Of all the stream areas sampled, the Lower Oaksprings tributary consistently had the lowest DO levels. Average dissolved oxygen concentrations in the 500 foot long stream reach ranged between 7.2 and 7.6 mg/L. These concentrations were typically 1.0 mg/L less than the Oaksprings inflow station, and are reflective of both warmer stream temperatures and the wetland's oxygen demand on the receiving stream system. Downstream DO levels generally improved, as a result of reaeration/mechanical turbulence, within 200-500 feet of the wetland. Results further showed that the Oaksprings tributary had no discernible effect on DO levels in the larger Gum Springs tributary (located 500 feet downstream of the wetland).

Summary

Results from the dissolved oxygen monitoring portion of the study revealed the following:

1. Baseflow DO levels generally do not appear to be a problem in urban streams; even in those draining highly impervious watersheds.

2. Some oxygen depletion was noted within the artificial wetland, as well as, downstream of both it and the wet pond. However, no anoxia was evident.

3. DO levels recovered within relatively short distances of the wet BMP's; generally, within 200 - 500 feet.

4. No discernible DO sag was observed during stormflow conditions.

Chapter III. Water Temperature - Biological Implications

This chapter represents a synthesis of major findings from both the water temperature monitoring and literature review portions of the study. Wherever possible, an attempt was made to relate monitoring results to potential effects on biota known or expected to occur in Maryland freshwater streams. In order to accomplish this objective, a holistic approach which examined the general temperature requirements of representative biological groups at all major levels of the aquatic food chain was used. Results are presented in a sequential manner, starting at the bottom of the food chain (Figure 38) with algae, and progressing to fish.

Because of the general controversy surrounding watershed urbanization and trout streams, a separate sub-section on trout (which also contains temperature monitoring results from the Gum Springs tributary area) has been included. For a more comprehensive overview of water temperature and stream biota the reader is referred to Appendix C. In addition, because of the absence of comprehensive, stream-specific biological data, the biological implications described herein should be viewed with a certain degree of caution.

1. Algae: General Temperature and Light Requirements

Light, water temperature, and flow are generally considered to be the primary factors regulating algal communities (Patrick, 1977). Most freshwater algae cannot grow at very low light intensities and appear to also be inhibited by high light intensity (Whitford & Schumacher, 1968). In addition, "every species of algae has a range of temperature tolerance, which is generally fairly wide, and a narrower range, typically near the upper end of the tolerance range in which optimum growth occurs" (Patrick, 1974).

The general temperature and light requirements and classification of the major groups of freshwater algae are summarized in Figure 39. As seen in Figure 39, oligothermal algae are coldwater forms which are generally restricted to waters ranging between 32 and 59°F. Mesothermal algae inhabit cool-warm temperature habitats between 59 and 86°F. The euthermal algae, which are characteristically warmwater forms, exhibit their greatest abundance at temperatures $\geq$ 86°F.

As a rule, diatoms dominate at temperatures between 68 - 86°F, green algae dominate between 86 and 95°F and blue-green algae dominate in waters $\geq$ 95°F (Patrick 1974). It is also important to note that, in most streams, diatoms are the overall dominant algal group. Red, brown and yellow-green algae typically comprise a relatively small portion of the stream algal community. Yellow-green algae are the dominant low temperature group (Whitford & Schumacher, 1986). They are typically restricted to cold streams and/or where present in warmer streams, to winter months.

Thermal Enrichment

In a study of the algae of White Clay Creek, PA, Patrick (1971) found that water temperatures averaging 86.7°F caused a major shift from a diatom-dominated community to one dominated by a mixture of greens, diatoms and blue-greens. Galli (1988) observed minor shifts in diatom community composition, as well as, an increase in both green and blue-green algae downstream of a small stormwater management wet pond. Maximum summer stream temperatures below this pond were in the 77.0 to 84.9°F range. Wilde and Tilly (1981), who conducted experiments on algal communities in artificial streams, concluded that sustained Delta-T increases of between 9.0 - 13.5°F (above ambient stream temperatures) may be sufficient to cause a significant species composition shift in a stream's algal community. In most streams, temperature shifts towards the upper limit and beyond bring about a shift in species composition; generally from diatom-dominated communities to those dominated by blue-green algae.

Temperature Monitoring Assessment

A review of water temperature monitoring results suggests that subtle shifts in the periphyton (attached algae) community species composition would have been expected to have occurred in some of the urban streams studied. At all developed watershed and BMP sites' diatoms would have continued to remain the dominant overall algal group. However, certain coldwater and/or light sensitive species may have either declined in numbers and/or been replaced by other, more temperature or light-tolerant species.

VOL 12 2 4597

R0057890

The scenario would most likely have occurred in stream reaches where considerable thermal enrichment and/or removal of riparian vegetation took place (e.g., Countryside outflow, Lower Oaksprings, White Oak tributary, and Tanglewood tributary). Also, it would be expected that green and blue-green algal species would have been represented in greater numbers in the warmer, open-lit sections of these streams.

While some temperature-related shifts in algal community species composition undoubtedly occurred, it is unlikely that they would have in themselves had an appreciable effect on either the macroinvertebrate or fish communities of these small urban streams. The principal reasons for this are: 1.) from an energy or food utilization perspective, the macroinvertebrate communities of eastern headwater streams are heavily dependent upon leaf litter. Macroinvertebrates which rely largely upon attached algae (periphyton) for a food source, generally comprise a small portion of this community and 2.) by in large, macroinvertebrates, not algae, are the principal food for fish inhabiting these headwater streams.

2. Macroinvertebrates: General Temperature Requirements of Aquatic Insects

Macroinvertebrates are frequently defined as animals without backbones that are large enough to be retained on a U.S. standard No. 30 sieve, 0.595 mm openings (Weber, 1973). In addition to serving as a major food source for fish, macroinvertebrates are an integral part of the normal energy/organic material processing system of streams. Aquatic insects, which in most environments comprise the largest portion of this heterogeneous group, were

VOL 12 2 4598
R0057891

examined in the study. General findings are described below.

Temperature - Physiological Relationships

As a group, aquatic insects demonstrate little ability to acclimate or compensate for temperature changes. Thus, when exposed to a new thermal regime, metabolic response is immediate and in the direction of the temperature change (Trapp & Hendricks, 1983).

While many aquatic insects can successfully complete their life cycles over a broad range of temperature conditions, many have very narrow and/or specific temperature requirements. As such, even relatively small temperature regime changes may have serious implications. For example, Sweeny and Vannote (1978) observed that changes of only 2.8 - 3.6°F, either warmer or cooler, from the normal temperature regime can reduce adult insect size and fecundity (the ability to produce viable off-spring), they both suggested that temperature increases of 3.6 - 5.4°F could eliminate sensitive species. Limited data also suggests that aquatic insects are adversely affected by exposure to high shock temperatures which approach their upper lethal limit. Thermal shocks may also interfere with the normal molting process and hence, may negatively effect insect growth and long-term survivability.

Temperature Requirements of Key Insect Groups

In general, water temperatures greater than 63.0°F have often been considered to be above the optimum for many stoneflies, mayflies, and

VOL 12 2 4 5 9 9 9

R0057892

caddisflies, and temperatures exceeding 70.0°F have been shown to stress severely most coldwater organisms (Gaufin and Nebeker, 1973; Ward and Stanford, 1979; Fraley, 1979).

As a group, stoneflies are the least temperature tolerant and are generally restricted to cold-cool flowing waters. Conversely, dragonflies and damselflies are generally associated with warmer streams and/or lakes and ponds. Mayflies and caddisflies, as well as Diptera (flies & midges), display considerable adaptivity and have successfully invaded all three of the major aquatic habitats depicted in Figure 40.

In addition, as a result of temperature regime alteration, mayflies, stoneflies, and other temperature sensitive or thermally-cued invertebrates are often reduced or eliminated below impoundments (Petts, 1984; Ward and Stanford, 1979; Fraley, 1979; Kondratieff and Voshell, 1981). All too frequently, only those forms with broad tolerance levels exist. Macroinvertebrate groups without aerial adults, such as snails, oligochaetes, amphipods, isopods, and turbellarians often increase in relative abundance in these streams (Ward and Stanford, 1979).

Temperature Monitoring Assessment

Results indicate that the thermal enrichment effects produced either through urbanization and/or associated BMP's, would severely effect coldwater aquatic insects. As seen in Figure 41, it is most likely that sensitive groups, such as stoneflies, would either be eliminated or severely restricted (for much of the year) at temperature levels comparable to those

observed at the moderately and highly developed watershed sites and at the wet pond, ED wetland, and ED dry pond outflow stations. While collectively more temperature tolerant, many mayfly and caddisfly species would similarly be eliminated, severely restricted and/or stressed at the preceding temperature levels.

Consequently, restructuring of the macroinvertebrate community would occur, with intolerant species and/or groups of insects being replaced by thermally-tolerant ones. It would also be expected that tolerant groups such as Diptera (flies & midges) would gain greater dominance in these stream systems. In addition, non-insect species would probably become more abundant. The preceding changes could, if particularly extensive, have a negative impact on the resident fish community.

VOL 12 2 4603

R0057896

3. Fish: General Temperature Requirements, Classification and Tolerance

Although fish may be found in waters with temperatures ranging from around zero to 111.0°F, no species can survive over this entire range. Each species has a characteristic range with upper and lower lethal limits and preferred temperature optima, which changes according to the age (or life cycle stage) of the fish. Furthermore, when water temperature changes, the rate of thermal equilibration in fish is generally rapid (Elliot, in Pickering, 1981). Owing to their smaller body mass and proportionately higher surface area, juveniles are far more vulnerable to the effect of rapid temperature changes than are adult fish.

Temperature Classification

Freshwater fish in temperate regions generally live within the 32.0 - 86.0°F temperature range. Maximum summer temperatures may exceed 86°F in shallow lakes, ponds and marshes, warmer southern streams, and/or in waters that receive a thermal discharge. Based on their thermal requirements, fish are generally placed into one of three categories:

- Stenotherm - coldwater fish, which have a physiological optimum < 68°F and an upper lethal temperature of ≤ 79°F. Representative examples include salmon, trout, and certain sculpins.

VOL 12 2 4604

R0057897

- Mesotherm - coolwater fish, which have a physiological optimum in the 68 - 84.4°F range and an upper lethal temperature of 82.4 - 93°F. Representative examples include pikes, perch, darters, and most species of minnows.

- Eurytherm - Warmwater fish, which have a physiological optimum > 82.4°F and an upper lethal temperature generally over 93°F. Representative examples include carp, goldfish, catfish, sunfish, and bass.

General Temperature Requirements of Maryland Freshwater Fish

Water temperature together with the volume of flow, water quality, and physical or structural habitat are the major factors which determine the fish community characteristics of streams. While it was beyond the scope of the study to examine all of these variables, an attempt was made to identify the general temperature requirements for Maryland freshwater fish. Thermal requirement data for 63 species of fish known or expected to occur in Maryland freshwater streams is presented in Appendix C. In addition, this information together with water temperature monitoring results have been graphically summarized in Figure 42.

The upper and lower critical temperature limits depicted in Figure 42 represent reasonably well-defined physiological temperature boundaries, beyond which, death is extremely likely. Also, temperatures outside of the optimum range may generally be viewed as being stressful. Finally, it is

VOL 12 2 4607

R0057900

important to note that a fish's ability to withstand thermal stress is largely a function of acclimation temperature, its age and vigor, and length of exposure.

Temperature Monitoring Assessment

Results presented in Figure 42 show that the vast majority of fish species would not be affected by the temperature increases produced either through urbanization and/or construction of BMP's. However, coldwater species such as trout would not be expected to survive at temperature levels observed at either the moderately or highly developed watershed sites or at any of the four BMP outflow locations. While generally regarded as being slightly more temperature tolerant than trout, sculpins would also be negatively impacted. As seen in Figure 42, sculpins would only be expected to survive at temperature levels observed at either the lightly developed watershed sites, or below the infiltration - dry pond.

The preceding findings underscore the point that moderate levels of watershed imperviousness and/or the improper introduction of BMP's, can have a devastating impact on sensitive coldwater streams and the fish communities which they support.

VOL 12 2 4608
R0057901

4. Trout and Thermal Stress

A. General Findings

With only one or two notable exceptions, natural coldwater stream fish communities in Maryland are generally restricted to higher altitude and/or spring-fed streams of the Appalachian and Piedmont provinces. The fish assemblage in these streams is often highly variable, but typically includes one or more species of trout (brook, and/or brown or rainbow), as well as, sculpins, and several minnow species. Maximum summer water temperatures in coldwater streams are normally less than 70°F (Winger, in Krumholz, 1981).

While the temperature requirements for brook, brown and rainbow trout are quite similar, the brown trout is generally regarded as being the more temperature tolerant and the brook trout the least. It is important to note that even within a given species the difference in thermal tolerance is often surprisingly large. Much of this is due to inherent genetic or racial differences within the species and adaptation to different thermal regimes.

All trout species are extremely sensitive to thermal pollution/stress. Sustained elevated water temperatures over 70°F are generally considered to be stressful, while those at or above 77°F are usually lethal. As previously noted, a fish's ability to withstand or resist the effects of thermal stress is heavily influenced by the acclimation temperature. Trout can, depending on the acclimation temperature, survive for varying periods of time at temperatures which are ultimately lethal. As seen in Figure 43, brown trout

acclimated at 59, 68, or 72°F survived slightly over 7 days at 77°F, 100 minutes at 82.4°F, and only 10 minutes at 86°F.

B. Gum Springs Thermal Regime

From a historical perspective, the Gum Springs tributary has supported a naturally reproducing brown trout population since at least the mid-1950's. During the past 10 - 12 years the Gum Springs tributary subwatershed has experienced considerable watershed development activity. Presently, this residentially developed basin, which includes the Oaksprings ED wetland - tributary system, is approximately 12 percent impervious.

Despite this background level of watershed imperviousness the Upper Gum Springs continues to support a healthy brown trout population. Unfortunately, this is no longer the case in Lower Gum Springs. Over the past 6 - 7 years, the resident trout population downstream of the Oak Springs tributary confluence has steadily declined (Gougeon, 1990). While much of this decline has been attributed to construction-related sediment pollution and increased stormflows, temperature regime alteration has been repeatedly implicated (Gougeon, 1990).

In an effort to document longitudinal thermal regime differences, thermograph thermometers were strategically located in both Upper and Lower Gum Springs. Water temperature monitoring results confirmed that under both baseflow and stormflow conditions Lower Gum Springs is warmer. They also revealed that the two stations behave very differently under large stormflow conditions. Major findings are described below.

VOL 12 2461!!
R0057904

1. While baseflow temperatures at Lower Gum Springs were typically 1 - 2°F warmer than those recorded at Upper Gum Springs, they were safely below levels considered to be stressful to trout (Figure 44).

2. Under stormflow conditions (Figure 45) both stations exceed the Class III temperature standards. Whereas only one percent of all storm events at Upper Gum Springs resulted in a temperature standard violation, 8 percent did so at Lower Gum Springs. Moreover, Lower Gum Springs stormflow temperatures reached a high of 74.5°F. This value was 3.1°F higher than the maximum stormflow temperature recorded at Upper Gum Springs.

3. The temperature regimes of both stations were generally unresponsive to runoff produced by small-medium size storm events (i.e., $\leq$ 1.0 inch of precipitation). Larger storms (those dropping $\geq$ 1.0 inches of rain), however, produced sharp temperature increases at both stations. Under these large stormwater inflow conditions, Gum Springs stream temperatures were observed to increase at rates of 4.3 - 9.7°F per hour. It should also be noted that the single largest 20 minute temperature increase, 7.2°F, occurred at the Upper Gum Springs station.

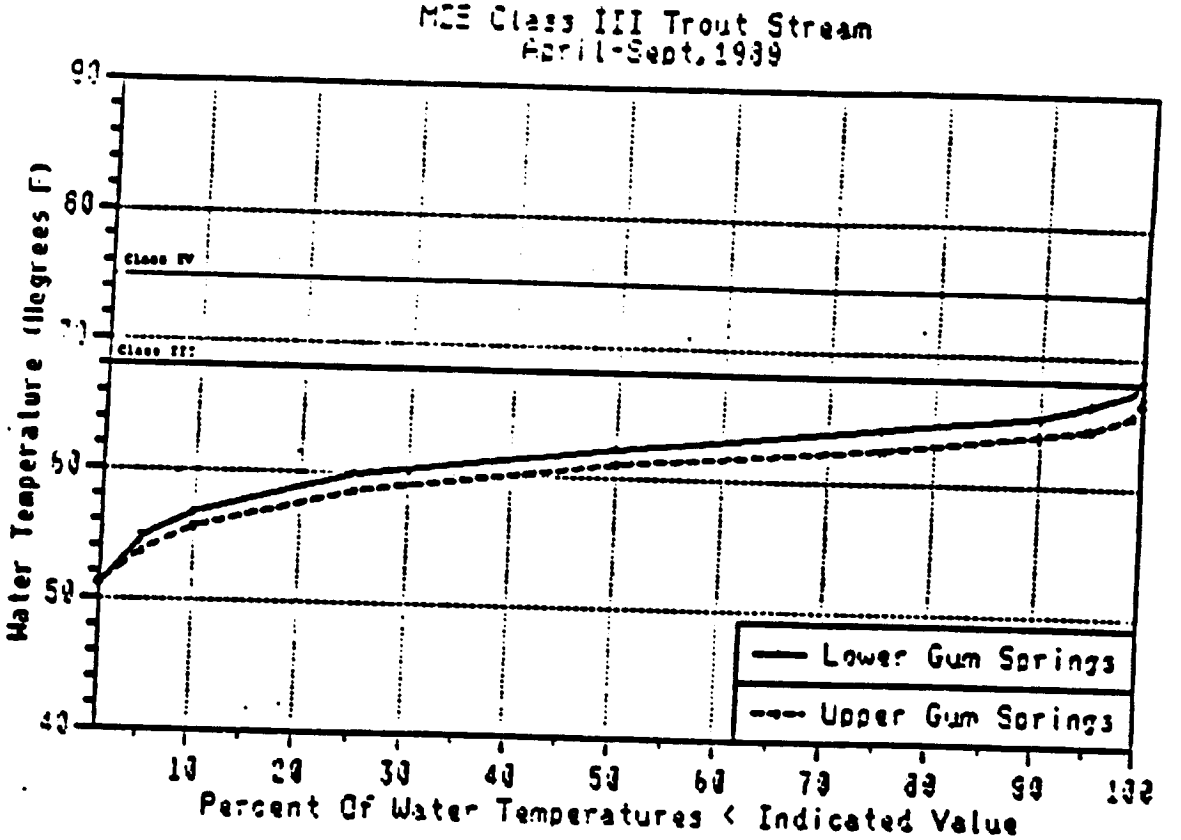
4. The principal differences between the two stations, under the large storm event scenario, were the magnitude of the temperature increase and the recovery rate. Results showed that temperature increases were higher and recovery slower at Lower Gum Springs. During these storm events, Upper Gum Springs temperatures typically remained

VOL 12 2 4 6 1 2

R0057905

FIGURE 44

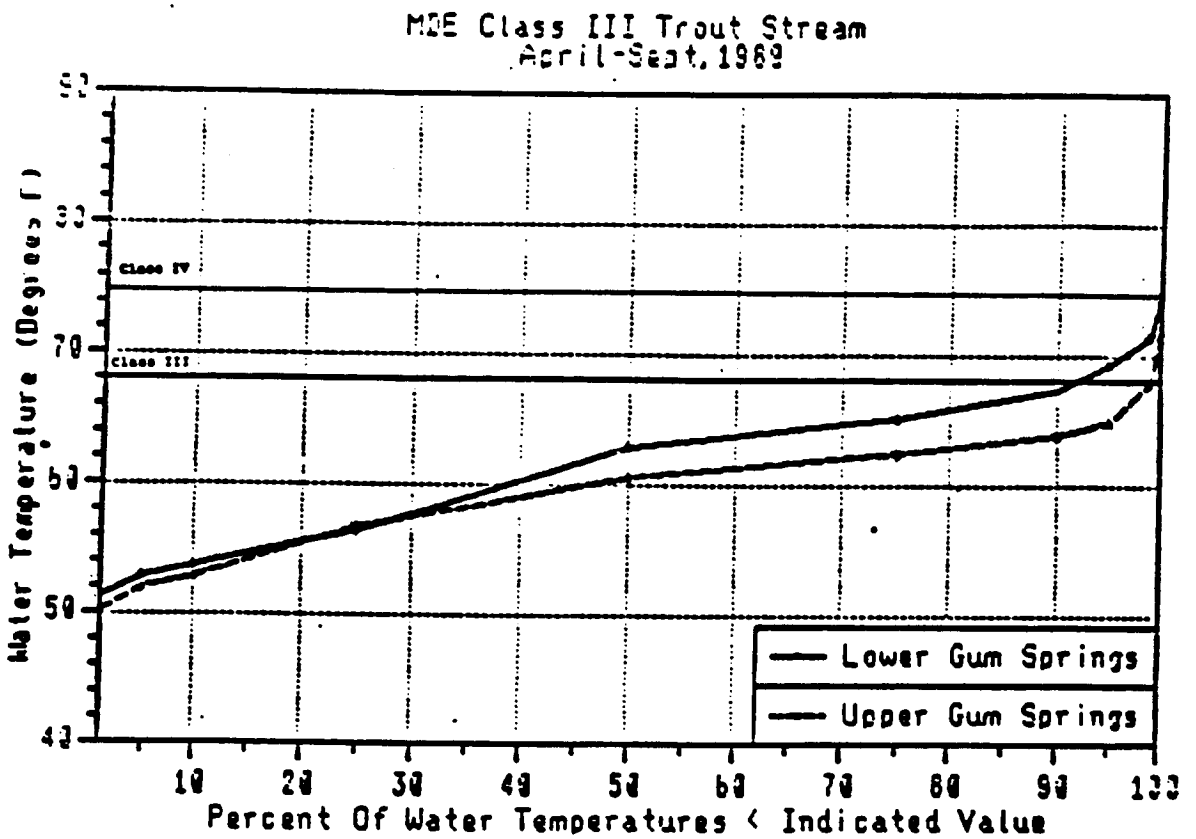
UPPER VERSUS LOWER GUM SPRINGS WATER TEMPERATURES UNDER BASEFLOW CONDITIONS



VOL 12 2 4613
R0057906

FIGURE 45

UPPER VERSUS LOWER GUM SPRINGS WATER TEMPERATURES UNDER STORMFLOW CONDITIONS



VOL 12 2 4614
R0057907

elevated for 6 - 12 hours before returning to normal. In contrast, water temperatures at Lower Gum Springs remained elevated for up to 2 - 3 days at a time. The long, Lower Gum Springs recovery period is attributable to the relatively slow release of large volumes of stormwater from the Oaksprings Ed wetland. During the study it was not unusual to see Lower Gum Springs temperatures remain at or above 70°F for periods of 30 - 40 hours. As previously noted, sustained temperatures $\geq$ 70°F are generally considered to be stressful to trout, especially young-of-year and juvenile trout, who are least tolerant of high temperatures and are first affected by thermal shock.

The preceding findings underscore the fragile nature of urban trout streams and their vulnerability to large inputs of stormwater runoff. Although the water temperature regimes of both Upper and Lower Gum Springs are still quite capable of supporting trout, the Lower Gum Springs is far more thermally stressed. It is also quite likely that additional watershed development, particularly in the headwaters, will cause further deterioration of the Gum Springs tributary thermal regime. This could conceivably result in the elimination of all trout from the stream.

VOL 12 2 4615

R0057908

Chapter IV. Land Use Control and Stormwater Management Program Implications

Through the process of urbanization, vegetation is removed from watersheds, formerly pervious surfaces are converted to hard, impermeable ones such as rooftops, streets and parking lots, and natural drainage networks are modified to convey runoff more efficiently. These processes act together to alter the thermal regime of urban, headwater streams. The extent to which the thermal regime of these streams is modified is largely a function of three major interrelated factors: 1.) watershed imperviousness levels, 2.) integrity of riparian canopy coverage, and 3.) the employment of stormwater BMP's. These factors, as related to land use and stormwater management control programs, are discussed in greater detail in the following sections.

Land Use Control Implications

1. Watershed Imperviousness Factor

For urban headwater streams, the level of watershed imperviousness largely determines the magnitude of change from the pre-development thermal regime. Results from this study show that a linear relationship exists between the level of imperviousness and mean, summer stream temperatures. In general, the mean summer water temperature of these streams will increase 0.14°F per one percent increase in watershed imperviousness. Other important findings are described below:

VOL 12 2 4616

R0057909

- Watershed imperviousness has a negative influence on stream temperatures under both baseflow and stormflow conditions. As seen in Table 18, the frequency of MDE temperature standards violations generally increases with increasing levels of imperviousness. This phenomenon occurs regardless of whether watershed stormwater management controls are present or absent. Reduction of groundwater flows, the urban heat island effect, removal of riparian vegetation, and drainage network alteration are primary causes of the problem;

- As the level of watershed imperviousness increases, the ratio of stormwater runoff to receiving stream flow increases. Consequently, the potential for large inputs of biologically harmful warm stormwater to urban stream increases. Because small urban streams have relatively low volumes of baseflow discharge, these streams are most susceptible to the effects of thermal loading;

- With increasing watershed imperviousness, the rainfall volume required to produce large storm temperature fluctuations decreases. As previously noted, at a 12 percent watershed imperviousness level over 0.7 inches of rainfall is generally required to produce a temperature "spike." Conversely, at a 60 percent imperviousness level, less than 0.2 inches of rainfall are needed to produce a comparable temperature spike.

VOL 12 2 4617

R0057910

Table 18. Summary: MDE Water Temperature Standards Violations Versus Watershed Imperviousness

Watershed Development Level	Percent Imperviousness (%)	Percent of Time MDE Temperature Std. Violated (%)

		Baseflow	Stormflow	Baseflow	Stormflow
Light	12.0	10	5	0	1
Moderate	30.0	25	1	25	1
High	60.0	67	57	12	10

VOL 12 2 4618

R0057911

2. Riparian Vegetation Removal Factor

Riparian vegetation plays a key role in insulating small streams from the warming effect of solar radiation. Other studies have shown that the removal of riparian vegetation can raise the summer water temperature of small streams by 11 - 20°F, and can lower winter water temperatures by 5 - 7°F. Results from this study revealed an average positive stream Delta-T of 1.5°F per 100 feet of flow through either open or poorly-shaded reaches.

The need for maintaining vegetated riparian buffers is critical for the protection of thermal regime in urban headwater streams; and particularly so, for trout streams.

3. Conflicting Stream Protection and Watershed Development Goals

All too often the goal of stream protection conflicts with land use development. Many of the environmental problems caused by urbanization, stream warming for one, cannot be completely mitigated by engineering means. Thus, far greater emphasis on land use control measures is required in sensitive streams.

Results from this study show that stream temperature regime changes occur at relatively low levels of watershed imperviousness (i.e., ≤ 12 percent). They also strongly suggest that trout and other coldwater biota will most likely be lost when watershed imperviousness exceeds 12 - 15 percent.

VOL 12 2 4619

R0057912

4. Thermal Regime Protection Strategy

Current water temperature class designations are not a reliable guide to the existing or future thermal regime status of headwater Piedmont streams. This is particularly the case for urban streams. In addition, it is clear that the long-term protection of thermally sensitive streams requires a holistic watershed management approach which includes, at a minimum, the following water temperature protection elements:

- Land use controls (which govern type, density and location of development within a watershed);
- Riparian/stream buffer requirements;
- Employment of temperature sensitive BMP's and stormwater conveyance systems;
- Long-term water temperature and biological monitoring at strategic stream locations within the watershed; and
- Routine long-term maintenance of BMP's and other associated infrastructure.

Not surprisingly, extraordinary land use, riparian management and stormwater management controls are needed to properly protect the resident

VOL 12 2 4620

R0057913

aquatic life of MDE Class III streams. The same watershed protection approach is also generally needed, on a case-by-case basis for thermally sensitive Class I and IV stream areas. This stream protection strategy requires that many difficult, and potentially costly, land use decisions be made.

Stormwater Management Program Implications

Stormwater management controls are employed in an attempt to mitigate the undesirable changes in watershed hydrology, water quality and stream ecology produced by urbanization. Unfortunately, the improper employment of these BMP's can exacerbate the thermal regime problems caused by watershed development. In thermally sensitive watersheds, the selection of appropriate stormwater management controls is often a difficult decision, fraught with potential water quality/quantity and environmental trade-offs. Major stormwater management program implications are discussed below.

1. BMP Thermal Performance

As previously noted, none of the four types of stormwater BMP's monitored were thermally neutral. Of the four practices, the infiltration-dry pond produced the smallest total Delta-T increases and had the fewest MDE Class III and IV temperature standards violations. The artificial wetland was next, with intermediate total Delta-T increases and temperature standards violations. The second highest Delta-T increases were associated with the extended detention dry pond. From a temperature performance standpoint, the wet pond finished last. This BMP produced the largest Delta-T increases,

VOL 12 2 4621
R0057914

maintained elevated downstream temperature conditions for months at a time, and had the highest percentage of Class III and IV temperature standard violations.

The preceding results strongly suggest that all of the major stormwater management practices commonly in use will generally amplify, to some extent, baseflow and/or stormflow Delta-T's. It is further evident that infiltration BMP's provide the greatest level of water temperature protection and are the most appropriate practice for use in thermally sensitive watersheds.

2. BMP Contribution to Stream Warming Problem

At low levels of watershed imperviousness, improper BMP selection can have a major negative effect on the water temperature regime of small, headwater Piedmont streams. This is particularly the case in coldwater stream systems, where the selection of conventional wet and/or extended detention BMP's could conceivably eliminate temperature sensitive species such as trout.

However, results from the study also show that at moderate levels of watershed imperviousness the potentially negative influence of BMP's on the receiving steam's temperature regime is reduced. This is due to the fact that the temperature regimes of these streams have been (or will be) modified by the background level of urbanization. Consequently, temperature sensitive biota will, even in the absence of BMP's, most likely be reduced and/or eliminated from these streams. At high levels of watershed imperviousness, the general impact of BMP's on the receiving stream temperature regime is minimal. In these streams, the need for providing high

VOL 12 2 4622
R0057915

levels of water quality and stream channel erosion control may outweigh temperature concerns.

3. BMP Design Elements Which Contribute to Thermal Loading

During the course of the study it became obvious that several BMP design elements were actually increasing total Delta-T's. Among the top five contributing factors were:

- undersized infiltration treatment system capacity;
- the presence of a large wet pool;
- poorly shaded pilot and outflow channels;
- poorly shaded storage pool areas; and
- excessively long periods of extended detention control.

4. BMP Temperature Reduction Methods

A number of BMP design features and methods could be employed to help reduce stream warming. Methods include, but are not limited to, the following:

VOL 12 2 4623

R0057916

- increasing, to the maximum practical extent possible, infiltration system treatment capacity;

- combining both infiltration water quality control and dry water quantity control within one, single facility;

- constructing BMP's as "off-line" rather than "on-line" facilities (this would help to reduce baseflow Delta-T's);

- incorporating baseflow diversion systems into "on-line" facilities;

- heavily shading pilot and outflow channels and storage pool areas with trees and shrubs;

- Incorporating narrow-width baseflow channels into BMP outflow channel design;

- limiting the maximum period of extended detention control to 6 - 12 hours;

- employing parallel pipe conveyance systems, so as to reduce the frequency and magnitude of receiving stream thermal loading;

- employing passive and/or mechanical systems to reduce baseflow/stormflow temperatures (e.g., cooling reservoirs, cooling chambers, and multiple-port releases for deep reservoirs).

VOL 12 2 4624

R0057917

- Employing, when full infiltration controls are neither practical nor feasible, alternative BMP's such as sand filters; and

- Avoiding the use of permanent pools in thermally sensitive watershed areas that are expected to have low to moderate levels of watershed imperviousness.

Several of the preceding methods and design features are experimental in nature and may or may not work until tested under field conditions. In addition, some of these design features may actually reduce the overall level of water quality or quantity control. It is further recognized that these innovative engineering approaches cannot totally eliminate the large Delta-T increases produced by large volumes of urban runoff. Also, the ability of these innovative BMP's to function as designed is dependant upon proper construction and long-term maintenance. Last, stormwater management program research priorities should include the monitoring of parallel pipe and baseflow diversion systems, multiple-port release wet ponds, sand filters, peat-sand filters and other promising thermally sensitive conveyance systems and BMP's.

Executive Summary

A comprehensive literature review was conducted in 1989 for the purpose of identifying the known or potential general effects of temperature regime modification on the biota of freshwater streams. The general temperature requirements for representative groups of stream biota, as well as, the principal environmental factors and human activities which influence water temperature were examined. The major findings of the study are summarized below:

- The water temperature of streams generally increases in a downstream, longitudinal fashion. Small headwater streams, which represent the largest overall group of streams, are normally cooler than larger main streams and rivers. Daily, seasonal, and annual temperature fluctuations are typically smaller in large rivers than in headwater streams.

- The volume of flow is the most important hydrologic variable influencing stream temperature. In general, thermal stability increases with increasing discharge. Groundwater inflow, via springs, etc., similarly increases the thermal stability of streams.

- Riparian vegetation has an overall moderating effect on the temperature of headwater streams. The removal of riparian vegetation can raise summer water temperatures by as much as 6-11°C and can lower winter temperatures by up to 4°C. Loss of shading can significantly alter the temperature and light regime of streams, thereby, possibly producing qualitative/quantitative changes within the resident biological community. It is further noted that all aquatic organisms are cold-blooded and therefore demonstrate little ability to acclimate or compensate for temperature changes.

