part of this Permit Application by reference. The Monitoring Program includes protocols for:

- "basic" sampling;
- bioassays;
- citizen complaints;
- sediment sampling;
- screening; and
- special tests (e.g., tap water).

"Basic" sampling includes dry weather observations and sampling, storm event sampling, and receiving water sampling.

Initiatives to coordinate stormwater quality monitoring are being discussed at the federal, state, and regional levels. These initiatives contemplate potential revisions in local stormwater monitoring programs including participation in special studies, increased data sharing, and modification of baseline data collection activities. It is anticipated that one or more of these initiatives may be implemented as early as fiscal year 1995/96. The Monitoring Program may be modified to reflect the participation of the Permittees in the coordinated monitoring programs or to reflect the findings of special studies.

This section summarizes the information provided in the Monitoring Program. It should be noted that the Monitoring Program may be modified throughout the next permit period to reflect findings, new information, and changing conditions in storm drain facilities and other environmental factors.

R0055366

9.1 OBJECTIVES OF THE MONITORING PROGRAM

The objectives of the monitoring program are to:

- assess mass loading rates from urban storm drain systems to the receiving waters;
- assess the influence of land uses on stormwater runoff quality;
- detect illegal discharges;
- conduct compliance monitoring of surface water quality;
- assess the effectiveness of various BMPs designed to control stormwater pollution;
- identify stormwater quality problem areas and/or trends;
- identify stormwater pollutants of concern;
- establish baseline conditions; and
- establish a database for future reference, research, and analysis.

9.2 MONITORING PROGRAM

The primary components of the Monitoring Program are:

- dry weather observations and sampling;
- storm event sampling;
- screening;
- sediment sampling; and
- receiving waters sampling.

Additionally, the monitoring program includes responding to citizen complaints and conducting special tests or studies.

9.2.1 Schedule for Implementation

During the 5-year permit period, the implementation schedule for various components of

VOL 12 2 2067

R0055367

the Monitoring Program will be:

Component	Year 1	Year 2	Year 3	Year 4	Year 5
Dry Weather	X	X	X	X	X
Storm Event	X	X	X	X	X
Screening		X	X	X	
Sediment Sampling	X	X	X	X	X
Receiving Waters	X	X	X	X	X
Bioassay	X				X

9.2.2 Monitoring and Sampling Locations

The twenty dry weather monitoring stations are located at Arlington, Anza, Bly, Box Springs, Hemet, La Sierra, Mag Center, Sunnymead, Sunnyslope, Temescal Channel, University, Lower San Sevaine, North Norco, Corona, Fairmont, Four Corners, Canyon Springs, Hospital, Trailer Park, and Perris Line J.

The ten storm event sampling stations are located at Anza, Box Springs, Mag Center, San Sevaine, Corona, Fairmont, Four Corners, Canyon Springs, Hospital, and Trailer Park.

The screening stations are located at Mag Center and Arlington.

The fourteen sediment sampling stations are located at North Norco, Anza Basin, Monroe Basin, Jurupa Basin, Rubidoux Basin, Kansas Basin, Marlborough Basin, Columbia Basin, Canyon Springs Basin, Perris Valley Drain, Salt Creek Channel Outlet, Hemet Channel, San Jacinto Drain, and Buena Vista Basin.

The six receiving water sampling stations are located at Lake Elsinore, Temescal Gravel Pit, Lake Evans, Santa Ana River, San Jacinto River, and Lake Mathews.

Stations for bioassay testing have not been identified at this time.

VOL 12 2 2068

R0055368

The locations of these various stations are depicted on maps included in the Consolidated Program for Water Quality Monitoring submitted to the three RWQCBs in October 1994.

9.2.3 Quality Assurance Program

The objective of the Quality Assurance Program is to ensure that the results of the Monitoring Program are based on reliable data. The Quality Assurance Program addresses the following elements of sample collection and analysis:

- development of standard sample collection and equipment maintenance procedures;
- education and training of sampling personnel;
- sample handling procedures;
- specification of standardized laboratory procedures;
- documentation including the development of standardized reporting forms; and
- development of standardized data management procedures.

9.2.4 Data Management

Field and laboratory data are maintained on a computer data base maintained by the RCFC&WCD which was based on a program entitled "Speedware." Critical limits for in-house evaluation of water quality data were developed by the RCFC&WCD based on a review of a combination of references. Water quality data generated by the Monitoring Program is evaluated based on comparison with these critical limits, which are viewed as typical of "raw surface water." The data and evaluation are provided in an annual report to the Santa Ana RWQCB.

9.2.5 Budget

The budget for the Monitoring Program in the Santa Ana Region for fiscal year 1994-95 is $194,100. The total budget for the Monitoring Program, including the Whitewater and

VOL 12 2 2069

R0055369

Santa Margarita River watersheds, is $307,900. Assuming no modifications to the Monitoring Program, it may be anticipated that the annual monitoring costs would be fairly constant over the next permit period, if adjusted for inflation. However, the actual costs may fluctuate depending on the implementation of coordinated regional, state, and federal monitoring initiatives. In addition, as previously noted the Monitoring Program may be modified to reflect findings, new information, and changing conditions in the storm drain facilities and other environmental factors. These modifications may also result in changes in the cost of the monitoring activities.

9.3 EVALUATION OF MONITORING DATA

9.3.1 Pollutant Loading

Analytical data collected under the Monitoring Program include data for receiving waters and stormwater discharges. These data are maintained on a common computer data base. However, due to the inherent variability of stormwater quality and the inexact nature of discharge measurements, the data will only provide a general indication of pollutant loading. In addition, due to this variability, many years of data will be needed to identify trends in pollutant loading, particularly as they may be attributable to the implementation of source control programs.

9.3.2 Source Identification

The primary focus of dry weather water quality monitoring is to assess whether the ongoing program to identify and eliminate illicit connections and illegal discharges to the municipal storm drain system is succeeding. Dry weather monitoring and discharge measurements in the Santa Ana region are conducted at 20 fixed stations. Wet weather sampling and discharge measurements are also conducted at some of these stations. These monitoring activities may provide information for source identification. Where water quality criteria are chronically exceeded, or where visual observations or citizen complaints point to possible polluting activities, efforts will be made to identify the source of the water quality problem. Sources may include illicit connections, illegal discharges, poor housekeeping practices by commercial or industrial entities, or certain land uses. Where sources are identified, follow-up actions to address these sources will be implemented.

VOL 12

2

2070

R0055370

9.3.3 Performance of Control Measures

As noted in Section 9.3.1, it will not be possible to evaluate the overall effectiveness of the municipal stormwater NPDES program through water quality monitoring due to the inherent variability and inexact nature of the data. The Permittees are participating in the development of coordinated stormwater monitoring programs on regional, state, and potentially, national, levels. During development of the coordinated monitoring programs, the Permittees will promote incorporation of special studies to evaluate specific stormwater quality control measures. These special studies may include evaluation of specific activities (e.g., street sweeping) and/or types of facilities (e.g., parking lot oil/water separators).

Section 10.0 describes the methods other than water quality monitoring which will be used to evaluate the effectiveness of the municipal stormwater NPDES program.

VOL 12

2

2071

R0055371

SECTION 10

2

2

2

VOL 12 2 2013

10.0 PROGRAM EVALUATION

The effectiveness of the municipal stormwater NPDES program (Stormwater/Cleanwater Protection Program) will be assessed on a regular and consistent basis. The evaluation component of the Stormwater/Cleanwater Protection Program will include a schedule for evaluation, a clear definition of what will be evaluated, a methodology for the evaluation of BMP implementation and effectiveness, and designation of responsibility for carrying out the evaluation. In addition, there will be a process to follow up on the information generated by the evaluation. The Stormwater/Cleanwater Protection Program will be revised based on the program evaluation.

10.1 PERFORMANCE STANDARDS

The Advisory Committee will be responsible for developing and adopting evaluation criteria for implementation and performance of the various components criteria for evaluation of the Stormwater/Cleanwater Protection Program. The Advisory Committee may elect to establish subcommittees to develop these criteria for specific program components. The criteria developed will include the concept that the BMPs identified in the DAMP will be implemented to the maximum extent possible. Standard implementation schedules and reporting formats will be developed for each BMP by the Advisory Committee for use by the Permittees. The Permittees will be required to document BMP implementation using a standard format according to an established schedule. The utilization of quantitative approaches (direct and indirect) for measuring implementation and effectiveness of BMPs will be used whenever possible. The evaluation and reporting methods developed will facilitate year-to-year comparisons.

The evaluation component of the Stormwater/Cleanwater Protection Program will assess the effectiveness of the Stormwater/Cleanwater Protection Program on at least four levels:

- extent of implementation of BMPs;
- indirect quantitative measures;
- indicators of public awareness; and
- water quality monitoring.

R0055373

10.1.1 Extent of Implementation of BMPs

Criteria to judge the extent of implementation of each of the BMPs included in the DAMP will be developed in 1995. The criteria will include minimum implementation levels to be achieved by the Permittees. The criteria will also provide that over the next permit period each BMP is implemented to the maximum extent practicable by the Permittees. The targeted completion date for developing these evaluation criteria for implementation is September 1, 1995.

The purchase and installation of equipment to implement BMPs will be documented and reported. Examples may include purchase and use of street sweepers, flow control devices, recycling bins, etc. Reporting will be simple and consist of a brief written description of the equipment and a photograph if it is very unusual.

Revisions to written procedures needed to implement BMPs will be developed and reported. Examples may include changes to written procedures for handling and storage of hazardous waste, equipment operation, etc. Reporting will consist of updating the Stormwater/Cleanwater Protection Program and compiling a copy of revised standard operating procedures for review by personnel.

When changes to practices that do not have written procedures are needed to implement BMPs, these changes will be reported. Examples may include changes in handling and storage of waste, equipment operation, equipment maintenance, cleaning practices, etc. Reporting will be simple and consist of a brief memo to personnel describing the revised practices.

Training may be needed where changes in personnel, routine operations and maintenance, or implementation of new practices are proposed. The number of personnel trained, the type of training given, and how often the training occurs will be reported in a memo.

Incremental costs incurred for implementation of BMPs will be reported. Such costs may include one-time and continuing costs. Expenditures of money are an indicator of the extent and level of efforts undertaken to implement the BMPs.

VOL 12 2 2074

R0055374

Under the Santa Ana Permit, Task XIII.f requires an evaluation of the need for additional BMPs, source controls, or structural control measures. However, the implementation of BMPs is relatively recent. Before recommending changes to BMPs or additional BMPs beyond those currently being implemented or proposed by the Permittees, a uniform data collection and reporting methodology will be established for each of the BMPs. This methodology will be used by the Permittees to allow for a uniform area-wide evaluation of BMP implementation. The uniform data collection methodology will be developed by June 1, 1996.

10.1.2 Indirect Quantitative Measures

Indirect quantitative measures will also be used for program evaluation. For some BMPs, it is possible to measure the volume or weight of material collected. As these materials are no longer available for contact with storm water, the total amount of storm water pollutants discharged is assumed to be reduced by this amount.

For other BMPs, reporting the frequency an amount of the action are reasonable measures for documenting effectiveness. For example, reporting the frequency of street sweeping and the number of curb miles swept per year are reasonable measures for documenting BMP effectiveness. Other examples include reporting the number of brochures distributed that identify alternative disposal methods, the number of inspections conducted, and the preventive maintenance tasks performed.

For structural controls, such as detention basins and drainage swales, visual inspections can provide useful information regarding performance. For example, patterns of sediment deposition can provide insight into the effectiveness of a structural control. Similarly, observations of floating or suspended material, oil and grease, discoloration, and odors in discharges are an indicator of performance. Such observations will be documented and used to modify maintenance practices or to recommend modifications to the control.

Some specific examples include the following:

- Street Sweeping – A method of evaluating the quantity and types of pollutants removed by street sweeping may be developed and implemented. This may include studying what kind of pollutants are removed by the sweeping,

VOL 12

2

2015

R0055375

measuring the size of the pollutants, and the volume or weight of material removed. The frequency of street sweeping the number of curb miles swept per year may also be reported.

- Use of 800 Hotline Number - In mid-October 1994, Riverside County implemented an 800 hotline number for citizens to report suspected stormwater pollution incidents. The frequency of the calls to the hotline will be used as an indicator of the level of awareness of the program and the number of pollution incidents in each Co-Permittee area.

- Waste Oil Recycling - Riverside County has begun collection of statistics on the amount of waste oil recycled. The assumption is that an increase in the amount of waste oil recycled results in a decrease in the amount of waste oil illegally disposed to the storm drain system. The amount of waste oil recycled will be used as an indicator of the effectiveness of this program in reducing stormwater pollution.

- Household Hazardous Waste Collection - Riverside County has implemented a household hazardous waste collection program. It is assumed that a portion of this hazardous waste would result in stormwater pollution if not properly disposed. The amount of household hazardous waste collected under this program will be used as an indicator of the effectiveness of this program in reducing stormwater pollution.

10.1.3 Indicators of Public Awareness

The effectiveness of the Stormwater/Cleanwater Protection Program public awareness campaign will be measured by increases in community participation at the County's household hazardous waste collection events, the use of the Stormwater/Cleanwater Protection Program toll-free telephone number, and program recognition in the general community. Telephone surveys will be conducted to measure the public's awareness of stormwater pollution issues and to gauge the effectiveness of the Stormwater/Cleanwater Protection Program public information efforts during the last three years of the next permit period.

10.1.4 Monitoring

Since BMPs have only been implemented for a short period, there is little or no monitoring data available to adequately assess their effectiveness in improving stormwater quality.

VOL 12 2 2076

R0055376

Methods to assess the effectiveness of the BMPs through stormwater monitoring will be evaluated and, where useful, implemented during the next permit period. However, stormwater quality monitoring is difficult to use in assessing BMP effectiveness for stormwater pollution prevention. The difficulty arises from storm event variability in frequency, duration, and magnitude. Further, monitoring data are being collected concurrent with implementation of many BMPs so that determining the true effectiveness of a specific BMP is unlikely and speculative, at best.

10.1.5 Level of Compliance with State Permit Programs

The Stormwater/Cleanwater Protection Program includes measures to promote compliance with the Industrial Permit and Construction Stormwater Permit. The number of notices of intent and permits issued to industries and construction projects in the Santa Ana River watershed will be obtained and evaluated as an indicator of the success of the Stormwater/Cleanwater Protection Program's activities. Enforcement actions and investigations related to State permit programs will be documented.

10.2 ANNUAL REPORTS

This section describes the annual reporting and Permittee performance evaluation processes which the municipal stormwater NPDES program has conducted during the first five-year permit period. The modifications to the processes planned for the next five-year permit period are described and the respective roles and responsibilities of the Principal Permittee, Co-Permittees, committees, and the Santa Ana RWQCB are presented. In general, the annual reports will discuss the program implemented during the previous year and present a plan that will be implemented during the current year. In addition, the findings of the evaluation of the previous year's program will be used to suggest changes that are appropriate for implementation during the next year, including revisions to the five-year plan.

10.2.1 Reporting Process

The process of annual reporting of the activities of the Permittees to comply with the Santa Ana Permit has evolved over the permit period. The first annual report (fiscal year 1990-

VOL 12 2 2071

R0055377

91) was produced by the Principal Permittee using information supplied by the Co-Permittees. The second and third annual reports (fiscal years 1991-92 and 1992-93) were compiled by the Principal Permittee using slightly modified reporting forms from the previous year, and some sections (e.g., monitoring) were added as new compliance programs were initiated. The fourth annual report (fiscal year 1993-94) was produced by the Principal Permittee using reporting formats developed by a consultant. Blank copies of the standardized reporting forms used by the Co-Permittees are included in Appendix J. In the future, the Advisory Committee will be utilized to assist in developing more effective report formats for fiscal year 1994-95 and throughout the next five-year permit period.

10.2.2 Evaluation Process

Evaluation of Permittee performance was included as a provision of the Santa Ana Permit (Item I.7). Other provisions in the Santa Ana Permit required annual reporting of progress on implementation of illicit connection and illegal discharge elimination programs and an evaluation of the progress of implementation of community-specific activities to reduce the discharge of pollutants in stormwater. The evaluation process conducted during fiscal year 1992-93 included information obtained from questionnaires completed by the Co-Permittees regarding the activities implemented that fiscal year.

10.2.3 Purposes of Annual Reporting

The main purpose of annual reporting is to demonstrate compliance with the Santa Ana Permit. A secondary purpose is to provide a mechanism for improving the implementation of activities or to provide information improving the management of stormwater pollution control programs. These are described below, followed by a summary of the format and content of the annual report.

10.2.3.1 Demonstration of Compliance

This requires the Permittees to provide detailed descriptions of, and pertinent data related to, activities they have implemented to reduce the discharge of pollutants in stormwater. Other information required to be reported include the results of the municipal stormwater monitoring activities, evaluation/assessment of control measure activities in reducing

VOL 12 2 2078

R0055378

pollutants in stormwater, and an evaluation/assessment of the performance of each Permittee in implementation of control measure activities.

10.2.3.2 Mechanism for Improvement

The annual report provides a mechanism for the Permittees to identify activities which are proven effective and to update the DAMP for their continued implementation, and to identify activities which are ineffective, or do not add significant benefit to reduction of pollutants in stormwater, and should no longer be included in the annual report, or implemented as activities of the stormwater pollution reduction effort. Activities which are proven effective include various education efforts (e.g., stenciling, pest brochure, tri-folds), illegal dumping response programs, illicit connection elimination programs, among others. Activities which are implemented for other purposes, and indirectly benefit stormwater pollution reduction efforts include litter control, recycling/collection of household hazardous wastes, stormwater facility maintenance, and street sweeping.

10.3 ANNUAL REPORTING FORMATS

Annual reports covering various elements of the compliance program will be submitted to the Santa Ana RWQCB by November 30 of each year during the next permit period. The annual reports include the items described below.

10.3.1 Water Quality Monitoring

The Water Quality Monitoring report will be submitted on August 31 of each year and will include a summary of the water quality and quantity data collected during the previous fiscal year. In addition, calculations of the pollutant loadings and an analysis of the data will be provided. Modifications to the water quality monitoring program based on the findings or resulting from coordination with regional, state, or federal initiatives will also be presented in conjunction with a budget for the monitoring program for the next fiscal year.

VOL 12 2 2079

R0055379

10.3.2 Progress Report

A Progress Report on the overall permit compliance program will be provided by September 30 of each year. This report will consist of several elements. The fiscal analysis will include a summary of funding, the sources of funding, and how it will be distributed. In addition, an estimate of the cost of each of the compliance program elements and the personnel or contracts that will be required to implement the program will be presented. Estimates for each of the subsequent remaining years of the permit will also be presented.

A program analysis addressing the evaluation of the effectiveness of the program will be included in the Progress Report. This will include a summary of the extent of implementation of BMPs and indirect quantitative measures, indicators of public awareness, monitoring, and the level of compliance with other SWRCB or RWQCB permit programs. Finally, the Progress Report will include a description of modifications to management of the program.

10.3.3 Illicit Connections and Illegal Discharges

A report on the illicit connection and illegal discharges control programs summarizing the following information will be included in the Annual Illegal Discharge Control Report:

- storm drain system inspections conducted;
- illicit connections and illegal discharges identified and eliminated;
- illicit connections and illegal discharges which have not been eliminated;
- enforcement actions taken to eliminate illicit connections or illegal discharges;
- public education pertaining to illicit connections and illegal discharges; and
- public employee training relative to illicit connections and illegal discharges.

10.3.4 Construction

A report on the construction inspection program summarizing the following information will be included in the Annual Report:

- number of inspections;
- standard mitigation measures implemented;
- follow-up actions taken;

VOL 12 2 2080

R0055380

- enforcement actions taken;
- planned modifications to the inspection program; and
- construction inspector training relative to stormwater pollution control.

10.4 SUB-ANNUAL MEETING

Annually, between April 15 and May 15, the Permittees will meet with the Santa Ana RWQCB to report on the implementation of that year's program, present a preliminary budget for the next fiscal year program addressing the funding issues for the upcoming budget process, and to discuss preliminary plans for the next year, including what revisions to the five year plan will be required. Feedback from these discussions will be used in preparation of the Annual Report.

10.5 INTERNAL REPORTING

A series of standardized reporting forms have been prepared for use in communicating compliance activities to the Santa Ana RWQCB. These forms are included in the DAMP.

10.6 STORMWATER MANAGEMENT PLAN REVISIONS

The DAMP will continue to evolve during the next permit period. However, to minimize confusion and promote compliance, the DAMP will only be formally updated once during the next permit period. An updated DAMP will be provided to each of the Permittees and the Santa Ana RWQCB.

SECTION 11

R0055382

California Regional Water Quality Control Board
Santa Ana Region
2010 Iowa Avenue, Suite 100
Riverside, CA 92507-2409

FACT SHEET

PROJECT

The attached pages contain information concerning an application for waste discharge requirements and a National Pollutant Discharge Elimination System (NPDES) permit, Order 95-____, NPDES No. CA _____, which prescribes waste discharge requirements for urban stormwater runoff from the cities and the unincorporated areas in Riverside County within the jurisdiction of the Santa Ana Regional Board. On January 3, 1995 the Riverside County Flood Control and Water Conservation District (RCFC&WCD), the County of Riverside, the Cities of Beaumont, Calimesa, Canyon Lake, Corona, Hemet, Lake Elsinore, Moreno Valley, Norco, Perris, Riverside, and San Jacinto (hereinafter collectively referred to as the Permittees), submitted NPDES Application No. _____ for an area-wide stormwater discharge permit under NPDES. The permit application was submitted in accordance with the previous NPDES permit (Order No. 90-104, NPDES No. CA 8000192) which expires July 1, 1995. Additionally, the permit application follows guidance provided by the staffs of the State Water Resources Control Board (State Board) and Regional Water Quality Control Boards (Regional Boards).

PROJECT AREA

The permitted area is delineated by the San Bernardino-Riverside County boundary line on the north and northwest, the Orange-Riverside County boundary line on the west, the Santa Ana-San Diego Regional Board boundary line on the south, and the Santa Ana Colorado River Basin Regional Board boundary line on the east. Areas of the County not addressed or which are excluded by the stormwater regulations and areas not under the jurisdiction of the Permittees are excluded from the area requested for coverage under this permit application. This includes the following areas and activities:

- federal lands and state properties, including, but not limited to, military bases, national forests, hospitals, colleges and universities, and highways;
- Native American tribal lands;

VOL 12 2 20083
R0055383

- open space and rural (non-urbanized) areas;
- agricultural lands; and
- utilities and special districts.

As a partial illustration, federal and state lands in Riverside County within the jurisdiction of the Santa Ana Regional Board, for which coverage under a municipal stormwater NPDES permit is excluded, are shown in Appendix A (Western Riverside County NPDES Permit Area).

CLEAN WATER ACT REQUIREMENTS

The Federal Clean Water Act (CWA) allows the United States Environmental Protection Agency (USEPA) to delegate its NPDES permitting authority to states with an approved environmental regulatory program. The State of California is one of the delegated states. The Porter-Cologne Act (California Water Code) authorizes the State Board, through its Regional Boards, to regulate and control the discharge of pollutants into waters of the State and tributaries thereto. Section 405 of the Water Quality Act (WQA) of 1987 added Section 402(p) to the CWA. Pursuant to Section 402(p)(4) of the CWA, the USEPA promulgated regulations for stormwater permit applications for stormwater discharges associated with industrial activities and municipal separate storm drain systems serving a population of 100,000 or more. This permit governing municipal stormwater discharges meets both the statutory requirements of Section 402(p)(3)(B) and all requirements applicable to an NPDES permit issued under the issuing authority's discretionary authority in accordance with Section 401(a)(1)(B) of the CWA.

AREA-WIDE STORMWATER PERMIT

To regulate and control stormwater discharges from the Riverside County area to the municipal storm drain systems, an area-wide approach is essential. The entire storm drain system is not controlled by a single entity; the RCFC&WCD, the County, several Cities and the State Department of Transportation (Caltrans), U.S. Army Corps of Engineers, in addition to other smaller entities, manage the systems. In addition to the Cities, the County and the RCFC&WCD, there are a number of other significant contributors of urban stormwater runoff to these storm drain systems. These include: large institutions such as the State university system, schools, hospitals, etc.; federal facilities such as military sites, etc.; State agencies such as Caltrans, water and wastewater management agencies such as Eastern and Western Municipal Water District; the National Forest Service and State parks. The Regional Board has issued a separate NPDES permit to Caltrans. In addition, Caltrans, and the other contributors identified, are not under the jurisdiction of the Permittees. The management and control of the entire flood control system cannot be effectively carried out without the cooperation and efforts of all these entities. Also, it would not be meaningful to issue a separate stormwater permit to each of the entities within

VOL 12 2 2084

R0055384

the permitted area whose land/facilities drain into the storm drain systems operated by the Permittees. The Regional Board has concluded that the best management option for the Riverside County area is to issue an area-wide stormwater permit to the RCFC&WCD, Riverside County, and the cities in Riverside County. A separate stormwater NPDES permit has been issued to Caltrans. Stormwater discharges from other state, federal, utility, or special district facilities and state or federal lands will either be added to the Riverside County permit or permitted separately.

Some of the RCFC&WCD storm drain systems discharge into storm drain systems controlled by other entities, such as the Orange County Flood Control District, which is (or will be) regulated under the Regional Board's Order No. 95-_____, NPDES No. CA _____. Some areas within Riverside County are within the Colorado River Basin and San Diego Regional Boards' jurisdiction. Permit requirements for stormwater runoff from the drainage areas of Riverside County within the jurisdiction of the San Diego and Colorado River Basin Regional Boards are addressed by these Regional Boards.

COORDINATION WITH OTHER REGIONAL AGENCIES

In developing best management practices and monitoring programs, consultation/coordination with other drainage management entities and other Regional Boards is essential. Regional Board staff will coordinate the program with other Regional Boards and other flood control entities/cities on an "as needed" basis. The permit/program process is at the same stage of development in both the Santa Ana and San Diego Regional Board areas of Riverside County. Common programs, reports, implementation schedules and efforts are desirable and will be utilized to the maximum extent practicable.

EXISTING FACILITIES AND PROGRAMS

Within the Santa Ana Region, the RCFC&WCD serves a population of approximately 930,000, occupying an area of approximately 1,360 square miles. The RCFC&WCD's system includes an estimated 200 miles of open and closed storm drains. The storm drain systems operated by the remaining Permittees include an estimated 57 miles of open and closed storm drains. Approximately one-quarter (1/4) of Riverside County drains into water bodies within this Regional Board's jurisdiction. Stormwater discharges from urbanized areas consist mainly of surface runoff from residential, commercial, and industrial developments. In addition, there are stormwater discharges from agricultural land uses, including dairy operations. However, the WQA specifically excludes agricultural discharges from regulation under this program. The constituents of concern and significance in these discharges are: total suspended solids, biochemical oxygen demand (BOD), chemical oxygen demand (COD), oil and grease (O&G), heavy metals, nutrients and organic chemicals such as base/neutral and acid extractables, pesticides and herbicides, and petroleum hydrocarbon components.

To protect the beneficial uses of waters of the State, the pollutants from all sources need

VOL 12 2 2005

R0055385

to be controlled. Recognizing this, and the fact that stormwater discharges contain pollutants, the Permittees and the Regional Board have all agreed that an area-wide stormwater permit is the most effective way to develop and implement a comprehensive stormwater management program in a timely manner. This area-wide stormwater permit contains requirements with time schedules that will allow the Permittees to continue to address water quality problems caused by urban stormwater runoff through their management programs to reduce pollutants in stormwater discharges to the maximum extent practicable.

PERMIT REQUIREMENTS

In accordance with Section 402(p)(3), as part of a program to reduce the pollutants in stormwater discharges to the maximum extent practicable, the Permittees have been required to submit existing management plans and programs being implemented or developed in the previous municipal stormwater NPDES permit to reduce pollutants in stormwater discharges. In addition, the Permittees will be required to report, review and/or revise the management programs and control measures in accordance with a time schedule approved by the Executive Officer of the Regional Board for this municipal permit.

If existing management programs are not effective in controlling pollutant loading and in achieving the water quality objectives of the receiving waters, additional programs shall be developed and implemented upon consultation and approval of the Executive Officer.

The permit also requires the development and implementation of management programs and/or best management practices (BMPs) during the life of the permit such that the quality of stormwater discharged can be improved and the water quality objectives of the receiving waters can be met ultimately. It is also expected that through implementation of these programs and/or BMPs the beneficial uses of the receiving waters will be protected.

BENEFICIAL USES

Stormwater flows which are discharged to municipal storm drain systems in Riverside County are tributary to various water bodies (inland surface streams and lake and reservoirs) of the state. The beneficial uses of these water bodies include municipal and domestic supply, agricultural supply, industrial service supply, industrial process supply, groundwater recharge, water contact recreation, non-contact water recreation, warm freshwater habitat, cold freshwater habitat, wildlife habitat, and preservation of rare and endangered species. The ultimate goal of this stormwater management program is to protect the beneficial uses of the receiving waters.

ANTIDEGRADATION ANALYSIS

The Regional Board has considered whether a complete antidegradation analysis, pursuant to 40 CFR 131.12 and State Board Resolution No. 68-16, is required for these stormwater

VOL 12 2 2086 6

R0055386

discharges. The Regional Board finds that the pollutant loading rates to the receiving waters will be reduced with the implementation of the requirements in this order. As a result, the quality of stormwater discharges and receiving waters will be improved, thereby protecting the beneficial uses of waters of the United States. This is consistent with the federal and state antidegradation requirements and a complete antidegradation analysis is not necessary.

PUBLIC WORKSHOP

The Regional Board recognizes the significance of Riverside County's Stormwater/Cleanwater Protection Program and will conduct, participate, and/or assist with at least one workshop every year during the term of this permit to promote and discuss the progress of the stormwater management program. The details of the annual workshop will be published in local newspapers and mailed to interested parties. Persons wishing to be included in the mailing list for any of the items related to this permit may register their name, mailing address and phone number with the Regional Board office at the address given below.

PUBLIC HEARING

The Regional Board will hold a public hearing regarding the proposed waste discharge requirements. The public hearing is scheduled to be held on Friday, June __, 1995, at 9:00 a.m. at the _____. Further information regarding the conduct and nature of the public hearing concerning these waste discharge requirements may be obtained by writing or visiting the Santa Ana Regional Board office, 2010 Iowa Avenue, Suite 100, Riverside, CA 92507.

WRITTEN COMMENTS

Interested persons are invited to submit written comments on the proposed waste discharge requirements and the Executive Officer's proposed determinations. Comments should be submitted by _____ either in person or by mail to:

Pavlova Vitale
California Regional Water Quality Control Board
Santa Ana Region
2010 Iowa Avenue, Suite 100
Riverside, CA 92507

INFORMATION AND COPYING

Persons wishing further information may write to the above address or call Pavlova Vitale at 909/782-4290. Copies of the application, proposed waste discharge requirements, and other documents (other than those which the Executive Officer maintains as confidential)

VOL 12 2 2087

R0055387

are available at the Regional Board office for inspection and copying by appointment scheduled between the hours of 10:00 a.m. and 4:00 p.m., Monday through Thursday (excluding holidays).

REGISTER OF INTERESTED PERSONS

Any person interested in a particular application or group for applications may leave his name, address and phone number as part of the file for an application. Copies of tentative waste discharge requirements will be mailed to all interested parties.

VOL 12 2 2008

R0055388

California Regional Water Quality Control Board
Santa Ana Region

ORDER NO. 95-____

NPDES NO. CA95_____

Waste Discharge Requirements
for the Riverside County Flood Control
and Water Conservation District,
the County of Riverside
and the Incorporated Cities of Riverside County
For Area-Wide Urban Stormwater Runoff
Within the Santa Ana Region of Riverside County

The California Regional Water Quality Control Board, Santa Ana Region (hereinafter called Regional Board), finds that:

1. On January 3, 1995, the Riverside County Flood Control and Water Conservation District (RCFC&WCD) in cooperation with the County of Riverside and the Cities of Beaumont, Calimesa, Canyon Lake, Corona, Hemet, Lake Elsinore, Moreno Valley, Norco, Perris, Riverside and San Jacinto (hereinafter collectively referred to as the Permittees), submitted National Pollutant Discharge Elimination System (NPDES) Application No. CA 95____ for an area-wide stormwater discharge permit under the NPDES.

2. The 1972 Clean Water Act (CWA) recognized the need to prohibit the discharge of pollutants to surface water bodies from point sources such as industrial facilities and municipal sewage treatment plants. The discharge of pollutants from point sources is regulated by the NPDES permit system, which requires technology-based controls for treatment of wastewater. Stormwater point source discharges were exempt from the NPDES permitting requirements unless these discharges were contaminated by industrial/commercial activity. The Regional Board recognized the water quality problems associated with stormwater from industrial facilities and has issued a number of stormwater permits for such facilities in accordance with the United States Environmental Protection Agency (USEPA) regulations.

3. In 1976, the USEPA issued new regulations establishing a comprehensive permitting program for all stormwater discharges except for rural runoff uncontaminated by industrial/commercial activity. Channelized stormwater runoff continued to be defined as non-point source unless designated otherwise by the permitting authority.

VOL 12 2 2089

R0055389

4. Since 1976, the USEPA has issued several revisions to the stormwater regulations. Section 405 of the Water Quality Act (WQA) of 1987 added Section 402(p) to the CWA. Pursuant to Section 402(p)(4) of the CWA, the USEPA was required to promulgate regulations for stormwater discharges associated with industrial activities and municipal separate storm drain systems serving a population of 100,000 or more, or area designated by the Director of the USEPA or permitting State agency.

5. On December 7, 1988, the USEPA published its proposed regulations for stormwater discharges in the Federal Register to solicit public comments. Final regulations were promulgated and published in the Federal Register on November 16, 1990.

6. The beneficial uses of a number of water bodies within Riverside County are threatened or impaired which may be in part due to urban stormwater runoff and non-stormwater flows from urbanized areas. These water bodies include the Santa Ana River, Reaches 3 and 4, Canyon Lake, Lake Elsinore, Lake Evans and Lake Mathews. A comprehensive stormwater and urban runoff management and regulatory program is essential for the protection of the water resources of the Region. The RCFC&WCD, the County of Riverside, the Cities in Riverside County, and the Regional Board have recognized this fact, and as a first step toward protecting water quality in the area, a comprehensive stormwater management program has been developed. This order outlines the existing programs and specifies additional requirements and/or modifications to achieve water quality objectives for the Riverside County drainage areas within the Santa Ana Region. The intent of this permit is to regulate pollutants associated with discharges of stormwater from municipal storm drain systems and improve water quality in the Region in a timely manner.

7. Within the Santa Ana Region, the RCFC&WCD serves a population of approximately 930,000, occupying an area of approximately 1,360 square miles. The RCFC&WCD's storm drain system includes an estimated 200 miles of opened and closed storm drains, and the systems operated by the remaining Permittees include an estimated 57 miles of opened and closed storm drains.

8. The discharges from the municipal storm drain system consists of surface runoff generated from various land uses in all the hydrologic drainage areas which discharge into water bodies in Riverside County. The quality of these discharges varies considerably and is affected by land use activities, basin hydrology and geology, season, the frequency and duration of storm events and point source discharges permitted by the Regional Board under NPDES. The constituents of concern and significance in these discharges are: total and fecal coliform, enterococcus, total suspended solids, biochemical oxygen

VOL 12 2 2090

R0055390

demand (BOD), chemical oxygen demand (COD), total organic carbon (TOC), oil and grease, heavy metals, nutrients, base/neutral and acid extractables, pesticides and herbicides, and petroleum hydrocarbon components.

9. There are several entities whose land/facilities drain into the Riverside County municipal storm drain systems operated by the Permittees. The RCFC&WCD operates approximately 85 percent of the storm drain systems within the Region, and has agreed to be the lead party in implementing the provisions of this order. The remaining storm drain systems are owned and operated by the County and Cities within the county and by the State Department of Transportation (Caltrans). The County of Riverside and the incorporated Cities within the county have agreed to cooperate with the RCFC&WCD in controlling and improving the quality of urban runoff from their respective areas. The RCFC&WCD has been named as the Principal Permittee and the County of Riverside and the incorporated Cities have been named as the Co-Permittees. Appendix B lists the incorporated Cities with their 1994 estimated populations. Of the eleven Cities, there are two Cities with an estimated 1994 population over 100,000. The Regional Board has issued a separate stormwater NPDES permit to Caltrans.

10. Due to the enormous variability in stormwater quality and the complexity of the urban runoff management program, this area-wide stormwater permit is categorized as a major NPDES permit. This area-wide stormwater permit requires all entities discharging stormwater/urban runoff into the storm drain systems or any surface water bodies to have appropriate controls for proper management of this runoff. The Regional Board has the discretion and authority to require non-cooperating entities to participate in this area-wide permit or obtain individual stormwater discharge permits, pursuant to 40 CFR 122.26(a). The entities listed in Appendix C are considered as potential permittees of stormwater to the Riverside County drainage areas. It is expected that these entities will also work cooperatively with the RCFC&WCD, the County of Riverside and Cities to manage urban runoff.

11. The RCFC&WCD, as the Principal Permittee, will obtain (within its powers) the cooperation of all entities in implementing the provisions of this order. The Permittees have agreed upon the responsibilities as described in the November 19, 1991 Implementation Agreement. This agreement will be revised to reflect this order. In general, the RCFC&WCD, as the Principal Permittee, is responsible for the monitoring program, general overall education program, the RCFC&WCD fiscal information, coordinating and submitting Permittee reports to the Regional Board and conducting inspections of the RCFC&WCD's storm drain systems. The County of Riverside and the incorporated cities, as the Co-Permittees, will develop and

VOL 12 2 2091 1

R0055391

implement site-specific compliance requirements, perform compliance monitoring and inspections, submit storm drain maps, fiscal and other information and compliance reports to the RCFC&WCD, exercise enforcement authority for achieving compliance with programs or BMPs, and review and implement stormwater management programs. The Regional Board will regulate stormwater discharges from state and federal facilities and activities, public utilities, and special districts and other stormwater discharges not under the jurisdiction of the Permittees.

12. The RCFC&WCD obtains its authority to control stormwater discharges, to prohibit discharges or connections to their facilities and to require compliance and carry out inspections of the storm drain systems within the District's boundaries from the RCFC&WCD Act. Various County and city ordinances which address industrial wastes and waste discharges, and land use within the unincorporated areas of Riverside County and Cities can be used by the Permittees to implement compliance activities. The Permittees have various forms of legal authority in place, such as charters, State Code Provisions for General Law Cities, city ordinances, and applicable portions of municipal codes and the State Water Code, to regulate stormwater/urban runoff discharges.

13. The RCFC&WCD has an active surface water quality monitoring program as described in detail in Appendix D of this Order. Initiatives to coordinate stormwater quality monitoring are being discussed at the federal, state and regional levels. These initiatives contemplate potential revisions in local stormwater monitoring programs including participation in special studies, increased data sharing, and modification of baseline data collection activities. It is anticipated that one or more of these initiatives may be implemented as early as fiscal year 1995/96. The Monitoring Program may be modified to reflect the participation of the Permittees in the coordinated monitoring programs or to reflect the findings of special studies.

14. A Water Quality Control Plan was adopted by the Regional Board on Month Day, 1994. The Plan contains water quality objectives and beneficial uses of waters in the Santa Ana Region.

15. The requirements contained in this order are necessary to implement the Water Quality Control Plan.

16. An attempt has been made to incorporate all of the essential elements of the federal stormwater regulations in this permit.

17. Stormwater discharges to the storm drain systems in Riverside County within the Santa Ana Region are tributary to various water bodies of the State. The

VOL 12 2 2092

R0055392

identified water bodies are as follows (only a portion of some of the water bodies listed below is within Riverside County):

A. Inland Surface Streams

a. Santa Ana River
Santa Ana River, Reaches 3 and 4

b. Tributary to South Bank Santa Ana River
Tequesquite Arroyo (Sycamore Creek)
Temescal Creek, Reaches 1, 2, 3, 4, 5 and 6
Temescal Tributaries
Coldwater Canyon Creek
Bedford Canyon Creek
Other tributaries to these creeks

c. Tributary to North Bank Santa Ana River
Day Creek
Sevaine Creek

d. San Jacinto River Basin
San Jacinto River, Reaches 1, 2, 3, 4, 5, 6 and 7
Bautista Creek - Headwaters to Debris Dam
Strawberry Creek
San Jacinto River, North Fork
Fuller Mill Creek
Stone Creek
Salt Creek
Other tributaries: Indian, Hurkey, Poppet and Potrero Creeks

e. San Timoteo Creek Area Streams
San Timoteo Creek, Reach 4
Little San Gorgonio Creek
Other Tributaries to these Creeks - Valley Reaches
Other Tributaries to these Creeks - Mountain Reaches

f. Reche Canyon
Reche Canyon

B. Lake and Reservoirs

a. Lake Evans
b. Lee Lake
c. Lake Mathews

VOL 12 2 2093

R0055393

d. Mockingbird Reservoir
e. Canyon Lake
f. Lake Elsinore
g. Lake Fulmor
h. Lake Hemet
i. Lake Perris

The beneficial uses of these water bodies include municipal and domestic supply (MUN), agricultural supply (AGR), industrial service supply (IND), industrial process supply (PROC), groundwater recharge (GWR), water contact recreation (REC-1), non-contact water recreation (REC-2), warm freshwater habitat (WARM), cold freshwater habitat (COLD), wildlife habitat (WILD), and preservation of rare and endangered species (RARE). The beneficial uses of individual water bodies are shown on Appendix E.

18. Stormwater discharged from the storm drain systems operated by the County of San Bernardino drain into various water bodies in the project/permit area. These water bodies include the Santa Ana River and San Timoteo Creek and various mountain creeks. The County of San Bernardino has been issued an area-wide stormwater permit (Order No. 90-) for effective control of the pollutants in the stormwater runoff discharged from its storm drain systems.

19. Numeric and narrative water quality standards exist (as found in the Basin Plan's Water Quality objectives) for the water bodies listed in Item No. 17 above. Currently, this Permit does not contain numeric limitations for any constituents because the impact of stormwater discharges on the water quality of the above named receiving waters has not been fully determined. Extensive water quality monitoring and analysis of the data are essential to make that determination. This order requires the Permittees to continue to monitor the stormwater discharges or begin monitoring as necessary, and to analyze the data. Additionally, since this order also requires development and implementation of BMPs by the Permittees, the pollutants in the stormwater runoff will be improved. The ultimate goal of the urban stormwater runoff management program is to attain water quality consistent with the water quality objectives for the receiving waters to protect the beneficial uses.

20. With respect to industrial activities, the Regional Board currently regulates discharges of point source process wastewater and non-process wastewater and stormwater discharges to storm drain systems through NPDES permits. Point source discharges other than stormwater will continue to be regulated by the Regional Board. Industrial stormwater dischargers are required to cooperate with the Permittees to control the discharge of pollutants in the stormwater runoff from individual facilities or to obtain individual industrial stormwater discharge or NPDES General Industrial or NPDES General Construction

VOL 12 2 2094

R0055394

Permits from the Regional Board.

21. Recognizing the need for public involvement and participation in the development and implementation of an effective stormwater/urban runoff management program, the Regional Board will conduct at least one workshop each year during the term of this permit. The purposes of the workshops will be to solicit comments and to inform the public of the progress of the program. Written comments submitted will be forwarded to the State Board, the USEPA, and the RCFC&WCD for their review and comments.

22. In accordance with California Water Code Section 13389, the issuance of waste discharge requirements for this discharge is exempt from those provisions of the California Environmental Quality Act (CEQA) contained in Chapter 3 (commencing with Section 21100), Division 13 of the Public Resources Code.

23. The Regional Board has considered an antidegradation analysis, pursuant to 40 CFR 131.12 and State Board Resolution No. 68-16, for this discharge. The Regional Board finds that the stormwater discharges are consistent with the Federal and State antidegradation requirements and a complete antidegradation analysis is not necessary.

24. The Regional Board has notified the Permittees and interested agencies and persons of its intent to issue waste discharge requirements for this discharge and has provided them with an opportunity to submit their written views and recommendations.

25. The Regional Board, in a public hearing, heard and considered all comments pertaining to the discharge and to the tentative requirements.

IT IS HEREBY ORDERED that the Permittees, in order to meet the provisions contained in Division 7 of the California Water Code and regulations adopted thereunder, and the provisions of the Clean Water Act, as amended, and regulations and guidelines adopted thereunder, shall comply with the following:

I. RESPONSIBILITIES OF PRINCIPAL PERMITTEE

The Principal Permittee shall be responsible to manage the program overall, including:

1. Conduct water quality and necessary hydrographic monitoring of the storm drain system as agreed to by the Executive Officer, as contained in the Consolidated Program for Water Quality Monitoring (Appendix D) and as noted in Section VI of this Order. Initiatives to coordinate stormwater quality

VOL 12 2 2095

R0055395

monitoring are being discussed at the federal, state and regional levels. These initiatives contemplate potential revisions in local stormwater monitoring programs including participation in special studies, increased data sharing, and modification of baseline data collection activities. It is anticipated that one or more of these initiatives may be implemented as early as fiscal year 1995/96. The Monitoring Program may be modified to reflect the participation of the Permittees in the coordinated monitoring programs or to reflect the findings of special studies.

2. Implement uniform methods and criteria for storm drain system inspections by all Permittees as agreed to by the Executive Officer, as contained in the Reconnaissance Survey Implementation Plan (Appendix F) and as noted in Section IV of this Order.

3. Conduct inspections/surveillance for illegal discharges to the storm drain facilities within its jurisdiction (ownership) as noted in Section IV of this Order.

4. Implement management programs, and implementation plans within its jurisdiction and powers as required by this Order.

5. Prepare and submit to the Regional Board all the reports, plans and programs as required by this Order.

6. Monitor the implementation of the plans and programs to determine their effectiveness in attaining water quality objectives to the MEP (maximum extent practicable).

7. Coordinate all the activities with the Regional Board.

8. Enact legislation and ordinances as necessary to establish legal authority within the scope and powers of the RCFC & WCD Act.

9. Obtain public input for any proposed management and implementation plans.

10. Pursue enforcement actions as necessary to ensure compliance with stormwater management programs and implementation plans within the scope and powers of the RCFC & WCD Act.

11. Respond to or arrange for a response to emergency situations such as accidental spills, leaks, illegal discharges, illicit connections etc. to prevent or reduce the discharge of pollutants to storm drain systems and waters of the United States.

VOL 12 2 2096

R0055396

II. RESPONSIBILITIES OF THE CO-PERMITTEES

The Co-Permittees shall be responsible to manage the program within their respective jurisdictions, including:

1. Conduct inspections/surveillance for illegal discharges to the storm drain facilities within their jurisdiction as noted in Section IV of this Order.

2. Conduct and coordinate with the Principal Permittee any surveys and characterizations needed to identify pollutant sources and drainage areas

3. Review, comment and approve management programs, monitoring programs (not stormwater sampling), implementation plans and other elements of the overall program.

4. Implement management programs, monitoring programs (not stormwater sampling) implementation plans and other elements of the overall program within each respective jurisdiction as required by this Order.

5. Submit storm drain facility system maps with periodic revisions as necessary to the Principal Permittee.

6. Prepare and submit all reports and other information to the Principal Permittee in a timely manner with sufficient time for the group report to be submitted, in accordance with Section IX, to the Executive Officer.

7. Adopt resolutions and ordinances as necessary to establish legal controls required for direction of staff or to enable enforcement action to prevent or prosecute stormwater pollution violations.

8. Pursue enforcement actions as necessary to ensure compliance with the stormwater management programs and the implementation plans.

9. Respond to or arrange for a response to emergency situation(s) such as accidental spills, illegal discharges, illicit connections, etc. to prevent or reduce the discharge of pollutants to the storm drain facilities and waters of the United States.

III. RESPONSIBILITIES OF THE RWQCB

1. The RWQCB shall review and provide written comments on reports, plans and other submittals within 60 days. Failure of the RWQCB to provide written comments within this time period will constitute approval.

VOL 12 2 2097

R0055397

2. The RWQCB shall institute investigation and enforcement actions in response to reports of non-compliance with the Industrial and Construction Stormwater Permits and illegal discharges, as appropriate, including those reported by the Permittees.

3. The RWQCB shall coordinate review and approval of NPDES Permits for discharge to surface waters or storm drain facilities in Riverside County with the Permittees. NPDES permits shall not be issued where there will be a conflict with the requirements of the Permit or objectives of the municipal stormwater compliance program.

4. The RWQCB shall regulate and assist in coordinating pollution control programs for stormwater and other discharges from areas and activities in Riverside County excluded from this Permit (e.g., Caltrans, state and federal facilities, agricultural activities, etc.).

5. The RWQCB shall facilitate municipal stormwater permit compliance activities by participating in meetings and providing guidance.

6. The RWQCB shall provide current listings of Notices of Intent (NOI) filed for compliance with the Industrial and Construction Stormwater Permits, SWRCB De-minimus Permit (proposed), General Dewatering Permit and others to the Permittees on request.

7. The RWQCB shall support and facilitate development and implementation of area-wide and regional stormwater compliance programs.

IV. GENERAL REQUIREMENTS

1. The Permittees shall prohibit illegal discharges from entering into the municipal storm drain facilities. Discharges conditionally allowed to enter storm drain facilities are specified in Section IV.

2. The Permittees have developed and begun implementation of best management practices (BMPs) to control discharges of pollutants to the maximum extent practicable to the waters of the United States. The BMPs so developed, are found in the Santa Ana Drainage Area Management Plan (DAMP) (Appendix G). The DAMP shall be up-dated and revised, if necessary, in accordance with Section IX (REPORTING).

VOL 12 2 2098

R0055398

V. ILLEGAL DISCHARGE CONTROL PROGRAM

1. The Permittees shall implement the Reconnaissance Survey Implementation Plan as developed by the Permittees, as the result of Order 90-104, and included in this Order as Appendix F. In addition or modification to said Plan the following shall apply:

   A. Storm drain systems not previously inspected must be inspected for illegal discharges and illicit connections during the first permit year. This applies to pipes 36 inches and larger built before June 1990 and channels with a bottom width larger than two feet or a depth greater than three feet.

   B. Underground storm drains previously inspected need not be inspected during this permit period.

   C. Channels will be inspected during the third year of the permit period for illegal discharges and illicit connections.

   D. All illicit connections identified shall be eliminated during this permit period.

   E. All illicit discharges identified shall be traced to their source and the source eliminated or permitted by the Regional Board.

   F. A yearly report shall be submitted to the Regional Board, by the month and day specified in Section IX (REPORTING), and shall include the following information:

      1. List of all drainage facilities inspected preformed during the year.

      2. List of all illegal and illicit connections and discharges found during the year and all previously found that have not been eliminated or permitted by the Regional Board.

      3. Information of all inspections, enforcement or other actions taken regarding illegal discharges, illicit connections, illegal disposal of wastes, etc. to public right of ways, public properties or receiving waters, that may or does cause water pollution.

      4. A description of how the Permittees preformed all the actions/duties listed above.

VOL 12 2 2099

R0055399

5. A Reconnaissance Survey Implementation Plan updated from the previous permit period shall be submitted in the first permit year. The up-date shall be complete with reporting forms and how the forms are processed, public personnel/inspector training information or process, who the internal enforcement agency or personnel are and the legal authority used (i.e. laws, ordinance, etc.) for enforcement. If an outside agency preforms the enforcement (i.e. a city has the County Environmental Health Department for enforcement) the agreement needs to be cited and the enforcement process described.

6. The up-dated Reconnaissance Survey Implementation Plan shall be submitted in accordance with Section IX REPORTING. Previous reconnaissance plans and reports have been submitted and are accepted by the Board; no retroactive revisions will be made other than those noted herein.

VI. DRAINAGE AREA MANAGEMENT PLAN

Submittals made for the DAMP under order 90-104 have been accepted and no revisions are required unless stated in this Order.

1. The Permittees have developed and are implementing Santa Ana Regional DAMP which is included in this Order as Appendix G. This plan has been approved by the Executive Officer and will meet the requirements of this section if properly implemented. Appendixes H through L included with this Order and noted below are the result of development of different portions of the DAMP. These Appendixes H through L are hereby included in the DAMP as DAMP Supplements A through E ; as noted below.

Appendix H	New Development Conditions Supplement "A"
Appendix I	Education Program Outline Supplement "B"
Appendix J	Stormwater Ordinance Supplement "C"
Appendix K	Soil Erosion Control Ordinance Supplement "D"
Appendix L	NPDES Reporting Forms Supplement "E"

2. The DAMP shall be reviewed, evaluated and revised as needed by the Permittees and an updated DAMP shall be submitted in accordance with Section IX (REPORTING). The Permittees shall address all the best management practices (BMPs) in the DAMP and its Supplements as well as

VOL 12 2 2/100

R0055400

the following:

A. Enforcement procedures/programs established by the cities and County for the enforcement of the Stormwater and the Soil Erosion Control ordinances.

B. BMPs or stormwater pollution prevention plans (SWPPPs) used by the Co-Permittees at their facilities, buildings and yards.

C. Hazardous/toxic waste collection programs.

D. Hazardous/toxic spill response

E. Cooperative action taken with or for the state in conjunction with the state's NPDES Construction General Permit.

F. Cooperative actions taken with or for the state in conjunction with the state's NPDES Industrial General Permit.

G. A listing of all of the Permittees' facilities or projects that are permitted with the NPDES Industrial or Construction General Permits.

3. The Permittees shall submit a DAMP progress report, except during the second permit year, assessing the progress of implementation of the DAMP and evaluating the effectiveness of the BMPs developed for the stormwater discharges. The yearly progress report will also address all of the items A through G listed in Section V.2 DRAINAGE AREA MANAGEMENT PLAN. The DAMP progress report will be submitted in accordance with the schedule in Section IX (REPORTING).

VII. WATER QUALITY MONITORING

1. The Principal Permittee shall implement the Consolidated Program for Water Quality Monitoring (CPWQM) included in this Order as Appendix D. The CPWQM was developed by the RCFC&WCD to address water quality monitoring in Regions 8 and 9 as a program for stormwater system monitoring, receiving water monitoring and data analysis of the monitoring. The CPWQM was written to also include monitoring in Region 7 once a permit is issued.

   The Board supports the concept of a consolidated monitoring program as long as the particular issues of concern of this Regional Board are addressed. In general, a study or pilot program in one Region will be acceptable by this Board as it is deemed to apply and need not be repeated in the Santa Ana

VOL 12 2 2101

R0055401

River watershed.

2. In addition to implementing the CPWQM the Permittees shall include in their monitoring program the following:

   A. The CPWQM shall have the following purposes:

      1. To assess the quality of stormwater entering receiving waters.

      2. To assess water quality status or changes in the receiving waters.

      3. To provide a basis for mass loading estimates.

      4. To provide support to the Illegal Discharge Control Program for the investigation and discovery of illegal discharges or sources of stormwater pollutants.

      5. To characterize pollutants 'produced' by different land uses.

      6. To support the selection, modification, or evaluation of BMPs implemented from the DAMP.

   B. In general the CPWQM shall be supportive of the other programs and activities of the overall NPDES Stormwater Program.

3. Data Analysis Report

   A. The results of the chemical analysis and quantitative data (such as flow, precipitation, and discharge data) shall be compiled according to the drainage area and storm events monitored. The mass loading rates for the pollutant of concern shall be calculated.

   B. An evaluation shall be performed for the calculated mass loading rates from the stormwater and receiving water monitoring. Any impact of the discharges from the storm drainage systems on the receiving waters shall be discussed, starting with the most significantly impacted receiving water bodies. The evaluation shall be concluded with recommendations and the corrective actions proposed for any resulting discrepancies.

4. The RCFC&WCD shall continue the implementation the CPWQM and shall submit a CPWQM progress report and Data Analysis report on the dates specified in Section IX (REPORTING).

VOL 12 2 2-102

R0055402

VIII. FISCAL ANALYSIS

1. A Fiscal Analysis report shall be submitted to the Regional Board on the dates specified in Section IX (REPORTING). The report shall include information on or an analysis of the following:

   A. Each Permittee's expenditures for the previous fiscal year.

   B. Each Permittee's budget for the current fiscal year.

   C. A description of the source of funds for items 1 and 2

   D. Contract services (relating to the NPDES Program) - describing the service provided and the amount charged for the service.

   E. A list of staff, type of work, estimated time dedicated to the stormwater program and estimated cost.

IX. PROGRAM ANALYSIS

1. Each year the Principal Permittee shall conduct an analysis of the effectiveness of the overall stormwater management program. If the water quality objectives of the receiving waters are violated as a result of urban stormwater runoff discharges, the Principal Permittee shall identify proposed action(s) which intend to result in the attainment of the water quality objectives. The Principal Permittee shall also propose a time schedule to implement the new action(s).

2. The Program Analysis Report shall provide information explaining or showing the institutional arrangements of the Permittees as a group and individually and the legal authority each has to implement or enforce the various programs of this Order as follows:

   A. a macro flow chart showing all the Permittees and their relationship with each other and other key agencies;

   B. a micro flow chart showing the internal relationships between each Permittee's departments and any external agencies;

   C. a chart of all the BMPs, programs, and actions and the responsible party; and

   D. a copy of all agreements for the implementation or performance of services related to the NPDES Stormwater

VOL 12 2 2103

R0055403

Program. Once submitted, such agreements need not be submitted the following years.

3. An evaluation of each BMP from the DAMP and other program elements prescribed in this Order implemented by each individual Permittee shall be included with the Program Analysis Report. The Principal Permittee shall develop standard reporting forms and methods for the evaluation. The proposed evaluation forms shall be submitted to the Regional Board for review and approval six months prior to submittal of the Program Analysis Report.

4. Existing data and information pertinent to this program shall be updated annually and submitted as part of the Program Analysis Report; unless covered elsewhere in this Order. The existing information and data to be updated shall include but not be limited to:

   A. Any changes or additions in storm drainage facilities, new outfalls, or any new major structural controls.

   B. Identification of land uses in each drainage area that is sampled during the previous year. The map shall show the storm drain system, drainage boundaries, sampling location and the following groups of land uses: commercial; industrial (including hospitals); parks, schools, and churches; residential; undeveloped and rural (less than one house per two-acres); and agriculture.

   C. Any additional industries subject to the State's General Industrial Activities Stormwater Permit identified during the last year.

X. REPORTING

1. All reports shall be signed by the Principal Permittee or duly authorized representative of the Permittees and shall be submitted to the Regional Board under penalty of perjury.

2. The Permittees shall be responsible for the submittal of the needed information, forms, data, or other materials needed to meet the requirements of each and every submittal with or without request from the Principal Permittee or the Regional Board to the Principal Permittee. Said information, forms, data, or other material submitted for reporting to the Regional Board shall be signed by a duly authorized representative of that Permittee under penalty of perjury.

3. Reports or submittals required in the previous sections of this Order shall be

VOL 12 2 2104

R0055404

submitted in accordance with the following schedule:

	Submittal/Report	Frequency	Date
A.	Water Quality Monitoring 1. Stormwater 2. Receiving Waters 3. Data Analysis	Yearly	August 31
B.	Progress Report 1. Fiscal Analysis 2. Program Analysis 3. Existing Data Update 4. DAMP Progress 5. Program Management	Yearly	September 30
C.	Illegal Discharge Control 1. Personnel Training/Reports 2. Facility/Channel Survey 3. Monitoring Investigations 4. Construction Controls 5. Illegal Reports & Actions 6. Enforcement Actions	Yearly	October 31
D.	DAMP Revision	Once	July 31, 1996
E.	Reconnaissance Survey Implementation Plan/ Illegal Discharge Control Plan Revision	Once	June 30, 1996

XI. EXPIRATION AND RENEWAL

1. This Order expires on July 1, 2000 and the Permittees must file a Permit Renewal Application in accordance with Title 23, Division 3, Chapter 9 of the California Code of Regulations as applicable not later than 180 days in advance of such expiration date as application for issuance of new waste discharge requirements. This Permit Renewal Application shall include, but not be limited to, the following:

   A. Summary of the results of the Monitoring Program.

   B. Summary of the DAMP BMPs implemented and evaluations of their effectiveness.

VOL 12 2 2105

R0055405

C. Summary of the Illegal Discharge Control Program

D. Evaluation of the need for additional BMPs, source control,and other control measures.

E. Proposed plan of urban stormwater runoff quality management activities that will be undertaken during the term of the next Order.

F. Any significant changes to the storm drain systems, outfall, detention or retention basins or dams, and other controls.

XII. CERTIFICATION

This Order shall serve as a NPDES permit pursuant to Section 402(p) of the Clean Water Act, or amendments thereto, and shall become effective 10 days after date of its adoption, provided that the Regional Administrator of the Environmental Protection Agency has no objection. If the Regional Administrator objects to its issuance, the permit shall not become effective until such objection is withdrawn.

I, Gerard J. Thibeault, Executive Officer, do hereby certify that the foregoing is a full, true, and correct copy of an order adopted by the California Regional Water Control Board, Santa Ana Region, on June 29, 1995.

Gerard J. Thibeault

ACKNOWLEDGEMENTS

This report was researched and written by Robert Iosco, Urban Water Quality Specialist, Northern Virginia Soil and Water Conservation District (NVSWCD), Fairfax, Virginia.

The author would particularly like to acknowledge the contributions of Jean R. Packard, Vice-Chairman and Director, NVSWCD, and Norman T. Jeffries, former Executive Director, NVSWCD. They reviewed many drafts and provided valuable insights. In addition, the entire NVSWCD staff deserves thanks for providing the overall assistance necessary to complete this project.

The project was funded by Grant # X-820828-01-0/1/2 from the Nonpoint Source Control Branch, Office of Water, U.S. Environmental Protection Agency, Washington, DC. The EPA Project Officer for this grant was Rod Frederick, Chief, Urban Sources Section, Nonpoint Source Control Branch.

Executive Summary

This manual defines the institutional and programmatic issues which are crucial to the success of runoff control programs in already urbanized or urbanizing areas. These nontechnical factors are often decisive in determining the effectiveness and success of such programs.

The manual describes strategies which local communities can use to develop the institutional frameworks needed to implement runoff control programs. The strategies are described in the program development section of the manual and in the case studies presented.

Each community will have different urban runoff management needs, environmental concerns and available resources. Yet, building an effective program requires certain common key steps. This manual lays out the essential elements, which will also be useful in preparing the management plans required by various Federal regulations and programs. In addition, retrofitting for runoff control may be necessary in some urban areas to achieve the water quality improvements necessary under current Federal and state mandates.

The Coastal Zone Act Reauthorization Amendments of 1990 (CZARA), §6217, required the development of the Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters (USEPA, 1993). States with coastal zone management programs are required to develop coastal nonpoint pollution control programs consistent with these Management Measures. The "Existing Development Management Measure" of Chapter Four (Urban Areas) requires development and implementation of programs to reduce pollution from existing development.

The National Pollutant Discharge Elimination System (NPDES) Storm Water Permit Program, established by §402(p) of the Clean Water Act, requires permits for certain municipal and industrial storm water discharges. In addition, this program requires the development of storm water management plans for the areas covered by the permit, which usually includes urbanized areas.

Both of these programs could involve the use of retrofits to achieve water quality improvements. While program requirements may differ based on the specific regulatory authority, the goals of these programs are complementary and many of the same management practices are applicable and satisfy the requirements of both programs. The case studies presented in this manual provide examples of the innovative ways in which many local governments are meeting the requirements of multiple programs to improve water quality. However, communities need to refer to

VOL 12 2 2 1 1 3

R0055413

applicable state and Federal regulations to assure that they are in compliance with all regulatory requirements.

The manual describes ways that local governments can approach the issues surrounding the implementation of urban runoff retrofit technology even when the control options are limited. It reviews appropriate "ultra-urban" technologies for situations where more conventional, land-intensive control practices are not feasible. Specific recommendations are summarized to help program implementation personnel develop strong institutional frameworks and create effective urban runoff control programs. The recommendations presented are largely based on the program implementation experiences of the case study communities featured in the manual. They include:

Problem Identification

- Identify problems clearly at the outset
- Define runoff control program objectives, requirements, and penalties

Priority & Goal Setting

- Consider innovative and cost effective retrofit methods
- Prioritize retrofit alternatives and set realistic goals to implement

Adequate Funding

- Identify stable and/or dedicated funding sources for urban runoff management programs
- Utilize cost-share approaches among agencies
- Utilize economic incentives to reduce amounts of stormwater discharges, e.g., utility fee reductions for reduced amounts of impervious surface
- Identify opportunities for public/private partnerships to conduct nonpoint source pollution control activities
- Obtain participation and support from private interests who will benefit from urban runoff control programs

VOL 12 2 2114

R0055414

Multilateral Approaches

- Use teams or multi-agency work groups wherever possible
- Create effective institutional structures
- Identify related Federal, state and local programs and assess their storm water control effectiveness and degree of interaction
- Designate a lead agency to coordinate program development and implementation
- Designate sufficient agency staff to support implementation projects

VOL 12 2 2115

R0055415

DEFINING THE PROBLEM OF URBAN RUNOFF MANAGEMENT

Introduction

This manual recommends strategies for communities to use to develop the institutional frameworks necessary for the successful implementation of urban runoff control projects, including retrofit projects in developed areas. It provides practical information for local government personnel who wish to develop such programs. While each community will have different runoff management needs and available resources, building an effective program requires certain common steps. This manual describes the step-by-step procedures necessary to develop effective programs to reduce nonpoint source pollution from urban runoff in developed areas.

Institutional factors have a significant impact on the effectiveness of urban runoff control programs. Because the development of institutional frameworks is vital to effective program implementation, this manual emphasizes program development, rather than specifying technical requirements for programs. (Technical manuals for the implementation of urban runoff controls are listed in the Bibliography.) It recommends strategies and outlines the step-by-step procedures which are necessary to develop urban nonpoint source pollution control programs.

Finally, in the accompanying case studies, this manual describes some approaches which local governments have successfully used to implement urban runoff control programs.

Purpose and Intended Audience of this Manual

This manual provides specific guidance to help local governments implement urban runoff programs. It does not track all regulatory requirements; these will differ by state and locality. Rather, it addresses certain elements of urban runoff control programs that are often problematic for municipalities considering program implemention. It is designed to help them through the program development and implementation process.

A local government wishing to develop an urban runoff control program for developed areas needs to base its approach on local conditions. This manual describes the basic issues in sufficient depth, with the use of examples, to enable a local government to design an effective program based on its particular needs.

The audience for this manual includes public agencies such as local environmental regulatory agencies; regional and local planning agencies; councils of governments; planning commissions, departments of public works, soil and water conservation

VOL 12 2 2116

R0055416

districts, and other agencies concerned with land use, development, and urban runoff management.

However, the general public also needs to be included along with interested environmental groups and elected officials as part of the process of managing urban runoff problems and issues; this manual seeks to impart a basic level of knowledge about these issues to the nonprofessional or nontechnical person.

The purpose of the case studies is to present alternatives for local governments to consider in formulating solutions to urban runoff problems. They have been chosen to provide examples of innovative and successful alternatives in the field.

Brief History of Runoff Control

Urban runoff has not always been recognized as a major contributor of pollutants. Historically, urban nonpoint source pollution has been overlooked by surface water regulation agencies at the local, state and federal levels. Efforts to control surface water quality degradation concentrated on point sources. Urban nonpoint source pollution control focused on street sweeping, used motor oil recycling, and public education.[1] In addition, local governments have historically been concerned mostly with urban runoff quantity control. Water quality concerns have now become equally important for municipalities because of federal and state mandates.

During the first fifteen years of the national program to abate and control water pollution, EPA and the states have focused most of their water pollution control activities on so-called "point sources," such as discharges through pipes from sewage treatment plants and industrial facilities. These point sources have been regulated by EPA and the states through the National Pollutant Discharge Elimination System (NPDES) permit program established by Section 402 of the Clean Water Act.

Congress also amended the Clean Water Act in 1987 to require EPA to establish phased NPDES requirements for storm water discharges. Storm water discharge permits will provide a mechanism for monitoring the discharge of pollutants to waters of the United States and for establishing appropriate controls.[2]

The attempts to control point source pollution have reduced pollutant loads and

VOL 12 2 2 1 1 1 7

R0055417

considerable progress has been made in restoring and maintaining water quality. However, the abatement of point source pollution did not solve all water quality problems. Recent studies and surveys by EPA and by state water quality agencies indicate that the majority of the remaining water quality impairments in our nation's rivers, streams, lakes, estuaries, coastal waters, and wetlands result from nonpoint source pollution and other nontraditional sources, such as urban storm water discharges and combined sewer overflows.

Congress amended the Clean Water Act in 1987 to focus greater national efforts on controlling nonpoint sources. Section 319 of the Act was enacted to establish a national program to control nonpoint sources of water pollution. In addition, Congress enacted Section 6217 of the Coastal Zone Act Reauthorization Amendments (CZARA) in 1990 to address the impact of nonpoint source pollution on coastal waters.

In recent years EPA introduced the Watershed Protection Approach (WPA) as a flexible framework for focusing and integrating current efforts and exploring innovative methods for achieving environmental objectives. The WPA focuses on four major elements: 1) identifying specific geographic locations; 2) integrating available authorities to deal with all pollution sources; 3) involving all stakeholders in analyzing and creating solutions; and 4) measuring effectiveness against clearly established objectives. These key elements are derived from experience gained over the past few years in many states and other EPA efforts such as the Clean Lakes and National Estuaries Programs.

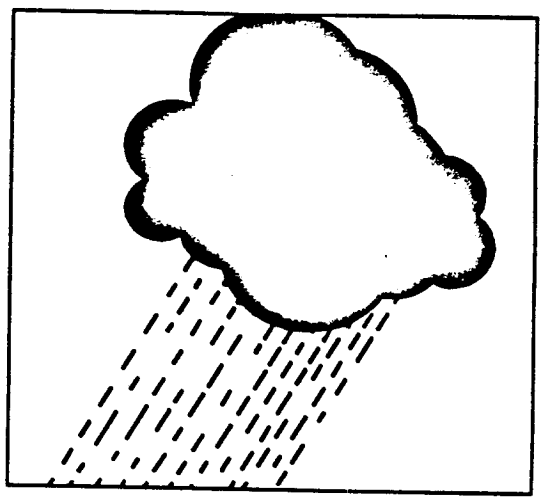
R0055418

How Urban Runoff Adversely Affects Water Resources



Urbanized areas and areas in which development has altered the natural hydrology and infiltration characteristics of the land typically experience increased surface runoff. Land development alters the natural balance between runoff and natural absorption areas by replacing them with greater amounts of impervious surface. The result is increased rates and volumes of surface runoff.

The negative impacts of urbanization on water quality has been well-documented in a number of sources, including the Nationwide Urban Runoff Program (NURP) and the States' reports written in response to the requirements of §305(b) and §319 of the Clean Water Act. For example, the States report that urban runoff and storm sewers are the second leading source of water quality impairment of lakes and estuaries, and the third leading source of water quality impairment of rivers in the United States.[3]

As a consequence of the increased quantity and rate of runoff, greater amounts of pollutants are carried into receiving waters, and water quality degradation increases. Other negative impacts include the increased susceptibility of eroded land to flooding, other hydrologic changes, and wildlife and in-stream habitat degradation. [See Box 1]

The Need for Urban Runoff Management

Many American cities contain areas in which buildings, parking facilities and urban streets and walkways cover almost one hundred percent of the land surface. This creates runoff conditions but offers no room for structural urban runoff quality management facilities such as extended dry detention or wet ponds. Even when redevelopment occurs within these areas, high land values usually require replacement by similarly intense land uses in order to provide economic viability for the project. Conventional best management practices (BMPs) are difficult, if not

[3]USEPA, The Quality of Our Nation's Water: 1992, Office of Water, EPA Document 841-S-94-002, March 1994, p. 10.

VOL 12 2 2119

R0055419

impossible, to implement in this context.

In such situations, innovative BMP applications requiring little or no above ground coverage are necessary in order to meet increasingly stringent Federal and state urban runoff pollution control requirements. In highly urbanized areas, the use of innovative urban quality control retrofitting is the primary option to improve the water quality of surface waters which receive runoff discharges from older urbanized areas.

VOL 12 2 2120

R0055420

Why worry about urban runoff?

What is the problem with urban runoff anyway?

Storm water runoff picks up pollutants and debris as it traverses developed areas, particularly parking lots and streets. During storm events, pollutants are picked up and flushed directly into local lakes, creeks, and streams, without being filtered by the soil or natural vegetative cover. This endangers water quality. Better pollution control is needed to reduce the amount of contamination affecting these water bodies.

Isn't new development the cause of all these problems?

New development, in many localities, has to meet strict regulations on the quality and quantity of storm water runoff. However, many of our current water quality problems are caused by runoff from older, developed areas. We can't solve the problem without retrofitting older stormwater control devices or installing them where none currently exist.

How can we solve this problem?

As the public becomes aware that there are problems with urban runoff quality, and begins to take action, the water quality of area streams and rivers should improve. As people learn that the storm drain at the end of the street flows straight to a nearby stream, they will be more interested in what drains to, or is dumped in, the street catch basin. They will also press their elected officials to incorporate stronger stormwater treatment standards into both new development and redevelopment projects in their community.

How urban runoff affects water resources.

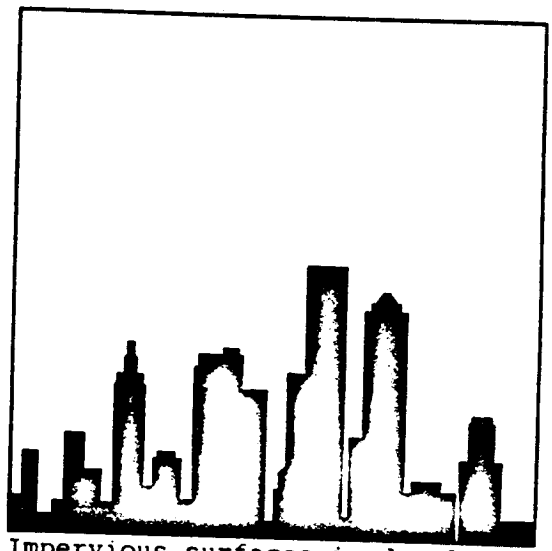
VOL 12 2 2121

R0055421

Retrofitting Developed Areas

As urbanization occurs, and areas of impervious surface increase, maintenance of water quality becomes increasingly difficult. Retrofit of structural controls is often the only feasible alternative for improving water quality in developed areas.

Ideally, as land is developed best management practices would be implemented to control present and future urban runoff problems. However, controlling pollutants in runoff from new development alone will not solve existing water quality problems. Therefore, retrofitting is necessary. It is also the primary option for developed areas to improve urban runoff water quality.



Impervious surfaces in developed areas may cover 100% of the land surface.

Retrofitting is a process that involves the modification of existing surface water runoff control structures or surface water runoff conveyance systems which were designed to control flooding, so they will also serve a water quality improvement function.

Retrofitting should also be considered as an opportunity to improve existing water quality best management practices. Existing practices may be inadequate or performing poorly, or they may simply lack the pollutant removal capability of newer BMP designs. The least expensive and most practicable retrofit opportunities often involve the improvement of existing urban BMPs. BMP retrofits are a widely used technique. The opportunity to improve existing urban BMPs at modest cost, or to convert older dry storm water detention ponds, for example, into more efficient wet extended detention ponds is afforded by a retrofit approach.

Factors such as the presence of existing development, or a community's financial constraints, may limit runoff management options; targeting may be necessary to identify priority pollutants and select the most appropriate retrofit methods. This is particularly true in highly urbanized areas where land is limited and the use of conventional pond systems is restricted.

In highly urbanized areas, sand filters or water quality inlets with oil grit separators

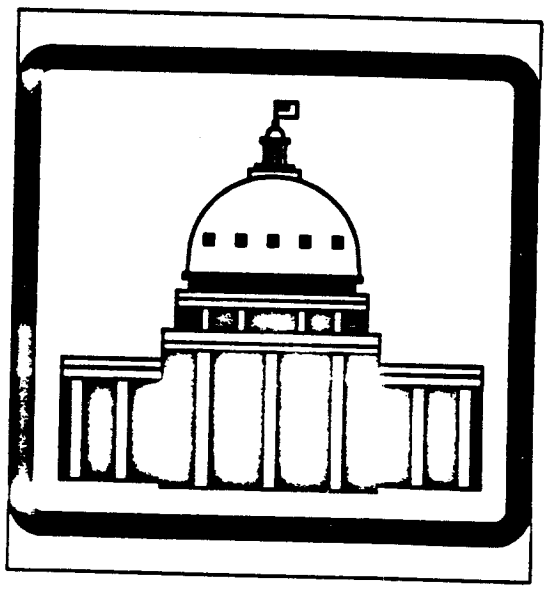
VOL 12 2 2122

R0055422

may be appropriate for retrofits because they do not limit land usage. Sand filters, however, may be a better alternative for treating hydrocarbon runoff from small sites than oil grit separators because sand is a superior filtering medium. Recent research questions the effectiveness of oil grit separators at removing hydrocarbon pollutants.[4]

Urban runoff retrofitting for nonpoint source pollution control includes a broad range of different techniques which attempt to reduce the adverse impacts of urban runoff on receiving waters. The types of retrofit techniques will differ depending upon where they are placed in the storm drainage network.

Local Governments' Compliance with Federal and State Regulations



The current storm water management requirements and drainage needs in major population centers are significant. EPA storm water permit regulations require large (>250,000) and medium (>100,000) size municipalities to have storm water discharge permits for discharges from their storm sewer systems under the National Pollutant Discharge Elimination System (NPDES) storm water permit program. Large- and medium-size municipalities nationwide are now applying for these permits which will require implementation of comprehensive storm water management programs to control storm water runoff.

In addition, Section 6217(g) of the Coastal Zone Act Reauthorization Amendments (CZARA) of 1990 requires States to develop coastal nonpoint source pollution control programs, including a management program to control runoff from existing development. The new coastal zone requirements are only applicable, however, in areas which are not subject to the NPDES storm water permitting regulations.

---

[4] Schueler, Thomas R., "Hydrocarbon Hotspots in the Urban Landscape: Can They Be Controlled?" in Watershed Protection Techniques. Volume 1(1), February 1994, p. 3-5.

VOL 12 2 2123

R0055423

The increasing stringency of federal, state and local regulations are all examples of the emphasis being placed on minimizing both point and nonpoint source pollution from urban runoff.

Summary of Selected Federal Water Quality Programs

Coastal Zone Management Act of 1972 (CZMA)

- established a program to encourage states to develop comprehensive programs to protect and manage coastal resources

Coastal Zone Act Reauthorization Amendments of 1990 (CZARA) §6217

- mandated state coastal programs to address nonpoint source pollution affecting coastal water quality and required the development of the Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters which states are to incorporate into their coastal nonpoint source programs

National Pollutant Discharge Elimination System (NPDES) Storm Water Permit Program

- established by §402(p) of the Clean Water Act; requires permits for certain municipal and industrial storm water discharges

Clean Water Act §319: Nonpoint Source Control Program

- initiated a national program which resulted in state nonpoint source management programs to control nonpoint sources of water pollution and protect groundwater

Clean Water Act §320: National Estuary Program

- focused point and nonpoint pollution control on geographically-targeted, high priority estuarine waters; controls are selected and implemented on a watershed basis

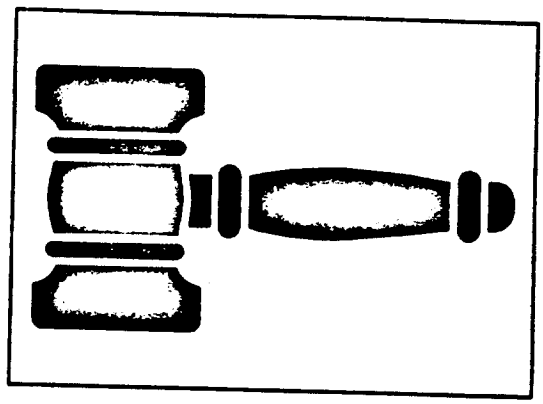
EPA's Watershed Protection Approach

- voluntary effort to align traditional regulatory and nonregulatory programs to support watershed protection in an integrated, holistic manner

VOL 12 2 2124

R0055424

While program requirements may differ based on the specific regulatory authority, the goals of these programs are complementary and many of the same management practices are applicable and satisfy the requirements of multiple programs. The case studies presented in this manual provide examples of the innovative ways in which many local governments are meeting the requirements of multiple programs. This manual will help communities develop and implement programs to improve water quality. However, communities need to refer to applicable state and Federal regulations to assure that they are in compliance with all regulatory requirements.



For example, some communities are not subject to NPDES permit requirements but may be subject to requirements under the Coastal Zone Act Reauthorization Amendments of 1990 ("CZARA"), and vice versa. In addition, some states have additional regulatory programs that may govern the management of storm water or runoff in the absence of Federal requirements. Other communities may not be subject to any regulatory requirements at this time, but the public is increasingly aware of runoff problems and their causes and some control of runoff is becoming inevitable.

R0055425

BRIEF SURVEY OF CURRENT METHODS AND TECHNIQUES

Types of Urban Runoff Retrofit Techniques[5]

Retrofit techniques can be differentiated depending upon where they are placed in the storm drainage network. Some of these are described below:

- Source retrofit: Use of techniques that attenuate runoff and/or pollutant generation before it enters a storm drain system, e.g., reducing impervious areas, using pollution prevention practices
- Open channel retrofit: These are installed within an open channel below a storm drain outfall, e.g., an extended detention shallow marsh pond system.
- Natural channel retrofit: Depending on the size of the channel and the area of the floodplain, a natural channel may provide several retrofit options
- Off-line retrofit: Involves the use of a flow-splitter to divert the first flush of runoff to a lower open area for treatment; used where land is available for off-line treatment
- Existing BMP retrofit: The retrofit of an existing BMP to improve its pollutant removal efficiency or capacity (ability to detain flow) or both.
- In-line retrofit: Used where there are space constraints that prevent the use of diversions to treatment areas.

Urban runoff retrofits involve a broad range of different techniques intended to reduce the adverse impacts of urban runoff on receiving waters. [See Box 2] The overall goal should be to achieve some reasonable degree of hydrologic control and pollutant removal (in relation to cost-effectiveness) as a result of the retrofit. Otherwise, the retrofit is not worth doing.

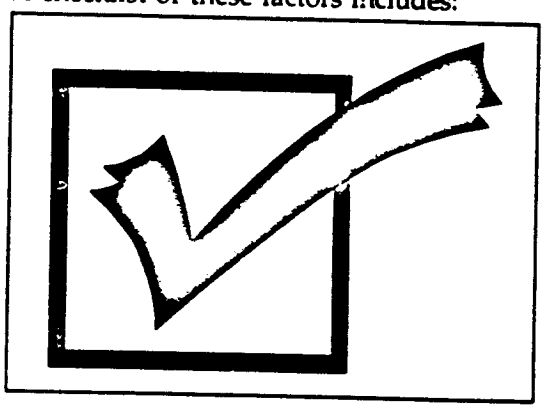
---

[5] as identified in MWCOG, Watershed Restoration Source Book, p. 59.

VOL 12 2 2126

R0055426

Technical factors affect the site-specific suitability of particular retrofit technologies. A checklist of these factors includes:



- land use
- climate
- size of drainage area
- soil permeability
- slopes
- depth to water table
- space requirements
- type and condition of the water resource to be protected
- depth to bedrock
- pollutants to be addressed
- maintenance access

Nonstructural Methods to Control Urban Runoff

Land use controls can be a cost effective means to control urban runoff. They have a maintenance cost/multiple use advantage over structural BMPs in many cases, and should be employed in redevelopment situations where appropriate. Furthermore, land use controls may be necessary along with structural measures in order for a jurisdiction to meet its water quality goals.

Strategies for implementing land use controls may include limits on impervious surfaces, encouragement for the preservation of open space, and promotion of cluster development. The use of nonstructural and structural best management practices for controlling urban nonpoint source pollution can also be required as a condition of development approval.

Zoning

Zoning is a powerful tool which communities can use to control the type of development or redevelopment allowed within their boundaries. Following are some examples of zoning controls that can be used to protect water resources:

- cluster development: constructing dwellings close together to preserve open space
- down-zoning: changing an established zone to require a lower density
- conditional zoning: allowing certain activities only under specified conditions that protect water resources

VOL 12 2 2121

R0055427

- overlay zoning: placing additional zoning requirements on an area that is already zoned for a specific activity or use; through the use of resource overlay zoning, high pollution activities can be controlled in sensitive areas

- open space preservation: protecting open space and buffer zones near water bodies, e.g., greenways or riparian corridors

Structural Runoff Controls for Highly Urbanized Areas[6]

1. Innovative Practices

In areas where impervious materials cover almost one hundred percent of the surface, conventional BMPs requiring large amounts of land and good soil conditions are usually not feasible. These types of BMPs include dry ponds, wet ponds, constructed wetlands and various sorts of infiltration devices.

On sites where standard BMPs are not feasible, one should consider the use of unconventional or innovative BMPs sometimes known as "ultra-urban" BMPs. These systems are designed to function by gravity flow between the components. They include: 1) sand filtration systems; 2) underground sand filters consisting of multiple chambers; 3) surface sand filters such as double-trench systems; and 4) peat/sand filtration systems.

Each is briefly described below:

Sand filtration systems: The City of Austin, Texas has developed a BMP which consists of a sedimentation and filtration basin and is appropriate for use on redevelopment sites where topography, space limitations and high value land do not allow the use of traditional BMPs. These filtration systems are primary water quality control structures. In order to ensure the long-term effectiveness of these systems, it is necessary to protect the filter media from excessive sediment loading. A sediment trapping structure is required to be located prior to the filtration basin. Austin sand filter sytems are particularly well-suited to regional storm water control.

Underground sand filters with multiple chambers: This is a system consisting of a structure containing three chambers, one each for pre-treatment, filtration and discharge. The first chamber is a pre-treatment facility performing the same function as a water quality inlet, removing floating debris and material such as oil and grease.

---

[6] A more detailed description of these controls and their effectiveness is provided in the Alexandria Supplement to the Northern Virginia BMP Handbook. [see Bibliography]

VOL 12 2 2128

R0055428

The second chamber is a filtration device, while the third is a clear well discharging directly to the storm sewer system. The District of Columbia uses underground sand filters as in-line facilities for both storm water quality and peak flow attenuation. One of the major advantages of the D.C. sand filter is that it does not take up any space on the surface, allowing full use of high-value urban land. This aspect makes it particularly attractive to land developers.

Surface sand filter systems: This system is usually referred to as the Delaware sand filter because it was developed for use in Delaware. Unlike the other filters described in this section, the surface sand filter system is intended to be an on-line facility, processing all runoff leaving the site up to the point where the overflow limit is reached. It consists of two parallel concrete trenches, one for sedimentation, the other for filtration. A major advantage of this filter design is that it requires a depth of only 30 inches from the ground surface to the bottom of the paved trench, making it useful in areas with high water tables. The simplicity of the design also facilitates maintenance.

Peat/sand filtration systems: Peat/sand filters are filtration systems which were first developed as alternative wastewater systems. Peat is an excellent natural filter of many types of effluents and pollutants and is just beginning to be used for urban runoff quality management. A peat/sand filter system should be considered for use on developments of several acres where the pollutant removal requirement is higher than could be expected to be achieved through the use of other ultra-urban BMPs. In addition, peat/sand filters require less site area than most conventional BMPs. However, it should be noted that, under certain conditions, peat filters can become net exporters of nutrients.

Use of Public Rights-of-Way

A retrofit technique which has been identified for use in a land-limited context is the use of public rights-of-way as an opportunity for runoff controls such as wet ponds, vegetated swales or meandering vegetated channels. This would include the use of land under bridges and overpasses, the median strips of roads and highways, and the exit ramp rights-of-way off major highways.

VOL 12 2 2129

R0055429

2. Retrofit Capability of Selected BMPs[7]

Extended Detention Ponds: Frequently used in retrofit applications, particularly within dry storm water management ponds.

Wet Ponds: Occasionally used in retrofit situations, particularly within dry storm water basins

Constructed Storm Water Wetlands: An effective retrofit technique. Can be achieved by adding wetland features to dry storm water basins.

Infiltration Trenches: Limited by soil conditions.

Infiltration Basins: Not recommended for retrofit settings, especially in the coastal zone.

Porous Pavement: Limited by soils which have been modified in most urbanized watersheds and are not capable of providing adequate infiltration.

Sand/Peat Sand Filters: Designed as end-of-pipe retrofits in several applications. A double-trench version has been designed for parking lot retrofits.

Grassed Swales: Although not suitable for ultra-urban areas because of the difficulty of preventing erosion in highly impervious areas, retrofit option may involve installing check dams to increase contact time in existing swales.

Filter Strips: Although the percentage of impervious surface in highly urbanized areas limits the usefulness of this practice as a water quality control device in ultra-urban settings, this type of retrofit is appropriate if enough land is available.

Water Quality Inlets: Although water-quality inlets are often used in ultra-urban areas, their low pollutant removal capability limits their usefulness as a retrofit technology.

[7] More detailed information on the retrofit capability of these practices can be found in A Current Assessment of Urban Best Management Practices. [see Bibliography]

VOL 12 2 2130

R0055430

DEVELOPMENT & IMPLEMENTATION OF AN URBAN RUNOFF CONTROL PROGRAM

While the program elements discussed in this section are considered important to program development and success, they do not necessarily fulfill all regulatory requirements which may be applicable to a given municipality. Planners and program managers should check on all relevant program requirements when developing their programs.

Important Program Elements

An urban runoff control and retrofit implementation program involves both technical and programmatic components and should include the following elements:

- technical capability
- use of appropriate technology
- implementation authority/enabling legislation
- funding mechanism or resource commitment
- institutional support structures

The case studies which are part of this manual demonstrate that local motivation is critical to the successful implementation of urban runoff controls. Also, successful implementation will not occur without a strong local commitment of personnel and resources. Regulations, ordinances, enabling legislation, design criteria, construction specifications, inspections and enforcement, and operations and maintenance procedures should all be clear and explicit. Appropriate technology for implementing runoff control measures must exist and must be at an affordable cost to the agency. If the foregoing are not present, implementation or continued successful program performance may not occur.

VOL 12 2 2131

R0055431

Important Elements for Program Success

- Technical Capability
- Design Criteria for Selection of Appropriate Technology
- Implementation Authority/Enabling Legislation
- Dedicated Funding Mechanism
- Staffing/Training/Institutional Support/Operations & Maintenance

The box above depicts some of the key elements for developing and conducting a successful urban runoff control program. All of them may significantly affect program outcome:

- technical capability and the choice of an appropriate technical solution
- implementation authority and a dedicated funding mechanism
- the often-neglected elements of program staffing, proper training, strong institutional support, and the proper operations and maintenance procedures

VOL 12 2 2132

R0055432

Building a Strong Institutional Foundation

Urban runoff management program practitioners strongly support the view that the success or failure of urban runoff control programs depends upon effective institutional frameworks. The following elements are often cited as crucial to program success:

Programmatic:

- adequate problem assessment
- BMP targeting and selection methodology (e.g., on-site vs. regional facilities)
- appropriate design criteria
- adequate staffing and training
- responsibility for success of total program vested in a single agency at an appropriate level of authority

Funding/Implementation:

- dedicated program funding, such as a storm water utility fee
- ease of operation and maintenance procedures
- administrative mechanism to ensure O & M is performed

Each of these elements must receive adequate institutional support if a successful urban runoff control program is to be implemented. In order to develop the necessary institutional frameworks, the local government should focus sustained attention on the institutional aspects of program development. There should be a recognition that developing an institutional framework is essential to support a successful multi-agency, long-term urban nonpoint source runoff program.

VOL 12 2 2133

R0055433

How can communities develop a successful program?

Each local government may have different tasks to complete to create a successful program. However, certain common threads run through all the case studies described in this manual and these can be instructive in helping local governments to put together effective urban runoff control programs.

A strong motivation to act is essential.

Frequently the strongest motivation to act is economic. In the Southeastern Massachusetts area case study, the closure of thousands of acres of shellfish beds due to contamination by storm water runoff resulted in millions of dollars of lost income to local residents and serious disruption to local economies.

For other communities, such as Austin, TX, protection of drinking water supplies is a high priority. Still others, such as Orlando, FL, are concerned about the water quality of the hundreds of lakes within its metropolitan region.

Teamwork is essential to accomplish your goals.

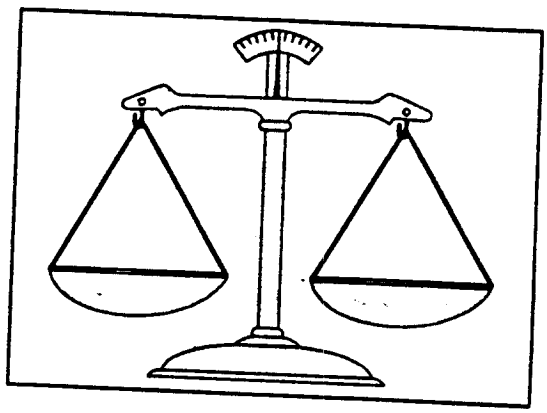
Pick the right people and the right organizations. The experience gained from the case studies proves that teamwork is necessary to achieve the desired results. The nature of the urban runoff problem means that any solution will cut across departmental, bureaucratic and organizational boundaries. The high cost of storm water control projects, especially retrofits, makes cost-sharing among organizations particularly advisable. So identify the key players early and make good working relationships a high priority. Don't neglect the important role of private organizations and interests.

The need for adequate staffing and training should be recognized.

VOL 12 2 2134

R0055434

Assessing Institutional Resources



Two initial goals should be considered by a local government interested in developing an urban runoff control program:

1) developing or improving its institutional capacity to mitigate the urban runoff water quality problems which it faces

2) ensuring that its institutional capacity matches its technical ability to deal with the problem.

Implementation personnel should evaluate the following factors as part of an initial assessment of institutional structures:

- Identify the key agencies and personnel

Determine who the key players are in the relevant agencies. Typically, there are four major groups involved in the institutional water quality decision-making process:

1) legislative
2) regulatory
3) consulting professionals
4) "users" such as developers, clients, citizens (also includes environmental advocacy groups)

The program manager should be aware that the typical bureaucratic organization of institutions into branches, divisions, departments, etc., can hamper the ability of the organization to carry out its program goals and hinder program effectiveness. The most successful programs find ways to break the bureaucratic logjam.

- Identify all relevant existing programs and assess their effectiveness

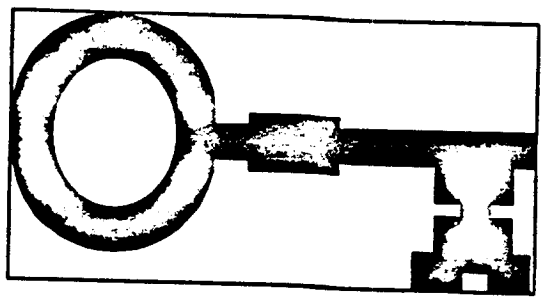
This may involve looking at an array of water quality programs scattered across different agencies and departments. Look for opportunities to modify these programs to reach the desired goals. Make sure that existing governmental structures are capable of implementing proposed programs. Finally, identify what new programs are needed.

VOL 12 2 2135

R0055435

- Determine the motivations and goals of the key agencies

They may be acting in response to a perceived problem such as a health hazard or to a water use impairment. Remember that not all organizations are subject to the same level of political pressure.



- Determine whether political support exists

This includes both established and grassroots structures. Political support for environmental issues becomes especially significant in times of resource constraints and competing interests.

- Identify appropriate pollution control techniques

Consult a BMP manual, such as those listed in the Bibliography, for the types of control mechanisms appropriate to a particular site.

- Identify funding options

This might include study of the feasibility of a dedicated funding source such as a storm water utility and development of a fee structure.

- Consider the limitations of available technology

The potential for solving a problem may be limited by many factors over which the implementing authority has no control. This includes performance limitations of technology as well as any site-specific constraints.

Conclusion

The importance of developing institutional structures cannot be overstated. Effective urban runoff management is greatly helped by the presence of strong institutional mechanisms. Furthermore, the case studies support the conclusion that where urban runoff quality control is institutionalized through dedicated funding mechanisms such as storm water utilities, innovative and comprehensive programs (including retrofit activity) are the rule.

VOL 12

2

2136

R0055436

Setting Priorities/Selecting Management Practices

Urban nonpoint source runoff problems may be numerous in a given area and the solutions are often complex. Funding to solve these problems is usually limited, so it is necessary to set priorities so that the worst problems can be targeted for attention.

A ranking methodology should be developed for a specific study area (e.g., a watershed) in order to encourage a phased approach and to allocate scarce resources optimally. Once particular waterbodies and sources have been targeted for action, the local government can then determine the most cost effective approach to solve the problem.

The following factors should be considered in the ranking process:

- waterbody importance
- type of use (recreation/aquatic life/drainage)
- status of use (impaired or denied uses)
- level of use
- pollutant loads

The key point to be made about the ranking process is that it should reflect local issues and concerns. The ranking factors can be assigned different degrees of weight based on the degree of local importance.

In evaluating and selecting appropriate control practices, local governments should consider:

- Does the practice selected meet any applicable regulatory requirements?
- Is the selected control buildable and effective?

Relying upon structural controls is different from the use of source controls and regulatory or non-structural controls. Complex structural controls pose both construction and future maintenance challenges that should not be overlooked.

Use the following as a checklist of the tests which the proposed BMP should pass to be considered for implementation:

- Does it meet regulatory requirements?
- Is it effective at pollutant removal?
- Can it gain public acceptance?
- Is it technically implementable/easily maintained?
- What are the associated costs?

VOL 12 2 2131

R0055437

The process of setting priorities and targeting urban runoff problems is a complex process consisting of many factors and should be performed in a systematic manner.

How To Overcome Roadblocks to Implementation

Two of the biggest "roadblocks" to implementation of urban runoff control retrofit projects are high cost and shortage of funding and the lack of available land in urbanized areas. Many participants in the urban runoff management and planning process describe the extreme difficulty of implementing urban runoff retrofits because of the lack of available land at highly urbanized sites and the lack of funding for these typically expensive projects. The most difficult sites are those where land for siting control practices is severely constrained or non-existent. The high cost associated with retrofitting older urban storm drainage systems requires a careful evaluation of pollutant reduction goals and the targeting of control practices.

Land Availability

In the urban context, land may be strictly limited and/or its value may be prohibitive for some uses. Practices requiring large land areas are simply not feasible. The three most used control devices for storm water quality management, viz., dry ponds, wet ponds, and infiltration devices, are not always suitable for urban retrofit situations because of space constraints or underlying soil conditions.

On sites where these types of conventional practices are not feasible, innovative and experimental approaches should be tried. Newer ultra-urban technologies that take up little or no above-ground space should be used. Performance monitoring should be done to verify effectiveness.

Cost of Implementation

The extremely high cost of retrofit projects - engineering studies, land acquisition, and the actual construction costs - raises the question of how realistic these projects are for many local governments to achieve. In addition to initial project cost, there is also the continuing and long-term cost associated with operations and maintenance. Some ways to reduce the high cost of these projects include:

- utilizing state or federal cost-share programs where available (e.g. FEMA floodplain "buyout" or EPA nonpoint source grants)
- encouraging multi-jurisdictional efforts to spread the cost and benefits
- soliciting volunteers and in-kind contributions to reduce project cost

VOL 12 2 2138

R0055438

- creation of special districts or dedicated funds such as storm water utilities

- low interest state revolving fund (SRF) loans for nonpoint source control projects

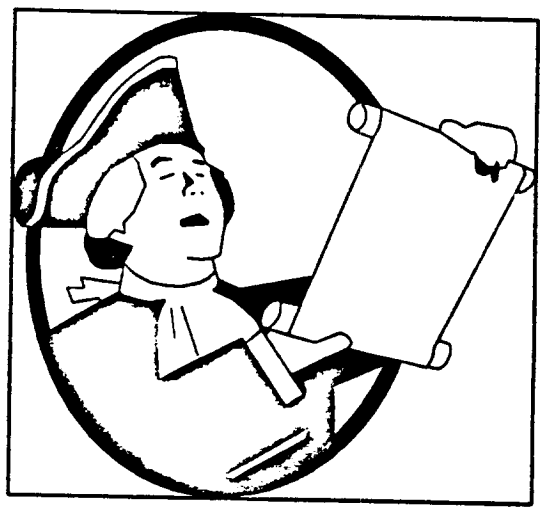
The use of high value urban land is the biggest obstacle to implementing retrofits for many municipalities. Land which would ordinarily be generating revenue for the municipality is removed from the tax rolls. This is a clear institutional disincentive to implement retrofits in highly urbanized areas. If a local government considers water quality improvement as a goal desired by the community, then the revenue loss might be viewed differently by the public, and would be easier to justify politically.

Localities are increasingly turning to methods of returning the costs of storm water discharges to individual property owners, through mechanisms such as storm water utility fees or storm drainage and flood control fees. The goal of these programs is to provide economic incentives to property owners to reduce the amount of storm water discharges from their land by offering credits for implementation of best management practices, as well as to reduce the burdensome cost to already fiscally-strained jurisdictions.

VOL 12 2 2139

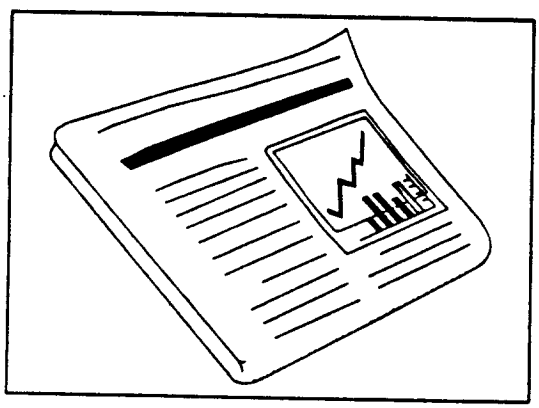
R0055439

Increasing Public Awareness



To ensure adequate support for urban runoff control programs, the public needs to be educated about the nature of urban nonpoint source pollution and the benefits of controlling urban runoff. These issues are not readily understood by large segments of the public. The need to heighten public awareness cannot be overemphasized.

Urban runoff control programs must have public backing and involvement to succeed. There is broad general support for environmental concerns and this support can be translated into political support for urban runoff control programs. However, adequate funds must be devoted to public information and education programs about the nature, causes and solutions of urban runoff and urban nonpoint source pollution. The public must recognize the seriousness of urban runoff pollution, and understand the importance of local commitment for a successful urban runoff management or retrofit program.



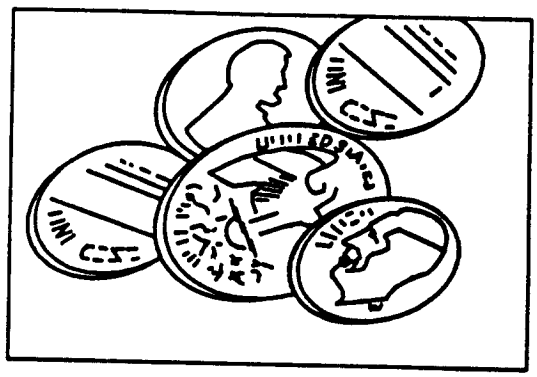
Public education is an essential tool for increasing public awareness and generating political support. Educational efforts typically include:

- program meetings and presentations
- program materials such as newsletters, fact sheets, brochures, and posters
- homeowner education programs
- media campaigns
- coordination with activist groups for program support

VOL 12 2 2140

R0055440

Creating a Stable Funding Mechanism



Runoff control programs are usually implemented at the local level. Local communities generally have limited budgets and limited staffing which impedes effective implementation. Sources of funding at the Federal and state levels are also limited and uncertain, and cannot be counted upon to provide total project funding.

One successful institutional response by many municipalities has been the establishment of storm water utilities. Some jurisdictions have used storm water utilities to fund the basic "hardware" of urban runoff management, while others have included funding for watershed planning and retrofitting programs.

Special taxing districts, such as a watershed improvement district, can levy taxes and borrow money to engage in a wide range of nonpoint source pollution control activities. A special taxing district is similar to a school district or a sanitary district and functions as a special governmental unit in a particular area. Real estate within its boundaries is appraised and taxed to fund program activities.

The purpose of a dedicated funding source such as a storm water utility or a special taxing district is to provide a stable and reliable method of financing storm water management programs. The development of comprehensive and effective programs requires a secure funding base.

[More information on funding options is provided below.]

VOL 12 2 2141

R0055441

Policies and Procedures vs. Programs and Institutional Frameworks.

Effective prevention and control of urban runoff pollution requires both defined policies and procedures, and effective programs and institutional structures. Just having policies on paper is no guarantee of an effective program. Institutions must be organized in such a way as to implement the policies and carry out the procedures.

Indeed, the implementation phase is just the final step in an often long process of planning and preparation. It must be accompanied by a real institutional committment to change ineffective and outmoded structures, to break through political or bureaucratic impasse, and to see that programs function effectively.

The question for the local program manager is: Are the local government's agencies organized to efficiently and effectively carry out runoff control activities? Are the various agencies involved clear about their responsibilities? Responsibilities of each involved party can become a major issue when urban nonpoint source control projects involve multiple agencies, as they almost always do.

The responsibility of each agency involved in an urban runoff control project should be clearly spelled out.

The complexity of developing and implementing urban runoff control programs, including the special considerations relative to retrofit situations, means that the following distinct phases should be well-known to the program manager:[8]

- planning phase: analyze, evaluate, plan
- preparation phase: prepare budget, allocate resources, and obtain permits
- pilot project phase: test selected BMPs
- full-scale implementation: construct selected BMPs
- evaluation/documentation: evaluate program effectiveness

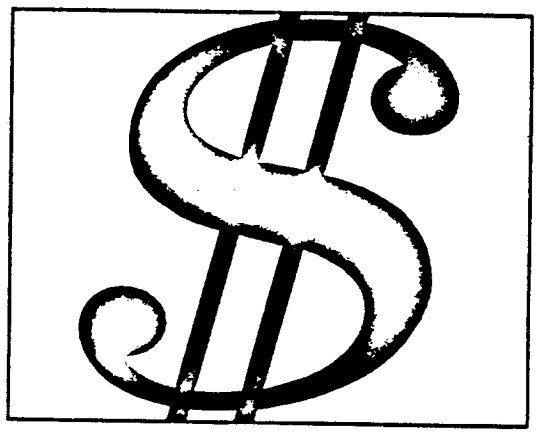
R0055442

Funding Options/Alternative Funding Approaches

Implementation of urban runoff control programs at the local level often requires non-Federal funding. Now that governments at all levels are facing fiscal constraints, alternative funding sources are becoming increasingly important. Following is a discussion of some of these approaches:



Local governments with strong institutional frameworks have led the way in the development of utilities specifically designed to abate NPS pollution or targeted at a particular type of NPS pollution:

- Local governments are using the utility concept to develop institutional approaches incorporating homeowner responsibility for some runoff management practices (e.g., septic system maintenance, small construction grading and landscaping permits requiring best management practices to control runoff)

- Storm water utilities are spreading all over the country as a way of providing a dedicated funding source for urban runoff control projects; a storm water utility is to storm water what a sewage utility is to sewage and a water utility is to drinking water. It is a dedicated funding source or "stand alone" service unit within the city government which generates revenues through fees for service. It is responsible for the operation, construction and maintenance of storm water management devices and for storm water system planning.

State revolving loan funds were very successful in the early years of point source pollution control and are now being adapted to nonpoint sources:

- State revolving loan funds, originally established for states to upgrade sewage treatment facilities through construction grants, may also be used to fund a wide variety of nonpoint source control projects and best management practices (BMPs)

VOL 12 2 2143

R0055443

Special fees and taxes are another source of dedicated project funds for nonpoint source pollution control:

- This approach involves the use of user fees/special taxes to fund nonpoint source pollution projects and programs, such as special taxes and fees on the sale of fertilizers and pesticides, waste disposal, and underground storage tanks

Some innovative approaches being used to fund urban nonpoint source pollution control programs include:

- Special tax districts, such as watershed improvement districts, which can be created to protect highly valued water bodies.
- Checkoff on tax forms to fund restoration and conservation programs.
- Revenue bonds, which are long-term municipal bonds guaranteed solely by the dedication of project funds.
- Public/private partnerships can be used to pay for capital and/or operating expenses for storm water facility projects when neither could fund them alone.
- An annual nonpoint source pollution control tax based on property size and land use (not on value) is being used in Puget Sound, Washington.
- The sale of special license plates in Maryland and Virginia has raised substantial amounts of money to restore the Chesapeake Bay.

Types of Funding Mechanisms Available to Local Governments

- General funds

  The use of general funds may require the re-allocation of existing revenues.

- Long-term borrowing

  Large structural BMPs may require funding through bond issues.

VOL 12 2 2144

R0055444

- Pro-rata share fees

  These fees are typically based on an assessment of the development's potential to contribute to urban runoff problems.

- Storm water utilities

  Utilities typically assess a fee based on the percentage of a site's impervious area.

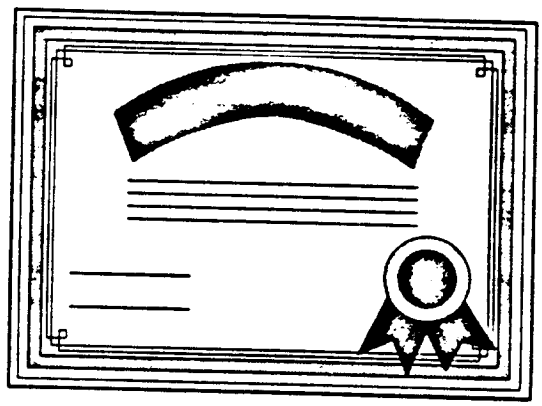
- Special assessment districts

  Funds for projects in a district can be raised by assessing fees to landowners in the district.

VOL 12 2 2145

R0055445

Elements of Successful Programs/Solutions



The case studies presented in this manual were selected as examples of exemplary local government initiatives in the area of urban runoff control and/or retrofit implementation. The case studies included are all "success stories," and they display certain common elements. Among these are the following:

- strong institutional motivation to act on problem
- political and/or grassroots support for action
- skilled personnel
- knowledge of available technologies
- dedicated funding source, such as a storm water utility fee
- an environment of institutional cooperation and a long-term commitment to work together
- targeting strategy/process to maximize use of limited resources

Many communities are recognizing the benefit of preventing ecological and habitat destruction to avoid the very high costs associated with the restoration of degraded resources. The most successful communities take a pro-active stance with regard to regulatory requirements, and use proper planning techniques to prevent degradation of water resources. They are realizing the economic, environmental and social benefits of protecting the existing ecosystem through land use controls, development restrictions and urban best management practices.

Conclusions and Recommendations

Effective urban runoff control programs are built upon numerous institutional, economic and technical factors. The most successful programs examined in this project displayed a strong institutional or programmatic focus, in additional to having a strong motivation (usually economic) to act on a problem. Furthermore, the case study communities displayed strong political and/or grassroots support for community action as well as skilled personnel.

Solutions must be tailored to each communities' particular circumstances, but the following recommendations may assist the interested community to more quickly develop an urban runoff control or retrofit program for developed areas.

VOL 12

2

2146

R0055446

Recommendations

- Identify and obtain stable, if not dedicated, funding sources for urban runoff programs, including retrofit programs.
- Utilize cost-share approaches among agencies to maximize resource impact and obtain participation and support from private interests benefitting from urban runoff control projects.
- Use team or multilateral approaches wherever possible; given the nature of urban runoff problems, most solutions will need to cut across bureaucratic and organizational boundaries.
- Focus effort initially on building institutional structures to support comprehensive urban runoff control programs.
- Identify water quality problems and prioritize retrofit alternatives.
- Identify all existing related programs and assess their effectiveness and modify where needed.
- Consider innovative, cost effective, and environmentally responsible ways of retrofitting.
- Utilize economic incentives (such as tax or fee reductions) to motivate property owners to employ runoff control and/or retrofit strategies.
- Make retrofit projects a condition of approval for redevelopment projects.
- Create a single management agency charged with overall responsibility to plan and coordinate program implementation and conduct and/or monitor operations and maintenance activities.
- Designate agency staff to support implementation of projects.
- Do adequate retrofit planning and realistic goal setting.
- Select knowledgeable contractors or contractors with a good track record in water quality and urban runoff control projects.

VOL 12 2 2147

R0055447

- Supervise, even direct if necessary, the construction phase of all projects.
- Educate developers, consultants, contractors, politicians and the general public about urban nonpoint source pollutions issues.
- Identify opportunities for public/private partnerships to conduct nonpoint source pollution control activities.

VOL 12 2 2148

R0055448

Introduction to the Case Studies

The following case studies exemplify many of the institutional, regulatory, planning and implementation issues discussed throughout this manual. They describe the experiences of selected local governments in dealing with the problem of urban runoff management in developed areas. Many of the approaches described in the case studies are highly innovative and will be useful guides for other localities considering the implementation of urban runoff control and/or retrofit programs.

This manual utilizes the case studies to illustrate some approaches which localities are successfully using to manage urban runoff problems. It provides examples of jurisdictions where institutional frameworks have been successfully developed to support urban runoff management and retrofit programs. Institutional issues are given great emphasis in the case studies, as in the main narrative, because institutional issues, rather than purely technical ones, are believed to be a common obstacle to the successful implementation of urban runoff management projects.

The case studies demonstrate the many different ways communities have developed and implemented urban runoff management programs. Each program is unique, based on the magnitude and negative impact of that community's urban runoff problem, the available resources and existing pollution control programs, and the existing regulatory context in which the local government is operating.

City of Alexandria, Virginia

Introduction

Municipalities are being confronted by increasingly stringent local, state, and Federal environmental regulations. Complying with these regulations is a challenge. The approach taken by the City of Alexandria, Virginia is a case study which illustrates this point.

Alexandria is situated on the tidal Potomac River, across and down river from Washington, DC. Because of its location, the City must comply with Virginia's "Chesapeake Bay Preservation Act." The Act's implementing regulations required the City to designate "Chesapeake Bay Preservation Areas" within its boundaries. The City as a whole was designated to be a preservation area. This designation means that development and redevelopment of land in the City must achieve specified storm water management criteria. For permitted development, nonpoint source pollution loads cannot exceed pre-development loads based on average land cover conditions. For redevelopment of land currently served by water quality best management practices (BMPs), nonpoint source pollution in post-development runoff cannot exceed the load existing prior to redevelopment. For redevelopment of land not currently served by water quality BMPs, a ten percent reduction in nonpoint source pollution in runoff must be achieved when compared to the load existing prior to redevelopment.

Meeting these storm water management criteria in Alexandria has indeed been a challenge. Implementing conventional water quality BMPs to control the quality of storm water discharges is often either economically impractical or physically impossible because of a number of factors such as a lack of physical space, extremely high land values, a high water table, or unsuitable soil conditions. The City has met the challenge by adopting and adapting for local use a class of BMPs dubbed "ultra-urban."

Ultra-urban BMPs are non-conventional BMPs that are particularly suited for use in highly urbanized areas. They are based on sand filter technology and are currently used in other parts of the United States. Alexandria has installed four of these ultra-urban BMPs in intensely developed areas. In order to facilitate the use of sand filter technology, the City has published design criteria for various ultra-urban BMPs in the Alexandria Supplement to the Northern Virginia BMP Handbook.

The Alexandria Supplement states that the standard types of BMP facilities such as dry ponds, wet ponds, and infiltration devices are not suitable for use in large areas of Alexandria because of space limitations or poor soil conditions. The planner, developer, or engineer is therefore urged to consider the use of unconventional or

VOL 12 2 2150

R0055450

innovative BMPs. It should be noted that infiltration is not the preferred method in Alexandria and will only be approved where it can be clearly demonstrated that it will work. Most areas of Alexandria do not contain soils that are conducive to the use of infiltration devices. (Marine clay is the prevalent soil type in Alexandria and the region.)

To complicate the problem, Alexandria, in common with many older cities developed in previous centuries, has sections of combined sanitary and storm sewers. During heavy or prolonged storm events, combined sewer overflows (CSOs) may occur, discharging directly into streams. Alexandria has applied for an NPDES permit for the CSOs from the Virginia Department of Environmental Quality.

Strategy

The development of design criteria to guide local developers, culminating in the Alexandria Supplement to the Northern Virginia BMP Handbook, resulted from the City's engineering staff consulting with jurisdictions across the country where similar ultra-urban technology is being proposed or has been implemented.

It should be noted that the City's strategy of implementing ultra-urban BMPs was essentially driven by the lack of available land and alternatives. Most other BMPs were fairly easily screened out because of the severe space constraints. Available technology aside, the other principal strategy issue requires that opportunities be seized as they arise, usually from redevelopment.

The general strategy employed in the implementation of these retrofits was one of exploiting any available opportunities. Cooperation was solicited from developers. The double trench Delaware sand filters which were implemented did not take up any valuable land above-ground and this was a strong selling point for bottom-line conscious developers. This allowed them full economic use of the land. The focus has been on available sites. Parking lots have been the chief sites suitable for the Delaware sand filters, and implementation has been limited to them.

One advantage of the Delaware sand filter for Alexandria is that it requires a total depth of 30 inches from the ground surface to the bottom of the paved trench. This is critical in portions of the city where the depth to groundwater is minimal. In addition, the simplicity of the system and the ready accessibility of the chambers for regular maintenance makes the Delaware-type filter very suitable for site conditions which are typical in Alexandria. This type of system is appropriate for up to five acres of 100% impervious cover.

Two [District of Columbia] underground vault sand filter systems were installed on a 3-acre townhouse development in the Winter/Spring of 1994. The principal advantage of these systems is that they may be placed under streets, and in cells of

VOL 12

2

2151

R0055451

parking garages, allowing full economic use of the surface areas.

Cost

The cost of implementing sand filter technology varies due to site-specific conditions. Most of the devices already implemented in Alexandria were prototypes, making accurate cost estimates difficult. However, a range based on the characteristic design of the Delaware, Austin, and District of Columbia designs can be estimated. The costs of Austin sand filters, typically suitable for large-scale sites, range from $13,000 to $19,000 per impervious acre. The D.C. sand filter, which is characterized by an underground vault with sediment and filtration chambers, originally cost around $35,000 per unit, but through economies such as pre-cast concrete and standardized design, costs have come down considerably to the $12,000 to $16,000 range. It should be borne in mind that the early models of these systems are essentially prototypes and that costs are highly variable. Economies of scale are likely to come about through routine implementation. The use of prefabrication and modular units may further reduce costs in the future.[9]

Effectiveness of Ultra-Urban BMPs compared with Conventional BMPs

Most of the (Delaware) double-trench sand filters implemented to date in Alexandria have not been subjected to long-term monitoring and Delaware does not rate these systems for nutrient removal efficiency. Based on long-term monitoring of sand filtration systems done by Austin, Texas, the Delaware system is rated at 80% suspended solids removal rate. Alexandria, however, recognizes a TP (total phosphorus) removal rate of 40%.[10]

The Virginia Chesapeake Bay Local Assistance Department has provided a grant to the City of Alexandria to monitor the performance of the first two Delaware sand filters constructed in the city.

Other Institutional Issues

This case study illustrates the benefit of having a committed public official dedicated to implementation of nonpoint source pollution control technology. The City Engineer has implemented retrofits mostly on his own initiative, having had relatively few bureaucratic obstacles to overcome.

R0055452

There are other programs described in case studies in this manual where institutional support comes from the "grass roots." It is vital to have public support for pollution control programs, but building support for these programs may sometimes require that public officials take the lead and steer programs past the numerous bureaucratic obstacles.

R0055453

Southeastern Massachusetts

This case study looks at storm water retrofit projects in the following areas of Cape Cod:

- Buzzards Bay/Buttermilk Bay:
  1) Sprague's Cove Storm Water Remediation Project (Town of Marion)
  2) Broad Marsh River Storm Water Remediation Project (Town of Wareham)
  3) Electric Avenue Beach Storm Water Demonstration Project (Town of Bourne)
  4) Hen Cove NPS Pollution Mitigation Project (Town of Bourne)
- Town of Yarmouth
- Town of Orleans

Existing Nonpoint Pollution Problems on Cape Cod

A Cape Cod Section 208 planning study identified the following pollutants in storm water runoff from urban sources at various locations on the Cape:

Organics: Oil and grease (hydrocarbons), benzene, xylene, and toluene from auto emissions or atmospheric deposition. Runoff from roads into Buzzards Bay is estimated to contribute 33,000 lbs. of petroleum hydrocarbons a year to the Bay.

Inorganics: Nitrates, phosphates, ammonia, chloride, sodium, calcium, potassium, barium, iron, cadmium, chromium, copper, lead, and zinc have all been identified in runoff from a section of Route 28 near Falmouth.

Biological: Bacteriological contaminants (mostly fecal coliform) in storm water runoff were strongly implicated in the closure of shellfish beds in Buttermilk Bay (Bourne).

I. Case Studies

Buzzards Bay Area

In Buzzards Bay, over 8,000 acres of shellfish beds are believed to be closed as a

VOL 12
2
2154
R0055454

direct result of storm water contamination. This represents an estimated economic loss of $24 million to communities in the Buzzards Bay area.[11] The Buzzards Bay Comprehensive Conservation Management Plan (CCMP) adopted in 1992 calls for the prevention of new storm water discharges to the Bay, as well as the remediation of existing discharges that pose a threat to water resources. The plan also calls for towns to inventory and prioritize storm water discharges for remediation. After towns have evaluated their storm water needs, they can proceed based on available resources. Funding, however, is one of the most significant factors affecting the ability of Southeastern Massachusetts area towns to deal with their urban runoff problems.

The development of the Buzzards Bay CCMP resulted in some significant accomplishments for the Buzzards Bay region:

- it established overlay district protection to limit nitrogen inputs to marine waters of Buttermilk Bay (a first in the nation)
- it resulted in the development of regional strategies, approaches and enforceable mechanisms as part of the Massachusetts Coastal Zone Management program

1. Electric Avenue Beach

Strategy and Rationale

An existing storm water system was retrofitted at Electric Avenue Beach in Bourne, Massachusetts as a demonstration project as part of the Buzzards Bay Project (a joint project of the Massachusetts Coastal Zone Management Program and the U.S. Environmental Protection Agency). The project was undertaken in response to high fecal coliform bacteria levels found in wet weather storm drain discharges to Buttermilk Bay, a tidal embayment in the towns of Bourne and Wareham at the northern end of Buzzards Bay. The Buzzards Bay Project funded the implementation of a storm water infiltration system in order to test the effectiveness of these systems in removing bacterial and nutrient contamination from the storm water runoff entering Buttermilk Bay.

The storm water infiltration system was designed to intercept a one-year design storm from the adjacent watershed and to avoid direct discharge of the first flush to the Bay. Instead, the flow enters a settling tank for removal of solids and floatable waste and is then discharged to infiltration galleys. The only flow which is

[11] Buzzards Bay Project, "Bay Watch," (Newsletter) Spring/Summer 1993 Vol. 7 (5), p. 1.

VOL 12 2 2155

R0055455

discharged from the original outfall is from a one-year storm or better. Monitoring provided by the Barnstable County Health Department has confirmed a reduction in bacterial loading.

There are other points which make this project noteworthy:

- the infiltration galleys are preceded by oil/grit chambers designed to reduce clogging in the infiltration devices
- because the infiltration devices are very close to the beach area, the distance to groundwater is approximately two feet - groundwater sampling has not shown any contamination, however
- a substantial reduction in construction costs was achieved by utilizing personnel from the Town of Bourne's Department of Public Works

One of the unique aspects of this demonstration project was that the EPA Region I and Buzzards Bay Project oversight staff utilized the Department of Public Works personnel from the Town of Bourne for construction of the storm water infiltration system. The significant institutional consideration here is that the experience gained by Town staff in the design of the demonstration project could be used for the construction and maintenance of additional storm water infiltration systems. This enhances the storm water quality control expertise of Town personnel and further institutionalizes the process.

Effectiveness

At the Electric Avenue demonstration project site in Bourne, monitoring indicates that the retrofit structures are removing over 95% of the fecal coliform from storm water runoff.

2. Hen Cove Nonpoint Source Pollution Mitigation Project

Storm water runoff pollution was implicated in the closure of shellfish beds and a swimming beach in Hen Cove. The Buzzards Bay Project assisted the Town of Bourne in retrofitting the adjacent storm drain systems so that pollutants are not discharged directly to the Cove.

Strategy and Rationale

The Hen Cove project targeted specific storm drain systems which currently allow direct discharge of untreated storm water into the Cove. The mitigation project incorporated the use of leaching chambers and the surrounding soil to treat the "first flush." (During heavier or more severe storms, excessive runoff will overflow into the

VOL 12 2 2156

R0055456

conventional storm drain system.) Several individual leaching chambers were placed under the road surface throughout the watershed (there are 13 so far). At each location, runoff from the road will be diverted into a storm drain with a settling basin to allow sediments and other solids to settle out. From the storm drain inlet, the storm water is then piped under the road surface into leaching chambers. The leaching chambers are pre-cast, perforated concrete structures which are surrounded by crushed stone. Storm water is temporarily stored in the chambers and in the voids between the crushed stone until it seeps into the surrounding soils. Groundwater monitoring will determine the success of this approach by determining the amount and type of pollution attenuation in the surrounding soils.

3. Sprague Cove Storm Water Remediation Project

The Buzzards Bay Project is working with the Town of Marion, Massachusetts, to reduce pollutants associated with storm water runoff entering Spragues Cove. Spragues Cove is a small, shallow embayment on the shore of Sippican Harbor. Currently its three-acre area of valuable shellfish beds is closed for shell-fishing because it exceeds both state and Federal bacteria standards for shellfishing.

The largest storm drain system drains approximately 64 acres of watershed directly in the Cove. The mitigation project will incorporate the use of a constructed wetland system to treat the "first flush."

Strategy and Rationale

Several treatment alternatives for the storm water draining into Spragues Cove were considered:

- No action. The drainage system continues to function and shellfishing areas remain closed because of high fecal coliform counts
- Mechanical treatment methods such as chlorination, ultraviolet light, ozone and reverse osmosis
- Physical methods of treatment such as infiltration, settling or constructed wetlands

The Town of Marion reviewed the alternatives and decided that a constructed wetland system met the objectives of the project. The system will include a settling basin, marshland vegetation, and an open, deep water pool. The settling basin allows for coarse sediments and particulates to settle out prior to entering the wetland treatment system. In the wetland itself, physical and biological processes will treat and remove pollutants from the water. The restored wetland system will have a hydraulic detention time of over 14 days.

VOL 12 2 215 1

R0055457

The wetland system will be constructed where a salt marsh previously existed. The site was filled decades earlier with dredge spoil from nearby Sippican Harbor. In addition to providing water quality improvements, the restored wetlands system will enhance the fish and wildlife habitat in the area. Currently the site has little habitat value.

Effectiveness

Existing research on using wetlands to treat wastewater for fecal coliform indicates that at least 95 percent or greater is typically removed. Fecal coliform counts associated with storm water from the Spragues Cove outfall are significantly lower than previously recorded levels. The water quality monitoring plan will be part of the quality assurance/quality control (QA/QC) plan required by the U.S. Environmental Protection Agency.

Costs and Funding

The Town of Marion and the Buzzards Bay Project obtained $25,000 through the Massachusetts Department of Environmental Protection's 319 grant program. The Town provided an in-kind match valued at $35,000 to cover the cost of construction, equipment and labor. The Town also donated the land on which the wetland system will be constructed (estimated value of $100,000 per acre). A total of two to three acres of land will be utilized for the project at a total cost of $200,000 to $300,000. Additionally, the U.S. Fish and Wildlife Service granted the Town $10,000 for the project under the Wetland Restoration Program. Planning and technical assistance will be provided by an interdisciplinary team from the Soil Conservation Service (SCS).

4. Broad Marsh River Storm Water Remediation Project

Broad Marsh River is a tributary to the Wareham River estuary. It is located in the Town of Wareham in the northern part of Buzzards Bay. The entire Broad Marsh River has been closed to shellfishing and some beaches closed to swimming due to high fecal coliform concentrations. The most significant source of pathogens and fecal coliform pollution in the river is associated with storm water runoff from discharges from adjacent storm drain systems. Other potential sources, such as migratory waterfowl and boats, have been deemed insignificant.

The primary objective of the storm water remediation project is to reduce the amount of pollution (mostly fecal coliform) from storm water runoff entering Broad Marsh River.

VOL 12 2 2158

R0055458

Strategy and Rationale

Several alternatives were considered for the treatment of storm water runoff from storm drain systems adjacent to the Broad Marsh River:

- No action. Fecal coliform pollution would continue unabated and result in the continued closure of shellfishing beds and many beach closures for swimming.
- Extended detention basins, wet ponds or constructed wetlands would be used to detain the first flush of runoff for at least 24 hours.
- Infiltration structures such as infiltration basin at the end of each storm drain system, or a series of leaching chambers under the existing road surface

The selected alternative was the use of leaching chambers placed under the road surface. The rationale for selecting this alternative is typical in many retrofit situations; detention basins were rejected because, as an "end-of-pipe" practice, they require considerable commitment of land to function properly. Since there are 16 storm water outfalls to this section of the Broad Marsh River, there would have to be 16 detention basins and this would require the acquisition of a large amount of land, including some dwellings. This choice was not deemed feasible. Infiltration basins located at the end of a pipe have a similar need for large land commitment. The leaching chamber option was chosen because leaching chambers placed under the road surface would minimize the disruption to the present drainage system and would not require a large land commitment.

Effectiveness

This project is not yet fully established. However, to demonstrate the effectiveness of the leaching chambers, the project will monitor a minimum of three chambers.

Costs and Funding

The Buzzards Bay Project was initially unable to fund the Broad Marsh River project. However, the Buzzards Bay Project together with the Town of Wareham, requested funding under the Massachusetts Department of Environmental Protection's 319 (Nonpoint Source) Program and successfully secured funding in the amount of $88,450 to help reduce pollution loadings from storm water runoff.

5. Town of Yarmouth

In 1991, the Town of Yarmouth implemented the retrofit of a drainage system to

VOL 12 2 2159

R0055459

eliminate the direct discharge of storm water runoff containing high fecal coliform counts to the Bass River. The drainage system was retrofitted to direct the flow into a retention basin to allow storm water to percolate through a gravel bed. This design also allowed for evaporation to remove pollutants. The retrofit substantially reduced fecal coliform counts from pre-retrofit levels and improved the water quality in several ways:

- it has reduced velocity, encouraging infiltration
- it further reduced the velocity through infiltration and evaporation
- fecal coliform counts are lower even after similar pre-retrofit rainfall events

Effectiveness

Water quality monitoring performed by the Barnstable County Department of Health Laboratory both before the retention basin retrofit and afterward revealed substantially reduced fecal coliform counts.[12]

6. Town of Orleans

The Town of Orleans, Massachusetts is a community on Cape Cod which has extensive coastal waters, including three estuaries. These waters contain important commercial shellfishing areas. In 1988, several areas within the Town's waters were closed to shellfishing due to bacterial contamination. Through sampling of storm drain outfalls and receiving waters, and from a review of existing water quality data, the Town identified storm water runoff as a significant source of contamination from bacteria and other pollutants to its coastal waters.

Strategy and Rationale

Three drainage areas were targeted as having significant adverse impacts on water quality in sensitive areas and in need of remediation. The Town's strategy was to: 1) identify the three high priority areas for development and implementation of pollution control measures; 2) establish a storm water management committee; 3) screen BMP alternatives to choose best available means to remove bacteria and solids; and 4) appropriate funds for study of conceptual approaches and engineering designs and for construction of the BMPs at the three high priority sites.