- Urbanization generally alters both the flow and temperature regime of local receiving streams. Reduction of base flow, loss of riparian vegetation, and the rapid delivery of large volumes of warm or cold stormwater runoff are among the principal thermal regime modifying factors cited. Summer runoff temperatures in urban watersheds can exceed 32°C and winter runoff may be 3-4°C colder than ambient stream temperatures.

- The damming of streams and rivers also generally alters the downstream thermal regime. The degree of modification is primarily a function of the release depth of the facility, its thermal stratification characteristics, and its hydraulic residence time. In the middle-Atlantic states, surface release facilities typically shift the normal temperature cycles of the receiving stream. The general resulting pattern is one in which the stream is slower to warm in the spring, slower to cool in the fall, and warmer during the summer.

- Water temperature has considerable influence on a number of water quality parameters. This is particularly the case with regard to dissolved oxygen, which is, absolutely essential for all higher forms of aquatic

VOL 12 2 4648

R0057941

life. The concentration of dissolved oxygen that is generally accepted as being the minimum required to maintain healthy warmwater and coldwater fish population and their support organisms, is 5.0 and 6.0 mg/L, respectively.

- Bacteria and fungi are the principal decomposers of organic materials in freshwater aquatic ecosystems. A high percentage of chromagenic bacteria present in a stream is generally indicative of non-thermally polluted conditions, whereas, the presence of thermophilic bacteria is indicative of thermal pollution. High or low temperature stress generally results in increased bacterial generation times, hence, reduced bacterial turnover rates and processing efficiency. Bacterial community diversity may be reduced at temperatures > 24.0-28.0°C and fungi are generally completely inhibited at temperatures $\geq$ 30°C.

- Based on their temperature requirements, freshwater algae are generally placed into one of the following categories: oligothermal - coldwater algae which are typically restricted to waters ranging between 0 and 15° C; mesothermal - algae which inhabit cool-warm water between 15 and 30°C; and euthermal - warmwater algae which exhibit their greatest abundance at temperatures $\geq$ 30°C. Diatoms, which are the overall dominant group of algae present in streams, are most abundant at temperatures 20-30°C. Water temperatures increases to 30°C and beyond generally causes a shift from a diatom- dominated community to one increasingly dominated by blue-green algae.

- In most freshwater ecosystems, aquatic insects are the largest group of macroinvertebrates present. Temperature greatly influences aquatic insect physiology, growth and development, reproductive success, and emergence. Water temperature regime increases of 2-3°C may be sufficient to eliminate sensitive insect species. In addition, many aquatic insects require fluctuating daily temperatures. Thermally constant conditions may therefore eliminate sensitive species.

- Water temperatures greater than 17°C have generally been considered to be above the optimum for many stoneflies, mayflies, and caddisflies, and temperatures exceeding 21°C have been shown to stress severely most coldwater organisms. As a group, stoneflies are the least temperature tolerant and are restricted to cold-cool flowing waters.

- Acclimation temperature and the period of exposure to temperatures outside the tolerance zone are the two most important factors which affect thermal tolerance and ultimately the lethal temperature of fish. Thermal stress can: negatively affect and disrupt feeding, disrupt the normal balance necessary for the initiation of spawning activities, reduce reproductive success, and predispose fish to disease and predation. Large rapid changes in water temperature (i.e., thermal shock) can be lethal when the normal escape swimming response is overwhelmed, or where no escape refugium exits. In general, juvenile

VOL 12 2 4649

R0057942

fish are far more susceptible, because of their smaller body mass, to thermal shock than adult fish.

- Based on their temperature requirements, fish are generally placed into one of three categories:

Category	Stream Type	Physiological Optimum (°C)	Upper Lethal Temperature (°C)	Representative Species
Stenotherm	coldwater	< 20.0	< 26.0	trout & salmon
Mesotherm	coolwater	20.0 - 28.0	28.0 - 34.0	pikes, perch, darters, and most minnows
Eurytherm	warmwater	> 28.0	> 34.0	carp, goldfish, sunfish, bass, etc.

- The percentage of fish species expected to be lost from coldwater river systems is typically five percent or less at temperatures below 20°C, but increases dramatically at temperatures > 22°C. Conversely, in warmwater river systems the estimated percentage of fish species lost is less than five percent at temperatures < 30.0°C. At temperatures above 30°C a catastrophic loss of fish species is predicted to occur in these systems.

VOL 12 2 4650

R0057943

Glossary of Terms

Acclimation Temperature - a relatively stable laboratory or field temperature, which fish and/or other organisms have physiologically adjusted to.

Anerobic - a condition in which no oxygen is present.

Coldwater Stream - cold streams which are generally capable of sustaining trout and/or their support organisms. The maximum summer water temperature in these streams seldom exceeds 21.0°C.

Coolwater Streams - streams which are too warm to support trout on a year-round basis, yet too cool to support a diverse warmwater fish community. Maximum summer water temperatures in these streams is typically less than 27°C.

Critical Thermal Maxima (CTM) - the upper zone of thermal resistance, generally characterized in fish by the loss of normal locomotary function and/or control.

Diapause - a dormant period in the life-cycle of aquatic insects brought about either by environmental factors (e.g., too hot or cold to permit normal activity) or through genetic programming.

Diurnal - having to do with a daily cycle, rhythm, or event.

Emergence - the life-cycle stage, normally the end stage, in which adult aquatic insects leave the water to mate and lay eggs.

Euthermal Algae - warmwater algae which are generally most abundant in streams when temperatures are $\geq$ 30°C.

Eurytherm - warmwater fish, which have a physiological optimum > 28.0°C. and an upper lethal temperature generally over 34°C.

Fecundity - the ability to successfully produce large numbers of healthy, viable off-spring.

Headwater Stream- typically, smaller tributary streams, whose stream order ranking is less than four (i.e., stream orders 1-3).

Lethal Temperature (LT) - temperature that is lethal to 100% of the tested specimens.

Lower Incipient Lethal Temperature (LILT) - the low temperature that is lethal to 50% of the tested specimens.

Mesotherm - coolwater fish, which have a physiological optimum in the 20-28°C range and upper lethal temperature of 28-34°C.

VOL 12 2 4651

R0057944

Mesothermal Algae - algae which inhabit cool-warm temperature habitats between 15 and 30°C.

Molting - the process by which aquatic insects, as well as other macroinvertebrates, shed and replace their exoskelton in order to permit additional growth in body size.

Oligothermal Algae - coldwater algae, which are generally restricted to water ranging between 0 and 15°C.

Periphyton - algae which are attached to rocks, wood or other objects on the streambed.

Physiological Optimum - the temperature or temperature range in which all life processes/functions occur at their optimal level(s).

Phytoplankton - free-floating or swimming algae present in the water column.

Refugium - a protected stream or reach which provides long-term safety, for aquatic biota, from either natural or human perturbations.

Resistance - the capacity, usually measured in time, of an organism to withstand temperatures which are outside of the tolerance zone.

Stenotherm - coldwater fish, which have a physiological optimum < 20°C and an upper lethal temperature < 26°C.

Stream Order - a system for classifying streams based on morphological-tributary branching characteristics. Under this system, streams without any tributaries are deemed first-order. Second order streams are formed below the confluence of two first-order streams, third-order streams are formed downstream of the confluence of two second-order streams, and so on and so forth.

Temperature Conversion Factor - Farenheit = 1.8 x °C + 32.

Thermal Capacity - the ability of a stream to store and/or retain heat.

Thermal Constancy - a prolonged, static condition in which water temperature fluctuations are generally less than 1°C.

Thermal Shock - a large and rapid change in ambient water temperature which may negatively affect resident stream biota.

Tolerance - the ability of an organism to function indefinitely under temperature conditions which are outside of the physiological optimum.

Upper Incipient Lethal Temperature (UILT) - the high temperature that is lethal to 50% of the tested specimens.

Warmwater Stream - generally larger, low-gradient streams in which maximum summer water temperatures may exceed 30°C.

VOL 12 2 4652

R0057945

Introduction

Life in all aquatic environments has its species composition and activity regulated by water temperature. Because all aquatic organisms are cold-blooded, or poikilothermal, the temperature of the surrounding water regulates their metabolism and ability to grow, reproduce and survive effectively. The well-known role of water temperature as a catalyst, depressant, stimulator, controller and killer of biota makes it the single most important physical parameter governing aquatic ecosystems. It is equally understood that temperature controls and directs a broad array of biological and chemical processes and activities in these systems.

Human activities such as agriculture, silviculture, industrial/power plant operations, urbanization, and the damming of rivers and streams are widely recognized as having the capacity to alter significantly both the thermal regime of the receiving body of water and the biological communities contained therein. Effects upon the receiving system can be subtle or profound, depending upon the extent of the departure from the normal temperature regime and the sensitivity of the resident biota. The growing concern over the potential thermal impacts to Maryland's freshwater streams, from both urban stormwater runoff and the various Best Management Practices (BMP's) employed for its control, provided the impetus for this study.

It is the purpose of this report to provide the reader with a broad overview of known, or potential, general effects of temperature regime modification on stream biota. In order to accomplish this objective a two-part, holistic ecosystem approach was required. Part one examined both the principal environmental factors and various human activities which influence the thermal regime of streams. Part two investigated the general thermal requirements of stream biota as well as the potential biological

VOL 12 2 4653

R0057946

affects associated with thermal regime modification. Potential biological consequences occurring at all general levels of the aquatic food chain were researched.

Data on temperature preference, lethal temperature limits, temperature induced metabolic stress, disruption of normal life cycles, impaired growth, behavioral and other stresses to aquatic life, related to water temperature is also summarized. It should be noted that special emphasis was placed upon collecting data for fish known or expected to occur in Maryland freshwater streams.

For organizational purposes this report has been divided into eight sections. In the first section, background information on the environmental factors which shape the temperature regime of natural streams is presented. The second section examines human activities, such as urbanization, and their influence on stream temperature regime. In the third section, major temperature-dissolved oxygen relationships are briefly outlined. The fourth section provides both insight into the important role which bacteria and fungi play in aquatic systems, as well as, temperature-related findings. The general temperature and light requirements, classification and seasonal distribution of algae are identified in the fifth section. Section six outlines the physiological/temperature requirements of some of the more important groups of aquatic insects. The general physiological/temperature requirements for 63 species of fish, known or expected to occur in Maryland freshwater streams, are featured in section seven. The eighth and final section, focuses on trout and their special temperature requirements. Additional temperature-related data is also presented in the appendices.

VOL 12 2 4654

R0057947

I. Environmental Influences on Stream Temperature

Distance From Source, Topography and Riparian Vegetation

It is well known that the temperature regime of streams under natural conditions is greatly influenced by climate, and that temperature changes with distance from the source. In general, water temperature increases in a longitudinal fashion (Figure 1). Headwater streams, stream order 1-3, are typically cooler than larger main streams and rivers (stream order 4 and above). The significance of this takes on added meaning in light of the fact that approximately 85 percent of the total stream mileage in the continental United States is comprised by headwater streams (Karr & Schlosser, 1977). Thermal changes occurring downstream from the source are largely determined by meteorological conditions, topography, riparian vegetation, and hydrological conditions.

In his study of small streams, Macan (1958) observed that these streams warmed up and reached equilibrium within very short distances from their sources. This is due to the responsiveness of the relatively small volume of water to both atmospheric variations and prevailing local conditions. Under natural conditions, headwater streams in temperate latitudes often exhibit annual temperature fluctuation ranges greater then 20°C (Ward & Stanford, 1979). Daily or diurnal fluctuations of 6°C are quite common during summer months and temperature variations as great as 14°C have been reported (Ward & Stanford, 1979).

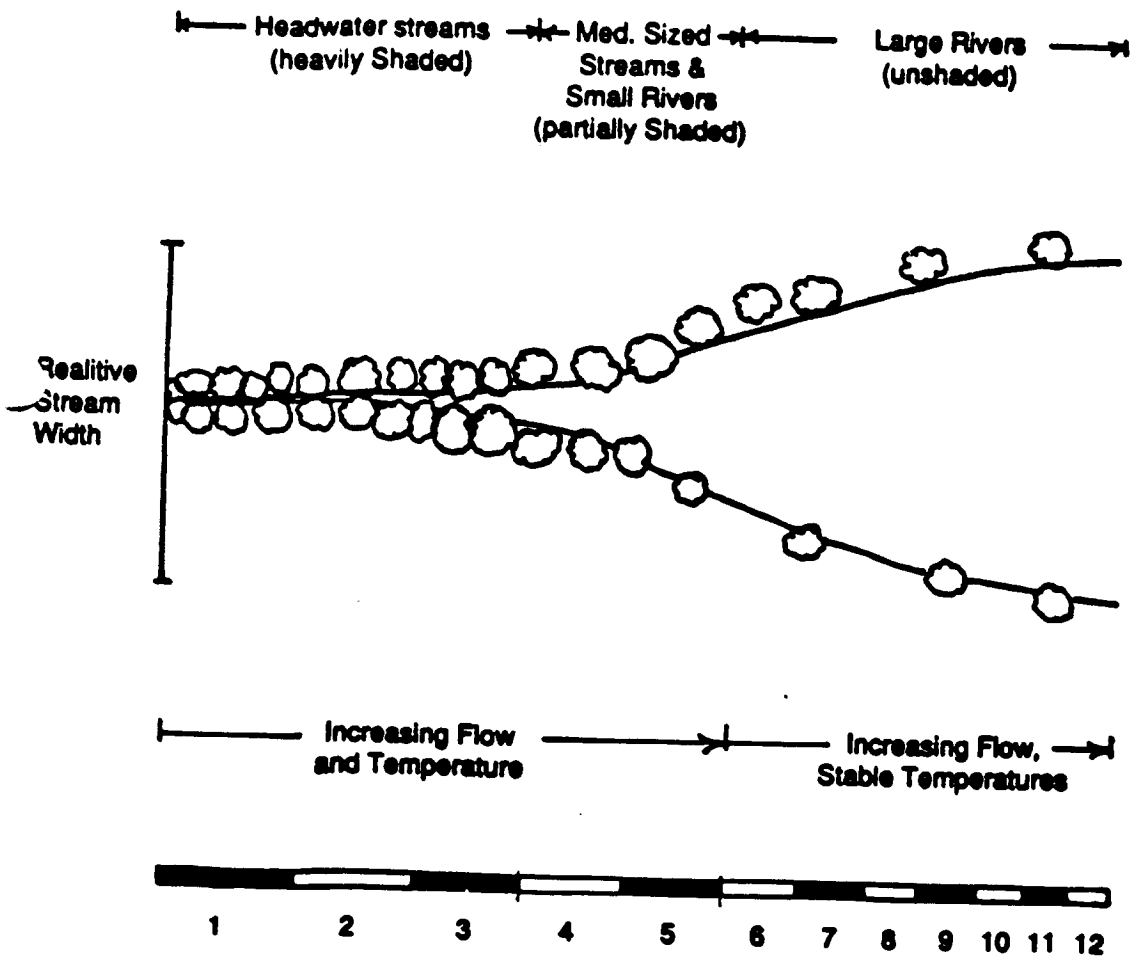
Headwater streams are also subject to the influence of local conditions

VOL 12 2 4655

R0057948

Figure 1

General Relationship Between Flow, Canopy Coverage, and Water Temperature Versus Relative Distance from Source



VOL 12 2 4656

R0057949

such as shading by canyon walls, steep undercut banks, and riparian vegetation. The extent to which the surface of a stream is exposed or shaded from direct solar radiation and its heating effect is determined by the topographic relief and aspect, in combination with channel form and riparian vegetation (Smith & Lavis, 1975).

Stream Discharge and Air Temperature

Of the various hydrological variables influencing the thermal regime of streams, the volume of discharge is generally regarded as being the most important. Flow variations directly affect the heat or thermal capacity of a stream (i.e., its ability to store and/or retain heat).

In general, the lower the discharge, the lower the capacity for heat storage and the more responsive the stream becomes to temperature changes via heat inputs (i.e., gains or loses heat more readily). At lower levels of discharge the prevailing water temperature is heavily dependant upon air temperature and other local environmental factors (Smith & Lavis, 1975). Conversely, an increase in flow will raise the thermal capacity of the stream (i.e., more energy will be required to either raise or lower its water temperature). As discharge generally increases in a downstream direction with increasing stream order, so to does thermal stability. In addition, during periods of high discharge the thermal conditions of the headwaters extend further downstream (Ward & Stanford, 1979).

Mean, maximum and minimum stream temperatures are greatly influenced by both the volume of discharge and local air temperature. Typically, the mean

VOL 12 2 4657

R0057950

monthly temperature of a natural stream is within a few degrees of the mean monthly air temperature when the air temperature is above freezing (Macan, 1958). In addition, the maximum water temperature in any of the warmer months is usually from 1-3°C higher than the mean monthly air temperature (Pluhowski, 1970). In much of North America, air and water temperatures both reach their respective maximums in July. During July, the maximum daily water temperature will generally average 3-4°C higher than the mean monthly water temperature for that month (Pluhowski, 1970).

Groundwater Input

Contributory aquifers which supply baseflow to streams also exert considereble influence on the water temperature regime. As a rule, groundwater has a major stabilizing effect on stream temperature. Streams which receive significant inputs of groundwater exhibit less daily and seasonal temperature variability than those receiving smaller amounts of groundwater. Spring-fed streams also tend to be cooler in summer and warmer in winter. The temperature of a spring is closely correlated to the depth of its groundwater source. Springs which have shallow groundwater sources tend to be warmer than those originating from deeper sources/strata.

In a study of the thermal characteristics of 76 springs in the Piedmont and Appalachian Provinces of Maryland, Otton and Hilleary (1985) reported maximum, minimum and median water temperatures of 19.2°C, 1.0°C, and 11.0°C, respectively. The same investigators also noted that the mean annual water temperature of these springs was within 1-2°C of the mean annual air temperature of the locality.

VOL 12 2 4658
R0057951

II. General Impacts of Human Activities on Stream Temperature and Biota

The number and types of human activities in a watershed which may affect stream temperature and the resident biological community are many, complex, and generally interrelated. Given the limited scope of the study, major emphasis was necessarily placed upon summarizing temperature findings relevant to freshwater streams present in the Middle-Atlantic States. In an attempt to facilitate reader understanding, a simplified graphical summary of the general thermal impacts of watershed perturbations has been included as Figure 2. Specific temperature information is presented in this and the following six sections.

Loss of Vegetative Cover

The moderating influence of vegetation, particularly forest-type vegetation, on watershed micro-climate and stream temperature is widely recognized. Trees shelter both ground and stream surface from the sun's rays, reduce wind velocities near the ground, and generally lower the evaporative loss of water. In the same way, riparian vegetation functions as a thermal insulator for streams. The removal and/or addition of riparian vegetation can either raise, lower, or maintain stream temperatures.

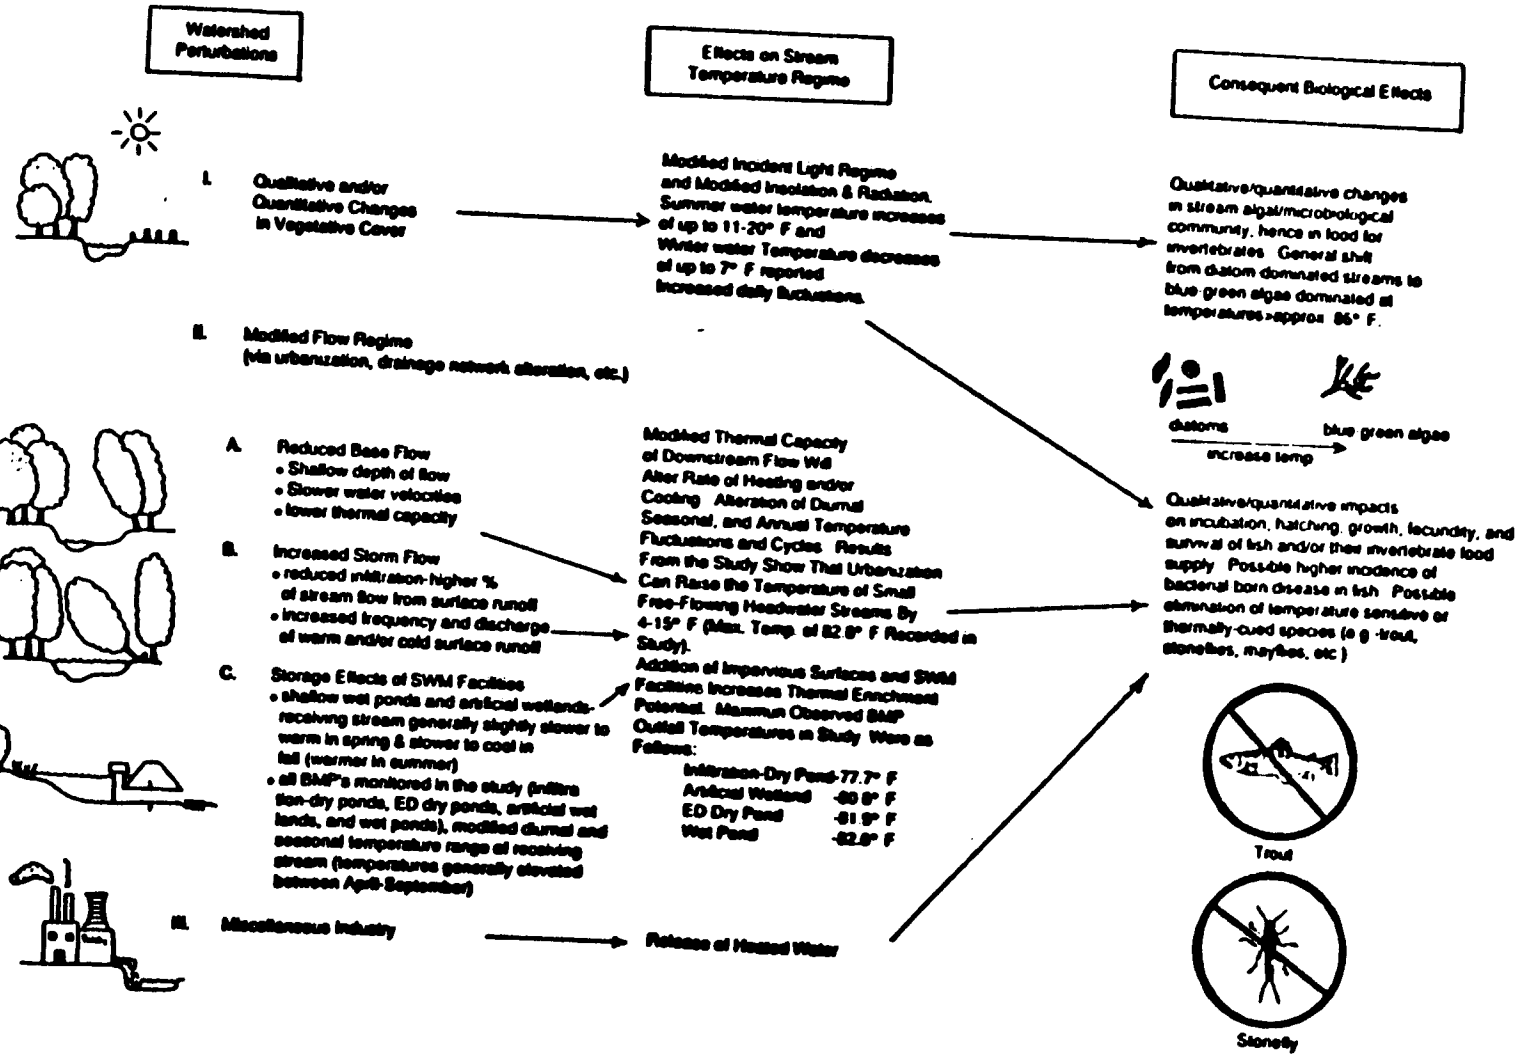
Several studies have shown that the partial and/or complete removal of riparian vegetation along headwater streams can raise summer water temperatures by as much as 6-11°C and can lower winter temperatures by up to 4°C (Gray & Eddington, 1969; Hewlett & Forston, 1982; Lynch et al., 1980;

VOL 12 2 4659

R0057952

Figure 2

Summary: General Impacts of Human Activities on Stream Temperature and Biota



R0057953

Klein, 1979; Karr & Schlosser, 1977). In addition, the removal of riparian vegetation can modify the incident light regime.

As illustrated in Figure 2, the modification of a stream's light and temperature regime may, depending on the degree of change and stream sensitivity, produce qualitative and/or quantitative changes in the biological community. In addition to possible changes in the algal-microbial food base, changes may also be felt at higher levels within the food chain. If the modification of the temperature and light regimes is particularly severe, it may become energetically impossible for sensitive species to continue living in the area. Under this scenario, a shift in community structure would probably occur; with sensitive species being replaced by more tolerant and possibly less desirable ones.

Flow Regime Modification

The hydrology of a stream changes in response to the nature and level of activities within its watershed (Figure 2). This is particularly the case when a watershed experiences the effects of urbanization. In a typical, moderately developed watershed, trees and other natural vegetation are replaced with impervious surfaces such as streets, parking lots and roof tops. The replacement of natural vegetation with impervious surfaces can increase local air and ground temperatures by as much as 12°C (Pluhowski, 1970; McPherson, 1990). Rainfall, which previously percolated into the soil to replenish groundwater supplies, is increasingly converted into surface runoff. Natural drainage networks are altered or permanently destroyed through a variety of grading, channelization and stream enclosure activities

VOL 12 2 4661
R0057954

designed to speed up the efficient removal of this runoff. Previously unregulated streams may also be dammed for water supply, stormwater management control, or a variety of other uses. The general direct and indirect effect of all these development-related changes on the flow and temperature regime of streams, exclusive of impoundments, are listed below:

- Higher peak discharges and increased volume of runoff per storm event: if storm flows are not effectively controlled, the receiving stream channel may widen by as much as two to four times over its original size (Schueler, 1987). The net effect is a reduction in both depth of flow and velocity during baseflow conditions. This, in combination with loss of bank-side vegetation, greatly increases both the amount of exposed stream surface area and length of time a unit volume of water is subject to the heating effects of solar radiation.

- Reduction in both groundwater input and associated baseflow levels resulting from the reduced level of infiltration in the watershed. This has the general double-effect of raising summer stream temperatures and lowering winter water temperatures (i.e., reduced thermal capacity). In particularly severe cases, small perennial headwater streams may become seasonally or completely dry;

- Rapid delivery of large volumes of warm or cold stormwater to the receiving stream: during certain summer storm events, runoff temperatures may exceed 32°C (Galli, 1988). Conversely, winter storm runoff may be as much as 3-4°C colder than the ambient

VOL 12 2 4662
R0057955

temperature of the receiving stream (Pluhowski, 1970).

Storage Effects of Impoundments

The extent to which artificial lakes, ponds, and marshes modify the temperature regime of a receiving stream is primarily a function of release depth (which changes relative to the impoundments water surface elevation), the thermal stratification characteristics of the facility, and the hydraulic residence time (Wright, 1967). Changes to the receiving stream's thermal regime generally fall under six broad categories;

- Increased diurnal constancy;
- Increased seasonal constancy;
- Summer temperature depression;
- Summer temperature elevation;
- Winter temperature elevation; and
- Thermal pattern changes.

In the temperate region, surface release facilities generally shift temperature cycles (slower to warm in the spring, slower to cool in the fall) and increase the seasonal temperature range (warmer in summer), rather than producing seasonal thermal constancy in the receiving streams (Kondratieff &

VOL 12 2 4663

R0057956

Voshell, 1980). Daily stream temperature fluctuations below surface release facilities are primarily a function of the mean depth of the facility. Very shallow ponds or marshes tend to amplify diurnal fluctuations, whereas deeper impoundments attenuate daily temperature changes. Deep hypolimnial release reservoirs typically produce seasonal thermal constancy in the receiving stream (winter-warm and summer-cool). Despite potentially great modification of the diurnal and seasonal temperature regimes, mean annual stream temperatures may not be greatly modified by impoundment.

VOL 12 2 4664
R0057957

III. Temperature - Dissolved Oxygen Relationships

The role of water temperature in influencing various water quality parameters and regulating biological communities cannot be overemphasized. This is particularly true with regard to dissolved oxygen, which is absolutely essential for the existence of all higher aquatic life. As seen in Table 1, an inverse relationship exists between temperature and the capacity of water to hold dissolved oxygen (i.e., as water temperature increases dissolved oxygen levels decrease).

TABLE 1. RELATIONSHIP BETWEEN TEMPERATURE AND MAXIMUM DISSOLVED OXYGEN CONCENTRATION IN WATER

Temperature °C	Maximum Oxygen Concentration (ppm)
0	14.6
10	11.3
20	10.7
30	7.6

Low dissolved oxygen levels can effect negatively the metabolism, respiration, behavior, distribution, migration, feeding rate, growth and reproduction of aquatic organisms. It can further increase their susceptibility, via increased stress levels, to a wide variety of toxic substances. Ultimately, if the reduction of dissolved oxygen is sufficiently extreme, death of the organism and perhaps the entire aquatic community may

VOL 12 2 4665

R0057958

ensue.

Anaerobic (zero oxygen) conditions at the sediment-water interface can also cause the release of nutrients, metals, and/or toxic substances, from the sediment into the overlying water column; thereby exacerbating water quality conditions. However, due to the natural turbulent flow of streams and their high reaeration potential, the preceding anaerobic scenario would only occur during periods of exceptionally low discharge and/or high organic pollutant loadings.

The concentration of dissolved oxygen which is generally accepted as being the minimum required to maintain healthy warmwater and coldwater fish populations and their support organisms, is 5.0 and 6.0 mg/L, respectively (EPA, 1976). However, the oxygen content of water cannot be used as an absolute value without taking both temperature and water velocity into consideration. Studies have shown that most species of aquatic insects and fish are able to tolerate short periods of low oxygen stress that may occur in streams if water temperatures are low and/or water velocities are relatively high. (Nebeker, 1972; Nebeker, 1973; Hoar & Randall, 1971).

VOL 12 2 4666

R0057959

IV. Bacteria and Fungi

Often overlooked, bacteria and fungi (together with algae) are the foundation upon which the aquatic food chain rests (Figure 3). Bacteria and fungi are primarily responsible for the decomposition of both particulate and dissolved organic materials present in aquatic systems. In addition, bacteria and fungi contribute to the recycling of inorganic nutrients and, where there is organic pollution present, to self-purification. These organisms serve as an important food item for many macroinvertebrates, particularly leaf shredders and filter-feeders. The vast majority of bacteria and fungi present in aquatic systems are essential and highly beneficial. However, a very small minority are pathogenic, causing disease in fish and other life forms (including humans).

The general role which bacteria and fungi play in aquatic systems is reasonably well understood. Unfortunately, relatively little information is available concerning changes in the natural microbial community structure and function resulting from thermal stress and thermal regime alteration. The following is an attempt to list, by category, some of the temperature-related findings and, where possible, identify important ecological linkages.

Water Temperature and Bacterial Communities

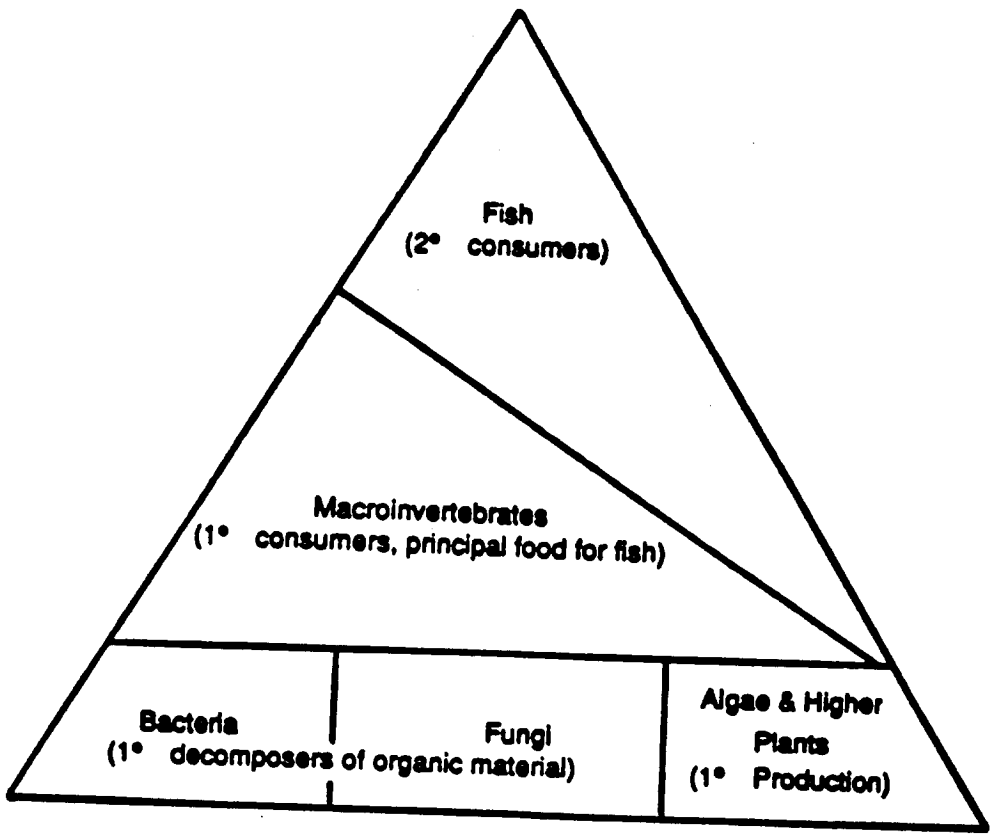
- Water temperature, not dissolved oxygen, is considered to be the most

VOL 12 2 4667

R0057960

Figure 3

Conceptual Food Chain for Freshwater Ecosystems



VOL 12 2 4668
R0057961

influential regulator of bacterial populations;

- Three groups of bacteria may be classified by their temperature requirements:

	Temperature (°C)		
	Minimum	Optimum	Maximum
Psychrophils (cold-loving)	-10 to + 5	+10 to +20	+13 to + 25
Mesophils (intermediate)	+10 to +15	+30 to +40	+30 to + 50
Thermophils (heat-loving)	+25 to +45	+50 to +75	+75 to +100

The preceding groups and boundaries are not sharply defined and the cardinal points are affected by other factors, such as nutrients, salinity, pH, and/or metabolic products;

- High or low temperature stress generally results in increased bacterial generation times, hence, reduced bacterial turnover rates and processing efficiency;

- Bacterial community diversity may be reduced at temperatures greater than 24-28°C;

- A high percentage of chromagenic bacteria, i.e., > 10 percent of total bacterial population, present in a stream is generally indicative of non-thermally polluted conditions. Conversely, the presence of Thermus aquaticus and/or other thermophilic bacteria is generally indicative of

VOL 12 2 4669

R0057962

thermal pollution.