---

[12] Town of Yarmouth, "Effects of Route 6 Storm Drainage Improvements on Water Quality in Bass River," November 11, 1992.

VOL 12 2 2160

R0055460

Prior to undertaking the projects, which are scheduled for completion in May, 1993, the Town acted on the consultant's recommendations and took the following actions:

- scoped potential solutions
- focus on BMPs for control of bacteria and solids
- prior to choosing BMPs, Town conducted field investigations, which included the following steps:

    - mapping drainage systems
    - analyzing pollution treatment alternatives
    - sizing treatment facilities
    - designing O & M programs

The BMP selection process identified the most feasible and cost effective practices for use in the three drainage systems which were to be retrofitted. In addition, the Town of Orleans Storm Water Quality Task Force was set up to insure the project's technical quality and to address local concerns.

A range of BMPs were considered for control of bacteria and solids and their associated nutrients. The following BMPs were considered for this project, because they are targeted for the control of solids and bacteria:

- extended detention ponds
- retention basins
- infiltration trenches (subsurface leaching gallies)
- filtration beds

A system of sub-surface leaching gallies was used at three sites because of limited land but suitable soil conditions; one site consisted of a detention basin upstream of a filter bed structure because soil conditions were too poor to permit infiltration.

Institutional Issues

The Town's principal institutional motivation for implementing the retrofit projects was the adverse economic impact of closed shellfish beds. Abating and controlling the bacterial contamination from storm water runoff was directly tied to economic concerns and this was a very strong motivation for the Town to organize a task force and to act on the problem. The Town appropriated funds to develop conceptual approaches and engineering designs, as well as for the construction of the necessary BMPs.

II. Regional Cooperation: Role of the Cape Cod Commission

The Cape Cod Commission works with towns on Cape Cod on various matters

VOL 12
2
2161
R0055461

including local transportation projects. In Barnstable County, shellfish bed closures were the principal motivation for the Commission to become involved with storm water issues. The Commission trys to de-politicize issues and use all "levers" available, including state environmental review processes, such as coastal zone management consistency review, to affect outcomes.

Strategy

The strategy employed by the Cape Cod Commission utilizes several different components to maximize the leverage which the Commission can employ to facilitate implementation of storm water retrofit projects on Cape Cod. They try to use all the "levers" available, such as coastal zone management consistency review and the implementation of the Buzzards Bay Management Plan as part of the National Estuary Program (EPA). The Cape Cod Commission works as a coordinator [much like MWCOG in Anacostia watershed restorations] with the Massachusetts Department of Public Works (Mass DPW) and local governments on storm water remediation and retrofitting as part of local transportation projects.

The Cape Cod Commission (through the Cape Cod Marine Water Quality Task Force) has developed a process for prioritizing storm water drainage mitigation projects. This process includes the development of a numerical index to rank proposed projects. The worksheet is keyed to the concerns of Barnstable County, viz., the safety and harvestability of shellfish beds, as well as the safety of areas used for swimming and recreation.

VOL 12 2 2162

R0055462

City of Austin, Texas

Background

The City of Austin, Texas, stretches from the Texas hill country of the Edwards Plateau, eastward to the Blackland Prairie and the Gulf Coastal Plain. A unique environment results from this rapid geologic and ecologic transition.

The Colorado River flows directly through the City. Three riverine lakes - Lake Travis, Lake Austin and Town Lake - are the three most downstream reservoirs of a chain of reservoirs on the Colorado River known as the Highland Lakes. These reservoirs are the City's main water supply, as well as being tourism and recreational resources.

Another key water resource in the area is the Edwards Aquifer, a limestone aquifer on the western side of the City. The aquifer is the sole source of water supply to several communities south of Austin.

These water resources are potentially threatened by water pollution resulting from storm water runoff and other sources of nonpoint pollution. In response to this threat, the City has developed one of the best watershed protection programs in the country. The keystone of this program is the Comprehensive Watersheds Ordinance.

Development of the Comprehensive Watersheds Ordinance

In order to protect water resources from degradation due to urban nonpoint source pollution, the City enacted several watershed protection ordinances in 1988. These ordinances were combined into a single code which applies to the entire city and to its extraterritorial jurisdiction. The City of Austin Land Development Code and the Environmental Criteria Manual provide guidance for water quality management. The 1988 regulations became the basic building blocks of the Austin storm water management and BMP implementation and retrofit program.

The original catalyst for the consolidation of the existing watershed protection ordinances was the comprehensive planning effort known as "Austin Tomorrow." This plan identified nonpoint source pollution as a potential threat to Austin's environmental and economic well-being.

Monitoring of Austin's creeks and lakes followed this study and in 1978 the Lake Austin Watershed Ordinance became the first water quality related ordinance and nonpoint source pollution control ordinance to be adopted in the region.

In 1981, the City of Austin joined the EPA-sponsored Nationwide Urban Runoff

VOL 12 2 2163

R0055463

Program (NURP) study and began monitoring its storm water structural controls in 1982. Subsequent watershed protection ordinances were passed from 1980-1984 to cover additional environmentally-sensitive areas.

By 1986, the City of Austin had had eight years of experience with watershed protection ordinances and appointed the Comprehensive Watersheds Ordinance Task Force to develop the consolidated ordinance and provide final review and recommendations for implementing the consolidation of the numerous existing ordinances.

Overview of the Comprehensive Watersheds Ordinance

The Comprehensive Watersheds Ordinance (CWO) was directed at preventing urban runoff pollution by placing requirements on proposed new development with Austin and its extraterritorial jurisdiction. Although the Comprehensive Watersheds Ordinance originally existed as a stand-alone document, it has since been incorporated into the City's Land Development Code. In addition, there have been several amendments to it since 1986 and more are anticipated in the future to better protect various sensitive areas. Nevertheless, knowledge of the evolution of the Ordinance is helpful to understanding Austin's strategy for urban nonpoint source pollution control.

Specific pollutants were not addressed in the Comprehensive Watersheds Ordinance. Control of specific pollutants was instituted only for the sensitive Barton Springs Zone, which recharges the Edwards Aquifer. Several ordinances for the protection of this sensitive area have been put in place over the last several years.

The Ordinance required a range of widely accepted and proven structural and nonstructural nonpoint source pollution controls to be included in new development projects. These controls included best management practices (BMPs) such as impervious cover limitations, water quality buffer zones, protection of critical environmental features, limitations on disturbance of the natural stream, erosion control practices, sedimentation and filtration basins, and wastewater disposal requirements. One significant aspect of the ordinance was the use of nonstructural controls to prevent and mitigate nonpoint pollution associated with development. The rationale behind this approach was that impervious cover limitations and buffer zone requirements have been proven to maintain the basic hydrologic balance.

Protection of non-drinking water supply watersheds in the eastern side of Austin were not given high priority. Downstream of Town Lake the Colorado River is not used for drinking water supply. Furthermore, clay soils dominate on the eastern side of the City; therefore, maintaining infiltration and recharge is not a critical goal in these watersheds.

VOL 12 2 2164

R0055464

Effectiveness of the Ordinance

The City of Austin standard sand filter design requires the first half inch of runoff from a site to be diverted into a sedimentation basin and then filtered through sand. This design is based on eight years of monitoring filter ponds of different designs.[13] The demonstrated removal efficiency of the sedimentation/filtration ponds for total suspended solids is 75% to 97%.

An important consideration learned from the Austin experience regarding effectiveness is that maintenance is critical to ensure BMP effectiveness, yet timely maintenance is problematic at both a local and nationwide level. Another is that the best protection for water resources is believed to be afforded by a combination of structural and non-structural controls as provided for in the Comprehensive Watersheds Ordinance. Structural controls alone are not always effective, nor can they prevent an increase in pollutants from high intensity developments.

Austin's non-degradation strategy for contributing watersheds is to limit the percent of impervious cover in new developments and to reduce post-development pollutant loads through a menu of storm water control practices, and a program of retrofitting storm water treatment measures in developed areas. Austin has incorporated this strategy into the framework of the City of Austin Land Development Code through a mechanism known as an "impervious cover cap." The impervious cover cap is established by setting a Maximum Sustainable Removal Rate for storm water treatment measures at 90%; beyond this point, storm water control measures cannot be relied upon to reduce the pollutant loads associated with additional impervious cover down to the pre-development level.

This strategy aims to reduce excessive reliance on storm water treatment measures because of their inherent limitations and risk of failure due to lack of maintenance and their need for replacement. Impervious cover levels, on the other hand, do not change over time, do not require maintenance, and their life span is infinite provided their nature is unchanged.

However, the Austin program recognizes that modification of the City's development regulations would provide only a partial solution to the problem of water quality degradation. It sees retrofitting of structural storm water controls as the only way to reduce pollutant loads from existing development and development projected but not

[13] Parrish, John H. and Stephen Stecher, "Nonpoint Source Pollution Control in the City of Austin." City of Austin, Environmental and Conservation Services Department, March 1991, p. 5.

VOL 12 2 2165

R0055465

yet built.[14]

The Austin program has recognized that, in light of the growing trend toward limiting building density and/or impervious cover as a means of nonpoint source control in residential areas, there is a need to establish a clear linkage between development density or impervious cover and pollutant loadings. In addition, the city recognized that more study is needed on the effects of types of land use on the quality of storm water runoff.

The City's Storm Water Monitoring Program has provided the city an opportunity to evaluate the effectiveness of its varied array of storm water quality controls, and also to assess whether they are over- or under-designed relative to site conditions.

First Flush of Runoff and its Effects on Storm Water Control Structure Design[15]

Austin's Environmental Resource Management Division published a report (1990) showing that the first 1/2 inch of runoff did not necessarily carry the bulk of the storm load. This was contrary to the prevailing assumption that the first 1/2 inch of runoff in a storm washes off 90% of pollutants from the impervious cover. The report suggested that for a development with 90% impervious cover, only 40% of the total storm load would be washed off in the first 1/2 inch of runoff.

The implication of the report for control structure design was that a control structure designed to capture and treat only the first 1/2 inch of runoff would only remove about 40% of the total annual load. The bypass or untreated annual load could be substantial. The report did not suggest an alternative structural control design; it merely raised the issue of a substantial amount of pollutant load in excess flow from a structure designed to capture and treat the first 1/2 inch. Changes to the City's Land Development Code in December 1993 resulted in the treatment volume increasing with the amount of impervious area on the site, starting at .50 inch plus .10 inch per 10% increase in impervious cover over 20% of the site.

However, urbanized watersheds should be targeted for priority control based on other findings. Another Austin study confirms that storm water runoff pollutant loads increase with watershed imperviousness, and that loading rates of urbanized

[14] Ibid., p. 15

VOL 12 2 2166

R0055466

creek watersheds were significantly higher than those from small suburban sites.[16]

Sand Filter Program

The City of Austin has developed a sand filtration best management practice for use in storm water quality management. The sand filtration systems are the primary water quality control structures.

The City had previously implemented a storm water monitoring program in 1984. This study was conducted to determine annual removal efficiencies of six storm water quality control structures, including three filtration basins, one wet pond, one sedimentation (dry) pond, and one retention/filtration basin system. The structures were monitored between 1984 and 1989, and comparative measurements of inflows and outflows were taken to determine concentrations of pollutants.

Effectiveness of removal for the following parameters was measured:

- Fecal coliform
- Total suspended solids (TSS)
- BOD/COD
- Nitrogen
- Phosphorus
- Heavy metals

The study[17] concluded that the sand filtration basin is an effective structural control measure for most of the described pollutant parameters. Sand filtration is a demonstrated success in Austin, although officials concede that maintenance is sometimes inadequate and sporadic.[18] There have also been some isolated technical and/or design failures, such as slope erosion and construction failures which have resulted in inadequately performing BMPs.

R0055467

Strategy

The Austin sand filter program was implemented in response to regulatory requirements, viz., the consolidation and enactment of several watershed protection ordinances in 1988. In addition, political pressure to act came from citizens demanding action to protect water quality. The City of Austin's Land Development Code and Environmental Criteria Manual provide documentation and guidelines for the City's water quality management efforts.

Prior to enactment of the watershed protection ordinances, the City implemented a storm water monitoring program in 1984 to evaluate storm water control measures and to develop a database to quantify the effects of impervious cover and land use on water quality and also to evaluate the effectiveness of various structural storm water control measures already in use.

The basic strategy and philosophy guiding the Austin program has been to make new development and redevelopment pay the costs attributable to its impact and to mitigate all impacts of new development. While this has been the strategy, it has not been possible to accomplish this for all aspects of the development process, such as permits and review. In addition, the City assumes responsibility for maintaining water quality controls for single-family development. This approach includes a provision for payment of a fee in lieu of constructing BMPs so as not to restrict development. "Fee in lieu of" funds are used for retrofit projects for existing development, but only within the most highly urbanized and developed watersheds classified as "urban" in the Land Development Code.[19]

There are many components to the Austin storm water management amd urban nonpoint pollution control program. These include retrofit watershed master planning, source control of pollutants, and public education. A current emphasis is on the public education component, which includes videos and posters with the theme of abating urban nonpoint source pollution.

Austin's strategy sees the key to a successful nonpoint source control program as the targeting of critical areas to achieve high pay-off returns. The City's focus is on potential deterioration of local water supplies, viz., Lake Travis, Lake Austin, Town Lake and the Edwards Aquifer. The Comprehensive Watersheds Ordinance requires the strongest nonpoint source controls in those developments in watersheds which contribute to the drinking water supply.

Targeting new development is seen as a cost effective method of preventing future nonpoint source problems. Required controls which are prescribed in the Ordinance

[19] Ibid.

VOL 12 2 2160

R0055468

can be included in the initial land planning. Since the primary controls set forth in the Ordinance are non-structural, raw land cost is the main cost for new development associated with nonpoint source controls. However, structural controls are also used and these have a cost to the developer. Since impervious cover limitations are the most important non-structural control specified in the Ordinance, retrofitting existing development has proven to be difficult. Retrofitting structural controls has also been difficult, due to limited location and high land costs.

The City's retrofit program uses public education as its main tool to build and keep the necessary public support for storm water management programs through the use of videos, posters, and other media. In addition, Austin has initiated a process of storm water retrofit master planning as a way of maximizing the scarce public resources available for this purpose.

Developing a strategy for controlling nonpoint source pollution from urbanized watersheds is particularly difficult, and much more complex than preventing nonpoint source pollution from developing watersheds. Retrofitting BMPs in urban areas is still a "pioneering" activity and involves considerable experimentation and cost. While there are an increasing number of localities pursuing retrofit strategies, there is no broad national experience with retrofit implementation.

BMP selection in retrofit situations is also problematic; for example, wet ponds are an excellent BMP for controlling nutrients, yet they are often very difficult to site under retrofit conditions.

Non-degradation Strategy[20]

Austin has developed a non-degradation strategy for a particularly sensitive and important area known as the Barton Springs Zone, which covers several watersheds. The strategy is "design-based" rather than being entirely a technology- or performance-based approach. The design-based approach requires that compliance be designed into a project before it is built based upon best available scientific and engineering principles. This strategy includes a City-funded program for retrofitting storm water controls.

Other elements of the non-degradation strategy include:

- strengthening existing regulations by limiting exemptions
- limiting impervious cover to levels at which generated pollutants can be

[20]Parrish/Stecher, "Nonpoint Source Pollution Control in the City of Austin," March 1991., p. 12

VOL 12 2 2169

R0055469

reduced to background levels by an array of storm water control practices

Importance of Non-structural Controls in Austin's Program

One of the distinctive features of Austin's storm water management strategy is the emphasis given to the use of non-structural controls. The basic assumptions of this approach are the following:[21]

- structural controls alone cannot prevent an increase in pollutants from high intensity development
- maintenance requirements are high for structural controls compared to the maintenance needed for impervious cover limitations and buffer zones
- sole dependence on structural controls is not wise for protecting the City's water resources; a combination of structural and non-structural controls is the best strategy

Institutional Issues

Austin created a city department of environmental conservation, the Environmental and Conservation Services Department, in 1987. Its central focus is resource conservation and environmental protection, as distinct from public works. This department is co-equal with other City departments. It oversees the work of public and private agencies under its jurisdiction. This institutional arrangement is clearly intended to provide support for effective environmental and regulatory (enforcement) action.

The Environmental and Conservation Services Department and the Department of Public Works "share" a drainage utility (storm water utility). Drainage projects are funded with fees from the drainage utility. "Storm water" is not separately identified on the utility bill, nor described as such officially.

Costs and Financing

Most storm water programs are funded by the drainage utility. or drainage fee. Public works drainage projects in the Capital Improvements Program are paid for with bond sales which are repaid with tax (general fund) revenues at this time.

---

[21]Parrish/Stecher, "Nonpoint Source Pollution Control in the City of Austin," p.6

VOL 12 2 2170

R0055470

Development is expected to "pay for itself," that is, development must pay for the cost of controls associated with that development. However, in reality, development fees pay for approximately 30% of the land development review and permit programs. Nevertheless, the program's emphasis on non-structural controls means that the cost for the City is considerably lower (because of less monitoring and inspection) than if structural controls were the sole means of control.

The Austin program also takes the view that preventing adverse water quality impacts from nonpoint source pollution is much less expensive than trying to restore water quality after it has been degraded. One of the stated goals of the Comprehensive Watersheds Ordinance is to avoid the cost of retrofitting existing development.

There are significant costs throughout the institutional structure related to control of nonpoint source pollution. Preventing NPS pollution can avoid or reduce other costs such as wastewater treatment, the need for dredging lakes and waterways, and health risks associated with toxics pollution. The Austin view is that the cost of restoration, retrofitting, dredging, advanced types of water treatment, development of new water supplies, and lost recreational and economic values can easily dwarf the cost of prevention.[22]

Other NPS Control Programs

The City of Austin has also initiated non-structural and low-structural development controls to limit impervious surface areas for storm water management purposes. They have established a critical zone in which no construction is allowed, as well as a transition zone where development is limited or not allowed in order to preserve riparian areas.

Other programs which the City has instituted to control urban nonpoint source pollution include the following pollution prevention and source control programs:

- household hazardous waste collection: provides for safe disposal of hazardous materials
- street cleaning and litter collection program
- xeriscape and integrated pest management (IPM) programs: minimizes inputs to the environment from fertilizers and pesticides; both approaches stress the minimal use of the least harmful substances to control pests and weeds; IPM is encouraged in municipal operations

[22]Parrish/Stecher, "Nonpoint Source Pollution Control in the City of Austin," p.7

VOL 12 2 2111

R0055471

BMP Siting Considerations

There is a diversity of opinion as to whether it is better to construct large regional BMPs or numerous smaller BMPs closer to pollutant sources. The preferred approach in Austin is to construct numerous smaller BMPs and capture water as close to the source as possible for the following reasons:

1) need to capture less water to achieve the pollutant removal desired

2) capital and maintenance costs are less if the BMPs are smaller

3) maintaining the natural hydrology is easier with smaller BMPs - in addition, the need for groundwater recharge is addressed, whereas if channeling water further down the watershed was done, groundwater recharge would not occur (or recharge of polluted water could occur before the runoff reached the treatment device)

4) protection of smaller waterways from pollution and channel erosion

Summary and Conclusion

Austin has attempted to come to terms with its nonpoint source pollution problems through implementation of the Comprehensive Watersheds Ordinance and other ordinances since 1986. The City recognizes the actual and potential costs of nonpoint source pollution as it relates to safeguarding of drinking and groundwater supplies, maintaining tourism and recreational opportunities, and protecting wildlife habitat, to name a few.

Austin is "ahead of the curve" in terms of meeting EPA and state water quality goals. These efforts will continue to pay benefits into the future. The development and implementation of the Comprehensive Watersheds Ordinance could be a model for other local governments in their efforts to control nonpoint source pollution.

Relevance of Austin's Watershed Approach for Other Jurisdictions

Austin's Comprehensive Watersheds Ordinance is easily transferable to other jurisdictions and to other hydrogeologic conditions. The Texas Water Commission cited Austin's Ordinance as an example of the kinds of controls which local governments in Texas could implement as part of the Nonpoint Source Management Plan which the state submitted to the U.S. Environmental Protection Agency.

VOL 12

2

2112

R0055472

Because the Ordinance is based on BMPs instead of on design or performance standards, it is widely applicable to other situations and does not require specialized staffs for its implementation. The Ordinance is accompanied by a technical manual which specifies the technical aspects of the controls which it requires.

Numerous other jurisdictions in Texas have adopted watershed protection ordinances based on the same framework as Austin's. Governmental entities across the country have requested copies of the Comprehensive Watersheds Ordinance for guidance on how to protect their water resources and control nonpoint source pollution.

City of Orlando, Florida

Introduction

The City of Orlando, Florida has taken a pioneering role in trying to solve its water quality problems related to urban storm water runoff. Protection of its numerous lakes and wetlands has been a primary motivation for action. Within the corporate limits of Orlando there are some 83 named lakes, which lie within five major drainage basins. The City has the distinction of having been designated a "National Storm Water City of the Year" by the U.S. Environmental Protection Agency. It earned this distinction because of its aggressive storm water management and retrofit program.

Some of the innovative storm water treatment systems and retrofit methods used in Orlando include storm water wetlands, alum injection, exfiltration, lake aeration, sediment control devices, trash screens and shoreline and littoral zone vegetation.

Some of the other approaches being used in Orlando are:

- storm drain retrofits and water quality enhancements when performing corrective maintenance (e.g., vertical volume recovery unit for drainage to Lake Lawsona)
- exfiltration basin retrofits to existing city storm drains
- littoral zone enhancement and revegetation with native aquatic plants
- creation of storm water wetlands for pre-treatment of runoff entering lakes (e.g., Lake Lorna Doone)
- depressional landscaping to encourage runoff infiltration (e.g., Lake Ivanhoe)

One of the many major retrofit projects in the Orlando area is the Lake Greenwood urban wetland, which is a wetland and storm water management system in an urban environment close to downtown Orlando.

R0055475

Evolution of the Florida Storm Water Program/Major Regulatory Components

The major components of Florida's storm water program are three pieces of legislation: the 1982 storm water permit requirements for new development; the 1987 Surface Water Improvement and Management Act (SWIM), which provided a framework for watershed planning; and the 1989 storm water legislation, which established program goals and extended program coverage to existing agricultural and forestry sources.

The Surface Water Protection and Management section of the 1989 storm water legislation provides the regulatory framework for the Florida storm water management program, particularly the watershed approach. This program was enacted by the Florida legislature to restore the state's degraded water bodies and to protect those still in good condition.

The landmark 1989 storm water legislation was intended to integrate the various existing storm water laws and programs into a comprehensive watershed management program. Most importantly, the 1989 law emphasized the watershed approach to correcting existing storm water deficiencies and it gave a regulatory impetus to retrofitting. The 1989 law also established the State Storm Water Demonstration Grant Program which provides matching grants for storm water treatment projects undertaken by local governments which have implemented storm water utilities. The grant program is clearly an inducement to Florida municipalities to set up storm water utilities.

Lessons Learned in Florida's Storm Water Program

The Florida storm water program has been successful at minimizing storm water problems associated with new growth, but it has been much less successful in restoring water bodies degraded by storm water discharges. The piecemeal approach cannot address one of the state's largest problems, however, the problem of retrofitting drainage systems, which includes:

- retrofitting of existing storm water drainage systems to reduce pollutant discharges to state waters
- correcting storm water infrastructure deficiencies related to the state's rapid growth

Livingston stresses that the solution is comprehensive and coordinated work

VOL 12 2 2176

R0055476

throughout the watershed.[23] He emphasizes the need to address land use, water resources, and infrastructure planning within a watershed context. He also states that a dedicated funding source, such as a storm water utility is also important for maintaining an effective program.

Lessons Learned in Orlando

The Orlando experience suggests that one of the requirements for successful urban runoff control and retrofit projects is the importance of control of the project and the need to write very good specifications so that water quality goals are met. Engineers and consultants may have an economic incentive to design BMPs which may not be commensurate with the implementing authority's water quality goals.

Experience reveals that engineers and consultants may sometimes have a mechanistic approach to problem solving and therefore advocate a hydraulic solution rather than water quality one in some instances. They know how to get the water off-site as quickly as possible, but this is not necessarily commensurate with a water quality solution.

The best way for the implementing authority to ensure success is to be in control of the project, to know the solution that is necessary, and then see that it is done correctly.

Greenwood Urban Wetland

The Greenwood Urban Wetland in Orlando is a constructed urban wetland located within a 522-acre drainage basin. Storm water runoff collected within the 522-acre sub-basin flows into Lake Greenwood, which lies at the lowest point in a 4.5 square mile urbanized area. The artificial wetland was built to alleviate flooding, to pre-treat storm water runoff prior to discharge into drainage wells (which discharge water to the upper Floridan acquifer), and to re-use the stored water to irrigate an adjacent cemetery and park. City-owned land which was previously vacant was excavated to form a series of ponds and a bypass stream leading to five drainage wells.

The storm water quality enhancement component of the wetland plan came about as a result of the City's concern for protecting its groundwater supply. Proximity to groundwater is a prime concern in most of Florida.

---

[23]Livingston, Eric H., "Lessons Learned from a Decade of Stormwater Treatment in Florida." Bureau of Surface Water Management, Florida Department of Environmental Regulation, Undated.

VOL 12 2 2117

R0055477

The storm water "treatment train" concept was incorporated into the Lake Greenwood urban wetland. The BMPs included in this treatment train are: a sediment and trash screening device; a littoral zone with vegetation; and aerators to increase microbiological activity.

Effectiveness of the Greenwood Urban Wetland

Water quality monitoring of Lake Greenwood was begun in 1987 - one year prior to the beginning of construction of the wetland. This was done to obtain a baseline profile and to ascertain the trophic state of the lake. Both before and immediately after construction, the lake exhibited eutrophic to hyper-eutrophic conditions. After completion of the project, the lake's trophic state indices were in the mesotrophic range.

Prior to construction, the water quality of Lake Greenwood was not in compliance with Florida Class III (recreation and wildlife propagation) water quality standards. Since construction, there have been no water quality standards violations of any parameters tested, including EPA-listed pesticides. Further monitoring of the storm water treatment system is being planned for wet weather pollutant removal efficiencies and further hydraulic analysis. An ongoing storm water monitoring program was begun in 1991.

Based on the preliminary sampling data, it is clear that the Lake Greenwood urban wetland storm water management system has enhanced water quality within the lake and also the quality of the water discharged to the drainage wells (which discharge to a major acquifer).

Development of Orlando's Storm Water Utility

Storm water projects in Orlando have traditionally been financed out of general fund revenues, as is common in most municipalities. In addition, Orlando has used revenue from a state gasoline tax for projects which also have a road/transportation component. Depending upon general fund revenues, however, often results in projects being deferred to pay for more critical governmental functions such as police and fire. The City has adopted an aggressive program of storm water system repair and replacement, pollution control, and lake enhancement. This problem has been funded in the past through the City's general property tax budget, but this source is no longer adequate for the scope of the problem today, particularly in view of increasingly stringent state and Federal water pollution control requirements.

To provide for the effective management and financing of a storm water system within the City of Orlando, the City established a storm water utility. The storm

VOL 12 2 2178

R0055478

water utility generates its revenue through user fees. A storm water service charge is levied on every parcel of land in the City. The fee is based on the amount of storm water which a particular parcel passes on to the storm water drainage system.

The storm water utility is responsible for the operation, construction and maintenance of storm water management devices, for storm water system planning and lake management.

Packed Bed Storm Water Filter Artificial Wetland[24]

One innovative project which was proposed by the City and implemented through a consultant was the "packed bed filter." This experimental storm water BMP will be used (just coming on line in July 1993) to treat a small but highly urbanized portion of the drainage basin which flows into Clear Lake. The project was initially proposed in response to concerns about the lake's water quality.

The drainage basin for Clear Lake consists of over three square miles of highly developed urban area. This retrofit technique became necessary because best management practices (BMPs) for new development are not appropriate in the highly urbanized and completely built-out Clear Lake basin. This innovative method of storm water treatment was selected both for its presumed pollutant removal efficiency, as well as the necessity of using a BMP which could function within a limited area where land utilization constraints exist.

The packed bed filter is an example of technology transfer - a common wastewater treatment technique which has application to urban storm water pollution treatment. The filter utilizes a treatment train of two components, one of which is a packed bed filter system planted with wetland macrophytes for nutrient uptake. Put more simply, the system is a packed-bed filter (similar to a trickling filter) with hydroponically-growing aquatic plants. During dry weather or low flow conditions, the device will treat water from Clear Lake using the continuous flow to maintain the planted beds.

The device has a limited storage volume, so a decision was made that in order to maximize the removal of the most pollutants, the goal would be to capture less than the first one-half inch of runoff from a larger acreage than a greater amount from a smaller acreage. It is hoped that this will result in the treatment of a dirtier waste stream and reduce the amount of pollutants reaching the receiving waters of Clear Lake.

Pollutant Removal Efficiency Cosiderations for Packed Bed Filters

Although the packed bed filter implemented by the City of Orlando has only recently been brought on line [July 1993], there are certain operational considerations for packed bed filters as they relate to treating urban storm water runoff. Packed bed systems intended to treat storm water do not have to meet the strict effluent quality criteria that would be required for wastewater. Indeed, the concentration of pollutants in storm water most closely resembles tertiary treated wastewater with the exception of solids concentrations. This is one reason why the packed bed storm water treatment system was designed to treat a larger flow with lesser removal efficiency than a higher removal rate from a smaller flow.

The packed bed filter employs the concept of a "treatment train." The concept of a treatment train of BMPs involves a series of unit operations designed to remove the largest amount of contaminants from runoff, typically greater than the pollutant removal achievable through individual unit operations.

The packed bed filter system is a new technology and a transfer of technology from wastewater treatment systems to storm water management systems. As an experimental practice for storm water treatment, many elements need to be monitored for their relation to long-term effectiveness:

- hydraulic residence time
- bed media
- plant materials for the packed beds
- depth
- travel length
- velocity
- liners

Use of Alum for Treatment of Storm Water Runoff

One technology showing promise is the use of alum to treat storm water runoff. Two lakes in Orlando, Lakes Dot and Lucerne, and one in suburban Winter Park, Lake Osceola, are having their storm water inputs from large urbanized drainage basins pre-treated with alum. The alum treatment concept was initially tested on Lake Ella in Tallahassee.

Alum treatment of storm water runoff was selected after an analysis of the pollution abatement alternatives. Conventional storm water management techniques such as retention, detention, or exfiltration were deemed not feasible due to space limitations, or because of the poor infiltration capacities of watershed soils. The alum is injected and mixes with the storm water in the storm sewer lines. Floc accumulation begins

VOL 12 2 2180

R0055480

immediately and the floc settles on the lake bottom.

Alum injection is wastewater treatment technology being adapted to storm water quality control. There is still some question whether it can be considered a retrofit technology, but its use as a pollution abatement alternative involves many of the hallmarks of a retrofit situation:

- infeasibility of conventional storm water management techniques such as retention/detention
- infeasibility of using exfiltration systems due to limitations of available space and poor infiltration capacities of watershed soils

Another Case Study in Florida

Lake Jackson Regional Storm Water Management System

Rapidly urbanizing areas in the Megginnis Arm watershed were causing water quality degradation in Lake Jackson in Leon County near Tallahassee. A regional storm water detention system was designed and constructed through a cooperative effort of the Florida Department of Environmental Regulation, the Northwest Florida Water Management District, and with funding from EPA's Clean Lakes Program and the State of Florida. The facility consists of a wet detention pond with a heavy sediment basin at the inflow, a sand filter system designed to filter particular pollutants from storm water, and a three-cell constructed wetland designed to remove dissolved pollutants such as nutrients.

Construction of the system was completed in 1983 at a cost $2,664,389. Maintenance operations, which consist of sediment and clay removal from the top of the filter fabric do not exceed $30,000 per year.

Effectiveness of the Lake Jackson facility

Florida State University researchers conducted a long-term storm water sampling program of the facility and its individual components. Overall, the facility has performed up to design specifications within the constraints of space and the technical level of the equipment used. However, the increasing urbanization of the watershed has resulted in larger volumes of storm water draining into the facility, well beyond its design capacity. To overcome these deficiencies, the facility was enlarged to provide longer detention of more storm water, allowing the facility to

VOL 12 2 2181

R0055481

detain larger storms and limiting the discharge of untreated storm water into Lake Jackson.

Lessons learned from Lake Jackson experience

Some of the lessons learned in the construction of the Lake Jackson regional storm water management system include the following design considerations:

- storage volume and the amount of water bypassing the system are critical design elements; the system should be designed based on maximum anticipated buildout in the watershed
- adequate funding must be provided to operate and maintain the system
- wetlands systems require some maintenance such as dredging to remove accumulated sediments and organic matter; they will not work indefinitely without maintenance

VOL 12 2 2182

R0055482

County of Fairfax, Virginia

Regulatory Context

Fairfax County, Virginia is subject to the following Federal and State legislation and programs:

- Amendments to the 1987 Clean Water Act requiring NPDES permits for storm water discharges
- Virginia storm water management regulations (at local option)
- Erosion and Sediment Control Law
- Chesapeake Bay Preservation Act
- Section 404 of the Clean Water Act (wetlands protection)
- Water quality requirements under the Reauthorization of the Clean Water Act pending Congressional consideration in 1994

The County may also be subject to some requirements related to recent coastal zone legislation to which Virginia as a coastal state would be subject. States must develop a coastal nonpoint source pollution control program as a requirement of the Coastal Zone Act Reauthorization Amendments of 1990 (CZARA). The State programs must be approved by EPA and NOAA by 1995.

Background[25]

Fairfax County has been involved in storm water control for more than 30 years. During the 1950s and 1960s, the emphasis was on storm water conveyance and channelization, which included delineation of flood plains and implementation of flood control projects. Beginning in 1972, on-site storm water detention was required for all new development. In the 1980s, water quality BMPs were required for new development in the southern areas of the County draining to the Occoquan reservoir, the major source of drinking water for Fairfax County.

In addition to the Master Drainage Plans which were prepared for all watersheds in

[25]County of Fairfax, Virginia. Draft. National Pollutant Discharge Elimination System. Municipal Storm Water Discharge Permit Application, Part 2. November 1992.

VOL 12 2 2183

R0055483

the County during the 1970s, a supplemental Regional Storm Water Management Plan was prepared in 1988. This plan provides for regional storm water control ponds to control both quantity and quality. Wherever opportunities exist, the County intends to expand the implementation of regional storm water management ponds from the current pilot project involving seven watersheds. Implementation of the planned storm water control facilities over the past 20 years has resulted in expenditures of approximately $60 million, financed primarily through storm bonds.

There are presently over 1,500 storm water management facilities located in the County. In addition, there are 30 major lakes and over 100 smaller lakes and ponds which function as BMPs and provide water quality benefits in Fairfax County.

In 1989, the Fairfax County Board of Supervisors adopted the "Regional Storm Water Management Plan." The adoption of this plan marked a shift in philosophy on implementing storm water management from reliance on on-site controls to what are viewed as more effective regional controls.

Current Activities

The Fairfax County Department of Public Works is currently in the process of obtaining various permits or implementing programs designed to provide water quality improvements. These activities include:

- obtaining an NPDES permit from the Virginia Department of Environmental Quality; part 2 of the application has been submitted and the County is awaiting approval from the State
- implementing on-site best management practice (BMP) requirements for new developments in Chesapeake Bay Preservation Areas to protect water quality
- implementing a regional storm water management program to provide water quality improvements for both existing and new development, and to protect downstream wetlands and habitat
- implementation of stream channel erosion protection projects
- adopted a Water Supply Protection Overlay District requiring BMPs in the watershed of the County's water supply reservoir
- re-zoned much of the Occoquan watershed [water supply reservoir] to Residential/Conservation District (R-C) with 5 acre minimum lots
- adoption of an Environmental Quality Corridor Policy to protect land

VOL 12 2 2184

R0055484

and surface water resources

Ongoing Activities

As part of the County program to comply with NPDES requirements, there is a 5-year monitoring program of selected storm water outfalls. The outfalls were selected based on different land uses and, based on the final monitoring results, typical pollutant loadings for each land use will be extrapolated.

There are approximately 44 regional storm water management facilities in the Difficult Run watershed alone. The County currently spends approximately $1 to $2 million per year on capital construction for storm water control facilities. However, prior to the recent downturn in the economy, typical drainage facility expenditures totalled $2 million to $4 million per year. Due to current economic conditions, the Fiscal Year 1994 appropriation has been reduced to $341,000.

To pay for these costs out of declining general fund revenues is becoming difficult for the County and this has led to discussion about establishing a storm water utility as a dedicated source of funding for storm water management and control. A storm water utility feasibility study is currently in progress.

Role of the Chesapeake Bay Preservation Act

In Virginia, the Chesapeake Bay Preservation Act (CBPA) is a significant storm water management program through its BMP requirements and use of buffers such as the environmentally sensitive Resource Protection Areas (RPA). The regulatory requirements of this program need to be considered by developers and local governments such as Fairfax County, in addition to other storm water management regulations.

Proposed Management Program

The County's proposed management program consists of the following elements:

- continuation of ongoing requirements and programs such as implementation of the Chesapeake Bay ordinance which requires structural BMPs on all new development
- implementation of suitable water quality control facilities
- providing inspection and maintenance of storm water management facilities

VOL 12 2 2185

R0055485

- increased public awareness of the importance of clean storm water

The County recognizes that the proposed management program will require additional County funds and is currently evaluating the feasibility of establishing a storm water utility to provide a dedicated funding source for storm water management.

The County will look for opportunities to retrofit storm water devices and to implement additional regional ponds in all the County's watersheds in existing developed areas that are now without water quality controls. The County's Comprehensive Land Use Plan also encourages the retrofitting of existing storm water management ponds to become more effective BMPs.

Regional Storm Water Management Plan

In 1989, the County Board of Supervisors adopted a "Regional Storm Water Management Plan" which proposed 134 regional ponds in the most rapidly developing watersheds in the County. The adoption of this plan marked a shift in Fairfax County's approach to implementing storm water management from onsite controls to regional controls. This shift was based on the belief that regional controls are more effective. Concerning the retrofit of existing facilities, proposed development plans are reviewed by the Department of Public Works for opportunities to implement regional storm water management to supplement the pilot Regional Storm Water Management Plan for developing watersheds. In addition, the feasibility of retrofitting existing or porposed flood management projects to include water quality is evaluated.

Non-structural BMPs: Environmental Quality Corridors

Environmental Quality Corridors (EQCs) are the primary non-structural best management practice used by the County to protect water resources. Although the core of the EQC system will be the County's stream valleys, lands may be included within the EQC system if they achieve any of the following:

- habitat quality
- corridor-like quality
- aesthetic quality
- pollution reduction capability

The stream valley component of the EQC system includes the following:

- 100-year flood plains and flood plain soils
- soils with development constraints adjacent to wetlands, streams, and steep slopes

VOL 12 2 2186

R0055486

- additional areas where above-described buffers are insufficient to protect water resources

Current Funding/Future Funding of Water Quality Programs[26]

There are ongoing County water quality programs which are supported out of the General Fund. These programs are:

- monitoring programs
- emergency response
- public awareness
- public facilities maintenance

The County's NPDES permit application clearly states the necessity of developing new funding sources for implementation of capital improvement projects for water quality.

The following point illustrates the tenuousness of funding water quality improvement projects out of general or bond funds: The currently approved bond referendum funds have almost been expended, and the latest storm bond referendum was defeated by voters in 1990. Neither the general or storm bond funds can be relied upon to provide stable funding for future storm water quality capital improvement needs.

Yet the County estimates that $11.79 million per year will be required to implement regional storm water management over the next decade, and to provide for maintenance of these facilities. County staff are determining the feasibility of establishing a storm water utility to provide long term capital as well as maintenance funds for the County's storm water control facilities.

In the interim, two methods to fund capital construction of water quality control improvements are being pursued. These are: use of storm drainage pro rata share program funds; and proffer agreements with developers. Both of these sources are relatively insignificant at the present time, due to the downturn in economic activity.

Cities of Eugene and Portland, Oregon

City of Eugene

Background

The City of Eugene developed its Comprehensive Storm Water Management Plan (CSWMP) in response to Clean Water Act regulations requiring medium-size cities and counties to improve and manage the quality of their storm water. The plan is a model of a rational and comprehensive approach to dealing with the problem of runoff from urbanized areas. From its beginning as a conventional program emphasizing flood control and rapid conveyance of storm water runoff off-site, the City has developed a plan which does not merely conform with, but exceeds, the evolving Federal mandates for water quality management.

The principal motivation for initiating development of the Comprehensive Storm Water Management Plan in 1991 was the imminent promulgation of a Federal mandate (NPDES) requiring jurisdictions of medium size (between 100,000 and 250,000 population), to reduce discharges of pollutants to receiving waters from storm water runoff.

The Comprehensive Storm Water Management Plan

The City's storm water management program goes further than meeting Federal and state water quality requirements. It has taken the problem of meeting its legal requirements and turned it into an opportunity to offer a broad-based solution through a **multiple objective approach** to protecting, enhancing and restoring the City's water quality.

The multiple objective approach of the Eugene plan includes storm water management. Wetlands adjacent to Amazon Creek and other drainage channels are considered to be hydrologically connected to the City's storm water conveyance system. The plan recognizes the central role that wetlands play in storm water management.

According to the plan, the five-year start-up phase of the storm water management program includes major program activities such as planning and administration, capital projects (including retrofitting), operations and maintenance, enforcement and inspections, and public communications and outreach. The City has already developed a storm water utility and user fee structure.

The City, however, did not have the necessary organizational structure and programmatic resources in place to address the many issues involved in managing

VOL 12 2 2/1/88

R0055488

storm water quality. It determined that the proper way to address the whole range of storm water issues was within a coordinated, comprehensive framework. Among the factors which influenced its decision to develop a comprehensive strategy were the following:

- commitments already made to implement the recently approved West Eugene Wetlands Plan (see below), as well as how the new mandates could be incorporated into this Plan
- a new proposed plan, the Natural Resources Functional Plan, aimed at protecting the city's riparian and waterways corridors; this plan calls for the City's urban runoff management plan to address the relationship between riparian habitat, water quality and flood conveyance
- implementation of other goals and policies contained in the city's general land use plan

The CSWMP encourages this multiple objectives approach to storm water management, including flood control, water quality treatment, and natural resources protection. In addition, it strengthens the existing ordinances and implementation activities already in place.

Relation of the Wetlands Plan to Storm Water Plan

Amazon Creek is the central drainage feature of Eugene. The channelization of Amazon Creek (completed in 1959) significantly altered the hydrologic and hydraulic conditions of the area. Although flood control benefitted the community and allowed agriculture, commercial, and residential development to spread westward in the city, it also had the unfortunate effect of hydrologically isolating surrounding wetlands. This isolation and the subsequent draining of wetlands resulted in environmental degradation.

Consequently, wetland restoration is a high priority for the City of Eugene. It proposes to begin this process through a demonstration project called the Lower Amazon Creek Restoration Project which aims to restore the hydrologic interchange with surrounding wetlands, and restore fish and wildlife habitat and other associated water resource values. This will be accomplished through the removal of levees, in whole or in part; through modifying culverts; and through breaching levees at selected locations.

In addition to restoration of historic wetlands, the city is developing a program to use constructed wetlands for storm water quality treatment. The City is interested in using these constructed wetlands to control (pre-treat) pollutants in urban runoff

VOL 12 2 2189

R0055489

which enters a natural wetland system in West Eugene.

This idea grew out of the preparation and planning to develop the West Eugene Wetlands Plan (WEWP), with the goal being the preservation of the natural system through the pre-treatment of runoff from areas of the City. Without such treatment, the degradation of the remaining existing natural wetlands would be a virtual certainty. Storm water management is seen as critical to the success of the WEWP, and to the survival of the wetlands themselves.

The use of constructed wetlands as a treatment process for urban runoff is emerging as an alternative to conventional processes. Some of the advantages to using constructed wetlands to temporarily store or treat storm water include:

- water quality improvement
- flood, erosion and storm damage reduction
- replenishing surface and ground water supply
- provision of fish and wildlife habitat
- aesthetic or amenity benefit[27]

Regulatory Issues

There are numerous Federal laws and regulations, executive orders, as well as comparable state and local regulations and ordinances which regulate activity in wetlands or potential wetland areas. Current Federal policy forbids the use or modification of natural wetlands to treat storm water.

Nevertheless, the following points should be borne in mind:

- wetlands are functionally part of many municipal separate storm sewers
- wetlands in urban areas may be dependent on storm water for their very existence

Therefore, the strict application of regulations which forbid the degradation of wetlands can have unintended consequences in watershed and wetland planning. The City of Eugene experience suggests that flexibility should be allowed when determining the level of appropriate protection for wetlands and that this can be accomplished through a planning process which involves the local community as well as Federal and state agencies which regulate these resources.

---

[27]City of Eugene, OR. Conceptual Engineering Design for Water Quality Workshop. Final Report. Department of Public Works, City of Eugene, OR, undated.

VOL 12 2 2/19/90

R0055490

Eugene's Existing Storm Water Program

The City's current storm water system has historically been focused on providing flood control services. With its emphasis on storm water conveyance and flood control, the existing program was in conflict with Federal mandates for water quality management. Since the natural water quality treatment systems, such as riparian areas, waterway corridors and wetlands have been extensively replaced with conventional, structural conveyance facilities, ways need to be found to not only stem the removal of natural systems, but seek opportunities to preserve them. The CSWMP recognizes this goal and integrates it into the plan.

The City is faced with significant and complex issues as it seeks to transform its existing storm water management program to meet the challenge of complying with Federal mandates and heightened citizens' expectations. The framework of the CSWMP will allow it to do this within a comprehensive planning context.

The City already has a dedicated revenue source to fund general and storm sewer capital projects, the storm water utility user fee. It is the major revenue source for the existing program, and is expected to be the principal revenue source for the new, expanded program. The City has reviewed and analyzed current policy in light of evolving Federal water quality mandates, and has refined its policy to include the following:

- that all users of the storm water system contribute to the financing of the program
- that property owners be encouraged to incorporate practices beyond the minimum required through the use of financial incentives such as fee reductions, etc.

Retrofitting and Eugene's Storm Water Management Plan

Eugene's CSWMP contains a specific capital facilities best management practice (BMP) for retrofitting existing facilities, where feasible and appropriate, to achieve water quality goals. These retrofits may include the installation of in-line sediment traps, detention/infiltration facilities, wetlands or riparian (re)vegetation, or simply the modification of flood control facilities (i.e., storm drain inlets, retention basins, or drainage channels) to function as water quality facilities.

Additionally, the capital facility BMP directly addresses the NPDES requirement that the City assess the existing drainage and flood control facilities in order to determine if retrofitting them would improve water quality.

VOL 12 2 2191 1

R0055491

The capital facilities program includes retrofitting as one of the major activities scheduled during the five-year start-up phase of the City's comprehensive storm water management program, with retrofit implementation commencing around 1996.

The activities conducted as part of the retrofitting component of the Plan, include:

- preparing a master list of existing facilities with relevant retrofit considerations for each type
- conducting an inventory of existing flood control facilities that will provide information necessary to determine whether retrofits of these facilities are feasible or not
- reviewing inventory results to select sites and facilities where retrofits would be most appropriate
- developing a preliminary plan for retrofitting, with a schedule and estimated costs
- developing funding plans for retrofits

Eugene's Public Outreach Effort

An important feature in the evolution of the City's program are the numerous methods for disseminating information about the development of the storm water management program. These methods range from neighborhood newspapers such as the Eugene Storm Water Connections, with general information about the City's storm water management program, to more targeted information sheets, brochures, and stickers, to community workshops to introduce citizens to storm water pollution issues.

VOL 12 2 2192

R0055492

Important Elements in Eugene's Program

The importance of the West Eugene wetlands to the overall stormwater management plan.

- the integration of natural resource elements into the overall stormwater management framework and looking at the watershed and how it functions as an integrated unit

The significance of the multiple objective planning approach and why it could be a model.

- opportunity to address urban runoff issues from a comprehensive perspective, including wildlife habitat, recreation, resource conservation education, etc.

The high level and quality of citizen involvement and how this reduces conflict.

- widespread citizen involvement with two-way communication and feedback mechanisms facilitates consensus decision-making

VOL 12 2 2-1-94

R0055494

City of Portland

Introduction

The City of Portland, Oregon, has developed innovative and comprehensive urban runoff control strategies to meet the water quality requirements of Federal and state legislation. Its program encompasses a wide range of activities for controlling both point and nonpoint source pollution. The range of activities alone - from transportation improvements to improved pesticides management - serves to illustrate the diffuse nature of nonpoint source pollution.

Portland's storm water management program has been designed to be a constantly evolving program which implements the management practices that succeed, modifies or eliminates those that do not, and seeks to develop the most efficient and productive practices throughout the program's life. Based on a balanced economic and environmental approach, its goal is to develop and implement the most successful municipal storm water permit program in the Pacific Northwest.

Storm Water Permit Program (NPDES) Activities

The City of Portland, whose total population is roughly 450,000, has been classified as a medium-size municipality for the purposes of the NPDES storm water permitting program because less than 250,000 people are served by its municipal separate storm sewer system. A significant portion of the city is served by combined storm and sanitary sewers, which are subject to other Clean Water Act regulations.

Under Oregon state-wide land use planning law, each city must define an urban growth boundary (UGB) within which urban development is confined. Once approved, they have the force of law. Within Portland's urban growth boundary, six other agencies operate "municipal-like" separate storm water conveyance systems. Together with the City, the six have become co-applicants for the Portland NPDES storm water permit application. The co-applicants include Multnomah County, Multnomah Drainage District #1, Peninsula Drainage Districts #1 and #2, the Port of Portland, and the Oregon Department of Transportation.

Although the permit has not yet been issued, the seven co-applicants are currently conducting a number of programs and practices that directly or indirectly improve the quality of storm water. While the NPDES permit application is a joint effort of all the co-applicants, each co-applicant has responsibility for implementation of their individual storm water management plan.

Significantly, from an institutional point of view, the City's NPDES program implementation schedule has been developed to coincide with the majority of the co-

VOL 12 2 2195

R0055495

applicants' fiscal year budget schedules. The goal of this action is ease of implementation, but it also represents a concrete and very sensible method for facilitating institutional cooperation.

NPDES Program Implementation Strategy

Portland's NPDES program strategy is to build on a foundation of existing urban runoff control practices. The City developed existing management program (EMP) fact sheets corresponding to each regulatory requirement. Portland's proposed NPDES management program emphasizes and builds upon existing storm water controls and management practices. The program intends to limit the introduction of new practices as much as possible, but where appropriate it will phase in new practices during the life of the permit.

However, BMPs were developed to meet NPDES requirements not covered by existing programs. The co-applicants have grouped BMPs into implementation categories:

- public education and involvement
- operations and maintenance procedures
- industrial and commercial controls
- illicit discharge controls
- new development standards
- structural controls
- planning/system preservation and development

Nonpoint Source Program Activities - Some Examples

1. Used Oil Recycling Program

The City has a comprehensive solid waste and recycling program, which includes used oil curbside pickup that properly recycles used oil. Although many jurisdictions maintain used oil recycling programs, few offer pickup of used motor oil as in Portland. (The City also provides yard debris, cardboard, paper, newspaper, and metals residential curbside pickup.)

2. "Skinny Streets" Program

The City Office of Transportation has implemented new design standards for certain street categories in an attempt to reduce environmental impacts, such as minimizing the impervious area of new streets and preserving existing vegetation.

VOL 12 2 2196

R0055496

3. Snow and Ice Control

Sand and gravel materials are used at varying levels and picked up as soon as possible after a storm has passed, which may take a few days or several weeks. By comparison, many jurisdictions remove these materials only after the winter has passed, if they collect them at all.

4. Pesticide/Herbicide Application

All applicators participate in an Integrated Pest Management (IPM) training program. In addition, the City Planning Bureau has landscape requirements which reduce the need for pesticides, herbicides, and fertilizer through the use of native plantings. They are also developing an environmental seed mix.

Approach to Institutional Issues

The process by which the Portland NPDES permit co-applicants put together their storm water permit application reveals some of the institutional issues which impact upon the ability of a jurisdiction to carry out effective storm water management. The seven jurisdictions have different institutional motivations and agendas and degrees of political accountability and these factors affect how they approach and deal with the problem of urban runoff management and control.

For example, the Oregon Department of Transportation (ODOT), one of the seven co-applicants in the permit process, has as its mission the building of roads, not managing storm water. Nevertheless, the ODOT maintains hundreds of miles of storm sewer pipes that collect and transport storm water surface runoff, in addition to open ditches and dry wells. It also has responsibility for 14 major storm sewer outfalls in Portland.

The ODOT, however, is not subject to the same direct political pressures to pursue its storm water management goals as, for instance, the City of Portland. The same holds for the special drainage districts, the Port of Portland and other co-applicants. This presents the potential for different outcomes. Such a divergence of institutional interests and objectives could potentially limit the effectiveness of the storm water management program.

However, the Portland experience illustrates how potentially problematic institutional issues can be dealt with early in the program planning process and the result is likely to be a more effective urban runoff control program. In the process of developing the storm water management plan, the City's consultants worked with all the co-applicants to define and clarify issues related to their proposed BMPs. As part of this process they considered:

VOL 12 2 2191

R0055497

- the department or division within the agency which would be affected by or involved with the implementation of the BMP;
- the agency's existing conditions related to the BMP, and the tasks necessary to implement it;
- the degree to which the implementation of the BMP is likely to affect existing staff and/or resources

The fact that the process used in Portland considers these sometimes subtle but important institutional concerns increases the probability of a successful outcome. It also points up the importance of "issue scoping" and framework development to ensure program effectiveness.

Program Funding

The City finances its storm water management activities through the levy of a drainage fee which is based on the amount of runoff allowed to flow into the storm sewer system. In 1992, the City initiated a storm water drainage discount program. Discounts in the drainage fee are given to propoerty owners who limit the quantity of storm water discharged from their property. The discount may be as high as one hundred percent.

Discounts for water quality are not cuurently included in this program, but the City code permits the imposition of such a fee and discount program in the future. The existing discount program is directed at sites with on-site disposal systems.

VOL 12 2 2198

R0055498

BMP Selection and Screening Factors used in Portland's Planning Process

- Life Cycle Costs - The approximate cost of initial implementation and future operation.

- Regulatory Requirements - Does it meet existing and anticipated Federal, state and local regulations?

- Pollutants - Does it offer reasonable control of the targeted pollutants?

- Implementability - Is it likely to be accepted and funded by the various public agencies, city departments, and the general public?

- Reliability - Does the BMP function predictably and is it effective over time?

- Environmental Impact - Consider the environmental impacts and benefits of the BMP.

- Equitability - How are the costs and benefits of the BMP distributed?

VOL 12 2 2199

R0055499

Portland's proposed NPDES stormwater management plan is innovative and has the following components:

- It emphasizes non-structural source controls including education and maintenance programs.
- It builds upon existing programs such as curbside recycling, household hazardous waste collection, etc.
- It encourages regional efforts and programs.
- It emphasizes cooperation among its NPDES co-applicants to improve water quality.
- It phases in management plans to allow for budgetary and resource constraints.

Portland's NPDES program highlights

VOL 12 2 22000

R0055500

Portland's Compliance Strategies

- Consider urban runoff issues as permanent issues which require a long-term planning approach.
- Share information and ideas and look for opportunities to cooperate on projects, or share costs with other jurisdictions, etc.
- Work closely with regulatory personnel throughout permit period to discern their objectives, priorities and intentions.
- Be creative and proactive in complying with permit and regulatory requirements.

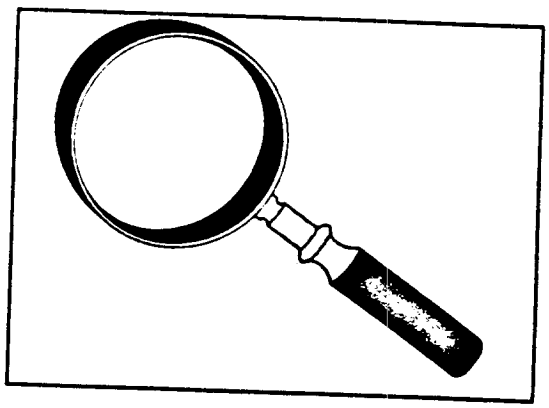
VOL 12 2 2201

R0055501

Glossary



Best Management Practice (BMP): A practice or combination of practices that are determined to be the most effective and practical (including technological, economic, and institutional considerations) means of controlling point and nonpoint pollutant levels compatible with environmental quality goals.

Constructed urban runoff wetlands: Those wetlands that are intentionally created on sites that are not wetlands for the primary purpose of wastewater or urban runoff treatment and are managed as such. Constructed wetlands are normally considered as part of the urban runoff collection and treatment system.

Drainage Basin: A geographic and hydrologic sub-unit of a watershed.

End of Pipe Control: Water quality control technologies suited for the control of existing urban storm water at the point of storm sewer discharge to a stream. Due to typical space constraints, these technologies are usually designed to provide water quality control rather than quantity control.

First Flush: The delivery of a disproportionately large load of pollutants during the early part of storms due to rapid runoff of accumulated pollutants. The first flush of runoff has been defined several ways (e.g., one-half inch per impervious acre).

Impervious cover cap: A mechanism which establishes a Maximum Sustainable Removal Rate for storm water control measures at 90%. The City of Austin, Texas has incorporated this concept into its Land Development Code. It is designed to avoid over-reliance on storm water control measures and recognizes their inherent limitations and risk of failure due to lack of maintenance.

Impervious surface: A hard surface area that either prevents or retards the entry of water into the soil mantle as under natural conditions prior to development and/or a hard surface area that causes water to run off the surface in greater quantities or at an increased rate of flow from the flow present under natural conditions prior to development. Common impervious surfaces include walkways, driveways, parking lots, concrete or asphalt paving, etc.

VOL 12 2 22022

R0055502

Municipal separate storm sewer systems: Any conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, manmade channels, or storm drains) that is owned or operated by the State or local government entity, is used for collecting or conveying storm water, and is not part of a publicly-owned treatment works (POTW).

NPDES: National Pollutant Discharge Elimination System, created by Section 402 of the Clean Water Act.

Post-development peak runoff: Maximum instantaneous rate of flow during a storm, after development is complete.

Retrofit: The creation or modification of an urban runoff management system in a previously developed area. This may include wet ponds, infiltration systems, wetland plantings and other BMP techniques for improving water quality. A retrofit can consist of the construction of a new BMP in a developed area, the enhancement of an older urban runoff management structure, or a combination of improvement and new construction.

Ultra-urban: Non-conventional BMPs that are particularly suited for use in highly urbanized areas; based on sand filter technology

Urban runoff: That portion of precipitation that does not naturally percolate into the ground or evaporate, but flows via overland flow.

Watershed: A drainage area or basin in which all land and water areas drain or flow toward a central collector such as a stream, river, or lake at a lower elevation. The land area that drains into a receiving waterbody.

Actions Speak LOUDER Than Legislation

Positive experiences provide direction for urban runoff management

Tom Mumley, Geoff Brosseau

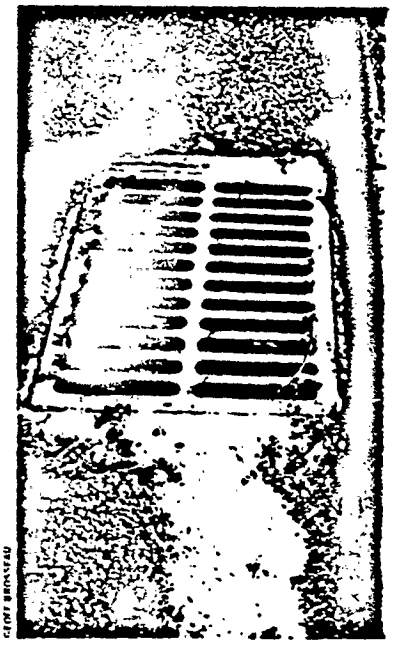
The current wrangling in the U.S. Congress over Clean Water Act (CWA) reauthorization and the potential for protracted debate over Coastal Zone Management Act (CZMA) reauthorization threaten to divert attention from pollution caused by urban runoff. The problem is too important to wait until legislators, lawyers, and technical experts find the perfect solution. While valuable research and discussion goes on, municipalities and states can establish successful programs to manage this complex process.

Three federal legislative initiatives exist to guide states in controlling urban runoff pollution: CWA Section 319, Coastal Zone Reauthorization Amendments of 1990 (CZARA) nonpoint program requirements, and CWA Section 402 stormwater permit requirements. All three initiatives rely on implementation of technically and economically effective best management practices or measures through a framework at the local level (see Table, *Legislation Covering Urban Runoff Pollution*).

CWA Section 319. States are required to prepare and implement nonpoint source management programs for their waters under CWA Section 319. These programs must identify best management practices (BMPs) and other measures to control individual nonpoint sources, such as urban runoff.

Most states have based their nonpoint source management programs on three general approaches: voluntary implementation of BMPs, regulatory-based encouragement, and direct regulation. Most programs rely primarily on voluntary mechanisms. Regulatory-based encouragement mechanisms, such as waiving the need for a permit if BMPs or management measures are implemented, are used sparingly, and direct regulation via permits are used even less frequently.

CZARA Section 6217. Section 6217 of CZARA requires states to restore and protect coastal waters by preparing a nonpoint source pollution control program. The act also required EPA to publish its guidance document, *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters* ((g) Guidance). The (g) Guidance defines management measures as "economically achievable measures for the control of pollutants...[that] reflect the greatest degree of pollutant reduction achievable through the application of the best available nonpoint pollution control practices," for each major source of pollution and identifies specific management practices for implementing them. The management measures are mandatory, the management practices are elective. One management measure mandates implementation of pollution prevention and education programs to reduce pollutants in urban runoff. Suggested management practices to achieve this measure include general public outreach, used oil and other material recycling programs, storm drain stenciling, and pollution prevention strategies for specific commercial businesses.



Eliminating illegal discharges is key to managing urban runoff pollution.

VOL 12 2 2207 F

R0055507

Legislation Covering Urban Runoff Pollution

	CWA[a] Section 319	CZARA[b] Section 6217	CWA Section 402
Levels of government	State and municipal	State and municipal	Federal, state, and municipal
General mandate	Nonpoint source management program	Coastal nonpoint pollution control program	Stormwater quality management programs
Method	Best management practices (BMPs) and management measures	Management measures and management practices	Management practices, control techniques, and system, design, and engineering methods
Goal	Reduce the level of pollution resulting from urban runoff to the maximum extent practicable	Restore and protect coastal waters through economically achievable measures for the control of pollutants from urban runoff	Reduce the discharge of pollutants from municipal separate storm sewer systems to the maximum extent practicable
Regulatory approach	Voluntary implementation of BMPs, regulatory-based encouragement, direct regulation	Enforceable policies and mechanisms (regulatory-based encouragement and direct regulation)	NPDES[c] permits (regulatory-based encouragement and direct regulation)

[a] *Clean Water Act*
[b] *Coastal Zone Act Reauthorization Amendments of 1990*
[c] *National Pollutant Discharge Elimination System*

CZARA also requires implementation of management measures through enforceable policies and mechanisms at the state, regional, or local level similar to the regulatory-based encouragement and direct regulation approaches of CWA Section 319. States also may consider economic incentives and disincentives or other innovative approaches. For example, if a nonpoint source is controlled voluntarily, an enforceable mechanism need not be imposed. Although the guidance includes management measures to control urban runoff, all stormwater discharges covered by the National Pollutant Discharge Elimination System (NPDES) stormwater permit program are excluded from coverage under Section 6217.

CWA Section 402. CWA Section 402 requires NPDES permits to be issued for large stormwater dischargers—industry and municipal separate storm sewers serving more than 100,000 people. Permits also may be issued on a case-by-case basis if EPA or a state determines that a smaller stormwater discharge contributes to a violation of a water quality standard or pollutes U.S. waters.

Section 402 mandates that discharge permits for municipal separate storm sewers include requirements for pollutant controls—management practices, control techniques, and system, design, and engineering methods. Aware of the difficulties in regulating discharges from municipal storm systems through traditional end-of-pipe treatment, Congress intended for EPA and delegated states to develop much broader permit requirements than those in wastewater permits.

Legislation and Regulatory Approaches

The legislative initiatives allow various approaches—voluntary, regulatory-based encouragement, or direct regulation—for urban runoff management. But how well does each work?

Voluntary implementation. If voluntary implementation alone worked, the country would not be facing environmental problems. The prevailing attitude toward the environment is often reluctance, even unwillingness, to do more than is required. Certainly, any legislative initiative should provide for voluntary actions, but to depend on it as the primary approach for reaching a goal is to ignore human nature.

Direct regulation. The use of direct regulation
- promotes consistency and accountability across programs and across the country,
- indicates that the problem is severe enough to warrant more of a command-and-control approach than a purely voluntary one,
- makes it easier for cities, counties, and businesses to commit limited resources to a program, and
- helps establish a baseline or default for considering regulatory-based encouragement approaches.

The use of direct regulation has the potential to cause problems, especially in dealing with stormwater discharges, if the approach is not

VOL 12 2 2208
R0055508

well implemented. Permitting of municipalities has a favorable track record in places like the San Francisco Bay area, where its implementation has included flexible requirements that are practical, constructive, and effective.

Regulatory incentives. Regulatory incentive uses the best of the voluntary and regulatory approaches to create a balanced, cooperative arrangement in which positive actions are encouraged and rewarded and negative actions are discouraged and punished. Although some might view it as forced volunteerism, this interpretation sells the approach far short of its potential.

Like direct regulation, regulatory incentive has been used by regulators and municipalities to create some of the most successful urban runoff management programs.

Beyond Legislative Initiatives

Which initiative—CWA, CZARA, or some hybrid—leads to the most effective and efficient urban runoff management programs possible?

Success has been determined more by the willingness of local individuals to work together than by the specific initiative. Where local individuals have taken charge of their programs, urban runoff management has been successful. Where local individuals have resisted, problems have occurred with all the initiatives.