- Chromagenic bacteria are most abundant at temperatures between 20 and 28°C (20-22°C optimal). However, sustained temperatures in the 26-28°C range are considered inhibitory;

- The lethal temperature for bacteria is generally not far above their optimum temperature range; and

- Results of bacterial studies conducted in White Clay Creek, Pa. (Bott, 1975), suggest that some bacterial communities may be better adapted to stream temperatures which are higher than the actual ambient temperatures.

Leaf Processing

- Bacteria and fungi are important in mediating the processing and cycling of leaf material and serve as an important component in the nutrition of aquatic invertebrates;

- Leaf-shredding/consuming aquatic invertebrates are in essence, fungivores who select leaves largely on the basis of the degree of microbial colonization;

- In temperate stream systems, fungi dominate the microbial biomass during the initial phases of processing deciduous leaves. Bacteria dominate the

VOL 12 2 4670

R0057963

latter phases of leaf processing;

- The temperature optimum for leaf processing for both fungi and bacteria appears to be 15-22°C, with bacterial optimums in the 18-22°C range;

- Many aquatic fungi exhibit poor growth at temperatures ≥ 25°C and are completely inhibited at temperatures ≥ 30°C.

Bacterial Fish Pathogens - Aeromonas sp.

- Aeromonas are a group of bacteria which cause "red sore" disease in fish and are also responsible for soft-tissue infection in scuba divers. The symptoms of red sore disease include scale erosion and sloughing, purulent lesions, and bleeding of the fins. Red sore disease is common in the southeastern United States and affects many important game fish such as largemouth bass;

- Aeromonas's survival in aquatic environments is enhanced at higher water temperatures (i.e., ≥ 30°C). It generally does not grow well at temperatures ≤ 15°C. Thus, it is present in very low numbers during seasons when the water temperature is low or in colder aquatic habitats;

- High infection levels in fish may well be related to the length of survival of Aeromonas in the water column (i.e., the longer the survival of Aeromonas the greater the potential exposure length for fish).

VOL 12 2 4671

R0057964

V. Algae

Based on their general community type, the algae of aquatic ecosystems are placed into one of two categories: 1) periphyton (algae which are attached to rocks, wood or other bottom objects) and 2) phytoplankton (free-floating or swimming algae present in the water column). Along a stream continuum, periphyton are commonly associated with headwater streams, whereas, phytoplankton become generally more abundant as one proceeds downstream, from large streams to rivers. Typically, periphyton are more abundant in headwater streams because the relatively shallow depth of flow and lower overall turbitity of these streams allows light to penetrate all the way to the bottom. In larger turbid streams and rivers, periphyton are often restricted to shallow, margin areas.

General Temperature and Light Requirements

Light, water temperature, and flow are generally considered to be the primary factors regulating algal communities (Patrick, 1977). Most freshwater algae cannot grow at very low light intensities and appear to also be inhibited by high light intensity (Whitford & Schumacher, 1968). In addition, "every species of algae has a range of temperature tolerance, which is generally fairly wide, and a narrower range, typically near the upper end of the tolerance range in which optimum growth occurs" (Patrick, 1974).

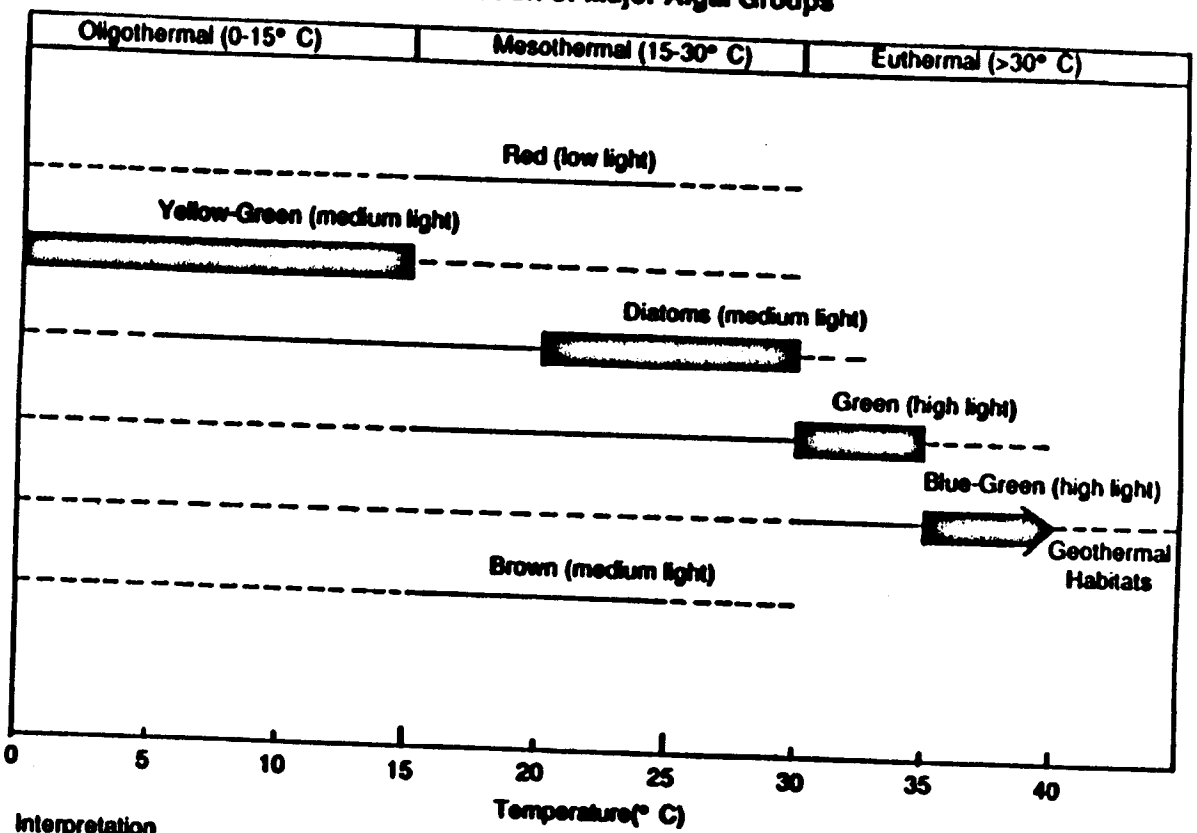
The general temperature and light requirements and classification of the major groups of freshwater algae are summarized in Figure 4.. As seen in

VOL 12 2 4672

R0057965

Figur

Summary: General Temperature and Light Requirements and Classification of Major Algal Groups



Interpretation

——— = Greatest number of representative species
- - - = Upper and lower temperature limits
▭ = Temperature range in which group is dominant
Oligothermal = Cold water forms, generally occuring between 0-15° C
Mesothermal = Temperate water forms, generally occuring between 15-30° C
Euthermal = Warm water forms, generally occuring at temperatures >30° C

Low Light = 200 foot candles
Medium Light = 500-1000 foot candles
High Light = >1000 foot candles

R0057966

Figure 4, oligothermal algae are coldwater forms which are generally restricted to waters ranging between 0 and 15°C. Mesothermal algae inhabit cool-warm temperature habitats between 15 and 30°C. The euthermal algae, which are characteristically warmwater forms, exhibit their greatest abundance at temperatures ≥ 30°C.

In general, diatoms dominate at temperatures between 20-30°C, green algae dominate between 30 and 35°C, and blue-green algae dominate in waters ≥ 35°C (Patrick, 1974). It is also important to note that, in most streams, diatoms are the overall dominant algal group. Red, brown and yellow-green algae typically comprise a relatively small portion of the stream algal community. Yellow-green algae are the dominant low temperature group (Whitford & Schumacher, 1968). They are normally restricted to cold streams and/or where present in warmer streams, to winter months.

The general temperature classification and seasonal distribution of 107 freshwater algae is presented in Appendix II. Other relevant temperature and ecological findings are listed as follows:

- According to Palmer (1977), the total number of algal species present in eastern rivers is generally between 70 and 140;
- Algae are an important food item for many macroinvertebrates and fish. However, both blue-green and yellow-green algae are generally considered to be a poor, unpalatable food source (largely due to the presence of exterior slime coating);

VOL 12 2 4674
R0057967

- In most streams, temperature shifts toward the upper limit and beyond bring about a shift in species composition; generally from diatom-dominated communities to those dominated by blue-green algae;

- In a study of the algae of White Clay Creek, Pa., water temperatures averaging 30.4°C caused a shift from a diatom-dominated community to one dominated by a mixture of greens, diatoms and blue-greens. Temperature increases to 32°C and beyond resulted in the death of most diatoms.

- Moderate increases in temperature toward the optimum growth range increases algal growth. Furthermore, small temperature increases from the lower end of the tolerance range toward the optimum temperature may increase algal diversity and biomass;

- The typical seasonal algal succession pattern in temperate ponds, lakes and reservoirs is as follows: diatoms dominate in spring, green algae are abundant in early summer, followed in late summer and early autumn by blue-greens, with diatoms reappearing in great abundance in late fall;

- Turbidites > 30 ppm JTU are often high enough to cut-off sunshine almost completely, except for a shallow layer very close to the surface;

- Temperature (ΔT) experiments conducted in artificial streams suggest that sustained ΔT increases of between 5 and 7.5°C, above ambient stream temperatures, may be sufficient to cause a significant species composition shift in the algal community (Wilde and Tilley, 1981);

VOL 12 2 4675

R0057968

- Shock exposures to high temperatures (i.e., if temperature rise is very large, if exposure continues for several hours, or if temperature is near the upper tolerance limit or beyond) can have deleterious effects and may cause death;

- Temperature increase stresses can be even more severe when accompanied by other stresses (e.g., pollution, light regime modification, and flow regime alteration).

R0057969

VI. Macroinvertebrates - Aquatic Insects

Macroinvertebrates are frequently defined as animals without backbones that are large enough to be retained on a U.S. Standard No. 30 sieve, 0.595 mm openings (Weber, 1973). In addition to serving as a major food source for fish, macroinvertebrates are an integral part of the normal energy/organic material processing system of streams. It is also noted that a relatively small group of macroinvertebrates have attained notoriety as important vectors of disease (e.g., mosquitoes, flies, and biting midges). Aquatic insects, which in most environments comprise the largest portion of this heterogeneous group shall be featured in this section.

Temperature - Physiological Relationships

As a group, aquatic insects demonstrate little ability to acclimate or compensate for temperature changes. Thus, when exposed to a new thermal regime, metabolic response is immediate and in the direction of the temperature change (Trapp & Hendricks, 1983).

Even relatively small temperature regime changes may have serious implications. For example, Sweeney and Vannote (1978) observed that changes of only 1-2°C, either warmer or cooler, from the normal temperature regime can reduce adult aquatic insect size and fecundity (the ability to produce viable off-spring), they both suggested that temperature increases of 2-3°C could eliminate sensitive species. Fecundity in aquatic insects is dependant

VOL 12 2 46771

R0057970

upon the adult size, which is largely determined by thermal conditions during the larval period (Sweeney, in Resh and Rosenberg, 1984). Available data suggest that adult body size is inversely related to ambient stream temperatures (Vannote and Sweeney , 1980).

While many aquatic insects can successfully complete their life cycles over a broad range of temperature conditions, many have very narrow and/or specific temperature requirements. An example of the latter case is the mayfly, Ephoron album, whose life cycle is graphically depicted in Figure 5. As seen in Figure 5, three essential stages in the life cycle of this mayfly (i.e., egg development and hatching and maturation of nymphs) are temperature-dependant. Ephoron eggs will not develop unless they have been exposed to freezing temperatures, nor will nymphs hatch from eggs until the temperature rises to about 10°C, and last, nymphs do not mature unless the temperature reaches 18-20°C and remains there for several months (Lehmkul, in Gibbons & Sharitz, 1974). Thus, temperature regime modifications which either disrupt or eliminate essential temperature cues and/or conditions would, in all likelihood, eliminate this species.

In addition to influencing egg incubation period, hatching success, duration of hatching, induction and termination of diapause, emergence, and length of the larval growth period, temperature affects the ingestion and assimilation of food (Nebeker, 1971; Sweeney, in Resh and Rosenberg, 1984; Elliot, 1978). Several aquatic insects exhibit more or less constant ingestion rates at low to intermediate temperatures and then either increase or decrease these rates at higher temperatures (Sweeney, in Resh and Rosenberg, 1984).

VOL 12 2 4678

R0057971

Figure 5

Legend

①-②-③-④ = Essential stage & temperature requirement in life cycle

—— = Required temperature, flexible duration

VOL 12 2 4679

R0057972

Although ingestion rates are usually greater at higher temperatures, assimilation rates are often lower (Heiman and Knight, 1975); hence growth rates may be impaired. Sweeney (1978) observed that metabolism in the mayfly nymph, Isonychia bicolor, doubled when temperature increased from 12.2°C to 20.5°C, and that increased respiration reduced net growth efficiency.

General Temperature Requirements

In general, water temperatures greater than 17°C have often been considered to be above the optimum for many stoneflies, mayflies, and caddisflies, and temperatures exceeding 21°C have been shown to stress severely most coldwater organisms (Gaufin and Nebeker, 1973; Ward and Stanford, 1979; Fraley, 1979). As seen in Figure 6, stoneflies are (as a group) the least temperature tolerant, and are generally restricted to cold-cool flowing waters. Conversely, dragonflies and damselflies are generally associated with warmer streams and/or lakes and ponds. Mayflies and caddisflies, as well as Diptera (flies & midges), display considerable adaptivity and have successfully invaded all three of the major aquatic habitats depicted in Figure 6.

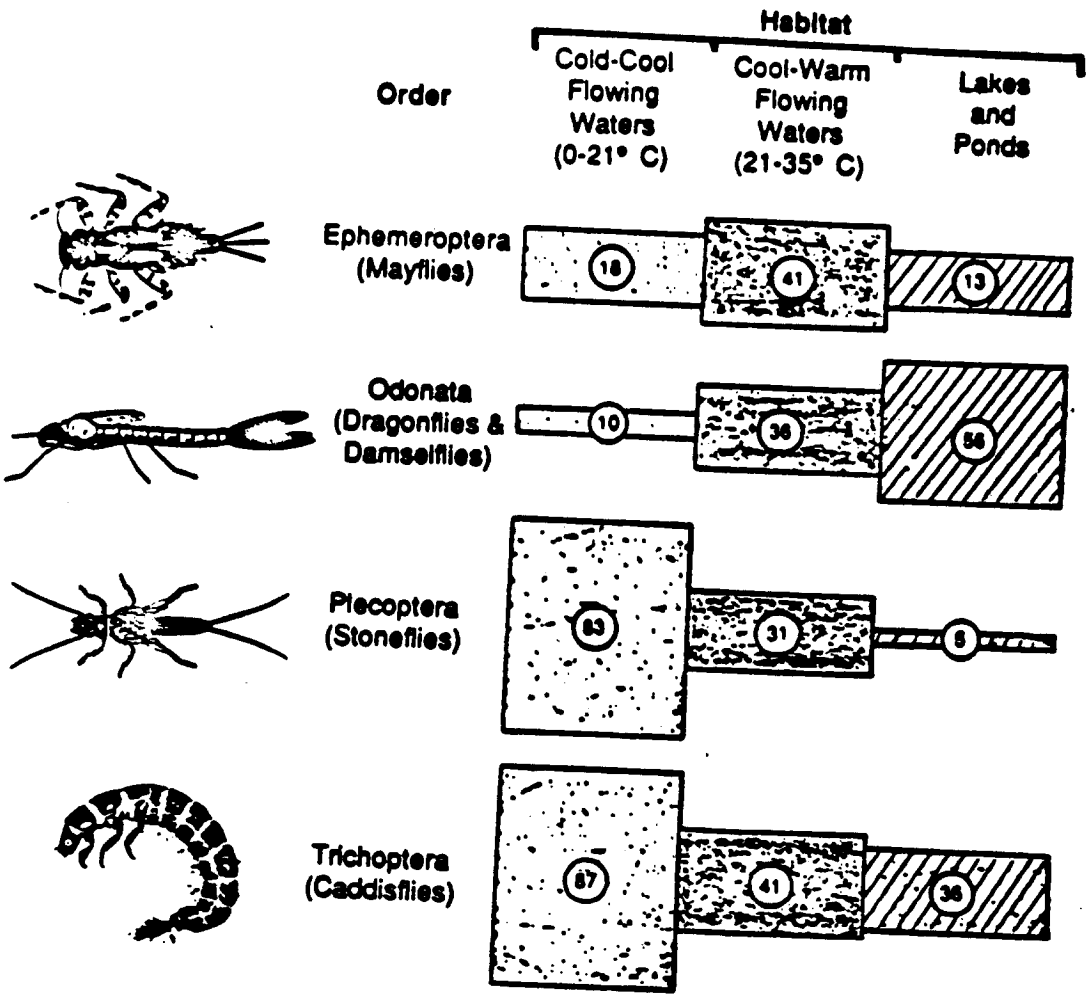
The known or expected upper limiting water temperatures for various groups of aquatic insect larvae are listed in Appendix III. In addition, a summary of some of the findings of the known temperature requirements and effects of temperature regime alteration are presented as follows:

- Gaufin and Nebeker (1973) recommended that in order to maintain a

VOL 12 2 4680
R0057973

Figure 6

General Habitat of Four Orders of North American Aquatic Insects [1/] (modified from Wiggins & Mackay, 1978)



1/ Number of genera per habitat is shown within each block.

VOL 12 2 4681
R0057974

well-rounded, diversified population of coldwater insects, maximum water temperatures should not exceed the requirements of coldwater fishes such as trout and salmon;

- As a result of temperature regime alteration, mayflies, stoneflies, and other temperature sensitive or thermally-cued invertebrates are often reduced or eliminated below impoundments (Petts, 1984; Ward and Stanford, 1979; Fraley, 1979; Kondratieff and Voshell, 1981). All too frequently, only those forms with broad tolerance levels exist. Macroinvertebrate groups without aerial adults, such as snails, oligochaetes, amphipods, isopods, and turbellarians, often increase in relative abundance in these streams (Ward and Stanford, 1979).

- Many aquatic insects, mayfly species in particular, require a fluctuating diurnal temperature regime. Constant diurnal temperatures may fail to provide the thermal range necessary to allow all body processes to operate optimally. Thermal heterogeneity may be especially important for species which undergo diapause during some portion of the life cycle;

- Seasonal thermal constancy, e.g., high winter and low summer temperatures, may directly influence aquatic insects in that it may eliminate or modify thermal stimuli essential for various life-cycle phenomena;

- The timing and duration of the emergence of aquatic insects is generally linked to water temperature, photoperiod, and/or both. An increase in

VOL 12 2 4682

R0057975

winter water temperatures may result in the premature emergence of adult aquatic insects. In all likelihood, these early emergers will also be physically smaller in size. Insects which emerge too early in the season may be killed or inactivated by low ambient air/ground temperatures.

- Respiration in some aquatic insect larvae is highly sensitive to short-term increases and decreases in temperature. Increased respiration rates, caused by higher temperatures; reduce net growth efficiency;

- The relationship between egg production and female dry weight is generally linear for most aquatic insects. Thus, any factor which reduces adult body size affects recruitment and the competitive ability of the subpopulation; and

- At both high and low stream temperature extremes, food storage used for egg formation may not be accumulated in sufficient quantities.

Thermal Shock Effects

Limited data suggests that aquatic insects are adversely affected by exposure to high shock temperatures which approach their upper lethal limit. It also appears that thermal shocks may possibly interfere with the normal molting process and hence, may negatively affect insect growth and long-term survivability. A brief summary of the thermal shock study findings, conducted on two representative caddisflies and one mayfly species, are listed below:

VOL 12 2 4683

R0057976

Experiments on the caddisfly, Brachycentrus americanus (Salmella and Anderson, 1978):

- No deaths occurred until water temperatures exceeded 32.9°C.
- Sharp decreases in survival occurred between 33-34°C, 100 percent mortality at 34.5°C;
- Feeding decreased with increasing temperature. Feeding during 16-day post-exposure period was affected at temperatures 3.6°C lower than those that directly affected survival (i.e., at approximately 29.3°C);
- Heat tolerance for Brachycentrus not affected by seasonal temperature change between 1-15°C.

Experiments on the mayfly, Isonychia sadleri and the caddisfly Hydropsyche (Sherberger et al., 1977):

- Isonychia - no significant mortality was observed below a shock temperature of 26.5°C. However, at shock temperatures of 26-29.0°C a significantly higher portion of shocked animals molted than the control specimens. Temperatures above 29°C reduced molting significantly. Successful molting is essential to aquatic insect growth and development;

VOL 12 2 4684

R0057977

- No significant effects of thermal shock on rheotaxis (response to water current) or phototaxis (response to light) observed in Isonychia (i.e., no observed behavioral changes);

- In the natural environment, mortality in Isonychia would be particularly noticeable at temperatures of 30-31°C;

- For Hydropsyche, no significant effects of thermal shock were observed at temperatures less than 28°C. Significant mortality occurred at temperatures between 36-38°C;

- High mortality in both insects would occur at temperatures $\geq$ 36°C.

VOL 12 2 4685

R0057978

VII. Fish

The ecological, recreational and commercial significance and value of fish is well known, and therefore requires no further mention. All fish are obligate poikilotherms (cold-blooded). With only one or two notable exceptions, fish lack a mechanism to maintain an internal body temperature independent of the temperature of surrounding waters. Fish are, therefore, essentially thermal conformers. Furthermore, when water temperature changes, the rate of thermal equilibration is generally rapid (Elliot, in Pickering, 1981).

General Temperature Requirements, Classification and Tolerance

Although fish may be found in waters with temperatures ranging from around zero to 44.0^{0}C, no species can survive over this entire range. Each species has a characteristic range with upper and lower lethal limits and preferred temperature optima, which changes according to the age (or life cycle stage) of the fish. Freshwater fish in temperate regions generally live within the 0-30°C temperature range. Maximum summer temperatures may exceed 30°C in shallow lakes, ponds and marshes, warmer southern streams, and/or in waters that receive a thermal discharge.

Based on their thermal requirements, fish are generally placed into one of three broad categories:

VOL 12 2 4686
R0057979

- Stenotherm - coldwater fish, which have a physiological optimum < 20°C and an upper lethal temperature of < 26°C. Representative examples include salmon and trout.

- Mesotherm - coolwater fish, which have a physiological optimum in the 20-28°C range and upper lethal temperature of 28-34°C. Representative examples includes pikes, perch, darters, and most species of minnows.

- Eurytherm - warmwater fish, which have a physiological optimum >28°C and an upper lethal temperature generally over 34°C. Representative examples include carp, goldfish, sunfish, and bass.

The contrasting thermal requirements of the stenothermal brown trout (Salmo trutta) and eurythermal carp (Cyprinus carpio) are illustrated in Figure 7. As seen in Figure 7, the tolerance zone, feeding zone and optimum growth zones for these two representative fish are markedly different. In general, there is an inverse relationship between tolerance and resistance to thermal stress. Coldwater fish, such as the brown trout, have fairly low tolerance but high resistance (i.e., can withstand temperatures outside the tolerance zone for longer periods); whereas, warmwater fish such as the carp, typically exhibit high tolerance but low resistance.

Research has additionally shown that acclimation temperature and the period of exposure to temperatures outside the tolerance zone are the two most important factors which affect thermal tolerance and ultimately the

VOL 12 2 4687

VOL 12 2 4688
R0057981

lethal temperature of fish. While there are several exceptions, as the age and size of a fish increases, there is typically a corresponding increase in the upper lethal temperature (Hoar & Randall, 1971). It is further noted that the egg is widely considered to be the critical stage for thermal stress (Hoar & Randall, 1971). Critical temperature limits for successful spawning and egg development are often far narrower than those for juvenile or adult fish.

Thermal Stress - Sublethal Effects

Brett (1956) divided stresses on fishes into four general categories and defined them as follows:

1. Lethal - (self-explanatory);
2. Inhibiting - a reduction in the ability of the fish to carry out its normal functions and hence a reduction in its probability for survival;
3. Loading - an undue burden on the fish with a rapid steady release of energy; and
4. Limiting - restriction of the supply of essential metabolites or interference with the chain of energy release.

Inhibiting, loading and limiting thermal stresses may all prove lethal when they continue over a long period of time.

One of the best known examples of temperature as an inhibiting-type stress is its effect on feeding activity. As illustrated by Figure 7., fish

VOL 12 2 4689

R0057982

typically feed over a relatively well-defined temperature range or zone. Temperatures outside of this normal feeding zone generally cause the cessation of feeding. Not surprisingly, if these inhibiting temperatures are maintained beyond the fish's resistance capacity, it will ultimately starve to death. While the resistance capacity or limit is a function of the size, body composition, and vigor of the fish, it is generally shorter under an elevated temperature scenario (due to higher metabolic rate). Other examples of temperature as an inhibiting stress include its potential disruption of the normal hormonal balance necessary for the initiation of spawning activities, reduction of reproductive success, and increased predisposition to disease and predation.

Temperature can also act as a loading stress on fish growth and activity. Using the brown trout in Figure 7. as an example, the growth for this species typically occurs between 4°-$19^{o}C$. The general lack of energy for growth outside this range is due to a combination of reduced energy intake, high energy losses in waste products, high metabolic demands at temperatures above $19^{o}C$ and possibly inhibition of metabolism below $4^{o}C$ (Elliot, in Pickering, 1981).

Thermal stress can also occur within the normal growth zone of fish when there are other limiting or stress-producing factors present (e.g., reduced oxygen concentration, enzyme substrates, and nutrients or essential ions). When the food supply is reduced, both the optimum temperature and temperature range for growth are reduced (Hoar & Randall, 1971). These physiological changes are due to the combined stress effects of both reduced energy intake (food) and the loading stress of temperature. As the energy intake is

VOL 12 2 4690
R0057983

reduced there is a significant decrease in the upper limits of the growth zone. Thus, thermal stress is not only lethal outside of the tolerance zone, but can also act subtly within the tolerance zone as an inhibiting stress, loading stress, or a loading stress in combination with other stresses (Hoar & Randall, 1971).

Temperature Detection, Avoidance and Thermal Shock

It is well known that fish possess considerable sensory powers to detect changing environmental conditions and have the response capability to select a new location. Studies have shown that fish can detect temperature changes of less than 0.5°C and are able to select a particular temperature or range of temperatures, that is, to their liking (Murray, 1971; Hoar & Randall, 1971). Moderately rapid changes of temperature normally do not elicit swimming responses in resting fish until relatively high temperatures are reached, but they do, however, affect the frequency of movement of active fish. Therefore, it is possible for fish to be caught "napping" by thermal shocks (i.e., large, rapid and potentially lethal temperature changes). In those cases where the normal escape swimming response is muted or overwhelmed, or where no escape refugium exists, the thermal shock may prove deadly.

Owing to their smaller body mass and proportionately higher surface area, juveniles are far more susceptible than adult fish to thermal shock. Thermal shock experiments conducted on trout have demonstrated that the internal body temperature of smaller fish (< 100g) changes rapidly, usually in less than 10 minutes; whereas larger adult fish may require over one hour (Elliot, in

VOL 12 2 4691

R0057984

Pickering, 1981).

It is also noted that the rate for heat exchange is usually higher for warming than for cooling, at least in larger fish (Hoar & Randall, 1971). Most of the heat transfer in fish occurs by conduction directly through the body wall. Heat transfer through the gills accounts for only some 10-30 percent of the total heat exchange between fish and the surrounding water (Elliot, in Pickering, 1981).

Thermal Characteristics of Maryland Freshwater Fish Communities

Water temperature together with the volume of flow, water quality and physical or structural habitat are the major factors which determine the fish community characteristics of streams. While it is beyond the scope of this study to examine all of these variables, an attempt was made to identify the general temperature requirements for Maryland freshwater fish. Thermal requirement data for 63 species of fish known or expected to occur in Maryland freshwater streams is presented in Appendix IV. In addition, this information has been graphically summarized in Figure 8, so as to facilitate the comparison of temperature requirements between representative fish families.

With only one or two notable exceptions, natural coldwater stream fish communities in Maryland are generally restricted to higher altitude and/or spring-fed streams of the Appalachian and Piedmont provinces. The fish assemblage in these streams is often highly variable, but typically includes one or more species of trout (brook, brown and/or rainbow), as well as,

sculpins, and several minnow species. Coldwater fish generally spawn when water temperatures are less than 10°C. Maximum summer water temperatures in coldwater streams are normally less than 21°C (Winger, in Krumholz, 1981).

Coolwater streams are somewhat ambiguous in terms of general definition, fish assemblage and temperature characteristics or limits. However, for the purposes of this study, coolwater streams will be defined as those which are generally too warm to support trout on a year-round basis, yet too cool to support a diverse warmwater fish community. The fish community of coolwater streams is typically dominated by minnows and includes representative species of darters, and suckers. Larger coolwater streams often include smallmouth bass, as well as, some warmwater fish species. In general, coolwater fish spawn when water temperatures are over 10°C. Maximum summer water temperatures in coolwater streams are generally less than 27°C.

Warmwater fish communities are most commonly associated with larger, low-gradient streams which have a relatively open canopy. Vis-a-vis coldwater streams, warmwater streams generally exhibit higher species diversity and support larger, overall numbers of fish (Sheldon, 1960). The typical warmwater stream fish assemblage includes representative bass, sunfish and catfish species, as well as, minnows. Most warmwater fish spawn when water temperatures are over 15°C. Maximum summer water temperatures in most North American warmwater streams seldom exceed 33-35°C (Winger, in Krumholz, 1981).

VOL 12 2 4695

R0057988

Thermal Enrichment

Bush et al., 1974, estimated the percentage of fish species which would be lost from six different North American coldwater and warmwater river systems under an elevated water temperature regime scenario. The estimates, which are graphically summarized in Figure 9, assumed that a fish species (adult and juvenile fish only) would be lost from a stream area either through death or emigration. Although these estimates should be viewed with a certain degree of caution, they do provide valuable insight into the potential fishery impacts stemming from thermal warming, or enrichment.

As seen in Figure 9, the percentage of fish species which would be expected to be lost from coldwater river systems is typically five percent or less at temperatures below 20°C. However, losses increase dramatically at temperatures greater than 22°C. Conversely, the estimated percentage of fish species lost from warmwater river systems is less than five percent at temperatures below 30°C. At temperatures above 30°C, a catastrophic loss of fish species is predicted to occur in these systems.

VIII. Trout and Thermal Stress

Detailed information on the temperature requirements for brook, brown and rainbow trout is presented in Appendix IV. Without question, these three species are the most important coldwater fish inhabiting Maryland streams. Of the three, only the brook trout is truly native to eastern North America. The brown and rainbow trout were each respectively introduced from Europe and western North America.

While the temperature requirements for these three species are quite similar, the brown trout is generally regarded as being the more temperature tolerant and the brook trout the least. It is important to note that even within a given species the difference in thermal tolerance is often surprisingly large. Much of this is due to inherent genetic or racial differences within the species and adaptation to different thermal regimes.

All trout species are extremely sensitive to thermal pollution/stress. Sustained elevated water temperatures over 20°C are generally considered to be stressful, while those at or above 25°C are usually lethal. As previously noted, a fish's ability to withstand or resist the effects of thermal stress is heavily influenced by the acclimation temperature. Trout can, depending on the acclimation temperature, survive for varying periods of time at temperatures which are ultimately lethal. As seen in Figure 10, trout acclimated at 15, 20, or 22°C survived slightly over 7 days at 25°C, 100 minutes at 28°C, and only 10 minutes at 30°C.

VOL 12 2 4698

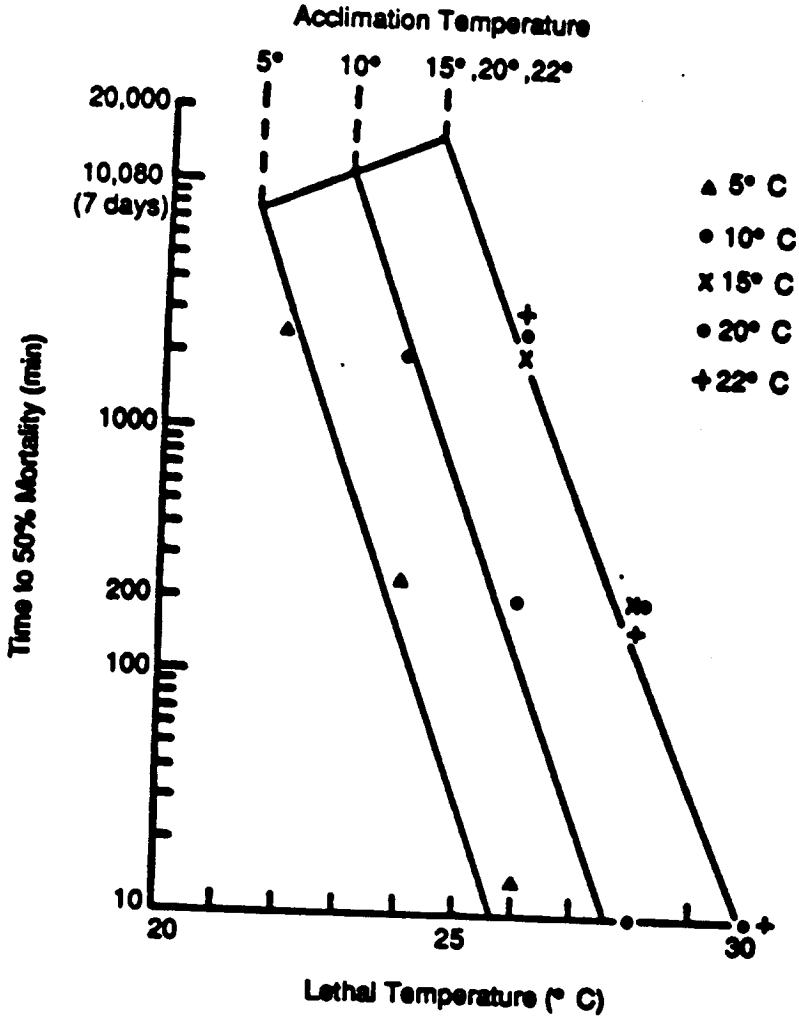
Figure 10

Relation Between Time, Acclimation Temperature and 50% Mortality of Brown Trout, Salmo trutta (from Elliot, 1981)



VOL 12 2 4699
R0057992

Many of the sublethal effects of thermal stress have already been discussed. When thermally stressed, the blood cortisol (i.e., a hormone) levels in trout become elevated. Chronic cortisol elevation suppresses many of the endocrine processes controlling sexual maturation, resulting in reduced gonad size in both sexes (Pickering, 1989). In addition, high blood cortisol levels act as an immunosuppressant; thereby, predisposing trout to infection by common fungal and bacterial pathogens. This can lead to increased mortality from diseases such as saprolegnia infection, furunculosis, and bacterial fin-rot (Pickering, 1989).

Abbreviations/Definitions:

O - Oligothermal: coldwater forms, generally occurring between 0-15°C;

M - Mesothermal: temperate-water forms, usually occurring between 15-30°C;

E - Euthermal: warmwater forms, generally occurring at temperatures > 30°C;

s - stenothermal: occurring over a temp. range of < 5°C;

m - metathermal: occurring over a temp. range of 5-15°C;

e - eurythermal: occurring over a temp. range of > 15°C;

S - Spring

Su - Summer

F - Fall

W - Winter

*Considered by some researchers to be a Green alga.

SUMMARY: WATER TEMPERATURE REQUIREMENTS - FISH

Family: Species	General Temp. Class.	Age or Size (mm or g)	Physio. Opt. (deg. C)	Preferred Temp. (deg. C)	CTMax (deg. C)	Ult (deg. C)	Lethal Temp (deg. C)	Reference
(rosyface shiner cont'd)		Adult (spawning)		<20.0*				Miller, 1964
		Adult (spawning)		20.0-20.2*	(25.0 A)			Mead, 1957
Notropis spilopterus (spotfin shiner)	Eurytherm	YOY	27.3	29.0				Kelling & Clift, 1983
		N/A		16.3-29.7 (6.0-30.0 A)				Cherry, et. al., 1975
		N/A		21.4-29.2 (12.0-36.0 A)			36.0	Cherry, et. al., 1977
		N/A		29.0(FP)			(7-D UL)	Stauffer, et. al., 1976
Pimephales notatus (bluntnose minnow)	Mesotherm	Adult (spawning)		>20.0				Scott & Crossman, 1973
		N/A			31.9 (15.0 A)			Kowalski, et. al., 1978
		N/A		15.7-28.9 (6.0-27.0 A)				Cherry, et. al., 1975
		N/A		19.3-29.0 (12.0-30.0 A)			32.0 (7-D UL)	Cherry, et. al., 1977
		N/A		23.0-29.0*				Stauffer, et. al., 1974
Pimephales promelas (fathead minnow)	Eurytherm	Eggs	26.1					Brungs, 1971
		Fry					34.0(ULt)	Brungs, 1971
		YOY		19.8-28.9 (12.0-27.0 A)			34.0	Cherry, et. al., 1975
		YOY		19.5-28.7 (12.0-30.0) (26.0-26.6FP)				Cherry, et. al., 1977
		Juvenile			32.4-34.0 (15.0 A)			Spieler & Roeske, 1977
		Adult (1.0g avg.)					35.1	Watenpaugh & Beitenger, 1985
		Adult (55mm avg.)		23.4(FP)				Jones & Irwin, 1962

DEFINITION OF TERMS AND ABBREVIATIONS

Temperature classification (after Hokanson, 1977):

Stenotherm - Ultimate lethal temperature <26 (deg. C)
Physiological optimum <20 (deg. C)
Mesotherm - Ultimate lethal temperature 28-34 (deg. C)
Physiological optimum 20-28 (deg. C)
Eurytherm - Ultimate lethal temperature >34 (deg. C)
Physiological optimum >28 (deg. C)

Age or Size:

mm - Length in millimeters.
g - Weight in grams
ML - Mean length
Avg - average length
Egg - Embryo inside egg envelope
Fry - Exogenous feeding, jerky swimming, and/or risen out of nesting site
Larvae - Can include fry stage, swimming is complete, and/or beginning of schooling
YOY - Young-of-year
Juvenile - older than young-of-year, but not sexually mature
Adult - Sexually mature
N/A - No age or size data reported

Temperature:

Physio. opt. - Physiological optimum for growth (unless otherwise indicated in the table).
Preferred temp. - Temperature preferred by laboratory specimens, for a given acclimation temperature; or temperature at which specimens were observed in the field.
CTMax - Critical thermal maxima: upper zone of thermal resistance; where a fish loses normal locomotary function and/or control
UILT - Upper incipient lethal temperature: temperature that is lethal to 50% of tested specimens.
Lethal Temperature- Temperature that is lethal to 100% of tested specimens.
FP - Final preferendum: temperature around which fish congregate in an infinite temperature gradient.
* - Data from field study.
A - Acclimation temperature (see Brett,1956).
7-D UL - Seven day upper lethal limit.
ULT - Upper lethal temperature: lethal temperature beyond which no acclimation is possible.

VOL 12 2 4744
R0058037

Appendix V.

Table 1. The fishes of Maryland and Delaware and their general distributions. An = anadromous, E = endemic, N = native, Nl = regarded as native but possibly introduced, I = introduced, IP = probably introduced, Ma = euryhaline or diadromous, ? = presence suspected in Delaware, * = recorded from Delaware (appears before species name). Lower case letters = rare or restricted distributions. Letters A-C correspond to various physiographic areas (see Figure 1) [i.e., A -Coastal Plain section of Delmarva peninsula; B - Coastal Plain of southern Maryland; C - eastern division of Piedmont (Chesapeake and Delaware bay drainage); D - western division of Piedmont (Potomac drainage); E -Blue Ridge, Ridge and Valley, Great Valley; F - Atlantic Slope drainage of Appalachian Plateau; G - Ohio basin drainage of Appalachian Plateau]. Explanations of superscript numbers appear at end of table.

CURTIS WILLIAMS & ASSOCIATES
PLANNING AND ENVIRONMENTAL CONSULTANTS

VOL 12 2 4781

CITY OF AUSTIN, TEXAS
COMPREHENSIVE WATERSHEDS ORDINANCE

Included herein is the City of Austin's Comprehensive Watersheds Ordinance, adopted May 8, 1986, which provides development standards designed to protect water quality and other environmental features throughout the City of Austin and its Extra-Territorial Jurisdiction.

The Comprehensive Watersheds Ordinance comprises the initial section of the City's environmental code, and is applicable to subdivisions and site developments. It combines five previously existing ordinances totalling 250 pages of subdivision and site development regulations into 50 pages and standardizes procedures and criteria, while approximately doubling the land area which is subject to watershed requirements as compared to the previous ordinances.

Also included are several pieces of supporting information, including a newspaper clipping, a companion set of recommendations for further water quality protection measures other than the ordinance, a summary of four "primary water quality control strategies" considered for use in the ordinance, a summary of the ordinance, and some graphics and sample calculations created to help explain concepts in the ordinance.

Mr. Curtis S. Williams, then in his capacity as Environmental Officer for the City's Office of Land Development Services, was the primary staff member responsible for drafting the ordinance and ushering it through the public review and approval process.

Comprehensive Watersheds Ordinance

CITY OF AUSTIN, TEXAS

ORDINANCE NO. 860508-V

AN ORDINANCE AMENDING THE AUSTIN CITY CODE OF 1981; ESTABLISHING A COMPREHENSIVE WATERSHEDS ORDINANCE FOR AUSTIN'S WATERSHEDS; PROVIDING STANDARDS FOR DEVELOPMENT WITHIN SUCH WATERSHEDS; REQUIRING COMPLIANCE FOR SUBDIVISIONS AND SITE DEVELOPMENTS; SUPERSEDING OTHER ORDINANCES; PROVIDING FOR SEVERABILITY; AND PROVIDING AN EFFECTIVE DATE.

BE IT ORDAINED BY THE CITY COUNCIL OF THE CITY OF AUSTIN:

PART 1. That the Austin City Code of 1981, hereby is amended to establish a new Chapter 13-15 (Environmental Code), Article II, (Comprehensive Watersheds Ordinance) as hereinafter stated:

DIVISION I. GENERAL PROVISIONS

SEC. 13-15-201. FINDINGS AND OBJECTIVES

The City Council hereby makes the following findings:

(a) Many of the watersheds within the City's jurisdiction contribute significantly to Austin's drinking water supply.

(b) Waterways and their associated watersheds within the City of Austin's jurisdiction represent significant and irreplaceable recreational and aesthetic resources and contribute directly to the City's public health.

(c) The continued economic growth of the City is dependent on an adequate quality and quantity of water, a pleasing natural environment, and recreational opportunities in close proximity to the City.

(d) All watersheds within the City's jurisdiction, and especially those with abrupt topography, sparse vegetation, and thin and easily disturbed soil, are vulnerable to non-point source pollution and sedimentation resulting from development activities.

(e) All watersheds within the City's jurisdiction are undergoing development or are facing development pressure.

(f) If watersheds within the City's jurisdiction are not developed in a sensitive and innovative manner, their water resources, natural environment, and recreational characteristics will be irreparably damaged.

(g) Protection of Critical Environmental Features such as caves, sinkholes, springs, canyon rimrocks, and bluffs, is necessary to protect water quality in those areas most susceptible to pollution.

(h) The City Council is the trustee of such water supply and the natural environment of all watersheds within the City's jurisdiction for existing and future generations of citizens of the City, as well as for downstream users of the Colorado River.

(i) The City Council is desirous of adopting appropriate development rules and regulations for the purpose of protection of the watersheds within its jurisdiction as a facet of its overall program for the control and abatement of pollution resulting from generalized discharges of pollution which are not traceable to a specific source such as storm sewer and wastewater discharges and urban runoff from rainwater.

VOL 12 2 4785

R0058078

(j) The City Council further finds that minimum standards should be adopted as an application of general principles for conservation and development to encourage innovative planning and design of urban developments to protect the water quality and recreational resources of Lake Austin, Lake Travis, Barton Creek, the Edwards Aquifer, and other watersheds within the City's jurisdiction, the purposes of which standards include:

1. To prevent or compensate for increases in soil erosion and sedimentation during and after development activities;

2. To prevent or compensate for increases in erosive velocities of runoff;

3. To prevent indiscriminate stripping of vegetation and unnecessary loss of soils;

4. To prevent or reduce increases in the pollutant concentrations and total pollutant loading of runoff drainage;

5. To prevent construction activity that may precipitate mass movement, slumping, or erosion of land surfaces;

6. To prevent unacceptable wastewater discharges from reaching Austin's creeks and lakes;

7. To prevent loss of recharge to localized aquifers supplying local seeps and springs essential to the maintenance of the ecosystem and the base flow and water quality of many of Austin's creeks; and,

8. To prevent loss of recharge to the Edwards Aquifer and to protect the quality of the recharge to the Edwards Aquifer.

SEC. 13-15-202. APPLICATION OF ARTICLE AND COORDINATION WITH OTHER ORDINANCES.

(a) This Article sets out special requirements for the development of land located in all watersheds within or partially within the City's jurisdiction. A person wishing to develop land in these watersheds must comply with the requirements and provisions of this Chapter. When the land being developed lies partially within and partially beyond the watershed boundary within the City's jurisdiction, this Article shall apply only to that portion of the land within the watershed subject to the City's jurisdiction.

(b) The requirements of this Article shall apply to all development of land proposed or undertaken by the City of Austin.

VOL 12 2 4786

R0058079

(c) In case of conflict between the requirements of this Article and any other ordinance, the more restrictive requirements shall govern.

(d) The Director of the Office of Land Development Services shall design and administer a system, including necessary forms, that coordinates the requirements of both this Article and the other provisions of this Chapter, minimizes duplication of requirements and conflict between same and facilitates the expeditious processing of plans and permits.

(e) The Director of the Office of Land Development Services shall determine the boundaries of designated watersheds and the Edwards Aquifer Recharge and Contributing Zones from existing maps prepared by the City of Austin and other public entities, plus additional topographic and hydrologic data as necessary to determine those boundaries. All questions concerning the exact boundary of the Edwards Aquifer Recharge Zone shall be recommended by the Chief Environmental Officer, and determined by the City Council. For all property within fifteen hundred feet (1500') of the designated boundary, the applicant shall provide a certified report by a qualified geologist or hydrologist as to whether recharge is affected by drainage on or from the property, based on field verification. For purposes of illustration, the watersheds and aquifer zone boundaries are identified on a map attached as Exhibit "A". Copies of the map are available for inspection at the offices of the City Clerk, Office of Land Development Services, Public Works Department, Planning and Growth Management Department and City/County Health Department.

SEC. 13-15-203. DEFINITIONS.

The following words, terms and phrases, when used in this Article, shall have the meanings ascribed to them in this Section, except where the context clearly indicates a different meaning:

Alternative Sewage Disposal Systems: Private sewage facilities other than a standard septic tank and/or soil absorption-type drainfield. Such systems include, but are not limited to, aerobic systems, lined evapotranspiration systems, low pressure-dosing trench fields, systems utilising greywater disposal and composting toilet systems.

Applicant: A person applying for plan approval under this Article.

Bluff: An abrupt vertical change in topography of more than forty (40) feet with an average slope steeper than four (4) feet of rise for one (1) foot of horizontal travel.

Canyon Rimrock: A horizontal outcrop and vertical face of a hard limestone layer paralleling the side of a canyon or surrounding a canyon head. Rimrock is further delimited by the presence of a steep rock substrate (greater than 60% slope) which has a vertical extent of at least

VOL 12 2 4787

R0058080

four (4) feet, and which has a recognizable horizontal continuity of at least fifty (50) feet. Around the edge of the Jollyville Plateau such features are normally encountered at the contact of the Edwards limestone and underlying strata. Elsewhere, rimrocks may occur locally in Glen Rose formations.

Catchment Area: The area, defined by topographic relief, which drains to a point recharge, or critical environmental feature.

Cave: A natural underground cavity, recess, chamber, or series of chambers generally produced by the solution of limestone by subterranean water.

Chief Environmental Officer: The Chief Environmental Officer of the City of Austin, as designated by the City Manager.

Centerline of a Waterway: The centerline of the waterway refers to existing topographically defined channels. If not readily discernible, the centerline shall be determined by (first) the low flow line, or (second) the center of the two year floodplain.

City of Austin Jurisdiction: All land located within the corporate limits of the City of Austin and including its extra-territorial jurisdiction.

Cluster Housing: Attached or detached residential housing that maximizes common open space by grouping housing units to minimize individual yards and which, for each detached unit, has a maximum lot area of fifteen thousand (15,000) square feet.

Commercial Development: All development other than recreational, open space, multi-family or other residential housing units.

Comprehensive Plan: The City of Austin's Comprehensive Plan, or an element thereof, adopted by ordinance by the City Council in accordance with the City Charter.

Contractor: Any person, other than owner, engaging in development on land located within the City of Austin's jurisdiction.

Crest of Bluff: A line on the ground parallel to and at the top of a bluff, beyond which the average slope is no steeper than one (1) foot of rise in two (2) feet of travel, for a horizontal distance of not less than forty (40) feet.

Critical Environmental Features: Features which have been determined to be of critical importance to the protection of one or more environmental resources. They include such features as bluffs, springs, canyon rimrocks, caves, sinkholes and wetlands.

VOL 12 2 4718 8

R0058081

Critical Water Quality Zone: Protection zones for waterway corridors as defined in Section 13-15-232 of this Article.

Development: Buildings, roads and other structures, construction, excavation, mining, dredging, grading, filling, clearing or removing vegetation, and the deposit of refuse, waste or fill. Lawn and yard care, including mowing of tall weeds and grass, gardening, tree care and maintenance, removal of trees or other vegetation damaged by natural forces, and ranching and farming shall not constitute development. Utility, drainage, and street repair, maintenance and installation which does not require land disturbance or result in additional impervious cover shall also not constitute development.

Drainfield: (Private sewage facility disposal area): Trench or bed utilized for final wastewater disposal.

Duplex (Two-Family Residential Housing Unit): One of the two (2) separate components of a detached building, each of which components is occupied or suitable for occupancy by only one family as a residence, and having kitchen, bath and sanitary facilities and appropriate appurtenances for such occupancy. Each of such separate components shall be deemed as one unit for the purposes of density calculation and the transfer of development rights.

Edwards Aquifer: The water-bearing substrata also known as the Edwards and Associated Limestones Aquifer. It includes the stratigraphic rock units known as the Edwards Formation and Georgetown Formation.

Edwards Aquifer Recharge Zone: The interim boundaries of the recharge zone shall encompass all land over the Edwards Aquifer recharging the same, as determined by the surface exposure of the geologic units comprising the Edwards Aquifer, including such areas overlain with quaternary terrace deposits. Permanent boundaries may be determined at a later date as part of a more comprehensive delineation of the entire recharge zone.

Edwards Aquifer Contributing Zone: All land generally to the west and upstream of the Edwards Aquifer Recharge Zone that provides drainage into the Edwards Aquifer Recharge Zone.

Faults and Fractures: Significant fissures or cracks in rock which may permit infiltration of surface water to underground cavities and channels.

Impervious Cover: Roads, parking areas, buildings, swimming pools, rooftop landscapes and other impermeable construction covering the natural land surface; this shall include, but not be limited to, all streets and pavement within the development. To calculate impervious cover see Section 13-15-243.

VOL 12 2 4789

R0058082

Individual On-Site Wastewater System (Private Sewage Facility): All systems and methods used for the disposal of sewage, other than organized sewage disposal systems. Private sewage facilities are usually composed of three units: the generating unit (the residence, institution, etc.), treatment unit (septic tank, etc.) and the disposal unit (the drainfield that may be an absorption trench or bed, or an evapotranspiration bed).

Intermediate Waterway: A channel, creek, stream, branch, or watercourse as defined in Sections 13-15-262, 13-15-272, and 13-15-282.

Legal Lot: A tract of land that existed in its present configuration prior to the effective date of the City of Austin Subdivision Ordinance.

Legally Platted Lot: A lot which is part of a subdivision approved by the City of Austin Planning Commission.

Major Waterway: A channel, creek, stream, branch or watercourse as defined in Sections 13-15-262, 13-15-272, and 13-15-282.

Minor Waterway: A channel, creek, stream, branch or watercourse as defined in Sections 13-15-262, 13-15-272, and 13-15-282.

Multi-Family Development: Any development having three (3) or more attached residential units in a single building.

Natural Drainage: A stormwater runoff conveyance system not altered by development.

Natural State: Substantially the same conditions of the land which existed prior to its development, including but not limited to the same type, quality, quantity and distribution of soils, ground cover, vegetation and topographic features.

Net Site Area: That area in the Uplands Zone, excluding land designated for wastewater irrigation, and then calculated to include all acreage on 0-15% slopes; added to forty (40) percent of the acreage on 15-25% slopes; added to twenty (20) percent of the acreage on 25-35% slopes.

One-Family Residential Housing Unit: A detached building occupied or suitable for occupancy by only one family as a residence, and having kitchen, bath and sanitary facilities and appropriate appurtenances for such occupancy.

Overland Drainage: Stormwater runoff which is not confined by any natural or man-made channel such as a creek, drainage ditch, storm sewer, or the like.

VOL 12 2 4790

R0058083

Owner: Any person, having a freehold interest in land within the City of Austin's jurisdiction, a leasehold interest therein, or a lesser tenancy thereon.

Permit: The application for a particular development subject to the provisions of this Article, approved development plan, special notes and other attachments thereto.

Person: Any individual, association, non-profit corporation, professional association, joint stock company, corporation, proprietorship, partnership, or joint venture.

Point Recharge Feature: Any cave, sinkhole, fault, joint or other specific natural feature situated over the Edwards Aquifer Recharge Zone which may be demonstrated to transmit or has the potential to transmit a significant amount of surface water into the subsurface strata. Guidelines to identifying and evaluating such features are maintained by the Chief Environmental Officer.

Plan: Any development proposal submitted to the City of Austin for approval under this Article, which includes but is not limited to subdivision plans, final plats or site development permits and the drawings, documents and other appurtenances as required by Division 3 for the subdivision or development of land located within the City of Austin's jurisdiction.

Recharge Basin: A man-made structure specifically designed to maintain or enhance the transmission of surface water into the subsurface strata.

Retail: Any commercial land use within the City of Austin defined by Chapter 13-2A of the City Code as general retail (GR) or local retail (LR).

Sedimentation and Filtration Basins: Basins required by this Article to provide water quality benefits through the sedimentation or filtration of runoff.

Sinkhole: A circular or oblong depression formed in soluble rock by the action of subterranean water which is a potential point of significant recharge.

Site Development Permit: Permit required from the Office of Land Development Services for development of other than single-family or duplex residential uses on a lot or tract of land, in accordance with the provisions of Chapter 9-10 of the City Code.

South Edwards Aquifer Recharge Zone: That portion of the Recharge Zone located south of the Colorado River, and north of the Blanco River.

VOL 12 2 4791

R0058084

Spoil: Excess material such as rocks, dirt, vegetation, debris, etc. generated as a result of development.

Spring: A point or zone of natural groundwater discharge having measurable flow and/or a pool, however small, and characterized by the presence of a mesic plant community adapted to the moist conditions of the site, typically including one or more of the following species:

maidenhair fern	(Adiantum capillis-veneris)
wild columbine	(Aquilegia canadensis)
southern shield fern	(Thelypteris kunthii)
Missouri violet	(Viola missouriensis)
wooly dicanthelium	(Dicanthelium lanuginosum)
spicebush	(Lindera benzoin)
nimblewill grass	(Muhlenbergia schreberi)
trillium	(Trillium spp.)
water-pimpernel	(Samolus parviflorus)
eastern sycamore	(Platanus racemosa)
green dragon	(Arisaema dracontium)
bushy bluestem	(Andropogon glomeratus)
water bentgrass	(Agrostis semiverticillata)
dwarf palmetto	(Sabal minor)

Subdivision: The division of land into one or more lots, as approved by the Planning Commission in accordance with the provisions of Chapter 13-3 of the City Code.

Suburban Watersheds: All watersheds within the City of Austin's jurisdiction which are not otherwise designated herein as "Urban", "Water Supply Suburban", or "Water Supply Rural". Such watersheds are shown on Exhibit "A", which is incorporated by reference herein and include, but are not limited to, South Boggy, Carson, Cedar, Cottonmouth, Country Club, Decker, Dry (South and East), Elm, Gilleland, Harris Branch, Maha, Marble, North Fork, Rinard, Walnut, and Wilbarger Creeks, the Colorado River (downstream of U.S. 183), and those portions of the Onion, Bear, Little Bear, Slaughter, and Williamson Creek watersheds which are not located in the Edwards Aquifer Recharge or Contributing Zones.

Two Family Residential Housing Unit: Duplex.

Uplands Zone: All land and waters that are not included within the critical water quality zone or water quality buffer zone.

Urban Watersheds: All watersheds as depicted on Exhibit "A", which is incorporated by reference herein including all land within the City's jurisdiction and draining to: Blunn, Buttermilk, East Boggy, East Bouldin, West Bouldin, Fort, Harper Branch, Little Walnut, Johnson, Shoal, Tannehill, and Waller Creeks, Town Lake/Colorado River (north side from Johnson Creek to U.S. 183), and Town Lake/Colorado River (south side from Barton Creek to U.S. 183).

VOL 12 2 4792

R0058085

Water Quality Buffer Zone: A buffer zone established parallel to all critical water quality zones and defined in Sections 13-15-264, 13-15-274, and 13-15-284.

Water Supply Rural Watersheds: All watersheds as depicted on Exhibit "A", which is incorporated by reference herein including all land within the City of Austin's jurisdiction and draining to: Lake Austin (excluding areas on the east side of the Lake south of and including Bull Creek), Lake Travis, Little Barton Creek, Barton Creek (excluding the area east of Barton Creek and north of Loop 360), and the portions of the Onion, Bear, Little Bear, and Slaughter (upstream of FM 1826) Creek watersheds which are located in the Edwards Aquifer Recharge or Contributing Zones.

Water Supply Suburban Watersheds: All watersheds as depicted on Exhibit "A", which is incorporated by reference herein including all land within the City's jurisdiction and draining to: Barton Creek (east of Barton Creek and North of Loop 360), Bull, West Bull, Dry (North and West), Taylor Slough, Lake and Rattan Creeks, Town Lake (south side from Barton Creek to Tom Miller Dam), Town Lake (north side from Johnson Creek to Tom Miller Dam), other Lake Austin (east side from Tom Miller Dam to Bull Creek), and those portions of the Williamson, Slaughter (downstream of FM 1826) and Brushy Creek watersheds which are located in the Edwards Aquifer Recharge or Contributing Zones.

Wetlands: Lands transitional between terrestrial and aquatic systems where the water table is usually at or near the surface or the land is covered by shallow water. Classification of areas as wetlands shall follow the "Classification of Wetlands and Deepwater Habitats of the United States" as published by the U.S. Fish and Wildlife Service (FWS/OBS-79/31).

SEC. 13-15-204. BURDEN OF PROOF

An applicant submitting plans for approval under this Article must establish that his or her plans comply with the requirements of this Article and with the applicable requirements of the rest of this Chapter. Compliance must be certified by a professional engineer registered in the State of Texas and knowledgeable in the field of Civil Engineering.

SEC. 13-15-205. VARIANCES

(a) Variances by Planning Commission

1. The Planning Commission may grant a variance from one or more requirements of this Article if an applicant requests the variance in writing and the Commission finds that, because of special circumstances applicable to the property involved, a strict application of the provisions prevents the owner of the property from enjoying the privileges or safety associated with other

VOL 12 2 4793

R0058086

similarly situated property with similarly timed development. Where such conditions are found, the variance permitted shall be the minimum departure from the terms of this Article and other ordinance requirements necessary to avoid such deprivation of privileges enjoyed by other property owners and to facilitate a reasonable use, which will not create significant probabilities of harmful environmental consequences. The Planning Commission may not grant a variance if it provides the applicant with any special privileges not enjoyed by other similarly situated property with similarly timed development, or if based on a special or unique condition which was created as a result of the method by which a person voluntarily subdivides or develops land.

2. The Planning Commission may grant a variance from one or more requirements of this Article, including but not limited to, Sections 13-15-232, 13-15-264, 13-15-274, and 13-15-284, if an applicant requests the variance in writing and the Commission finds that the application of such provisions leaves the property owner without any reasonable, economic use of the entire property. Where such conditions are found, the variance permitted shall be the minimum departure from the terms of this Article and other ordinance requirements necessary to establish a reasonable, economic use of the entire property.

3. The applicant has the burden of proving his or her entitlement to the variance.

4. Before acting on a variance request under the Subsection, the Planning Commission shall consider the review and recommendations of the Environmental Board.

5. The Planning Commission shall prepare written findings of fact justifying its grant or denial of the variance request.

(b) Administrative Variances

1. The Director of the Office of Land Development Services may grant a variance from the provisions of Sections 13-15-232(d), 13-15-234(d), 13-15-236(a), 13-15-248(b), and 13-15-274(d) when such variance is determined to be consistent with the standards and intent of the pertinent Section.

2. The applicant has the burden of proving his or her entitlement to the variance.

3. The Director shall make written findings justifying the grant or denial of each variance.

VOL 12 2 4794

R0058087

(c) The Director of the Office of Land Development Services shall prepare and maintain in the Office of Land Development Services for public inspection:

1. A written summary of variances granted and denied under Subsections (a) and (b); and,

2. The contents of the files, including the appeal record if there was an appeal, for each variance acted on by the Planning Commission.

SEC. 13-15-206. APPEALS

(a) Appeal of Planning Commission Variances. Any citizen of the City of Austin or any person owning property in a watershed within which a project is located may appeal the granting or denial of a variance by the Planning Commission pursuant to Section 13-15-205(a) of this Article, by filing a written notice with the Office of Land Development Services on or before the tenth (10th) calendar day after such decision. Said notice shall point out with specificity why, in the opinion of the appellant, the decision of the Planning Commission was improper. The City Council shall set a public hearing on the appeal within forty-five (45) calendar days of the date the notice was filed. If there are multiple appeals by the same granting or denial of a variance, or if the appeal is combined with an appeal for the approval or denial of a site plan, the Council shall decide all appeals at the same hearing. The appellant has the burden of proof on appeal and the Council must decide the appeal solely on the record before the Planning Commission, the written appeal, the written response to the appeal from the applicant, and written reports or other relevant and necessary information from appropriate City departments as may be requested by the Council. After considering the appeal, the Council may affirm the decision of the Planning Commission, reverse it, or modify it to comply with the requirements of this Article.

(b) Appeal of Administrative Variances. Any citizen of the City of Austin or any person in a watershed within which a project is located may appeal the granting or denial of an administrative variance to the Planning Commission. The appeal must be delivered to the Director of the Office of Land Development Services within ten (10) calendar days after the date of the Director's decision. The Director shall transmit the appeal with the plan to the Planning Commission, which shall decide all appeals relating to a particular plan when it acts on the plan. The applicant has the burden of proof on appeal. The decision of the Planning Commission shall be final on the appeal of an administrative variance.

VOL 12 2 4795

R0058088

(c) Appeal of Site Development Permit. Any citizen of the City of Austin or any person owning property in the watershed within which the project is located may appeal the approval or denial of a site development permit by the Director of the Office of Land Development Services to the City Council by filing a written notice with the Office of Land Development Services on or before the tenth calendar day after such decision. Appeal may not be taken, however, from disapproval of a site development permit application pending receipt of additional information. Said notice shall point out with specificity why, in the opinion of the appellant, the decision of the Director of the Office of Land Development Services was improper. The City Council shall set a public hearing on the appeal within forty-five (45) calendar days of the date the notice was filed. The appellant has the burden of proof on appeal and the Council must decide the appeal solely on the basis of the permit application file, the written appeal, the written response to the appeal from the applicant, if any, oral argument at the Council hearing, written reports or other relevant and necessary information from the appropriate City departments as may be requested by the Council. After considering the appeal, the Council may affirm the action of the Director of the Office of Land Development Services, reverse it, or modify it to comply with the requirements of this Article.

SEC. 13-15-207. EXEMPTIONS

(a) This Article shall not apply to watersheds defined as "Urban". However, development in Urban Watersheds is subject to the requirements of the Town Lake Critical Water Quality Zone, and all commercial and multi-family development within 500 feet of the 429.0-foot contour of Town Lake must provide sedimentation/filtration basins in accordance with Section 13-15-238 of this Article.

(b) Except as provided in subsections (c), (d), and (e), this Article shall not apply to any development for which a preliminary plan, final plat, site development permit, Travis County development permit, zoning site plan, planned unit development, planned development agreement, or development phasing agreement was approved by the applicable governmental authority, prior to the effective date, or a land use plan for an out-of-City MUD approved by the City Council after a public hearing which occurred prior to the effective date, or a land use plan with permanent zoning for an in-city MUD, which was approved by the City Council prior to the effective date.

(c) This Article shall apply to subdivisions and site developments that were approved before the effective date of this ordinance and that propose to withdraw water from the South Edwards Aquifer and propose residential development other than single-family residential with a maximum density of two units per acre.

VOL 12 2 4796

R0058089

(d) Development otherwise exempt under subsection (b) loses its exemption unless, on the effective date or within five years after the effective date of this Article, the development:

1. has or obtains a site development permit or building permit;

2. has or obtains an approved final plat for at least 50 percent of the land area of the development shown on the preliminary plan;

3. has or obtains permanent zoning tied to a site plan;

4. is or becomes part of an approved site plan or land use plan for a planned unit development, municipal utility district, planned development agreement, or development phasing agreement.

(e) Even though it is exempt under this section, a commercial or multi-family development with more than 20 percent impervious cover must provide sedimentation/filtration basins in accordance with sections 13-15-238 of this Article.

(f) This Article shall not apply to the subdivision of land that proposes a residential density of not more than one, one-family housing unit for every five acres and is appropriately restricted to that residential density.

(g) This Article shall not apply to the resubdivision or reconfiguration of any tract exempted by this section which does not result in an overall increase in density or impervious cover above that on the exempted subdivision or plan. Applicants may change lot sizes and dimensions, roadway alignments, subdivide commercial and multi-family lots into smaller lots, and reallocate impervious cover or transfer density among lots so long as the overall impervious cover and density on the originally approved plan do not increase. In addition, areas reserved for wastewater irrigation and not restricted against future development may be subdivided and resubdivided when no longer needed for irrigation purposes; provided, however the subdivision or resubdivision of such irrigable area shall be required to comply with this Article.