Setting up a well-organized, flexible management program at the local level is essential to controlling urban runoff pollution. The key challenge is to focus appropriate management actions on the most important sources. Two factors make this difficult: lack of complete data on water quality problems and pollutant sources, and the competition for limited resources between problem identification and pollution control.

A good management program includes a decision-making process that enables appropriate early actions while new information is being gathered. The framework of the program must be flexible enough to allow managers to improve problem identification and phase in additional actions, as necessary.

The following program elements are integral to establishing the framework of an urban runoff management program.

Program management. Successful management programs require involvement and coordination of numerous local government entities. For this coordination to succeed, it must follow defined procedures for decision making. Making joint decisions also requires defining roles and responsibilities for a wide range of agencies, (such as city, county, and flood management), departments (such as, public works and planning), and individuals; coordinating procedures among participating agencies and departments; and demonstrating legal authority and adequate fiscal resources.

Public information and participation. Public education is essential for a successful and cost-effective management program. General nonpoint source education, specific education programs focused on individual pollution sources and activities, and opportunities for public involvement are important components.

Illicit discharge elimination and prevention. A focus on illicit connections and illegal dumping, the most obvious and crucial sources of pollutants in urban runoff, is a key component of a management program. The program must identify pollution sources, prevention or control measures, public education initiatives, system surveillance, and, if necessary, enforcement procedures. Program managers must decide whether discharges are insignificant discharges from fixed or mobile sources, discharges that might be acceptable if authorized and managed in accordance with a permit, or those that must be prohibited. Coordinating discharge control measures with municipal wastewater agencies may be necessary.

Flo the Racoon, the official mascot of the storm drain program in Palo Alto, Calif., helps build community involvement.

Industrial and commercial sources. A management program also must identify industrial and commercial categories of urban runoff pol-

R0055509

VOL 12 2 2009

lution. The significance of industrial or commercial sources depends on the characteristics of a municipality and its oversight of such sources. After identifying local sources, municipalities should develop appropriate management strategies such as outreach and inspection programs. Coordination with other outreach, inspection, and regulatory programs also is essential to avoid redundant or conflicting actions and to avoid unnecessary focus on clean businesses.

New development and redevelopment. Cities in the process of development or redevelopment can use a full range of treatment and source control measures. The significance of this action area depends on its characteristics, development or redevelopment potential, and existing planning and permitting procedures. Control measures can be instituted at any stage—from site planning and design, through ground breaking and construction, to facility and property management.

Public agency activities. Many public agencies already have programs that benefit water quality. Among the activities that can benefit an urban runoff pollution program are improved storm drain system design, operation, and maintenance; flood management activities; operation and maintenance of streets and roads; and management of public facilities, such as maintenance yards, parks and recreational facilities, parking facilities, schools, hospitals, and other institutions.

Program evaluation. The effectiveness and efficiency of an urban runoff program must be documented. Specific activities include monitoring, such as identifying municipality and watershed characteristics or initiating pilot studies, documenting actions, and reporting activities to program decision makers, the public, and state and federal agencies.

Most successful urban runoff management programs have incorporated a sound decision-making and management framework that includes all these elements. Successful programs also have common attributes that go beyond this framework. Each of the following attributes, taken alone, may not ensure a program's success, but taken together, they make success much more likely.

Comprehensive scope. An effective program must weigh the significance of a wide range of real or potential problems, sources, activities, and actions. Cost-effective and efficient actions in one program area often depend on coordination with other activities. If the scope of a program is limited, actions taken within its framework may have a negative impact on another area.

Watershed approach. Urban runoff water quality problems are caused by the cumulative effects of many varied sources. Urban runoff management programs are essentially watershed management programs. Inherent to the concept of watershed management are stakeholder involvement, water quality assessment, problem identification, and a well-defined plan of action to correct problems. A watershed-based approach embraces communication, collaboration, and coordination among municipalities within the watershed. By using this approach, municipalities are able to focus resources when and where they will achieve the greatest benefit.

Consensus-based partnerships. Agreements and institutional arrangements within or between agencies are more easily established in a cooperative, consensus-based atmosphere. No entity is capable of assuming all responsibilities of a urban runoff management program. Program success also depends on the cooperation and support of affected sources—the public, businesses, and other agencies.

Phased approach and continuous improvement. Urban runoff management programs evolve and mature over time to reflect changing conditions. Successful programs are based on continuous evaluation and improvement. Actions that have certain and cost-effective benefits are implemented first; actions with less certain applicability and benefits are implemented on a reduced level or pilot scale to evaluate their effectiveness.

Local leadership. Local leadership is essential for a successful program. Key individuals at the local level either can make a program work or stand in its way.

Whatever direction or legislative initiative Congress and President Clinton finally select should promote these common attributes of successful programs and encourage the use of a consistent, comprehensive management framework. Specific initiatives should provide for a variety of approaches, because urban runoff is highly variable, as are watersheds. What may work in one situation or locale will not work everywhere. Legislation and regulations alone cannot ensure success. Success depends on the people and the approaches taken in translating legislation and regulations into programs and progress.

Tom Mumley is the urban runoff program manager at the San Francisco Bay Regional Water Quality Control Board, and ***Geoff Brosseau*** *is executive director of the Bay Area Stormwater Management Agencies Association in Oakland, Calif.*

Editor's Note

Many thanks to those of you who reviewed and commented on the previous drafts of the manual. Much of the continued improvement of the manual has been, and will continue to be, the result of reviewers' comments and constructive criticisms.

The final version of the manual has been prepared following review of the June, 1991 "Public Review Draft" that was distributed to some 900 reviewers last summer. Technical workshops were held in Everett, Bellevue, Tacoma, and Olympia during August and September, 1991. Written comments were received from 55 reviewers.

Changes in the Puget Sound Stormwater Management Program

The Puget Sound Stormwater Management Program mandated by the Puget Sound Water Quality Management Plan (PSWQMP) has changed substantially since the release of the 1991 draft manual. There are no longer two "companion" rules. The language requiring the adoption of local stormwater management programs has been placed in the PSWQMP instead of being contained in rule form.

The Puget Sound Water Quality Management Plan states that local stormwater management programs are to be consistent with the Plan, as well as Ecology's guidance, model ordinances and Stormwater Management Manual. Ecology is to monitor compliance with the Plan requirements, reviewing the status of each local program every two years. Information on implementation schedules and procedures for reviewing local programs are provided in the "Stormwater Program Guidance Manual for the Puget Sound Basin" (hereafter referred to as the Guidance Manual), a companion to this manual. Copies of either this manual or the Guidance Manual can be obtained by calling (206) 438-7116 or (206) 438-7059. The cost is not known for certain as we go to press, but should be approximately $40.00 (U.S.) for either manual. Do not send us funds, as a bill will be sent with the manual.

Changes Made to the Manual

Changes were made to the 1991 draft manual based both on new information available and comments received. Some things didn't change: for example, we are still emphasizing the use of infiltration where appropriate. A reduced release rate of 50% of the pre-developed discharge rate has been retained for streambank erosion control. The correction factors have been kept but they are only necessary for streambank erosion control BMPs. The 7-day design storm has not been incorporated at this time. Further hydrologic modelling and analysis is planned for this year with the goal of providing more accurate and easy-to-use methods (see "Unfinished Business", below).

Volume IV

- Information on golf courses has been included.
- Street sweeping has been added as a BMP.

Status Reports

Detailed information on NPDES, the Sediment Standards, the relationship of BMPs to the water quality standards, and information on program requirements can be found in the Guidance Manual. Included below are some other status reports.

Training and Technical Assistance

In July, 1992 we will be conducting our first workshops for local government staff. These day-long workshops will be sited throughout the basin and provide an overview of Ecology's stormwater management program. Based on input received at these workshops, we will develop other training sessions.

Eventually we will be providing a wide range of training and technical assistance to both local government staff and others. As a start, funds have been committed to the Center for Urban Water Resources Management at the University of Washington for three different tasks. The first is to continue their popular on-site visits to local jurisdictions. The second task will be to develop a half day (approximate) course on erosion and sediment control which would be appropriate for construction site personnel. The course would then be taped and distributed. The third task is to implement a "hotline" for local government personnel questions. This task would also include cataloging the information that the Center now has available, and includes funding for some applied research. We hope to continue some form of this funding from year to year.

We also anticipate developing a videotape of approved erosion and sediment control BMPs.

Vactor Waste Disposal Issues

We recognize that the lack of accepted procedures and locations for the disposal of waste from maintenance activities is one of the greatest problems confronting stormwater operation and maintenance programs. Disposal of the liquid and solid waste material from vactor trucks and other maintenance operations is a concern because of the potential to contaminate surface or ground water. Some existing disposal practices may violate dangerous waste regulations, or otherwise be harmful to the environment.

In order for Ecology to develop guidelines that address appropriate disposal practices, more information is needed on the nature of vactor wastes. In response to this data gap, two grants from EPA have been used to collect and analyze vactor waste samples. Final results of the sampling will be available in September, 1992.

We will be using the sampling results and other available data to develop disposal options. At this time it is not known if disposal procedures will be issued as guidelines or a rule (regulation).

2

2216

R0055514

New Development/Redevelopment

- The threshold for land disturbing activities between small parcels and large parcels has been increased to 1 acre (page I-2-2).
- The size threshold of 11.5% for redevelopment sites greater than 1 acre in size was dropped. 5,000 square feet is used as the trigger, regardless of the size of the development (page I-2-4).
- A "documented water quality problem" is now defined (page I-2-4).

Minimum Requirements

- Many editorial changes were made to better clarify the content and rationale for the Minimum Requirements. The modifiers "General" and "Special" for Minimum Requirements were dropped, and the requirements arranged in a more logical order. Objectives were added for each Minimum Requirement.
- The Erosion and Sediment Control "General Criteria" were moved from Chapter II-4 to Chapter I-2, and consolidated as Minimum Requirement #1, Erosion and Sediment Control.
- The off-site analysis requirement (now Minimum Requirement #8, Off-site Analysis and Mitigation) was simplified.
- The ability to use an implemented and adopted basin plan to modify the Minimum Requirements was included (see Minimum Requirement #9, Basin Planning).

Remainder of Chapter I-2

- More specific information and two examples of experimental BMPs have been provided.

Chapter I-3

- A Small Parcel BMP checklist which can be used "as-is" or modified by the local government has been added. Completion of this checklist can be considered to have met the Small Parcel Erosion and Sediment Control Requirements.
- Large parcels require the development of a "Stormwater Site Plan" which is in turn made up of a Large Parcel Erosion Control Plan (LPESC) and a Permanent Stormwater Quality Control Plan (PSQC). The LPESC addresses erosion and sediment control during the construction phase, and the PSQC plan addresses permanent stormwater management facilities.

Chapter I-4

- The BMP selection process has been revised to more clearly define the type of pollution problem that a BMP is targeted to control. The problem may be water quality (WQ), which addresses either nutrients or conventional pollutants, streambank erosion control (SBEC), source control or, as is most likely, a combination of these types.

VOL 12 2 2217

R0055515

Ecology's Solid and Hazardous Waste program is currently working on revisions to Ch. 173-304 WAC, the minimum functional standards for solid waste facilities. These revisions may be an appropriate mechanism for addressing vactor waste. Contaminated soils have been identified as one of five issues that are to be addressed in the proposed revisions, and vactor waste will be looked at as part of this issue. The proposed process for these revisions is to collect information this summer, publish a draft EIS with draft rule language in December of 1992, a final EIS in April of 1993, and adopt final rules in September of 1993.

We intend to prepare a supplemental guidance paper on disposal procedures when we have enough information to begin to answer key questions about the characteristics of these materials.

SEPA Checklist and DNS

A SEPA checklist was filled out for the Stormwater Management Manual as it was determined that the manual was subject to SEPA review as a non-project action. The DNS was published in the March 16-20, 1992 SEPA Register. There was no comment period required.

Status of the WSDOT Manual

WSDOT is required to develop their Highway Runoff Manual within 6 months after this manual is published. Roads and right-of-way issues will be addressed in this manual, and we anticipate that local governments will also be able to make use of this information.

Technical Advisory Committee

The technical advisory groups (TAGs) that were originally constituted by Ecology need to be reconstituted. We anticipate developing those TAGs into a standing advisory committee to review experimental BMPs in consultation with Ecology and provide review of the many technical questions still on our agenda. We expect to reformulate this committee later this year as part of the manual update process.

Unfinished Business

In a field as complex and rapidly changing as stormwater management, there will always be "unfinished business". The PSWQMP requires that the manual be updated yearly. Based on the progress of some ongoing research projects, we anticipate that the next version of the manual will include the results of the HSPF runoff files research done at the University of Washington.

Other additions we hope to make are the use of the 7-day storm for streambank erosion control, and the inclusion of more detailed isopluvial maps for the entire Puget Sound basin.

We still do not have a definitive answer as to the cost of implementing these new procedures. We have funds available for development of a document similar to a Small Business Economic Impact Statement (SBEIS), and hope to have this complete within the next year. Related to the economic question as a whole is whether or not the cost is relatively higher for small commercial sites than for larger sites. This is one of the major problems we hope to address with the SBEIS.

VOL 12 2 2218

R0055516

Because of problems with the use of small (less than 1 inch) orifice sizes, runoff from small commercial developments cannot now be adequately controlled through the use of wet ponds. There is no easy solution to this problem, and we hope that local governments will work together with developers to develop and implement alternatives to site-specific wet ponds in the future.

Lastly, we hope to be able to desktop publish the manual in order to make it more user friendly than it currently is. In time, we may also have both a "pocket" version of the manual and a computerized version available.

FOREWORD

For years stormwater management has meant controlling water quantity. Increased runoff is directly related to an increase in impervious surfaces (roads, parking lots and rooftops) which prevent runoff from soaking into the ground.

Today we recognize that stormwater runoff also contributes to water quality degradation. Stormwater carries excessive amounts of sediment from exposed construction sites, and other pollutants which wash off streets and parking lots, industrial sites and residential lawns and gardens. These pollutants include oil and grease, pesticides and fertilizers, harmful bacteria and metals such as lead, cadmium and copper.

What is the State Doing About Urban Stormwater?

In response to stormwater quality problems, the Puget Sound Water Quality Management Plan directed Ecology to:

- Develop guidance consisting of program implementation guidance for local governments including model ordinances;
- Develop a technical manual addressing erosion and sediment control, runoff control and control of pollution from urban land uses; and
- Work with the Washington State Department of Transportation (WSDOT) on a program to control runoff from state highways in the Puget Sound basin.

This manual, which is essentially a stormwater Best Management Practices (BMP) manual, has been developed in response to the above requirements. It is intended for use by local governments, tribes, and WSDOT in the Puget Sound basin (see Figure 1). A more complete description of Ecology's program is found in Chapter I-1.

Acknowledgements

This manual could never have been completed without the contributions of many local government public works and planning officials, representatives from other state agencies, and other affected and interested parties including industries and tribes. Their insights and practical knowledge gained from years of experience in the field have been particularly valuable. In addition, their useful comments and thorough review of earlier drafts improved the quality and utility of the manual.

We would also like to thank the Puget Sound Water Quality Authority for their successful endeavors to obtain support and funding for stormwater as an element of the Puget Sound Water Quality Management Plan. In particular, we would like to thank Vallana Piccolo who has diligently attended technical advisory group meetings and provided helpful review throughout the manual development process.

R0055529

Members of each of the three technical advisory groups are acknowledged in the appropriate volume of the manual. In addition, we would like to express our appreciation to the following persons, all of whom contributed extensively to the manual.

Randall Parsons (now in another position with King County), as Senior Engineer with the King County Storm and Surface Water Division, was responsible for developing the King County Surface Water Design Manual which formed the basis for much of the information contained in thie manual.

Dr. Gary Minton, of Resource Planning Associates, was the principal author of Volume IV - Urban Land Use BMPs, and thus made a substantial contribution to the development of this manual.

Dr. Richard Horner, director of the Center for Urban Water Resources Management at the University of Washington, provided the basis for the biofiltration chapter in Volume III. Together with the Puget Sound Wetlands and Stormwater Research Committee, he authored the guidance for the management of natural wetlands found in the same volume.

Thomas Schueler, author of the Urban Land Uses BMP Manual published by the Metropolitan Washington (D.C.) Council of Governments graciously consented to the use of some illustrations and text from that manual.

All other references are noted as they occur in the manual and are listed at the end of each chapter.

We are particularly grateful to the other members of Ecology's Urban Nonpoint Management Unit: Gerald Anderson (now with Ecology's Southwest Regional Office), Ann Wessel, Melany Lee, Gary Kruger, Gary Cooper, Kim Van Zwalenburg (now with Ecology's Shoreland Program), Heather Saunders (now with Thurston County) and many other Ecology staff members for their help and suggestions during the development of this manual.

We would like to apologize in advance for any errors of omission or commission; while all due diligence has been exercised, inevitably errors creep in to a work of this size and complexity. Any questions or further comments regarding the manual should be directed to either Helen Pressley (206) 438-7089 or Pat Hartigan (206) 493-9454.

Peter B. Birch, Ph.D, Helen E. Pressley and Patrick D. Hartigan

CHAPTER I-1

INTRODUCTION

I-1.1 EFFECTS OF URBANIZATION

The pre-settlement Puget Sound basin was primarily forested in alder, maple, fir, hemlock and cedar. The area's bountiful rainfall supported the forest and the many creeks, springs, ponds, lakes and wetlands. The forest system provided protection by intercepting rainfall in the canopy, reducing the possibility of erosion and the deposition of sediment in waterways. The trees and the forest duff layer absorbed large amounts of runoff releasing it slowly to the streams through interflow in the soil.

As settlement occurred and the population grew, trees were logged and land was cleared for buildings, parking lots and pasture. Roads were cut through slopes, and low spots, often wetlands, were filled. Drainage patterns were irrevocably altered.

Once areas are cleared, the increase in compacted and impervious surfaces in turn increases both the volume of surface runoff, the peak rate of flow, and decreased ground water recharge. Runoff that was previously slowly released to streams through interflow now runs quickly off the surface directly into the streams. This increases both the velocity and total quantity of flow causing streambank erosion and general habitat destruction. Sediment from increasingly eroded and unstable streambanks and cleared areas is deposited downstream filling ponds, streambeds and stormwater facilities. An additional consequence is that summer base flows are greatly reduced because of a lack of interflow.

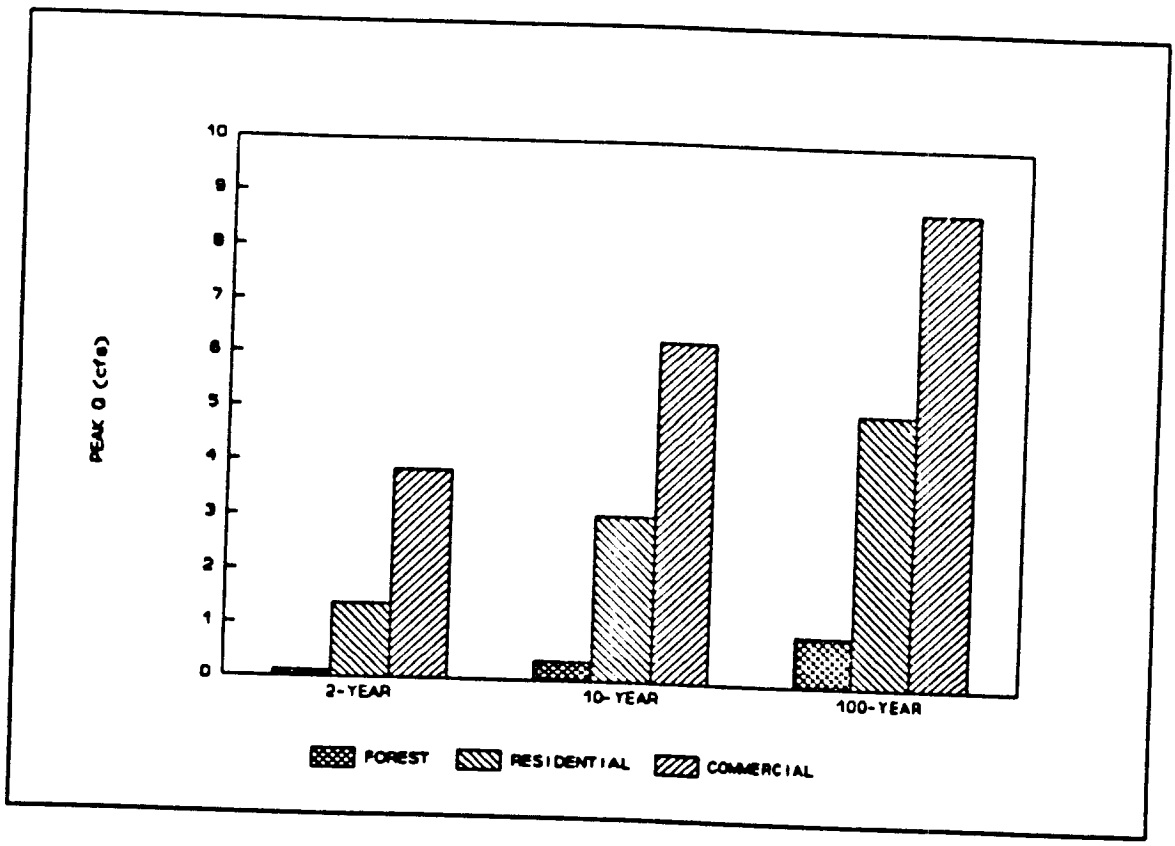
Runoff from urban areas has been shown to contain many different types of pollutants, depending on the nature of the activities in those areas. The runoff from roads and highways is contaminated with oil and grease, lead, cadmium and other pollutants. Uncontrolled runoff from industrial areas can contain PCBs, heavy metals, high pH concrete dust, and many other toxic chemicals. Residential areas contribute herbicides, pesticides, fertilizers and animal waste to runoff. All of these contaminants can seriously impair beneficial uses of receiving waters.

Aquatic life is greatly affected by urbanization within an ecosystem. Habitats are drastically altered when a stream changes its configuration and deposits its sediment load in response to urbanization. Natural riffles, pools, gravel bars and other areas are altered or destroyed. Spawning areas, particularly those of salmonids, are lost. Urbanization also tends to cause an increase in water temperature as vegetation which shades the water is removed. A rise in water temperature may cause algal blooms which reduces the amount of dissolved oxygen in the water. The lack of dissolved oxygen can cause fish and other aquatic organisms to die. When a species' habitat requirements are not met they either move elsewhere or die off, and other species, often exotic and undesirable, move in to take their place.

While the impacts of urbanization can be readily conceptualized, the magnitude of the problem may not be generally realized. This can be illustrated by looking at the hydrologic regime and the pollutant loads of different land use types. Figure I-1.1 illustrates the former by showing the increases in peak flow rates resulting from the conversion of forest land to residential and commercial development. The changes in flow rates and hydrologic regimes can cause severe erosion of streambanks and severely degrade aquatic habitat. Figure I-1.2 illustrates the change in the pollutant load (the product of runoff volume and pollutant concentration) of total phosphorus for different land uses as compared to pre-development conditions. It is not unusual for loads to increase by several hundred to several thousand percent

R0055536

FIGURE I-1.1[1]
PEAK RUNOFF FLOW RATES FOR DIFFERENT LAND USES
FOR THE 2, 10, AND 100-YEAR, 24-HOUR DESIGN STORM EVENTS



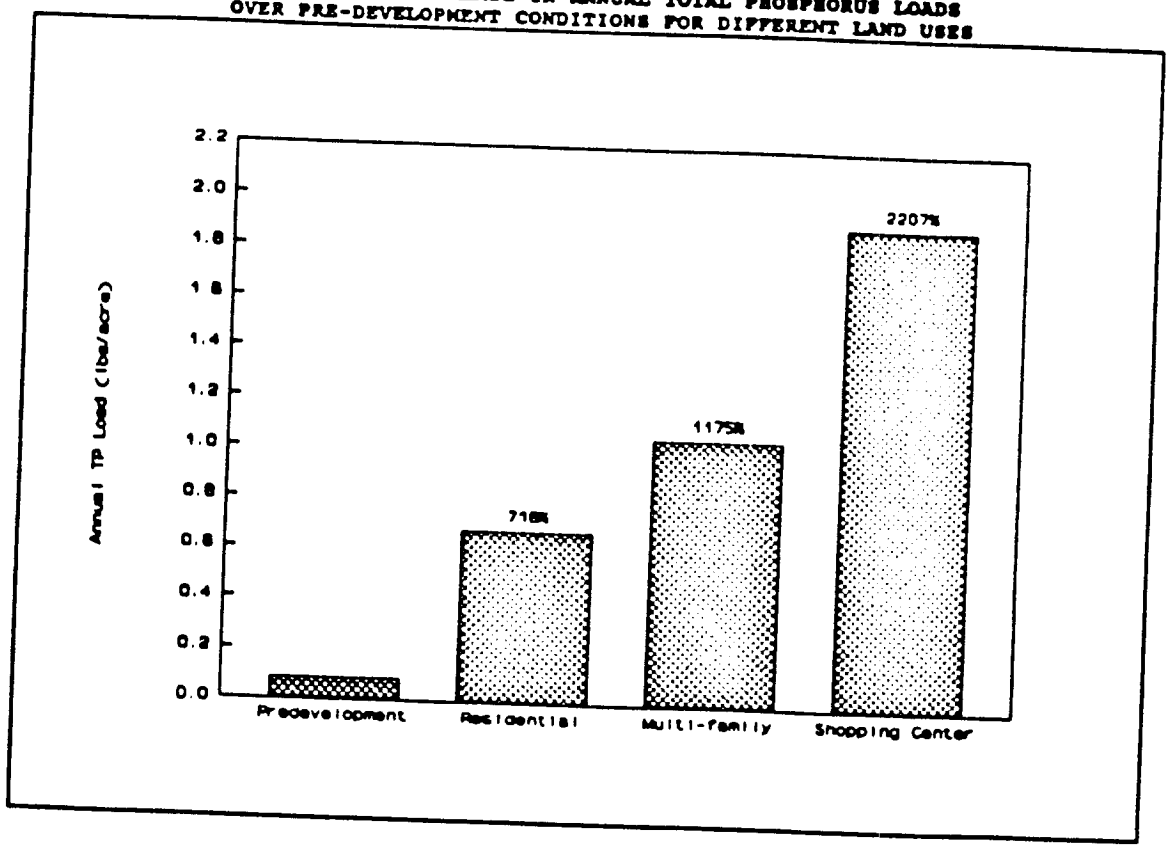
over pre-development conditions. Thus, two primary objectives of stormwater management programs need to be the control of runoff flows and the reduction of pollutant loads.

It can be difficult to quantify cause-and-effect relationships when evaluating changes in hydrologic regimes and pollutant loads caused by urbanization. Experiences locally and elsewhere have shown, however, that urbanization can be a significant cause of pollution problems with both short-term and long-term impacts prevailing. Short term changes in water quality can restrict contact recreation, stress aquatic organisms, and damage shellfish beds. Long-term impacts on stream morphology often occur when urbanization changes natural hydrologic conditions. The long-term accumulation of pollutants into receiving waters can also create problems which can be particularly difficult to correct, such as eutrophication, polluted groundwater, and contaminated sediments.

VOL 12 2 2239

R0055537

FIGURE I-1.2[2]
HYPOTHETICAL INCREASE IN ANNUAL TOTAL PHOSPHORUS LOADS
OVER PRE-DEVELOPMENT CONDITIONS FOR DIFFERENT LAND USES



While urbanization has already significantly impacted water resources in the Northwest, there are many opportunities to control future impacts as well as reduce existing ones. As better policies and improved control strategies are developed the effects of urbanization should be slowed and eventually controlled to the extent that beneficial uses that have been lost are restored. One potentially significant change on the horizon is an increased emphasis in managing stormwater as a resource. As human population growth continues stormwater may be used increasingly to augment water supplies, recharge aquifers, improve fisheries, and provide public recreation.

I-1.2 DEVELOPMENT OF BEST MANAGEMENT PRACTICES (BMPS) TO IMPROVE WATER QUALITY

Best Management Practices are defined as physical, structural, and/or managerial practices that, when used singly, or in combination, prevent or reduce pollution of water. The types of BMPs are source control, runoff treatment, and streambank erosion control. Source control BMPs, as the term implies, aim to prevent pollution, or other adverse effects of stormwater, from occurring. Examples of

VOL 12 2 2 2 4 0
R0055538

source control BMPs include methods as various as using mulches and covers on disturbed soil, putting roofs over outside storage areas, tracking down and eliminating illicit connections to storm drains. Runoff treatment BMPs include facilities that remove pollutants by simple gravity settling of particulate pollutants, filtration, biological uptake, and soil adsorption. Streambank erosion control BMPs typically control the rate, frequency, and flow duration of stormwater runoff releases. Examples of runoff treatment and streambank erosion control BMPs detention ponds, biofiltration swales, infiltration trenches, and dry vaults.

The primary purpose of using BMPs is to protect beneficial uses of water resources through the reduction of pollutant loads and concentrations, and by reducing streambank erosion and protecting stream habitat in general. If it is found that, after the implementation of BMPs, beneficial uses are still threatened or impaired, then additional controls may be required.

Stormwater management programs should keep in mind that it is generally more cost effective to prevent impacts using source control than using runoff treatment to remove pollutants. However, since source controls cannot prevent all impacts, some combination of measures will always be needed. The need to provide streambank erosion control BMPs depends on whether a development site discharges to a stream system, either directly or indirectly.

Runoff treatment BMPs can accomplish impressive levels of pollutant load reductions if properly designed and maintained. However, the increase in pollutant loads from urban areas is typically so large that, even with the use of BMPs, it is unlikely they will be reduced to levels approximating pre-development conditions. Figure I-1.3 illustrates this by presenting a typical pre-development pollutant load and comparing it with loads from a multi-family (MF) development. With no controls, the urban load increases nearly 1200 percent above the pre-development level. The figure illustrates the loads which theoretically would result if BMPs were applied with removal efficiencies of 50, 75, and 90 percent, respectively (the latter an extremely high level which may not be generally attainable, though infiltration can achieve this). As can be seen, even at high levels of treatment, substantial increases over pre-development levels occur, e.g., with a 75 percent removal efficiency the load is over 200 percent higher than the pre-development load. While using pre-development conditions as a basis of comparison may not be always justified, it does offer insight into the potential impacts of urbanization.

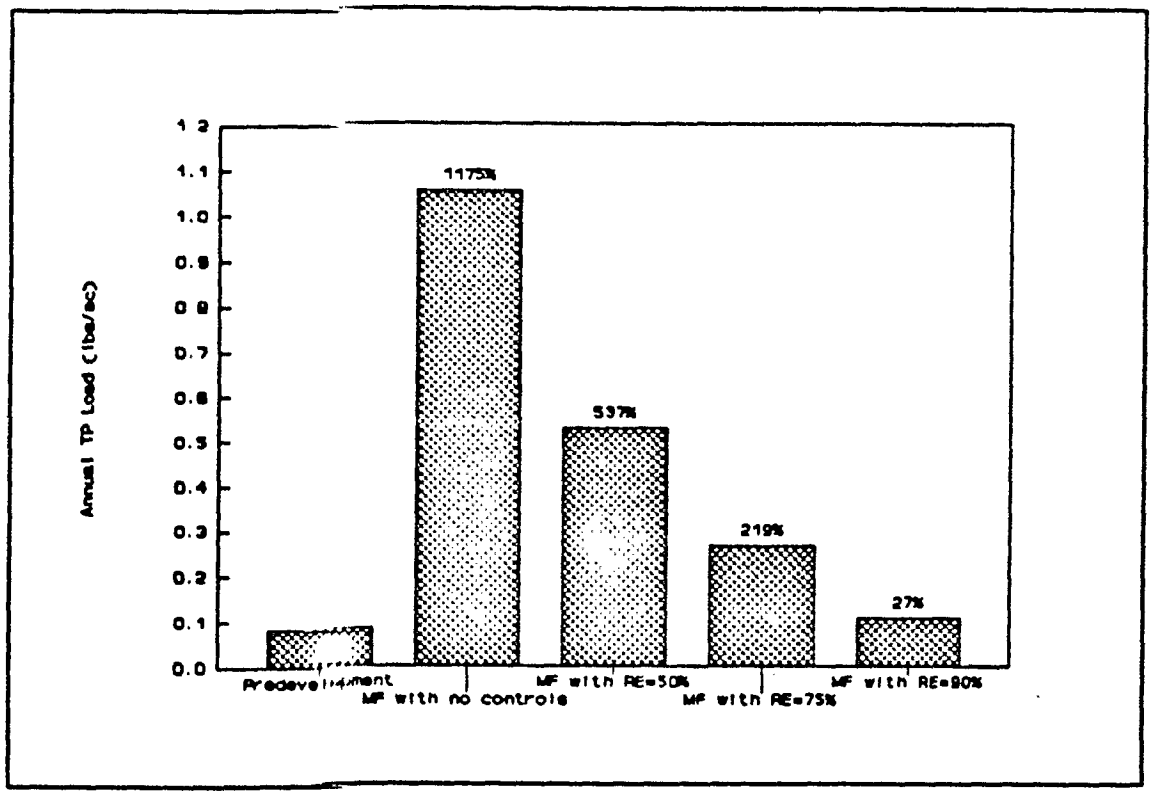
Streambank erosion control can be accomplished by BMPs which detain runoff flows and also by those which physically stabilize eroding streambanks. Both types of measures may be necessary in urban watersheds. BMPs which detain runoff can reduce peak flow rates to near pre-development conditions and are to be designed attempt to replicate the natural hydrologic regime. The need to control streambank erosion is gaining widespread attention as it is often the single largest source of sedimentation within a watershed and is a major factor contributing to the destruction of aquatic habitat.

Streambank erosion is largely due to increases in bankfull flow conditions which occur in urban watersheds. In undisturbed watersheds the bankfull condition generally occurs only about once in every two years on average. In urbanized watersheds both the frequency and duration of the bankfull condition can increase many fold, because of the effect of impervious surfaces on surface runoff. Bankfull conditions are a highly erosive state and, as the frequency and duration of their occurrence increases, the greater the amount of erosion results. While it may be impossible to totally recreate the frequency and duration of the pre-development bankfull condition, BMPs should be designed with that as an objective. Conventional detention practices which control peak flow rates from large, infrequent storms for flood control purposes are only partially effective at reducing the frequency and duration of bankfull flow conditions. One particularly effective practice which is

VOL 12 2 2241

R0055539

FIGURE I-1.3[1]
HYPOTHETICAL INCREASE IN ANNUAL POLLUTANT LOADS FOR A MULTI FAMILY DEVELOPMENT OVER PRE-DEVELOPMENT CONDITIONS UNDER VARIOUS CONTROL SCENARIOS



RE = Annual Removal Efficiency

gaining attention is infiltration, because of it's ability to decrease both peak rates and volumes, and increase summer stream baseflows. If infiltration is not feasible the alternative is large detention ponds that store runoff and release it at a very slow rate to minimize erosion and habitat destruction in general.

In summary, it is clear that treatment BMPs alone cannot normally be expected to solve all water quality problems caused by stormwater runoff. They must be complemented with source controls. The effectiveness of comprehensively implemented BMP programs have yet to be demonstrated. Many doubt their effectiveness. However, given the large number of measures now available (and new ideas that are being generated) future results may be surprising. The key will be the correct balance between education and enforcement for source control, and proper design and operation and maintenance for treatment.

VOL 12 2 2242

R0055540

I-1.3 ECOLOGY'S STORMWATER PROGRAM

The 1991 Puget Sound Water Quality Management Plan requirements form the foundation of the stormwater program developed by the Department of Ecology. The Plan was first adopted in 1987, updated in 1989, and again in 1990, 1991 and 1992. The Plan and Ecology's stormwater programs apply to the cities and counties, and WSDOT, in the Puget Sound basin. What follows is a summary of the major elements of the Plan requirements.

I-1.3.1 Local Stormwater Program

Basic Stormwater Program for All Counties and Cities

The 1992 revisions to the PSWQMP changed the implementation of Ecology's program from a rules-based program to one implemented through language contained in the Plan. RCW 90.70.070(1) states "In conducting planning, regulatory, and appeals actions, the state agencies and local governments identified in the plan must evaluate, and incorporate as applicable, subject to the availability of appropriated funds or other funding sources, the provisions of the plan, including any guidelines, standards, and timetables contained in the plan."

The 1992 Plan language calls for all jurisdictions in Puget Sound to adopt a basic stormwater program (Plan element SW-1). Densely populated urbanized areas in the Sound are to implement additional requirements for comprehensive urban stormwater programs, and, in accordance with EPA regulations, meet the requirements of municipal stormwater NPDES permits (Plan element SW-2). Supplemental guidance, including model ordinances, and this technical manual are being prepared to describe how local governments can implement their stormwater programs and meet the requirements of the rules.

The Plan requires all 111 local jurisdictions to implement stormwater management programs which include:

- Ordinances for all new development and redevelopment which address control of off-site water quality, the use of source control BMPs, the effective treatment of the water quality design storm, the use of infiltration where appropriate, the protection of stream channels and wetlands, and erosion and sediment control.
- Operation and maintenance programs for new and existing public and private stormwater systems.
- Record keeping of new public and private drainage systems and facilities.
- Adoption of either Ecology's technical manual or a manual with substantially equivalent technical standards.
- Education programs to educate citizens about stormwater and its effects on water quality, flooding, and fish/wildlife habitat, and to discourage illicit dumping into storm drains.
- Coordination with provisions of the Growth Management Act, where appropriate.
- Basin planning.

Proposed schedule:

All cities and counties will be required to adopt ordinances and a technical manual that is "substantially equivalent" to this manual, and meet operation and maintenance requirements by July 1, 1994.

Comprehensive Stormwater Programs for Urban Areas

The Plan also sets standards and procedures for comprehensive stormwater programs

VOL 1 2 2 2 2 4 3

R0055541

that will be implemented by all urbanized areas. This program is in addition to the requirements of the basic stormwater programs described above.

Urbanized areas will be identified by the U.S. Bureau of Census definition.

These programs will address runoff from new and existing industrial, commercial, public facilities and residential areas, including streets and roads.

At minimum, each urban stormwater program shall include:

- Identification and ranking of potentially significant pollutant sources and their relationship to the drainage system and water bodies through an ongoing assessment program.
- Investigations and corrective actions of problem storm drains, including sampling.
- Programs for operation and maintenance of storm drains, detention systems, ditches, and culverts.
- A water quality response program, to investigate sources of pollutants, spills, fish kills, illegal hookups, dumping, and other water quality problems. These investigations should be used to support compliance/enforcement efforts.
- Assurance of adequate local funding for the stormwater program through surface water utilities, sewer charges, fees, or other revenue-generating sources.
- Local coordination arrangements such as interlocal agreements, joint programs, consistent standards, or regional boards or committees.
- Ordinances requiring implementation of stormwater controls for new development and redevelopment.
- A stormwater public education program aimed at residents, businesses, and industries in the urban area.
- Inspection, compliance, and enforcement measures.
- An implementation schedule.
- If, after implementation of the control measures listed above, there are still discharges that cause significant environmental problems, retrofitting of existing development and/or other water quality controls of discharges from new and existing development may be required.

Schedule:

Ecology shall review municipal NPDES Part 1 and 2 applications on the schedule established by EPA. Ecology shall write and issue individual NPDES permits on the following schedule: November 1993 for large municipalities; and May 1994 for medium municipalities. All urbanized areas shall implement programs by the year 2000.

I-1.3.2 Technical Manual and Guidance

This manual is part of the guidance package being developed by Ecology. Along with this manual, supplemental guidance will be provided to assist local governments in implementing their stormwater management programs. Examples include:

- Guidance on stormwater utility formation
- An example Erosion and Sediment Control Plan
- Model ordinances
- Guidance for an education program
- NPDES stormwater permit guidance
- Maintenance program guidance
- Guidance on developing a manual that is "substantially equivalent" to Ecology's manual

VOL 12 2 2244

R0055542

This guidance is currently in draft form and will be released at approximately the same time that this version of the manual is released.

I-1.3.3 Puget Sound Highway Runoff Program

Ecology has worked with the Washington State Department of Transportation (WSDOT) to adopt a rule and develop a program to control the quality of runoff from state highways in the Puget Sound basin. WSDOT will:

- Adopt a Highway Runoff Manual equivalent to Ecology's technical manual to use as guidance for managing highway runoff
- Adopt a vegetation management program
- Include BMPs a part of new construction projects
- Inventory and retrofit existing state highways with water quality BMPs where practicable
- Monitor where applicable
- Submit biennial reports to Ecology

Public workshops were held on the draft rule in January 1990, at Port Townsend, Everett and Tacoma, and meetings were held with the tribes. Public hearings were held in Bremerton on March 13, in Everett on March 14, and in Tacoma on March 15, 1991.

Schedule:

The Highway program was signed May 21, 1991 and became effective on June 21,1991.

I-1.4 DEVELOPMENT OF THIS MANUAL

The Puget Sound Water Quality Authority (PSWQA) recognized the need for overall guidance for stormwater quality improvement, and incorporated requirements to implement a cohesive, integrated approach in the Puget Sound Water Quality Management Plan (PSWQMP or Plan). This technical manual, as mentioned above, has been developed in response to one of the plan's stormwater elements (SW-3.1). It emphasizes source control BMPs as the first and most cost effective method of eliminating or reducing pollution of stormwater. Source control BMPs are the more desirable method of controlling pollution and reducing erosion than are treatment BMPs because once sediment or pollutants enter runoff it is considerably more difficult and expensive to remove them. Treatment BMPs should only be used as a second line of defense to remove pollutants that could not be controlled by source control BMPs.

A primary purpose of this manual is to set out the Minimum Requirements and provide guidance on how to prepare and implement stormwater site plans. These plans are required for new development and redevelopment on both large subdivisions and small parcels, and must meet all of the applicable Minimum Requirements contained in Chapter I-2. These requirements are, in turn, satisfied by the application of BMPs. In doing so the plans will address the impacts of new development and redevelopment on stormwater runoff, and to the maximum extent practicable, mitigate deleterious effects.

The stormwater site plans developed by using this manual are not a substitute for an adopted and implemented comprehensive basin plan. Knowledge gained from a basin plan can be used to better select locations for on-site facilities, and plan regional facilities where needed. In addition, basin plans allow for the construction and siting of facilities so that environmentally sensitive areas are not affected by unwise development.

VOL 12 2 2245

R0055543

A second important purpose of the manual is to provide information for users who are retrofitting BMPs to existing development. Retrofitting will primarily occur when a local government or Ecology has detected a stormwater drainage problem emanating from existing development and, as a result, has directed the implementation of BMPs to correct the problem.

A third purpose of the manual is to provide a reference source for users who wish to prepare technical bulletins, leaflets, etc. for purposes of education and/or specialized BMP implementation. Examples would include technical leaflets for individual homeowners, local governments, homeowners' associations, and business operators.

I-1.5 USERS OF THE MANUAL

The users of this manual will be engineers, planners and environmental scientists from local government and private industry. Local government officials will use the manual as a reference for reviewing stormwater site plans, for retrofitting of BMPs, and for providing technical advice in general. Private industry will primarily use the manual for information on how to develop and implement stormwater site plans, and as a reference for technical specifications of BMPS.

We anticipate that Ecology's NPDES stormwater permit writers will use this manual as a reference, and affected industries and municipalities will also use it to determine design criteria for the BMPs required as part of their permit.

I-1.6 ORGANIZATION OF THE MANUAL

The manual is organized into four volumes. Volume I provides an introduction and overview, a description of the Minimum Requirements, guidance on preparation of a stormwater site plan, and a method for selecting BMPs according to the requirements and the needs of the site. The glossary and notation information are found at the back of Volume I.

Volume II covers erosion and sediment control. BMPs for construction sites and other areas are covered, and BMPs for Small Parcels are also included. Information on NPDES construction permits, and the methodology for developing an Erosion and Sediment Control plan are also discussed.

The two topics covered in Volume III are runoff treatment and streambank erosion control. BMPs for infiltration, detention, conveyance systems, and other stormwater facilities are covered. Also included are hydrologic methods for calculating flow rates and volumes for sizing of drainage facilities.

Volume IV addresses control of runoff pollution produced by urban land uses. These include commercial, industrial, residential and public agency land uses.

I-1.7 HOW TO USE THIS MANUAL

The chapters in Volume I should be read first. Once a preliminary selection of BMPs has been made, those specific BMPs (found in Volumes II, III or IV) should be reviewed.

The Minimum Requirements contained in Chapter I-2 form the basis for all stormwater site plans. They are indicated in bold print. The standards set by this manual are the minimum requirements, and all other manuals will have to be substantially equivalent to that minimum standard. Local governments have the option of enacting stricter standards than those outlined in this manual, using parts of this manual

VOL 12 2 2246

R0055544

and developing appropriate other sections for their local area, or developing an entirely new manual for use by their government.

An effort has been made to be as flexible as possible to enable local governments to tailor site plans to their specific requirements. As long as Minimum Requirements in Chapter I-2 are met, the exact methods used to meet them are up to the local government. If other technical manuals are developed and used, they must be reviewed by Ecology as part of the local government's basic stormwater program and determined to be "substantially equivalent ". Supplementary guidelines which will be issued at or around the time of this version of this manual will describe the process for determining whether or not a manual is of an equivalent technical standard.

Once the preliminary BMP selection is made a stormwater site plan including an ESC plan can be completed. Overall stormwater site plan requirements are found in Chapter I-3. A final BMP selection should be made taking into account the appropriateness to the site, the cost, and the relative advantages and disadvantages of each BMP. Much of the information needed to assist in this decision is found under each specific BMP entry.

---

[1] Figure I-1.1 was developed from the SBUH model for a 10-acre site with the following conditions: Forest with CN = 64; Residential site with 25% impervious cover, CN = 75 and 98 for pervious and impervious areas, respectively; Commercial site with 75% impervious cover (same CN's as for residential site).

[2] Data for Figures I-1.2 and I-1.3 were derived from the EPA's National Urban Runoff Program and work by Thomas Schueler. The following assumptions were made:

Annual rainfall = 40 inches Annual runoff coefficient Rv = Pj*(.05+.009*IC)
Annual fraction of rainfall which generates runoff (Pj) = 0.9

Land Use Condition	Impervious Cover (%)	Annual Runoff Coefficient Rv	Concentration TP (mg/L)
Pre-development	2	0.07	0.15
Residential	30	0.32	0.26
Multi-family	50	0.50	0.26
Shopping Center	95	0.91	0.26

CHAPTER I-2

MINIMUM REQUIREMENTS FOR ALL NEW DEVELOPMENT AND REDEVELOPMENT

I-2.1 INTRODUCTION

The 1991 Puget Sound Water Quality Management Plan (as amended) requires all counties and cities within the Puget Sound drainage basin to adopt ordinances to control runoff from new development and redevelopment by July 1994. The Plan also directs local governments to adopt stormwater programs which include minimum requirements for new development and re-development set by the Plan and in guidance developed by Ecology. These ordinances are to address:

"... at a minimum: (1) the control of off-site water quality and quantity (as related to quality) impacts; (2) the use of source control best management practices and treatment best management practices; (3) the effective treatment, using best management practices of the storm size and frequency (design storm) as specified in the manual for proposed development; (4) the use of infiltration, with appropriate precautions, as the first consideration in stormwater management; (5) the protection of stream channels and wetlands; and (6) erosion and sedimentation control for new construction and re-development projects."

This chapter has been developed in response to the direction in the Plan. The reader is also referred to Volume II of the "Stormwater Program Guidance Manual for the Puget Sound Basin" (hereafter referred to as the Guidance Manual), a companion to this technical manual, which contains a model ordinance that incorporates these Minimum Requirements.

There are several sets of requirements for proposed new development and redevelopment that are applied depending on the type and size of the proposed development. In general, small sites are required to control erosion and sedimentation from construction activities while larger sites must also provide permanent control of stormwater runoff. Sites being redeveloped must generally meet the same minimum requirements as new development sites for the portion of the site being redeveloped. In addition, redevelopment sites must provide source control BMPs for the entire site. There may also be situations in which additional controls are required for sites, regardless of type or size, as a result of basin plans or special water quality concerns.

Development sites are to demonstrate compliance with the Minimum Requirements through the preparation of Stormwater Site Plans (SSP). The plans are described in detail in Chapter I-3 and in the Guidance Manual.

Two major components of these plans are an Erosion and Sediment Control (ESC) Plan and a Permanent Stormwater Quality Control (PSQC) Plan. The ESC plan is intended to be temporary in nature to control pollution generated during the construction phase only, primarily erosion and sediment. The PSQC is intended to provide permanent BMPs for the control of pollution from stormwater runoff after construction has been completed. For small sites, this requirement is met by implementing a Small Parcel Erosion and Sediment Control Plan.

A flow chart demonstrating these requirements is shown in Figure I-2.1.

Definitions:

> New development - means the following activities: land disturbing activities, structural development, including construction, installation or expansion of a building or other structure; creation of impervious surfaces; Class IV - general forest practices that are conversions from timber land to other uses;

R0055547

and subdivision, short subdivision and binding site plans, as defined in Ch.58.17.020 RCW. All other forest practices and commercial agriculture are not considered new development.

Redevelopment - means, on an already developed site, the creation or addition of impervious surfaces, structural development including construction, installation or expansion of a building or other structure, and/or replacement of impervious surface that is not part of a routine maintenance activity; and land disturbing activities associated with structural or impervious redevelopment.

Impervious surface - means a hard surface area which either prevents or retards the entry of water into the soil mantle as under natural conditions prior to development, and/or a hard surface area which causes water to run off the surface in greater quantities or at an increased rate of flow from the flow present under natural conditions prior to development. Common impervious surfaces include, but are not limited to, roof tops, walkways, patios, driveways, parking lots or storage areas, concrete or asphalt paving, gravel roads, packed earthen materials, and oiled, macadam or other surfaces which similarly impede the natural infiltration of stormwater. Open, uncovered retention/detention facilities shall not be considered as impervious surfaces.

Land disturbing activity - means any activity that results in a change in the existing soil cover (both vegetative and nonvegetative) and/or the existing soil topography. Land disturbing activities include, but are not limited to demolition, construction, clearing, grading, filling and excavation.

Source control BMP - A BMP that is intended to prevent pollutants from entering stormwater. A few examples of source control BMPs are erosion control practices, maintenance of stormwater facilities, constructing roofs over storage and working areas, and directing wash water and similar discharges to the sanitary sewer or a dead end sump.

Throughout this Chapter, guidance to meet the requirements of the 1991 Puget Sound Water Quality Management Plan (as amended) is written in bold and supplemental guidelines that serve as advice and other materials are not in bold.

I-2.2 EXEMPTIONS

- Commercial agriculture, and forest practices regulated under Title 222 WAC, except for Class IV General forest practices that are conversions from timber land to other uses, are exempt from the provisions of the minimum requirements. All other new development is subject to the minimum requirements.

I-2.3 SMALL PARCEL MINIMUM REQUIREMENTS

- The following new development shall be required to control erosion and sediment during construction, to permanently stabilize soil exposed during construction, to comply with Small Parcel Requirements 1 through 4, and to prepare a Small Parcel Erosion and Sediment Control Plan:

  (a) Individual, detached, single family residences and duplexes.
  (b) Creation or addition of less than 5,000 square feet of impervious surface area.
  (c) Land disturbing activities of less than one acre.

VOL 12 2 2250

R0055548

Objective: The objective of this requirement is to address the cumulative effect of sediment coming from a large number of small sites.

Supplemental Guidelines: Small parcels under 5,000 sq.ft. in size and individual, detached, single family residences and duplexes, require the simplified erosion and sediment controls contained in a Small Parcel Erosion and Sediment Control Plan (SPESC). This plan is required to fulfil the Small Parcel Minimum Requirements outlined below in Section I-2.3. The Small Parcel BMPs found in Section II-5.10 in Volume II are used to develop the plan. A complete description of a Small Parcel ESC Plan can be found in Section I-3.3. The SPESC plan is meant to be temporary in nature to deal with erosion and sediment generated during the construction phase only. Local governments may choose to apply additional permanent, site-specific stormwater controls to small parcels.

One method of proof of compliance could be the use of a checklist similar to that found in Figure I-3.1. This list can be adapted as necessary to include individual requirements of a local government.

SMALL PARCEL REQUIREMENT #1 Construction Access Route

- Construction vehicle access shall be, whenever possible, limited to one route. Access points shall be stabilized with quarry spall or crushed rock to minimize the tracking of sediment onto public roads.

Supplemental Guidelines: If sediment is inadvertently transported onto public roads, roads shall be cleaned thoroughly at the end of the day by shoveling or sweeping. Street washing should only be done after the bulk of the sediment has been removed by sweeping.

SMALL PARCEL REQUIREMENT #2 Stabilization of Denuded Areas

- Soil stabilization. All exposed and unworked soils shall be stabilized by suitable application of BMPs, including but not limited to sod or other vegetation, plastic covering, mulching, or application of ground base on areas to be paved. All BMPs shall be selected, designed and maintained in accordance with an approved manual. From October 1 through April 30, no soils shall remain exposed for more than 2 days. From May 1 through September 30, no soils shall remain exposed for more than 7 days.

Supplemental Guidelines: BMPs should be selected which are appropriate for the time of the year and anticipated duration of use.

SMALL PARCEL REQUIREMENT #3 Protection of Adjacent Properties

- Adjacent properties shall be protected from sediment deposition by appropriate use of vegetative buffer strips, sediment barriers or filters, dikes or mulching, or by a combination of these measures and other appropriate BMPs.

SMALL PARCEL REQUIREMENT #4 Maintenance

- All erosion and sediment control BMPs shall be regularly inspected and maintained to ensure continued performance of their intended function.

SMALL PARCEL REQUIREMENT #5 Other BMPs

- As required by the local Plan Approval Authority, other appropriate BMPs to mitigate the effects of increased runoff shall be applied.

VOL 12 2 2251

R0055549

I-2.4 NEW DEVELOPMENT AND REDEVELOPMENT - APPLICATION OF MINIMUM REQUIREMENTS

I-2.4.1 New Development

All new development that includes the creation or addition of 5,000 square feet, or greater, of new impervious surface area, and/or land disturbing activity of one acre or greater, shall comply with Minimum Requirements #1 through #11 in Sections I-2.5 through I-2.15 and prepare a Stormwater Site Plan.

All new development that includes the creation or addition of 5,000 square feet, or greater, of new impervious surface area, and land disturbing activity of less than one acre, shall comply with Minimum Requirements #2 through #11 in Sections I-2.6 through I-2.15 and the Small Parcel Minimum Requirements found in section I-2.2, above. This category of development shall also prepare a Stormwater Site Plan that includes a Small Parcel Erosion and Sediment Control Plan.

This section does not apply to the construction of individual, detached, single family residences and duplexes. Those types of new development are included in the Small Parcel Minimum Requirements.

Objective: The objective of this standard is to define the application of the Minimum Requirements. The objective of these requirements is to reduce pollution and minimize erosion and sedimentation from new development.

Supplemental Guidelines: Basin planning is encouraged and may be used to tailor certain of the Minimum Requirements to a specific basin (see Minimum Requirement #9). The Minimum Requirements for Small Parcels are found in Section I-2.2. See page I-2-1 for the definition of new development. See Chapter I-3 for a description of Stormwater Site Plans.

I-2.4.2 Redevelopment

A. Where redevelopment of ≥ 5,000 square feet occurs:

The new development Minimum Requirements #1 through #11, Sections I-2.5 through I-2.15, shall apply to that portion of the site that is being redeveloped, and source control BMPs shall be applied to the entire site, including adjoining parcels if they are part of the project. A Stormwater Site Plan shall be prepared.

B. In addition to the above requirements, where one or more of the following conditions apply, a Stormwater Site Plan shall also be prepared that includes a schedule for implementing the Minimum Requirements to the maximum extent practicable, for the entire site, including adjoining parcels if they are part of the project. An adopted and implemented basin plan (Minimum Requirement #9) may be used to develop redevelopment requirements that are tailored to a specific basin.

1. Existing sites greater than 1 acre in size with 50% or more impervious surface.

2. Sites that discharge to a receiving water that has a documented water quality problem. Subject to local priorities, a documented water quality problem includes, but is not limited to water bodies:

   (i) Listed in reports required under section 305(b) of the Clean Water Act, and designated as not supporting beneficial uses;

VOL 12 2 2252

R0055550

(ii) Listed under section 304(l)(1)(A)(i),304(l)(1)(A)(ii), or 304(l)(1)(B) of the Clean Water Act as not expected to meet water quality standards or water quality goals;

(iii) Listed in Washington State's Nonpoint Source Assessment required under section 319(a) of the Clean Water Act that, without additional action to control nonpoint sources of pollution cannot reasonably be expected to attain or maintain water quality standards.

3. Sites where the need for additional stormwater control measures have been identified through a basin plan, the watershed ranking process under Ch. 400-12 WAC, or through Growth Management Act planning.

Objective: The objective of the redevelopment standard is to reduce pollution from existing sites. The long-term goal of this standard is to accomplish this reduction through development and implementation of basin plans.

Supplemental Guidelines: Minimum Requirements 1 through 11 always apply to the portion of the site that is being redeveloped, if the redevelopment is over 5,000 sq. ft. in size. In addition, source control BMPs are always required for the entire site. A basin plan could be used to vary the thresholds for application of the minimum requirements to the entire site, beyond the portion of the site that is being redeveloped. See Chapter I-3 for the description of a Stormwater Site Plan.

I-2.5 MINIMUM REQUIREMENT #1: EROSION AND SEDIMENT CONTROL

- All new development and redevelopment that includes land disturbing activities of ≥1 acre shall comply with Erosion and Sediment Control Requirements 1 through 14, below. Compliance with the Erosion and Sediment Control Requirements shall be demonstrated through implementation of a Large Parcel Erosion and Sediment Control Plan.

  All new development and redevelopment that includes land disturbing activities of <1 acre shall comply with the Small Parcel Minimum requirements found in section I-2.2, above. Compliance with the Small Parcel Requirements shall be demonstrated through implementation of a Small Parcel Erosion and Sediment Control Plan.

Objective: To control erosion and prevent sediment from leaving the site.

Supplemental Guidelines:

Large parcels are defined as those >1 acre in size. Parcels of this size are required to implement a Large Parcel ESC plan which meets the Erosion and Sediment Control Requirements found in Minimum Requirement #1. Additionally, a Permanent Stormwater Quality Control Plan (PSQC) must be developed which meets Minimum Requirements 2 through 11. An acceptable Stormwater Site Plan (SSP) for a large parcel contains both of these elements, the ESC plan, and the PSQC, and fulfills all the Minimum Requirements.

VOL 12 2 2253

R0055551

If an ESC plan is found to be inadequate (with respect to the Erosion and Sediment Control Requirements), then the Plan Approval Authority[1] within the Local Government will require that other BMPs be implemented, as appropriate.

Erosion and Sediment Control Minimum Requirements

Guidance to meet the requirements of the 1991 Puget Sound Water Quality Management Plan (as amended) is written in bold, and supplemental guidelines that serve as advice and other materials are not in bold.

The following erosion and sediment control requirements shall be met:

EROSION AND SEDIMENT CONTROL REQUIREMENT #1: Stabilization and Sediment Trapping

- **All exposed and unworked soils shall be stabilized by suitable application of BMPs. From October 1 to April 30, no soils shall remain unstabilized for more than 2 days. From May 1 to September 30, no soils shall remain unstabilized for more than 7 days. Prior to leaving the site, stormwater runoff shall pass through a sediment pond or sediment trap, or other appropriate BMPs.**

Supplemental Guidelines: This criterion applies both to soils not yet at final grade and soils at final grade. The type of stabilization BMP used may be different depending on the length of time that the soil is to remain unworked.

Soil stabilization refers to BMPs which protect soil from the erosive forces of raindrop impact and flowing water. Applicable practices include vegetative establishment, mulching, plastic covering, and the early application of gravel base on areas to be paved. Soil stabilization measures should be selected to be appropriate for the time of year, site conditions, and estimated duration of use. Soil stockpiles must be stabilized or protected with sediment trapping measures to prevent soil loss.

These requirements are *especially* important in areas adjacent to streams, wetlands or other sensitive or critical areas.

EROSION AND SEDIMENT CONTROL REQUIREMENT #2: Delineate Clearing and Easement Limits

- **In the field, mark clearing limits and/or any easements, setbacks, sensitive/critical areas and their buffers, trees and drainage courses.**

EROSION AND SEDIMENT CONTROL REQUIREMENT #3: Protection of Adjacent Properties

- **Properties adjacent to the project site shall be protected from sediment deposition.**

Supplemental Guidelines: This may be accomplished by preserving a well-vegetated buffer strip around the lower perimeter of the land disturbance, by installing perimeter controls such as sediment barriers, filters or dikes, or sediment basins, or by a combination of such measures.

Vegetated buffer strips may be used alone only where runoff in sheet flow is expected. Buffer strips should be at least 25 feet in width. If at any time it is found that a vegetated buffer strip alone is ineffective in stopping sediment movement onto adjacent property, additional perimeter controls must be provided.

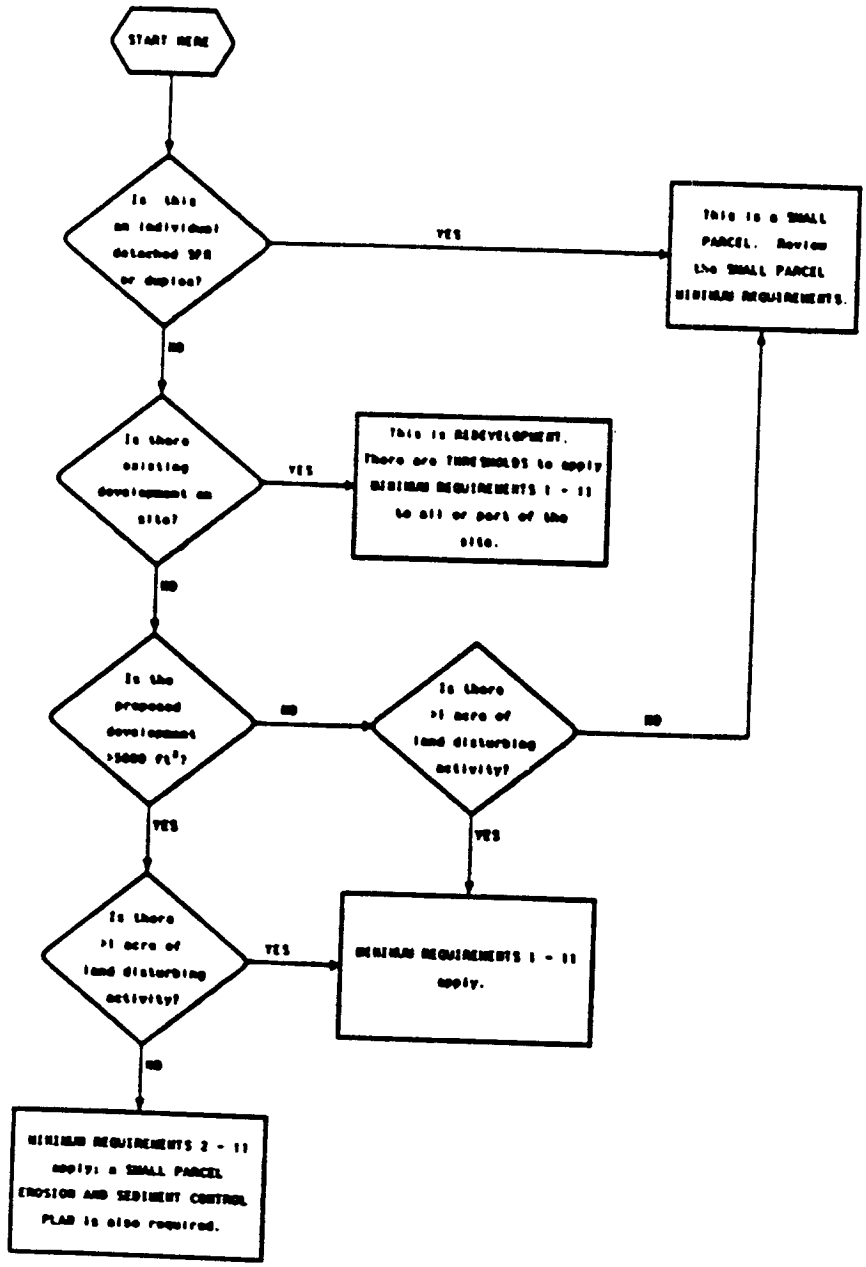
---

[1] The Plan Approval Authority is defined as that department within a local government that has been delegated authority to approve erosion and sediment control plans.

VOL 12 2 2254

R0055552

Figure I-2.1 Flowchart Demonstrating Minimum Requirements



VOL 12 2 2255

R0055553

EROSION AND SEDIMENT CONTROL REQUIREMENT #4: Timing and Stabilization of Sediment Trapping Measures

- Sediment ponds and traps, perimeter dikes, sediment barriers, and other BMPs intended to trap sediment on-site shall be constructed as a first step in grading. These BMPs shall be functional before land disturbing activities take place. Earthen structures such as dams, dikes, and diversions shall be seeded and mulched according to the timing indicated in Erosion and Sediment Control Requirement #1.

EROSION AND SEDIMENT CONTROL REQUIREMENT #5: Cut and Fill Slopes

- Cut and fill slopes shall be designed and constructed in a manner that will minimize erosion. In addition, slopes shall be stabilized in accordance with Erosion and Sediment Control Requirement #1.

Supplemental Guidelines: Consideration should be given to the length and steepness of the slope, the soil type, upslope drainage area, ground water conditions, and other applicable factors. Slopes which are found to be eroding excessively within two years of construction must be provided with additional slope stabilizing measures until the problem is corrected.

1. Roughened soil surfaces are preferred to smooth surfaces on slopes (see BMP E2.35 in Chapter II-5).

2. Interceptors (see BMP E2.55 in Chapter II-5) should be constructed at the top of long steep slopes which have significant drainage areas above the slope. Diversions or terraces may also be used to reduce slope length.

3. Concentrated stormwater should not be allowed to flow down cut or fill slopes unless contained within an adequate temporary or permanent channel, or pipe slope drain (see BMP E2.25 in Chapter II-5).

4. Wherever a slope face crosses a water seepage plane which endangers the stability of the slope, adequate drainage or other protection should be provided (BMPs E2.30 and E2.75 in Chapter II-5).

EROSION AND SEDIMENT CONTROL REQUIREMENT #6: Controlling Off-site Erosion

- Properties and waterways downstream from development sites shall be protected from erosion due to increases in the volume, velocity, and peak flow rate of stormwater runoff from the project site.

EROSION AND SEDIMENT CONTROL REQUIREMENT #7: Stabilization of Temporary Conveyance Channels and Outlets

- All temporary on-site conveyance channels shall be designed, constructed and stabilized to prevent erosion from the expected velocity of flow from a 2-year, 24-hour frequency storm for the developed condition. Stabilization adequate to prevent erosion of outlets, adjacent streambanks, slopes and downstream reaches shall be provided at the outlets of all conveyance systems.

EROSION AND SEDIMENT CONTROL REQUIREMENT #8: Storm Drain Inlet Protection

- All storm drain inlets made operable during construction shall be protected so that stormwater runoff shall not enter the conveyance system without first being filtered or otherwise treated to remove sediment.

VOL 12 2 2256

R0055554

EROSION AND SEDIMENT CONTROL REQUIREMENT #9: Underground Utility Construction

- The construction of underground utility lines shall be subject to the following criteria:

  (i) Where feasible, no more than 500 feet of trench shall be opened at one time.

  (ii) Where consistent with safety and space considerations, excavated material shall be placed on the uphill side of trenches.

  (iii) Trench dewatering devices shall discharge into a sediment trap or sediment pond.

EROSION AND SEDIMENT CONTROL REQUIREMENT #10: Construction Access Routes

- Wherever construction vehicle access routes intersect paved roads, provisions must be made to minimize the transport of sediment (mud) onto the paved road. If sediment is transported onto a road surface, the roads shall be cleaned thoroughly at the end of each day. Sediment shall be removed from roads by shoveling or sweeping and be transported to a controlled sediment disposal area. Street washing shall be allowed only after sediment is removed in this manner.

EROSION AND SEDIMENT CONTROL REQUIREMENT #11: Removal of Temporary BMPs

- All temporary erosion and sediment control BMPs shall be removed within 30 days after final site stabilization is achieved or after the temporary BMPs are no longer needed. Trapped sediment shall be removed or stabilized on site. Disturbed soil areas resulting from removal shall be permanently stabilized.

EROSION AND SEDIMENT CONTROL REQUIREMENT #12: Dewatering Construction Sites

- Dewatering devices shall discharge into a sediment trap or sediment pond.

EROSION AND SEDIMENT CONTROL REQUIREMENT #13: Control of Pollutants Other Than Sediment on Construction Sites

- All pollutants other than sediment that occur on-site during construction shall be handled and disposed of in a manner that does not cause contamination of stormwater.

EROSION AND SEDIMENT CONTROL REQUIREMENT #14: Maintenance

- All temporary and permanent erosion and sediment control BMPs shall be maintained and repaired as needed to assure continued performance of their intended function. All maintenance and repair shall be conducted in accordance with an approved manual.

EROSION AND SEDIMENT CONTROL REQUIREMENT #15: Financial Liability

- Performance bonding, or other appropriate financial instruments, shall be required for all projects to ensure compliance with the approved erosion and sediment control plan.

I-2.6 MINIMUM REQUIREMENT #2: PRESERVATION OF NATURAL DRAINAGE SYSTEMS

- Natural drainage patterns shall be maintained, and discharges from the site shall occur at the natural location, to the maximum extent practicable.

VOL 12 2 22577

R0055555

Objective: To preserve and utilize natural drainage systems to the fullest extent because of the multiple stormwater benefits these systems provide.

Supplemental Guidelines: Natural drainage systems provide many water quality benefits and should be preserved to the fullest extent possible. In addition to conveying and attenuating stormwater runoff, these systems are less erosive, provide ground water recharge, and support important plant and wildlife resources. Effective utilization of the natural system can maintain environmental and aesthetic attributes of a site as well as be a cost-effective measure to convey stormwater runoff.

Creating new drainage patterns requires more site disturbance and can upset stream dynamics of the drainage system, thus tending to increase erosion and sedimentation. Creating new discharge points can create significant streambank erosion problems as the receiving water body typically must adjust to the new flows. Newly created drainage patterns can seldom, if ever, provide the multiple benefits of natural drainage systems. Where no conveyance system exists at the adjacent downstream property line and the discharge was previously unconcentrated flow or significantly lower concentrated flow, then measures must be taken to prevent downstream impacts. Necessary drainage easements may be obtained from downstream property owners.

I-2.7 MINIMUM REQUIREMENT #3: SOURCE CONTROL OF POLLUTION

- Source control BMPs shall be applied to all projects to the maximum extent practicable. Source control BMPs shall be selected, designed, and maintained according to an approved manual.

  An adopted and implemented basin plan (Minimum Requirement #9) may be used to develop source control requirements that are tailored to a specific basin, however, in all circumstances, source control BMPs shall be required for all sites.

Objective: The intention of source control BMPs is to prevent stormwater from coming in contact with pollutants. They are a cost effective means of reducing pollutants in stormwater, and, therefore, should be a first consideration in all projects.

Supplemental Guidelines: A list of many source control BMPs is provided in the BMP selection chapter, Chapter I-4. For construction sites see Chapter II-5; for post-construction development sites see Volume III; for specific urban land uses see Volume IV.

I-2.8 MINIMUM REQUIREMENT #4: RUNOFF TREATMENT BMPS

- All projects shall provide treatment of stormwater. Treatment BMPs shall be sized to capture and treat the water quality design storm, defined as the 6-month, 24-hour return period storm. The first priority for treatment shall be to infiltrate as much as possible of the water quality design storm, only if site conditions are appropriate and ground water quality will not be impaired. Direct discharge of untreated stormwater to ground water is prohibited. All treatment BMPs shall be selected, designed, and maintained according to an approved manual.

  Stormwater treatment BMPs shall not be built within a natural vegetated buffer, except for necessary conveyance systems as approved by the local government.

VOL 12 2 2258

R0055556

An adopted and implemented basin plan (Minimum Requirement #9) may be used to develop runoff treatment requirements that are tailored to a specific basin.

Objective: The purpose of runoff treatment is to reduce pollutant loads and concentrations in stormwater runoff using physical, biological, and chemical removal mechanisms. When site conditions are appropriate infiltration can potentially be the most effective BMP for runoff treatment.

Supplemental Guidelines: See Volume III. The water quality design storm (see Appendix AI-2.1) is intended to capture more than 90 percent of the annual runoff.

Infiltration can provide both treatment of stormwater, through the ability of certain soils to remove pollutants, and volume control of stormwater, by decreasing the amount of water that runs off to surface water. Infiltration can be very effective at treating stormwater runoff but soil conditions must be appropriate to achieve effective treatment while not impacting ground water resources. Methods currently in use such as direct discharge into dry wells do not achieve adequate water quality treatment and are therefore not permitted.

If stormwater is being discharged to a stream, see I-2.9, Streambank Erosion Control for additional requirements.

If stormwater is being discharged to a wetland, see I-2.10, Wetlands for additional requirements.

I-2.9 MINIMUM REQUIREMENT #5: STREAMBANK EROSION CONTROL

- The requirement below applies only to situations where stormwater runoff is discharged directly or indirectly to a stream, and must be met in addition to meeting the requirements in Minimum Requirement #4, Runoff Treatment BMPs:

  Stormwater discharges to streams shall control streambank erosion by limiting the peak rate of runoff from individual development sites to 50 percent of the existing condition 2-year, 24-hour design storm while maintaining the existing condition peak runoff rate for the 10-year, 24-hour and 100-year, 24-hour design storms. As the first priority, streambank erosion control BMPs shall utilize infiltration to the fullest extent practicable, only if site conditions are appropriate and ground water quality is protected. Streambank erosion control BMPs shall be selected, designed, and maintained according to an approved manual.

  Stormwater treatment BMPs shall not be built within a natural vegetated buffer, except for necessary conveyance systems as approved by the local government.

  An adopted and implemented basin plan (Minimum Requirement #9) may be used to develop streambank erosion control requirements that are tailored to a specific basin.

Objective: To reduce streambank erosion which results from increased runoff due to development. The standard is intended to reduce the frequency and magnitude of bankfull flow conditions, which are highly erosive and increase dramatically as a result of development. Conventional flood detention practices do not adequately control streambank erosion because only the peak rate of flow is decreased, not the *frequency* and *duration* of bankfull conditions.

Supplemental Guidelines: See Chapter III-4. Reduction of flows through infiltration decreases streambank erosion and helps to maintain base flow throughout the summer months. However, infiltration should only be used where ground water

VOL 12 2 2259

R0055557

quality is not threatened by such discharges. The use of an artificial treatment system, such as an aquatard (see Chapter III-3) shall be considered in areas with highly permeable soils. Treatment of the water quality design storm must be accomplished prior to discharge to these soils. If highly permeable soils are present they should be utilized for streambank erosion control by infiltrating flows greater than the water quality design storm.

I-2.10 MINIMUM REQUIREMENT #6: WETLANDS

- The requirements below apply only to situations where stormwater discharges directly or indirectly through a conveyance system into a wetland, and must be met in addition to meeting the requirements in Minimum Standard #4, Runoff Treatment BMPs.

  (a) Stormwater discharges to wetlands must be controlled and treated to the extent necessary to meet the State Water Quality Standards, Ch. 173-201 WAC, or Ground Water Quality Standards, Ch. 173-200 WAC, as appropriate.

  (b) Discharges to wetlands shall maintain the hydroperiod and flows of existing site conditions to the extent necessary to protect the characteristic uses of the wetland. Prior to discharging to a wetland, alternative discharge locations shall be evaluated, and natural water storage and infiltration opportunities outside the wetland shall be maximized.

  (c) Created wetlands that are intended to mitigate for loss of wetland acreage, function and value shall not be designed to also treat stormwater.

  (d) In order for constructed wetlands to be considered treatment systems, they must be constructed on sites that are not wetlands and they must be managed for stormwater treatment. If these systems are not managed and maintained in accordance with an approved manual for a period exceeding three years these systems may no longer be considered constructed wetlands. Discharges from constructed wetlands to waters of the state (including discharges to natural wetlands) are regulated under Ch. 90.48 RCW, Ch. 173-201 WAC, and Ch. 173-200 WAC.

  (e) Stormwater treatment BMPs shall not be built within a natural vegetated buffer, except for necessary conveyance systems as approved by the local government.

  An adopted and implemented basin plan (Minimum Requirement #9) may be used to develop requirements for wetlands that are tailored to a specific basin.

Objective: To ensure that wetlands receive the same level of protection as any other waters of the state. Wetlands are extremely important natural resources which provide multiple stormwater benefits, including ground water recharge, flood control, and streambank erosion protection. They are easily impacted by development unless careful planning and management are conducted. Wetlands can be severely degraded by stormwater discharges from urban development due to pollutants in the runoff and also due to disruption of natural hydrologic functioning of the wetland system. Changes in water levels and the duration of inundations are of particular concern.

Supplemental Guidelines: See Chapter III-5. These requirements are a management tool to assist in meeting the state water quality standards. While it is always necessary to pre-treat stormwater prior to discharge to a wetland, there are limited circumstances where wetlands may be used for detention of stormwater.

VOL 12 2 2260

R0055558

Definitions: See glossary for definitions of wetlands, constructed wetland, created wetland, and abandonment.

I-2.11 MINIMUM REQUIREMENT #7: WATER QUALITY SENSITIVE AREAS

- Where local governments determine that the Minimum Requirements do not provide adequate protection of water quality sensitive areas, either on-site or within the basin, more stringent controls shall be required to protect water quality.

  Stormwater treatment BMPs shall not be built within a natural vegetated buffer, except for necessary conveyance systems as approved by the local government.

  An adopted and implemented basin plan (Minimum Requirement #9) may be used to develop requirements for water quality sensitive areas that are tailored to a specific basin.

Objective: To ensure protection of water quality in sensitive areas.

Supplemental Guidelines: Water quality sensitive areas are areas that are sensitive to a change in water quality, including but not limited to, lakes, ground water management areas, ground water special protection areas, sole source aquifers, critical aquifer recharge areas, well head protection areas, closed depressions, fish spawning and rearing habitat, wildlife habitat, and shellfish protection areas. Areas such as steep or unstable slopes or erosive stream banks which can cause water quality problems should also be included. Water quality sensitive areas may be identified through jurisdiction-wide inventories, the watershed planning process required under Ch. 400-12 WAC, critical area designation in accordance with Ch. 365-190 WAC, local drainage basin planning, and/or on a site-by-site basis (e.g. using a threshold determination under SEPA).

I-2.12 MINIMUM REQUIREMENT #8: OFF-SITE ANALYSIS AND MITIGATION

- All development projects shall conduct an analysis of off-site water quality impacts resulting from the project and shall mitigate these impacts. The analysis shall extend a minimum of one-fourth of a mile downstream from the project. The existing or potential impacts to be evaluated and mitigated shall include, at a minimum, but not be limited to:

  (i) excessive sedimentation
  (ii) streambank erosion
  (iii) discharges to ground water contributing or recharge zones
  (iv) violations of water quality standards
  (v) spills and discharges of priority pollutants

Objective: To ensure that future impacts from the project will be controlled and/or existing impacts will not be aggravated by the project.

Supplemental Guidelines: Further information on off-site analysis is being developed.

I-2.13 MINIMUM REQUIREMENT #9: BASIN PLANNING

- Adopted and implemented watershed-based basin plans may be used to modify any or all of the Minimum Requirements, provided that the level of protection for surface or ground water achieved by the basin plan will equal or exceed that which would be achieved by the Minimum Requirements in the absence of a basin

VOL 12 2 2261

R0055559

plan. Basin plans shall evaluate and include, as necessary, retrofitting of BMPs for existing development and/or redevelopment in order to achieve watershed-wide pollutant reduction goals. Standards developed from basin plans shall not modify any of the above requirements until the basin plan is formally adopted and fully implemented by local government. Basin plans shall be developed according to an approved manual.

Objective: To promote watershed-based planning as a means to develop and implement comprehensive water quality protection measures. Primary objectives of basin planning are to reduce pollutant loads and hydrologic impacts to streams and wetlands.

Supplemental Guidelines: While Minimum Requirements #3 through #7 establish protection standards for individual sites, they do not evaluate the overall pollution impacts and protection opportunities which could exist at the watershed level. In order for a basin plan to serve as a means of modifying the minimum requirements it must be formally adopted by all jurisdictions that have responsibilities under the basin plan, and construction and regulations called for by the plan must be complete. This is what is meant by an adopted and implemented basin plan.

Basin planning provides a mechanism by which the on-site standards can be evaluated and refined based on an analysis of an entire watershed. Basin plans are especially well-suited to develop control strategies to address impacts from future development and to correct specific problems whose sources are known or suspected. Basin plans can be effective at addressing both long-term cumulative impacts of pollutant loads and short-term acute impacts of pollutant concentrations, as well as hydrologic impacts to streams and wetlands.

In general, the standards established by basin plans will be site-specific but may be augmented with regional solutions for Source Control (Minimum Requirement #2) and Streambank Erosion Control (Minimum Requirement #4).

I-2.14 MINIMUM REQUIREMENT #10: OPERATION AND MAINTENANCE

- An operation and maintenance schedule shall be provided for all proposed stormwater facilities and BMPs, and the party (or parties) responsible for maintenance and operation shall be identified.

Objective: To ensure that stormwater control facilities are adequately maintained and operated properly.

Supplemental Guidelines: Inadequate maintenance is likely the leading cause of failure for stormwater control facilities. The description of each BMP in Volume II and III includes a section on maintenance. The Guidance Manual also includes a section on developing an operation and maintenance program and a model operation and maintenance ordinance.

I-2.15 MINIMUM REQUIREMENT #11: FINANCIAL LIABILITY

- Performance bonding or other appropriate financial instruments shall be required for all projects to ensure compliance with these standards.

Objective: To ensure that development projects have adequate financial resources to fully implement stormwater management plan requirements and that liability is not unduly incurred upon local governments.

VOL 12 2 22662

R0055560

Supplemental Guidelines: The type of financial instrument required is less important than ensuring that there are adequate funds available in the event that non-compliance occurs.

I-2.16 EXCEPTIONS

- Exceptions to Minimum Requirements #1 through #10 may be granted prior to permit approval and construction. An exception may be granted following a public hearing, provided that a written finding of fact is prepared, that addresses the following:

  (i) The exception provides equivalent environmental protection and is in the overriding public interest; and that the objectives of safety, function, environmental protection and facility maintenance, based upon sound engineering, are fully met;

  (ii) That there are special physical circumstances or conditions affecting the property such that the strict application of these provisions would deprive the applicant of all reasonable use of the parcel of land in question, and every effort to find creative ways to meet the intent of the Minimum Requirements has been made;

  (iii) That the granting of the exception will not be detrimental to the public health and welfare, nor injurious to other properties in the vicinity and/or downstream, and to the quality of waters of the state; and

  (iv) The exception is the least possible exception that could be granted to comply with the intent of the Minimum Requirements.

Supplemental Guidelines: Ecology encourages the Plan Approval Authority to impose additional or more stringent criteria as appropriate for their area. Additionally, criteria which may be inappropriate or too restrictive for an area may be modified through basin planning (Minimum Requirement #9). Modification of any of the minimum requirements which are deemed inappropriate for the site may be done by granting an exception.

The exception procedure is an important element of the plan review and enforcement programs. It is intended to maintain a necessary flexible working relationship between local officials and applicants. Plan Approval Authorities should consider these requests judiciously, keeping in mind both the need of the applicant to maximize cost-effectiveness and the need to protect off-site properties and resources from damage.

I-2.17 EXPERIMENTAL BMPs

Experimental best management practices are defined as BMPs which have not been tested and evaluated by the Department of Ecology in collaboration with local governments and technical experts. Some so-called Experimental BMPs will likely be minor variations on an existing theme. In that case, Ecology would review and approve or disapprove the BMP in as timely a manner as possible. Where new designs are developed (examples as below, in Section I-2.17.2), the review will be extended through the use of a standing committee of technical experts. These persons will review and comment on the practice, and Ecology will then determine whether or not these BMPs should be approved and/or added to this manual.

VOL 12 2 2263

R0055561

I-2.17.1 Approval of Experimental BMPs

Approval to use an Experimental BMP may be granted subject to initial approval by the Department of Ecology and the local government. If such Experimental BMPs prove useful they may be incorporated into later editions of this manual following appraisal of the results and appropriate technical review conducted by Ecology in collaboration with local governments and other interested parties. Approval to use an Experimental BMP will only be granted when a suitable contingency plan using approved BMPs has been provided by the applicant to be used in the event that the Experimental BMP does not perform adequately.

In addition, several Experimental BMPs have been included in the manual. People may wish to use these BMPs on a trial basis, subject to approval by the local government and provision of a contingency plan. In any event, use of Experimental BMPs is encouraged whenever applied research is being undertaken so that more information is made available to facilitate judgement on their applicability and possible adoption as an approved.

I-2.17.2 Example Experimental BMPs

The two BMPs described below are examples of Experimental BMPs where a thorough design review and monitoring process is occurring. Both designs have undergone significant modification based on the monitoring data collected and both are still in the prototype stage. Please note that these examples are presented for informational purposes only. While these Experimental BMPs appear to be effective at controlling some types of pollutants, Ecology is not in a position to confirm or deny their efficacy at this time.

The two Experimental BMPs that are currently under development are a catchbasin filter system designed by Emcon Northwest, and a compost stormwater treatment system designed by W&H Pacific.

Catchbasin Filter System

EMCON Northwest, Inc. has recently developed a catchbasin filter (patent pending) that prevents sediments and other contaminants from entering storm drainage systems. The catchbasin filter is inserted in the catchbasin just below the grating. The catchbasin filter is equipped with a sediment trap and up to three layers of a fiberglass filter material (see Figure II-5.26). This type of system may not be applicable in all catchbasins but would work well at construction sites, industrial facilities, service stations, marinas/boatyards, etc.

During research and development of the catchbasin filter, EMCON Northwest, Inc. has found that particulates as small as 15 microns are retained by the filter. Additionally, high levels of particulate heavy metals, oil and grease and TSS have been removed at both industrial facilities and construction sites. This system would be useful in small drainage areas, and for treatment of highly turbid runoff prior to discharge.

For further information, contact John MacPherson at EMCON Northwest Inc., (206) 485-5000.

Compost Stormwater Treatment System

W&H Pacific worked with the Washington County Dept. of Land Use and Transportation (WCDLUT), Oregon, to develop this experimental BMP. The United Sewage Agency (USA) provided sampling and laboratory analysis for the project; the Portland Metropolitan Service District (Metro) provided additional funding; and the University of Washington College of Forest Resources was contracted to perform bench-scale

VOL 12 2 2264

R0055562

leaching and adsorption capacity tests on selected composts. The compost chosen for the prototype facility was made from deciduous leaves collected in the fall; other types of compost evaluated were not satisfactory.

This project is a good example of intergovernmental cooperation and interaction between public and private sectors in developing new and potentially cost-effective technology for stormwater pollution control. The goal of the project was to effectively treat road runoff using a BMP which reduced the amount of land necessary.

The prototype test facility is located at S.W. 185th Avenue in Washington County, Oregon, and serves a total drainage area of 72 acres. The facility is designed for a peak hydraulic loading of 6.7 cfs (one-third the 2-year design storm). Higher flows are bypassed. Nine storms were monitored in 1991, and the system has been successful in removing, to low levels, many types of conventional pollutants .

The prototype facility utilized 3% of the land area required for a properly designed stormwater detention pond sized for the same site conditions.

The project recently won an Engineering Excellence Grand Award from the Consulting Engineers Council of Oregon, as well as a national Grand Award from the American Consulting Engineers Council.

For further information on this experimental BMP, contact Bill Stewart at W&H Pacific, (503) 626-0455.

VOL 12

APPENDIX AI-2.1

DERIVATION OF THE WATER QUALITY DESIGN STORM

In instances where the stormwater management requirement is treatment to remove pollutants only without an additional requirement to control peak rate discharge there arises the need to establish an appropriate design storm for sizing of treatment BMPs. This design storm needs to be the minimum size to provide treatment of all the runoff volume from the site except that from relatively rare floods. Sizing a treatment facility for infrequent storms would result in a large facility that would be greatly under-utilized most of the time. The cost becomes prohibitive to treat a few extra percent of the total runoff volume.

TABLE AI-2.1 ANALYSIS OF SEA-TAC RAINFALL FROM 1950 - 1977 (Prepared by Resource Planning Associates (1))

Storm Event Size	Precip. Amount	# of Events	Rainfall Amount of Larger Events	Proportion of Total[2]
1-month, 24-hr.	0.65"	390	415"	62%
6-month, 24-hr.	1.35"	58	101"	91%
1-year, 24-hr.	1.60"	31	55"	95%
2-year, 24-hr.	2.00"	9	23"	98%

[2] The total rainfall from 1950 to 1977 was 1,100". The proportion of total represents the amount of rainfall accounted for by that storm size, and smaller sizes. For example the 1-month, 24-hour storm, and smaller storms, accounted for 1,100 - 415/1,100 = 62%.

Table AI-2.1 shows that relatively small storms account for a considerable proportion of the total rainfall; for example the 6-month, 24-hour, and smaller storms, accounted for over 90% of the total rainfall during the period 1950 through 1977; 98% of the rainfall was accounted for by storm sizes up to the 2-year, 24-hour storm. Of course the proportion of runoff produced by the rainfall for any particular surface type will increase with increasing storm size. On the other hand, smaller storms may tend to produce runoff with higher concentrations of some pollutants because of the "first flush" effect which may occur in highly impervious areas following a dry spell. Therefore, as a first approximation, it seems reasonable to simply assume that the proportion of rainfall is approximately equal to the proportion of runoff.

Having arrived at this point, the next step is to decide what is an appropriate runoff proportion to use in sizing the water quality storm. Ideally we would want to treat 100% of all runoff but the data in Table AI-2.1 show that the incremental proportion of rainfall (and hence runoff) accounted for rapidly diminishes for storm sizes larger than the 6-month, 24-hour storm. This means that the marginal costs for treating stormwater will rapidly increase when facilities are sized for storms larger than the 6-month, 24-hour storm. This point is demonstrated by considering a simple example using a one acre urban site with a curve number of 95 and time of concentration of 10 minutes. Using the SBUH method the following peak runoff rates and runoff volumes were obtained:

2 2 2 6 6 6

R0055564

Storm Event	Precip.	Peak Runoff	Volume
1-mo., 24-hr.	0.65"	0.061 cfs	1000 cu-ft
6-mo., 24-hr.	1.3"	0.21 cfs	3000 cu-ft
1-yr., 24-hr.	1.6"	0.28 cfs	4010 cu-ft
2-yr., 24-hr.	2.0"	0.38 cfs	5380 cu-ft

Since the treatment facility size will be in proportion to the peak runoff or runoff volume we can next compare the facility size required for each design storm with the proportion of total runoff generated by that and smaller storms (estimated from Table AI-2.1). (For this example we can use the total runoff volume as the indicator of required facility size.)

Storm Event	Facility Size	Proportion of Runoff
1-mo., 24-hr.	1000 cu-ft	62%
6-mo., 24-hr.	3000 cu-ft	91%
1-yr., 24-hr.	4010 cu-ft	95%
2-yr., 24-hr.	5380 cu-ft	98%

From this we can calculate that greatly diminishing returns are achieved by increasing the facility size beyond that needed for the 6-month, 24-hour storm. Sizing the facility for a 1-year, 24-hour storm instead of a 6-month storm requires an increase of about 33% for an increase of only 4% of volume treated from an already high value of approximately 90%. Further increasing the size to that required for the 2-year, 24-hour storm requires a further increment of about 36% for a further gain of only 3% in the long term runoff volume treated.

Therefore, as a first approximation, it seems reasonable to select the 6-month, 24-hour design storm as the Water Quality design storm.

(However, protection of beneficial uses in receiving waters will always be required. Therefore there may be instances, depending on the nature of the pollutants to be controlled and the receiving waters, that the 6-month storm will be deemed inadequate by the local government and/or Ecology or other State agencies. In these instances a larger design storm shall be chosen.)

Having selected the 6-month, 24-hour design storm as the first approximation, the next step is to determine a method for estimating the size of the storm, given that the isopluvial maps do not provide values for less than the 2-year storm. One method is to plot the logarithm of the return period against the precipitation value for the published storms - the 2, 5, 10, 25, 50 and 100-year frequencies. This was done for several locations around the Puget Sound basin - Bellingham, Everett, Seattle, Tacoma and Olympia. In each case a near perfect regression line was obtained, except that the slope and intercept varied in accordance with the differences in rainfall received at the various locations. Each regression line was then extrapolated to the 6-month frequency and rainfall value estimated. The ratio of the 6-month value to the 2-year value was then determined for each station. This ratio was found to average 0.64 with little variation between the stations. Therefore, for a rule of thumb method, the 6-month, 24-hour design storm can be estimated for any location within the Puget Sound basin as 0.64 times the 2-year, 24-hour storm value.

APPENDIX AI-2.2

ADDITIONAL BASIN PLANNING GUIDANCE AS APPLIED TO THE MINIMUM REQUIREMENTS

Basin Planning Applied to Source Control (Minimum Requirement #3)

Basin plans should identify potential sources of pollution and develop strategies to eliminate or control these sources to the fullest extent possible. At a minimum, a basin plan should include the following source control strategies:

(1) Detection and correction of illicit discharges to storm sewer systems, including the use of dry weather sampling and dye-tracing techniques;
(2) Identification of existing businesses, industries, utilities, and other activities which may store materials susceptible to spillage or leakage of pollutants into the storm sewer system;
(3) Elimination or control of pollutant sources identified in (2);
(4) Identification and control of future businesses, industries, utilities, and other activities which may store materials susceptible to spillage or leakage of pollutants into the storm sewer system;
(5) Training and Public education

Basin Planning Applied to Runoff Treatment (Minimum Requirement #4)

Basin plans should develop runoff treatment standards to reduce pollutant loads based on an evaluation of the water resources to be protected within or downstream of a watershed. The evaluation must include an analysis of existing and future conditions. Additional levels of control beyond Minimum Requirement #4 may be justified in order to control the impacts of future development. While direct cause-and-effect impacts will rarely be known for future development, standards should be developed based on an evaluation of pollutant loads and modeling of receiving water conditions.

Runoff treatment standards developed from a basin plan must apply to individual development sites. Regional treatment BMPs, in general, will not be considered an acceptable substitute for on-site treatment standards for two primary reasons. One is the stream systems upstream of regional facilities are defined as waters of the state and shall be protected (i.e., they are not to be considered as simply conveyance systems to the regional facility). Second, the pollutant removal effectiveness of regional treatment BMPs has not been demonstrated to be equivalent to on-site treatment BMPs. Regional BMPs may offer some advantages in construction and operation and maintenance costs and Ecology may approve such BMPs on a case-by-case basis.

On-site standards developed from basin planning can be flexible provided that the level of runoff treatment for all sites in a watershed is equivalent to that which would be achieved by Minimum Requirement #3. For example, site A may be able to achieve a higher pollutant load reduction goal than site B and this is acceptable provided that the two sites together achieve the equivalent level of treatment provided by the Minimum Requirement #3.

Basin plans shall evaluate retrofitting opportunities, such as installation of extended detention outlets for existing stormwater detention facilities.

Basin Planning Applied to Streambank Erosion Control (Minimum Requirement #5)

Basin planning is well-suited to control streambank erosion for both existing and future conditions. Streambank erosion control standards developed from a basin plan may include a combination of on-site, regional, and stream protection/rehabilitation

VOL 12 2 2268

R0055566

measures. On-site standards shall be the primary mechanism to protect streambanks from the impacts of future conditions. Regional streambank erosion control BMPs are to used primarily to correct existing downstream streambank erosion problems. Stream protection/rehabilitation measures may be applied wherever streambank erosion problems currently exist which will not be corrected by on-site or regional BMPs.

Basin Planning Applied to Wetlands and Water Quality Sensitive Areas (Minimum - Requirements #6 and #7, respectively)

Basin planning should be used to develop additional protection standards for wetlands and water quality sensitive areas. These standards must include source control, runoff treatment, and streambank erosion control standards. Additional standards may also be developed which are specific to the needs of the wetland or sensitive area to be protected, such as management of a wetland's hydrology and hydroperiods, establishment of buffer zones for wellheads, and ground water contributing and recharge zones, and management of streamflows for the benefit of fish populations.

CHAPTER I-3

PREPARATION OF STORMWATER SITE PLANS

I-3.1 INTRODUCTION

The purpose of this chapter is to provide summarized guidelines on how Erosion and Sediment Control (ESC) Plan and Permanent Stormwater Quality Control (PSQC) Plans, the plans which make up a Stormwater Site Plan (SSP) can be prepared. The thresholds and Minimum Requirements for these plans are described in detail in Chapter I-2. More details on plan preparation with examples of forms and submittal requirements are provided in the "Stormwater Program Guidance Manual for the Puget Sound Basin", (known hereafter as the Guidance Manual), a companion manual to this technical manual available from the Urban Nonpoint Management Unit.

The goal of this chapter is to provide a framework for uniformity in plan preparation. Such uniformity will promote predictability throughout the region and help secure prompt governmental review and approval. Properly drafted engineering plans and supporting documents will also facilitate the operation and maintenance of the proposed system long after its review and approval.

Please note that this chapter describes <u>how</u> to prepare a Stormwater Site Plan - the specific BMPs and design methods and standards to be used are contained in Volumes II-IV. ESC plans are covered in detail in Chapter II-4, and an example ESC plan is shown (to be drafted) in the Guidance Manual. Guidelines for selecting BMPs are given in Chapter I-4. Note also that all plans, except small parcel plans, shall be stamped by a professional engineer licensed in the State of Washington. All land boundary surveys used, and any legal descriptions prepared, except those for small parcels, must be stamped by a professional land surveyor licensed in the State of Washington.

I-3.2 REQUIREMENTS AND CONTENTS OF STORMWATER SITE PLANS

Three types of stormwater site plans are covered here. The first is a Small Parcel Erosion and Sediment Control (SPESC) Plan. Small parcels, such as individual single family dwellings cause water quality problems during the construction period rather than after construction (except in aggregate, which is addressed elsewhere). As a result, the small parcel Minimum Requirements (Chapter I-2) and Small Parcel BMPs (Chapter II-4) intentionally address ESC-related concerns.

The second type of plan is a hybrid of the simpler Small Parcel ESC and the more elaborate Stormwater Site Plan (SSP). Proposed developments with >5,000 ft^2 of impervious surface and land disturbing activities of <1 acre planned shall implement the Small Parcel ESC Plan. The Minimum Requirements for these plans are found in section I-2.2. In addition to the Small Parcel ESC Plan, developments of this size are required to implement a full-scale Permanent Stormwater Quality Control Plan (PSQC) which satisfies the remaining Minimum Requirements found in Chapter I-2.

Lastly, new development or redevelopment which meets the criteria set forth in Section I-2.4 must develop and implement both a full-scale ESC and SSP.

I-3.3 SMALL PARCEL EROSION AND SEDIMENT CONTROL PLANS

The following new development shall be required to control erosion and sediment during construction, to permanently stabilize soil exposed during construction, to comply with the Small Parcel Requirements 1 through 4, and to prepare a SPESC:

VOL 12 2 2 2 7 1 1

R0055569

Figure I-3.1 Checklist for Small Parcel Minimum Requirements (adapted from the City of Redmond)

The applicant shall submit two copies of a site improvement and drainage plan on 8½ by 11" paper showing the following:

- ☐ Provide the name, address, and phone number of owner or contact person.
- ☐ Designate north arrow, lot number and plat, address, date and street name fronting structure.
- ☐ Show all proposed structures and any existing structures on the site.
- ☐ Locate and size all streams, swales or drainage channels on or within 25 feet of the site which may involve or affect the drainage of the site to be developed. Indicate all existing stormwater pipes.
- ☐ Indicate the direction and location of surface water runoff entering the site from all adjacent property.
- ☐ Indicate what type of system(s) will be used to convey runoff away from the proposed structures.
- ☐ Phase clearing so that only those areas that are actively being worked are uncovered. From October 1 through April 30, no soils shall remain exposed for more than 2 days. From May 1 through September 30, no soils shall remain exposed for more than 7 days.
- ☐ Indicate where excavated basement soil stockpiles (if applicable) will be located. The stockpile should be covered until the stockpile is either used or removed. Piles should be situated so that sediment does not run into the street or adjoining yards.
- ☐ Backfill basement walls, where applicable, as soon as possible and rough grade the lot.
- ☐ Remove excess soil from the site as soon as possible after backfilling.
- ☐ Stabilize denuded areas of the site by mulching, seeding, planting, or sodding.
- ☐ Adjacent properties shall be protected from sediment deposition by appropriate use of vegetative buffer strips, sediment barriers or filters, dikes or mulching, or by a combination of these measures and other appropriate BMPs.
- ☐ If a lot has a soil bank higher than the curb, a trench or berm should be installed moving the bank several feet behind the curb. This will reduce the occurrence of gully and rill erosion while providing a storage and settling area for stormwater.
- ☐ Construction vehicle access shall be, whenever possible, limited to one route. Indicate the location of the construction entrance. Apply gravel or crushed rock to the driveway area and restrict truck traffic to this one route. Driveway paving can be installed directly over the gravel. This measure requires periodic inspection and maintenance including washing, top-dressing with additional stone, reworking and compaction.

VOL 12 2 2212

R0055570

- Provide for periodic street cleaning to remove any sediment that may have been tracked out. Sediment should be removed by shovelling or sweeping and carefully removed to a suitable disposal area where it will not be re-eroded.

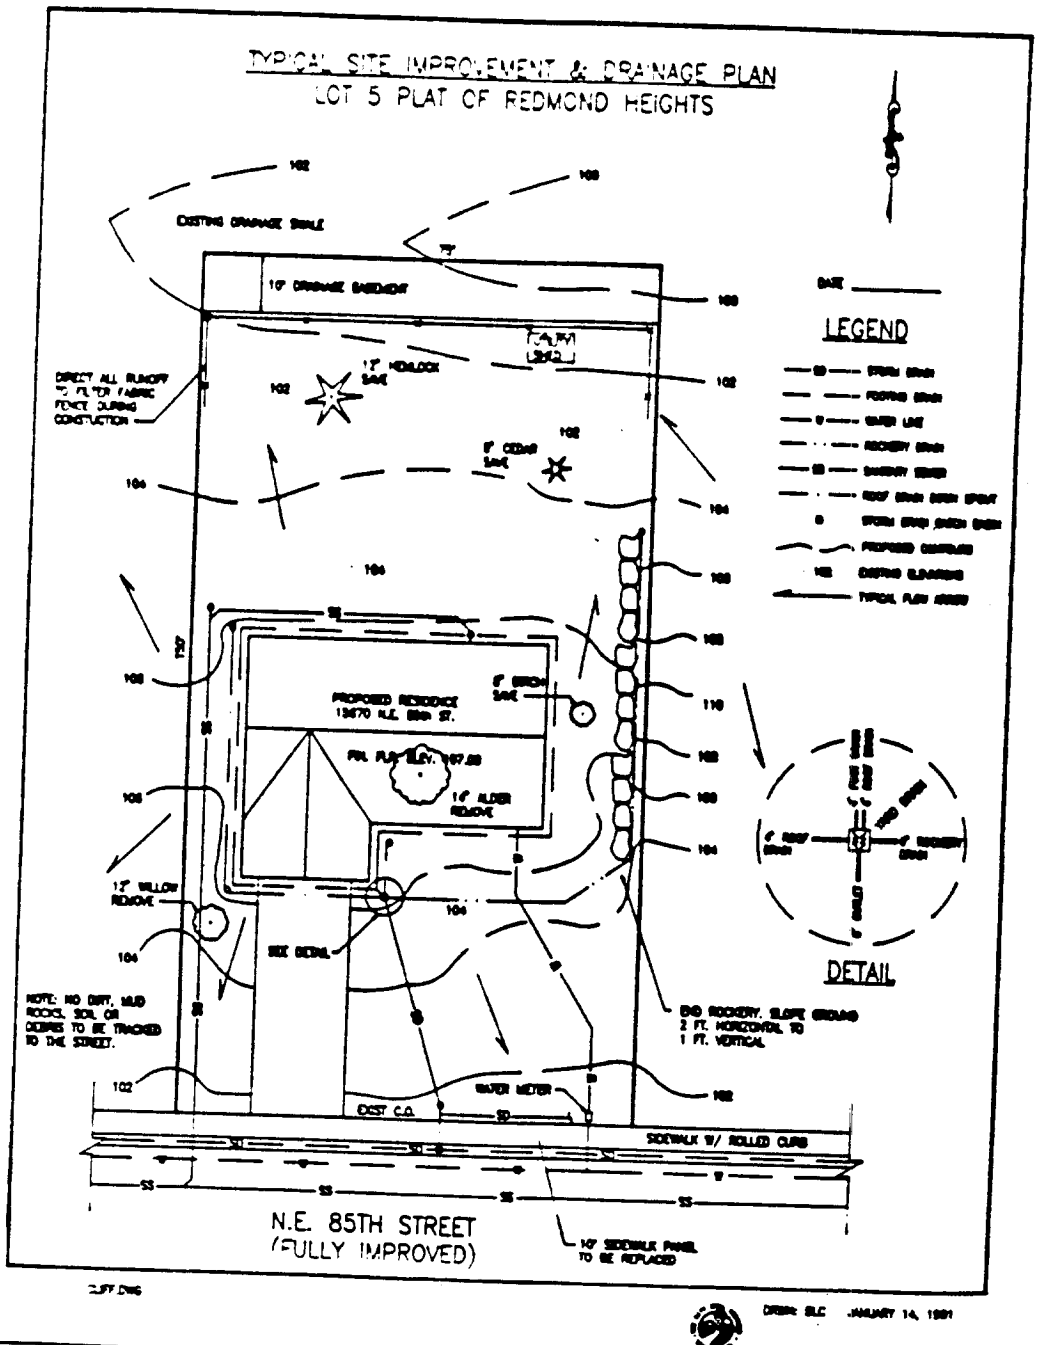
- Inspect all erosion and sediment control BMPs installed regularly, especially after any large storm. Maintenance, including removal and proper disposal of sediment should be done as necessary (generally when one-half or more of the total capacity of the system is filled with sediment).

For further information on small parcel BMPs, please see Chapter II-5, Section II-5.10.

VOL 12 2 2713

R0055571

Figure I-3.2 Typical Site Improvement and Drainage Plan



VOL 12 2 2714

R0055572

(a) Individual, detached, single family residences and duplexes.
(b) Creation or addition of less than 5,000 square feet of impervious surface area.
(c) Land disturbing activities of less than 1 acre.

The contents of a Small Parcel ESC Plan will depend upon the exact nature of the project. It will generally contain some elements of the full ESC as determined by the local government. The Small Parcel ESC must describe how the small parcel erosion control requirements will be met.

A Small Parcel ESC Plan should contain a plot plan which includes:

- A vicinity map to clearly locate property
- An accurate location of the structure and its access
- All applicable setback requirements
- Location of all applicable ESC BMPs
- Existing site features or water quality sensitive areas, if appropriate.

The checklist found in Figure I-3.1 can also be used.

All proposed developments where >5,000 ft^2 of impervious surface and land disturbing activities of <1 acre are planned, shall implement the Small Parcel Requirements found in section I-2.2. In addition to the Small Parcel ESC Plan, developments of this size are required to implement a full-scale Stormwater Site Plan which satisfies the remaining Minimum Requirements found in Chapter I-2.

I-3.4 LARGE PARCEL EROSION AND SEDIMENT CONTROL PLANS

As set forth in Chapter I-2, all new development and redevelopment that includes *land disturbing activities* over an area 1 acre and greater requires an ESC Plan as a subset of the Stormwater Site Plan (SSP). Land disturbing activities are defined as any activity that results in a change in the existing soil cover (both vegetative and nonvegetative) and/or the existing topography. Land disturbing activities include construction, clearing, grading, filling, and excavation.

A Large Parcel Erosion and Sediment Control Plan (ESC Plan) shall provide for the interception and treatment of all potential silt-laden runoff that could occur during clearing, grading, construction and site stabilization. The ESC Plan must provide measures to assure that no silt-laden runoff leaves the site during construction and stabilization. As mentioned earlier, if only land disturbing activities are proposed, only a LPESC Plan is required. Also, relevant parts of the SSP should be included when only a ESC Plan is required, these include a plot plan and preliminary conditions summary.

A Large Parcel Erosion and Sediment Control Plan should, at a minimum, include the following:

- Location of clearing limits and easements, setbacks, water quality sensitive areas and their buffers.
- Locations and descriptions of all erosion and sediment control measures for each phase of construction.
- Cross sections of fill or excavations.

ESC plans are explained in detail in Chapter II-4, and an example ESC Plan (to be drafted) is shown in the Guidance Manual.

I-3.5 STORMWATER SITE PLANS

The Puget Sound Water Quality Management Plan (PSWQMP) requires that all jurisdictions within the Puget Sound Basin adopt ordinances requiring stormwater controls (for example, site plans, including ESC plans) for all new development and redevelopment as defined below.

New Development Standard

New development - means the following activities: land disturbing activities, structural development, including construction, installation or expansion of a building or other structure; creation of impervious surfaces; Class IV - general forest practices that are conversions from timber land to other uses; and subdivision, short subdivision and binding site plans, as defined in Ch.58.17.020 RCW. All other forest practices and commercial agriculture are not considered new development.

All new development that includes the creation or addition of 5,000 square feet, or greater, of new impervious surface area, and/or land disturbing activity of one acre or greater, shall comply with Minimum Requirements #1 through #11 in Sections I-2.5 through I-2.15 and prepare a Stormwater Site Plan.

All new development that includes the creation or addition of 5,000 square feet, or greater, of new impervious surface area, and land disturbing activity of less than one acre, shall comply with Minimum Requirements #2 through #11 in Sections I-2.6 through I-2.15 and the Small Parcel Minimum Requirements found in section I-2.2, above. This category of development shall also prepare a Stormwater Site Plan that includes a Small Parcel Erosion and Sediment Control Plan.

This section does not apply to the construction of individual, detached, single family residences and duplexes. Those types of new development are included in the Small Parcel Minimum Requirements.

Redevelopment Standard

Redevelopment - means, on an already developed site, the creation or addition of impervious surfaces, structural development including construction, installation or expansion of a building or other structure, and/or replacement of impervious surface that is not part of a routine maintenance activity; and land disturbing activities associated with structural or impervious redevelopment.

A. Where redevelopment of ≥ 5,000 square feet occurs:

   The new development Minimum Requirements, Sections I-2.5 through I-2.15, shall apply to that portion of the site that is being redeveloped, and source control BMPs shall be applied to the entire site, including adjoining parcels if they are part of the project.

B. Where one or more of the following conditions apply, a Stormwater Site Plan shall be prepared that includes a schedule for implementing the Minimum Requirements to the maximum extent practicable, for the entire site, including adjoining parcels if they are part of the project. An adopted and implemented basin plan (Minimum Requirement #9) may be used to develop redevelopment requirements that are tailored to a specific basin.

VOL 12 2 2282

R0055580

1. Existing sites greater than 1 acre in size with 50% or more impervious surface.

2. Sites that discharge to a receiving water that has a documented water quality problem.

A documented water quality problem includes, but is not limited to water bodies:

(i) Listed in reports required under section 305(b) of the Clean Water Act, and designated as not supporting beneficial uses;

(ii) Listed under section 304(l)(1)(A)(i), 304(l)(1)(A)(ii), or 304(l)(1)(B) of the Clean Water Act as not expected to meet water quality standards or water quality goals;

(iii) Listed in Washington State's Nonpoint Source Assessment required under section 319(a) of the Clean Water Act that, without additional action to control nonpoint sources of pollution cannot reasonably be expected to attain or maintain water quality standards.

3. Sites where the need for additional stormwater control measures has been identified through a basin plan.

The Stormwater Site Plan (SSP) should be a comprehensive report containing all technical information and analysis necessary to evaluate the proposed stormwater facilities. In addition, the SSP should provide the necessary information to prepare final construction plans, profiles, details, notes and specifications for all stormwater facilities.

The Stormwater Site Plan contains the following sections:

I. Project Overview
II. A plot plan, including:
- locations of structures, other impervious surfaces
- locations of stormwater runoff control facilities
- lot layout
- setback requirements
- existing site features
- water quality sensitive areas
- road rights-of-way and easements

III. Preliminary Conditions Summary
IV. Off-Site Analysis
V. Analysis and design of proposed stormwater runoff control facilities, including treatment and source control BMPs, and streambank erosion control requirements.
VI. Special Reports and Studies
VII. Basin and Community Planning Areas
VIII. Other Permits
IX. Erosion and Sediment Control Plan (see I-3.4)
X. Bond Quantities Worksheet, Retention/Detention Facility Summary Sheet and Sketch, and Declaration of Covenant
XI. Maintenance and Operations Manual

The SSP must be stamped and dated by a professional civil engineer licensed in the State of Washington. Every SSP should contain each of the sections listed above.

VOL 12 2 2283

R0055581

If a section does not apply, the applicant may simply mark with "N/A." This standardized format will allow a quicker, and more efficient review of information. A consistent format will also provide accurate, time efficient researching of SSPs approved for other projects in the same basin.

Additional information may be required if the development impacts water quality sensitive areas. The extent of the additional information which will be required can be estimated at the initial application screening, but not determined definitively until as late as the SEPA Threshold Determination.

For further details on the SSP consult the local government, and the Guidance Manual.

I-3.6 OTHER PERMITS AND PLAN REQUIREMENTS

Other agencies, such as those listed below, may require a stormwater site plan to describe the proposed project's impact on surface, ground and stormwater. The applicant should take care to note that these other agency requirements are separate from, and in addition to, the local government's requirement for a stormwater site plan. The applicant is responsible to coordinate joint agency review. Some permits or applications can be reviewed simultaneously by more than one agency; others may require the applicant to obtain one type of permit or approval prior to another agency's review. Agency Permit/Approvals that may be necessary include but are not limited to:

AGENCY	REQUIREMENT
Washington State Department of Transportation	Developer/Local Agency Agreement
Washington State Department of Ecology	Short Term Water Quality Modification Approval and/or Dam Safety Permit
Washington State Department of Fisheries	Hydraulic Project Approval
Washington State Department of Wildlife	Hydraulic Project Approval
United States Army Corps of Engineers	Section 404 Permit & Section 10 Permit/letter of permission

The publication "Commonly Required Environmental Permits for Washington State" #90-29 is now available from the Department of Ecology. It covers these permit requirements (and many more) in a general fashion, and directs the reader to the proper agency for assistance.

CHAPTER I-4

BMP SELECTION PROCESS FOR PERMANENT STORMWATER QUALITY CONTROL PLANS

I-4.1 INTRODUCTION

The purpose of this chapter is to provide guidance for selecting permanent BMPs for new development and redevelopment sites (including retrofitting of redevelopment sites). The task of selecting BMPs is necessary in order to complete the Permanent Stormwater Quality Control Plan, an important component of the Stormwater Site Plan (see Chapters I-2 and I-3 for guidance on these plans). Please note that guidelines for the Erosion and Sediment Control Plan and appropriate BMPs are not covered in this chapter; for guidance on these BMPs refer to Volume II of this manual.

Ecology's pollution control strategy is to first emphasize pollution *prevention* and, second, pollution *treatment*. By preventing pollution from occurring in the first place the need for treatment can be reduced or, in some cases, eliminated. The three stormwater control objectives that are intended to implement this strategy, and the classification of BMPs for each objective, are the following:

(i) Pollution prevention using *source control* BMPs
(ii) Pollution treatment using *runoff treatment* BMPs
(iii) Protection of stream ecosystems from erosion and sedimentation using *streambank erosion control* BMPs

The classification system for BMPs is presented in Section I-4.2. A step-by-step process for selecting BMPs is provided in Section I-4.3.

I-4.2 CLASSIFICATION OF BMPs

BMPs have been classified based on their ability to implement the pollution control strategy described above. Pollution prevention is accomplished through the use of source control BMPs. Treatment is provided by runoff treatment BMPs. A third classification that overlaps both prevention and treatment is that of streambank erosion control. Figure I-4.1 provides a schematic of the classification system and Table I-4.1 lists the BMPs according to this system.

Note: Table I-4.1 does not include natural and created wetlands as these are not considered to be BMPs. The primary stormwater management objective for natural wetlands will be to protect or enhance the beneficial uses of these systems. This means that stormwater must be treated prior to discharge to these wetlands. It does not mean that stormwater discharges to natural wetlands are prohibited; if this were to occur then these wetlands would be severely damaged or lost. See Minimum Requirement #6 and Chapter III-5 for stormwater management guidance for natural wetlands.

Table I-4.1 does include a Constructed Wetland (BMP RD.09); this is an artificial wetland located on a non-wetland site for the exclusive purpose of managing stormwater. Created wetlands designed for a mitigation project should not be used for stormwater treatment as stormwater may be detrimental to the beneficial uses being mitigated for (e.g. wildlife habitat or contact recreation).

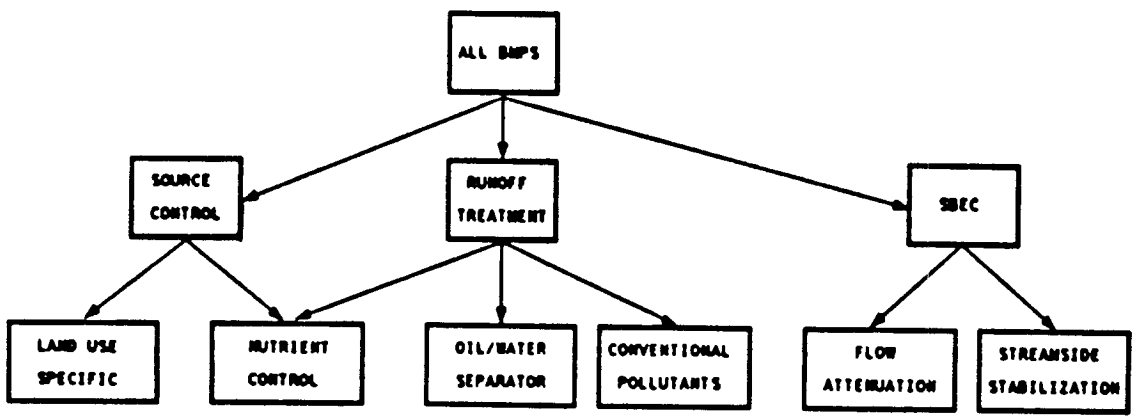
VOL 12 2 2900

I-4.2.1 Source Control BMPs

Source control BMPs are designed to prevent pollutants from entering stormwater by eliminating the source of pollution or preventing contact of pollutants with rainfall and runoff. Source control BMPs are either specific to the type of land use being proposed for development or are intended to control a specific type of pollution problem existing within a watershed, such as nutrients that may contribute to eutrophication. Examples of source control BMPs include reducing or eliminating use of a pesticide, covering areas used to store chemicals, and street sweeping during dry weather conditions.

Figure I-4.1
Classification of Stormwater BMPs



I-4.2.2 Runoff Treatment BMPs

Runoff treatment BMPs are designed to remove pollutants that are contained in runoff. Treatment BMPs utilize a variety of mechanisms to remove pollutants from stormwater including sedimentation, filtration, plant uptake, ion exchange, adsorption, and bacterial decomposition. Examples of runoff treatment BMPs include infiltration trenches, wet ponds, biofiltration swales, and vegetative filter strips. The goal of runoff treatment BMPs is to provide effective treatment of at least 90 percent of the runoff generated by development. To achieve this goal, these BMPs are sized to treat the 6-month, 24-hour design storm (also referred to as the water quality design storm, or the runoff treatment design storm).

Ecology has identified two categories of pollutants that are targeted for runoff treatment; "conventional" pollutants and "nutrients." Conventional pollutants are those that are typically associated with particulates and that can be treated by a range of BMPs. Examples of conventional pollutants are total suspended solids, heavy metals, and fecal coliform. Nutrients, on the other hand, exist in both suspended and dissolved phases and can be more difficult to control. Examples of

R0055588

nutrients are phosphorus and nitrogen. Nutrients can be a concern for both surface water and ground water. Eutrophication of lakes is typically caused by nutrients and ground water contamination by nitrates is also a common problem.

A subcategory of runoff treatment BMPs is those that provide pretreatment in order to protect primary treatment BMPs from siltation. The selection of pretreatment BMPs is described further in the BMP selection process (Section I-4.3) and illustrated in Table I-4.6.

A special category of runoff treatment BMPs includes those designed to remove oil contained in runoff. Oil, being lighter than water, typically floats on top of the water column and different removal techniques may be needed for treatment. Oil will, however, often adhere to suspended solids. Oil concentrations in urban runoff are often too low to justify the use of oil/water separators, but some land uses may require these BMPs, especially when the possibility of spills is present. There are three basic types of oil/water separators. Spill control (SC-type) are designed only to capture spills, while API and CPS-type separators are specifically designed to remove free oil from the water column. Sand filtration BMPs are currently allowed as an interim alternative to API and CPS oil/water separators in this edition of the manual. The ability of sand filtration to remove free oil shows promise but is under further investigation.

I-4.2.3 Streambank Erosion Control BMPs

Streambank erosion control (SBEC) BMPs are designed to prevent or control the excessive erosion that typically occurs in streams located in urbanizing watersheds. This erosion results not only because of the dramatic increase in peak flow rates from runoff but also due to increases in the frequency and duration of high flow conditions. Conventional flood control ponds are only marginally effective at controlling streambank erosion because they control only peak flow rates. The goal of streambank erosion control BMPs is to replicate, to the extent possible, the pre-existing hydrologic regime in streams by attenuating runoff from development sites and slowly releasing it back to the natural system.

The two-year return period storm has been identified as a key event for controlling streambank erosion. The two-year storm is typically the event in which streams are flowing "bankfull," a highly erosive condition. Urbanization increases the frequency and duration of bankfull conditions, thus greatly accelerating the streambank erosion process. Larger storms, such as the 10-year and 100-year events, are also important for streambank erosion control. These storms may periodically alter the morphology of streams and are important for the transport and deposition of sediments necessary for the ecological health of stream systems.

Ecology's streambank erosion control standards attempt to replicate, to the extent practicable, the stream flow conditions that would occur under natural conditions for specified design storms. Accordingly BMPs are to be designed to meet the following on-site detention requirements:

- Limit the peak rate of runoff to 50 percent of the *existing site condition* 2-year, 24-hour design storm, with a correction factor applied;
- Maintain the peak flow rate of runoff for the *existing site condition* 10-year and 100-year, 24-hour storms, with a correction factor applied.

The correction factor is applied to the BMP volume and should range from 20 to 50 percent for sites with impervious cover ranging from 20 to 100 percent. A correction factor is necessary to account for the inadequacies of current hydrologic analysis methods. Improved methods are under development and should be available no later than 1993. See Chapter III-1 for more details.

VOL 12 2291

R0055589

Definition: Existing site condition means - (a) For developed sites with stormwater facilities that have been constructed to meet the standards in the Minimum Requirements of this manual, existing site conditions shall mean the existing conditions on the site.

(b) For developed sites that do not have stormwater facilities that meet the Minimum Requirements, existing site conditions shall mean the conditions that existed prior to local government adoption of a stormwater management program. If in question, the existing site conditions shall be documented by aerial photograph records, or other appropriate means.

(c) For all sites in water quality sensitive areas as identified under Minimum Requirement #7, Water Quality Sensitive Areas, existing site conditions shall mean undisturbed forest, for the purpose of calculating runoff characteristics.

(d) For all undeveloped sites outside of water quality sensitive areas, existing site conditions shall mean the existing conditions on the site.

Ecology recognizes, however, that the flow attenuation criteria described above may not be adequate in itself to protect streams since, in many cases, damage may have already occurred. To partially address this, a group of *streamside stabilization* BMPs are provided that are designed to correct *existing* problems (see Table I-4.1).

An additional point to keep in mind is that site-specific BMPs designed to meet the above criteria may only be partially effective at controlling the cumulative effects of runoff from all sites in a watershed. For effective control of streambank erosion it may be necessary to develop and implement watershed-wide strategies that address impacts from both new and existing development on a regional level. Minimum Requirement #9, Basin Planning, is intended to facilitate such strategies.

I-4.2.4 Infiltration

Infiltration is Ecology's highest priority for both runoff treatment and streambank erosion control, provided proper conditions exist for its use. Infiltration can provide multiple benefits, including pollution removal, control of streambank erosion, ground water recharge, and flood control. One condition that can limit the use of infiltration is the need to protect ground water quality. No discharge of *untreated* stormwater to ground water will be allowed. To adequately address the protection of ground water when evaluating infiltration it is important to understand the difference between soils that are suitable for runoff treatment or streambank erosion control, or both. Sufficient organic content to remove pollutants must be present for soils to provide runoff treatment. Examples are silty and sandy loams. These soils may have fairly low percolation rates that could render them infeasible for infiltrating the large volumes of runoff required for streambank erosion control. Coarser soils, such as gravelly sands, can provide streambank erosion control but are wholly inadequate for providing treatment of runoff. The use of coarser soils for infiltrating runoff is allowable, but runoff treatment must *always* precede discharge to these soils. Thus, there will be instances when soils are suitable for treatment but not streambank erosion control, and vice versa.

I-4.2.5 On-line vs. Off-line Configuration

Some BMPs can combine runoff treatment and streambank erosion control into the same facility or can be located together in series; either of these configurations will be called "on-line" systems. In other cases runoff treatment must be provided separate from streambank erosion control; an "off-line" system. On-line systems are typically detention-type BMPs that maintain a "permanent pool" of water for runoff treatment purposes and also have a "live storage" volume above the permanent pool to temporarily detain runoff for streambank erosion control purposes (See Figure I-4.2

VOL 12 2 2292

R0055590

for an illustration of "dead" and "live" storage concepts). Off-line systems are typically those that are not capable of providing streambank erosion control (e.g., water quality infiltration trench) or whose pollutant removal mechanisms are not compatible with providing streambank erosion control (e.g., oil/water separator). The decision as to which configuration to use is discussed in the description of each individual BMP provided in Chapters III-3 through III-7.

The ability of detention-type BMPs to provide both runoff treatment and streambank erosion control into the same facility can be an important one. This feature can be useful for controlling stormwater pollution from existing development sites by retrofitting existing flood control ponds to provide extended detention of the 6-month, 24-hour storm.

I-4.3 STEP-BY-STEP SELECTION PROCESS FOR BMPS

A five step BMP selection process is presented that uses the classification scheme presented in Figure I-4.1. A summary of the steps is depicted in Figure I-4.3; a detailed description follows.

I-4.3.1 STEP 1: DETERMINE STORMWATER CONTROL SCENARIO FROM TABLE I-4.2

The purpose of Step 1 of the BMP selection process is to determine if some or all of the three stormwater control objectives are to be achieved by an individual development, i.e., Source Control, Runoff Treatment, and Streambank Erosion Control.

Use Table I-4.2 to evaluate the eight possible stormwater control scenarios that could apply to a development site. The table presents the appropriate classification and sequence of runoff control BMPs required for each scenario. Upon completion, the user can then proceed to Step 2 to select individual BMPs.

STEP 1A: Determine if Oil/Water Separator BMPs are Required Based on Land Use Type

The requirement to use oil/water separators is dependent upon the specific land use proposed for development. Volume IV describes all of the major urban land use types (both public and private) that are likely to occur in either a proposed new development or in an existing development. While a number of activities may require the use of spill control (SC-type) separators, only a few will necessitate API or CPS-type separators. At a minimum, the following land use types have been identified as requiring API or CPS-type oil/water separators:

- Industrial Machinery and Equipment, Trucks and Trailer Aircraft, Parts and Aerospace, Railroad Equipment
- Log Storage and Sorting Yards
- Airfields and Aircraft Maintenance
- Fleet Vehicle Yards
- Railroads
- Gas Stations
- Retail/Wholesale Vehicle and Equipment Dealers
- Vehicle Maintenance and Repair
- Construction Businesses (paving, heavy equipment storage and maintenance, storage of petroleum products)

As an alternative to an API or CPS-type oil/water separator, a sand filtration BMP may be used to provide treatment of oil *(Note: This alternative is being recommended on an interim basis and further evaluation is necessary)*. See Chapter III-3 for more information on sand filters.

Figure I-4.3 Summary of Steps for BMP Selection Process

PRELIMINARY STEP: Review Chapter I-2 prior to starting the BMP selection process.

STEP 1: Determine Stormwater Control Scenario from Table I-4.2

STEP 1A: Determine if Oil/Water Separator BMPs are Required based on Land Use Type

STEP 1B: Determine if Nutrient Control is Required *in addition* to Treatment of Conventional Pollutants

STEP 1C: Determine if Streambank Erosion Control is Required

STEP 1D: Determine Final Stormwater Control Scenario from Table I-4.2

STEP 2: Select Source Control BMPs

STEP 2A: Select Source Control BMPs based on Land Use Type

STEP 2B: Select Source Control BMPs for Nutrient Control, if required, as determined from Step 1B

STEP 2C: Prepare Final Source Control BMP List

STEP 3: Select Runoff Treatment and Streambank Erosion Control BMPs

STEP 3A: Select type of Oil/Water Separator, if required, as determined in Step 1A

STEP 3B: Determine initial order of preference of runoff treatment BMPs from Table I-4.4

STEP 3C: Determine initial order of preference of streambank erosion control BMPs from Table I-4.5

STEP 3D: Screen BMPs based on Comparative Stormwater Benefits and Restrictions using Table I-4.6

STEP 3E: Screen Runoff Treatment and Streambank Erosion Control BMPs based on Other Physical Factors

STEP 3F: Prepare Modified BMP List

STEP 3G: Prepare Final BMP List

STEP 4: Complete Stormwater Site Plan

STEP 4A: Complete Permanent Stormwater Quality Control Plan

STEP 4B: Review other Stormwater Site Plan requirements

STEP 4C: Complete Stormwater Site Plan

STEP 5: Submit Final Stormwater Site Plan to the Plan Approval Authority

5. O/W Separator Required:	YES	
Nutrient Control Required:	NO	Source Control → O/W Separator → Runoff Treatment (Conventional)
Streambank Erosion Control:	NO	
6. O/W Separator Required:	YES	
Nutrient Control Required:	NO	Source Control → O/W Separator → Runoff Treatment → SBEC (Conventional)
Streambank Erosion Control:	YES	
7. O/W Separator Required:	YES	
Nutrient Control Required:	YES	Source Control → O/W Separator → Runoff Treatment → SBEC
Streambank Erosion Control:	YES	(including nutrients) (Nutrients)
8. O/W Separator Required:	YES	
Nutrient Control Required:	YES	Source Control → O/W Separator → Runoff Treatment
Streambank Erosion Control:	NO	(including nutrients) (Nutrients)

Explanation:

SBEC = "Streambank Erosion Control"

O/W separator requirement is based on specified land uses. See Step 1A.

Runoff treatment requirement is to provide treatment of the 6-month, 24-hour design storm. Requirement for nutrient control is determined by local government of Plan Approval Authority. See Step 1B.

Streambank erosion control requirement determined by local government of Plan Approval Authority. See Step 1C.

Nutrient treatment is *in addition* to treatment of conventional pollutants. See Step 1B.