(h) Development exempt from this Article under this section is governed by the applicable watershed ordinance, if any, in effect on the effective date of this ordinance. Development exempt under subsection (f) is not subject to any watershed ordinance.

(i) The impervious cover limits of Divisions 6, 7, and 8 of this Article shall not apply to roadway construction pursuant to a City of Austin Capital Improvements Program if the limits would require the condemnation of adjacent pervious land. Development adjacent to the roadway shall account for the roadway's impervious cover in accordance with Section 13-15-242(e) of this Article.

VOL 12 2 4797

R0058090

(j) This Article shall not apply to a legal lot, as defined in Section 13-15-203, provided, however, that the provisions of this Article shall become applicable to such lot in the event that development of the property requires subdivision approval.

(k) This Article shall not apply to the development of any tract of land that was previously exempted from the Lake Travis Watershed Ordinance by specific action of the City Council.

(l) Notwithstanding any other provisions of this section, any final plat approved prior to the effective date of this Article for which a site development permit, building permit or site plan has not been approved within 10 years from the effective date shall be subject to its provisions.

(m) The impervious cover provisions of Division 6, 7, and 8 of this Article shall not apply to any public school district project; and provided additionally, that any public school district projects for sites acquired prior to the effective date of the ordinance shall be exempt from its provisions.

SEC. 13-15-208. WAIVERS

(a) A developer may apply in writing to the Director of Land Development Services to waive some or all of the requirements of this Article, except as provided in subsection (g), if an application for a preliminary plan, major project review, or site development permit for the development was accepted as complete for filing before the effective date of this Article. The Director must receive an application for Waiver within ninety (90) calendar days after the effective date of this Division or waiver under this Section is barred.

(b) The Director of Land Development Services shall review each application for waiver to determine whether the developer in preparing the preliminary plan or site development permit application relied in good faith on the applicable watershed ordinance then in effect and whether the reliance was reasonable and substantial. In making this determination the Director shall consider when the preliminary plan or site development permit application was filed and the time, effort, and money expended by the developer in preparation. The Director shall recommend in writing for or against the requested waiver, based on the determination of reliance. The Director shall forward the recommendation, together with a concise, written explanation of the basis for the recommendation, the waiver application, and the application for a preliminary plan or site development permit, to the Planning Commission within 30 calendar days from the date the waiver application was received.

(c) The Planning Commission shall consider the recommendation at a public hearing within 30 calendar days from the date it receives the recommendation. After the public hearing the Planning Commission may

VOL 12 2 4198

R0058091

approve, disapprove, or modify the recommendation, in accordance with the standard described in subsection (b), and the Planning Commission shall forward its written recommendation on the waiver application to the City Council within 75 calendar days after the application was received by the Director of Land Development Services.

(d) The City Council shall hold a public hearing on the Planning Commission's recommendation within 30 calendar days after it receives the recommendation. After the hearing the City Council may approve, disapprove, or modify the recommendation in accordance with the standard described in subsection (b).

(e) A developer has the burden of proving his or her entitlement to the requested waiver before the Director of Land Development Services, the Planning Commission, and the City Council.

(f) A development for which some or all of the requirements of this Article have been waived becomes subject to the waived requirements unless, within five years from the effective date of this Division, the development:

1. has or obtains a site development or building permit;

2. has or obtains an approved final plat and site plan for at least 50 percent of the land area of the development shown on the preliminary plan;

3. has or obtains permanent zoning tied to a site plan;

4. is or becomes part of an approved site plan or land use plan for a planned unit development, municipal utility district, planned development agreement; or development phasing agreement.

(g) Notwithstanding the approval of a waiver under this section, commercial or multi-family development with more than 20 percent impervious cover must provide sedimentation/filtration basins in accordance with section 13-15-238 of this Article.

SEC. 13-15-209. HARDSHIP PROVISIONS

(a) Any person owning title to property within any of the watersheds to which this ordinance is applicable may request administrative review of the effect of this ordinance upon an individual tract if such review is requested on or before May 1, 1987.

(b) An administrative review shall consist of an analysis by the Office of Land Development Services of the effect of the application of the ordinance upon a tract held in ownership by any person on or before the date of passage of this ordinance to determine:

VOL 12 2 4799

R0058092

1. The percentage of net development in square feet of impervious cover or residential units lost, if any, by virtue of the application of this ordinance to the tract in question as compared with the net development possible under ordinances and available utility service existing on the date of passage of this ordinance.

2. The development configuration most likely to maximize the economic value of the tract under application of the terms of this ordinance.

(c) In case any tract has its net development in square feet of impervious cover or residential units reduced by 50% or more, by application of the terms of this ordinance, the following procedures shall apply:

1. The owner of the tract may develop the tract according to the terms of this ordinance, without application of other provisions of this section.

2. The owner may request that the Office of Land Development Services develop a site specific plan to protect water quality utilizing any combination of the provisions contained in Sections 13-15-231 - 13-15-290 of this ordinance, including density controls, impervious cover limitations and structural controls, which shall, in the opinion of the Office of Land Development Services, accomplish substantial protection of water quality in the run-off of water occurring from said tract to any minor, intermediate, or major waterway in any area regulated by this ordinance. In developing such a site specific plan, the Office of Land Development Services shall balance the techniques of water quality protection with the maximization of the economic utilization of the tract in order to achieve the most cost effective plan affording substantial protection of water quality. The burden of producing all other elements of the plan other than the element prepared by the Office of Land Development Services for the property shall be distributed according to pre-existing requirements.

3. Any plan developed by the Office of Land Development Services under paragraph (2) above shall be presented to the person owning such land for approval by such person within sixty (60) days of the request for the development of such plan in order that such plan may be presented to the City Council for adoption. If the owner wishes to present the plan to the City Council for adoption, the plan shall be presented to the Council for adoption by ordinance within thirty (30) days of written acceptance of the plan by the owner.

VOL 12 2 4800

R0058093

4. The City Council shall consider the plan and action upon the plan shall be approved or disapproved according to the requirements for consideration of ordinances within sixty (60) days following its presentation to the Council by the Office of Land Development Services, following acceptance by the owner.

(d) This section shall be a remedy available in addition to all other exemptions and remedies provided a person owning title to property under this division.

SEC. 13-15-210. RESERVED

DIVISION 2. MAINTENANCE AND ENFORCEMENT

SEC. 13-15-211. MAINTENANCE

All developments of land located within the City of Austin's City limits or extra-territorial jurisdiction shall comply with the provisions of this Section.

a) All sedimentation and filtration basins and their appurtenances required for commercial and multi-family development shall be maintained by the property owner.

(b) Maintenance of sedimentation and filtration basins for single-family or duplex residential development shall be by the City of Austin.

(c) The maintenance of all sedimentation and filtration basins and their appurtenances shall be to the standards and specifications of the City of Austin's "Design Guidelines for Water Quality Control Basins", as prepared by the Department of Public Works.

(d) Duly authorized inspectors of the City shall have the right of entry on the land or premises where property owners are required to maintain drainage facilities or detention/filtration facilities, for the purpose of inspection of the maintenance required. The Public Works Department shall inspect the premises of each such facility approved pursuant to this Article at least once per year. Where noncompliance is found, the City shall request in writing that the property owner comply. This notice shall describe the measures required to be taken. If, within one (1) month of the notice, the maintenance required is not accomplished, the City shall either:

1. Cause the necessary restoration to be accomplished and assess the property owner for the City's actual cost, or

2. Bring an action for mandatory injunction to require the property owner to accomplish the necessary maintenance.

VOL 12 2 4801

R0058094

(e) A Dedicated Fund shall be set up by the City to maintain and monitor basins for single-family and duplex uses and to monitor basins for other residential and commercial uses. The subdivider or developer shall pay into the fund as per the adopted Fee Schedule of the City of Austin. These fees shall be paid at the time the subdivider posts fiscal requirements for his or her subdivision, or at the time of site development permit approval.

(f) An annual report shall be made by the Director of Public Works to the City Council about the status of the program and the funds.

SEC. 13-15-212. INSPECTIONS

(a) Any person or his successor and assigns who has filed a plan for approval pursuant to this Article shall agree in writing to allow entry on the land or premises which is the subject of such application for the purpose of inspection of conditions on the premises during the approval stage and during development and construction by duly authorized inspectors of the City.

(b) The City shall cause such inspections to be made of the land or premise during development and construction so as to assure full compliance with all terms, conditions, requirements, and agreements to which the person obtaining approval of a plan under this Article is bound.

(c) The applicant shall designate one person or legal entity, with a current street address, to which notice shall be given pursuant to this Article.

(d) Any permit holder shall agree to allow entry on the land or premises which is the subject of the permit for the purpose of the aforementioned inspection.

SEC. 13-15-213. PRE-CONSTRUCTION CONFERENCE

(a) A pre-construction conference shall be required for all development under this ordinance.

(b) Subsequent to installation of erosion and sedimentation controls, and prior to beginning construction, a permit holder shall request in writing and attend, along with his design engineer, contractor, and field engineer, an erosion and sedimentation control inspection coordinated and scheduled by the Director of Public Works, and attended by all relevant City departments. Said conference shall take place on the site. The permit holder should be prepared to demonstrate that the erosion and sedimentation controls are in compliance with the Erosion and Sedimentation Control Manual, and to

VOL 12 2 4802

R0058095

present a plan including, but not limited to future erosion and sedimentation controls, tree protection measures, and drainage, utility and street layouts. The conference must be held within ten (10) days of the receipt of the request or permit holder may proceed with construction.

SEC. 13-15-214. CRIMINAL ENFORCEMENT

(a) It shall be unlawful for any person, corporation, partnership, joint venture, contractor, agent, owner, or any person having physical control of land situated in whole or in part within watersheds located within the City's jurisdiction to undertake, to engage in, perform, authorize, allow, direct, or permit development on that land unless a valid current plan has been approved by the City of Austin and the appropriate development permits obtained by the owner, design engineer, or contractor authorizing that development.

(b) An owner of land situated in whole or in part within a watershed commits a violation of Subsection (a) hereof by personally undertaking, engaging in, or performing development on that property without having first obtained a valid, current development permit from the City of Austin authorizing said development; by agreeing, allowing, permitting, authorizing, or directing another to openly and notoriously perform, engage in, or undertake development on his/her property where no valid, current permit has been obtained; by knowingly allowing another to engage in, perform, or undertake development on his property without his consent where no such valid permit has been obtained.

(c) A contractor commits a violation of Subsection (a) hereof when said contractor, with or without the owner's consent, engages in, performs, or undertakes development upon property situated in whole or in part within the watersheds located within the City's jurisdiction without having obtained or secured a current, valid development permit issued by the City of Austin to that contractor. A true copy of the permit shall be kept at the site at all times during development. The contractor shall cause the permit to be immediately available at the site for examination upon request by any authorized City inspector, as evidenced by an identification card bearing the seal of the City of Austin, naming the inspector, and signed by a person purporting to be empowered to issue said identification card. Evidence of the contractor's failure to have displayed the copy of the permit at the site upon request by an authorized City inspector shall constitute prima facie evidence that there is no valid, current City development permit for development of the site.

(d) Any person to whom a development permit has been issued by the City of Austin pursuant to this Article commits a violation thereof, punishable hereunder, if such person fails to observe and perform the terms and conditions stated in such permit.

VOL 12 2 4803

R0058096

(e) Any person violating any of the provisions of this Article, upon conviction, shall be fined in an amount not exceeding $1,000. Each violation hereof occurring during a calendar day shall be a distinct and separate offense from such a violation occurring during the next preceding or next following calendar day.

(f) It shall not be necessary for the complaint filed in any case hereunder to negate any exception, whether exemption or variance, contained in this Article concerning any prohibited act; but, any such exception made herein may be used as a defense by any person charged by such complaint.

(g) Nothing herein shall limit the City's authority to seek injunctive or other civil relief available under the law.

SEC. 13-15-215. CEASE AND DESIST ORDER

(a) When either the Office of Environmental Resource Management (ERM), Public Works Department, Water and Wastewater Utility, Electric Utility, or Building Inspection Department determines that there has been noncompliance with any material term, condition, requirement or agreement under this Article, the person who either has or should have obtained an approved development permit shall be ordered to cease and desist from allowing further development and/or from allowing transportation of construction material to the alleged noncompliant site until such site is in compliance with this Article.

(b) Said cease and desist order ("Red Tag") shall be in writing and shall be posted on the site.

(c) The City shall bring suit in a court of competent jurisdiction to restrain and enjoin any person attempting or allowing development or construction without an approved development permit or any person failing or allowing failure to cease and desist from further development or construction under Subsection (a).

(d) No further City inspection or utility connections shall be made until such site is in compliance with this ordinance, as determined by the Chief Environmental Officer of the City.

SEC. 13-15-216. APPEAL OF CEASE AND DESIST ORDER

(a) Appeal of a cease and desist order, issued pursuant to Section 13-15-215, may be made by the person aggrieved to the Chief Environmental Officer. Such appeal shall be perfected by giving written notice containing the following information to the Chief Environmental Officer within three (3) days of the posting on the site of the cease and desist order:

VOL 12 2 4804

R0058097

1. The name and address of the person making the appeal
2. The facts surrounding the particular ruling
3. The ruling of the issuing department
4. The technical reasons why the ruling should be set aside.

(b) Within a period of three (3) days from the filing of the appeal, the Chief Environmental Officer or his designee shall hear the appeal together with technical testimony of the person making the appeal, or his technical expert, and the department, and make a decision either affirming or reversing the department's decision within two (2) days thereafter. The person requesting the hearing shall be notified of the decision in writing. The notification shall be accompanied by a statement of the reasons for the decision.

(c) Appeal of the Chief Environmental Officer's decision may be made by the person aggrieved to the Planning Commission. Such appeal shall be perfected by giving a written notice containing the following information to the Chairman of the Planning Commission within three (3) days after the receipt of the decision of the Chief Environmental Officer:

1. The name and address of the person making the appeal.
2. The facts surrounding the particular ruling.
3. The rulings of the issuing department and Chief Environmental Officer.
4. The technical reasons why the ruling should be set aside.

(d) The Planning Commission shall hear the appeal at the next regular meeting following receipt of the notice. If the appeal is not heard by the Planning Commission within twenty (20) days from the filing of the appeal with the Commission, the appeal shall be deemed granted.

(e) Appeal under this Section shall not stay the cease and desist order.

SEC. 13-15-217. CERTIFICATE OF COMPLIANCE OR OCCUPANCY

No City utilities may be connected to a site unless a certificate of compliance is issued by the Department of Public Works when the development is completed pursuant to requirements of this Article for areas outside the City limits or until the Building Inspection Department issues a certificate of occupancy with the written concurrence of the Director of Public Works for areas within the City limits. Requests by the developer/owner for a certificate of compliance or occupancy for development other than single-family or duplex residential housing construction shall be accompanied by a certificate prepared and signed by a professional engineer registered in the State of Texas attesting to the completion of the project in substantial conformance with the development permit.

SEC. 13-15-218.-220. RESERVED

VOL 12 2 4805

R0058098

DIVISION 3. REQUIREMENTS FOR SUBMISSION OF DEVELOPMENT PLAN

SEC. 13-15-221. APPROVAL AND PREAPPLICATION CONFERENCE

(a) Before subdividing land located in the watersheds in the City's jurisdiction, an applicant must first obtain approval from the Planning Commission of the plans and plat required by this Division and by the other provisions of this Chapter.

(b) No commercial or multi-family development shall be undertaken on any land, tract or parcel within the City's jurisdiction until the effective date of a site development permit for said development issued by the Director of the Office of Land Development Services.

(c) For developments exceeding one hundred acres in size, a prospective applicant shall request in writing, prior to submitting a plan for approval, a development preapplication conference coordinated and scheduled by the Director of the Office of Land Development Services and attended by the applicant and representatives of all relevant City departments. Applicants should be prepared to present a conceptual plan at that time, including, but not limited to conceptual drainage, land use, utility and street layout. The conference must be held within ten (10) days of the request or the applicant may proceed to submit a plan.

SEC. 13-15-222. PLAN SUBMISSION REQUIREMENTS - GENERAL

(a) An applicant seeking approval of a plan must file copies of a plan of the proposed development with the Director of the Office of Land Development Services and pay the filing fee required by ordinance.

(b) Applicants for subdivisions for uses other than single-family or duplex residential may submit information demonstrating compliance with this Article for individual lots at the time of Site Development Permit Application, provided that the applicant demonstrates that such lots have access consistent with this Article and appropriately restricts the plat to assure compliance at a later date.

(c) The plan shall meet all requirements and conditions established by the other Sections of this Article and shall meet additional requirements set forth below. The proposed plan shall be certified as complete and accurate and in compliance with the provisions of this Article by a professional engineer registered in the State of Texas and knowledgeable in the field of Civil Engineering.

(d) An applicant seeking approval of a plan under this Article must submit the following information; unless the Director of the Office of Land Development Services determines that due to the scope and nature of the proposed development, some of the information is unnecessary:

VOL 12 2 4806

R0058099

1. A topographic map, with two foot contour intervals, at a scale of 1 inch to 100 feet for subdivision plans and 1 inch to 40 feet for site development plans, each meeting national map accuracy standards showing:

   a. All development or improvements on the site that are existing and those that are proposed.

   b. The limits of the one-hundred (100) and twenty-five (25) year floodplains, based on existing channel conditions, of all creeks and major drainage channels prior to any alteration of land assuming fully developed watershed conditions exist.

   c. The location, type, acreage, and percentage of impervious cover, including both existing and proposed for each slope category and the totals.

   d. The delineation of each Major, Intermediate, and Minor Waterway as defined herein.

   e. The delineation of the Critical Water Quality Zone, Water Quality Buffer Zone, Upland Zone, and Edwards Aquifer Recharge Zone, as applicable.

   f. The two year floodplains where needed to determine the Critical Water Quality Zone.

   g. The location of any Critical Environmental Features such as point recharge features, canyon rimrocks, bluffs, and wetlands, and required setbacks therefrom.

2. A slope map drawn at the same scale as the topographic map for those sites having greater than fifteen percent (15%) slopes, depicting slopes of 0-15%, 15-25%, 25-35%, and over 35%. Slopes may be calculated based on contour intervals not to exceed five (5) feet. The slope map shall show:

   a. All development or improvements on the site including adequate building sites for any single-family or duplex lots, exclusive of any required setbacks and easements and any slopes over 25%, and based on the assumed impervious cover defined in Section 13-15-243(c).

   b. Areas of cut and fill in excess of four (4) feet, or, for roadways, cut and fill outside the right-of-way.

   c. The location of proposed spoil disposal sites.

VOL 12 2 4807

R0058100

d. The location of wastewater lines, drainfields, and effluent irrigation areas, effluent holding ponds, and tailwater control berms.

e. Buffer zones for commercial, multi-family, or cluster development, where applicable.

3. An engineer's report including:

a. A drainage study addressing the design criteria set forth in the Drainage Criteria Manual.

b. The land area calculated in acres for each slope class and each water quality zone within the development.

c. The net site area, as calculated herein, along with detailed calculations and the methodology used to calculate total allowed and proposed impervious cover or density for the development, as well as all transfer of development rights calculations. The total impervious area shall be separated into areas of streets, off-street parking, commercial areas, tennis courts and other recreational areas, and residential areas. All pedestrian sidewalks within street rights-of-way or parallel to private streets may be excluded from the impervious cover calculations.

d. An erosion/sedimentation control plan consistent with the requirements of Section 13-15-233.

e. Roadway and driveway preliminary profiles for those portions of all roadways and driveways crossing slopes in excess of fifteen percent (15%).

f. A vegetative description delineating ground cover types, defining the cover-types by general species composition and range of tree diameters. The vegetative description shall be accompanied by an aerial photograph at a scale of 1" = 400 ft. A mylar overlay accompanying the photograph shall show approximate locations and identities of all trees and definable groups of trees with crown diameters equal to or greater than forty (40) feet and showing the approximate locations and identities of any other significant plant material.

g. An engineer's seal, signature, and statement certifying that the plan is complete, correct, and in compliance with this Article, along with the Engineer's Summary Letter.

4. A request and justification for a variance according to Section 13-15-205.

VOL 12 2 4808

R0058101

SEC. 13-15-223. ENVIRONMENTAL ASSESSMENT

For all developments located in watersheds designated as "Water Supply Suburban" or "Water Supply Rural", an Environmental Assessment is required which includes the following information; unless the Director of the Office of Land Development Services determines that due to the scope and nature of the proposed development some of the information is unnecessary:

(a) A hydrogeologic element which:

1. Generally describes the topography, soils, and geology of the site.

2. Identifies springs and significant point recharge features on the site.

3. Demonstrates that proposed drainage patterns will protect the quality and quantity of recharge at those points, as required by Section 13-15-239.

(b) A vegetative element which:

1. Includes either a tree survey of all trees with a diameter of eight inches (8") or more measured four and one-half (4-1/2) feet above natural grade level or, upon approval of the City Arborist, a set of nine by nine inch aerial photographs providing complete, stereo coverage of the area photographed between the months of April and November at a scale no greater than one inch equals four hundred feet.

2. Includes, for all commercial and multi-family sites, a vegetative survey which shows the approximate location of and identifies all significant plant material on the site.

3. Demonstrates that the design of the plan has been accomplished to preserve to the greatest extent reasonable any significant trees and vegetation on the site and to provide maximum erosion control and overland flow benefits from such vegetation.

(c) A wastewater element, where applicable, which:

1. Includes calculations of drainfield or wastewater irrigation areas as required by this Article.

2. Provides environmental justification for sewer line locations in Critical Water Quality Zones, where applicable, and describes construction techniques and standards for wastewater lines.

3. Describes alternative wastewater disposal systems to be used over the Edwards Aquifer Recharge Zone.

VOL 12 2 4809

R0058102

4. Discusses any proposed on-site collection and treatment systems, their treatment levels, and impacts on receiving watercourses, including the Edwards Aquifer, as required by this Article.

(d) Identification of any Critical Environmental Features as required by this Article, and proposed means for protection of such areas.

(e) Environmental justification for spoil disposal locations or roadway alignments, as required in Sections 13-15-235, 13-15-236, and 13-15-237.

(f) Methods proposed to achieve overland flow, and justification to use enclosed storm sewers, where proposed.

(g) A description of any industrial uses proposed, as well as a program for pollution abatement as required by this Article.

SEC. 13-15-224. FINAL PLAT

In addition to satisfying other requirements of this Article, a final plat, where applicable, must:

(a) Contain on the face of the plat or place in a separate covenant the following notes, as applicable, which:

1. Incorporate by reference the terms and requirements of this Article of this Chapter, which shall be required in all cases;

2. Restricts the land in the subdivision to the impervious cover limitations of this Article;

3. Provides for the maintenance of structural water quality controls as required by Section 13-15-211;

4. Provides for separate approval of any driveway with grades in excess of fourteen (14) percent when applicable under Section 13-15-248;

5. Provides for joint-use driveways when applicable under Section 13-15-248;

6. Limits cut and fill on any lot to a maximum of four (4) feet, as required in Section 13-15-235.

7. Requires erosion controls to be installed for single-family and duplex construction.

8. Specifies the transfer of development rights used.

VOL 12 2 4810

R0058103

(b) Contain a statement dedicating to the City of Austin those water quality basins required under Section 13-15-211 to be maintained by the City.

(c) Be accompanied by such restrictive covenants, easements or contracts as may be necessary and appropriate to ensure adequate property owner maintenance of water quality basins under Section 13-15-211 and/or to facilitate the use of joint-use driveways under Section 13-15-248.

(d) Be accompanied by a fee in the amount established by ordinance; such fee to be used for the purpose of funding a program for maintaining and monitoring water quality basins and other drainage facilities and conveyances as described in Section 13-15-238.

SEC. 13-15-225.-230. RESERVED

DIVISION 4. GENERAL STANDARDS

SEC. 13-15-231. COMPLIANCE

All plans submitted shall comply with the provisions of this Division and any other applicable provisions of this Article.

SEC. 13-15-232. CRITICAL WATER QUALITY ZONES

(a) Critical water quality zones shall be established along all intermediate, minor and major waterways with drainage basins as defined in Sections 13-15-262, 13-15-272, and 13-15-282. The zone line shall be delineated parallel to each such waterway according to the size of the drainage basin:

1. For minor waterways, the zone line shall be defined by the limits of the one hundred year floodplain; provided that it shall never extend beyond one hundred (100) feet on each side from the centerline of the waterway; provided further that the line shall never be located less than fifty (50) feet on each side from the centerline of the waterway.

2. For intermediate waterways, the zone line shall be defined by the limits of the one hundred year floodplain; provided that it shall never extend beyond two hundred (200) feet on each side from the centerline of the waterway; provided further that the line shall never be located less than one hundred (100) feet on each side from the centerline of the waterway.

3. For major waterways, the zone line shall be defined by the limits of the one hundred year floodplain; provided that it shall never be located greater than four hundred (400) feet on each side from

VOL 12 2 4811 1

R0058104

the centerline of the waterway; provided further however, that the line shall never be located less than two hundred (200) feet on each side from the centerline of the waterway.

4. Notwithstanding all of the above, in no event shall the Critical Water Quality Zone extend beyond the crest of a bluff, as defined in Section 13-15-203.

(b) The floodplain delineation shall be based on a channel in its unaltered state, unless modifications are approved pursuant to regulations adopted by the City Council, and shall assume fully developed watershed conditions.

(c) Critical water quality zones shall be established along Lake Travis, Lake Austin, and Town Lake. The zone line shall be delineated parallel to the normal pool levels of Lake Travis (681.0 foot contour), Lake Austin (492.8 foot contour), and Town Lake (429.0 foot contour), and shall extend a horizontal distance of seventy-five (75) feet inland for proposed detached single-family residential development, and one hundred (100) feet for other residential or commercial development.

(d) The critical water quality zone shall remain free of all construction activity, development and alterations except that the following may be permitted:

1. Arterial, collector, and residential street crossings only as provided below:

   a. Major waterways may be crossed by arterial streets that are identified in the City of Austin Roadway Plan.

   b. Intermediate waterways may be crossed by arterial and collector streets, provided, however, that no collector street crossing shall be within two thousand five hundred (2,500) feet of any other collector or arterial street crossing on the same waterway; provided further, however, that in those watersheds designated as "Water Supply Suburban" or "Water Supply Rural", no collector street crossing shall be within one mile of any other collector or arterial street crossing on the same waterway.

   c. Minor waterways may be crossed by arterial and collector streets, provided, however, that no collector street crossing shall be within one thousand (1,000) feet of any other crossing of a collector or arterial street on the same waterway; provided further, however, that in those watersheds designated as "Water Supply Suburban" or "Water Supply Rural", no collector street crossing shall be within two thousand (2,000) feet of any other collector or arterial street crossing on the same waterway.

VOL 12 2 4812

R0058105

d. Minor waterways may be crossed by a residential or commercial street only when necessary to provide access to property which cannot otherwise be safely accessed.

e. The Director of the Office of Land Development Services may vary these requirements prior to, or at the time of, plan approval, after receiving a report from the Urban Transportation Department.

2. Fences that do not obstruct flood flows.

3. Public and private parks, golf courses and open spaces, other than parking lots, when a program of fertilizer, pesticide and herbicide use is approved by the Office of Land Development Services, provided, however, that in watersheds designated as Water Supply Rural or where the Critical Water Quality Zone lies within the South Edwards Aquifer Recharge Zone, park development is limited to trails and facilities (other than stables and corrals for animals) for hiking, jogging, nonmotorized biking, and nature walks.

4. Boat docks, piers, wharves, or marinas, and necessary access and appurtenances, along Lake Travis, Lake Austin, and Town Lake, where otherwise permitted by the City of Austin. All treated building materials that will be submerged in water must be approved by the Office of Land Development Services prior to a waterway development permit being issued.

5. Detention basins, utilities, maintenance, and floodplain alterations as permitted by Chapter 9-10, Article IV, Division 1 and 2, and other provisions of this Article.

SEC. 13-15-233. EROSION AND SEDIMENTATION CONTROL.

(a) Erosion and sedimentation controls, as specified in the Erosion and Sedimentation Control Manual, are required for all construction and development, including but not limited to, commercial, multi-family, single-family and duplex construction. Moreover, the construction of all roads, utilities, parks, golf courses, water quality and detention basins, and all other activities utilizing clearing, trenching, grading, or other construction techniques shall comply with the Manual.

(b) Applications for waterway or site development permits shall be accompanied by a proposed construction sequence to demonstrate an acceptable plan for erosion control and tree protection during the construction period and restoration of the land after the construction period and shall be submitted to the Director of the Office of Land Development Services for review. All measures for erosion control and restoration shall be performed in accordance with the Erosion and Sedimentation Control Manual.

VOL 12 2 4813

R0058106

(c) Projects shall not be considered complete until restoration has been made, the required vegetation established, and certified by the Public Works Department for acceptance as installed. In the event the City accepts maintenance responsibility for the streets, drainage facilities and utilities prior to completion of restoration requirements, a separate and enforceable agreement to ensure completion of restoration requirements shall be entered into by the City of Austin and the developer.

(d) After two (2) days written notice to the permit holder of the plan, modifications from the approved erosion control and construction sequencing plans may be made in the field if the City inspector deems the controls or sequencing inappropriate or inadequate and has confirmed his/her findings with the Office of Land Development Services, and has their written approval. Minor changes which result in an upgrading of erosion controls or simply reflect the progression of construction on a site, may be accomplished in the field without such written approval.

SEC. 13-15-234. CLEARING AND TEMPORARY SITE DISTURBANCES

(a) Clearing for road construction shall not be permitted before final plat approval. Work done on the ground in preparation of site development or final plat approval shall be limited to surveying and geological testing. Areas cleared for surveying and testing shall not exceed a width of fifteen (15) feet, and no trees with a diameter greater than eight inches (8") shall be removed.

(b) Clearing for the temporary storage of spoils or construction equipment shall be designated on the construction plans and shall be restored in accordance with the Erosion and Sedimentation Control Manual. The topsoil should be protected against erosion during and after the site grading operations. Where practical, the existing vegetation should be left in place.

(c) The length of time between roughcutting and final surfacing of roadways may not exceed eighteen (18) months. If an applicant does not meet this deadline, the Director of the Public Works Department shall notify him in writing that the City will complete the streets or revegetate the disturbed area at his expense unless he does so within sixty (60) days after the date of the notice.

(d) Roadway clearing width within a subdivision shall not exceed twice the roadway surface width or the width of the dedicated right-of-way, whichever is less. Right-of-way widths shall not be increased to provide additional clearing under this provision. Such roadway clearing width may be varied by the Director of the Office of Land Development Services where, in the Director's opinion, unusual topographic conditions necessitate such a variance. Clearing for

VOL 12 2 4814

R0058107

short run road (300 feet or less) construction problem areas may be increased to two and one-half times the roadway width, right-of-way permitting. In cases where, due to slopes, clearing activities would normally result in cleared materials sliding onto areas beyond the clearing widths specified above, retaining walls or other methods shall be utilized to prevent such sliding.

SEC. 13-15-235. CUT AND FILL

(a) No fill on any lot or other land within the subdivision, except within roadway right-of-way, shall exceed a maximum of four (4) feet of depth. Fill placed under foundations with sides perpendicular to the ground, or with pier and beam construction, need not comply with this requirement, but must be placed in a manner consistent with Section 13-15-237. Backfill for utility construction or wastewater drainfields is also exempt from this provision.

(b) Except for structural excavation, no cut on any lot or other land within the subdivision, other than within roadway right-of-way, shall be greater than four (4) feet. For the purposes of this Subsection, structural excavation means excavation required for construction of building foundations consistent with Section 13-15-237, but shall not include cuts for private or public roads or driveways where structural side-slope stabilization (containment) is proposed. Cuts for utility installation or wastewater drainfield excavation are exempt from this provision, subject to restoration of such areas to natural grade.

(c) Cut and fill for roadways shall be contained within allowable roadway clearing widths.

(d) In all cases, slopes generated by cut and fill shall be stable, giving full consideration to soil characteristics and erosion potential. Techniques to be used are to be specified with the final plat. Slopes exceeding a 3 to 1 ratio, other than cuts which are determined to be stable, must be stabilized by permanent structural means (e.g., dry stack walls, terraces, exposed aggregate concrete walls, etc.), and approved by the Director of the Office of Land Development Services.

SEC. 13-15-236. SPOIL DISPOSAL

(a) Spoil disposal sites shall not be located within the one-hundred (100) year floodplain or on slopes greater than fifteen (15) percent gradient unless the Director of the Office of Land Development Services finds that a necessary public benefit is derived from the use of the spoil. Such benefits may include, but are not limited to:

1. Roadways.

2. Stormwater detention facilities, after consideration of reports from the Public Works Department and the Environmental Review Division of the Office of Land Development Services.

VOL 12 2 4815

R0058108

3. Public or private park sites, after consideration of reports from the Environmental Review Division and the Parks and Recreation Department.

4. Building sites as per Section 13-15-235.

(b) Spoil disposal sites shall be located such that reasonable access to the site is available. Access routes shall utilize existing and approved roadways wherever possible and shall not be located within waterways except where no reasonable alternative is available, or when used to construct water quality and/or detention basins. Plans should address the restoration of such access roads and basins.

(c) Restoration and revegetation shall be carried out in conformance with the Erosion and Sedimentation Control Manual, with particular emphasis on the Section entitled "Standards for Land Grading".

SEC. 13-15-237. CONSTRUCTION ON SLOPES

(a) No roadways or driveways shall be constructed on slopes in excess of fifteen percent (15%) except where necessary to provide primary access to areas of flatter slopes, constituting a minimum of two (2) contiguous acres or building sites for at least five (5) residential units. Cuts and fills on roadways or driveways are to be restored as described herein.