R0055594

VOL 12 2 2296

STEP 1B: Determine if Nutrient Control is Required in Addition to Treatment of Conventional Pollutants

The requirement to provide nutrient control is determined by the Plan Approval Authority. In general, nutrient control will be needed for surface waters if eutrophication is a concern, or for drinking water supplies (surface or ground) if the threat of nitrate contamination exist. The decision to require nutrient control should be based on an assessment of receiving water bodies within the local government's jurisdiction. Should nutrient control be mandated then both Source Control and Runoff Treatment BMPs shall be required. Sources of information used to make this determination should include, at a minimum, the following:

(i) Those waterbodies reported under section 305(b) of the Clean Water Act, and designated as not supporting beneficial uses;

(ii) Those listed under section 304(l)(l)(A)(i), 304(l)(l)(A)(ii), or 304(l)(l)(B) of the Clean Water Act;

(iii) Those listed in Washington State's Nonpoint Source Assessment required under section 319(a) of the Clean Water Act.

(iv) Sites where the need for additional stormwater control measures has been identified through a basin plan, the watershed ranking process under Ch. 400-12 WAC, or through Growth Management Act planning.

STEP 1C: Determine if Streambank Erosion Control is Required

There are two decisions that must be made in this step. First, is attenuation of peak flows required per Minimum Requirement #5? Second, is there an *existing* streambank erosion problem that requires corrective action?

For attenuating runoff flows, streambank erosion control will be required when stormwater discharges are made either directly or indirectly through a conveyance system into a stream. The streambank erosion control requirement is established by the Plan Approval Authority. Situations where streambank erosion control may not be required are when there is a direct discharge to a bay, lake, or Puget Sound. A discharge to a regional detention pond could also waive this requirement, but only if the pond is designed to provide a level of protection to downstream segments equivalent to Ecology's streambank erosion control requirement.

In cases where a streambank erosion problem already exists, streamside stabilization measures may be required. The selection and design of these BMPs will be made on a case-by-case basis. Where basin plans (see Minimum Requirement #9) have been implemented there may be different or additional streambank erosion control standards.

STEP 1D: Determine Stormwater Control Scenario from Table I-4.2

There are eight (8) possible outcomes, or stormwater control scenarios, from the determinations made in Steps 1A, 1B, and 1C. Table I-4.2 summarizes each scenario and defines the classification and sequence of BMPs that are to be used for each.

I-4.3.2 STEP 2: SELECT SOURCE CONTROL BMPs

Two different source control selections must be made in this step. First, select BMPs based on the type of land use proposed for development. Land use-specific source control BMPs are required for all developments. Second, select source control BMPs to provide control of nutrients, if necessary, as determined in Step 1B.

VOL 12 2 2291

R0055595

STEP 2A: Select Source Control BMPs based on Land Use Type

The first task for the user is to fill out a checklist that identifies the key activities that may result in stormwater contamination (see Table I-4.3). If the user is a private business, then examine the table of contents of Chapter IV-2 to locate the particular grouping in which that business falls. If the user is a public entity, then examine Chapter IV-3. After locating the particular grouping in which that business or public entity falls, turn to the page indicated to identify the appropriate source control BMPs (Table I-4.1 lists source control BMPs).

VOL 12 2 2298

VOL 12 2 2299

R0055597

Effective maintenance programs must be considered an integral part of a source control program. See, in particular, Chapters IV-3 and IV-4 for guidance on conducting maintenance.

STEP 2B: Select Source Control BMPs for Nutrient Control, if required, as determined from Step 1B

Sources of nutrients in urban runoff include fertilizers used for landscaping, grass clippings, leaf litter, car washing operations, and pet wastes. These sources should be managed to prevent contact with and transport by stormwater. Impervious areas adjacent to landscaped areas can be significant sources of nutrients when leaves and grass clippings are deposited on them. In addition, atmospheric deposition of nutrients onto impervious surfaces can generate significant amounts of pollution.

The following can be considered to be appropriate source control BMPs for nutrient control (see Chapter IV-4 for detailed guidance):

- BMP S1.90, Vegetation Management/Integrated Pest Management
- BMP S2.00, Maintenance of Storm Drainage Facilities
- BMP S2.20, Street Sweeping of impervious areas (e.g., curbs where accumulation of leaf litter occurs).

Additional maintenance guidance provided in Chapter IV-3 should also be considered and incorporated in this step.

STEP 2C: Prepare Final Source Control BMP List

Final selection of source control BMPs is made after consulting the detailed standards and specifications in relation to site specific conditions. For this the user is referred to Volume IV. A detailed description of each BMP will be found there that will enable final selections to be made.

I-4.3.3 STEP 3: SELECT RUNOFF TREATMENT AND STREAMBANK EROSION CONTROL BMPS

The goal of this step is to select BMPs that meet the runoff treatment and streambank erosion control requirements identified in Step 1D.

To avoid confusion, the selection of oil/water separators is made prior to selection of other BMPs. Note that a distinction is made between runoff treatment and streambank erosion control BMPs. It is important to understand the fundamental difference between these two functions when selecting BMPs. Some BMPs can combine both of these functions into the same facility. See the discussion in Section I-4.2.

STEP 3A: Select Type of Oil/Water Separator, if required, as determined from Step 1A.

Spill control (SC-type) separators will often be required in cases where storage of petroleum-based products occurs. API or CPS-type oil/water separators may be required where high traffic volumes or extensive use of petroleum-based products occur. A knowledge of the oil and grease characteristics (e.g., particle size, specific gravity) will be useful for selecting the correct type of separator. Consult Chapter III-7 for detailed design criteria. Sand filtration BMPs may also be used for treating oil in stormwater runoff on an interim basis (see Chapter III-3).

VOL 12 2 2300

R0055598

STEP 3B: Determine Initial Order of Preference of Runoff Treatment BMPs from Table I-4.4

Use Table I-4.4 to determine the initial order of preference for runoff treatment BMPs. The rationale for the initial order of preference is based primarily on the relative effectiveness of the various BMPs at removing pollutants. Note that a wider range of options exist if nutrient control is not required. Infiltration is the preferred practice for treatment, provided that proper soil conditions exist and ground water is adequately protected.

Table I-4.4 Initial Order of Preference of Runoff Treatment BMPs*

Rank	Nutrient Control Required	Nutrient Control Not Required
1	Infiltration (BMP RI.05, 10, 20, 30)	Infiltration (BMP RI.05, 10, 20, 30)
2	Constructed Wetland (BMP RD.09) or Wet Pond with marsh (BMP RD.06)	Constructed Wetland (BMP RD.09) or Wet Pond - with marsh (BMP RD.06) or Wet Pond - without marsh (BMP RD.05) or Biofiltration Swale (BMP RB.05) or Vegetative Filter Strip (BMP RB.10) or Sand Filtration (BMP RF.05 or RF.10)
3	(No other BMPs recommended)	Wet Vault/Tank (BMP RD.15)

* Pretreatment BMPs are not included in this list.

Note: BMPs with the same rank number have an equal level of preference, e.g., if nutrient control is not required then any of the six types of BMPs listed are equally acceptable.

STEP 3C: Determine Initial Order of Preference of Streambank Erosion Control BMPs

Use Table I-4.5 to determine the initial order of preference for streambank erosion control BMPs. Two types of streambank erosion control BMPs are illustrated, i.e., those that detain and *attenuate flows* and those that are used to *stabilize* eroding streambanks. The rationale for the initial order of preference is, in both cases, to replicate the natural condition to the maximum extent practical. Recall the restrictions on the use of infiltration, i.e., proper soil conditions must exist and ground water quality must be protected.

Table I-4.5
Initial Order of Preference of Streambank Erosion Control BMPs

Rank	Flow Attenuation	Streamside Stabilization
1	Infiltration (see Table I-4.1)	Vegetative Streambank Stabilization (BMP RS.05) or Bioengineering Method (BMP RS.10)
2	Detention (see Table I-4.1)	Structural Stabilization (BMP RS.15)

VOL 12 2 2301

R0055599

STEP 3D: Screen BMPs based on Comparative Stormwater Benefits and Restrictions

Use Table I-4.6 to evaluate the comparative benefits and restrictions that may apply to the types of BMPs selected in steps 3B and 3C (initial order of preference). This table provides important information such as whether a BMP can achieve control of nutrients as well as conventional pollutants, whether a BMP requires or provides pretreatment, and if streambank erosion control can be provided. Some BMPs can achieve multiple purposes while others cannot.

Note in Table I-4.6 that similarly named *infiltration* BMPs may serve different purposes. Ones that are labeled "WQ" (acronym for "Water Quality") are primarily intended to provide treatment of runoff and may not be appropriate for fully infiltrating the large volumes of runoff required for streambank erosion control. Water Quality (WQ) BMPs will typically have soils of relatively low permeability that contain organic matter; examples are silty and sandy loams. It is extremely important that they be protected from sedimentation that could clog the soil pore spaces; thus pretreatment is always required for Water Quality infiltration BMPs.

Infiltration BMPs that are labeled "SBEC" (an acronym for Streambank Erosion Control) are not suitable for runoff treatment and are to be used exclusively for providing streambank erosion control. These BMPs will typically utilize well drained soils that are low in organic material and are less prone to clog; examples are coarse sands and gravelly sands. Treatment of stormwater runoff must always precede discharge to SBEC infiltration BMPs.

A detailed description with design criteria for each runoff treatment and streambank erosion control BMP is provided in Volume III.

STEP 3E: Screen Runoff Treatment and Streambank Erosion Control BMPs based on Other Physical Factors

Two of the most important physical factors to consider are the total contributing catchment area and the types of soils on the site. Many BMPs can only be applied within relatively narrow ranges of catchment area and soil type, as shown in Tables I-4.7 and I-4.8. Note that in some situations a BMP may or may not be feasible and final selection should be based on a detailed examination of the site conditions and the standards and specifications.

Table I-4.9 presents a matrix that shows whether a BMP is also subject to other physical restrictions. Solid squares indicate that a factor is generally not a restriction while an unshaded square indicates that a restriction which may prohibit the use of a BMP. A partially shaded square indicates that a factor could restrict the use of a BMP, but careful site planning and BMP design may overcome the restriction.

As a general rule pond BMPs face fewer restrictions than do infiltration BMPs.

The nature of each of the physical factors outlined in the screens is described below.

BMP Drainage Area (Table I-4.7)

Pond BMPs generally require more drainage area than other BMPs. Infiltration trenches, vaults/tanks, and biofilters are more suitable for smaller areas. Wet pond-type BMPs located on small sites may lose their "permanent pool" during summer months but should retain the permanent pool during the winter months when the majority of rainfall occurs. Measures should be taken to ensure that the "shallow marsh" BMPs (BMP RD.06 and BMP RD.09) do not lose their vegetation during dry periods. See Chapter III-3 for further guidance.

VOL 12 2 2302

R0055600

TABLE I-4.6
COMPARATIVE STORMWATER MANAGEMENT BENEFITS AND RESTRICTIONS
FOR RUNOFF TREATMENT AND STREAMBANK EROSION CONTROL BMPs

BMP ID	BMP Name	Treats Conventional Pollutants?	Provides Nutrient Control?	Pre-treatment Required?	Provides Pre-treatment?	Provides SBEC?	Notes
RI.05	WQ Infiltration Basin	Yes	Yes	Yes	No	Option	Proper soil conditions required
RI.06	SBEC Infiltration Basin	No	No	No	No	Yes	Use of excessively drained soils

RS.05	Vegetative Streambank Stabilization	No	No	No	No	Yes	
RS.10	Bioengineering Methods of Streambank Stabilization	No	No	No	No	Yes	
RS.15	Structural Streambank Stabilization	No	No	No	No	Yes	

WQ = "Water Quality" SBEC = "Streambank Erosion Control"

1 Can be used for pretreatment of oil to protect wet pond-type BMPs from siltation
2 Exception is when oil/water separators are required for specific land uses (see Volume IV)
3 Provides *pretreatment* only
4 Not an acceptable pretreatment BMP for water quality infiltration BMPs
5 Provides *oil treatment* only
6 Assumes low influent concentration of suspended solids.

R0055601

It should be noted that the drainage area served does not have to be fixed. By creatively using local topography and drainage the catchment area can be varied. For example the drainage of a site could be divided to facilitate use of infiltration trenches. However, this technique may not be used to justify use of a vault or tank.

Soil Type (Table I-4.8)

The permeability of the soil underlying a BMP has a profound influence on its effectiveness. This is particularly true for infiltration BMPs, that are best suited in silty to loamy soils for *runoff treatment* and coarser soils for *streambank erosion control*. They cannot be used on sites that have final infiltration rates (f) of less than 0.5 inches per hour. Wet pond-type BMPs will need to be lined when located over permeable soils in order to maintain a permanent pool. Likewise, biofiltration-type BMPs may need to be lined so that runoff is not lost to infiltration before adequate treatment has taken place.

Other Physical Factors (Table I-4.9)

Slope

Steep slopes restrict the use of several BMPs. For example, biofiltration swales must be situated on sites with slopes of less than 5%. Infiltration BMPs are not suitable when the slope exceeds 15%.

High Water Table

The water table acts as an effective barrier to exfiltration and can sharply reduce the efficiency of an infiltration system. If the high water table extends to within three (3) feet of the bottom of an infiltration BMP, the site is seldom suitable.

Depth to Bedrock/Hardpan/Till

The downward exfiltration of stormwater is also impeded if a bedrock or till layer lies too close to the surface. If the impervious layer lies within two (2) feet below the bottom of the infiltration BMP the site is not suitable. Similarly, pond BMPs are often not feasible if bedrock lies within the area that must be excavated.

Proximity to Foundations and Wells

Since infiltration BMPs divert runoff back into the soil, some sites may experience problems with local seepage. This can be a real problem if the BMP is located too close to a building foundation. Another risk is ground water pollution, hence the requirement to site infiltration systems more than 100 feet away from drinking water wells.

Maximum Depth

Wet ponds are also subject to a maximum depth limit for the "permanent pool" volume. Deep ponds (greater than 6 feet) may stratify during summer and create low oxygen conditions near the bottom resulting in re-release of phosphorus and other pollutants back into the water.

High Sediment Input

Many BMPs are unable to handle the large loads of sediment that may occur during construction. Infiltration BMPs are particularly susceptible to rapid clogging and subsequent failure if significant sediment loads are allowed to enter the structure. Therefore infiltration BMPs must not be installed until all the land in the contributing drainage area is properly stabilized. Although sediment loads drop

VOL 12 2 2304

R0055602

sharply after construction is completed, gradual clogging of infiltration systems can still occur. Thus infiltration ponds and trenches require a pretreatment device to filter out sediment and other coarse material before they reach the facility (see Chapter III-3).

Pond BMPs can be can be used for sediment control during the construction phase with proper conversion, clean out and regrading. Even after construction sediment deposits will build up, and must be removed periodically. The cost and scope of sediment removal can be reduced by sediment forebays.

STEP 3F: Prepare Modified BMP List

The initial BMP selection may have to be modified after completing Steps 3A through 3E. Verify that the proposed BMPs will still meet the source control, runoff treatment, and streambank erosion control requirements established in Step 1. Modify the list as necessary.

STEP 3G: Prepare Final BMPs

Final selection of runoff control BMPs is made after consulting the detailed standards and specifications in relation to site specific conditions. For this the user is referred to Volume III. A detailed description of each BMP will be found here that will enable final selections to be made.

I-4.3.4 STEP 4: COMPLETE STORMWATER SITE PLAN

The purpose of this step is to complete development of the Stormwater Site Plan so that it can be submitted to the local government or Plan Approval Authority for approval. The user must first complete development of the Permanent Stormwater Quality Control Plan, including design and construction drawings.

STEP 4A: Complete development of the Permanent Stormwater Quality Control Plan

Compile the final list of source control, runoff treatment, and streambank erosion control BMPs and proceed to design them using the detailed guidance in Volumes III and IV.11 To complete the Permanent Stormwater Quality Plan both a report and a set of construction drawings must be completed. Refer to Chapter I-3 and the "Stormwater Program Guidance Manual for the Puget Sound Basin" for guidance on completing this plan *(Note: This guidance has not been completed at publication time. It is scheduled to be completed in 1992).*

STEP 4B: Review other Stormwater Site Plan requirements

The Permanent Stormwater Quality Control Plan is but one of several documents that are required for the Stormwater Site Plan. Review Chapter I-3 and the "Stormwater Program Guidance Manual for the Puget Sound Basin" for further details.

STEP 4C: Finalize Stormwater Site Plan

Incorporate all other documents and site plans required for the completion of the Stormwater Site Plan.

I-4.3.5 STEP 5: SUBMIT FINAL STORMWATER SITE PLAN TO PLAN APPROVAL AUTHORITY

The Plan Approval Authority may be the local government. Check with your local government to determine who within that government is the Plan Approval Authority.

Vault/Tank (Wet or Dry)	0 - 5
Biofiltration Swale	0 - 10
Vegetative Filter Strip	0 - 10
Oil/Water Separator	0 - 5

* These BMPs maintain a permanent pool that, ideally, should not go dry. To maintain a permanent pool will typically require a minimum drainage area. This is especially important for constructed wetlands and wet ponds that utilize a shallow marsh system (i.e., wet pond for nutrient control). Wet ponds that do not utilize a shallow marsh system may be allowed to periodically go dry but only during the summer dry season. In some cases a smaller drainage area than that shown above may be acceptable. See the criteria for individual BMPs in Chapter III-4.

GLOSSARY AND NOTATION

Note: The following terms are provided for reference and use with this manual. They shall be superseded by any other definitions for these terms adopted by ordinance unless they are defined in a Washington State WAC or RCW or are used and defined as part of the Minimum Requirements for all new development and redevelopment.

AASHTO classification - The official classification of soil materials and soil aggregate mixtures for highway construction, used by the American Association of State Highway and Transportation Officials.

Absorption - The penetration of a substance into or through another, such as the dissolving of a soluble gas in a liquid.

Adjacent steep slope - A slope with a gradient of 15 percent or steeper within five hundred feet of the site.

Adsorption - The adhesion of a substance to the surface of a solid or liquid; often used to extract pollutants by causing them to be attached to such adsorbents as activated carbon or silica gel. Hydrophobic, or water-repulsing adsorbents, are used to extract oil from waterways when oil spills occur. Heavy metals such as zinc and lead often adsorb onto sediment particles.

Aeration - The process of being supplied or impregnated with air. In waste treatment, the process used to foster biological and chemical purification. In soils, the process by which air in the soil is replenished by air from the atmosphere. In a well aerated soil, the soil air is similar in composition to the atmosphere above the soil. Poorly aerated soils usually contain a much higher percentage of carbon dioxide and a correspondingly lower percentage of oxygen.

Aerobic - Living or active only in the presence of free (dissolved or molecular) oxygen.

Aerobic bacteria - Bacteria that require the presence of free oxygen for their metabolic processes.

Aggressive plant species - Opportunistic species of inferior biological value that tend to out-compete more desirable forms and become dominant; applied to native species in this manual.

Algae - Primitive plants, many microscopic, containing chlorophyll and forming the base of the food chain in aquatic environments. Some species may create a nuisance when environmental conditions are suitable for prolific growth.

Algal bloom - Proliferation of living algae on the surface of lakes, streams or ponds; often stimulated by phosphate over-enrichment. Algal blooms reduce the oxygen available to other aquatic organisms.

American Public Works Association or APWA - the adopted edition of the Washington State Chapter of the American Public Works Association.

Anadromous - Fishes ascending rivers from the sea for breeding.

Anaerobic - Living or active in the absence of oxygen.

Anaerobic bacteria - Bacteria that do not require the presence of free or dissolved oxygen for metabolism.

VOL 12 2 2310

R0055608

Annual flood - The highest peak discharge on average which can be expected in any given year.

Antecedent moisture conditions - The degree of wetness of a watershed or within the soil at the beginning of a storm.

Anti-seep collar - A device constructed around a pipe or other conduit and placed through a dam, levee, or dike for the purpose of reducing seepage losses and piping failures.

Anti-vortex device - A facility placed at the entrance to a pipe conduit structure such as a drop inlet spillway or hood inlet spillway to prevent air from entering the structure when the pipe is flowing full.

Applicant - The person who has applied for a development permit or approval.

Approved manual - means a stormwater management manual approved by Ecology.

Appurtenances - Machinery, appliances, or auxiliary structures attached to a main structure, but not considered an integral part thereof, for the purpose of enabling it to function.

Aquifer - A geologic stratum containing ground water that can be withdrawn and used for human purposes.

As-built drawings - Engineering plans which have been revised to reflect all changes to the plans which occurred during construction.

As-graded - the extent of surface conditions on completion of grading.

BSBL - See Building set back line.

Background - A description of pollutant levels arising from natural sources, and not because of man's immediate activities.

Backwater - Water upstream from an obstruction which is deeper than it would normally be without the obstruction.

Bankfull discharge - A flow condition where streamflow completely fills the stream channel up to the top of the bank. In undisturbed watersheds, the discharge conditions occurs on average every 1.5 to 2 years and controls the shape and form of natural channels.

Base flood - A flood having a one percent chance of being equaled or exceeded in any given year. This is also referred to as the 100-year flood.

Base flood elevation - The water surface elevation of the base flood. It shall be referenced to the National Geodetic Vertical Datum of 1929 (NGVD).

Baseline sample - A sample collected during dry-weather flow (i.e., it does not consist of runoff from a specific precipitation event).

Basin plan - A plan and all implementing regulations and procedures including but not limited to land use management adopted by ordinance for managing surface and storm water quality and quantity management facilities and features within individual subbasins.

Bearing capacity - The maximum load that a material can support before failing.

Bedrock - The more or less solid rock in place either on or beneath the surface of the earth. It may be soft, medium, or hard and have a smooth or irregular surface.

VOL 12

2 2 3 1 1 1

R0055609

Bench - a relatively level step excavated into earth material on which fill is to be placed.

Berm - A constructed barrier of compacted earth, rock or gravel.

Best management practice (BMP) - Physical, structural, and/or managerial practices that, when used singly or in combination, prevent or reduce pollution of water, and have been approved by Ecology.

Biochemical oxygen demand (BOC) - An indirect measure of the concentration of biologically degradable materials present in organic wastes. The amount of free oxygen utilized by aerobic organisms when allowed to attack the organic material in an aerobically maintained environment at a specified temperature (20°C) for a specific time period (5 days), and thus stated as BOD_5. It is expressed in milligrams of oxygen utilized per liter of liquid waste volume (mg/l) or in milligrams of oxygen per kilogram of waste solution (mg/kg = ppm = parts per million parts). Also called biological oxygen demand.

Biodegradable - Capable of being readily broken down by biological means, especially by bacterial action. Degradation can be rapid or may take many years depending upon such factors as available oxygen and moisture.

Bioengineering - Restoration or reinforcement of slopes and stream banks with living plant materials.

Biofilter - A designed, vegetated treatment facility where the more or less simultaneous processes of filtration, infiltration, adsorption and biological uptake of pollutants in stormwater takes place when runoff flows over and through . Vegetation growing in these facilities acts as both a physical filter which causes gravity settling of particulates by regulating velocity of flow, and also as a biological sink when direct uptake of dissolved pollutants occurs. The former mechanism is probably the most important in western Washington where the period of major runoff coincides with the period of lowest biological activity.

Biofiltration - The process of reducing pollutant concentrations in water by filtering the polluted water through biological materials.

Biological control - A method of controlling pest organisms by means of introduced or naturally occurring predatory organisms, sterilization, the use of inhibiting hormones, or other means, rather than by mechanical or chemical means.

Biological magnification - The increasing concentration of a substance along succeeding steps in a food chain. Also called biomagnification.

Bollard - A post (may or may not be removable) used to prevent vehicular access.

Bond - A surety bond, cash deposit or escrow account, assignment of savings, irrevocable letter of credit or other means acceptable to or required by the manager to guarantee that work is completed in compliance with the project's drainage plan and in compliance with all local government requirements.

Borrow area - A source of earth fill material used in the construction of embankments or other earth fill structures.

Buffer - The zone contiguous with a sensitive area that is required for the continued maintenance, function, and structural stability of the sensitive area. The critical functions of a riparian buffer (those associated with an aquatic system) include shading, input of organic debris and coarse sediments, uptake of nutrients, stabilization of banks, interception of fine sediments, overflow during high water events, protection from disturbance by humans and domestic animals, maintenance of wildlife habitat, and room for variation of aquatic system boundaries

VOL 12 2 2312

R0055610

over time due to hydrologic or climatic effects. The critical functions of terrestrial buffers include protection of slope stability, attenuation of surface water flows from storm water runoff and precipitation, and erosion control.

Building setback line (BSBL) - A line measured parallel to a property, easement, drainage facility or buffer boundary, that delineates the area (defined by the distance of separation) where buildings, or other obstructions are prohibited (including decks, patios, outbuildings, or overhangs beyond 18 inches). Wooden or chain link fences and landscaping are allowable within a building setback line. In this manual the minimum building setback line shall be 5 feet.

CIP - See Capital Improvement Project.

Capital Improvement Project or Program (CIP) - A project prioritized and scheduled as a part of an overall construction program or, the actual construction program.

Catchbasin - A chamber or well, usually built at the curb line of a street, for the admission of surface water to a sewer or subdrain, having at its base a sediment sump designed to retain grit and detritus below the point of overflow.

Catchline - The point where a severe slope intercepts a different, more gentle slope.

Catchment - Surface drainage area.

Channel - A feature that conveys surface water and is open to the air.

Channel, constructed - Channels or ditches constructed (or reconstructed natural channels) to convey surface water.

Channel, natural - Streams, creeks, or swales that convey surface/ground water and have existed long enough to establish a stable route and/or biological community.

Channel stabilization - Erosion prevention and stabilization of velocity distribution in a channel using vegetation, jetties, drops, revetments, and/or other measures.

Channel storage - Water temporarily stored in channels while enroute to an outlet.

Channelization - Alteration of a stream channel by widening, deepening, straightening, cleaning, or paving certain areas to change flow characteristics.

Check dam - Small dam constructed in a gully or other small watercourse to decrease the streamflow velocity, minimize channel scour, and promote deposition of sediment.

Chemical oxygen demand (COD) - A measure of the amount of oxygen required to oxidize organic and oxidizable inorganic compounds in water. The COD test, like the BOD test, is used to determine the degree of pollution in water.

Civil engineer - a professional engineer licensed in the State of Washington in Civil Engineering who is experienced and knowledgeable in the practice of soils engineering.

Civil engineering - the application of the knowledge of the forces of nature, principles of mechanics and the properties of materials to the evaluation, design and construction of civil works for the beneficial uses of mankind.

Clay lens - A naturally occurring, localized area of clay which acts as an impermeable layer to runoff infiltration.

VOL 12
2
2313
R0055611

Clearing - The destruction and removal of vegetation by manual, mechanical, or chemical methods.

Closed depression - An area which is lowlying and either has no, or such a limited, surface water outlet that during storm events the area acts as a retention basin.

Cohesion - The capacity of a soil to resist shearing stress, exclusive of functional resistance.

Coliform bacteria - Microorganisms common in the intestinal tracts of man and other warm-blooded animals; all the aerobic and facultative anaerobic, gram-negative, nonspore-forming, rod-shaped bacteria which ferment lactose with gas formation within 48 hours at 35°C. Used as an indicator of bacterial pollution.

Commercial agriculture - Those activities conducted on lands defined in RCW 84.34.020(2), and activities involved in the production of crops or livestock for wholesale trade. An activity ceases to be considered commercial agriculture when the area on which it is conducted is proposed for conversion to a nonagricultural use or has lain idle for more than five (5) years, unless the idle land is registered in a federal or state soils conservation program, or unless the activity is maintenance of irrigation ditches, laterals, canals, or drainage ditches related to an existing and ongoing agricultural activity.

Compaction - densification of a fill by mechanical means.

Compensatory storage - New excavated storage volume equivalent to the flood storage capacity eliminated by filling or grading within the flood fringe. Equivalent shall mean that the storage removed shall be replaced by equal volume between corresponding one foot contour intervals that are hydraulically connected to the floodway through their entire depth.

Compost - Organic residue or a mixture of organic residues and soil, that has undergone biological decomposition until it has become relatively stable humus.

Composting - A controlled process of degrading organic matter by microorganisms. Present day composting is the aerobic, thermophilic decomposing of organic waste to relatively stable humus. Humus with no more than 25 percent dead or living organisms is stable enough not to reheat or cause odor or fly problems. It can undergo further, slower decay.

Comprehensive planning - Planning that takes into account all aspects of water, air, and land resources and their uses and limits.

Conservation district - A public organization created under state enabling law as a special-purpose district to develop and carry out a program of soil, water, and related resource conservation, use, and development within its boundaries, usually a subdivision of state government with a local governing body and always with limited authority. Often called a soil conservation district or a soil and water conservation district.

Constructed wetland - those wetlands intentionally created on sites that are not wetlands for the primary purpose of wastewater or stormwater treatment and managed as such. Constructed wetlands are normally considered as part of the stormwater collection and treatment system.

Contour - An imaginary line on the surface of the earth connecting points of the same elevation.

Conveyance - A mechanism for transporting water from one point to another, including pipes, ditches, and channels.

VOL 12 2 2314

R0055612

Conveyance system - The drainage facilities, both natural and man-made, which collect, contain, and provide for the flow of surface and stormwater from the highest points on the land down to a receiving water. The natural elements of the conveyance system include swales and small drainage courses, streams, rivers, lakes, and wetlands. The human-made elements of the conveyance system include gutters, ditches, pipes, channels, and most retention/detention facilities.

Cover crop - A close-growing crop grown primarily for the purpose of protecting and improving soil between periods of permanent vegetation.

Created wetland - means those wetlands intentionally created from nonwetland sites to produce or replace natural wetland habitat (e.g., compensatory mitigation projects).

Critical Areas - at a minimum, areas which include wetlands, areas with a critical recharging effect on aquifers used for potable water, fish and wildlife habitat conservation areas, frequently flooded areas, geologically hazardous areas, including unstable slopes, and associated areas and ecosystems.

Critical depth - The depth which minimizes the specific energy of flow (E).

Critical Drainage Area - An area with such severe flooding, drainage and/or erosion/sedimentation conditions that the area has been formally adopted as a Critical Drainage Area by rule under the procedures specified in an ordinance.

Critical flow - Flow at the critical depth and velocity.

Critical reach - The point in a receiving stream below a discharge point at which the lowest dissolved oxygen level is reached and stream recovery begins.

Culvert - Pipe or concrete box structure which drains open channels, swales or ditches under a roadway or embankment. Typically with no catchbasins or manholes along its length.

Cut - Portion of land surface or area from which earth has been removed or will be removed by excavating; the depth below original ground surface to excavated surface.
Cut-and-fill - Process of earth moving by excavating part of an area and using the excavated material for adjacent embankments or fill areas.

DNS - See Determination of nonsignificance.

Dead storage - The volume available in a depression in the ground below any conveyance system, or surface drainage pathway, or outlet invert elevation that could allow the discharge of surface and stormwater runoff.

Dedication of land - Refers to setting aside a portion of a property for a specific use or function.

Degradation - (Biological or chemical) The breakdown of complex organic or other chemical compounds into simpler substances, usually less harmful than the original compound, as with the degradation of a persistent pesticide. (Geological) Wearing down by erosion. (Water) The lowering of the water quality of a watercourse by an increase in the pollutant loading.

Degraded (disturbed) wetland (community) - A wetland (community) in which the vegetation, soils, and/or hydrology have been adversely altered, resulting in lost or reduced functions and values; generally, implies topographic isolation; hydrologic alterations such as hydroperiod alteration (increased or decreased quantity of water), diking, channelization, and/or outlet modification; soils alterations such as presence of fill, soil removal, and/or compaction; accumulation

VOL 12 2 2315

R0055613

of toxicants in the biotic or abiotic components of the wetland; and/or low plant species richness with dominance by invasive weedy species.

Denitrification - The biochemical reduction of nitrates or nitrites in the soil or organic deposits to ammonia or free nitrogen.

Depression storage - The amount of precipitation that is trapped in depressions on the surface of the ground.

Design engineer - The professional civil engineer licensed in the State of Washington who prepares the analysis, design, and engineering plans for an applicant's permit or approval submittal.

Design storm - A prescribed hyetograph and total precipitation amount (for a specific duration recurrence frequency) used to estimate runoff for a hypothetical storm of interest or concern for the purposes of analyzing existing drainage, designing new drainage facilities or assessing other impacts of a proposed project on the flow of surface water. (A hyetograph is a graph of percentages of total precipitation for a series of time steps representing the total time during which the precipitation occurs.)

Detention - the release of stormwater runoff from the site at a slower rate than it is collected by the stormwater facility system, the difference being held in temporary storage.

Detention facility - an above or below ground facility, such as a pond or tank, that temporarily stores stormwater runoff and subsequently releases it at a slower rate than it is collected by the drainage facility system. There is little or no infiltration of stored stormwater.

Detention time - The theoretical time required to displace the contents of a stormwater treatment facility at a given rate of discharge (volume divided by rate of discharge).

Determination of Nonsignificance (DNS) - The written decision by the responsible official of the lead agency that a proposal is not likely to have a significant adverse environmental impact, and therefore an EIS is not required.

Development - For the purposes of this document any activity that requires a permit or approval, including but not limited to a building permit, grading permit, shoreline substantial development permit, conditional use permit, unclassified use permit, zoning variance or reclassification, planned unit development, subdivision, short subdivision, master plan development, building site plan, or right-of-way use permit. See also the definitions for new development, redevelopment and land disturbing activities.

Discharge - Outflow; the flow of a stream, canal, or aquifer. One may also speak of the discharge of a canal or stream into a lake, river, or ocean. (Hydraulics) Rate of flow, specifically fluid flow; a volume of fluid passing a point per unit of time, commonly expressed as cubic feet per second, cubic meters per second, gallons per minute, gallons per day, or millions of gallons per day.

Dispersed discharge - Release of surface and stormwater runoff from a drainage facility system such that the flow spreads over a wide area and is located so as not to allow flow to concentrate anywhere upstream of a drainage channel with erodible underlying granular soils.

Ditch - A long narrow excavation dug in the earth for drainage with its top width less than 10 feet at design flow.

Divide, Drainage - The boundary between one drainage basin and another.

VOL 12 2 2316

R0055614

Drain - A buried pipe or other conduit (closed drain). A ditch (open drain) for carrying off surplus surface water or ground water.

(To) Drain - To provide channels, such as open ditches or closed drains, so that excess water can be removed by surface flow or by internal flow. To lose water (from the soil) by percolation.

Drainage - Refers to the collection, conveyance, containment, and/or discharge of surface and storm water runoff.

Drainage basin - A geographic and hydrologic subunit of a watershed.

Drainage channel - A drainage pathway with a well-defined bed and banks indicating frequent conveyance of surface and stormwater runoff.

Drainage course - A pathway for watershed drainage characterized by wet soil vegetation; often intermittent in flow.

Drainage easement - A legal encumbrance that is placed against a property's title to reserve specified privileges for the users and beneficiaries of the drainage facilities contained within the boundaries of the easement.

Drainage pathway - The route that surface and stormwater runoff, leaving any part of the site, follows downslope.

Drainage review - An evaluation by Plan Approving Authority staff of a proposed project's compliance with the drainage requirements in this manual or its technical equivalent.

Drainage, Soil - As a natural condition of the soil, soil drainage refers to the frequency and duration of periods when the soil is free of saturation; for example, in well-drained soils the water is removed readily but not rapidly; in poorly drained soils the root zone is waterlogged for long periods unless artificially drained, and the roots of ordinary crop plants cannot get enough oxygen; in excessively drained soils the water is removed so completely that most crop plants suffer from lack of water. Strictly speaking, excessively drained soils are a result of excessive runoff due to steep slopes or low available water-holding capacity due to small amounts of silt and clay in the soil material. The following classes are used to express soil drainage:

Well drained - Excess water drains away rapidly and no mottling occurs within 36 inches of the surface.

Moderately well drained - Water is removed from the soil somewhat slowly, resulting in small but significant periods of wetness. Mottling occurs between 18 and 36 inches.

Somewhat poorly drained - Water is removed from the soil slowly enough to keep it wet for significant periods but not all of the time. Mottling occurs between 8 and 18 inches.

Poorly drained - Water is removed so slowly that the soil is wet for a large part of the time. Mottling occurs between 0 and 8 inches.

Very poorly drained - Water is removed so slowly that the water table remains at or near the surface for the greater part of the time. There may also be periods of surface ponding. The soil has a black to gray surface layer with mottles up to the surface.

Drawdown - Lowering of the water surface (in open channel flow), water table or piezometric surface (in ground water flow) resulting from a withdrawal of water.

VOL 12 2 2311

R0055615

Drop-inlet spillway - Overall structure in which the water drops through a vertical riser connected to a discharge conduit.

Drop spillway - Overall structure in which the water drops over a vertical wall onto an apron at a lower elevation.

Drop structure - A structure for dropping water to a lower level and dissipating its surplus energy; a fall. A drop may be vertical or inclined.

Dry weather flow - The combination of sanitary sewage, and industrial and commercial wastes normally found in sanitary or storm sewers during the dry weather season of the year. Also that flow in streams during the dry season.

EIS - See Environmental Impact Statement.

ESC - Erosion and Sediment Control (Plan).

Earth material - any rock, natural soil or fill and/or any combination thereof.

Easement - The legal right to use a parcel of land for a particular purpose. It does not include fee ownership, but may restrict the owners use of the land.

Embankment - A structure of earth, gravel, or similar material raised to form a pond bank or foundation for a road.

Emergent plants - Aquatic plants that are rooted in the sediment but whose leaves are at or above the water surface. These wetland plants often have high habitat value for wildlife and waterfowl, and can aid in pollutant uptake.

Emergency spillway - A vegetated earth channel used to safely convey flood discharges in excess of the capacity of the principal spillway.

Energy dissipator - Any means by which the total energy of flowing water is reduced. In stormwater design, they are usually mechanisms that reduce velocity prior to, or at, discharge from an outfall in order to prevent erosion. They include rock splash pads, drop manholes, concrete stilling basins or baffles, and check dams.

Energy gradient - The slope of the specific energy line (i.e., the sum of the potential and velocity heads.)

Engineering geologist - a geologist experienced and knowledgeable in engineering geology.

Engineering geology - the application of geologic knowledge and principles in the investigation and evaluation of naturally occurring rock and soil for use in the design of civil works.

Engineering plan - A plan prepared and stamped by a professional civil engineer. An engineering plan contains a Technical Information Report and Site Improvement Plans which are described in detail in Chapter I-3.

Enhancement - To raise value, desirability, or attractiveness of an environment associated with surface water.

Environmental Impact Statement (EIS) - A document that discusses the likely significant adverse impacts of a proposal, ways to lessen the impacts, and alternatives to the proposal. They are required by the national and state environmental policy acts when projects are determined to have significant environmental impact.

VOL 12

2

2 3 1 8

R0055616

Erodible granular soils - Soil materials that are easily eroded and transported by running water, typically fine or medium grained sand with minor gravel, silt, or clay content. Such soils are commonly described as Everett or Indianola series soil types in the SCS classification. Also included are any soils showing examples of existing severe stream channel incision as indicated by unvegetated streambanks standing over two feet high above the base of the channel.

Erosion - The wearing away of the land surface by running water, wind, ice, or other geological agents, including such processes as gravitational creep. Also, detachment and movement of soil or rock fragments by water, wind, ice, or gravity. The following terms are used to describe different types of water erosion:

Accelerated erosion - Erosion much more rapid than normal or geologic erosion, primarily as a result of the influence of the activities of man or, in some cases, of the animals or natural catastrophes that expose bare surfaces (e.g., fires).

Geological erosion - The normal or natural erosion caused by geological processes acting over long geologic periods and resulting in the wearing away of mountains, the building up of floodplains, coastal plains, etc. Synonymous with natural erosion.

Gully erosion - The erosion process whereby water accumulates in narrow channels and, over short periods, removes the soil from this narrow area to considerable depths, ranging from 1 to 2 feet to as much as 75 to 100 feet.

Natural erosion - Wearing away of the earth's surface by water, ice, or other natural agents under natural environmental conditions of climate, vegetation, etc., undisturbed by man. Synonymous with geological erosion.

Normal erosion - The gradual erosion of land used by man which does not greatly exceed natural erosion. See Natural erosion.

Rill erosion - An erosion process in which numerous small channels only several inches deep are formed; occurs mainly on recently disturbed and exposed soils. See Rill.

Sheet erosion - The removal of a fairly uniform layer of soil from the land surface by runoff.

Splash erosion - The spattering of small soil particles caused by the impact of raindrops on wet soils. The loosened and spattered particles may or may not be subsequently removed by surface runoff.

Erosion classes (soil survey) - A grouping of erosion conditions based on the degree of erosion or on characteristic patterns. Applied to accelerated erosion, not to normal, natural, or geological erosion. Four erosion classes are recognized for water erosion and three for wind erosion.

Erosion/sedimentation control - Any temporary or permanent measures taken to reduce erosion; control siltation and sedimentation; and ensure that sediment-laden water does not leave the site.

Erosion and sediment control facility - A type of drainage facility designed to hold water for a period of time to allow sediment contained in the surface and stormwater runoff directed to the facility to settle out so as to improve the quality of the runoff.

Escarpment - A steep face or a ridge of high land.

VOL 12 2 2319

R0055617

Estuarine wetland - Generally, an eelgrass bed; salt marsh; or rocky, sandflat, or mudflat intertidal area where fresh and salt water mix. (Specifically, a tidal wetland with salinity greater than 0.5 parts per thousand, usually semi-enclosed by land but with partially obstructed or eporadic access to the open ocean).

Estuary - An area where fresh water meets salt water, or where the tide meets the river current (e.g., bays, mouths of rivers, salt marshes and lagoons). Estuaries serve as nurseries and spawning and feeding grounds for large groups of marine life and provide shelter and food for birds and wildlife.

Eutrophication - Refers to the process where nutrient over-enrichment of water leads to excessive growth of aquatic plants, especially algae.

Evapotranspiration - The collective term for the processes of evaporation and plant transpiration by which water is returned to the atmosphere.

Excavation - the mechanical removal of earth material.

Exfiltration - The downward movement of runoff through the bottom of an infiltration BMP into the soil layer or the downward movement of water through soil.

Existing site conditions means - (a) For developed sites with stormwater facilities that have been constructed to meet the standards in the Minimum Requirements of this manual, existing site conditions shall mean the existing conditions on the site.

(b) For developed sites that do not have stormwater facilities that meet the Minimum Requirements, existing site conditions shall mean the conditions that existed prior to local government adoption of a stormwater management program. If in question, the existing site conditions shall be documented by aerial photograph records, or other appropriate means.

(c) For all sites in water quality sensitive areas as identified under Minimum Requirement #7, Water Quality Sensitive Areas, existing site conditions shall mean undisturbed forest, for the purpose of calculating runoff characteristics.

(d) For all undeveloped sites outside of water quality sensitive areas, existing site conditions shall mean the existing conditions on the site.

Experimental best management practice (BMP) - A BMP that has not been tested and evaluated by the Department of Ecology in collaboration with local governments and technical experts.

FIRM - See Flood Insurance Rate Map.

Fertilizer - Any material or mixture used to supply one or more of the essential plant nutrient elements.

Fill - a deposit of earth material placed by artificial means.

Filter fabric - A woven or nonwoven, water-permeable material generally made of synthetic products such as polypropylene and used in stormwater management and erosion and sediment control applications to trap sediment or prevent the clogging of aggregates by fine soil particles.

Filter fabric fence - A temporary sediment barrier consisting of a filter fabric stretched across and attached to supporting posts and entrenched. The filter fence is constructed of stakes and synthetic filter fabric with a rigid wire fence backing where necessary for support.

VOL 12 2 2320

R0055618

Filter strip - A strip of vegetation used to retard or collect sediment for the protection of diversions, drainage basins, or other structures. Often used in conjunction with a level spreader to keep flow from becoming channelized in the filter strip.

Flocculation - The process by which suspended colloidal or very fine particles are assembled into larger masses or floccules which eventually settle out of suspension. This process occurs naturally but can also be caused through the use of such chemicals as alum.

Flood - An overflow or inundation that comes from a river or any other source, including (but no limited to) streams, tides, wave action, storm drains or excess rainfall. Any relatively high stream flow overtopping the natural or artificial banks in any reach of a stream.

Flood control - Methods or facilities for reducing flood flows and the extent of flooding.

Flood control project - A structural system installed to protect land and improvements from floods by the construction of dikes, river embankments, channels, or dams.

Flood frequency - The frequency with which the flood of interest may be expected to occur at a site in any average interval of years. Frequency analysis defines the "n-year flood" as being the flood that will, over a long period of time, be equaled or exceeded on the average once every "n" years.

Flood fringe - That portion of the floodplain outside of the floodway which is covered by floodwaters during the base flood; it is generally associated with standing water rather than rapidly flowing water.

Flood Hazard Areas - Those areas subject to inundation by the base flood. Includes, but is not limited to streams, lakes, wetlands, and closed depressions.

Flood Insurance Rate Map (FIRM) - The official map on which the Federal Insurance Administration has delineated many areas of flood hazard, floodway, and the risk premium zones.

Flood Insurance Study - The official report provided by the Federal Insurance Administration that includes flood profiles and the FIRM.

Flood peak - The highest value of the stage or discharge attained by a flood; thus, peak stage or peak discharge.

Floodplain - The total area subject to inundation by the base flood including the flood fringe and floodway.

Flood-proofing - Adaptations that ensure a structure is substantially impermeable to the passage of water below the flood protection elevation that resists hydrostatic and hydrodynamic loads and effects of buoyancy.

Flood protection elevation - the base flood elevation or higher as defined by the local government.

Flood protection facility - Any levee, berm, wall, enclosure, raise bank, revetment, constructed bank stabilization or armoring, that is commonly recognized by the community as providing significant protection to a property from inundation by flood waters.

Flood routing - An analytical technique used to compute the effects of system storage dynamics on the shape and movement of flow represented by a hydrograph.

VOL 12 2 2321

R0055619

Flood stage - The stage at which overflow of the natural banks of a stream begins.

Floodway - The channel of the river or stream and those portions of the adjoining floodplains which are reasonably required to carry and discharge the base flood flow. The portions of the adjoining floodplains which are considered to be "reasonably required" is defined by flood hazard regulations.

Forebay - An easily maintained, extra storage area provided near an inlet of a BMP to trap incoming sediments before they accumulate in a pond or wetland BMP.

Forest practice - Any activity conducted on or directly pertaining to forest land and relating to growing, harvesting, or processing timber, including but not limited to:

a. Road and trail construction.
b. Harvesting, final and intermediate.
c. Precommercial thinning.
d. Reforestation.
e. Fertilization.
f. Prevention and suppression of diseases and insects.
g. Salvage of trees.
h. Brush control.

Forested communities (wetlands) - In general terms, communities (wetlands) characterized by woody vegetation that is greater than or equal to 6 meters in height; in this manual the term applies to such communities (wetlands) that represent a significant amount of tree cover consisting of species that offer wildlife habitat and other values and advance the performance of wetland functions overall.

Freeboard - The vertical distance between the design water surface elevation and the elevation of the barrier which contains the water.

Frequently flooded areas - the 100-year floodplain designations of the Federal Emergency Management Agency and the National Flood Insurance Program or as defined by the local government.

Frost-heave - The upward movement of soil surface due to the expansion of water stored between particles in the first few feet of the soil profile as it freezes. May cause surface fracturing of asphalt or concrete.

Frequency of storm (design storm frequency) - The anticipated period in years that will elapse, based on average probability of storms in the design region, before a storm of a given intensity and/or total volume will recur; thus a 10-year storm can be expected to occur on the average once every 10 years. Sewers designed to handle flows which occur under such storm conditions would be expected to be surcharged by any storms of greater amount or intensity.

Functions - The ecological (physical, chemical, and biological) processes or attributes of a wetland without regard for their importance to society (see also values). Wetland functions include food chain support, provision of ecosystem diversity and fish and wildlife habitat, floodflow alteration, ground water recharge and discharge, water quality improvement, and soil stabilization.

Gabion - A rectangular or cylindrical wire mesh cage (a chicken wire basket) filled with rock and used as a protecting agent, revetment, etc., against erosion. Soft gabions, often used in streambank stabilization, are made of geotextiles filled with dirt, in between which cuttings are placed.

Gage or gauge - Device for registering precipitation, water level, discharge, velocity, pressure, temperature, etc. Also, a measure of the thickness of metal;

VOL 12 2 2 3 2 2 2

R0055620

e.g., diameter of wire, wall thickness of steel pipe.

Gaging station - A selected section of a stream channel equipped with a gage, recorder, or other facilities for determining stream discharge.

Geologist - A person who has earned a degree in geology from an accredited college or university or who has equivalent educational training and has at least five years of experience as a practicing geologist or four years of experience and at leaet two years post-graduate study, research or teaching. The practical experience shall include at least three years work in applied geology and landslide evaluation, in close association with qualified practicing geologists or geotechnical professional/civil engineers.

Geologically hazardous areas - areas that because of their susceptibility to erosion, sliding, earthquake or other geological events, are not suited to the siting of commercial, residential or industrial development consistent with public health or safety concerns.

Geometrics - The mathematical relationships between points, lines, angles and surfaces used to measure and identify areas of land.

Geotechnical professional civil engineer - A practicing, geotechnical/civil engineer licensed as a professional Civil Engineer with the State of Washington who has at least four years of professional employment as a geotechnical engineer in responsible charge, including experience with landslide evaluation.

Grade - The slope of a road, channel, or natural ground. The finished surface of a canal bed, roadbed, top of embankment, or bottom of excavation; any surface prepared for the support of construction such as paving or the laying of a conduit.

(To) Grade - To finish the surface of a canal bed, roadbed, top of embankment or bottom of excavation.

Gradient terrace - an earth embankment or a ridge-and-channel constructed with suitable spacing and an acceptable grade to reduce erosion damage by intercepting surface runoff and conducting it to a stable outlet at a stable nonerosive velocity.

Grassed waterway - A natural or constructed waterway, usually broad and shallow, covered with erosion-resistant grasses, used to conduct surface water from an area at a reduced flow rate. See also biofilter.

Ground water - Water in a saturated zone or stratum beneath the land surface or a surface water body.

Ground water recharge - Inflow to a ground water reservoir.

Ground water table - The free surface of the ground water, that surface subject to atmospheric pressure under the ground, generally rising and falling with the season, the rate of withdrawal, the rate of restoration, and other conditions. It is seldom static.

(the) Guidance Manual - "The Stormwater Program Guidance Manual for the Puget Sound Basin"; a companion manual to this technical manual which contains program implementation guidance for local governments. Examples of the guidance contained are model ordinances, public education information, and guidance on setting up a stormwater utility.

Gully - A channel caused by the concentrated flow of surface and stormwater runoff over unprotected erodible land.

VOL 12 2 2 3 3 2 3

R0055621

Habitat - The specific area or environment in which a particular type of plant or animal lives. An organism's habitat must provide all of the basic requirements for life and should be protected from harmful contaminants.

Hardpan - A cemented or compacted and often clay-like layer of soil that is impenetrable by roots.

Harmful pollutant - A substance that has adverse effects to an organism including immediate death, chronic poisoning, impaired reproduction, cancer or other effects.

Head (Hydraulics) - The height of water above any plain of reference. The energy, either kinetic or potential, possessed by each unit weight of a liquid, expressed as the vertical height through which a unit weight would have to fall to release the average energy possessed. Used in various compound terms such as pressure head, velocity head, and head loss.

Head loss - Energy loss due to friction, eddies, changes in velocity, or direction of flow.

Heavy metals - Metals of high specific gravity, present in municipal and industrial wastes, that pose long-term environmental hazards. Such metals include cadmium, chromium, cobalt, copper, lead, mercury, nickel, and zinc.

Humus - Organic matter in or on a soil, composed of partly or fully decomposed bits of plant tissue or from animal manure.

Hydraulic gradient - Slope of the potential head relative to a fixed datum.

Hydrodynamics - means the dynamic energy, force, or motion of fluids as affected by the physical forces acting upon those fluids.

Hydrograph - A graph of runoff rate, inflow rate or discharge rate, past a specific point over time.

Hydrologic cycle - The circuit of water movement from the atmosphere to the earth and return to the atmosphere through various stages or processes as precipitation, interception, runoff, infiltration, percolation, storage, evaporation, and transpiration.

Hydrologic Soil Groups - A soil characteristic classification system defined by the U.S. Soil Conservation Service in which a soil may be categorized into one of four soil groups (A, B, C, or D) based upon infiltration rate and other properties.

Hydrology - The science of the behavior of water in the atmosphere, on the surface of the earth, and underground.

Hydroperiod - a seasonal occurrence of flooding and/or soil saturation; it encompasses depth, frequency, duration, and seasonal pattern of inundation.

Hyetograph - A graph of percentages of total precipitation for a series of time steps representing the total time in which precipitation occurs.

Illicit discharge - All non-stormwater discharges to stormwater drainage systems that cause or contribute to a violation of state water quality, sediment quality or ground water quality standards, including but not limited to sanitary sewer connections, industrial process water, interior floor drains, car washing and greywater systems.

Impact basin - A device used to dissipate the energy of flowing water. Generally constructed of concrete in the form of a partially depressed or partially submerged vessel, it may utilize baffles to dissipate velocities.

VOL 12 2 2324

R0055622

Impervious - A surface which cannot be easily penetrated. For instance, rain does not readily penetrate paved surfaces.

Impervious surface - means a hard surface area which either prevents or retards the entry of water into the soil mantle as under natural conditions prior to development, and/or a hard surface area which causes water to run off the surface in greater quantities or at an increased rate of flow from the flow present under natural conditions prior to development. Common impervious surfaces include, but are not limited to, roof tops, walkways, patios, driveways, parking lots or storage areas, concrete or asphalt paving, gravel roads, packed earthen materials, and oiled, macadam or other surfaces which similarly impede the natural infiltration of stormwater. Open, uncovered retention/detention facilities shall not be considered as impervious surfaces.

Impoundment - A natural or man-made containment for surface water.

Improvement - Streets (with or without curbs or gutters), sidewalks, crosswalks, parking lots, water mains, sanitary and storm sewers, drainage facilities, street trees and other appropriate items.

Infiltration - means the downward movement of water from the surface to the subsoil.

Infiltration facility (or system) - A drainage facility designed to use the hydrologic process of surface and stormwater runoff soaking into the ground, commonly referred to as a percolation, to dispose of surface and stormwater runoff.

Ingress/egress - The points of access to and from a property.

Inlet - A form of connection between surface of the ground and a drain or sewer for the admission of surface and stormwater runoff.

Insecticide - A substance, usually chemical, that is used to kill insects.

Interception (Hydraulics) - The process by which precipitation is caught and held by foliage, twigs, and branches of trees, shrubs, and other vegetation. Often used for "interception loss" or the amount of water evaporated from the precipitation intercepted.

Interflow - That portion of rainfall that infiltrates into the soil and moves laterally through the upper soil horizons until intercepted by a stream channel or until it returns to the surface for example, in a wetland, spring or seep.

Intermittent stream - A stream or portion of a stream that flows only in direct response to precipitation. It receives little or no water from springs and no long-continued supply from melting snow or other sources. It is dry for a large part of the year, ordinarily more than three months.

Invasive weedy plant species - Opportunistic species of inferior biological value that tend to out-compete more desirable forms and become dominant; applied to non-native species in this manual.

Invert - The lowest point on the inside of a sewer or other conduit.

Invert elevation - The vertical elevation of a pipe or orifice in a pond which defines the water level.

Isopluvial map - A map with lines representing constant depth of total precipitation for a given return frequency.

Lag time - The interval between the center of mass of the storm precipitation and the peak flow of the resultant runoff.

VOL 12 2 2325

R0055623

Lake - An area permanently inundated by water in excess of two meters deep and greater than 20 acres in size as measured at the ordinary high water marks.

Land disturbing activity - means any activity that results in a change in the existing soil cover (both vegetative and nonvegetative) and/or the existing soil topography. Land disturbing activities include, but are not limited to demolition, construction, clearing, grading, filling and excavation.

Landslide - Episodic downslope movement of a mass of soil or rock that includes but is not limited to rockfalls, slumps, mudflows, and earthflows. For the purpose of these rules, snow avalanches are considered to be a special case of landsliding.

Landslide Hazard Areas - Those areas subject to a severe risk of landslide.

Large Parcel Erosion and Sediment Control Plan" or "LPESC Plan" - a plan to implement BMPs to control pollution generated during land disturbing activity. Guidance for preparing a Large Parcel ESC Plan is contained in Chapter II-4. *[Note: Ecology will be adding a sample Large Parcel ESC Plan to the Guidance Manual.]*

Leachate - Liquid that has percolated through soil and contains substances in solution or suspension.

Leaching - Removal of the more soluble materials from the soil by percolating waters.

Legume - A member of the legume or pulse family, Leguminosae, one of the most important and widely distributed plant families. The fruit is a "legume" or pod. Includes many valuable food and forage species, such as peas, beans, clovers, alfalfas, sweet clovers, and vetches. Practically all legumes are nitrogen-fixing plants.

Level spreader - A temporary ESC device used to spread out stormwater runoff uniformly over the ground surface as sheet flow (i.e., not through channels). The purpose of level spreaders are to prevent concentrated, erosive flows from occurring, and to enhance infiltration.

Local government - Any county, city, or town having its own incorporated government for local affairs.

Low flow channel - An incised or paved channel from inlet to outlet in a dry basin which is designed to carry low runoff flows and/or baseflow, directly to the outlet without detention.

Lowest floor - The lowest enclosed area (including basement) of a structure. An area used solely for parking of vehicles, building access, or storage, in an area other than a basement area, is not considered a building's lowest floor, provided that the enclosed area meets all of the structural requirements of the flood hazard standards.

MDNS - A Mitigated Determination of Nonsignificance (See DNS and Mitigation).

Manning's equation (Hydraulics) - An equation used to predict the velocity of water flow in an open channel or pipelines:

$$V = \frac{1.486 R^{2/3} s^{1/2}}{n}$$

where:

V is the mean velocity of flow in feet per second
R is the hydraulic radius in feet
S is the slope of the energy gradient or, for assumed uniform flow, the slope of the channel in feet per foot; and

VOL 12 2 2326

R0055624

n is Manning's roughness coefficient or retardance factor of the channel lining.

Mass wasting - The movement of large volumes of earth material downslope.

Master Drainage Plan - A comprehensive drainage control plan intended to prevent significant adverse impacts to the natural and manmade drainage system, both on and off-site.

Mean annual water level fluctuation - Derived as follows--

(1) Measure the maximum water level (e.g., with a crest stage gage, Reinelt and Horner 1990) and the existing water level at the time of the site visit (e.g., with a staff gage) on at least eight occasions spread through a year.

(2) Take the difference of the maximum and existing water level on each occasion and divide by the number of occasions.

Mean depth (Hydraulics) - Average depth; cross-sectional area of a stream or channel divided by its surface or top width.

Mean velocity - The average velocity of a stream flowing in a channel or conduit at a given cross-section or in a given reach. It is equal to the discharge divided by the cross-sectional area of the reach.

Measuring weir - A shaped notch through which water flows are measured. Common shapes are rectangular, trapezoidal, and triangular.

Mechanical analysis - The analytical procedure by which soil particles are separated to determine the particle size distribution.

Mechanical practices - Soil and water conservation practices that primarily change the surface of the land or that store, convey, regulate, or dispose of runoff water without excessive erosion.

Metals - Elements, such as mercury, lead, nickel, zinc and cadmium, that are of environmental concern because they do not degrade over time. Although many are necessary nutrients, they are sometimes magnified in the food chain, and they can be toxic to life in high enough concentrations. They are also referred to as heavy metals.

Mitigation - means, in the following order of preference:

(a) Avoiding the impact altogether by not taking a certain action or part of an action;

(b) Minimizing impacts by limiting the degree or magnitude of the action and its implementation, by using appropriate technology, or by taking affirmative steps to avoid or reduce impacts;

(c) Rectifying the impact by repairing, rehabilitating or restoring the affected environment;

(d) Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action; and

(e) Compensation for the impact by replacing, enhancing, or providing substitute resources or environments.

VOL 12 2 2 3 2 7

R0055625

Modification, Modified (wetland) - A wetland whose physical, hydrological, or water quality characteristics have been purposefully altered for a management purpose, such as by dredging, filling, forebay construction, and inlet or outlet control.

Monitor - To systematically and repeatedly measure something in order to track changes.

Monitoring - The collection of data by various methods for the purposes of understanding natural systems and features, evaluating the impacts of development proposals on such systems, and assessing the performance of mitigation measures imposed as conditions of development.

NGPE - See Native Growth Protection Easement.

NGVD - National Geodetic Vertical Datum (see Base flood elevation).

NPDES - The National Pollutant Discharge Elimination System as established by the Federal Clean Water Act.

National Pollutant Discharge Elimination System (NPDES) - The part of the federal Clean Water Act, which requires point source dischargers to obtain permits. These permits are referred to as NPDES permits and, in Washington State, are administered by the Washington State Department of Ecology.

Native Growth Protection Easement (NGPE) - An easement granted for the protection of native vegetation within a sensitive area or its associated buffer. The NGPE shall be recorded on the appropriate documents of title and filed with the County Records Division.

Natural location - means the location of those channels, swales, and other non-manmade conveyance systems as defined by the first documented topographic contours existing for the subject property, either from maps or photographs, or such other means as appropriate.

New development - means the following activities: land disturbing activities, structural development, including construction, installation or expansion of a building or other structure; creation of impervious surfaces; Class IV - general forest practices that are conversions from timber land to other uses; and subdivision and short subdivision of land as defined in RCW 58.17.020. All other forest practices and commercial agriculture are not considered new development.

Nitrate (NO_3) - A form of nitrogen which is an essential nutrient to plants. It can cause algal blooms in water if all other nutrients are present in sufficient quantities. It is a product of bacterial oxidation of other forms of nitrogen, from the atmosphere during electrical storms and from fertilizer manufacturing.

Nitrification - The biochemical oxidation process by which ammonia is changed first to nitrites and then to nitrates by bacterial action, consuming oxygen in the water.

Nitrogen, Available - Usually ammonium, nitrite, and nitrate ions, and certain simple amines available for plant growth. A small fraction of organic or total nitrogen in the soil is available at any time.

Nonpoint source pollution - Pollution that enters a water body from diffuse origins on the watershed and does not result from discernible, confined, or discrete conveyances.

Normal depth - The depth of uniform flow. This is a unique depth of flow for any combination of channel characteristics and flow conditions. Normal depth is calculated using Manning's Equation.

VOL 12 2 2328

R0055626

Nutrients - Essential chemicals needed by plants or animals for growth. Excessive amounts of nutrients can lead to degradation of water quality and algal blooms. Some nutrients can be toxic at high concentrations.

Off-site - Any area lying upstream of the site that drains onto the site and any area lying downstream of the site to which the site drains.

Off-system storage - Facilities for holding or retaining excess flows over and above the carrying capacity of the stormwater conveyance system, in chambers, tanks, lagoons, ponds, or other basins that are not a part of the subsurface sewer system.

On-site - The entire property that includes the proposed development.

Ordinary High Water Mark - The term ordinary high water mark means the line on the shore established by the fluctuations of water and indicated by physical characteristics such as a clear, natural line impressed on the bank; shelving; changes in the character of soil destruction on terrestrial vegetation, or the presence of litter and debris; or other appropriate means that consider the characteristics of the surrounding area.

The ordinary high water mark will be found by examining the bed and banks of a stream and ascertaining where the presence and action of waters are so common and usual, and so long maintained in all ordinary years, as to mark upon the soil a character distinct from that of the abutting upland, in respect to vegetation. In any area where the ordinary high water mark cannot be found, the line of mean high water shall substitute. In any area where neither can be found, the channel bank shall be substituted. In braided channels and alluvial fans, the ordinary high water mark or substitute shall be measured so as to include the entire stream feature.

Orifice - An opening with closed perimeter, usually sharp-edged, and of regular form in a plate, wall, or partition through which water may flow, generally used for the purpose of measurement or control of water.

Outlet - Point of water disposal from a stream, river, lake, tidewater, or artificial drain.

Outlet channel - A waterway constructed or altered primarily to carry water from man-made structures, such as terraces, tile lines, and diversions.

Overflow - A pipeline or conduit device, together with an outlet pipe, that provides for the discharge of portions of combined sewer flows into receiving waters or other points of disposal, after a regular device has allowed the portion of the flow which can be handled by interceptor sewer lines and pumping and treatment facilities to be carried by and to such water pollution control structures.

Overflow rate - Detention basin release rate divided by the surface area of the basin. It can be thought of as an average flow rate through the basin.

Overtopping - To flow over the limits of a containment or conveyance element.

Peak discharge - The maximum instantaneous rate of flow during a storm, usually in reference to a specific design storm event.

Peak-shaving - Controlling post-development peak discharge rates to pre-development levels by providing temporary detention in a BMP.

Percolation - The movement of water through soil.

Percolation rate - The rate, usually expressed as a velocity, at which water moves through saturated granular material.

VOL 12 2 2329

R0055627

Permanent Stormwater Quality Control (PSQC) Plan - a plan which includes permanent BMPs for the control of pollution from stormwater runoff after construction and/or land disturbing activity has been completed. For small sites, this requirement is met by implementing a Small Parcel Erosion and Sediment Control Plan. Guidance on preparing a PSQC Plan is contained in Chapter I-3 and Chapter I-4. *[Note: Ecology will add a sample Large Parcel ESC Plan to the Guidance Manual.]*

Permeability rate - The rate at which water will move through a saturated soil. Permeability rates are classified as follows:

a. Very slow - Less than 0.06 inches per hour.
b. Slow - 0.06 to 0.20 inches per hour.
c. Moderately slow - 0.20 to 0.63 inches per hour.
d. Moderate - 0.63 to 2.0 inches per hour.
e. Moderately rapid - 2.0 to 6.3 inches per hour.
f. Rapid - 6.3 to 20.0 inches per hour.
g. Very rapid - More than 20.0 inches per hour.

Permeable soils - Soil materials with a sufficiently rapid infiltration rate so as to greatly reduce or eliminate surface and stormwater runoff. These soils are generally classified as SCS hydrologic soil types A and B.

Person - Any individual, partnership, corporation, association, organization, cooperative, public or municipal corporation, agency of the state, or local government unit, however designated.

Perviousness - Related to the size and continuity of void spaces in soils; related to a soil's infiltration rate.

Pesticide - A general term used to describe any substance - usually chemical - used to destroy or control organisms; includes herbicides, insecticides, algicides, fungicides, and others. Many of these substances are manufactured and are not naturally found in the environment. Others, such as pyrethrum, are natural toxins which are extracted from plants and animals.

pH - A measure of the alkalinity or acidity of a substance which is conducted by measuring the concentration of hydrogen ions in the substance. A pH of 7.0 indicates neutral water. A 6.5 reading is slightly acid.

Physiographic - Characteristics of the natural physical environment (including hills).

Planned unit development (PUD) - A special classification authorized in some zoning ordinances, where a unit of land under control of a single developer may be used for a variety of uses and densities, subject to review and approval by the local governing body. The locations of the zones are usually decided on a case-by-case basis.

Plat - A map or representation of a subdivision showing the division of a tract or parcel of land into lots, blocks, streets, or other divisions and dedications.

Plunge pool - A device used to dissipate the energy of flowing water that may be constructed or made by the action of flowing. These facilities may be protected by various lining materials.

Point discharge - The release of collected and/or concentrated surface and storm water runoff from a pipe, culvert, or channel.

Pollution - Contamination or other alteration of the physical, chemical, or biological properties, of waters of the state, including change in temperature, taste, color, turbidity, or odor of the waters, or such discharge of any liquid,

VOL 12
2
2330
R0055628

gaseous, solid, radioactive or other substance into any waters of the state as will or is likely to create a nuisance or render such waters harmful, detrimental or injurious to the public health, safety or welfare, or to domestic, commercial, industrial, agricultural, recreational, or other legitimate beneficial uses, or to livestock, wild animals, birds, fish or other aquatic life.

Prediction - For the purposes of this document an expected outcome based on the results of hydrologic modelling and/or the judgment of a trained professional civil engineer or geologist.

Pretreatment - The removal of material such as gross solids, grit, grease, and scum from flows prior to physical, biological, or physical treatment processes to improve treatability. Pretreatment may include screening, grit removal, stormwater, and oil separators.

Priority peat systems - Unique, irreplaceable fens that can exhibit water pH in a wide range from highly acidic to alkaline, including fens typified by Sphagnum species, Ledum groenlandicum (Labrador tea), Drosera rotundifolia (sundew), and Vaccinium oxycoccos (bog cranberry); marl fens; estuarine peat deposits; and other moss peat systems with relatively diverse, undisturbed flora and fauna. Bog is the common name for peat systems having the Sphagnum association described, but this term applies strictly only to systems that receive water income from precipitation exclusively.

Professional civil engineer - A person registered with the State of Washington as a professional engineer in civil engineering.

Project - The proposed action of a permit application or an approval which requires a drainage review.

Puget Sound basin - Puget Sound south of Admiralty Inlet (including Hood Canal and Saratoga Passage); the waters north to the Canadian border, including portions of the Strait of Georgia; the Strait of Juan de Fuca south of the Canadian border; and all the lands draining into these waters as mapped in Water Resources Inventory Areas numbers 1 through 19, set forth in WAC 173-500-040.

R/D - See Retention/detention facility.

Rare, threatened, or endangered species - Plant or animal species that are regional relatively uncommon, are nearing endangered status, or whose existence is in immediate jeopardy and is usually restricted to highly specific habitats. Threatened and endangered species are officially listed by federal and state authorities, whereas rare species are unofficial species of concern that fit the above definitions.

Rational method - A means of computing storm drainage flow rates (Q) by use of the formula Q = CIA, where C is a coefficient describing the physical drainage area, I is the rainfall intensity and A is the area. This method is no longer used in the technical manual.

Reach - A length of channel with uniform characteristics.

Receiving waters - Bodies of water or surface water systems receiving water from upstream manmade (or natural) streams.

Recharge - The flow to ground water from the infiltration of surface and stormwater runoff.

Redevelopment - On an already developed site, the creation or addition of impervious surfaces, structural development including construction, installation or expansion of a building or other structure, and/or replacement of impervious surface that is

VOL 12
2
2331
R0055629

not part of a routine maintenance activity; and land disturbing activities associated with structural or impervious redevelopment.

Regional - An action (here, for stormwater management purposes) that involves more than one discrete property.

Regional detention facility - A stormwater quantity control structure designed to correct existing excess surface water runoff problems of a basin or subbasin. The area downstream has been previously identified as having existing or predicted significant and regional flooding and/or erosion problems.

This term is also used when a detention facility is used to detain stormwater runoff from a number of different businesses, developments or areas within a catchment. The use of regional detention facilities may be more efficient than on-site stormwater treatment although the preferred option is to include some on-site stormwater treatment through the use of grassy swales etc. even when regional detention facilities are used.

Release rate - The computed peak rate of surface and stormwater runoff for a particular design storm event and drainage area conditions.

Residential density - The number of persons per unit of residential land area. Net density includes only occupied land. Gross density includes unoccupied portions of residential areas, such as roads and open space.

Restoration - Actions performed to reestablish wetland functional characteristics and processes that have been lost by alterations, activities, or catastrophic events in an area that no longer meets the definition of a wetland.

Retention - The process of collecting and holding surface and stormwater runoff with no surface outflow.

Retention/detention facility (R/D) - A type of drainage facility designed either to hold water for a considerable length of time and then release it by evaporation, plant transpiration, and/or infiltration into the ground; or to hold surface and stormwater runoff for a short period of time and then release it to the surface and stormwater management system.

Retrofitting - The renovation of an existing structure or facility to meet changed conditions or to improve performance.

Return interval - A statistical term for the average time of expected interval that an event of some kind will equal or exceed given conditions (e.g., a stormwater flow that occurs every 2 years).

Rhizome - A modified plant stem that grows horizontally underground.

Riffles - Fast sections of a stream where shallow water races over stones and gravel. Riffles usually support a wider variety of bottom organisms than other stream sections.

Rill - A small intermittent watercourse with steep sides, usually only a few inches deep. Often rills are caused by an increase in surface water flow when soil is cleared of vegetation.

Riprap - A facing layer or protective mound of stones placed to prevent erosion or sloughing of a structure or embankment due to flow of surface and stormwater runoff.

Riparian - Pertaining to the banks of streams, wetlands, lakes or tidewater.

VOL 12 2 2 3 3 3 2

R0055630

Riser - A vertical pipe extending from the bottom of a pond BMP that is used to control the discharge rate from a BMP for a specified design storm.

Rodenticide - A substance used to destroy rodents.

Runoff - Water originating from rainfall and other precipitation that is found in drainage facilities, rivers, streams, springs, seeps, ponds, lakes and wetlands as well as shallow ground water.

SCS - Soil Conservation Service, U.S. Department of Agriculture.

SCS Method - A hydrologic analysis based on the Curve Number method (National Engineering Handbook - Section 4: Hydrology, August 2971).

SEPA - See State Environmental Policy Act.

Salmonid - A member of the fish family Salmonidae. Chinook, coho, chum, sockeye and pink salmon; cutthroat, brook, brown, rainbow and steelhead trout; Dolly Varden, kokanee and char are examples of salmonid species.

Saturation point - In soils, the point at which a soil or an aquifer will no longer absorb any amount of water without losing an equal amount.

Scour - Erosion of channel banks due to excessive velocity of the flow of surface and stormwater runoff.

Sediment - Fragmented material that originates from weathering and erosion of rocks or unconsolidated deposits, and is transported by, suspended in, or deposited by water.

Sedimentation - The depositing or formation of sediment.

Sensitive emergent vegetation communities - Assemblages of erect, rooted, herbaceous vegetation, excluding mosses and lichens, at least some of whose members have relatively narrow ranges of environmental requirements, such as hydroperiod, nutrition, temperature, and light. Examples include fen species such as sundew and, as well as a number of species of Carex (sedges).

Sensitive life stages - Stages during which organisms have limited mobility or alternatives in securing the necessities of life, especially including reproduction, rearing, and migration periods.

Sensitive scrub-shrub vegetation communities - Assemblages of woody vegetation less than 6 meters in height, at least some of whose members have relatively narrow ranges of environmental requirements, such as hydroperiod, nutrition, temperature, and light. Examples include fen species such as Labrador tea, bog laurel, and cranberry.

Settleable solids - Those suspended solids in stormwater that separate by settling when the stormwater is held in a quiescent condition for a specified time.

Sheet erosion - The relatively uniform removal of soil from an area without the development of conspicuous water channels.

Sheetflow - Runoff which flows over the ground surface as a thin, even layer, not concentrated in a channel.

Shoreline development - The proposed project as regulated by the Shoreline Management Act. Usually the construction over water or within a shoreline zone (generally 200 feet landward of the water) of structures such as buildings, piers, bulkheads, and breakwaters, including environmental alterations such as dredging and

VOL 12 2 2 3 3 3 3

R0055631

filling, or any project which interferes with public navigational rights on the surface waters.

Short circuiting - The passage of runoff through a BMP in less than the design treatment time.

Siltation - The process by which a river, lake, or other water body becomes clogged with sediment. Silt can clog gravel beds and prevent successful salmon spawning.

Site - The portion of a piece of property which is directly subject to development.

Slope - Degree of deviation of a surface from the horizontal; measured as a numerical ratio, percent, or in degrees. Expressed as a ratio, the first number is the horizontal distance (run) and the second is the vertical distance (rise), as 2:1. A 2:1 slope is a 50 percent slope. Expressed in degrees, the slope is the angle from the horizontal plane, with a 90° slope being vertical (maximum) and 45° being a 1:1 or 100 percent slope.

Sloughing - The sliding of overlying material. It is the same effect as caving, but it usually occurs when the bank or an underlying stratum is saturated or scoured.

Small Parcel Erosion and Sediment Control Plan or "SPESC Plan" - a plan for small sites to implement temporary BMPs to control pollution generated during the construction phase only, primarily erosion and sediment. Guidance for preparing a Small Parcel ESC Plan is contained in Chapter I-3.

Soil - The unconsolidated mineral and organic material on the immediate surface of the earth that serves as a natural medium for the growth of land plants.

Soil group, hydrologic - A classification of soils by the Soil Conservation Service into four runoff potential groups. The groups range from A soils, which are very permeable and produce little or no runoff, to D soils, which are not very permeable and produce much more runoff.

Soil horizon - A layer of soil, approximately parallel to the surface, that has distinct characteristics produced by soil-forming factors.

Soil profile - A vertical section of the soil from the surface through all horizons, including C horizons.

Soil structure - The relation of particles or groups of particles which impart to the whole soil a characteristic manner of breaking; some types are crumb structure, block structure, platy structure, and columnar structure.

Soil permeability - The ease with which gases, liquids, or plant roots penetrate or pass through a layer of soil.

Soil stabilization - The use of measures such as rock lining, vegetation or other engineering structures to prevent the movement of soil when loads are applied to the soil.

Sorption - The physical or chemical binding of pollutants to sediment or organic particles.

Source control BMP - A BMP that is intended to prevent pollutants from entering stormwater. A few examples of source control BMPs are erosion control practices, maintenance of stormwater facilities, constructing roofs over storage and working areas, and directing wash water and similar discharges to the sanitary sewer or a dead end sump.

VOL 12 2 2334

R0055632

Specific energy - The total energy within any system with respect to the channel bottom, equal to the potential head plus velocity and pressure heads.

Spillway - A passage such as a paved apron or channel for surplus water over or around a dam or similar obstruction. An open or closed channel, or both, used to convey excess water from a reservoir. It may contain gates, either manually or automatically controlled, to regulate the discharge of excese water.

State Environmental Policy Act (SEPA) - The Washington State law intended to minimize environmental damage. SEPA requires that state agencies and local governments consider environmental factors when making decisions on activities, such as development proposals over a certain size and comprehensive plans. As part of this process, environmental documents are prepared and opportunities for public comment are provided.

Steep slope - Slopes of 40 percent gradient or steeper.

Storm drains - The encloseed conduits that transport surface and stormwater runoff toward points of discharge (sometimes called storm sewers).

Storm drain system - Refers to the system of gutters, pipes, streams, or ditches used to carry surface and stormwater from surrounding lands to streams, lakes, or Puget Sound.

Storm frequency - The time interval between major storms of predetermined intensity and volumes of runoff for which storm sewers and other structures are designed and constructed to handle hydraulically without surcharging and backflooding, e.g., a 2-year, 10-year or 100-year storm.

Storm sewer - A sewer that carries stormwater and surface water, street wash and other wash waters or drainage, but excludes sewage and industrial wastes. Also called a storm drain.

Stormwater - That portion of precipitation that does not naturally percolate into the ground or evaporate, but flows via overland flow, interflow, channels or pipes into a defined surface water channel, or a constructed infiltration facility.

Stormwater drainage system - constructed and natural features which function together as a system to collect, convey, channel, hold, inhibit, retain, detain, infiltrate, divert, treat or filter stormwater.

Stormwater facility - A constructed component of a stormwater drainage system, designed or constructed to perform a particular function, or multiple functions. Stormwater facilities include, but are not limited to, pipes, swales, ditches, culverts, street gutters, detention basins, retention basins, constructed wetlands, infiltration devices, catchbasins, oil/water separators, sediment basins and modular pavement.

Stormwater Management Manual for the Puget Sound Basin or "Manual" - this manual as prepared by Ecology that contains BMPs to prevent, control or treat pollution in stormwater [or a technically equivalent Manual approved by Ecology].

Stormwater Program - Either the Basic Stormwater Program or the Comprehensive Stormwater Program as appropriate to the context of the reference. See the "Stormwater Program Guidance Manual for the Puget Sound Basin" for a complete description of the requirements of each program.

Stormwater Site Plan - a plan which includes an Erosion and Sediment Control (ESC) Plan and/or a Permanent Stormwater Quality Control Plan (PSQC). For small sites, this plan is the equivalent of a Small Parcel Erosion and Sediment Control Plan. Guidance on preparing a Stormwater Site Plan is contained in Chapter I-3.

VOL 12
2
2335
R0055633

Stream gaging - The quantitative determination of stream flow using gages, current meters, weirs, or other measuring instruments at selected locations. See Gaging station.

Streambanks - The usual boundaries, not the flood boundaries, of a stream channel. Right and left banks are named facing downstream.

Stream classification - The following stream classification which applies to all streams.

1. Type 1 streams are all streams inventoried as Shorelines of the State under Ch. 90.58 RCW.

2. Type 2 streams are all streams smaller than Type 1 streams that flow year around during years of normal rainfall, or are used by salmonids.

3. Type 3 streams are streams that are intermittent or ephemeral during years of normal rainfall and are not used by salmonids.

Streams - Those areas where surface waters flow sufficiently to produce a defined channel or bed. A defined channel or bed is indicated by hydraulically sorted sediments or the removal of vegetative litter or loosely rooted vegetation by the action of moving water. The channel or bed need not contain water year-round. This definition is not meant to include irrigation ditches, canals, storm water runoff devices or other entirely artificial watercourses unless they are used to convey Type 1 and 2 streams naturally occurring prior to construction. Those topographic features that resemble streams but have no defined channels (i.e. swales) shall be considered streams when hydrologic and hydraulic analyses done pursuant to a development proposal predict formation of a defined channel after development.

Structure - A catchbasin or manhole in reference to a storm drainage system.

Stub-out - A short length of pipe provided for future connection to a storm drainage system.

Subbasin - A drainage area which drains to a water course or waterbody named and noted on common maps and which is contained within a basin.

Subcatchment - A subdivision of a drainage basin (generally determined by topography and pipe network configuration).

Subcritical flow - Flow at depths greater than the critical depth.

Sub-division retention/detention facility - A retention/detention facility which is both (1) located within or associated with a short or formal plat sub-division containing only single family or duplex residential structures located on individual lots; and 2) which is required to handle excess runoff generated by development of an area of which two-thirds or more is designated for single family or duplex residential structures located on individual lots.

Subdrain - A pervious backfilled trench containing stone or a pipe for intercepting ground water or seepage.

Subgrade - A layer of stone or soil used as the underlying base for a BMP.

Subsoil - The B horizons of soils with distinct profiles. In soils with weak profile development, the subsoil can be defined as the soil below the plowed soil (or its equivalent of surface soil), in which roots normally grow. Although a common term, it cannot be defined accurately. It has been carried over from early days when "soil" was conceived only as the plowed soil and that under it as the "subsoil."

VOL 12 2 2336

R0055634

Substrate - The natural soil base underlying a BMP.

Supercritical flow - Flow at depths less than the critical depth.

Surcharge - The flow condition occurring in closed conduits when the hydraulic grade line is above the crown of the sewer.

Surface and stormwater - Water originating from rainfall and other precipitation that is found in drainage facilities, rivers, streams, springs, seeps, ponds, lakes, and wetlands as well as shallow ground water.

Surface and stormwater management system - Drainage facilities and any other natural features which collect, store, control, treat and/or convey surface and stormwater.

Suspended solids - Organic or inorganic particles that are suspended in and carried by the water. The term includes sand, mud, and clay particles (and associated pollutants) as well as solids in stormwater.

Swale - A shallow drainage conveyance with relatively gentle side slopes, generally with flow depths less than one foot.

Terrace - An embankment or combination of an embankment and channel across a slope to control erosion by diverting or storing surface runoff instead of permitting it to flow uninterrupted down the slope.

Tile, Drain - Pipe made of burned clay, concrete, or similar material, in short lengths, usually laid with open joints to collect and carry excess water from the soil.

Tile drainage - Land drainage by means of a series of tile lines laid at a specified depth and grade.

Time of concentration - The time period necessary for surface runoff to reach the outlet of a subbasin from the hydraulically most remote point in the tributary drainage area.

Toe of slope - a point or line of slope in an excavation or cut where the lower surface changes to horizontal or meets the exiting ground slope.

Top of slope - a point or line on the upper surface of a slope where it changes to horizontal or meets the original surface.

Topography - General term to include characteristics of the ground surface such as plains, hills, mountains; degree of relief, steepness of slopes, and other physiographic features.

Total dissolved solids - The dissolved salt loading in surface and subsurface waters.

Total solids - The solids in water, sewage, or other liquids, including the dissolved, filterable, and nonfilterable solids. The residue left when the moisture is evaporated and the remainder is dried at a specified temperature, usually 130°C.

Toxic - Poisonous, carcinogenic, or otherwise directly harmful to life.

Tract - A legally created parcel of property designated for special nonresidential and noncommercial uses.

Trash rack - A structural device used to prevent debris from entering a spillway or other hydraulic structure.

VOL 12 2 2337

R0055635

Travel time - The estimated time for surface water to flow between two points of interest.

Treatment BMP - A BMP that is intended to remove pollutants from stormwater. A few examples of treatment BMPs are detention ponds, oil/water separators, biofiltration swales and constructed wetlands.

Turbidity - Dispersion or scattering of light in a liquid, caused by suspended solids and other factors; commonly used as a measure of suspended solids in a liquid.

Underdrain - Plastic pipes with holes drilled through the top, installed on the bottom of an infiltration BMP which are used to collect and remove excess runoff.

Undisturbed buffer - A zone where development activity shall not occur, including logging, and/or the construction of utility trenches, roads, and/or surface and stormwater facilities.

Undisturbed low gradient uplands - Forested land, sufficiently large and flat to infiltrate surface and storm runoff without allowing the concentration of water on the surface of the ground.

Unstable slopes - those sloping areas of land which have in the past exhibited, are currently exhibiting, or will likely in the future exhibit, mass movement of earth.

Unusual biological community types - Assemblages of interacting organisms that are relatively uncommon regionally.

Urbanized area - Areas designated and identified by the U.S. Bureau of Census according to the following criteria: an incorporated place and densely settled surrounding area that together have a maximum population of 50,000.

USEPA - The United States Environmental Protection Agency.

Values - Wetland processes or attributes that are valuable or beneficial to society (also see Functions). Wetland values include support of commercial and sport fish and wildlife species, protection of life and property from flooding, recreation, education, and aesthetic enhancement of human communities.

Vegetation - all organic plant life growing on the surface of the earth.

Water body - Surface waters including rivers, streams, lakes, marine waters, estuaries, and wetlands.

Water quality - A term used to describe the chemical, physical, and biological characteristics off water, usually in respect to its suitability for a particular purpose.

Water quality BMP - A BMP specifically designed for pollutant removal.

Water quality design storm - The 6-month 24-hour design storm.

Water quality standards - Minimum requirements of purity of water for various uses; for example, water for agricultural use in irrigation systems should not exceed specific levels of sodium bicarbonate, pH, total dissolved salts, etc. In Washington, the Department of Ecology sets water quality standards.

Water quality swale - An open vegetated drainage channel intended to optimize water quality treatment of surface and stormwater runoff by following the specific design criteria described in the manual.

VOL 12 2 2338

R0055636

Watershed - a geographic region within which water drains into a particular river, stream, or body of water as identified and numbered by the State of Washington Water Resource Inventory Areas (WRIAs) as defined in Chapter 173-500 WAC.

Water table - The upper surface or top of the saturated portion of the soil or bedrock layer, indicates the uppermost extent of ground water.

Weir - Device for measuring or regulating the flow of water.

Weir notch - The opening in a weir for the passage of water.

Wetlands - Those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas. This includes wetlands created, restored or enhanced as part of a mitigation procedure. This does not include constructed wetlands or the following surface waters of the state intentionally constructed from sites that are not wetlands: Irrigation and drainage ditches, grass-lined swales, canals, agricultural detention facilities, farm ponds, and landscape amenities.

Wetland edge - Delineation of the wetland edge shall be based on the U.S. Army Corps of Engineers Wetlands Delineation Manual, Technical Report Y-87-1, U.S. Army Engineers Waterways Experiment Station, Vicksburg, Miss. (1987)

Wetponds and wetvaults - Drainage facilities for water quality treatment that contain permanent pools of water that are filled during the initial runoff from a storm event. They are designed to optimize water quality by providing retention time in order to settle out particles of fine sediment to which pollutants such as heavy metals absorb, and to allow biologic activity to occur that metabolizes nutrients and organic pollutants.

Zoning ordinance - An ordinance based on the police power of government to protect the public health, safety, and general welfare. It may regulate the type of use and intensity of development of land and structures to the extent necessary for a public purpose. Requirements may vary among various geographically defined areas called zones. Regulations generally cover such items as height and bulk of buildings, density of dwelling units, off-street parking, control of signs, and use of land for residential, commercial, industrial, or agricultural purposes. A zoning ordinance is one of the major methods for implementation of a comprehensive plan.

VOL 12 2 2 3 3 9

R0055637

NOTATION

This list of notations is provided only as a guide to some of the notations used in this report. The exact definition and units are listed when the symbol is used. Since the same symbol can be used for different design methods, the exact definition should be obtained directly from the appropriate section of the report.

A	=	drainage area (mi^2), also full cross-sectional area of culvert barrel (ft^2)
A_b	=	top surface area of basin (ft^2), also area of pond bottom (ft^2)
A_d	=	drainage area
A_p	=	surface area of porous asphalt pavement (ft^2)
A_s	=	surface area of swale (ft^2), also average surface area for detention BMP
A_t	=	total area (acres)
C	=	estimated runoff coefficient
CN	=	SCS runoff curve number
ΔCN	=	change in curve number
D	=	interior height of culvert barrel (ft)
D_{50}	=	median stone diameter (riprap)
d	=	average permanent pool depth of a detention BMP
d_b	=	basin depth (ft)
d_c	=	critical depth (ft)
d_p	=	depth of porous asphalt paving stone subbase (ft)
d_s	=	depth of swale check dam (ft)
dt	=	time interval in minutes
d_x	=	a mixture of riprap sizes where the percent of stone by weight is <x (the specified diameter)
E	=	designated fraction of particulates to be removed by a BMP
f	=	final infiltration rate of soil (in/hr)
f_d	=	infiltration rate including a safety factor of two
g	=	acceleration due to gravity, 32.2 ft/sec^2
H	=	stage height (ft) or water depth above pond bottom, also $H = H_f + H_o + H_{ca}$; head on orifice
H_c	=	specific head at critical depth ($d_c + V_c^2/2g$) (ft)

VOL 12 2 2340

R0055638

H_d	=	design depth of pond
H_e	=	entrance head loss (ft) = $K_e(V^2/2g)$
H_{ex}	=	exit head loss (ft) = $V^2/2g$
H_f	=	Friction loss (ft) = $V^2n^2L/2.22R^{1.33}$ Note: if $(H_f + TW - LS) < D$, adjust H_f such that $(H_f + TW - LS) = D$. This will keep the analysis simple and still yield reasonable results (erring on the conservative side)
HW	=	headwater depth above inlet invert (ft)
h_o	=	distance from the hydraulic grade line at the 2-year flow on the outflow pipe to the overflow elevation
I	=	inflow at time 1 and time 2
I(t)	=	instantaneous hydrograph, in cfs (SBUH hydrograph method)
i	=	hydraulic gradient (ft/ft)
K_e	=	entrance loss coefficient
k	=	time of concentration velocity factor (feet/second)
k_c	=	time of concentration velocity factor; channel flow
k_s	=	time of concentration velocity factor; shallow flow
L	=	distance of flow across a given segment, also length of culvert (ft), also width of emergency overflow weir
MB_d	=	mean tributary basin elevation above sea level (ft)
M_s	=	potential average snowmelt during storms (in)
m	=	number of flow segments
N_s	=	number of check dams along total length of swale
n	=	Manning's "n"
n_s	=	sheet flow; Manning's effective roughness coefficient
O	=	outflow at time 1 and time 2
P	=	rainfall depth (inches)
P_R	=	the total precipitation at a site for the 24-hour design storm event for the given return frequency (R)
Q	=	flow or discharge (cfs), also runoff depth from overlying area of dry well (ft), also orifice area
Q_a	=	after development depth of runoff (inches)
Q_b	=	before development depth of runoff (inches)
Q_c	=	depth of runoff from contributing area (ft)

VOL 12 2 2341

R0055639

Q_d	=	runoff depth in inches over a given area
Q_o	=	average release rate from detention BMP
Q_s	=	depth of runoff controlled by vegetated swale (inches)
Q_t	=	release rate for orifice
Q_{total}	=	total flow at maximum head
Q(t)	=	the routed flow of the runoff hydrograph (SBUH method)
$Q_{10\%}$	=	the flow that is not exceeded more than 10% of the time during the months of adult (salmonid) migration
ΔQ	=	change in runoff depth (inches)
Δq	=	change in peak discharge (cfs)
R	=	hydraulic radius (ft) in Manning's equation
R(t)	=	the total runoff depth at time increment dt, in inches; also known as precipitation excess
S	=	storage at time 1 and time 2, also culvert barrel slope (ft/ft)
S(H)	=	storage (ft^3) at stage height (H)
S_d	=	the largest volume from an initial pond sizing
S_f	=	friction slope = $n^2V^2/2.21R^{4/3}$
S_o	=	slope of flow path (ft/ft), also bottom slope
T	=	width of swale or vegetated filter strip
T_c	=	time of concentration (hrs)
T_t	=	travel time of overland flow across separate flow path segments
$T_{1,2,n}$	=	the consecutive flow paths of different land cover categories having significant differences in flow path slope
TW	=	tailwater depth above invert of culvert outlet (ft) Note: if TW < (D + d_c)/2, set TW = (D + d_c)/2.
t_d	=	design detention time of a BMP
Δt	=	time interval; time 2 - time 1
V	=	average velocity across the land cover (ft/sec), also barrel velocity (fps), also mean velocity
V_c	=	flow velocity at critical depth (fps)
V_{max}	=	maximum allowed velocity of runoff in a biofilter
V_{pp}	=	permanent pool volume
V_r	=	void ratio

VOL 12 2 2342

R0055640

V_{soil}	=	settling velocity of the deign soil particle
W_{50}	=	the median stone size (riprap)
w	=	settling velocity of target particle
y	=	depth of flow
y_n	=	normal flow depth
z	=	basin side slope ratio (h:v)
z^1, z^2	=	side slope ratio of swale cross section (h:v)
α	=	energy coefficient which corrects for the non-uniform distribution of velocity over the channel cross-section

Purpose of this Volume

This volume of the manual provides technical information to help in controlling erosion and sedimentation from new construction activities in the Puget Sound basin. Detailed standards and specifications for BMPs as well as background information on the erosion process and how it may be controlled are included. These BMPs are to be used to develop a detailed Erosion and Sediment Control Plan, as set out in Minimum Requirement #1 (see Chapter I-2). For a general overview of the entire stormwater program, please refer to Chapter I-1 in Volume I.

The target audience includes both officials in local governments who are responsible for administering ordinances pertaining to construction activities, and the development community. In a broader sense, this volume is intended for both engineers and planners because minimization of erosion requires good planning as well as good engineering and, most importantly, close collaboration between the two disciplines.

Chapter Contents

Chapter II-1 provides a general overview of the erosion and sedimentation process and the basic principles by which it may be controlled.

Chapter II-2 explores the concept of BMPs. Seven major problem areas that are encountered during the construction process are discussed, and the various erosion and sedimentation control BMPs that can be applied to each of these areas are briefly described.

Chapter II-3 contains BMPs to deal with pollutants other than sediment. This chapter has been included because many pollutants are adsorbed by or otherwise associated with sediment. Many of these pollutants can be generated during the construction process as a result of the use of petroleum products, fertilizers, pesticides, and other construction chemicals. Some of these pollutants may be hazardous. This chapter outlines how the generation of these wastes can be minimized, and for those that are generated, how they should be handled and disposed of.

Information on NPDES stormwater construction permits and the preparation of an Erosion and Sediment Control (ESC) plan can be found in Chapter II-4.

Chapter II-5 presents the design standards for erosion and sediment control BMPs. BMPs are the means by which Minimum Requirement #1 can be satisfied. In some cases the standards and specifications of BMPs are more in the form of guidelines, such as seeding mixtures for cover practices. In most others the standards and specifications are the minimum technical requirements. Examples include the depth of sediment traps, length of construction entrances etc. Some of the BMPs are simple and easy to apply, such as mulching, but others such as sediment ponds require design by a professional engineer, using the standards set out in this manual. Best management practices for individual family lots and small sites may be found at the end of Chapter II-5.

Acknowledgements

This volume of the manual was compiled by adapting existing manuals with advice from a technical advisory group comprised of people representing local agencies and other interested parties within the Puget Sound basin. The major sources of material include:

CHAPTER II-1

THE EROSION AND SEDIMENTATION PROCESS

II-1.1 IMPACTS OF EROSION AND SEDIMENTATION

Erosion and sedimentation produced by land development damages the environment and is costly to society. Fisheries resources, recreational resources, and aesthetic qualities may be lost or severely degraded. Harbors, lakes, and rivers fill and must be dredged. Sediments become contaminated.

Contractors, consultants, regulators, and inspectors can significantly affect soil loss. When land is developed, erosion increases by 2-40,000 times (1,2). Such erosion is estimated to produce approximately 70 percent of all sediment produced in this country (7). However, using good erosion control practices can greatly reduce this. For example, a study in Lake Tahoe Basin compared practices at two similar construction sites (3). Without erosion control, estimated soil loss exceeded background levels by 100-1000 times. Using good erosion control practices, soil loss was only double background levels.

Everyone is affected by damages from increased erosion and sedimentation. There are a variety of ways.

- The soil loses nutrients as clays, silts, and fine organic matter wash away. Reestablishing vegetation is difficult. The contractor must either import costly topsoil or apply fertilizers.
- Sediment clogs culverts and storm sewers resulting in frequent and costly maintenance. Without maintenance culverts may wash out and storm sewers fail. Siltation also decreases flow capacities.
- Landslides cause damage on-site and off-site.
- Detention facilities fill rapidly with sediment increasing cleaning costs.
- Infiltration devices may become clogged. This has been cited as the major cause of their failure.
- As velocity decreases, streams deposit sediment requiring dredging of obstructed channels. Additionally, harbors must be dredged more often to keep them open for navigation.
- Lakes age more rapidly. As the sediment builds, shallow areas may become covered by waterlilies or weeds. Increased nutrients may cause algal blooms, which deplete oxygen and can lead to fish kills.
- We lose aesthetics. Many citizens value clean streams. An eroded, silt-clogged stream or lake is ugly.
- Turbidity (water cloudiness) and suspended sediment increases. This impairs the feeding ability of aquatic animals, clogs gill passages of fish, and reduces photosynthesis.
- Fish spawning is seriously impacted. Clean gravels provide a habitat for fish eggs and permit a free flow of well oxygenated water around the eggs and alevines (young with egg yolk still attached). Sediment-clogged gravel prevents successful spawning. Sedimentation following spawning can smother the eggs or alevines.

R0055650

The costs associated with these damages vary. Some are easy to quantify, others more difficult. The loss of aesthetic values or of recreational values is hard to quantify. People prefer to canoe in clear streams. Others, who would prefer to water-ski close to home, are confronted with a lake clogged with sediment and weeds. The costs for restoration and management of a single lake can easily run into the millions of dollars.

Reductions in spawning habitat, and thus reduction in salmon and trout production, cause economic losses to sports fisheries and traditional Native American fisheries. When lost, natural production is replaced by hatchery production. The public incurs expenses for construction, operation, and maintenance of hatcheries, and loses the natural production which many people consider superior.

Most quantifiable are the maintenance costs of man-made structures and harbors. Increased maintenance is necessary for culverts, storm sewers, retention/detention facilities, dams, rivers, and harbors. Harbor maintenance, for example, is expensive. The Seattle District of the U.S. Army Corps of Engineers, which does about one-third of the maintenance dredging in Puget Sound, currently budgets about $706,000 yearly for direct costs of dredging. This does not include administrative and other associated costs. Total yearly costs for dredging and administration for the Corps, the Ports and others runs into several million dollars. As city, county, state, and federal taxpayers, we all pay for these costs.

Impact Prevention

The problems listed above make it imperative to minimize erosion on construction sites. This is achieved through control of runoff. Knowledge of the erosion and sedimentation process is helpful in understanding the role of BMPs in runoff control.

II-1.2 THE EROSION AND SEDIMENTATION PROCESS

Soil erosion is defined as the removal and loss of soil by the action of water, ice, gravity, or wind. This section deals principally with soil erosion caused by the force of falling and flowing water.

The erosion process includes the detachment and transport of soil particles. The force of raindrops falling on bare or sparsely vegetated soil detaches soil particles. Water running along the ground surface picks up these particles and carries them along. As runoff increases in velocity and concentration, it detaches more soil particles, cuts rills and gullies into the soil surface, and adds to its sediment load.

II-1.2.1 Types of Water Erosion

Types of erosion caused by falling and flowing water are illustrated in Figure II-1.1; they include raindrop, sheet, rill and gully, and stream and channel erosion.

1. Raindrop Erosion: Erosion resulting from the direct impact of falling drops of rain on soil particles. This impact dislodges soil particles so that they can then be easily transported by runoff.

2. Sheet Erosion: The removal of a layer of exposed surface soil by the action of raindrop splash and runoff. The water moves in broad sheets over the land and is not confined in small depressions.

3. Rill and Gully Erosion: As runoff flows it concentrates in rivulets, cutting grooves called rills into the soil surface. If the flow of water is sufficient, rills may develop into gullies.

VOL 12 2 2353

R0055651

4. Stream and Channel Erosion: Increased volume and velocity of runoff may cause erosion of the stream or channel banks and bottom.

II-1.2.2 Sedimentation

Sedimentation is defined as the settling out of soil particles transported by water (Figure II-1.2). Sedimentation occurs when the velocity of water in which soil particles are suspended is slowed for a sufficient time to allow particles to settle out. Heavier particles, such as sand and gravel, settle more rapidly than fine particles such as clay and silt.

II-1.3 FACTORS INFLUENCING EROSION

The inherent erosion potential of any area is determined by four interrelated, principal factors: soil characteristics, vegetative cover, topography, and climate (Figure II-1.3).

II-1.3.1 Soil Characteristics and the Geology of the Puget Sound Basin

Soil properties which influence erosion by rainfall and runoff are those factors which affect the infiltration capacity of a soil and those which affect the resistance of the soil to detachment and being carried away by falling or flowing water. The vulnerability of a soil to erosion is called erodibility. Some key factors which control erodibility are:

- particle size and gradation
- organic content
- soil structure
- soil permeability

Particle Size

Soils that contain high proportions of silt and very fine sand are generally the most erodible and are easily detached and carried away. The erodibility of these soils is decreased as the percentage of clay or organic matter increases. Clay acts as a binder and tends to limit erodibility. Most soils with a high clay content are relatively resistant to detachment by rainfall and runoff. Once eroded, however, clays are easily transported and settle out slowly.

Organic Content

Organic matter creates a favorable soil structure, improving its stability and permeability. This increases infiltration capacity, delays the start of erosion, and reduces the amount of runoff.

Soil Structure

Organic matter, particle size and gradation affect soil structure (the arrangement, orientation, and organization of particles). Well-drained and well-graded gravels and gravel mixtures with little or no silt are the least erodible soils. Their high permeability and infiltration capacity helps prevent or delay runoff.

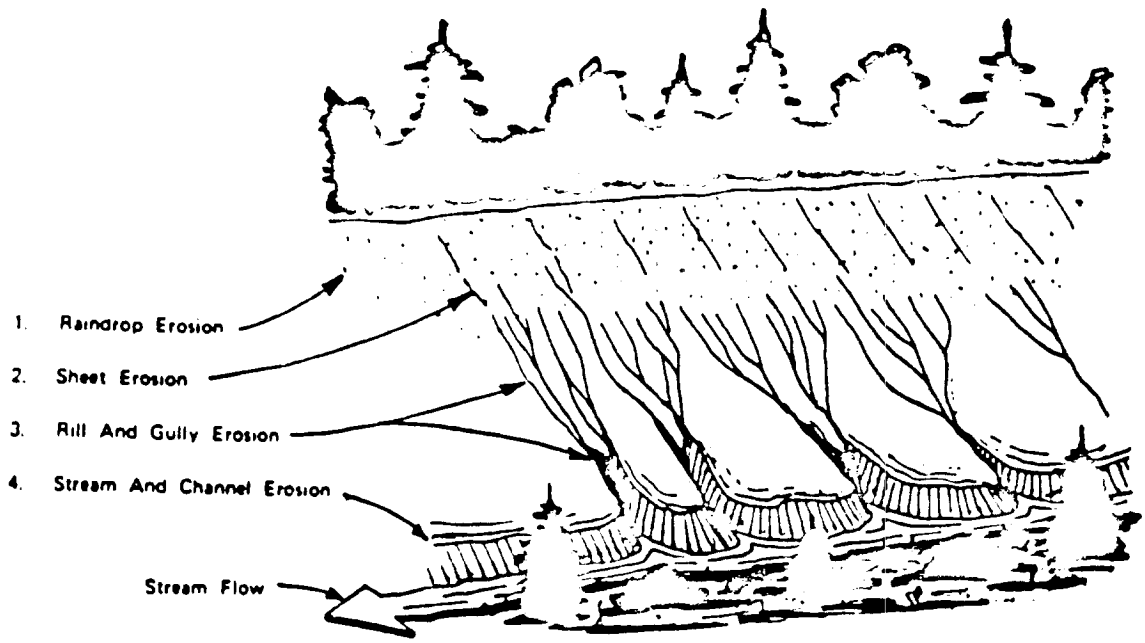
Soil Permeability

Soil permeability refers to the ease by which water passes through a given soil. Clay soils have high water holding capacity relative to sands and gravels, but poor infiltration characteristics. Although clay particles are harder to detach, they are more vulnerable to erosion because they tend to increase runoff.

VOL 12 2 2354

R0055652

Figure II-1.1 Types of Erosion



The Puget Lowland and Associated Watersheds

The landscape of Puget Sound is the product of a long history of mountain-building and subsidence, glaciation and volcanism, erosion and deposition. In addition, the makeup of surface soils is affected to varying degrees by landslide and slopewash activities. The fundamental geologic division in the Puget Sound region is between the Puget Lowland and the Cascade and Olympic mountain ranges. The terrain of the Puget Lowland is made up of a series of rolling plateaus (drift plains) cut by steep-sided valleys. The drift plains are built of unconsolidated sediment deposited during glacial and non-glacial periods during the past two million years. These deposits range from a thin veneer over bedrock hills to a depth of 3,600 feet in the deepest basin.

Two kinds of large valleys cross the lowlands. The longest and deepest of these (Hood Canal, Central Puget Sound, Lake Washington-Duwamish-Puyallup, Sammamish and Snoqualmie troughs) trend roughly north-south and were carved in their present form during the most recent glaciation. Their shapes reflect the direction of flow in ice streams and/or subglacial rivers in the bottom of the continental glaciers that filled the lowland. On the other hand, the canyons of the Nooksack, Skagit, Stillaguamish, Green, Puyallup, Nisqually and Olympic drainages were excavated by streams flowing off the retreating ice sheet and down the Cascade and Olympic mountains.

Although bedrock is not exposed extensively in the Puget Sound region, its underlying structure controls runoff and erosion. The properties of rocks, glacial

VOL 12 2 2355

R0055653

underlying structure controls runoff and erosion. The properties of rocks, glacial deposits and soils exposed at the ground surface determine their reactions to weathering and erosion, and their ability to absorb and transmit water.

Glacial Deposits

Glacial deposits can be divided into two broad categories: till and outwash. The till, and underlying sediments, have undergone one or more glaciations. The weight of up to 4,000 feet of ice has compacted these deposits and can greatly affect their mechanical and hydraulic properties, particularly if the deposit is fresh and undisturbed. Till deposits contain large amounts of silt or clay, often intermixed with large cobbles, and have low percolation rates. Only a small fraction of infiltrated precipitation reaches the regional ground water table through the till. The rest moves laterally through the thin surface soil above the till deposit (generally as shallow subsurface flow), often reemerging at the base of hillslopes. Soils may become saturated during large storms and produce significant amounts of surface runoff. The peak runoff rate from till areas is therefore generally quite high. The lateral flow of subsurface water may also make some types of soil more vulnerable to sloughing.

In most of the drift plains, the outwash sediment deposited by streams that flowed off the front of the ice sheet are common. For the most part these sediments are coarse-grained, well-bedded, porous and loose. Some of these deposits are now terraces along modern stream valleys. Most outwash soils have high percolation rates, and rainfall in these areas is quickly absorbed. Creeks draining outwash deposits often intersect the ground water table and receive most of their flow from ground water discharge. Even for the largest storms, stream flow response is slow, with peak flow often lagging several days behind the rainfall that produced it. Erosion associated with outwash soils is much less than that associated with till. In contrast, erosion of fine-grained sandy outwash can be particularly severe.(8)

II-1.3.2 Vegetative Cover

Vegetative cover (Figure II-1.4) plays an extremely important role in controlling erosion by:

- Shielding the soil surface from the impact of falling rain.
- Slowing the velocity of runoff, thereby permitting greater infiltration.
- Maintaining the soil's capacity to absorb water.
- Holding soil particles in place.

By limiting the removal of existing vegetation, and by decreasing duration of exposure, soil erosion can be significantly reduced. Special consideration should be given to the maintenance of existing vegetative cover on areas of high erosion potential such as erodible soils, steep slopes, drainageways, and the banks of streams.

II-1.3.3 Topography

The size and shape of a watershed influences the amount and rate of runoff. Several control measures, described in Chapters II-2 and II-5, deal with protecting vulnerable areas from high concentrations of runoff.

Slope length and steepness are key elements in determining the volume and velocity of runoff. As slope length and/or steepness increase, the rate of runoff increases and the potential for erosion is magnified.

VOL 12 2 2356

R0055654

Slope orientation is also a factor in determining erosion potential (Figure II-1.5). For example, a slope that faces south and contains droughty soils may have such poor growing conditions that vegetative cover will be difficult to reestablish.

II-1.3.4 Climate

The frequency, intensity, and duration of rainfall and temperature are fundamental factors in determining the amounts of runoff produced. As the volume and/or the velocity of runoff increase, the capacity of runoff to detach and transport soil particles increases.

Where storms are frequent, intense, or of long duration, erosion risks are high (Figure II-1.6). Seasonal changes in temperature, as well as variations in rainfall, help to define the high erosion risk period of the year. If precipitation falls as snow, no erosion will take place. In the spring, however, melting snow adds to the runoff, and erosion potential will be high. Because the ground is still partially frozen, its infiltration capacity is reduced.

The Puget Sound basin and adjacent areas vary significantly in storm intensity and duration from most of the rest of the country. This area is characterized in fall, winter and spring by storms that are mild in intensity and long-lasting in duration. Rainfall in the summer is sporadic and mild. Statistical analysis of the rainfall patterns in this area indicate that storms occur, on the average, every two days in the fall, winter and early spring, and every 7 days in the late spring and summer. These climatic differences are significant because storms in this area require the use of different management tools than do storms in other parts of the country.

II-1.4 BASIC PRINCIPLES: A SUMMARY

From this brief discussion of the erosion process and the factors that influence erosion, seven major principles of erosion and sedimentation control can be summarized.

1. Plan the development to fit the site.
2. Minimize the extent of the disturbed area and duration of exposure.
3. Stabilize and protect disturbed areas as soon as possible.
4. Keep runoff velocities low.
5. Protect disturbed areas from runoff.
6. Retain sediment within the corridor or site area.
7. Implement a thorough maintenance and follow-up program.

Each of these principles is discussed below in more detail.

1. Plan the Development to Fit the Particular Topography, Soils, Drainage Patterns, and Natural Vegetation of the Site.

   Detailed designing should be employed to assure that roadways, buildings, and other permanent features of the development conform to the natural characteristics of the site. Large graded areas should be located on the most level portion of the site. Areas subject to flooding should be avoided and floodplains should be kept free from filling and other development. Areas with steep slopes, erodible soils and soils with severe limitations for the intended uses should not be utilized without overcoming the limitations

through sound engineering practices. For instance, long steep slopes can be broken by benching, terracing, or constructing diversion structures (see Chapter II-2.).

Erosion control, development, and maintenance costs can be minimized by selecting a site suitable by its nature for a specific proposed activity, rather than attempting to modify a site to conform to a proposed activity. This kind of planning can be more easily accomplished where there is a general land use plan based upon a comprehensive inventory of soils, water, and other related resources.

2. Minimize the Extent of the Area Exposed at One Time and the Duration of Exposure.

When earth changes are required and the natural vegetation is removed, keep the area and the duration of exposure to a minimum. Plan the phases or stages of development so that only the areas which are actively being developed are exposed. All other areas should have a good cover of temporary or permanent vegetation or mulch. Grading should be completed as soon as possible after it is begun. Then immediately after grading is complete, permanent vegetative cover should be established in the ar As cut slopes are made and as fill slopes are brought up to grade, these eas should be revegetated as the work progresses. This is known as staged seeding. Minimizing grading of large or critical areas during the period October-April reduces the risk of erosion.

3. Stabilize and Protect Disturbed Areas as Soon as Possible.

Two methods are available for stabilizing disturbed areas: mechanical (or structural) methods and vegetative methods. In some cases, these are combined in order to retard erosion. These control measures are discussed in Chapter II-2.

4. Keep Runoff Velocities Low.

The removal of existing vegetative cover and the resulting increase in impermeable surface area during development will increase both the volume and velocity of runoff. These increases must be taken into account when providing for erosion control. Slope changes should be designed to keep slope length and gradient to a minimum. Short slopes, low gradients, and the preservation of natural vegetative cover can keep runoff velocities low. This will limit erosion hazards.

5. Protect Disturbed Areas from Stormwater Runoff.

Measures can be utilized to prevent off-site water from entering and running over the disturbed area. These protective measures are described in Chapter II-2.

6. Retain Sediment Within the Corridor or Site Area.

Sediment can be retained by two methods: (1) by filtering runoff as it flows and (2) by detaining sediment-laden runoff for a period of time so that soil particles settle out. The best way to control sediment, however, is to prevent erosion in the first place.

7. Implement a Thorough Maintenance and Follow-Up Program.

This last principle is <u>vital</u> to the success of the six other principles. A

the erosion and sediment control practices. These practices must be maintained just as construction equipment must be maintained and materials checked and inventoried. An example of applying this principle would be to start a routine "end of day check" to make sure that all control practices are working properly.

CHAPTER II-2

BEST MANAGEMENT PRACTICES FOR PROBLEM AREAS ON CONSTRUCTION SITES

II-2.1 BEST MANAGEMENT PRACTICES

Understanding the basic processes of erosion and sedimentation and the basic principles of control provides the foundation for developing and implementing a successful erosion and sedimentation control plan. This chapter will outline the types of erosion and sediment control measures (Best Management Practices) that can be applied before, during and after the development process. Best Management Practices (BMPs) are defined as physical, structural, and/or managerial practices, that when used singly or in combination, prevent or reduce pollution of water and have been approved by Ecology.

The purpose of this chapter is to provide guidelines and background information that will assist in choosing the most suitable BMPs to control erosion and sediment from construction sites. This is done by describing the major problem areas and the appropriate BMPs that could be implemented to manage the problem. Complete standards and specifications for each BMP are provided in Chapter II-5.

Best Management Practices are those practices that are currently believed to provide the most effective, practicable means of preventing or reducing pollution generated by non-point sources. They are used to implement the general principles presented in the previous chapter. Most importantly, they change with time, as we discover or become aware of other practices that better accomplish their purposes.

Most of the BMPs presented in this manual either minimize erosion or control sedimentation. In any construction project, it is most important to do everything feasible to prevent erosion first. Stabilizing slopes, creating natural vegetation buffers, diverting runoff frc exposed areas, controlling the volume & velocity of runoff and conveying that runoff away from the development area all serve to decrease erosion. Silt fences, sediment traps and diversions all trap sediment before it leaves the site. Sedimentation control should only deal with the sediment produced from unavoidable erosion.

Best Management Practices fall into a number of categories. Frequently they are split into cover BMPs, including grasses, mulches or other materials used to stabilize soil surfaces, or structural BMPs including check dams, sediment ponds (basins)[1], diversions and other structural techniques. Most sites require the use of several types of BMPs to adequately control erosion and sedimentation, so vegetative BMPs and structural BMPs are often used together to address a single problem. BMPs may be temporary or permanent. Soil that is exposed for a lengthy time is a large contributor to erosion and it should be stabilized as soon as possible. Thus, a temporary control measure (vegetative or structural), may be used because more grading will be needed later in the project or because putting in a permanent control is not immediately feasible. Measures left in place for a year or less are generally considered temporary (Figure II-2.1). In some cases temporary BMPs can be planned into a development in such a way that they may become permanent as completion of various phases of the development occurs. For example, sediment ponds can, with modification, function as permanent detention ponds (Figure II-2.2).

Monitoring and Maintenance

No matter whether BMPs are temporary or permanent, structural or vegetative, monitoring and maintenance of BMPs is vital. The importance of maintenance has been supported by a survey of BMPs by the King County Conservation District (1).

[1] The terms sediment pond and sediment basin are used interchangeably.

Preliminary results indicate that the major reason for BMP failure is poor maintenance. BMPs should be inspected regularly, particularly before, during, and after a major storm. Specific maintenance requirements of individual BMPs are dealt with in Chapter II-5.

II-2.1.1 Problem Areas

The remainder of this chapter will examine particular problem areas of the construction site (such as slopes or surface drainageways) and will describe which BMPs best alleviate problems associated with each area. The areas are:

1. Slopes
2. Streams and Waterways
3. Surface Drainageways
4. Enclosed Drainage Inlets and Outfalls
5. Large, Flat Surface Areas
6. Borrow Areas
7. Adjacent Properties

A listing of the BMPs and the problem area, or areas, they are appropriate for, is presented as a uniform coding system in Table II-2.2 at the end of this chapter. This has been introduced to promote uniformity in the specification and presentation of BMPs on Erosion and Sedimentation Control (ESC) plans. Each BMP has been assigned a specific number, code and symbol.

Assigned numbers should be used to identify BMPs in the narrative or other written portions of the plan, while the practice symbol should be used to identify practices on the map or site plan. The BMP can be further defined to indicate whether it is proposed as a temporary or permanent measure by using the notation "t" or "p". For example SOp = permanent sodding; STt = temporary sediment trap. The practice symbols are based upon similar systems used in other states such as Virginia and Maryland. We hope that the system will become widely used so that ESC plans will become more uniform and understandable throughout the Puget Sound basin.

Note: The American Society of Agricultural Engineers (ASAE) is proposing to standardize mapping symbols for erosion and sediment control structures and practices. These symbols differ somewhat from those now in this manual, as they are based on another resource. Since those symbols are still in the discussion stage, we have chosen to continue to use the practice symbols found in the Virginia manual.

II-2.2 SLOPES

Slopes greatly increase the potential for erosion. As slope length and steepness increase, runoff velocity increases. This increases the capacity of water to detach and transport soil particles. Steeper slopes usually have faster runoff velocities, less infiltration and more erosion than less steep slopes.

Modifying a slope by clearing existing vegetative cover also increases its vulnerability to erosion. Vegetation slows down runoff velocity and root systems hold soil particles in place. Vegetation maintains the soil's capacity to absorb precipitation. The following conditions indicate a need for special care when modifying or creating a slope:

VOL 12 2 2367

R0055665

1. Extensive length.[2]

2. Moderate to extreme steepness. (greater than about 7%)

3. High soil erodibility.

4. Difficulty of reestablishing vegetative cover.

Vegetative stabilization, diversion measures, slope drains and slope stabilization measures may counteract problems created by modifying slopes.

II-2.2.1 Vegetative Stabilization Techniques (BMPs E1.10, E1.15, E1.30, E1.35, E1.40)

Vegetative Buffer Strips

Maintaining a natural vegetative buffer or filter strip at the base of a slope retains sediment on site and is the preferred method for control of erosion. If the natural vegetative cover is left, other cover techniques such as mulch or plastic covering will not have to be used. Undisturbed vegetation is by far the best method to maintain unstable slopes. If the natural vegetative covering must be disturbed, methods such as placing sod strips at intervals along the face of the slope also help (Figure II-2.8). These measures help slow runoff, trap sediment, and reduce the volume of runoff.

Grass or grass and legumes are the most commonly used plant material for stabilizing slopes. Plants are usually established in one of three ways (Figure II-2.9):

1. Hydro-seeding: A mixture of seeds, fertilizer, and water is sprayed on the slope. A mulch and a mulch tacking agent can also be applied. This method is effective on large areas.

2. Standard seeding: Seed is drilled or broadcast either mechanically or by hand. A cultipacker or similar tool is used after seeding to make the seedbed firm and to provide seed covering. The proper timing of seeding, mulching, and watering is important for areas seeded in this manner.

3. Sodding: Sod strips are laid across the slope and in this way instant cover is provided. Sod should be placed on a prepared bed and pegged on steep slopes. Watering is important. This method is effective and is often used on steep slopes.

II-2.2.2 Diversion Measures Used to Control Erosion (BMP E2.55)

A dike, ditch or a combination dike/ditch can divert runoff from the face of an exposed slope. For short slopes, placing these diversion measures at the top works well. For longer slopes, placing the dikes or ditches across the slope at intervals effectively reduces slope length. Temporary diversions must remain in place until slopes have been permanently restabilized.

Diversion ditches can be bare channels, vegetatively stabilized channels, or channels lined with a hard surface material (Figure II-2.3). To determine what size and design is appropriate for each situation consider the following:

1. The amount of runoff to be diverted.

2. The velocity of runoff in the diversion.

[2] As a general rule there will be a potential hazard if slope lengths exceed the following: 0-7% - 300 feet; 7-15% - 150 feet; >15% - 75 feet.

VOL 12 2 2368

R0055666

3. The erodibility of the soils on the slope.

4. The erodibility of the soils within the channel.

When properly constructed, diversions minimize runoff over disturbed slopes. They may also collect runoff and divert it to a sediment trap or pond.

Since diversions concentrate the volume of surface runoff, they increase its erosive force. The contractor should release runoff onto a stabilized area to reduce erosion potential. Gradually reducing the slope of the diversion channel is sometimes adequate. The contractor may also use level spreaders, or stormwater conveyance channels such as grassed waterways (Figure II-2.4).

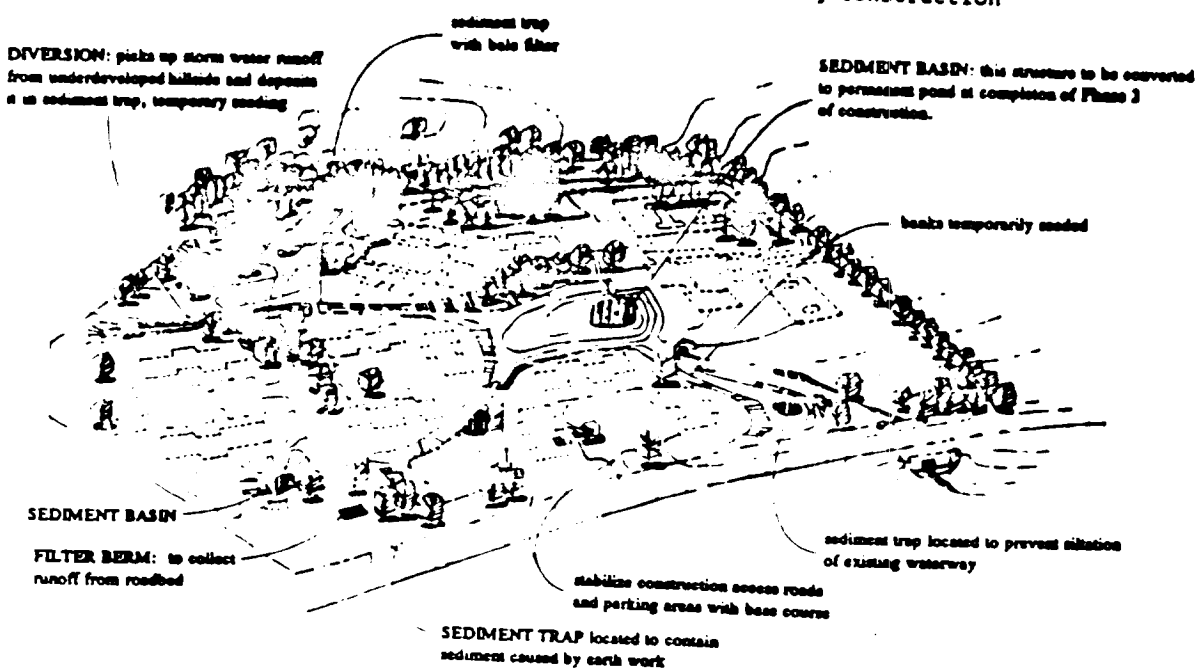
II-2.2.3 Slope Drains (BMPs E2.25, E2.70)

Where disposing of runoff laterally is unsatisfactory, the contractor may drain it over the slope face. Slope drains can run down the surface of the slope as sectional downdrains, paved chutes, or pipes placed beneath the ground surface (Figure II-2.5).

On-surface sectional downdrains are usually pipes made of corrugated metal, bituminous fiber, or other material; these slope drains are temporary. Paved chutes covered with a surface of concrete or bituminous material are usually permanent. Subsurface pipes are also permanent.

The contractor should protect against erosion at the inlet; otherwise undercutting at the lip of the drain and piping under the drain frequently occur. Compacting the soil carefully at the mouth of the slope drain and anchoring it adequately can prevent this undercutting. Also, any areas cleared to construct the drain should be revegetated and stabilized.

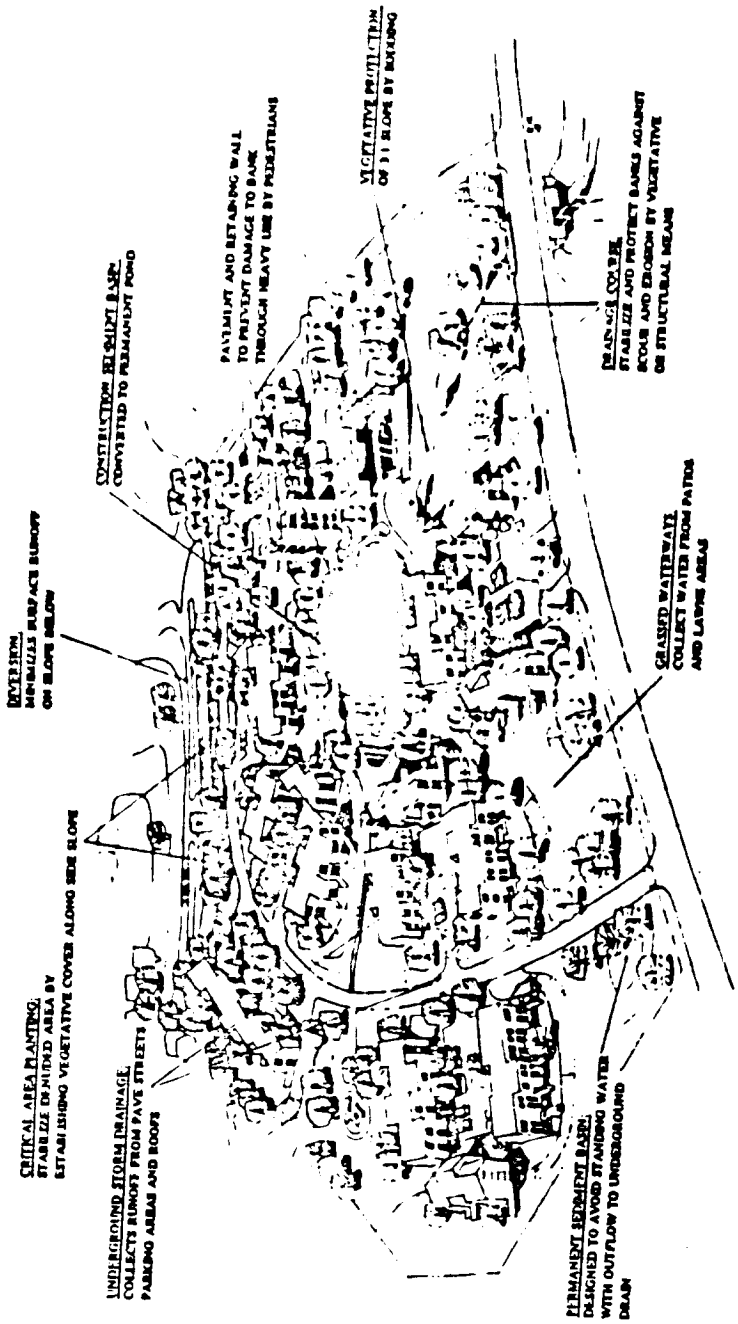
Figure II-2.1 Temporary Control Measures Used During Construction



VOL 12 2 2369

R0055667

Figure II-2.2 Many Temporary Measures can be Made Permanent



VOL 12 2 2310

R0055668

At the slope drain outlet, energy dissipators (such as riprap) are frequently necessary. Not using a dissipator can result in serious erosion problems at the outflow end of the drain. The dissipator slows the velocity of the runoff to a nonerosive level. Riprap is one effective energy dissipator.

II-2.2.4 Structural Slope Stabilization Measures (BMPs E2.35, E2.40, E2.45)

The most effective way to decrease erosion is to avoid modifying slopes. The angle of repose naturally achieved is the most stable for that soil type and situation. However, during construction it is often necessary to modify existing slopes or to create non-natural slopes. Cut and fill slopes are a good example.

One way to stabilize slopes is to reduce their steepness. To choose an appropriate slope ratio we consider the soil's stability, drainage characteristics, and erodibility. The type of vegetative cover and the type of maintenance are also important.

To reduce extreme slope a developer may use retaining walls (Figure II-2.6). Retaining walls are often used when a slope is too steep to establish and maintain vegetation. They obviate disturbance of the upper parts of natural slopes when lower parts are disturbed. Thus, trees or other naturally stable vegetation can be maintained. The cost of building retaining walls is significant but many areas are difficult or impossible to stabilize otherwise. Another way to protect slopes against erosion is to reduce length by using diversions or benches, as previously mentioned.

When slopes are disturbed, leaving them rough reduces velocity and increases infiltration rates. Rough slopes hold water, seed, and mulch better than smooth slopes.(2) Slope surfaces can be roughened by running wheeled construction equipment across the slope, or tracked equipment up and down the slope face. The grooves created by the construction equipment should run across the slope horizontally, and not up and down the slope. Slopes can also be scarified to produce the desired surface roughness (Figure II-2.7).

A suitable soil, good seedbed preparation, and adequate lime and fertilizer are required for all of these methods. However, special precautions need to be taken to avoid nutrients (especially phosphorus) from fertilizers being washed into waterways.

If final grading is delayed more than a few days, the contractor should stabilize exposed slopes immediately after completing rough grading. For short periods of protection either temporary mulching or temporary seeding and mulching together should be used.

When slopes are cut to final grade, permanent vegetative stabilization measures are implemented. Selecting appropriate plant materials depends on:

1. Soil and climate conditions.
2. Duration, quantity, and velocity of runoff.
3. Time required to establish cover.
4. Maintenance requirements.
5. Site use.