(b) No building or parking areas shall be constructed on slopes in excess of fifteen percent (15%), provided, however, that buildings and parking structures may be located on slopes of 15% - 25% when the following criteria are met:

1. Impervious cover on 15-25% slopes shall not exceed ten percent (10%) of the total area of 15-25% slope.

2. Structures located upslope of slopes between 15% - 25% and not using terracing techniques shall be constructed utilizing pier and beam techniques. Fill shall be placed to blend with the natural contour. No vertical walls shall extend beyond the lowest finished floor elevation, other than necessary to screen mechanical appurtenances, and shall be stepped, if appropriate. Terraced fill and walls shall be a maximum 1 to 1 running grade limited to four (4) feet in height for each terrace. This Section shall not apply to single family and duplex construction.

3. Structures located downslope of slopes between 15-25% should be terraced and consolidated into the hillside. Structural excavation shall not exceed a maximum of eight (8) feet in depth, except by terracing. Areas of cut not hidden from view shall be effectively screened by additional landscaping.

VOL 12 2 4816

R0058109

4. Hillside vegetation shall not be disturbed other than that necessary to locate the structure. All disturbed areas shall be restored with native vegetation.

5. If terraces are not provided, cuts and fills are to be restored to 3 to 1 slopes and revegetated. Restored slopes shall be limited to as short a length as possible.

SEC. 13-15-238. SEDIMENTATION AND FILTRATION BASINS

(a) Where required, water quality sedimentation-filtration or detention-sedimentation basins shall be situated and constructed to capture, isolate, and hold at least the first one-half (1/2) inch of runoff from all contributing areas and shall be shown on the slope map with details of construction.

(b) The basins and drainage into the basins shall be designed in accordance with the Department of Public Works' "Design Guidelines For Water Quality Control Basins" as approved by City Council after public hearing and as administratively approved from time to time.

(c) Water quality sedimentation-filtration basins shall not be required for greenbelts, open space, golf courses and other similar uses.

(d) Except as provided in Section 13-15-238(e), all basins located in the Edwards Aquifer Recharge Zone shall have impervious liners. The location of such basins and drainage to them shall avoid recharge features (faults, fractures, sinkholes, etc.) to the greatest extent possible.

(e) Basins in the Edwards Aquifer Recharge Zone which drain residential areas with up to 40% impervious cover may be designed to recharge the groundwater. Applicants shall identify any opportunities for such recharge on the plan submitted under Section 13-15-223. The recharge basins shall include sedimentation/filtration and shall be designed according to Public Works guidelines. Approval shall be by the Office of Land Development Services.

SEC. 13-15-239. CRITICAL ENVIRONMENTAL FEATURES

(a) Except as provided in Section 13-15-239(d) and (e), no construction other than for yards or hiking trails shall be undertaken within one hundred fifty (150) feet of a critical environmental feature, and the natural vegetative cover shall be retained in this buffer zone to the maximum practical extent. No clearing, alteration, or development of any kind shall be permitted within fifty (50) feet of a critical environmental feature, except hiking trails for educational purposes as designated by the Parks and Recreation Department. No residential

VOL 12 2 4817

R0058110

lot shall encompass or be located closer than fifty (50) feet from a critical environmental feature. Wastewater disposal and irrigation areas shall never be located less than one hundred fifty (150) feet from a critical environmental feature.

(b) Drainage patterns shall be designed to protect critical environmental features from runoff from developed areas, or to maintain the catchment areas of recharge features in a natural state, (except as provided in Section 13-15-239 (d)), and special erosion controls shall be utilized where necessary to avoid impacts of erosion or sedimentation. Approved recharge basins, under Section 13-15-238(e) above, which discharge to point recharge features may be located within the setbacks required by this Section, but shall not be located less than fifty (50) feet from a critical environmental feature.

(c) Except as provided in Section 13-15-239 (e), point recharge features with topographically defined catchment basins extending beyond the setbacks required in Section 13-15-239 (a) shall have a construction setback coinciding with the limit of the upslope extent of the catchment, not to exceed a total of three hundred (300) feet.

(d) Except where prohibited or precluded by Section 13-15-239 (f), for recharge features with a catchment area of less than one and one-half (1.5) acres, the one hundred fifty (150) foot buffers required by Section 13-15-239 (a) may be reduced to the limits of the catchment, but shall not be reduced to less than fifty (50) feet from a critical environmental feature.

(e) Where buffer zones around recharge features and bluffs are proposed to be less than those required by (a) above, the burden of proof shall be on the applicant to demonstrate that : 1) the proposed measure(s) protect and preserve all characteristics of the feature which define it as a critical environmental feature; or 2) the feature is not a critical environmental feature as defined in Section 13-15-203. Provided however, that in no instance shall setbacks be less than fifty (50) feet from the critical environmental feature.

(f) No provision herein shall limit the applicant, the Chief Environmental Officer, or the Office of Land Development Services from recommending for Planning Commission approval additional or alternative measures necessary to protect characteristics of specific CEFs which may be unrelated directly to water quality protection.

SEC. 13-15-240. INNOVATIVE MANAGEMENT PRACTICES

Innovative runoff management practices designed to address the requirements of Sections 13-15-238 and 13-15-239 of this Article, enhance recharge of groundwater, and maintain the function of critical environmental features

VOL 12 2 4818

R0058111

are encouraged. Innovative practice proposals shall be reviewed by the Department of Public Works and the Chief Environmental Officer and approved by the Director of the Office of Land Development Services.

Innovative practices shall be judged on technical merit, the degree to which they meet the intent of the ordinance in regard to water quality protection and improvement, resource protection and impact mitigation, the advantages over standard practices required by this ordinance and the anticipated maintenance requirements.

SEC. 13-15-241. WASTEWATER TREATMENT

Projects utilizing wastewater package treatment plants for sewage disposal are recommended to:

(a) In watersheds designated as "Water Supply Suburban" or "Water Supply Rural", obtain an irrigation (no-discharge) permit from the State meeting a minimum BOD/TSS treatment level of 10/15 mg/l or a minimum BOD/TSS/NH_3-N/PHOSPHORUS treatment level of 5/5/2/1 mg/l if irrigating land over the Edwards Aquifer Recharge Zone; or

(b) In watersheds not designated as per (a) above, obtain an irrigation (no-discharge) permit from the State meeting a minimum BOD/TSS treatment level of 10/15 mg/l or a minimum BOD/TSS/NH_3-N/PHOSPHORUS treatment level of 5/5/2/1 mg/l if discharging directly to a waterway other than the Colorado River or 10/15 mg/l if discharging directly to the Colorado River.

(c) If it is desired to deviate from the requirements in (b) above then the proposal must be accompanied by a comprehensive environmental assessment of the individual and cumulative impacts of the discharge on surface water and groundwater quality such that instream modeling studies performed by a professional engineer registered in the State of Texas with expertise in the water quality area indicates that baseline water quality will not be degraded below predevelopment conditions as a result of the proposed discharge.

SEC. 13-15-242. IMPERVIOUS COVER CALCULATIONS

(a) Impervious cover calculations shall include all roads, driveways, parking areas, buildings, decking, rooftop landscapes and other impermeable construction covering the natural land surface. Swimming pool surface water area for pools which discharge to the storm drainage system shall also be included. Sidewalk impervious cover is not included. Water quality and detention basins, swales, and other conveyances for drainage purposes only shall not be calculated as impervious cover.

VOL 12 2 4819

R0058112

(b) Impervious cover credit shall not be given for permeable or interlocking pavers or for existing impervious cover; provided, however, that a maximum of twenty percent (20%) credit may be given when permeable pavers are approved by the Office of Land Development Services in accordance with Section 13-15-241 (Innovative Management Practices) for recharge enhancement purposes.

(c) For calculation purposes, impervious cover for one-family or duplex lots shall be assumed as follows:

Lot Area	Impervious Cover
1 acre or greater	5,000 sq. ft.
10,000 sq. ft. - 1 acre	3,000 sq. ft.
5,750 sq. ft. - 10,000 sq. ft.	2,500 sq. ft.
less than 5,750 sq. ft.	2,000 sq. ft.

(d) Impervious cover calculations shall include each roadway within a proposed development only up to a maximum pavement width of forty-four (44) feet. Requirements for detention, sedimentation, or filtration of runoff from such roadways are not affected by this provision.

(e) Development adjacent to roadways built as a City of Austin Capital Improvements Program project after the effective date of this ordinance shall include in its impervious cover calculations pavement width for the roadway up to a maximum of forty-four (44) feet and the associated right-of-way, or one-half the pavement width and right-of-way for roadways external to but adjacent to the development.

SEC. 13-15-243-245. RESERVED

DIVISION 5. ADDITIONAL STANDARDS FOR WATER SUPPLY WATERSHEDS

SEC. 13-15-246. COMPLIANCE

In addition to the requirements listed above, all development in watersheds designated as "Water Supply Suburban" and "Water Supply Rural" categories shall conform to the requirements in this Part.

SEC. 13-15-247. ROADWAYS

(a) In watersheds designated as Water Supply: Rural and Water Supply: Suburban Class I, street and right-of-way design for local and residential collector streets in the Critical Water Quality Zone and the Water Quality Buffer Zone must comply with the alternative urban street standards for streets without curbs and gutters set out in Division 2.1 of Article IV of the Subdivision Chapter, subject to the density limitations of that Division.

VOL 12 2 4820

R0058113

(b) Commercial and industrial streets may be designed to maximize overland drainage through the use of frequent curb openings, roadside swales, or other means. Arterial streets shall be designed in accordance with the City of Austin's Roadway Plan.

(c) Roadways in the Upland Zone may utilize the alternative urban street standards set out in Division 2.1 of Article IV where consistent with transportation concerns, and the density limitations of Division 2.1.

(d) Street right-of-way width established under Section 13-3-83 of the Subdivision Chapter may be varied by the Planning Commission for areas located outside the City limits within the "Water Supply Rural" and "Water Supply Suburban" watersheds after the Commission has considered:

1. Reports from the Department of Urban Transportation and the Office of Land Development Services, in which the adequacy of proposed alternative widths have been assessed.

2. The applicant's written justification for the variance.

3. The applicant's preliminary plans of the streets proposed to be built under the proposed variance.

(e) The requirement for curbs and gutters in urban subdivisions may be waived by the Planning Commission after the Commission has considered reports from the Directors of the Department of Urban Transportation and the Office of Land Development Services, in which the adequacy of proposed alternatives to satisfying the needs for storm drainage, traffic safety and the general public welfare are assessed.

SEC. 13-15-248. DRIVEWAYS

(a) Every lot shall be reasonably accessible by vehicle from the roadway to the probable building site. For a minimum travel distance of twenty-five (25) feet from the right-of-way edge, the driveway grade may exceed fourteen (14) percent only with specific approval of surface and geometric design proposals by the Urban Transportation Department and the Office of Land Development Services. This required specific approval shall be so noted on the subdivision plat with approval to be obtained when specific driveway plans are submitted by the builder.

(b) A joint-use driveway may be utilized to access up to eight (8) residential units, as an alternative to a public or private street. For joint-use driveways, paving width shall be no less than twenty (20) feet. Such driveways may utilize a design speed no lower than ten (10) mph. The Director of the Office of Land Development Services

VOL 12 2 4821

R0058114

shall consider recommendations from the Urban Transportation Department on driveway grades and length for each site prior to approving a joint-use driveway. The use of joint-use driveways does not eliminate the requirements of adequate road frontage for each lot. The joint use driveways shall be shown on the preliminary plan. A note shall be placed on the final plat indicating the lots utilizing the joint use driveways for access and prohibiting access to such lots except by way of the joint use driveways.

SEC. 13-15-249. OVERLAND FLOW

(a) Drainage patterns should be designed to prevent erosion, maintain infiltration and recharge of local seeps and springs, and attenuate the harm of contaminants collected and transported by stormwater. Overland sheet flow and natural drainage features and patterns shall be maintained whenever possible and the dispersion of runoff back to sheet flow shall be a primary objective of drainage design where possible, depending on volumes and velocities of runoff for the subdivision, as opposed to concentrating flows in storm sewers and drainage ditches.

(b) Construction of enclosed storm sewers and impervious channel linings are permitted only when the Director of the Office of Land Development Services, on the basis of competent engineering evidence, concludes that such storm sewers or impervious linings are the preferred option.

(c) If storm sewers are deemed necessary as specified in (b) above, an applicant shall design his/her drainage system to mitigate its harmful impact on water quality by using structural devices or other methods to prevent erosion and dissipate discharges from outlets wherever practicable, and by locating discharges to maximize overland flow through buffer zones or grass-lined swales.

SEC. 13-15-250. WASTEWATER RESTRICTIONS

(a) Sewer lines shall not be located in Critical Water Quality Zones other than for necessary crossings, except upon approval of a variance from this Section by the Planning Commission which shall be considered pursuant to an environmental assessment and the applicant evaluating the environmental impacts of alternative sewer alignments. At the request of the Environmental Review Division of the Office of Land Development Services, the applicant shall examine and evaluate alternative alignments prior to the Planning Commission hearing on the variance request. In the event it is concluded that the wastewater line should be in the Critical Water Quality Zone, it shall be located outside the two (2) year floodplain except as consistent with regulations adopted by the City Council.

VOL 12 2 4822

R0058115

(b) Unsewered lots overlying the Edwards Aquifer Recharge Zone shall use alternative sewage disposal systems which utilize final effluent disposal other than conventional soil absorption drainfields, and shall be installed in accordance with this Article and Chapter 6-5 of the City Code.

(c) Residential lots utilizing on-site wastewater disposal systems shall be at least one (1) acre in size and shall have at least one half (1/2) acre of contiguous land with slope of less than fifteen (15) percent gradient or have at least three quarters (3/4) of an acre of contiguous land with less than twenty-five (25) percent gradient; provided, however, that such systems shall not be located within the Critical Water Quality Zone.

(d) All construction of sewer systems within the Edwards Aquifer Recharge Zone shall comply with the special construction standards of Section VII-B of the City of Austin manual, Standard Specifications for Water and Wastewater Utility Construction.

(e) Projects utilizing wastewater treatment by land application shall have at least eight thousand (8,000) square feet of irrigated land per living unit equivalent (L.U.E.), as defined by the City of Austin Water and Wastewater Department or at least seven thousand (7,000) square feet of irrigated land per living unit equivalent (L.U.E.) and six (6) inches of topsoil. No irrigation shall be allowed on slopes of greater than fifteen (15) percent gradient or in the Critical Water Quality Zone or one hundred (100) year floodplain. Package treatment plants shall have at least one hundred (100) days of storage capacity available in the event of wet weather conditions or plant failure. All such systems shall provide for forty-eight (48) hours of storage capacity if utilizing subsurface effluent disposal. No irrigation shall take place during wet weather conditions.

(f) Commercial development must locate all disposal areas outside of the 40% buffer zone as required in Section 13-15-285(b)(2).

SEC. 13-15-251. BLASTING

(a) Blasting on property located directly over the Edwards Aquifer Recharge Zone is limited to areas outside of the Critical Water Quality Zone and Water Quality Buffer Zone, unless the applicant demonstrates that no feasible alternative exists.

(b) Blasting is prohibited within three hundred feet (300') of any Critical Environmental Feature, as defined in Section 13-15-203, unless the applicant demonstrates that no feasible alternative exists.

VOL 12 2 4823

R0058116

SEC. 13-15-252. INDUSTRIAL USES

(a) An applicant proposing any industrial use, as defined in the City of Austin Zoning Code (Ch. 13-2A), and which is not completely enclosed within a building or buildings, must provide a pollutant attenuation plan which:

1. Proposes methods to capture the first one-half (1/2) inch of runoff from developed areas to contain and filter pollutants generated on-site as specified in Section 13-15-238 of this Chapter.

2. Retains dust and other particulate matter on-site, to the greatest extent feasible.

(b) The design of storage facilities for hydrocarbon or hazardous substances, including leak detection systems, spill containment areas, or other control measures shall meet the requirements as set out in 9-10-530, (Hazardous Materials Ordinance).

SEC. 13-15-253.-260. RESERVED

DIVISION 6. SUBURBAN WATERSHEDS - MAXIMUM DEVELOPMENT INTENSITY

SEC. 13-15-261. COMPLIANCE

All development located in watersheds designated herein as "Suburban" must comply with the provisions of this Division, which are summarized in Table 1 (Exhibit "B", which is incorporated herein by reference).

SEC. 13-15-262. WATERWAY DEFINITIONS

Minor, intermediate, and major waterways shall be designated for any channel, creek, stream, branch or watercourse according to drainage area as follows:

Waterway	Drainage Area
Minor	320 acres - 640 acres
Intermediate	640 acres - 1280 acres
Major	over 1280 acres

SEC. 13-15-263. CRITICAL WATER QUALITY ZONE

The critical water quality zone shall remain free of all development activity, except as provided for by Section 13-15-232 of this Article.

VOL 12 2 4824

R0058117

SEC. 13-15-264. WATER QUALITY BUFFER ZONE

(a) Water quality buffer zones shall be established parallel to all critical water quality zones, except for minor waterways and along the shoreline of Town Lake, and shall extend from the outer boundaries of the critical water quality zone for one hundred and fifty feet (150') along major waterways and one hundred feet (100') along intermediate waterways.

(b) The projected impervious cover in any development or portion thereof that lies within the water quality buffer zone shall not exceed thirty (30) percent of the land area of the zone, exclusive of land within a one hundred year floodplain.

(c) Detention/sedimentation and sedimentation/filtration basins may be located in the water quality buffer zone.

13-15-265. UPLANDS ZONE

(a) The projected impervious cover for all one-family residential development of land in the uplands zone with minimum lot sizes of 5,750 square feet or more shall not exceed fifty (50) percent of the net site area, or sixty (60) percent if transfers of development intensity are made in accordance with Section 13-15-266 herein.

(b) The projected impervious cover for all one-family and two-family residential development of land in the uplands zone, other than those subject to (a) above, shall not exceed fifty-five (55) percent of the net site area, or sixty (60) percent if transfers of development intensity are made in accordance with Section 13-15-266 herein.

(c) The projected impervious cover for multi-family residential development of land in the uplands zone shall not exceed sixty (60) percent of the net site area, or seventy (70) percent if transfers of development intensity are made in accordance with Section 13-15-266 herein.

(d) The projected impervious cover for commercial development of land in the uplands zone shall not exceed eighty (80) percent of the net site area, or ninety (90) percent if transfers of development intensity are made in accordance with Section 13-15-266 herein.

SEC. 13-15-266. TRANSFER OF DEVELOPMENT INTENSITY

(a) For every one acre of land in the critical water quality zone which is dedicated to the City in fee simple and the gift is approved by the City, the applicant is entitled to an additional twenty thousand (20,000) square feet of impervious cover on lands in the uplands zone. Dedication of land under this section may be credited toward satisfaction of the requirements of the Parkland Dedication Ordinance in accordance with regulations adopted by the City Council.

VOL 12 2 4825

R0058118

(b) For every one acre of land in the water quality buffer zone which is left undeveloped and undisturbed and is not included in impervious cover calculations elsewhere, the applicant is entitled to an additional twenty thousand (20,000) square feet of impervious cover on lands in the uplands zone.

(c) For every one acre of land in the uplands zone which is located within a buffer of a Critical Environmental Feature and which is left natural and undisturbed, the applicant is entitled to an additional twenty thousand (20,000) square feet of impervious cover on lands elsewhere in the uplands. Such buffer area may also be included in the net site area calculations for the upland zone.

(d) Eighty-five (85) percent of the transfer credit in (b) is permitted for golf courses and other recreational uses which are restored using predominantly native plants and grasses and which provide a plan for minimizing the use and impact of pesticides, herbicides and fertilizers. Fifty (50) percent of the transfer credit is permitted for land used for wastewater disposal.

(e) For every one acre of land in the uplands zone which is utilized for wastewater irrigation; is legally restricted against any future development, and leaves the irrigation area in a natural state (other than for necessary irrigation lines and tailwater control berms), the applicant is entitled to an additional twenty thousand (20,000) square feet of impervious cover elsewhere in the uplands zone.

(f) Development intensity may not be transferred to a receiving tract whose boundary is beyond a one-mile radius from the transferring tract unless the tracts are either contiguous and under single ownership or are not separated by and owned by someone other than the applicant.

(g) Development intensity rights may not be transferred unless the transferring tract is platted concurrently with the receiving tract and all rights are transferred from the transferring tract at that time.

(h) An applicant transferring development intensity must note the transfer on the plats of both the transferring and receiving tracts, in a manner satisfactory to the Director of Land Development Services, and must file in the deed records a restrictive covenant, approved by the City Attorney, that runs with the transferring tract.

SEC. 13-15-267. STRUCTURAL CONTROLS

(a) Sedimentation/filtration basins shall be required to serve all commercial and multi-family development with impervious cover in excess of twenty (20) percent of the net site area.

VOL 12 2 4826

R0058119

(b) Detention/sedimentation or retention/sedimentation basins shall be required for all other residential development with impervious cover in excess of twenty (20) percent of the net site area.

(c) Sedimentation/filtration [and detention/sedimentation] basins shall be designed in accordance with the provisions of Section 13-15-238.

SEC. 13-15-268.-270. RESERVED

DIVISION 7. WATER SUPPLY SUBURBAN WATERSHEDS - MAXIMUM DEVELOPMENT INTENSITY

SEC. 13-15-271. COMPLIANCE

All development located in watersheds designated herein as "Water Supply Suburban" must comply with the provisions of this Division which are summarized in Table 1 (Exhibit "B", which is incorporated herein by reference), according to the following subcategories:

(a) Class I: Bull, West Bull, Dry (North), Dry (West), Taylor Slough, other Lake Austin (east side from Tom Miller Dam to Bull Creek), Town Lake (north side from Johnson Creek to Tom Miller Dam), Town Lake (south side from Barton Creek to Tom Miller Dam), Barton Creek (east of Barton Creek and north of Loop 360), and that portion of the Slaughter Creek watershed (downstream of FM 1826) which is located in the Edwards Aquifer Recharge or Contributing Zones.

(b) Class II: That portion of the Williamson Creek watershed which is located in the Edwards Aquifer Recharge or Contributing Zones.

(c) Class III: Those portions of the Lake, Rattan, Buttercup, and Brushy Creek watersheds which are located in the Edwards Aquifer Recharge or Contributing Zones.

SEC. 13-15-272. WATERWAY DEFINITIONS

Minor, intermediate and major waterways shall be designated for any channel, creek, stream, branch, or watercourse according to Class I, II, or III designation and drainage area as follows:

	Drainage Area (acres)		
Waterway	Class I	Class II	Class III
Minor	128-320	128-320	320-640
Intermediate	320-640	320-640	640-1280
Major	over 640	over 640	over 1280

VOL 12 2 4827

R0058120

SEC. 13-15-273. CRITICAL WATER QUALITY ZONE

The critical water quality zone shall remain free of all development activity, except as provided for by Section 13-15-232 of this Article.

SEC. 13-15-274. WATER QUALITY BUFFER ZONE

(a) Water quality buffer zones shall be established parallel to all critical water quality zones, except along the shorelines of Lake Austin and Town Lake, and shall extend from the outer boundaries of the critical water quality zone for three hundred feet (300') along major waterways, two hundred feet (200') along intermediate waterways, and one hundred feet (100') along minor waterways.

(b) No development other than that permitted in the Critical Water Quality Zone is permitted in the water quality buffer zone where such zone lies over the South Edwards Aquifer Recharge Zone.

(c) Except as restricted by (b), the projected impervious cover in any development or portion thereof that lies within the water quality buffer zone shall not exceed the following maximums within the zone, exclusive of land within a one hundred year floodplain:

	Class I	Class II	Class III
Impervious Cover:	18%	30%	30%

(d) No detention and/or sedimentation/filtration basins which serve development in the uplands zone shall be permitted in the water quality buffer zone; provided, however, that sedimentation/filtration basins to serve that portion of any development located in the buffer zone shall be permitted in the buffer zone, and that the Director of the Office of Land Development Services may administratively vary the requirement where it is determined that locating a pond in the buffer minimizes environmental impact.

SEC. 13-15-275. UPLANDS ZONE

(a) The projected impervious cover for all one-family residential development of land in the uplands zone with minimum lot sizes of 5,750 square feet or more shall not exceed the maximums specified below based on the net site area, or the maximums specified if transfers of development intensity are made in accordance with Section 13-15-276 herein:

	Class I	Class II	Class III
Impervious Cover	30%	40%	45%
With Transfer	40%	55%	50%

VOL 12 2 4828

R0058121

(b) The projected impervious cover for all one-family and two-family residential development of land in the uplands zone, other than those subject to (a) above, shall not exceed the maximums specified below based on the net site area, or the maximums specified if transfers of development intensity are made in accordance with Section 13-15-276 herein:

	Class I	Class II	Class III
Impervious Cover	30%	40%	55%
With Transfer	40%	55%	60%

(c) The projected impervious cover for multi-family residential development of land in the uplands zone shall not exceed the maximums specified below based on the net site area, or the maximums specified if transfers are made in accordance with Section 13-15-276 herein:

	Class I	Class II	Class III
Impervious Cover	40%	60%	60%
With Transfer	55%	65%	65%

(d) Except as provided by Subsections (e) and (f) below, the projected impervious cover for commercial development of land in the uplands zone shall not exceed the maximums specified below based on the net site area, or the maximums specified if transfers are made in accordance with Section 13-15-276 herein:

	Class I	Class II	Class III
Impervious Cover	40%	60%	65%
With Transfer	55%	70%	70%

(e) Notwithstanding (d) above, the projected impervious cover for retail commercial development in Class I watersheds shall not exceed fifty (50) percent of the net site area, or sixty (60) percent if transfers of development intensity are made in accordance with Section 13-15-276 herein, for all land within one thousand feet (1000') of the right-of-way of two intersecting roadways, each designated as a Major Arterial, Parkway, Expressway, or Freeway in the Austin Metropolitan Area Roadway Plan, as in effect on January 1, 1986 where at least one of the roadways is designated a Parkway, Expressway, or Freeway, limited, however, to intersections which are located within the City limits of the City of Austin or which are annexed thereto at a later date or which request limited or full purpose annexation at the time for final plat approval.

VOL 12 2 4829

R0058122

(f) Notwithstanding (d) above, the projected impervious cover for retail commercial development in Class I watersheds shall not exceed sixty (60) percent of the net site area, or seventy (70) percent if transfers of development intensity are made in accordance with Section 13-15-276 herein, for all land within one thousand five hundred feet (1500') of the right-of-way of two intersecting roadways maintained by the State, where such intersections are located within the City limits of the City of Austin or are annexed thereto at a later date or which request limited or full purpose annexation at the time of final plat approval.

(g) The distances specified from the above intersections are intended to create 1000 foot squares at each corner under (e) and 1500 foot squares at each corner under (f), for impervious cover calculations purposes.

(h) Impervious cover allowances for development subject to (e) and (f) above shall be pro-rated according to retail, other commercial, or residential land uses within those areas when mixed-use development is proposed.

(i) Nothing herein limits the authority of the City Council in the zoning process to limit impervious cover below the maximum specified for tracts determined by the Council to be particularly sensitive environmentally, including but not limited to, having a critical water quality zone or critical environmental feature on or near the site.

SEC. 13-15-276. TRANSFER OF DEVELOPMENT INTENSITY

(a) Except as limited in (c), for every one acre of land in the critical water quality zone which is dedicated to the City or another in fee simple and the gift is approved by the City, the applicant is entitled to additional impervious cover on lands in the uplands zone as follows:

	Class I	Class II	Class III
Impervious Cover (Sq. Ft.)	15,000	20,000	20,000

Dedication of land under this section may be credited toward satisfaction of the requirements of the Parkland Dedication Ordinance in accordance with regulations adopted by the City Council.

(b) Except as limited in (c) and (d), for every one acre of land in the water quality buffer zone which is left undeveloped and undisturbed and is not included in impervious cover calculations elsewhere, the applicant is entitled to additional impervious cover on lands in the uplands zone as follows:

VOL 12 2 4830

R0058123

	Class I	Class II	Class III
Impervious Cover (Sq. Ft.)	15,000	20,000	20,000

(c) Only one-half of the above transfer credit is permitted for land which lies over the South Edwards Aquifer Recharge Zone.

(d) Eighty-five (85) percent of the transfer credit in (b) is permitted for golf courses and other recreational uses which are restored using predominantly native plants and grasses and which provide a plan for minimizing the use of pesticides, herbicides, and fertilizers. Fifty (50) percent of the transfer credit is permitted for land used for wastewater disposal.

(e) For every one acre of land in the uplands zone which is located within a buffer of a Critical Environmental Feature and which is left natural and undisturbed, the applicant is entitled, in addition to net site area calculations for that land, to additional impervious cover on lands elsewhere in the uplands zone as follows:

	Class I	Class II	Class III
Impervious Cover (Sq. Ft.)	15,000	20,000	20,000

(f) For every one acre of land in the uplands zone which is utilized for wastewater irrigation, is legally restricted against any future development, and leaves the area in a natural state (other than for necessary irrigation lines and tailwater control berms), the applicant is entitled to additional impervious cover elsewhere in the uplands zone as follows:

	Class I	Class II	Class III
Impervious Cover (Sq. Ft.)	15,000	20,000	20,000

(g) Development intensity may not be transferred to a receiving tract whose boundary is beyond a one-mile radius from the transferring tract unless the tracts are either contiguous and under single ownership or are not separated by and owned by someone other than the applicant.

(h) Development intensity rights may not be transferred unless the transferring tract is platted concurrently with the receiving tract and all rights are transferred from the transferring tract at that time.

(i) An applicant transferring development intensity must note the transfer on the plats of both the transferring and receiving tracts, in a manner satisfactory to the Director of Land Development Services, and must file in the deed records a restrictive covenant, approved by the City Attorney, that runs with the transferring tract.

VOL 12 2 4831

R0058124

SEC. 13-15-277. STRUCTURAL CONTROLS

(a) Sedimentation/filtration basins shall be required to serve all development with impervious cover in excess of twenty (20) percent of the net site area.

(b) Sedimentation/filtration and detention/sedimentation basins shall be designed in accordance with the provisions of Section 13-15-238.

SEC. 13-15-278.-280. RESERVED

DIVISION 8. WATER SUPPLY RURAL WATERSHEDS - MAXIMUM DEVELOPMENT INTENSITY

SEC. 13-15-281. COMPLIANCE

All development located in watersheds designated herein as "Water Supply Rural" must comply with the provisions of this Division, which are summarized in Table 1 (Exhibit "B", which is incorporated by reference herein).

SEC. 13-15-282. WATERWAY DEFINITIONS

Minor, intermediate, and major waterways shall be designated for any channel, creek, stream, branch, or watercourse according to drainage area as follows:

Waterway	Drainage Area
Minor	64 acres - 320 acres
Intermediate	320 acres - 640 acres
Major	over 640 acres

SEC. 13-15-283. CRITICAL WATER QUALITY ZONE

The critical water quality zone shall remain free of all development activity, except as provided for by Section 13-15-232 of this Article.

SEC. 13-15-284. WATER QUALITY BUFFER ZONE

(a) Water quality buffer zones shall be established parallel to all critical water quality zones, except along Lake Austin and Lake Travis, and shall extend from the outer boundaries of the critical water quality zone for three hundred feet (300') along major waterways, two hundred feet (200') along intermediate waterways, and one hundred feet (100') along minor waterways.

VOL 12 2 4832

R0058125

(b) No development other than that permitted in the Critical Water Quality Zone is permitted in the water quality buffer zone where such zone lies over the South Edwards Aquifer Recharge Zone.

(c) Except as restricted by (a), development in the water quality buffer zone is limited to:

1. Development authorized in the critical water quality zone;

2. Streets;

3. Drainage facilities;

4. Public and private parks and open space; and,

5. One and two-family residential housing units developed at an average density of one unit or less for every three (3) acres, exclusive of land within a one hundred year floodplain, with a minimum lot size of two (2) acres.

(d) Each lot or part of a lot located in both the water quality buffer zone and the critical water quality zone must have at least two (2) acres in the water quality buffer zone.

(e) No detention and/or sedimentation/filtration basins shall be permitted in the water quality buffer zone.

SEC. 13-15-285. UPLANDS ZONE

(a) Residential development in the uplands zone is limited to:

1. One and two-family residential housing units at an average density of one unit or less for every two (2) acres of net site area, with a minimum lot size of three-quarter acre, or up to one unit or less for every acre with a minimum lot size of one-half acre if transfers of development intensity are made in accordance with Section 13-15-286 herein.

2. Cluster housing at an average density of one (1) unit or less for each one (1) acre of net site area, or up to two (2) units per acre if transfers of development intensity are made in accordance with Section 13-15-286. Developments in watersheds other than Lake Austin or Lake Travis shall leave, or restore if necessary, at least forty percent (40%) (all in the uplands zone) of his/her proposed cluster housing site in or to its natural state and shall leave it in that state to serve as a buffer located contiguous to the development for the purpose of receiving overland drainage.

VOL 12 2 4833

R0058126

(b) Commercial development in the uplands zone is permitted, if:

1. Except as provided by Subsections (c), (d), and (e) below, the proposed impervious cover on the commercial site does not exceed twenty (20) percent of the net site area, or up to twenty five (25) percent if transfers of development intensity are made in accordance with Section 13-15-286 herein; and

2. Upon completion of development the applicant leaves or restores if necessary, at least forty (40) percent (all in the uplands zone) of his/her proposed commercial site in or to its natural state and leaves it in that state to serve as a buffer located contiguous to the development to receive runoff from the development for the purposes of overland drainage.