Figure II-2.5 Slope Drains

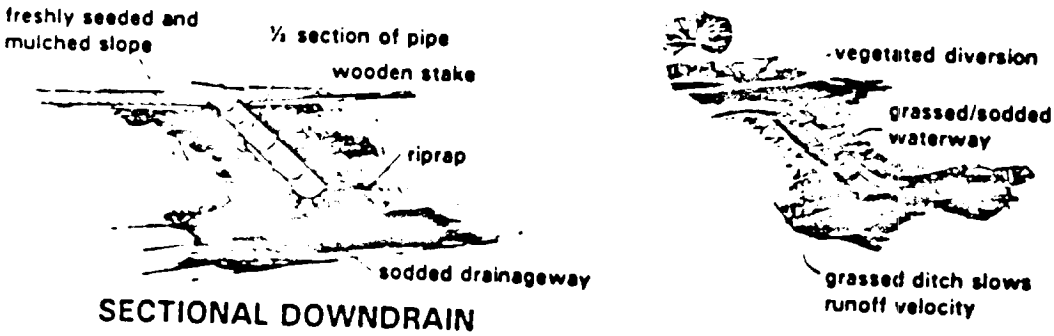

Figure II-2.6 Use of Retaining Walls

VOL 12 2 2374

R0055672

Establishing grass successfully requires that contractors:

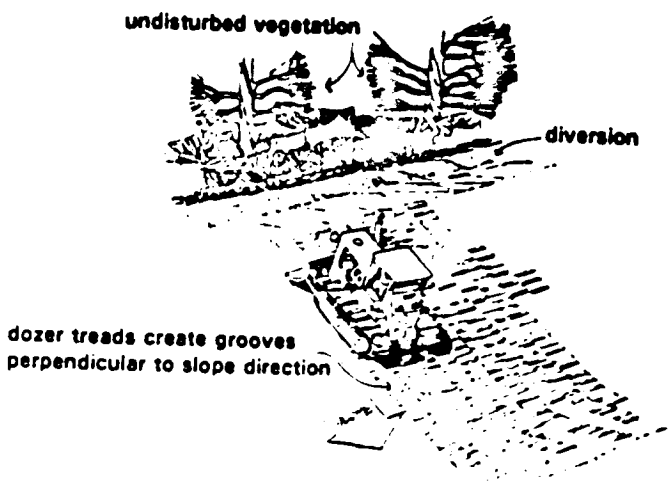
1. Select proper seeding mixture for the site.
2. Observe seeding dates.
3. Cover area to be seeded with topsoil.
4. Prepare seedbed and plant properly.
5. Apply the correct amount of fertilizer for the specific seed or plant type.
6. Protect slope from wind and water erosion during establishment.
7. Ensure that adequate water is available during establishment and in dry periods, if necessary (by natural or other means).

Clear plastic covering provides immediate protection to slopes that cannot be prepared and seeded during the seeding period and/or during initial establishment of seeded areas. However, plastic covering also increases the quantity and velocity of runoff, requiring safe disposal of it onto stabilized areas. Additionally, plastic becomes a disposal problem once it is removed from the slopes it is protecting. Generally, mulches are a better solution for covering exposed areas.

Mulches

Mulching after permanent seeding as well as before seeding protects exposed areas for short periods. Mulches decrease the impact of falling rain, slow runoff velocity and increase the capacity of the soil to absorb water. Mulches hold seeds in place, preserve soil moisture, and insulate germinating seeds from the extremes of heat and cold. Many mulches are available: these include straw and woodchips.

Figure II-2.7 Slope Roughening



Unvegetated Slopes Should Be Temporarily Scarified To Minimize Runoff Velocities

VOL 12
2
2375
R0055673

Most mulches must be anchored. Another alternative is to disc the mulch just enough to anchor it. While tacking agents can be used, they are only effective under the right conditions and cannot be used to try and solve problems with unsuitable soils or excessively steep slopes.

Special Problems

On fill slopes, compaction can be a major factor in erosion control. In addition to other compaction controls required by the nature of the project, the minimum criterion recommended for successful erosion control on fill slopes is to meet or exceed the standards described in WSDOT Standard Specifications Section 2-03.3(14)C "Compacting Earth Embankments."(3) Running heavy equipment over the fill usually compacts it adequately. Formal testing may not be required. On cut slopes, ground water seepage can cause erosion problems. Seepage causes piping and soil slippage. (4)

Slope is an important factor in the success of vegetative restabilization measures. On steep slopes (2:1 or steeper; 2 feet horizontal distance to 1 foot vertical rise) normal tillage equipment cannot be used to prepare a seedbed. Stormwater runoff will result in the loss of seeds, fertilizer, and soil. Sod can be used to stabilize steep slopes instead of seeding where grades are more than 2:1. Sod on steeper slopes must be anchored with pegs.

Sandy soils present a special problem for establishing vegetation, especially in areas where the sand is deep and droughty. American beach grass is one solution to this problem. This plant is established by hand planting live plants.

Steeply sloped areas such as lake shores and road banks involve three special considerations:

1. To ensure probability of successful stabilization, banks should consist of slopes that are 2:1 or flatter.

2. The toe of the slope must be protected from undercutting or other erosive forces by mechanical means where necessary.

3. Water seepage coming out on the face of the slope should be intercepted by a properly designed drainage system (Figure II-2.10).

II-2.2.5 Summary

This section reviewed a range of choices available for erosion control on slopes. These measures may protect other areas exposed during development. A summary follows:

1. Diversion measures: Diversions can intercept stormwater runoff before it reaches disturbed slopes or other exposed areas. They can also collect runoff and convey it to a sediment basin or other suitable location.

2. Vegetative buffer strips: Natural vegetative filters retain sediment on-site. The contractor can significantly reduce erosion on slopes through proper application of these control measures.

3. Slope stabilization control measures: Slopes can be stabilized both mechanically and vegetatively. A slope exposed for longer than a few days should be stabilized by using temporary mulching and seeding. Retaining walls reduce slope and stabilization problems.

II-2.3 STREAMS AND WATERWAYS

Protecting streams and waterways on and near sites undergoing development and protecting areas downstream from development involves three goals:

1. The increased sediment loads carried by surface runoff from areas under construction must not be allowed to enter streams.

2. Stream banks must be protected from erosion hazards caused by increases in runoff volume and velocity.

3. The rates of release of increased volumes of runoff into streams and waterways and the velocity of flow in stream channels must be controlled.

There are several characteristics that serve to identify streams that are particularly vulnerable to erosion. Streams which have a small channel capacity and steep banks are very susceptible to erosion. Streams which flow through areas of erodible soil and streams with sharp meanders or bends in the channel alignment are also prone to erosion (4). Before development begins, nearby streams should be analyzed to identify potential problem areas.

II-2.3.1 Streambank Stabilization Measures (BMPs E2.75-2.90)

The maintenance of existing vegetation on stream banks is a fundamental principle of erosion and sedimentation control. Streambank vegetation serves to stabilize the soil, slow runoff and dissipate its erosive energy, and to filter sediment from runoff. To prevent the destruction of streambank vegetation, stream crossing and construction traffic along the banks must be controlled. Culverts or temporary bridges for vehicle crossings should be constructed only where necessary (Figure II-2.11).

(Note: federal, state and local permits may all be required before streambank (or near streambank) work can commence - see Chapter I-3.

Vegetative Measures

Where stream banks must be disturbed or where existing cover is inadequate, grass or grass-legume mixtures may be established. Immediately after grading on stream banks has been completed, vegetative restabilization measures must be initiated. Willows and other natural vegetation, as well as grass and legumes, are recommended for the protection of stream banks. Woody vegetation is used where ice damage may occur.(6)

Structural Measures

Stream banks can be protected from erosion by structural as well as vegetative measures. Where vegetation will not provide sufficient protection, banks can be protected with revetments and deflectors, as well as other mechanical measures. However, willows and other vegetation can also be used in conjunction with structural measures. This is a biomechanical approach. Biomechanical and vegetative methods are always preferred over purely structural measures, which only should be used when absolutely necessary.

Revetments, which cover the banks, are commonly used where sharp bends or constrictions in the stream channel (such as culverts, bridges, or grade control structures) occur. Riprap, gabions, sacked concrete, and concrete or asphalt paving are commonly used as revetment materials. Deflectors consist of jetties or pilings that angle outward from the bank in a downstream direction and deflect currents away from vulnerable bank areas (Figure II-2.12).

II-2.3.2 Sediment Control Measures (BMPs E2.60, E3.10 through 3.40)

The first essential step in preventing sediment from entering streams and waterways is to control erosion on construction sites. A second necessary step in sediment control is to trap sediment that is transported by runoff before it reaches streams and waterways or leaves the construction site.

To trap sediment, the runoff must be detained for a sufficient period of time (up to 40 hours or longer) to allow the suspended soil particles to settle out. The amount of sediment which is deposited will depend on the speed at which runoff flows through the sediment trap, the length of time that runoff is detained, and the size and weight of the soil particles which are in suspension (6).

Several techniques are available for controlling the amount of sediment which reaches streams and waterways. Vegetative filter strips (preferably strips left in their natural state) between streams and development areas serve to slow runoff and filter out sediment. Check dams can also be constructed in drainageways. Check dams placed at regular intervals within a drainage channel are a temporary sediment control measure that is easy and economical to construct (Figure II-2.13). Barriers are constructed of bags filled with peagravel or crushed rock and stacked in an interlocking manner which is designed to trap sediment and reduce the velocity of flow. Bags filled with peagravel tend to filter the water. They do not totally block the flow like sandfilled bags.

Piping, or undercutting, can be reduced by setting the bags at least 6 inches into the bottom of the drainageway and compacting excavated soil along the upstream side (Figure II-2.14).

Streams may also be protected from increased sediment loads by trapping runoff in sediment basins or ponds before it is released into stream channels. In addition to trapping sediment, these basins are designed to release runoff at nonerosive rates. Such sediment basins can be constructed by excavating a pit or by construction of an impoundment (Figure II-2.15).

Sediment basins often consist of an earthen dam, mechanical spillway (including a perforated riser pipe), and an emergency spillway. The construction of sediment basins should be completed before clearing and grading begin. They are generally located at or near the low point of the site. Points of discharge from sediment basins must be stabilized. In many developments these temporary sediment basins may be converted into permanent retention/detention basins (Figure II-2.16).

II-2.3.3 Summary

The two categories of BMPs used to protect streams and waterways from erosion and sedimentation are:

1. Streambank stabilization BMPs: Streambanks can be stabilized by using vegetative or mechanical control techniques. Deciding which method is appropriate includes factors such as the volume and velocity of water in the stream, the gradient and shape of the stream, and maintenance of control measures.

2. Sedimentation control BMPs: It is necessary to prevent sediment from entering streams and waterways and this can be done by using vegetative filters and sediment traps or basins and check dams. Sediment traps and basins can be either temporary or permanent. Sediment traps are usually temporary and are removed and filled in after construction. Permanent sediment ponds may become a part of the final development in the form of ponds or small lakes. These ponds can be attractive after development is completed.

VOL 12 2 2380

R0055678

II-2.4 SURFACE DRAINAGEWAYS

Surface runoff, and runoff intercepted by erosion control measures such as diversions, must be collected by drainageways and let out in stabilized areas, storm sewers, or sediment basins. The design of these drainageways ensures that runoff is transported without risk of erosion or flooding. Unless surface drainageways are adequately designed, constructed, and maintained, they can become a major source of sediment pollution.

Development should be planned to maintain and utilize the naturally stabilized drainageways that exist on a site. Increases in runoff volume and velocity because of changes in soil and surface conditions during and after construction must be anticipated and controlled to the maximum extent possible. Where the capacity of the natural site drainage channels is exceeded, additional capacity, stabilizing vegetation, and/or structural measures may be needed.

Allowable design velocities vary with soil conditions, the character of the channel lining, and anticipated runoff volume. Formulas and techniques for determining runoff flows, channel cross sections, slopes, stabilizing covers, and design velocity are discussed in Volume III, Chapter III-2 instead of this volume to avoid duplication in BMPs.

II-2.4.1 Grade Control Structures

To reduce the velocity of runoff in drainageways, a variety of grade control structures can be used. These structures can be either temporary or permanent depending on the long-range requirements for the site. Pipe drops and drop spillways can be used.

II-2.4.2 Summary

Erosion and sedimentation from surface runoff can be minimized through the use of the following:

1. Grassed waterways: These channels may be stabilized through seeding and mulching or with sod, and are the preferred form of conveyance.

2. Lined channels: Lined channels should be used where water velocities are high, but are an undesirable alternative to grassed waterways.

3. Grade control structures: In some cases, grade control structures are necessary to reduce runoff velocity to non-erosive levels. Care should be taken to ensure the protection of channel sides and bottoms.

II-2.5 ENCLOSED DRAINAGE: INLET AND OUTFALL CONTROL

The capacity of vegetated drainage channels may be exceeded by the increases in runoff caused by construction activities. As a result, vegetatively-lined channels may scour and erode. Enclosed storm sewers can safely convey runoff of high concentrations and velocities; they can also serve to decrease the velocity of runoff and release it at preferred rates of flow. The following factors should be considered in determining when to use a storm sewer:

1. Whether or not existing enclosed storm sewers are available within reasonable proximity to the site or if there is a natural outlet available.

2. What the actual size of paved areas is and what the ratio of paved areas is to vegetated areas.

VOL 12 2 2381

R0055679

The installation of storm sewers, grassy swales, and other runoff control systems before major building construction begins can aid in controlling site runoff and in avoiding erosion hazards. Volume III contains BMPs for runoff quality and quantity control.

Diversions and surface drainageways are needed to intercept runoff and to convey runoff to storm sewers.

II-2.5.1 Drain Inlet Sediment Filters (BMPs E3.30, E3.35)

The capacity of the storm sewer system itself can be severely impaired by sediment deposits within the system. Sediment should be prevented from entering the enclosed storm sewer by the use of small sediment traps or sumps and filters at system inlets. Filters made of crushed rock, gravel, or sod, can be placed at inlets where sediment traps cannot be constructed (Figures II-2.17 and II-2.18). It is essential to regularly check and clean out these sediment traps and filters to insure that they function properly.

II-2.5.2 Enclosed Drains and Sediment Basins (BMP E3.40)

Where enclosed drainage systems do not tie into existing storm drainage mains, consideration must be given to the location and design of the enclosed drainage system outlet. These outlets must be resistant to erosion. The rate of release must be controlled and the energy of flow must be dissipated. It is essential that sediment be removed from runoff before it is released from the site or corridor. Sediment basins are frequently used at storm sewer outlets during construction.

II-2.5.3 Summary

Enclosed storm sewer systems can safely convey high velocities and large volumes of runoff as well as aid in preventing erosion during and after construction. Sediment must be prevented from entering the storm sewer system and it must be removed from runoff. The following BMPs achieve these purposes:

1. Drain inlet sediment filters prevent sediment from entering the storm sewer system.

2. Enclosed drains and sediment basins mus be carefully located and designed to:

   a. Trap sediment that may be in storm water before it is released off the site or downstream.

   b. Control the volume and velocity of runoff.

The use of temporary control measures can reduce the accumulation of sediment in an enclosed drainage system.

II-2.6 LARGE, FLAT SURFACE AREAS

II-2.6.1 Exposed Surfaces (BMPs E1.10, E1.15, E2.10, E2.15, E3.10, E3.40)

Although erosion rates on steep exposed slopes are higher than on flat or gently sloping areas, all areas of exposed soil are vulnerable to erosion. If erosion control is ignored on large areas of nearly flat or gently sloping land, it will be possible for significant amounts of soil to be eroded. Clearing, grading, and vegetative restabilization in these areas can be timed so that the extent of exposed area and the duration of exposure is minimized. These areas require prompt

VOL 12 2 2385

R0055683

vegetative restabilization. Temporary seeding or mulching is required where large areas will not be permanently stabilized within recommended time limits. Diversions, sediment barriers, or traps constructed on the lower side of large disturbed areas should be used to intercept and collect sediment.

Rights-of-way and parking areas that are being prepared for paving must be protected from rainfall and runoff. Diversions should be constructed to protect these areas from runoff before clearing and grading begin.

Areas that are being prepared for paving should be properly compacted because compaction makes the exposed surface area less vulnerable to erosion. Cleared rights-of-way may be covered with crushed aggregate to reduce erosion. Where rights-of-way will not be used for construction traffic, they can be seeded with a temporary cover.

Gravel or stone filter berms should be used at intervals along the gradient right-of-way to intercept runoff and direct it to stabilized areas, drainageways, or enclosed drainage system inlets. Filter berms also serve to slow and filter runoff and collect sediment. These berms can be crossed by construction equipment.

II-2.6.2 Paved Surfaces (BMP E3.25)

An increase in paved or compacted surface area on a site greatly increases the rate of site runoff. For example, a 20 percent increase in paved area can cause runoff to more than double during a heavy rainfall (8). In addition, the velocity of runoff moving across a paved surface is higher than the velocity of runoff moving across an area of exposed earth or vegetation. Pavement provides very little resistance to flow and does not allow any infiltration. Runoff draining from a paved surface area is also often highly concentrated.

The concentration of runoff leaving paved areas is highly erosive. After construction is complete, the paved roadway itself can serve as a drainageway with curbs and gutters conducting runoff to enclosed drainage system inlets. Where it is not economically feasible to install curbs and gutters, paved surfaces should be designed so that runoff will travel the shortest possible distance across the paved areas. This will prevent large accumulations of runoff from leaving paved areas at high velocities in any one area.

Well-stabilized drainageways will be necessary to receive and convey the increased volumes and velocities of runoff from paved surfaces. Where concentrated flows of runoff leave paved surface areas, outlet points must be especially well stabilized.

II-2.6.3 Summary

The amount of erosion on flat and gently sloping surface areas can be significant. Erosion on these areas can be minimized by:

1. Scheduling development in phases: The extent of the exposed area and the duration of exposure should be kept to a minimum.
2. Vegetative restabilization: Prompt surface stabilization with either temporary or permanent vegetative cover minimizes erosion.
3. Sediment traps: These measures trap soil eroded from exposed surface areas before it is carried off the site or into waterways.

Areas being prepared for paving should be protected from erosion by the use of:

1. Gravel or stone filter berms: Filter berms slow and filter runoff and divert runoff from the exposed right-of-way.

VOL 12 2 2386

R0055684

2. Compaction: Compaction reduces the vulnerability of the exposed right-of-way to erosion, but increases the velocity and amount of runoff.

3. Aggregate cover: Aggregate cover stabilizes the soil surface while allowing the movement of construction equipment on the right-of-way.

By implementing the control measures listed above, soil erosion on exposed surface areas and areas adjacent to paved surfaces can be minimized.

II-2.7 BORROW AND STOCKPILE AREAS (BMPs E1.10, E1.20, E1.35, E1.50, E2.35, E2.55)

Borrow areas, especially those that are located off the development site, cannot be ignored in erosion and sedimentation control planning. Borrow areas, as well as stockpile and spoil areas, must be stabilized.

Borrow and stockpile areas present the same set of problems for the control of erosion and sedimentation as exposed cut and fill slopes. All areas are erodible. Runoff should be diverted from the face of the slopes which are exposed in the excavation process. The runoff must then be conveyed in stabilized channels to stable disposal points.

The BMPs used to control erosion on slopes, such as the top of dikes, diversions, slope drains, etc., should also be used in borrow areas. Only those sections of the borrow area which are currently needed to supply fill should be stripped. Immediately after the required fill has been taken, the exposed area should be stabilized. If practical, each phase of the borrow operation should be:

1. graded
2. covered with topsoil
3. seeded with permanent vegetation and mulched

If final grading is delayed for more than a few days, temporary seeding should be used. By properly timing the disturbance of the natural cover in the borrow area in carefully planned phases, the area of exposed soil and the duration of exposure are reduced and, therefore, erosion losses are reduced.

The topsoil from borrow areas is stripped and stockpiled for later redistribution on the disturbed area. These stockpiles should be located on the uphill side of the excavated area wherever possible so that they can act as diversions. Stockpiles should be shaped and seeded with temporary cover. They can also be covered with plastic and circled at the bottom with a ditch to catch the runoff.

Where borrow areas are off the development site, a separate system for trapping sediment from the borrow area is needed. After the excavation is complete, borrow areas must be restored. Regrading to ensure proper drainage and to blend the borrow area with the surrounding topography is required. Stockpiled topsoil is then redistributed and permanent vegetative cover established.

II-2.8 ADJACENT PROPERTIES

The protection of adjacent properties and waterways from accelerated erosion and sedimentation is an important concern. Relevant BMPs for protecting adjacent properties have already been discussed under the previous problem areas. The following list illustrates some of the BMPs which can be used:

1. Sediment traps

2. Diversions

CHAPTER II-3

GUIDELINES FOR CONTROLLING POLLUTANTS OTHER THAN SEDIMENT ON CONSTRUCTION SITES

II-3.1 INTRODUCTION

Potential pollutants other than sediment associated with construction activity, include numerous hazardous wastes as well as other solid and liquid wastes. Hazardous wastes include pesticides (insecticides, fungicides, herbicides, rodenticides etc.), petrochemicals (oils, gasoline, asphalt degreaser etc.) and other construction chemicals such as concrete products, sealer, paints, and wash water associated with these products. Other wastes include paper, wood, garbage, sanitary wastes, and fertilizer.

Practices must be used that prevent these potential pollutants from leaving the construction site. Good erosion and sediment control, coupled with stormwater management, will deter the movement of large amounts of sediment off the site. [It must be recognized, however, that pollutants carried in solution in runoff water, or fixed with sediment crystalline structures (e.g., crystalline clays), will be carried through the erosion and sediment control defenses.] Pollutants such as oils, waxes, and water-insoluble pesticides, form surface films on water and on solid particles, and also, oil films serve as a medium for concentrating water-soluble insecticides. Other than by use of very costly water-treatment facilities, or long runoff water detention periods, these pollutants become nearly impossible to control once present in the runoff.

The most economical and effective controls for pollutants other than sediment generated on construction sites, are the exercise of good "housekeeping" practices, and an awareness by construction workers, planners, engineers, and developers of the need and purpose of compliance with federal, state, and local regulations. For example, most pesticides can kill forms of life other than their pest targets. Certain insecticides can persist for months or years in soil and water, and many toxic chemicals can be passed along plant and animal food chains. Similarly, high levels of nutrients (principally phosphorus and nitrogen) from fertilizers used to revegetate exposed subsoils in graded areas may enter waterways and ponds, and increase the growth of algae at the surface to such an extent that light penetration in the water column is decreased. The end result is over-enrichment (or eutrophication). In confined water bodies, over-enrichment can lead to complete deoxygenation of the water and consequent death of fish and other organisms.

Ways must be found to protect ponds, wetlands, lakes, streams, and coastal and estuarine water bodies from damage by sediment and other pollutants generated during construction activities.

The variety of pollutants and the severity of the damage they cause depend upon a number of factors. The most significant of these include:

1. The nature of the construction activity.
2. The physical characteristics of the construction site, including such factors as weather, time of year for construction, topography, soil condition, drainage systems, etc.
3. The proximity, quantity, and quality of the receiving waters (i.e., the amount and purity of the water receiving the contaminated runoff).

It is reasonable to expect, for example, that potential pollution resulting from fertilizers used during revegetation would be more severe on a highway or housing

R0055693

development than for a shopping center development. This is because highways and housing developments usually have far greater landscaping requirements than shopping centers which are composed mostly of rooftops and pavement.

The physical characteristics of the construction site have a major bearing on the potential severity of pollution from construction activities. As in the case of sediment, the vast majority of all pollutants are carried into the receiving waters via runoff. The amount of runoff coming from a construction site is dependent upon hydrologic factors. These include the amount, intensity, and frequency of rainfall; the infiltration rate of the soil; surface roughness; and the length and steepness of the ground slope. Large areas denuded or stripped of vegetation, long slopes, steep slopes, tight soils, and high intensity rainfall are all factors conducive to heavy runoff.

Another physical factor influencing the severity of pollution is the proximity of the pollutant, or potential pollutant, to the receiving water. For example, fertilizers applied to a streambank are more apt to cause water pollution than fertilizers applied to a slope well upland of the waterway.

The following information deals with the nature and control of various construction-related pollutants, other than sediment.

II-3.2 BMP C1.10 PESTICIDE CONTROL

Although the word "pesticide" has come to mean only those chemicals which attack insect populations, here the word is used to include herbicides and rodenticides as well as chemicals commonly known as pesticides. Insecticides, rodenticides, and herbicides have historically been used on construction sites to increase health and safety, maintain a pleasant environment, and reduce maintenance and fire hazards. Often, rodents are attracted to construction sites and rodenticides are used.

Pesticides shall only be used in conjunction with Integrated Pest Management (IPM). IPM utilizes a needs assessment which determines which method to use and the necessity of controlling a pest population. Pesticides should be the tool of last resort; methods which are the least disruptive to the environment and to human health should be used first (1). IPM as a BMP is further discussed in Volume IV, Chapter IV-4, BMP S1.90.

If pesticides must be used, clearance for use of any of these chemicals is often required by restrictive federal and state regulations. All pesticides should be stored and applied in accordance with regulations of the State Department of Agriculture, WAC 16-228-185. EPA has produced a pamphlet "Suspended, Canceled and Restricted Pesticides" (Jan. 1985), which includes information on many pesticides. As it is more than five years old, it is wise to check with EPA's Region 10 Pesticides Branch, Seattle, if any questions regarding the use of pesticides arise. An awareness of the need to adhere to recommended dosages, type of application equipment, time of application, cleaning of application equipment, and safe disposal of these chemicals, will go far in limiting the pollution of waterways. Application rates should conform to registered label direction. Many of these compounds are considered "Dangerous Wastes" and must be disposed of properly. Disposal of excess pesticides and pesticide-related wastes should conform to registered label directions for the disposal and storage of pesticides and pesticide containers set forth in applicable federal, state and local regulations. General disposal procedures are:

- Dispose of through a licensed waste management firm or treatment, storage and disposal company (TSD).
- Use up, or give away to garden center, landscape service, etc.

VOL 12 2 2396

R0055694

- Triple rinse containers before disposal, reuse rinse waters as product.

"Hazardous Waste Pesticides - Determining if Your Pesticide is a Hazardous Waste," booklet #[illegible]-14 provides guidance and is available from Ecology's Publications Office. For more information call Hazards Line (587-3292) or Hazardous Substance Information Hotline (1-800-633-7585).

Pesticide storage areas on the construction site should be protected from the elements, from vandals, and from the curious. Warning signals should be placed in areas recently sprayed or treated with the most dangerous pesticides. Persons involved in the mixing and application of these chemicals, to be in compliance with the law, must wear suitable protective clothing.

Other practices include:

- Set aside a locked, weather-resistant storage area.
- Lids should be tightly closed.
- Keep in a cool, dry place. Many pesticides rapidly lose their effectiveness if stored in areas exposed to heat.
- In case of a leak, put original container into a larger container and label it properly.
- Check containers periodically for leaks or deterioration.
- Keep a list of products in storage.
- Use plastic sheeting to line the area.
- The applicator must follow the notification requirements of the WDSA. Neighbors on properties adjacent to the one being sprayed should also be notified prior to spraying.
- All storage sheds, dumpsters or other storage facilities should be regularly monitored for leaks and repaired as necessary. Remind workers during subcontractor or safety meetings about proper storage and handling of materials.

II-3.3 BMP C1.20 HANDLING OF PETROLEUM PRODUCTS

Petroleum products are widely used during construction activities. They are used as fuels and lubricants for vehicular operations, power tools, and general equipment maintenance. These pollutants include oils, fuels such as gasoline, diesel oil, kerosene, lubricating oils, and grease. Asphalt paving can be a pollutant source as it continues to release various oils for a considerable length of time. Most of these pollutants adhere to soil particles and other surfaces easily.

One of the best modes of control is to retain sediments containing oil on the construction site. Soil erosion and sediment control practices can effectively accomplish this. Improved maintenance and safe storage facilities will reduce their chances of contaminating construction sites. One of the greatest concerns confronting uses of these petroleum products is the method for waste disposal. Oil and oily wastes such as crankcase oil, cans, rags, and paper dropped in oils and lubricants, can be best disposed of in proper receptacles or recycled (call 1-800-RECYCLE). Waste oil for recycling should not be mixed with degreasers, solvents, antifreeze, or brake fluid. The dumping of these wastes in sewers and other drainage channels is illegal and could result in fines or job shutdown. A further

VOL 12 2 2397

R0055695

source of these pollutants is leaky vehicles. Proper maintenance of equipment and installation of proper stream crossings will further reduce pollution of water by these sources. Stream crossings should be minimized through proper planning of access roads.

Guidelines for storing petroleum products are as follows:

- Store products in weather-resistant sheds where possible.
- Create shelter around area with cover and wind protection.
- Line the storage area with double layer of plastic sheeting or similar material.
- Create impervious berm around the perimeter.
- Capacity of bermed area should be 110 percent of largest container.
- All products should be clearly labeled.
- Keep tanks off the ground.
- Keep lids securely fastened.
- Contact local fire marshall for more information.
- Post information for procedures in case of spills. Persons trained in handling spills should be on-site or on call at all times.
- Materials for cleaning up spills should be kept on-site and easily available. Spills should be cleaned up immediately and the contaminated material properly disposed of.
- Specify a staging area for all vehicle maintenance activities. This area should be located away from all drainage courses.
- All storage sheds, dumpsters or other storage facilities should be regularly monitored for leaks and repaired as necessary. Remind workers during subcontractor or safety meetings about proper storage and handling of materials.

II-3.4 BMP C1.30 NUTRIENT APPLICATION AND CONTROL

Inorganic nutrient pollution is most often caused by fertilizers used in revegetating graded areas. The use of proper soil-stabilization measures, sediment control, and stormwater detention structures can be effective means of keeping these materials out of waterways. Only small amounts of inorganic nutrients are beneficial to the productivity of waterways, while excess amounts result in over-enrichment (eutrophication).

Nutrient pollution can be minimized by working fertilizers and liming materials into the soil to depths of 4 to 6 inches, and by proper timing of the application. Hydro-seeding operations, in which seed, fertilizers and lime are applied to the ground surface in a one-step operation, are more conducive to nutrient pollution than are conventional seedbed-preparation operations, where the fertilizers and lime are tilled into the soil. In the case of surface dressings, control can be achieved by applying the required quantity of fertilizer in more than one operation. For example, an area requiring an application of 500 lbs. per acre of fertilizer could be dressed with about 125 lbs. per acre at four separate times over the growing season.

VOL 12 2 2398

R0055696

Use of fertilizers containing little or no phosphorus may be required by local authorities if the development is near sensitive water bodies. In any event great care should be taken to use only the minimum amount of phosphorus needed, as determined by soil tests, or advice from the local Conservation District or Soil Conservation Service.

Near sensitive surface waters, the addition of lime can affect the pH (or acidity) of runoff and receiving waters. Importation of topsoil is better than heavily liming and fertilizing exposed subsoil.

II-3.5 BMP C1.40 SOLID WASTE HANDLING AND DISPOSAL

Solid waste is one of the major pollutants caused by construction. Solid waste is generated from trees and shrubs removed during land clearing for construction of streets and parking facilities, and during the installation of structures. Other wastes include wood and paper from packaging and building materials, scrap metals, sanitary wastes, rubber, plastic and glass pieces, masonry products, and others. Food containers such as beverage cans, coffee cups, lunch-wrapping paper and plastic, cigarette packages, leftover food, and aluminum foil contribute a substantial amount of solid waste to the construction site.

The major control mechanism for these pollutants is to provide adequate disposal facilities. Collected solid waste should be removed and disposed of at authorized disposal areas. Frequent garbage removal helps maintain construction sites in a clean and attractive manner. Waste containers should be labelled and located in a covered area. Lids should be kept closed at all times. Any useful materials should be salvaged and recycled. For instance, masonry waste can be used for filling borrow pits; trees and brush from land-clearing operations can be converted into woodchips through mechanical chippers and then used as mulch in graded areas. Sanitary facilities must be convenient and well maintained to avoid indiscriminate soiling of adjacent areas. Selective (rather than wholesale) removal of trees is helpful in conservation of soil and reduction of wood wastes. Indiscriminate removal of trees and other beneficial vegetation should be avoided.

Soil erosion and sediment control structures capture much of the solid waste from construction sites. Constant removal of litter from these structures will reduce the amount of solid waste despoiling the landscape. The extension of local and state anti-litter ordinances to cover construction sites is also a viable control mechanism. Adherence to these regulations by construction personnel reduces unnecessary littering through carelessness and negligence.

II-3.6 BMP C1.50 USE OF CHEMICALS DURING CONSTRUCTION

Many types of chemicals may be used during construction activities. These chemical pollutants include paints, acids for cleaning masonry surfaces, cleaning solvents, asphalt products, soil additives used for stabilization and other purposes, concrete-curing compounds, and many others. These materials are carried by sediment and runoff from construction sites.

A large percentage of these pollutants can be effectively controlled through implementation of source control soil erosion and sedimentation control practices. By using only the recommended amounts of these materials and applying them in a proper manner, pollution can be further reduced. As in the case of other pollutants, good housekeeping is the most important means of controlling pollution.

The correct method of disposal of wastes varies with the material. Wash-up waters from water-based paints may go into a sanitary sewer, but wastes from oil-based paints, cleaning solvents, thinners, and mineral spirits must be disposed of through

VOL 12 2 2399

R0055697

a licensed waste management firm or TSD. Disposal of concrete products, additives, and curing compounds depends on the product. Information is available from the local health department or the Hazardous Substance Information Hotline (1-800-633-7585).

II-3.7 OTHER POLLUTANTS

Other pollutants include concrete wash water from concrete mixers, acid and alkaline solutions from exposed soil or rock units high in acid, and alkaline-forming natural elements.

The control of these pollutants involves good site planning and pre-construction geological surveys. Neutralization of these pollutants often provides the best treatment. Sealing of fractures in the bedrock with grout and bentonite will reduce the amount of acid or alkaline seepage from excavations. Adequate treatment and disposal of concrete further reduces pollution.

II-3.8 GENERAL GUIDELINES

General guidelines for managing or minimizing any of the above hazardous wastes are as follows:

II-3.8.1 BMP C1.60 Managing Hazardous Products

- Buy and use only what is needed. Leftovers need to be stored, re-used, given away, recycled or disposed of safely.
- Read labels and follow directions on the label. Hazardous products may be labeled:

Danger	Poisonous	Volatile
Combustible	Caustic	Explosive
Warning	Corrosive	Flammable
Caution		

- Try to keep products in original containers and always keep them well-labeled. If the product must be transferred to smaller containers, use the proper size funnel and avoid spills. Label all containers.
- Labels can fall off with weathering. To prevent, cover with transparent tape. To relabel, use a metal tag attached to the container or use a stencil and spray paint.
- Do not mix chemical substances unless recommended by the manufacturer.
- Use in well-ventilated areas. Protect skin, eyes, nose, and mouth when necessary by wearing gloves, respirator, or other protective clothing.
- Keep corrosive liquids away from flammable liquids.
- Look for nontoxic or less toxic options (check with the State Department of Ecology Office of Waste Reduction at 1-800-822-9933).
- Use all of the product before disposing of the container.
- There are private firms that specialize in the cleanup of spills.

VOL 12 2 2400

R0055698

VOL 12 2 2401

II-3.8.2 BMP C1.70 Equipment Washing

Thinners or solvents should not be discharged into the sanitary or storm sewer systems when cleaning large machine parts where discharge of water is required. Use alternative methods for cleaning larger equipment parts such as high pressure, high temperature water washes, or steam cleaning.

Equipment washing detergents can be used and wash water discharged into the sanitary system if grit is removed from the solution first. The water discharged into the sewer must not exceed the discharge limits set by the Sewer Authority.

Small parts can be cleaned with degreasing solvents which are reused after filtering or recycled. These solvents should not be discharged into any sewer. Further information is available from the Department of Ecology.

II-3.8.3 BMP C1.80 Spill Control Planning and Cleanup

Construction site supervisors shall adopt a spill control plan and identify persons responsible for implementing the plan if a spill of a dangerous or hazardous waste should occur. Any spill that occure, regardless of the size and/or type of spill, should be reported to the following agencies:

- If the spill of a hazardous substance could reach surface waters, the following agencies must be notified (there are fines for failing to notify):

  National Response Center 1-800-424-8802 (24-hour)

- Locally, notify the regional Department of Ecology offices:

  Northwest Region - Redmond 649-7000 (24-hour)
  Southwest Region - Olympia 753-2353 (24-hour)

- Within the City of Bellevue

  Storm & Surface Water Utility 455-7846 (24-hour)

- For spills within salt water

  U.S. Coast Guard 286-5440

There are fines for failing to notify the appropriate authority when a spill occurs.

Some of the important components of a spill control plan are:

- Establish who to notify in the event of a spill, particularly if it is hazardous.
- Provide specific clean-up instructions for different products handled on site.
- Assign a person to be in charge of clean-up assistance.
- Prepare spill containment and clean-up lists that are easy to find and use.
- Post a summary of the clean-up plan at appropriate locations.
- If a spill occurs, demobilize it as quickly as possible.

R0055699

- If there is a change that the spill could enter a storm drain or sewer, plug the inlet and turn off or divert any incoming water.
- Cover the spill with absorbent material such as kitty litter or sawdust. Do not use straw. Dispose of the used absorbent per Ecology or manufacturer's instructions. If the spill is flammable, dispose of as directed by the local fire marshal.
- Keep the area well ventilated.

II-3.8.4 BMP C1.90 Treatment and Disposal of Contaminated Soils

Contaminated ground water or soil may be encountered during earthwork activities or by the spill or leak of a hazardous product. The contaminant may be known or unknown. Sampling and laboratory tests may be required to determine whether a landfill can accept the contaminated soil. In some cases it is possible to reduce the hazardous potential of the soil by aerating it, for example. Local health departments can supply the necessary procedures. Private firms can also be consulted for disposal.

The Model Toxics Control Act, Ch. 70.105 RCW, requires that Ecology's Toxic Cleanup Program be notified if contaminated soil or ground water is encountered during a project.

II-3.8.5 BMP C 2.00 Concrete Trucks/Spray Washing of Exposed Aggregate Driveways and Walkways

The washout from a concrete truck should be disposed of into:

- A designated area which will later be backfilled: a slurry pit.
- An area where the concrete wash can harden, be broken up, and then put in the dumpster.
- A location which is not subject to surface water runoff, and more than 50 feet away from a storm drain, open ditch, or receiving water.

Never Dump Into:

- Sanitary sewer
- Storm drain
- Soil or pavement which carries stormwater runoff.

When spray washing driveways or walkways to expose the aggregate, all wash water should be diverted or sprayed to the sides, not down the driveway. If water must run down the driveway towards the street or sidewalk, it should be diverted at the bottom to a sump or sediment trap.

II-3.8.6 BMP C2.10 Use of Sandblasting Grits

If used to clean old buildings where lead, cadmium, or chrome-based paints were applied, the sandblasting grits are a hazardous waste. They cannot be washed into any sewer system. Contact a licensed waste management firm or TSD facility.

II-3.8.7 BMP C2.20 Disposal of Asbestos and PCBs

Use and disposal of these potential pollutants are regulated by both state and federal agencies. For further information, contact:

VOL 12 2 2402

CHAPTER II-4

NPDES STORMWATER PERMIT REQUIREMENTS AND THE DEVELOPMENT OF LARGE PARCEL EROSION AND SEDIMENT CONTROL PLANS

INTRODUCTION

Two different types of requirements commonly must be satisfied for construction sites. Those sites larger than 5 acres must comply with the requirements that will be contained In the baseline General NPDES Stormwater Permit (now under development). All new development and redevelopment sites larger than 1 acre must comply with Erosion and Sediment Control Requirements 1 through 14 (see Chapter I-2). This compliance is demonstrated through the submittal of an Erosion and Sediment Control (ESC) Plan.

II-4.1 NPDES STORMWATER PERMITS

EPA's National Pollutant Discharge Elimination System Permit (NPDES) regulations for stormwater (40 CFR Parts 122, 123 and 124) became effective on November 16, 1990. Washington is a NPDES delegated state which requires Ecology to administer NPDES permits. Cities and counties with a population of 100,000 and greater that have separate storm sewer systems, most industries that discharge stormwater associated with industrial activities or storage of raw materials, and construction sites 5 acres in area and greater are required to apply for NPDES permits. Stormwater from industrial uses that does not come in contact with industrial activities or storage of raw materials or products, such as runoff from roofs and parking lots, generally does not require a NPDES permit.

The purpose of the new stormwater NPDES regulations is to:

- Prohibit non-stormwater discharges into storm sewers
- Reduce discharge of stormwater-borne pollutants to the maximum extent practicable
- Establish a permit system for stormwater discharges

The Stormwater Management Program that Ecology and the Puget Sound Water Quality Authority are preparing for the Puget Sound Basin will be as consistent as possible with NPDES requirements. The thrust of the Stormwater Program is to direct the 111 cities and counties in the Basin to adopt and implement programs to prevent water pollution and enhance water quality for themselves and privately owned facilities in their jurisdiction. NPDES is a statewide permit program that Ecology will administer directly to cities, counties and regulated industrial facilities including construction sites.

Construction activity including clearing, grading and excavation activities that result in the disturbance of five acres or more will require a permit. Parcels less than five acres in area that are part of a common plan of development or sale totaling five acres or more will also be required to obtain a permit. Ecology anticipates that at the point that a permit program is developed, that construction sites will be covered as part of the baseline general permit to be published in final form in August, 1992. Once the permit is finalized, the contractor will be required to send to Ecology a Notice of Intent to begin construction 30 days before construction is to begin. At this time, details are not finalized.

Applications for coverage under the baseline permit should be submitted after Ecology adopts the permit (targeted for August, 1992), but before the current federal deadline of October 1, 1992. Applications will consist of filing a NOTICE

VOL 12 2 2405

R0055703

OF INTENT (NOI). Ecology has not yet decided on the information requirements for a NOTICE OF INTENT. Proposed requirements for a Notice of Intent will be discussed at public workshops and hearings.

At this time there will be no charges associated with the filing of the NOI. Ecology charges a fee for permits as allowed under State regulation, Chapter 173-224 WAC. That regulation does not identify a fee for facilities which will be covered under the baseline permit for storm water. Ecology plans to seek an increased legislative appropriation for the next biennium (July 1, 1993-June 30, 1995) to administer storm water permits. Fees would be set by amending the fee rule. There will be opportunities for public comment on the fee proposals. Subject to the appropriation and adoption of the amended fee regulation, fees for storm water permits would become effective after July 1, 1993.

PROPOSED ECOLOGY INDUSTRIAL/CONSTRUCTION PERMIT DEADLINES

May, 1992	Ecology holds public workshops, hearing on baseline permit.
August, 1992	Projected adoption of Ecology's baseline permit (including construction activities). The permit is effective 30 days later.
After 10/31/92	New industries must submit a NOTICE OF INTENT (to Ecology), and develop a pollution prevention plan (to be retained by the industry), before commencement of construction of a storm water discharge. EPA has proposed that these be completed at least 30 days prior to commencement.

II-4.2 INTRODUCTION TO LARGE PARCEL EROSION AND SEDIMENT CONTROL PLANS

This section is designed to provide an overview of the important components and process for developing, reviewing and implementing Large Parcel Erosion and Sediment Control (ESC) plans for construction sites. A separate example LPESC plan will be provided in the Stormwater Program Guidance Manual for the Puget Sound Basin currently being developed as a companion document to this manual. Small Parcel ESC requirements can be found in Chapters I-3 and II-5.

Section II-4.3 contains basic information which all site planners and plan reviewers should become familiar with. It describes criteria for plan format and content, ideas for improved planning effectiveness and sources of technical assistance.

Section II-4.4 outlines and describes a recommended step-by-step procedure for developing an erosion and sediment control plan from data collection to finished product. This procedure is written in general terms to be applicable to all types of projects.

Site planners, as well as local plan approving authorities, are urged to become familiar with the contents of this chapter so that plans will

eventually become more standardized and thus more meaningful throughout the Puget Sound basin.

VOL 12 2 2406

R0055704

II-4.3 GENERAL GUIDELINES

II-4.3.1 What is a Large Parcel Erosion and Sediment Control Plan?

A Large Parcel ESC plan is a document which describes the potential for erosion and sedimentation problems on a construction project over 1 acre in size and explains and illustrates the measures which are to be taken to control those problems. The plan has a written portion known as a narrative and an illustrative portion known as a map or site plan.

The LPESC plan should be an independent entity. While it is a good idea to include erosion and sediment control standards and specifications in contract documents, the erosion and sediment control plan itself should be a separate document which can stand alone.

A LPESC plan is required for all new development and redevelopment where greater than 1 acre of land disturbing activities occur. See Chapter I-2 for more specific information on which type of planning is appropriate.

II-4.3.2 What is an "Adequate" Plan?

An erosion and sediment control plan must contain sufficient information to satisfy the Plan Approval Authority of the local government that the problems of erosion and sedimentation have been adequately addressed for a proposed project. The length and complexity of the plan should be commensurate with the size of the project, the severity of site conditions, and the potential for off-site damage.

In general, plans for constructing a few homes in a small subdivision do not need to be as complex as a plan for a large shopping center development or a large subdivision. Also, plans for projects undertaken on flat terrain will generally be less complicated than plans for projects constructed on steep slopes where the erosion potential is higher. The greatest level of planning and detail should be evident on plans for projects which are large in size, directly adjacent to flowing streams, other sensitive areas, or high value properties where damage may be particularly costly or detrimental to the environment.

The primary requirements that determine the adequacy of a plan are the Erosion and Sediment Control standards found in Minimum Requirement #1, described in Chapter I-2. Each of these Erosion and Sediment Control Requirements applicable to a project should be satisfied in the LPESC Plan unless a specific variance is granted by the Plan Approval Authority. The design and implementation of the LPESC plan should specifically fulfill all the Erosion and Sediment Control Requirements contained within Minimum Requirement #1 unless an exemption has been granted by the local government. As a guide to format, the site planners and plan reviewers should use the checklist contained in Section II-4.4.6. The step-by-step procedure outlined in this section is recommended for the development of all plans.

II-4.3.3 A Narrative is Important

The narrative is a written statement which explains and justifies the erosion and sediment control decisions made for a particular project. The narrative is especially important to the Plan Approval Authority because it contains concise information concerning existing site conditions, construction schedules, and other pertinent items which are not contained in a typical site plan.

The narrative is also important to the construction superintendent and inspector who are responsible to see that the plan is implemented properly. It provides them with a single report which describes where and when the various erosion and sediment control BMPs should be installed.

VOL 12 2 2407

R0055705

VOL 12 2 2408

II-4.3.4 BMP Standards and Specifications

Chapters II-3 and II-5 of this volume of the manual contain standards and specifications for BMPs. These standards apply within the Puget Sound drainage basin except where an adopted and implemented basin plan is in place (see Minimum Requirement #9 in Chapter I-2). Wherever any of these BMPs are to be employed on a site, the specific title and number of the BMP should be clearly referenced in the narrative and marked on the plan. By referencing this manual properly, (or, the locally adopted technical equivalent of this manual) the site planner can reduce the need for detailed drawings and lengthy descriptions of the practices in the plan.

Modifications to standard practices or new innovative conservation practices may also be employed, but such practices (Experimental BMPs) must be thoroughly described and detailed to the satisfaction of Ecology and the Plan Approval Authority of the local government before they may be used (see Section I-2.17).

II-4.3.5 General Principles in Selecting BMPs for a Large Parcel Erosion and Sediment Control Plan

- Prevention of pollutant release is superior to pollutant capture later. Select source control BMPs as a first step.
- Selection of BMPs must depend on site characteristics and the construction plan.
- The proper first step is a site drainage analysis. Determine where runoff will enter, cross and exit the site.
- Flowing water has a tendency to concentrate in channels instead of flowing as sheet flow.
- Determine whether subsurface water is a factor.
- Divert runoff from exposed areas wherever possible.
- Existing vegetation is the most effective erosion control.
- Limit and phase clearing.
- Use materials found on the site wherever possible.
- Incorporate natural drainage features whenever possible, using adequate buffers and protecting areas where flow enters the drainage system.
- Keep structures simple.
- Minimize slope length and steepness.
- Keep runoff velocities low.
- Reduce the tracking of sediment off-site.
- Select and install controls that can be maintained.
- Select appropriate BMPs from Chapter II-3 for the control of pollutants not associated with sediment.

II-4.3.6 Standard Practice Coding System

Site planners are urged to use the standard numbering and coding system for BMPs contained in this manual. Table II-2.2 in Chapter II-2 lists each practice with its

R0055706

designated number, symbol, and code. Use of this coding system will result in increased uniformity of plans and increase their readability to plan reviewers, job superintendents, and inspectors Puget Sound-wide. Since the BMPs in Chapter II-3 are not site-specific, they have not been given codes or symbols.

II-4.3.7 Comprehensive Site Planning

Erosion and sediment control planning should be an integral part of the site planning process, not just an afterthought. The potential for soil erosion should be a significant consideration when deciding upon the layout of buildings, parking lots, roads, and other facilities. Adverse environmental impacts and costly erosion and sediment control measures can be minimized if the site design can be adapted to existing site conditions and good conservation principles are used. Additionally, if thought is given to the design of temporary erosion control devices, they may be able to be converted into permanent facilities as well.

II-4.3.8 Who is Responsible for Preparing a Plan?

The owner or lessee of the land being developed has the responsibility for plan preparation and submission. The owner or lessee may designate someone (i.e., an engineer, architect, contractor, etc.) to prepare the plan, but he/she retains the ultimate responsibility. It is important for the developer to comply with the requirements of the local government and Minimum Requirement #1 contained in Chapter I-2 of this manual.

II-4.3.9 Technical Assistance

Possible sources of erosion and sediment control planning assistance within the state include:

1. Conservation Districts: These districts have elected representatives (directors) from each locality. One of the primary functions of these districts is to provide assistance to landowners for soil conservation planning and implementation. The USDA-Soil Conservation Service provides conservation districts with technical assistance. Requests for assistance in preparing erosion and sediment control plans for a construction site can be made through a district.

2. USDA-Soil Conservation Service: The Soil Conservation Service (SCS) provides technical assistance or conservation planning and implementation to landowners throughout the country through local conservation districts. In addition, the SCS is involved in soil surveys within the state. Requests can be made through a Soil Conservation Service field office for a soil survey on a specific site. These requests will be acted upon according to local priorities.

II-4.4 STEP-BY-STEP PROCEDURE

The five basic steps in producing a LPESC plan are summarized below:

Step 1 - Data Collection

A. Topography
B. Drainage
C. Soils
D. Ground Cover
E. Adjacent Areas
F. Existing Development
G. On and Off-Site Utilities

VOL 12 2 2409

R0055707

Step 2 - Data Analysis

A. Topography - Slope gradients, lengths
B. Drainage - Outline existing natural and manmade drainage patterns
C. Soils - Erodibility (K) factors, permeability
D. Ground Cover - Trees, grassy areas, sensitive or endangered vegetation
E. Adjacent Areas - Streams, roads, buildings, etc.

Step 3 - Site Plan Development

A. Fit development to terrain
B. Locate construction in the least critical areas
C. Utilize cluster development whenever possible
D. Minimize paved areas
E. Utilize the natural drainage system and natural drainage locations whenever possible

Step 4 - Plan for Erosion and Sediment Control

A. Determine limits of clearing and grading
B. Divide the site into drainage areas
   - Consider each area separately
C. Select erosion and sediment control BMPs, emphasizing source control and vegetative BMPs.
   - Vegetative, especially buffers, preservation of natural vegetation and flagging
   - Structural
   - Management measures
D. Plan for stormwater management

Step 5 - Include BMPs for the Control of Pollutants Other Than Sediment

A. Review Chapter II-3 in this volume
B. Select appropriate BMPs based on the practices which will be used on-site.

Step 6 - Plan Preparation

A. Narrative
B. Site Plan

Note: The LPESC plan may be a subset of the Stormwater Site Plan. Full details on how to prepare the Stormwater Site Plan and how the LPESC plan is integrated into it are provided in Chapter I-3. In particular, most of the work for steps 1 and 2 will have been done when preparing the Site Improvement Plan Base Map. The actual LPESC plan is part of the Site Improvement Plan. All the hydrologic and hydraulic information used to analyze and size the ESC facilities must be included in Section IX of the Technical Information Report.

II-4.4.1 Step 1 - Data Collection

Inventory the existing site conditions to gather information which will help develop the most effective erosion and sediment control plan. The information obtained should be plotted on a map and explained in the narrative portion of the plan.

A. Topography - A small-scale topographic map of the site should be prepared to show the existing contour elevations at intervals of from 1 to 5 feet depending upon the slope of the terrain.

B. Drainage Patterns - All existing drainage swales and patterns on the site should be located and clearly marked on the topographic map including all

VOL 12 2 2410

R0055708

existing underground storm drain pipe systems.

C. Soils - Major soil type(s) on the site should be determined and shown on the topographic map. Soils information can be obtained from a soil survey if one has been published for the county. If a soil survey is not available, a request can be made to a district Soil Conservation Service Office. Commercial soils evaluations are also available. Soils information should be plotted directly onto the map or an overlay of the same scale for ease of interpretation.

D. Ground Cover - The existing vegetation on the site should be shown. Such features as tree clusters, grassy areas, and unique or sensitive vegetation should be shown on the map. Unique vegetation may include existing trees above a given diameter. Local requirements regarding tree preservation should be investigated. In addition, existing denuded or exposed soil areas should be indicated.

E. Adjacent Areas - Areas adjacent to the site should be delineated on the topographic map. Such features as streams, roads, lakes, wetlands, and wooded areas, etc., should be shown. These features should receive special attention during the construction project because of the potential for off-site damage.

F. Existing Development - Existing buildings and facilities (if any) on-site or adjacent to the site should be shown on the topographic map.

G. On and Off-Site Utilities - Identify all utility corridor locations, roadways, associated clearing limits and BMPs for all on-site and off-site utility construction.

II-4.4.2 Step 2 - Data Analysis

When all of the data in Step 1 are considered together, a picture of the site potentials and limitations should begin to emerge. Determination should be made to determine those areas which have potential critical erosion hazards. The following are some important points to consider in site analysis:

A. Topography - The primary topographic considerations are slope steepness and slope length. Because of the effect of runoff, the longer and steeper the slope, the greater the erosion potential. When the percent of slope has been determined, areas of similar steepness should be outlined. Slope gradients can be grouped into three general ranges of soil erodibility:

0-7% - Low erosion hazard
7-15% - Moderate erosion hazard
>15% - High erosion hazard

Within these slope gradient ranges, the greater the slope length, the greater the erosion hazard. Therefore, in determining potential critical areas the planner should be aware of excessively long slopes. As a general rule, the erosion hazard will become critical if slope lengths exceed the following values:

0-7% - 300 feet
7-15% - 150 feet
>15% - 75 feet

These distances may be shorter in areas with highly erodible soils.

B. Natural Drainage - Natural drainage patterns which consist of overland flow, swales and depressions, and natural watercourses, should be identified in order to plan around critical areas where water will concentrate. Where it is

VOL 1 2 2 4 1 1 1

R0055709

possible, natural drainageways and discharge locations should be used to convey runoff over and off the site to avoid the expense and problems of constructing an artificial drainage system. Man-made ditches and waterways will become part of the erosion problem if they are not properly stabilized. Care should also be taken to be sure that increased runoff from the site will not erode or flood the existing natural drainage system. Possible sites for stormwater retention and detention should also be located at this point.

The site should also be checked for areas of saturated soil and/or areas where ground water may be encountered during construction. Construction in these areas should be avoided where possible.

C. Soils - Such soils properties as flood hazard, natural drainage, depth to bedrock, depth to seasonal water table, permeability, shrink-swell potential, texture, and erodibility should exert a strong influence on land development decisions.

D. Ground Cover - Ground cover is the most important factor in terms of preventing erosion. Any existing vegetation which can be saved will prevent erosion better than any constructed BMP. Trees and other vegetation protect the soil and beautify the site after construction. If the existing vegetation cannot be saved, consider such practices as staging construction, temporary seeding, or temporary mulching. Staging of construction involves stabilizing one part of the site before disturbing another. In this way, the entire site is not disturbed at once and the time without ground cover is minimized. Temporary seeding and mulching involve seeding or mulching areas which would otherwise lie open.

Buffers around water bodies or other sensitive areas should be delineated and the clearing limits flagged.

E. Adjacent Areas - An analysis of adjacent properties should focus on areas downslope from the construction project. Water bodies which will receive direct runoff from the site are a major concern. The potential for sediment pollution and/or downstream channel erosion and deposition should be considered and addressed. The potential for sediment deposition on adjacent properties due to sheet and rill erosion should also be analyzed so that appropriate sediment trapping measures can be planned.

II-4.4.3 Step 3 - Site Plan Development

After analyzing the data and determining the site limitations, the planner can then develop a site plan. Locate the buildings, roads, and parking lots and develop landscaping plans to exploit the strengths and overcome the limitations of the site. The following are some points to consider when making these decisions:

A. Fit the development to the terrain. The development of an area should be tailored to the existing site conditions to avoid unnecessary land disturbance and minimize erosion hazards and costs and other environmental impacts.

B. Confine construction activities to the least critical areas. Any land disturbance in highly erodible areas will necessitate the installation of more costly control measures.

C. Cluster buildings together. This minimizes the amount of disturbed area, concentrates utility lines and connections in one area, and provides more open natural space. The cluster concept not only lessens the erodible area and the amount of impervious surface, it reduces runoff, and generally reduces development costs.

VOL 12 2 2412

R0055710

D. Minimize impervious areas. Keep paved areas such as parking lots and roads to a minimum. This goes hand in hand with cluster developments in eliminating the need for duplicating parking areas, access roads, etc.

E. Utilize the natural drainage system. The natural drainage system and natural drainage locations of a site should be preserved instead of replaced with storm drains or concrete channels. The potential for downstream damages due to increased runoff can thus be minimized.

II-4.4.4 Step 4 - Plan for Erosion and Sediment Control

When the layout of the site has been decided upon, a plan to control erosion and sedimentation from the disturbed areas must be formulated. The Erosion and Sediment Control Requirements listed in Minimum Requirement #1 in Chapter I-2 establish a minimum level of control required for all projects.

The following general procedure is recommended for ESC control planning:

A. Determine limits of clearing and grading. Decide exactly which areas must be disturbed in order to accommodate the proposed construction. Pay special attention to critical areas. Show all limits of clearing for flagging in the field.

B. Divide the site into drainage areas. Determine how runoff will travel over the site. Consider how erosion and sedimentation can be controlled in each small drainage area before looking at the entire site. Remember, it is easier to control erosion than to contend with sediment after it has been carried downstream.

C. Select erosion and sediment control BMPs. Erosion and sediment control BMPs can be divided into three broad categories: cover practices, structural practices, and management measures. Cover practices, such as leaving buffer strips, seeding and mulching are the preferred BMPs and should be used first. Structural practices, such as sediment ponds and inlet protection should be implemented only after cover practices are used as a first line of defense. Management measures are construction management techniques such as staging construction which, if properly utilized, can minimize the need for physical controls and possibly reduce costs.

1. Cover Practices - Keep in mind that the first line of defense is to prevent erosion. This is accomplished by protecting the soil surface from raindrop impact and overland flow of runoff using source control BMPs. The best way to protect the soil surface is to preserve the existing ground cover. Where land disturbance is necessary, temporary seeding or mulching can be used on areas which will be exposed.

   Erosion and sediment control plans must contain provisions for permanent stabilization of disturbed areas. Selection of permanent vegetation should include the following considerations:

   a. establishment requirements
   b. adaptability to site conditions
   c. aesthetics
   d. maintenance requirements

2. Structural Practices - Structural practices are generally more costly and less efficient than are source controls. However, they are usually necessary since not all disturbed areas can be protected with vegetation. They are often used as a second or third line of defense in series with other vegetative or structural practices to capture sediment before it leaves the site.

VOL 12 2 2413

R0055711

VOL 1 2

It is very important that structural practices be selected, designed, and constructed according to the standards and specifications in Chapter II-5 of this volume. Improper use or inadequate installation can create problems which are greater than the structure was designed to solve.

3. Management Measures - Good construction management is as important as physical practices for erosion and sediment control, and there is generally little or no cost involved. Following are some management considerations which can be employed.

   a. Sequence construction so that no area remains exposed for an unnecessarily long period of time.

   b. Temporary seeding should be done immediately after grading.

   c. When possible, avoid grading activities during November through March since these months have the highest potential for erosive rainfall.

   d. On large projects, stage the construction so that one area can be stabilized before another is disturbed.

   e. Develop and carry out a regular maintenance schedule for erosion and sediment control practices.

   f. Physically mark off limits of land disturbance on the site with tape, signs or other methods, so the workers can see areas to be protected.

   g. Make sure that all workers understand the major provisions of the erosion and sediment control plan.

   h. Responsibility for implementing the erosion and sediment control plan should be designated to one individual (preferably the job superintendent or foreman).

D. Properties and waterways downstream from the development site shall be protected from erosion due to increases in volume, velocity and peak flow rate of stormwater runoff.

2 2 4 1 4

II-4.4.5 Step 5 -Include BMPs for the Control of Pollutants Other than Sediment

A. Review Chapter II-3 in this volume - This chapter provides information on common construction practices which cause pollution other than erosion and sedimentation. These range from nutrient and pesticide control to disposal of solid and/or dangerous wastes.

B. Select appropriate BMPs based on the practices which will be used on-site - Based on the type of work to be done on-site, select the appropriate BMPs and include their use in the narrative plan. Areas where equipment washing may occur or where contaminated soils may be located on the site also should be noted on the site plan.

II-4.4.6 Step 6 - Prepare the Plan

All of the necessary planning work has been done in steps 1 through 5. The final step consists of consolidating the collected information and developing it into a specific erosion and sediment control plan for the project.

R0055712

The plan consists of two parts: a narrative and a site plan. The narrative verbally explains the problems and their solutions with all necessary documentation. Justification should be provided for all solutions. The site plan is a series of maps or drawings pictorially explaining information contained in the narrative.

Following is a checklist of items which should be included in a narrative and on a site plan. This checklist can be used by a site planner as a quick reference to determine if all the major items are included in the erosion and sediment control plan.

II-4.4.7 Checklist for Erosion and Sediment Control Plans

Narrative

- ☐ Project description - Briefly describe the nature and purpose of the land disturbing activity, and the amount of grading involved.
- ☐ Existing site conditions - A description of the existing topography, vegetation, and drainage.
- ☐ Adjacent areas - A description of neighboring areas such as streams, lakes, residential areas, roads, etc., which might be affected by the land disturbance. Provide perimeter control of runoff on all necessary property boundaries.
- ☐ Soils - A brief description of the soils on the site giving such information as soil names, mapping unit, erodibility, permeability, depth, texture, and soil structure.
- ☐ Critical areas - A description of areas on the site which have potential serious erosion problems.
- ☐ Erosion and sediment control BMPs - A description of the BMPs which will be used to control erosion and sedimentation on the site. Specify the construction sequence.
- ☐ Permanent stabilization - A brief description, including specifications, of how the site will be stabilized after construction is completed.
- ☐ Stormwater management considerations - Will the development of the site result in increased peak rates of runoff? Will this potentially result in channel degradation downstream? If so, consideration must be given to stormwater control structures on the site (see Minimum Requirement #5 in Chapter I-2).
- ☐ Maintenance - A schedule of regular inspections and repair of erosion and sediment control structures should be set forth.
- ☐ Calculations - Any calculations made for the design of such items as sediment ponds, diversions, waterways, and calculations for runoff and stormwater detention basin design (if applicable). All calculations must bear the signature and stamp of an engineer licensed in the State of Washington.
- ☐ Non-ESC BMPs Required - Indicate which BMPs from Chapter II-3 will be used on-site.

Site Plan

- ☐ Vicinity map - A small map locating the site in relation to the surrounding area.
- ☐ Existing contours - Existing contours of the site should be shown on a map.

VOL 12 2 2415

R0055713

- ☐ Existing vegetation - The existing tree lines, grassy areas, or unique vegetation should be shown on a map.
- ☐ Soils - The boundaries of the different soil types should be shown on a map.
- ☐ Indicate north - The direction of north in relation to the site should be shown.
- ☐ Critical erosion areas - Areas with potentially serious erosion problems should be shown on a map.
- ☐ Existing drainage patterns - The dividing lines and the direction of flow for the different drainage areas should be shown on a map.
- ☐ Final contours - Changes to the existing contours should be shown on a map. Use a bold dashed line showing developed condition drainage divides.
- ☐ Limits of clearing and grading - Areas which are to be cleared and graded should be outlined on a map.
- ☐ Cut and Fill Slopes - Show all cut and fill slopes, indicating top/bottom of slope catch lines.
- ☐ Conveyance -
  - (1) Designate locations for grass-lined swales, interceptor trenches, or ditches.
  - (2) Show all drainage pipes, ditches, or cut-off trenches associated with erosion/sediment control.
  - (3) Provide all temporary pipe inverts or minimum slopes and cover.
  - (4) Show grades, dimensions, location, and direction of flow in all ditches and swales.
  - (5) Provide details of bypassing off-site runoff around clearing limits/disturbed areas and sediment pond/trap.
  - (6) Indicate locations and outlets of any possible dewatering systems.
- ☐ Location of BMPs - The locations of the erosion and sediment control and stormwater management BMPs used on the site should be shown on a map. In particular, locate the construction entrance and detail. Specify length, width, thickness and rock size of the entrance.
- ☐ Sediment Control Facilities -
  - (1) Show all the locations of sediment trap(s)/pond(s) (if required) and all associated pipes and structures.
  - (2) Dimension pond berm widths and all inside and outside pond slopes.
  - (3) Indicate the trap/pond storage required and the depth, length, and width dimensions.
  - (4) Provide typical section views throughout pond and outlet structure.
  - (5) Provide typical details of gravel cone and standpipe, and/or other filtering devices.

VOL 12 2 2416

R0055714

(6) Detail stabilization techniques for outlet/inlet.

(7) Detail control/restrictor device location and details.

(8) Specify mulch and/or recommended cover of berms and slopes.

(9) Provide rock specifications and detail for rock check dam, if used.

(10) Specify spacing for rock check dams as required for actual slopes on-site.

(11) Provide front and side sections of typical rock check dams.

(12) Indicate locations and provide details and specifications for silt fabric fence (include installation detail).

- ☐ Detailed drawings - Any structural practices used that are not referenced to this manual or other local manuals should be explained and illustrated with detailed drawings.

- ☐ Non-ESC BMPs - Indicate any equipment washdown areas, areas of contaminated soils or other BMPs used where there are site-specific requirements.