(c) Where commercial or multi-family development is either zoned appropriately by the City of Austin, is designated for such use by the City's Comprehensive Plan, is designated as such by a Municipal Utility District land plan which is part of an approved consent agreement with the City, or constitutes a maximum of five (5) percent of a subdivision with the remainder restricted to other residential or open space uses, impervious cover shall not exceed forty (40) percent of the net site area in the uplands zone, or up to fifty (50) percent if transfers of development intensity are made in accordance with Section 13-15-286 herein, and subject to the forty (40) percent buffer zone requirement of (b)(2) above.

(d) Notwithstanding (b) and (c) above, the projected impervious cover for retail commercial development shall not exceed fifty (50) percent of the net site area, or sixty (60) percent if transfers of development intensity are made in accordance with Section 13-15-286 herein, for all land within one thousand feet (1000') of the right-of-way of two intersecting roadways, each designated as a Major Arterial, Parkway, Expressway, or Freeway in the Austin Metropolitan Area Roadway Plan, as in effect on January 1, 1986, where at least one of the roadways is designated a Parkway, Expressway, or Freeway, limited, however, to intersections which are located within the City limits of the City of Austin or which are annexed thereto at a later date or which request is limited or full purpose annexation at the time of final plat approval.

(e) Notwithstanding (b) and (c) above, the projected impervious cover for retail commercial development shall not exceed sixty (60) percent of the net site area, or seventy (70) percent if transfers of development intensity are made in accordance with Section 13-15-286 herein, for all land within one thousand five hundred feet (1500') of the right-of-way of two intersecting roadways, maintained by the State, where such intersections are located within the City limits of the City of Austin or are annexed thereto at a later date or which request limited or full purpose annexation at the time of final plat approval.

VOL 12 2 4834

R0058127

(f) The distances specified from the above intersections are intended to create 1000 foot squares at each corner under (d) and 1500 foot squares at each corner under (e), for impervious cover calculation purposes.

(g) Impervious cover allowances for development subject to (d) and (e) above shall be pro-rated according to retail, other commercial, and residential land uses within those areas when mixed-use development is proposed.

(h) Nothing herein limits the authority of the City Council in the zoning process to limit impervious cover below the maximum specified for tracts determined by the Council to be particularly sensitive environmentally, including but not limited to having a critical water quality zone or critical environmental feature on or near the site.

(i) Development subject to (d) and (e) above is exempt from the forty percent buffer requirement for commercial development, but must provide filtration as per Section 13-15-287(b).

(j) Development or related activity necessitating restoration to the natural state is authorized in the forty (40) percent buffer zones above only for fences, utilities which cannot reasonably be located elsewhere, irrigation lines other than when associated with wastewater disposal, and access for these purposes and to the building site and clearing necessary for these purposes.

SEC. 13-15-286. TRANSFER OF DEVELOPMENT INTENSITY

(a) Except as limited by (c) and (d) below, for every one acre of land in the critical water quality zone or water quality buffer zone which is dedicated to the City or another in fee simple and the gift is approved by the City, the applicant is entitled to an additional one (1) one-family residential housing unit or to an additional six thousand (6,000) square feet of impervious cover for commercial or multi-family residential development in the uplands zone. Dedication of land under this section may be credited toward satisfaction of the requirements of the Parkland Dedication Ordinance in accordance with regulations adopted by the City Council.

(b) Except as limited by (c) and (d) below, for every one acre of land in the water quality buffer zone which is left undeveloped and undisturbed and is not included in density calculations elsewhere, the applicant is entitled to an additional one (1) one-family residential housing unit or to an additional six thousand (6,000) square feet of impervious cover for commercial or multi-family residential development in the uplands zone. Parkland gifts in (a) are counted separate from this provision and the transfers are cumulative.

VOL 12 2 4835

R0058128

(c) Only one-half of the above transfer credits are permitted for water quality buffer zone land which lies over the South Edwards Aquifer Recharge Zone.

(d) Eighty-five (85) percent of the transfer credits for water quality buffer zone land is permitted for golf courses and other recreational uses which are restored using predominantly native plants and grasses and which provide a plan for minimizing the use of pesticides, herbicides, and fertilizers. Fifty (50) percent of the transfer credit is permitted for land used for wastewater disposal, if within the water quality buffer zone.

(e) For every one acre of land in the uplands zone which is located within a buffer of a Critical Environmental Feature and which is left natural and undisturbed, the applicant is entitled, in addition to net site area calculations for that land, to an additional one (1) one-family residential housing unit or to an additional six thousand (6,000) square feet of impervious cover for commercial or multi-family residential development elsewhere in the uplands zone.

(f) For every one (1) acre of land in the uplands zone which is utilized for wastewater irrigation, is legally restricted against any future development, and leaves the irrigation area in a natural state (other than for necessary irrigation lines and tailwater control berms), the applicant is entitled to an additional one (1) one-family residential housing unit or to an additional six thousand (6,000) square feet of impervious cover for commercial or multi-family residential development elsewhere in the uplands zone.

(g) Development intensity may not be transferred to a receiving tract whose boundary is beyond a one-mile radius from the transferring tract unless the tracts are either contiguous and under single ownership or are not separated by and owned by someone other than the applicant.

(h) Development intensity rights may not be transferred unless the transferring tract is platted concurrently with the receiving tract and all rights are transferred from the transferring tract at that time.

(i) An applicant transferring development intensity must note the transfer on the plats of both the transferring and receiving tracts, in a manner satisfactory to the Director of Land Development Services, and must file in the deed records a restrictive covenant, approved by the City Attorney, that runs with the transferring tract.

SEC. 13-15-287. STRUCTURAL CONTROLS

(a) Except as required by Subsection (c) for one-family and two-family residential development in the Lake Austin and Lake Travis watersheds,

VOL 12 2 4836

R0058129

sedimentation/filtration basins shall be required to serve all residential and commercial development elsewhere in the Water Supply Rural Watersheds if the net site area contains more than 20 percent impervious cover; and either

1. There is less than 75 percent vegetative cover in the 40 percent buffer zone; or

2. More than 50 percent of the land in the 40 percent buffer zone has slopes in excess of 15 percent.

(b) Sedimentation/filtration basins shall be required to serve all commercial development if the net site area contains more than forty (40) percent impervious cover.

(c) Sedimentation/filtration basins shall be required to serve all one-family and two-family residential development in the Lake Austin and Lake Travis watersheds if the net site area contains more than 20 percent impervious cover.

(d) If structural controls are required by Subsection (a), an applicant may locate them in the 40 percent buffer zone if they are located to maximize overland flow and recharge in the undisturbed remainder of the 40 percent buffer zone.

(e) Sedimentation/filtration basins shall be designed in accordance with the provisions of Section 13-15-238.

SEC. 13-15-288.-290. RESERVED

PART 2. That Section 13-3-3 (Subdivisions) of the Austin City Code of 1981 is hereby amended to read as follows:

SEC. 13-3-3. COMPLIANCE REQUIRED.

No person shall create a subdivision of land within the City limits or within its extra-territorial jurisdiction without complying with the provisions of this Chapter. All plats and subdivisions of any such land shall conform to the rules and regulations set forth in this Chapter and to the provisions of Chapter 13-15, Article II (Comprehensive Watersheds Ordinance).

PART 3. That Division 1 of Article V (Special Requirements for Site Development and Use in Water Quality Related Environmentally Sensitive Areas) of Chapter 9-10 of the Austin City Code of 1981 is hereby amended to read as follows:

VOL 12 2 4837

R0058130

SEC. 9-10-161. SITE DEVELOPMENT PERMIT REQUIRED

No development shall be undertaken on any land, tract, parcel, or lot within the City limits or within its extra-territorial jurisdiction until a site development permit for said development has been obtained by the owner of said property from the Director of the Office of Land Development Services. This requirement shall not apply to any single-family or duplex residential structures or appurtenances thereto where one such structure is built per legal lot. No waterway development permit is required where a site development permit has been issued within the City limits, such site development permit has become effective and where all requirements of Article IV, Division 2 of Chapter 9-10 are met.

SEC. 9-10-162. COMPLIANCE REQUIRED

All development of land governed by this Article shall conform to the rules and regulations set forth in this Chapter and to the provisions of Chapter 13-15, Article II (Comprehensive Watersheds Ordinance).

SEC. 9-10-163. APPLICATION

(a) Application for a site development permit shall be submitted to the Director of the Office of Land Development Services and shall be accompanied by a site development plan.

(b) The Director of the Office of Land Development Services shall design and administer a system, including necessary forms, that coordinates the requirements of this Article and Division and the rest of this Chapter, minimizes duplication of requirements and conflict between them, and facilitates the expeditious processing of site development applications.

SEC. 9-10-164. FEES

Applications for permits required by the provisions of this Article shall be accepted only upon payment of the appropriate fees as established by ordinance.

9-10-165. ADVERTISING APPLICATION

(a) Within two (2) days of the filing of any application for a site development permit, the City shall place signs on property under application for the purposes of advertising said permit. The signs shall meet the following requirements:

1. Each sign shall be no smaller than eighteen (18) inches by thirty (30) inches;

VOL 12 2 4838

R0058131

2. Each sign shall include the words "Proposed Site Development Permit," plus such other information as may be determined necessary by the Director of the Office of Land Development Services.

(b) Signs placed on the property involved must be within ten (10) feet of any property line paralleling any established or proposed street and must be visible from that street.

(c) All required signs shall remain on the property until final disposition of the permit request is determined.

SEC. 9-10-166. ISSUANCE

(a) A site development permit not denied or disapproved by the Director of the Office of Land Development Services within twenty (20) days following the date of application therefore shall issue automatically to the applicant.

(b) If the Director of the Office of Land Development Services denies the permit or disapproves it pending receipt of additional information, he shall notify the applicant in writing via certified mail. His/her letter to the applicant shall be accompanied by a detailed statement of the reasons for such action, which reasons must be based on standards contained herein.

(c) The permit shall be effective ten (10) days after issuance unless an appeal is filed.

SEC. 9-10-167-170. RESERVED

PART 4. That the provisions of Chapter 9-10, Article V (Special Requirements for Site Development and Use in Water Quality Related Environmentally Sensitive Areas), Divisions 2 through 5; Chapter 13-3, Article VII (Special Requirements for Subdivisions in Environmentally Sensitive Areas); Secs. 13-3-116 through 13-3-126 (Lake Austin Watershed); Section 13-3-5.1 (Special Requirements for Lake Austin Peninsula); and Ordinance No. 840308-k (Lake Travis Watershed) are hereby superseded by this ordinance for all projects subject to its provisions.

PART 5. This ordinance shall be reviewed by the City Council no later than two (2) years after its effective date.

PART 6. If any provision, section, sentence, clause, or phrase of this ordinance, or the application of same to any person or set of circumstances, is for any reason held to be unconstitutional, void, or invalid (or is for any reason unenforceable), the validity of the remaining portions of this ordinance or its application to other

VOL 12 2 4839

R0058132

persons or sets of circumstances shall not be affected thereby, it being the intent of the City Council of the City of Austin adopting, and of the Mayor in approving this ordinance, that no portion hereof or provision or regulation contained herein shall become inoperative or fail by reason of any unconstitutionality or invalidity of any other portion, provision, or regulation.

PART 7. This ordinance shall become effective ten (10) days following the date of its passage as provided by the City Charter of the City of Austin.

BACKGROUND MATERIALS

4842

R0058135

7. Alternative Street Standards - develop roadway standards which minimize environmental disruption when located on steep slopes, across waterways, or over Recharge areas.

8. Streambank Erosion Control Assessment - undertake a comprehensive assessment of existing streambank erosion problem areas, evaluate streambank erosion potential and identify needs for streambank erosion control in urban and suburban watershed.

9. Wastewater Treatment - implement program for upgrading City's treatment plants to conform with the Governor's Committee recommendations for the Colorado River and its tributaries; also evaluate methods to assure long-term reliability of sewer lines, lift stations and plants.

10. Environmental Education - develop programs to educate the public about lawn care practices, oil and grease disposal, litter control, and agricultural runoff.

11. Edwards Aquifer Fund - assess feasibility of public/private fund for purchase of key recharge sites or other environmentally sensitive lands within the Recharge Zone, or for educational purposes.

12. Impact Mitigation Fund - assess feasibility of a percentage set-aside fund for impact mitigation on C.I.P. projects.

13. Industrial Waste Management Program - continue to improve spill response capability and improve compliance for storm sewer discharges.

14. Evaluation of Budget - review, at least every two years, the budget and funding of the items in this program in order to allow completion of projects in a timely and efficient manner.

We recognize that the Comprehensive Watersheds Ordinance, while representing a significant initial step, cannot alone be considered a water quality protection program for the City of Austin and feel that these other endeavors are necessary to assure that Austin's lakes, creeks, tributaries, and groundwater are adequately protected.

Sincerely,

Pat Malone, Chairman
Comprehensive Watersheds Ordinance Task Force

Legal humor, for the record

U.S. District Judge Jerry Buchmeyer of Dallas writes a regular and wonderfully funny column for the *Texas Bar Journal*. He has thieved some material from a volume called *More Humor in the Court*. I blave it from him. These have to do with taking depositions, sworn statements. As Judge Buchmeyer notes, lawyers are taught how to take a deposition but too often, not what May Happen when they do. Herewith:

Q: Are you married?
A: No, I am divorced.
Q: What did your husband do before you divorced him?
A: A lot of things that I didn't know about.

* * *

Q: Now, at the time you married Mr. Smith in December '78, did you love him?
A: Yes.
Q: Why?

* * *

Q: What is your name?
A: Ernestine McDowell.
Q: And what is your marital status?
A: Fair.

* * *

Q: Do you know how far pregnant you are right now?
A: I will be three months Nov.
Q: Apparently, then, the date of conception was Aug. 8?
A: Yes.
Q: What were you and your husband doing at that time?

* * *

Q: Wasn't this dog your favorite dog? Weren't you the favorite of this dog?
A: He never specified that. He never related that to me.

* * *

Q: Now, officer, besides the

Expanded creek rules drafted on urban runoff

Streams lacking protection targeted for pollution limits

By Robert Cullick
American-Statesman Staff

The city staff is writing ordinances that would expand pollution safeguards to creeks not protected by special development laws and is revising ordinances that already protect certain watersheds.

The move to expand coverage of city ordinances began in late summer, when an *American-Statesman* series pointed out that ordinances designed to mitigate urban runoff only protect creeks that empty into the Colorado River upstream of city water intake pipes. Eastern creeks, which join the Colorado downstream of Longhorn Dam, have no protection.

Staff for several offices, boards, and commissions began writing proposed changes to the watershed ordinances and caused confusion as to who was taking the lead role.

City Manager Jorge Carrasco announced plans in August to propose an expansion of coverage to Walnut Creek. The Environmental Board, whose role has been bolstered to include water quality protection, began writing an ordinance to cover the northern section of the Edwards Aquifer. Members of the Planning Commission began a subcommittee investigation. Mayor Frank Cooksey called for a moratorium on development in the Bear Creek and Onion Creek watersheds while an ordinance was being written for those areas.

The false starts ended in late October, when City Council member Smoot Carl-Mitchell introduced a resolution that directed the city staff to take the lead in developing ordinances.

The ordinances are to combat urban runoff — rainwater that washes chemicals, organic matter, and debris off roofs, pavements, and yards into storm sewers and city creeks, which carry the runoff into the Colorado.

Council member Smoot Carl-Mitchell helps focus the drafting process.

The pollution, directly attributed to growth, is filling the Colorado with sediment and adding pesticides, fecal coliform bacteria, and such heavy metals as lead, arsenic, and chromium. It also contains organic matter and petrochemicals that can debilitate the river as raw sewage does.

Curtis Williams, environmental coordinator for the Office of Land Development Services, is leading the effort to write ordinances to satisfy those in the environmental community calling for stricter rules and to calm the fears of developers, bankers, and business interests worried the laws will shut down growth throughout the county.

Williams was moved from the once independent Office of Environmental Resource Management when it was pruned and made part of the Planning and Growth Management Department. His move to Land Development Services was widely supported by environmental activists at City Hall.

Williams is appealing for a little time. There have been complaints that citywide water quality ordinances would be overly restrictive.

"I think they need to see what comes out," Williams said. "A lot of people's minds will be put at ease." Specifications of the intensity of development "will be high enough to do the development that is contemplated," he said. A draft of the staff proposal to the City Council will be out in early December, he said.

The Williams proposal could be considered a "measured response." Travis County and parts of Williamson County would be divided into several categories, depending on the level of pollution abatement desired.

Depending on the level of protection, the city would use one or more of four strategies. In all cases, development along creeks, including the laying of utility lines in creek bottoms, would be restricted.

Much of the area covered by the proposed ordinance is covered by watershed ordinances. Williams said he hopes to streamline the ordinances to make them more consistent and comprehensible.

Lake Travis, Lake Austin, and Barton Creek would receive the most restrictive protection. Inner city creeks — Shoal, Bouldin, Waller, and others — would receive the least protective, least restrictive controls since development of the watersheds is nearly complete.

In between would be protections for the eastern creeks that flow into the Colorado downstream of the city water intake. The protections there would allow more intensive development than in the western part of the county. Single family housing would not be affected in much of the eastern area

R0058137

VOL 12 2 4845

City of Austin
Founded by Congress, Republic of Texas, 1839
Municipal Building, Eighth at Colorado, P.O. Box 1088, Austin, Texas 78767 Telephone 512/499-2000

March 5, 1986

Mayor Frank C. Cooksey
and Councilmembers
City Hall
Austin, Texas

Dear Mayor Cooksey,

The Comprehensive Watersheds Ordinance Task Force recommends for your consideration, the following fourteen point program to address water quality needs in Austin, particularly in the urban watersheds. It was the belief of the Task Force that if the already heavily impacted Urban Watersheds were exempted from this ordinance, a program of retrofit and rehabilitation was necessary. Some of these items are applicable to all watersheds in Austin and are meant as guidance on future programs that the City should consider in addition to the ordinance this Task Force is transmitting to you. We urge you to consider these suggestions in future plans for water quality protection.

1. Urban Watersheds Retrofit Feasibility Study - identify locations, in major commercial areas, parks, schools, etc., to locate water quality control retrofit structures within the "Urban" watersheds, and develop control practices (including non-traditional approaches) suitable for urban watersheds.

2. Zoning Policies - develop a set of zoning policies, particularly oriented to the "Urban" watersheds, through which additional water quality protection can be assured, e.g., setbacks from creeks lower intensity near creeks, filtration, etc.

3. Erosion and Sedimentation Control Manual - amend to incorporate "Guidelines for Water Quality Ponds," and other technical criteria from the ordinance if appropriate.

4. Floodplain Ordinance - finalize ordinance to better define "natural and traditional character" of waterways and permitted floodplain alterations.

5. Water Quality Monitoring Program - annual and periodic status reports on the monitoring program, along with specific goals to be evaluated.

6. Drainage Criteria Manual - amend to provide criteria for overland flow and alternatives to direct discharges to waterways.

VOL 12 2 4 8 4 6

R0058139

Table 3

Water Quality Strategies for Austin Watersheds

Type of Watershed	Water Quality Strategies	Justification
Exempt Watersheds: (Urban) Blunn, East Boggy, East Bouldin, Johnson, Shoal, Town Lake (MoPac - Hwy. U.S. 183) Waller, West Bouldin, Fortview, Tannehill	Structural Controls - Commercial and Multi-family exceeding 3 acres	Highly urbanized watersheds already developed in most areas. Very little land area available for Water Quality protection other than through minimal structural controls.
Urban Watersheds: (Suburban) Buttermilk, Carson, Cottonmouth, Country Club, Decker, Dry, Elm, Gilleland, Harris Branch, Maha, Marble, Onion, South Boggy, Town Lake (MoPac to Tom Miller Dam), Walnut, Little Walnut, Wilbarger, Williamson, Slaughter, Bear, Colorado River	Water Quality Zones Impervious Cover Limitations Structural Controls	Public health, recreation, and aesthetic benefits of Water Quality protection only, intense development and urban services committed or planned.
(Water Supply - Suburban) Water Supply - Moderate Intensity Aquifer-related Slaughter, Aquifer-related Williamson, Brushy, Bull Creek, Lake Creek, Rattan	Water Quality Zones (strict) Impervious Cover Limitations (strict) Structural Controls	Drinking Water Supply; Edwards Aquifer recharge; relatively flat topography; committed or planned for moderate development intensity. Likelihood of urban services in the future.
(Water Supply - Rural) Water Supply - Low Intensity Aquifer-related Onion, Barton, Aquifer- related Bear and Little Bear, Lake Austin, Lake Travis	Water Quality Zones (strict) Density Controls Very Limited Commercial Development	Drinking water supply; Edwards Aquifer recharge; steeper topography; little Committment for intense development. Lack of urban services in the future. Needs low maintenance and administrative strategies.

PRIMARY
WATER QUALITY CONTROL STRATEGIES

WATER QUALITY ZONES - Critical Water Quality Zones and Buffer Zones around creeks to provide pollutant removal through overland flow and to minimize disturbance in close proximity to creeks.

DENSITY CONTROLS - Directly limits the amount of pollutants generated from a site by limiting the intensity of development and activity on the site.

IMPERVIOUS COVER LIMITATIONS - Indirectly limits the amount of pollutants generated from a site by limiting the impervious surfaces associated with development on a particular site.

STRUCTURAL CONTROLS - Engineering design which provides for pollutant removal through the use of sedimentation and filtration ponds.

R0058141

Exemptions continued:

- Resubdivisions of preliminary or final subdivisions approved prior to 5/19/86 when not increasing density or impervious cover.
- Subdivisions within a MUD (approved by 5/19/86) that is outside the City.
- Subdivisions within an in-City MUD approved by 5/19/86 with zoning approved by 5/19/86.

B. Waivers - All waivers must be requested through the Environmental Review Division and must go to the Planning Commission and City Council for approval. Waivers must be submitted within 90 days of 5/19/86.

- Subdivisions in the process as of 5/19/86 and not otherwise exempt.
- Site development permits in the process as of 5/19/86 and not otherwise exempt (an approved preliminary or final subdivision).

C. Hardship Provisions

- from 5/19/86 until 5/1/87 any property owner may request that OLDS staff review their project or property to determine the amount of impervious cover or residential units that are lost under this ordinance as compared to previous ordinances.
- if this loss exceeds 50% staff and the applicant may work out a compromise that the applicant can take to the City Council for approval or opt to comply with the new ordinance.

IV. Water Quality Zones

- Critical Water Quality Zones are established along creeks with drainage basins over certain sizes (depends on which category). Each waterway is classified as major, minor, or intermediate. Generally defined as the floodplain but there are minimums and maximums (e.g. Water Supply Rural: Drainage basin between 64 and 320 acres: minor waterway) - no development in the CWQZ.

VOL 12 2 4849

Table 2

Watershed Category Characteristics

Watersheds	Water Quality and Supply	Topography	Development Intensity	Utility Service
Exempt	Creeks highly disturbed	Relatively flat	Intense development	Committed, in place
	Drainage function		Already substantially built out	
Urban	Creeks disturbed in some areas	Flat to rolling	Intense development planned or committed	Planned or committed
	Public health, recreational, aesthetic benefits			
Water Supply - Moderate Intensity	Drinking water supply	Flat to rolling	Moderate densities committed or planned	Planned for the near future
	Edwards Aquifer recharge			
Water Supply - Low Intensity	Drinking water supply	Flat to steep	Low intensity limited commercial	Not currently planned
	Edwards aquifer recharge

VOL 12 2 4851

Comprehensive Watersheds Ordinance

Summary

I. Ordinance Structure

- Combines site development and subdivision regulations in one document.
- Note that if a commercial subdivision wishes to submit the specific information on individual lots during site development, it is now automatic - no variance needed.
- Beyond the basic submittal requirements, an environmental assessment is required for all water supply watersheds.
- There are two tiers of standards: general standards for all watersheds and additional standards for water supply watersheds.
- Final three sections set out the development intensities and structural control requirements.

II. Categories

- Urban - Downtown watersheds.
- Suburban - Eastern watersheds. Non-water supply.
- Water Supply Suburban - watersheds committed to a certain development intensity and level of City services, near-western part of the City - Already had previous watershed ordinance
- Water Supply Rural - watersheds with little or no committed City services for western boundaries of City. Had previous watershed ordinances.

III. Exemptions, Waivers, Hardships
(see attachment for Exemptions and Waivers)

A. Exemptions

- "Urban" watersheds
- All final plats for subdivisions with an approved preliminary prior to 5/19/86.
- Site development permits for lots which are legal lots or part of an approved preliminary or final prior to 5/19/86.
- Site development permits for tracts with approved zoning site plans, PDA's, PUD site plans, waterway development permits, County development permits approved prior to 5/19/86.

R0058144

General Standards continued:

- Spoil Disposal - cannot be placed in 100 year floodplain or on slopes over 15% unless placed in a planned roadway area, stormwater detention facility, building site or parks site.

- Construction on Slopes - no roadway or driveways on slopes over 15% unless providing access to flatter slopes, no structures on slopes over 15% except 10% impervious cover allowed on slopes of 15-25% as long as specified containment or terracing is done.

- Sedimentation/Filtration Basins - Basins required for certain types of development over specified impervious cover. To be designed in accordance with new Design Guidelines drafted by Public Works.

- Critical Environmental Features - 50-150 foot setbacks required from springs, seeps, bluffs, canyon rimrocks, wetlands, faults or sinkholes.

- Innovative Management Practices - allows applicants to submit plans to recharge groundwater via CEF's where deemed appropriate.

- Wastewater Treatment - recommends that wastewater package treatment plants meet certain discharge or no discharge standards that were established by the Governor's Task Force on the Colorado River.

- Impervious Cover Calculations - no credit for pervious pavers, residential impervious cover assumptions for different lot sizes, sets out limits for calculating roadway impervious cover.

B. Additional: Water Supply Watersheds

- Roadways - alternative urban standards for local and residential collectors, gives Planning Commission authority to vary roadway widths when recommended by staff.

- Driveways - limits grades to 14% without UTD approval and limits joint use driveways to accessing 8 units.

- Overland Flow - preference for overland flow, use of enclosed storm sewers only with permission from CLDS.

VOL 12 2 4852

Water Quality Zones continued:

- Water Quality Buffer Zones are established parallel to all CWQZ's except for minor waterways in the Suburban category. Sizes of Buffer Zones differ depending on type of waterway and which category; WQBZ's allow for limited development, between 18-30% impervious cover depending on category (1 unit per 3 acres in Water Supply Rural).

V. Submittal Requirements

A. General

- topo map, floodplain limits, slope map, net site area and impervious cover calculations, location of Critical Environmental Features, areas of cut and fill in excess of four feet and a vegetative description (other minor requirements such as spoils disposal areas also).

B. Water Supply Watersheds

- Environmental Assessment - includes three elements; a hydrogeologic, wastewater and vegetative assessment.

VI. Standards

A. General

- CWQZ - no development except limited roadway crossing, utilities and certain park uses.

- Erosion and Sedimentation Control - all projects must submit a plan and comply - using the Erosion and Sedimentation Control Manual for guidance.

- Clearing and Temporary Site Disturbance - limits surveying width to 15 feet, length of time between roughcutting and surfacing cannot exceed 18 months, limits roadway clearing width to twice the surface width.

- Cut and Fill - no cut and fill over four feet except for within roadway right-of-way and for structural excavation.

VOL 12 2 4853

Net Site Area

Assume:

Total Site:	100 acres
CWQZ:	10 acres (all 0-15% slope)
WQBZ:	10 acres (5 ac. 15-25%; 5 ac. 25-35%)
Uplands:	80 acres
0 - 15%:	50 acres
15 - 25%:	10 acres
25 - 35%:	10 acres
35% +:	10 acres

Example: Water Supply Suburban Class I (MF/Comm)

CWQZ = No development
WQBZ = 18% impervious x 10 ac. = 1.8 acres
Net Site Area =
50 ac (0-15%) x 100% = 50 ac.
10 ac (15-25%) x 40% = 4 ac.
10 ac (25-35%) x 20% = 2 ac.

Net Site Area: 56 ac.

Allowable Impervious = 40% x 56 ac. = 22.4 acres
Total = 24.2 acres

With Transfer (no development in WQBZ, dedicate CWQZ) 22.4 acres
20 acres x 15,000 sq. ft./ac. 6.9 acres
Total allowable impervious with transfer: 29.3 acres

ACKNOWLEDGMENTS

The study was sponsored by AMSA (the Association of Metropolitan Sewerage Agencies) under the general direction of Ken Kirk, the Executive Director, and the AMSA Board of Directors. This study was funded in part under a cooperative agreement (Project ID No. X823736010) from the U.S. Environmental Protection Agency (EPA). Greg Schaner provided technical direction and served as AMSA's Project Manager. Paula Dannenfeldt and Mark Hoeke of AMSA were instrumental in the coordination and production of the final report. Tim Dwyer of EPA's Office of Wastewater Management served as the Project Officer for EPA. Ross Brennan, EPA's CSO Matrix Manager, provided advice throughout the study.

Consultant support was led by Mike Sullivan of Limno-Tech, Inc., the primary author of this report. Karen Gontasz of Limno-Tech, Inc. produced nearly all of the graphics and assisted with layout. Greg Welter of O'Brien & Gere Engineers, Inc. provided technical assistance in all aspects of the study. Dwight MacArthur of O'Brien & Gere, Inc. assisted with field interviews and general review. Phil Braswell of TLI Systems facilitated the Work Group and Focus Group meetings.

Members of the Work Group that guided the project are as follows:

Cliff Arnett	Columbus Water Works, Columbus, GA
Mary Belefski	EPA Office of Water, Washington, DC
Tom Brueckner	Narragansett Bay Commission, Providence, RI
Nicole Cromwell	Save the Bay, Providence, RI
Gary Fujita	Detroit Water and Sewer Department, Detroit, MI
Larry Gaugler	EPA Region II, New York, NY
Mike Hershfield	Center for Marine Conservation, Washington, DC
Stephen John	National League of Cities, Washington, DC
Jeff Jordan	City of South Portland, ME
Victor McMahan	American Rivers, Washington, DC
Drew Mihocko	City of Philadelphia Water Department, Philadelphia, PA
Michele Pla	San Francisco Dept. of Public Works, San Francisco, CA
Pravan Sangani	West Virginia Department of Environmental Protection
Steve Silva	EPA Region I, Boston, MA
Dean Studer	Illinois Environmental Protection Agency
C.D. Vu	Pennsylvania Department of Environmental Resources

The Participants at Focus Group meetings and field interviews conducted as part of this study made an extremely valuable contribution to this effort, and they are recognized for their support in Appendix A. In addition, those individuals who provided assistance with anecdotal information and examples are also recognized for their support in Appendix A.

PERFORMANCE MEASURES FOR THE NATIONAL CSO CONTROL PROGRAM

EXECUTIVE SUMMARY

BACKGROUND AND PURPOSE

The National Combined Sewer Overflow (CSO) Control Policy (the CSO Policy) was signed on April 8, 1994. This signing culminated a lengthy process of policy development and negotiation among CSO communities, the U.S. Environmental Protection Agency (EPA), the states, and environmental groups. Based upon the National Pollution Discharge Elimination System (NPDES), the CSO Policy establishes a consistent national approach for controlling CSOs.

Highlights of the CSO Policy are its recognition of the site-specific nature of combined sewer systems (CSSs), and the variability of receiving water conditions and CSO impacts on receiving waters. The CSO Policy also provides flexibility to CSO communities so that control programs can be developed to fit local needs. In addition, the CSO Policy recognizes the cost burden to CSO communities, and allows for staged implementation.

Consistency within the CSO Policy is established by requirements for all CSO communities to implement Nine Minimum Controls (NMCs). Consistency is also established by requiring CSO communities to develop comprehensive long-term control plans (LTCPs) tailored to site-specific conditions.

Building upon the CSO Policy and associated guidance from EPA and the states, CSO communities are in varying stages of implementing the NMCs and developing LTCPs. Large investments in time and money are being directed toward CSO control across the nation. It is widely recognized that measuring and tracking the success of CSO control is necessary. In particular, there is a need to identify and quantify environmental benefits associated with CSO control efforts so that rate payers, elected officials and the public at large will be able to assess the investment in CSO control and its anticipated benefits.

The ***purpose of this report*** is to describe and recommend series of performance measures that are recommended for use by utilities and local government agencies to track improvements and benefits associated with CSO control. Performance measures provide a means for the quantification and documentation of the results and effectiveness of CSO control efforts. They can be used to measure and report progress toward achieving goals and objectives, and they can be instrumental in guiding management activities.

This study was sponsored by AMSA (the Association of Metropolitan Sewerage Agencies), and was partially funded under a cooperative agreement with EPA.

VOL 12 2 4861

R0058154

STUDY METHODOLOGY

The study was designed to maximize the number of participants involved and the amount of input received from parties having a substantial interest in CSO control. A Work Group formed by AMSA consisting of representatives from the major stakeholders involved in the CSO Policy development guided the study elements, developed and applied selection criteria, and made all of the final recommendations. Separate Focus Group meetings targeted at CSO communities, environmental groups, and state and federal permitting authorities were used to obtain additional ideas and to hear concerns related to CSO control and performance measures. Field interviews with CSO communities were utilized to determine the applicability and usefulness of performance measures. Work Group discussions and deliberations resulted in the final selection of recommended performance measures and production of this document.

STUDY FINDINGS

In addition to recommending performance measures for CSO control, the Work Group developed a summary of observations regarding CSO control and the selection of performance measures. These observations and the recommended performance measures are described separately below.

Observations

Basic Principles: Urban waters are very complex. CSO discharges are one of many sources of pollution that contribute to water quality and other environmental problems. Other sources include storm water, septic systems, upstream nonpoint source pollution and agricultural runoff, municipal and industrial wastewater, atmospheric deposition, and contaminated bottom sediments. In order to place the CSO performance measures into context, several basic principles were used to guide their development:

- Performance measures in this study are primarily for local use by CSO communities.
- CSSs and the impacts of CSO discharges are very site specific. CSO control is expensive and largely dependent on local funding. Difficult choices have to be made by CSO communities. Performance measures provide a means to guide management activities and to track results.
- A menu-like framework provides CSO communities with the opportunity to select appropriate performance measures to match locally defined objectives.
- Some performance measures have value at the watershed level where multiple sources impact water quality and environmental conditions.
- Some performance measures have value for tracking the programmatic effectiveness of CSO control programs at the national or state levels.
- Data for some performance measures are more appropriately gathered by agencies other than local governments.

VOL 12 2 4862

R0058155

Categories of Performance Measures: The potential performance measures considered by the Work Group fell into four categories. These are:

- Administrative Measures.
- End-of-Pipe Measures.
- Receiving Water Measures.
- Ecological, Human Health and Resource Use Measures.

The Work Group recognized the need to identify environmental measures that connected program activities and dollars spent on environmental infrastructure with measurable improvements in water quality, habitat and the beneficial use of receiving waters. The difficulty of isolating CSO impacts in complex urban waters receiving pollutants from many sources was also recognized. The complexity of urban waters makes it difficult to use the results of ambient or ecological monitoring to reliably establish cause and effect relationships between CSOs and environmental conditions. Therefore, the Work Group observed that the four categories encompassed a sufficiently broad range of performance measures from which CSO communities could make selections based upon local needs.

Designated Uses: It was observed that CSO discharges can contribute to nonattainment of designated uses in urban waters. However, nonattainment is often not dependent on a single source. Instead, multiple sources are usually responsible. The Work Group observed that environmental management directed at the attainment of designated uses in urban receiving waters is more likely to be successful if all pollution sources are addressed in the context of a watershed approach.

Locally Defined Objectives: The Work Group recognized the site specific nature of CSO control and potential opportunities to focus on locally defined objectives and anticipated benefits that go beyond regulatory requirements. For example, water bodies avoided by the public before CSO controls were implemented are transformed into popular greenways; water-based recreation activity increases; blighted urban waterfronts become valuable sites for residential or commercial redevelopment. In these and other examples, elimination of odors or nuisances and improvement of water quality and habitat enhance the desirability of the water and shoreline for public use and enjoyment. Regulatory requirements can help to create the conditions for increased recreational and economic activity. The quantification of performance measures for locally defined objectives is a valuable way to track benefits associated with CSO control.

Watershed Approach: Because of the broad variety of pollution sources affecting urban waters, the Work Group found that CSO control should be viewed in the context of watershed management. In particular, many of the receiving water, human health, ecological and resource use measures quantify impacts or effects that are often governed by sources beyond CSOs. Further, the importance of the watershed approach is clearly

VOL 12 2 4863

R0058156

recognized in the CSO Policy where it is stated that:

> ***"Permitting authorities are encouraged to evaluate water pollution control needs on a watershed management basis and coordinate CSO control with other point and nonpoint source activities."*** **(Section I.B.)**

In recognition of the importance of the watershed approach, the Work Group identified performance measures that were particularly suitable for tracking environmental change on a watershed basis.

Cost Considerations: The Work Group found that cost is an important factor in the consideration of performance measures. In particular:

- The cost of obtaining data for the performance measures should be commensurate with the usefulness of the data.
- The cost of obtaining data for the performance measures should not represent an extra burden to CSO communities beyond what was stated or intended in the CSO Policy.
- The cost of CSO control is not a performance measure per se, but should be tracked to put the economic investment of CSO control into context.

Recommended Performance Measures

The Work Group identified and recommended twenty-four individual performance measures to be used to track and quantify the results of CSO control. The recommended performance measures are summarized in the attached table. All twenty-four were considered to be *Appropriate for General Use* by CSO communities. Four were additionally identified as *Appropriate for Tracking on a National Basis*. This limited group of measures would be particularly useful in tracking the overall status of the CSO Control Program, and reduction in the occurrence of CSO discharges to receiving waters.

A menu-like framework was developed for the performance measures to encourage CSO communities to select the most appropriate performance measures to meet their needs. The LTCP and local knowledge of the CSS, receiving waters, and impacts should be used to guide CSO communities in the selection of a subset of performance measures that will demonstrate the results of CSO control.

Many of the performance measures will not be appropriate for all or most CSO communities. For example, tracking beach closures is not warranted where there are no beaches. Similarly, tracking nutrient load reduction may not be warranted in CSO communities where the nutrient load associated with CSOs is not considered to be a problem. Common sense, local conditions and cost effectiveness should drive the selection of performance measures.

VOL 12 2 4864

R0058157

Summary of Recommended Performance Measures

ADMINISTRATIVE	END-OF-PIPE	
• Documented Implementation of NMCs (1) • Status of LTCP(1) • Waste Reduction	Flow Measurement • Wet Weather Flow Budget • CSO Frequency(1) • CSO Frequency in Sensitive Areas(1) • CSO Volume • CSO Volume in Sensitive Areas • Dry Weather Overflows	Pollutant Load Reduction • BOD Load • TSS Load • Nutrient Load • Floatables
RECEIVING WATER	**ECOLOGICAL/HUMAN HEALTH/RESOURCE USE**	
• Dissolved Oxygen Trend • Fecal Coliform Trend • Floatables Trend • Sediment Oxygen Demand Trend • Trend of Metals in Bottom Sediments	• Shellfish Bed Closures • Benthic Organism Index • Biological Diversity Index • Recreational Activities • Beach Closures • Commercial Activities	

(1) Appropriate for National Tracking

A two-page description of each performance measure provides a general discussion of the expected results for each measure, the conditions that are appropriate, and why the data is important. Examples and anecdotal information have been provided where available. The description also contains a single-page Profile Sheet for each performance measure. The Profile Sheets provide a readily available visual reference for managers that will be helpful in selection of the most appropriate performance measures.

RECOMMENDATIONS FOR IMPLEMENTATION

Assessment of the effectiveness of controls and measuring improvements in receiving waters and other benefits is a major part of CSO control. Specific recommendations on the identification and selection of performance measures as well as the major elements of implementing data collection and reporting programs are outlined. Comments on state and federal use of performance measures are also provided.

RELATIONSHIP TO OTHER NATIONAL PROGRAMS

CSO performance measures can be related to other ongoing national programs including wet weather program efforts such as the urban wet weather and stormwater activities, the establishment of national environmental goals and indicators, and the interagency coordination of water quality monitoring. Most of these efforts are conducted in partnership by EPA and other federal agencies, states, tribes, local governments, and private entities. The principal national programs and relevant projects related to goals, environmental indicators, and performance measures are described.

VOL 12 2 4865

R0058158

1.0 INTRODUCTION

1.1 BACKGROUND AND PURPOSE

The National Combined Sewer Overflow (CSO) Control Policy (the CSO Policy) was signed by Carol Browner, the Administrator of the U.S. Environmental Protection Agency (EPA), on April 8, 1994 (EPA, 1994). This signing culminated a lengthy process of policy development and negotiation among CSO communities, EPA, the states, and environmental groups. Based upon the National Pollution Discharge Elimination System (NPDES), the CSO Policy establishes a consistent national approach for controlling CSOs.

Highlights of the CSO Policy are its recognition of the site-specific nature of combined sewer systems (CSSs), and the variability of receiving water conditions and impacts. The CSO Policy also provides flexibility to CSO communities so that control programs can be developed to fit local needs. In addition, the CSO Policy also recognizes the cost burden to CSO communities, and it allows for staged implementation of controls.

Consistency within the CSO Policy is established by requirements for all CSO communities to implement Nine Minimum Controls (NMCs). The NMCs are technology-based controls that can be used to abate CSO problems without extensive engineering studies or substantial construction costs. The NMCs place emphasis on maintenance and proper operation of the CSS to ensure maximum use of the collection system and treatment capacity of the publicly owned treatment works (POTWs). Consistency is also established by requiring CSO communities to develop comprehensive long-term control plans (LTCPs) tailored to site-specific conditions. The development of LTCPs is a comprehensive effort that leads to the identification and implementation of technically feasible, effective and affordable controls.

Building upon the CSO Policy and associated guidance from EPA and the states, CSO communities are in varying stages of implementing the NMCs and developing LTCPs. Large investments in time and money are being directed toward CSO control across the nation. It is widely recognized that measuring and tracking the success of CSO control is necessary. In particular, there is a need to identify and quantify environmental benefits associated with CSO control efforts so that rate payers, elected officials and the public at large will be able to assess the investment in CSO control and anticipated benefits.

The purpose of this report is to describe a series of performance measures that are recommended for use by utilities and local government agencies to track improvements and benefits associated with CSO control.

These performance measures were developed in a study sponsored by AMSA (the Association of Metropolitan Sewerage Agencies) and supported under a cooperative agreement with EPA. A Work Group representative of the major stakeholders instrumental in developing the CSO Policy carried out the assessment of performance

VOL 12 2 4866

R0058159

measures. The stakeholders included utilities and local government agencies responsible for operating CSSs (referred to as CSO communities), non-governmental environmental advocacy groups, and federal and state NPDES permitting authorities. The report is organized as follows:

Section 1.0: Introduction.
Section 2.0: Description of Study Methodology.
Section 3.0: Study Findings.
Section 4.0: Recommendations for Implementation.
Section 5.0: Relationship to Other National Programs.

The remainder of this section provides additional background on the CSO Policy and performance measures.

1.2 KEY PRINCIPLES AND EXPECTATIONS OF THE CSO POLICY

The CSO Policy contains four key principles intended to ensure that CSO controls are cost-effective and meet the requirements of the Clean Water Act (CWA) of 1972 and its amendments. These are:

- Provide clear levels of control that would be presumed to meet appropriate health and environmental objectives.
- Provide sufficient flexibility to CSO communities, especially those that are financially disadvantaged, to consider the site-specific nature of CSOs and to determine the most cost-effective means of reducing pollutants and meeting CWA objectives and requirements.
- Allow a phased approach for implementation of CSO controls considering a community's financial capability.
- Review and revise, as appropriate, water quality standards and their implementation procedures when developing LTCPs to reflect the site-specific wet weather impacts of CSOs.

The CSO Policy also clearly defines expectations for permittees, state water quality standards authorities, and other NPDES permitting and enforcement authorities. These expectations include:

- Permittees should implement the NMCs as soon as practical, but no later than January 1, 1997.
- Permittees should give priority to sensitive areas.
- Permittees should develop LTCPs.
- State water quality standards authorities should review and revise, as appropriate, state water quality standards during the CSO long-term planning process.

VOL 12 2 4867

R0058160

1.2.1 Nine Minimum Controls

The NMCs that are to be implemented and documented by all CSO communities by January 1, 1997 are described briefly in Table 1-1. The selection and implementation of control measures should be based upon site-specific conditions and characteristics of the CSS. Documentation of the NMCs may include operation and maintenance plans, revised sewer use ordinances for industrial users, sewer system inspection reports, infiltration/inflow studies, pollution prevention programs, public notification plans, and facility plans.

1.2.2 Long Term Control Plans

The LTCP is a comprehensive plan that recognizes the site-specific nature of CSOs and their impacts on receiving waters. The long term planning approach consists of four major elements: system characterization; development and evaluation of alternatives; selection and implementation of controls; and compliance monitoring. A primary objective of the LTCP is to develop and evaluate a reasonable range of CSO control alternatives sufficient to meet water quality standards, including attainment and protection of designated uses on CSO-impacted receiving waters. The CSO Policy allows flexibility in allowing a CSO community to select controls that are cost-effective and tailored to meet local conditions.

Two general approaches to attainment of water quality standards are recognized in the CSO Policy. These are the "demonstration" approach and the "presumption approach." Both approaches provide CSO communities with targets for controls that achieve compliance with the CWA, particularly the protection of designated uses. Under the "demonstration" approach, water quality modeling or other tools are used to demonstrate that predicted CSO discharges resulting from the LTCP would be sufficient to attain water quality standards. The "presumption" approach is based upon the premise that a LTCP that meets certain minimum defined performance criteria in terms of expected frequency of overflow or percent capture of the CSO pollutant load would be presumed to provide an adequate level of control to meet the water quality-based requirements of the CWA.

CSO communities are encouraged to meet and coordinate frequently with state water quality standards authorities and NPDES permitting authorities, and to engage the general public in the planning process through public participation activities. In particular, the development of goals, the evaluation of alternatives, and the consideration of the local financial impacts of the LTCP should be a collaborative effort among all of the participating interests. The development of performance measures or other measures of success to quantify environmental improvements and benefits related to CSO control is also a major element of the LTCP. Because of the site-specific nature of CSSs and CSO impacts, a strong linkage between performance measures and locally defined objectives is essential.

R0058161

Table 1-1 Summary of the Nine Minimum Controls

1. **Proper operation and regular maintenance programs for the sewer system and the CSOs.** This control should consist of a program that clearly establishes operation, maintenance, and inspection procedures to ensure that a CSS and treatment facility will function in a way to maximize treatment of combined sewage and still comply with NPDES permit limitations.

2. **Maximum use of the collection system for storage.** This control consists of making relatively simple modifications to the CSS to enable the system to store wet weather flows until downstream sewers and treatment facilities can handle them.

3. **Review and modification of pretreatment requirements to ensure that CSO impacts are minimized.** The objective of this control is to minimize the impacts of discharges into CSSs from nondomestic sources during wet weather events, and to minimize CSO occurrences by modifying inspection, reporting, and oversight procedures within an approved pretreatment program.

4. **Maximization of flow to the POTW for treatment.** This control entails simple modifications to the CSS and treatment plant to enable as much wet weather flow as possible to reach the treatment plant.

5. **Elimination of CSOs during dry weather.** This control includes any measures taken to ensure that the CSS does not overflow during dry weather conditions.

6. **Control of solid and floatable materials in CSOs.** This control is intended to control, if not eliminate, visible floatables and solids using relatively simple measures including baffles, screens, racks, booms and skimmer vessels.

7. **Pollution prevention programs to reduce contaminants in CSOs.** This control is intended to keep contaminants from entering the CSS and prevent subsequent discharge to receiving waters through street cleaning, public education, solid waste collection and recycling.

8. **Public notification to ensure that the public receives adequate notification of CSO occurrences and CSO impacts.** The intent of this control is to inform the public of the location of outfalls, the actual occurrence of CSOs, the possible health and environmental effects of CSOs, and the recreational or commercial activities curtailed as a result of CSOs.

9. **Monitoring to effectively characterize CSO impacts and the efficacy of CSO controls.** This control involves visual inspections and other simple methods to determine the occurrence and apparent impacts of CSOs.

VOL 12 2 4869

R0058162

1.2.3 Guidance Documents

EPA has developed a series of guidance documents to assist CSO communities and NPDES authorities with interpretation of the CSO Policy and its implementation. These guidance documents provide specific information on the NMCs, the development of LTCPs, and other technical, financial and permitting issues. A list of guidance documents is as follows:

Combined Sewer Overflows - Guidance for Long Term Control Plan (EPA, 1995a)
Combined Sewer Overflows - Guidance for Nine Minimum Controls (EPA, 1995b)
Combined Sewer Overflows - Guidance for Screening and Ranking (EPA, 1995c)
Combined Sewer Overflows - Guidance for Funding Options (EPA, 1995d)
Combined Sewer Overflows - Guidance for Permit Writers (EPA, 1995e)

Complete references are provided in Section 6.0 These documents are available from the EPA Office of Water's Document Center, or through EPA's PIPES electronic bulletin board (BBS). The modem BBS number is (703) 749-9216. The World Wide Web address is *http://www.ehsg.saic.com/pipes.*

1.3 PERFORMANCE MEASURES

EPA has established five strategic goals focused on water resources. These are the protection and enhancement of public health; the protection and enhancement of ecosystems; the attainment of uses designated by states and tribes; the improvement of ambient conditions; and the reduction in pollutant loadings. Addressing CSOs on a consistent basis across the nation is one of several programs intended to achieve these goals.

In order to assess the progress and success of individual programs such as the CSO control program, or the cumulative effect of multiple programs on a watershed basis, it is important to compare the quality of the environment and change over time with a well chosen set of performance measures. Traditionally, simple quantitative or administrative measures of program activities were used extensively for this purpose. These include measures such as the number of permits issued, the number of controls implemented, and other measures of an administrative nature. It has become increasingly clear in recent years that environmental measures are also very important as they explain more about the health and condition of the water bodies themselves, and the designated uses of water bodies that management programs are trying to protect. Toward this end, environmental measures provide a means to quantify and track the chemical, physical and biological integrity of the nation's waters.

VOL 12 2 4870
R0058163

1.4 POTENTIAL USERS OF PERFORMANCE MEASURES

Performance measures provide a medium for the quantification and documentation of the results and effectiveness of CSO control efforts. They can be used to measure and report progress toward achieving goals and objectives, and they can be instrumental in guiding management activities. A clear understanding of the objectives of CSO control at each level of government is necessary if performance measures are to be implemented effectively.

At the local level, performance measures can be used by CSO communities to measure and report progress in achieving locally defined goals and objectives. Performance measures can also be used to guide management activities, and to communicate environmental improvement and change to rate payers, elected officials and the public at large. Return on investment is an important consideration. CSO communities are making substantial investments in CSO control. Performance measures provide a means to track environmental benefits that can be related back to the investment.

At the state level, performance measures can be used by resource and NPDES permitting authorities to track compliance and implementation, and to quantify change in environmental conditions. State objectives and the state permitting strategy will need to be consistent with recommended performance measures. Statewide coordination will improve the usefulness of performance measures in that information for select measures can be tracked and aggregated on a watershed or statewide basis.

At the regional and national levels, performance measures can be used in several ways. These are to track the overall status of programmatic requirements; to track the effectiveness of controls; and to track real improvements in the environment on regional and national levels. As noted by the Government Accounting Office (GAO), "in order to manage for environmental results, EPA needs measures both of the nature and level of its own activities, and of the effects of current levels of pollution and contamination on people and the environment" (GAO, 1988).

VOL 12 2 4871

R0058164

2.0 STUDY METHODOLOGY

2.1 OVERVIEW

The study was designed to maximize the number of participants involved and the amount of input received from parties having a substantial interest in CSO control. A Work Group formed by AMSA consisting of representatives from the major stakeholders involved in the CSO Policy development guided the study and made all of the final recommendations. Separate Focus Group meetings targeted at CSO communities, environmental groups, and state and federal permitting authorities were used to obtain additional ideas and to hear concerns related to CSO control and performance measures. Field interviews with CSO communities were utilized during the later stages of the study to determine the applicability and usefulness of performance measures. Work Group discussions and deliberations resulted in the final selection of recommended performance measures and production of this document.

2.2 WORK GROUP

AMSA convened a Work Group with eighteen members to provide direction and guidance to the study. Each member of the Work Group had extensive experience with CSO operations, wet weather issues, and urban water quality. The Work Group held four public meetings that were professionally facilitated.

At its first meeting in March, 1995, the Work Group received briefings from EPA on the subjects of environmental indicators, wet weather programs, the CSO Policy, and the Intergovernmental Task Force on Monitoring Water Quality. The Work Group developed four categories for performance measures. These were administrative measures, end-of-pipe measures, receiving water measures, and a category encompassing ecological, human health and resource use measures. During a brainstorming session, a first-cut preliminary list of forty-eight performance measures was identified (see Appendix B). The Work Group also provided direction for the convening of regional Focus Group meetings in order to reach out to CSO communities, regulatory agencies, environmental interests and the general public to obtain additional ideas on performance measures for CSO control.

At its second meeting in June, 1995, the Work Group reviewed the results of the Focus Group meetings and initiated a process to screen the first-cut preliminary list and other suggestions received from the Focus Groups. The selection criteria used in the screening process were as follows:

- Is the measure directly linked to CSOs?
- Is the measure quantifiable and "trendable" (i.e., can change be tracked over time)?
- Is the measure reasonable regarding the cost of data collection and analysis?
- Is the measure objective?
- Is the measure flexible?

VOL 12 2 4872

R0058165

- Is the measure an indicator of water quality conditions?
- Is the measure useful in system management?
- Is the measure meaningful at the local, state and national level and to the public?
- Is the measure consistent across related programs (e.g., storm water, etc.)?

Screening produced a shorter list of performance measures that were evaluated in field interviews with CSO communities.

At its third meeting in September, 1995, the Work Group reviewed the results of the field interviews and finalized a set of recommended performance measures and units of measurement. The Work Group also discussed the organization of the final report and its distribution and promotion.

At its fourth and last meeting in November, 1995, the Work Group reviewed a Draft Final Report and made final changes and modifications to the performance measures and other recommendations.

2.3 FOCUS GROUP MEETINGS

During May and June, 1995, AMSA convened a series of six Focus Group meetings to review and refine the list of potential performance measures for CSO control. Three Focus Group meeting were held in Boxborough, MA, for New England-based CSO communities, regulatory agency representatives, and environmental interests. An additional three Focus Group meetings were held in Fort Mitchell, KY, for Ohio River Valley representatives for the same interest groups. The meetings were attended by approximately eighty-five participants (see listing in Appendix A). Each participant brought a wealth of experience and knowledge related to CSO systems, CSO impacts and CSO controls to the discussion of performance measures. All six Focus Group meeting were professionally facilitated and followed a similar process:

- Participants developed and discussed an extensive list of potential performance measures, and related their concerns about CSO control and performance measurement.
- Participants voted to identify the most important performance measures.
- Participants ranked the first-cut list of forty-eight performance measures developed by the Work Group at its March meeting according to their relative importance: high, medium or low.

Several key performance measures were discussed at all of the Focus Group meetings and were determined to be very important across all interest groups. These were:

- The frequency and volume of overflows (normalized for precipitation).
- Documented compliance (implementation) with the NMCs.

VOL 12 2 4873

R0058166

- Use attainment (or use impairment), as generally indicated by instream measures of fecal coliform and dissolved oxygen.
- Aesthetics, including consideration of waterfronts as an economic amenity.

Several key concepts that performance measures should incorporate were discussed at each Focus Group meeting. Because of their importance to the development and implementation of performance measures, these concepts are highlighted below:

- All four of the categories of performance measures (administrative; end-of-pipe; receiving water; and ecological/human health and resource use measures) may have a role in tracking performance and benefits.
- Use of performance measures at the local level should be linked to locally defined objectives, and to site specific control plans.
- It may be very difficult to determine CSO control benefits in urban waters affected by multiple sources including point sources, urban storm water, sanitary sewer overflows (SSOs), septic systems, and agricultural sources.
- CSO control should be viewed in the context of watershed management.
- The presence of raw waste discharges to urban waters is unsettling regardless of impacts, and there is a certain *peace of mind factor* associated with CSO control.

Focus Group rankings of the first-cut performance measures are in Appendix B.

2.4 FIELD INTERVIEWS

During August and September, 1995, field interviews were conducted in order to test the appropriateness of performance measures in CSO communities of different size, at different stages in planning and implementation, in different geographic areas, and with different receiving water impacts. In order to do this, interviews were scheduled with CSO managers, POTW operators, public works staff involved in the maintenance and operation of collection systems, laboratory staff, CSO consultants, permit writers, and environmental groups. A total of eighteen CSO communities and six regulatory and environmental organizations participated in the field interviews. All but one of the CSO communities (Atlanta, GA) were visited in-person by one or more members of the study team. The participating CSO communities (grouped by population) and were:

CSO Communities Greater than 100,000	CSO Communities 20,000 to 100,000	CSO Communities Less than 20,000
King County (Seattle), WA	Portland, ME	Mechanics Falls, ME
Monroe County, NY	Everett, WA	Rockland, ME
Middlesex County, NJ	Newark, OH	Skowhegan, ME
Atlanta, GA	Perth Amboy, NJ	Bath, ME
Akron, OH	New Brunswick, NJ	Gardiner, ME
	So. Portland, ME	Anacortes, WA
	Augusta, ME	

VOL 12 2 4874

R0058167

Other participating agencies and organizations were:

Other Agencies and Organizations
Maine Department of Environmental Protection
Washington Department of Ecology
New Jersey Department of Environmental Protection and Energy
Casco Bay National Estuary Program, Maine
Ohio Environmental Protection Agency
EPA Region X, Seattle, WA

The individuals representing these agencies are listed in Appendix A.

The field interviews focused on a short list of twenty-six performance measures screened and identified by the Work Group at its second meeting. Two central questions were asked for each performance measure at the interviews:

Is the performance measure applicable in your system?

If applicable, what is your assessment of the measure as a useful and practical way to track environmental improvement associated with CSO control?

The results of the interviews were quantified for each measure into a composite score associated with high, medium and low applicability. Where indicated as applicable, the results were also quantified for high, medium and low usefulness. The results of the field interviews reinforced the general findings of the Focus Groups. The results also enabled the Work Group to separate those performance measures with broad applicability from those applicable on a site-specific basis. In addition, performance measures that were nearly universally judged as "not applicable" and "not useful" were eliminated from further consideration.

2.5 REPORT PREPARATION

A Draft Final Report was prepared by the study consultants and distributed to the Work Group, AMSA staff, and select staff at EPA for review. Review comments, suggestions and ideas were submitted to the study consultants at the fourth Work Group meeting and incorporated into a Revised Draft Final Report. The Final Study Report was approved for publication and distribution by AMSA following another round of review and comments by the Work Group.

VOL 12 2 4875

R0058168

3.0 STUDY FINDINGS

3.1 INTRODUCTION

The formulation of study findings by the Work Group was based upon a broad variety of information sources and dialog. The information, advice and recommendations received at the Focus Group meetings and field interviews were extremely valuable and provided firsthand knowledge from dozens of CSO communities and receiving water situations. The Work Group also received briefings from EPA staff on the National Environmental Goals Project and the Office of Water Environmental Indicators Project. In addition, the study consultants provided advice and suggestions in the areas of water quality and the design, operation and maintenance of CSSs. Finally, the Work Group drew upon the collective experience of its members in the administration and operation of public utilities; permit writing; environmental assessment; environmental advocacy; city management; and the development of public policy. It was this experience base that enabled the Work Group to engage in technical and policy discussions and debate that led to the finalization of recommendations.

The study findings are presented in two subsections. These are:

- **Observations:** The observations are study findings that are useful for understanding CSO control and the selection of performance measures. This subsection provides information on basic principles, the categories of performance measures, designated uses, locally defined objectives, and cost considerations.

- **Recommended Performance Measures:** The recommended performance measures are described in detail in this subsection. The description indicates what the performance measure is trying to track, units of measurement, and where its use might be appropriate. Examples and anecdotal information are also included. In addition, individual Profile Sheets provide a brief overview for each performance measure. Profile Sheets cover applicability and use, advantages and disadvantages, potential data sources, probable reporting agencies, cost of data collection, and other information in a consistent manner.

3.2 OBSERVATIONS

General observations and findings developed by the Work Group are as follows:

3.2.1 Basic Principles

Urban waters are typically very complex. CSO discharges are one of many sources of pollution that contribute to impaired or poor water quality and other environmental problems in urban waters. Other sources include storm water, failed septic systems, upstream nonpoint source pollution and agricultural runoff, municipal and industrial

VOL 12 2 4876

R0058169

wastewater, atmospheric deposition, and contaminated bottom sediments. In order to place the CSO performance measures into context, several basic principles were used to guide their development. These basic principles are as follows:

- Performance measures were developed in this study primarily for local use by CSO communities.
- CSSs and the impacts of CSO discharges are very site specific. CSO control is expensive and largely dependent on local funding. Difficult choices have to be made by CSO communities. Performance measures provide a means to guide management activities and to track results.
- A menu-like framework for performance measures provides CSO communities with a way in which to select performance measures to match local needs and objectives.
- Some performance measures have value at the watershed level where multiple sources impact water quality and environmental conditions.
- Some performance measures have value for tracking the programmatic effectiveness of CSO control programs at state or national levels.
- Data for some performance measures are more appropriately gathered by agencies other than local governments.

The Work Group believed it will be important for readers to keep these basic principles in mind as they review and consider the recommended performance measures.

3.2.2 Categories of Performance Measures

The potential performance measures considered by the Work Group fell into four categories:

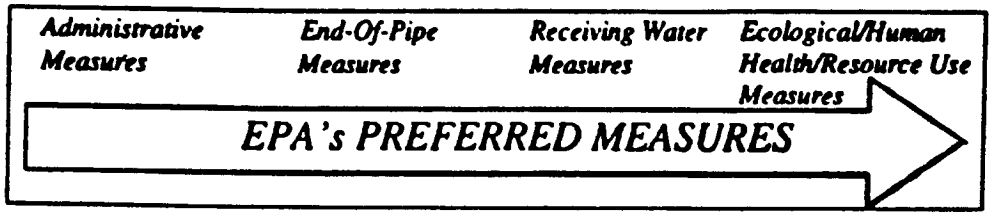
- Administrative Measures.
- End-of-Pipe Measures.
- Receiving Water Measures.
- Ecological, Human Health and Resource Use Measures.

As shown in Figure 3-1, EPA recommends that preference be given to the use of data from the categories containing receiving water, ecological, human health and resource use measures (e.g., improvements in ambient water quality, increased numbers and diversity of aquatic life, fewer beach closures, etc.). These preferred environmental measures provide tangible, results-oriented data for measuring performance. In contrast, the use of data from the less preferred categories containing administrative and end-of-pipe measures (e.g., number of permits issued, dollars spent, overflow volume, etc.) provides little tangible evidence of environmental change and improvement. Measures from within these categories track the results of administrative activities and changes in loadings, but do not directly address changes in ambient or environmental conditions.

VOL 12 2 4877

R0058170

Fig. 3-1 Preferred Data for Measuring Environmental Results



From the outset of the study, the Work Group endeavored to identify "preferred" environmental measures that connected program activities and dollars spent on environmental infrastructure with measurable improvements in water quality, habitat, human health, and the beneficial use of receiving waters. However, following extensive review and discussions, the Work Group found that reliance on environmental measures alone would not be satisfactory. In complex urban waters it is often difficult to isolate CSO impacts with specific water quality and environmental measures on account of the many pollutant sources that affect these waters. The results of ambient or ecological monitoring can rarely be used to reliably establish cause and effect relationships between CSOs and environmental conditions. While the preferred environmental measures are important, they are not often definitive. Consequently, the Work Group found that a balanced approach with equal emphasis on all four categories and consideration of a broad spectrum of performance measures is warranted. Individual performance measures from within each category will be useful and appropriate for tracking CSO control.

Use of a broad spectrum of performance measures across these categories will allow local government officials, policy makers, and the public to assess the effectiveness of CSO controls, the general health of the environment, and changes in its condition. It will also provide a means to meet several program management needs articulated by the Government Accounting Office (GAO, 1988). These are:

- Assess progress in meeting program objectives.
- Help allocate scarce resources.
- Identify areas to target resources and marshal support for current programs.
- Serve as part of a performance and accountability system.

3.2.3 Designated Uses

The attainment of designated uses was discussed extensively by the Work Group as a central goal of CSO control efforts. It was recognized that CSO discharges can contribute to nonattainment of designated uses in urban waters. However, nonattainment is often not dependent on a single source. Instead, multiple sources are usually responsible. The Work Group observed that environmental management directed at the attainment of designated uses in urban receiving waters is more likely to be successful if all pollution sources are addressed in the context of a watershed approach.

VOL 12 2 4878

R0058171

As background, designated uses are water uses identified in state water quality standards. Designated uses can vary from one water body to the next, or from one reach to another within water bodies. Examples of designated uses include cold or warm water fisheries, shellfish harvesting, public water supply, contact recreation (including swimming), agricultural water, and navigation. As required under the CWA, designated uses must be achieved and maintained.

Designated uses for water bodies are determined by states or tribes. Regulatory authorities often reference designated uses and the maintenance of designated uses in NPDES permits. As prescribed under Section 305(b) of the CWA, states, tribes, and other jurisdictions assess and report on the status of surface waters every two years in State 305(b) Water Quality Assessment Reports. These assessments report on whether or not designated uses are being supported. They are generally based upon available physical, chemical and biological information as well as direct observation and professional judgment. Varying degrees of use support are quantified on a state-wide basis in categories such as fully supporting, fully supporting but threatened, partially supporting, and not supporting. A relative assessment of the causes of nonsupport of designated uses is typically included in the 305(b) reports. Examples of causes include pesticides, metals, nutrients, organic enrichment and pathogen indicators. Sources of water quality problems that impact designated uses are also assessed on a state-wide basis. Sources can include industrial point sources, municipal point sources, CSOs, agriculture, construction, etc.

The Work Group recognized that CSO communities will benefit from coordination with state resource and regulatory agencies concerning designated uses and the reporting of use support in state 305(b) reports. The Work Group also recognized that the CSO Policy and other federal regulations provide several options if it appears that designated uses and water quality standards may not be appropriate for wet weather conditions. These include review of water quality standards and use attainability analysis. CSO communities, NPDES permitting authorities, the states, and other stakeholders may need to discuss this issue in the formulation of LTCPs and in the development of wet weather programs on a watershed basis.

3.2.4 Locally Defined Objectives

There is a natural tendency in discussions of CSO control planning and implementation to emphasize regulatory requirements. The CSO Policy states that one of its main purposes is "to expedite compliance with the requirements of the CWA" (CSO Policy, Section I.A.). Attainment of designated uses through control of CSOs and other pollution sources is related to compliance with CWA mandates as reflected in state water quality standards. In short, much of the focus in CSO control planning, and consequently many of the performance measures in this report, deal with federal or state mandates.

This regulatory focus should not cause CSO Communities to lose sight of what the Work Group called "locally defined objectives." Many potentially useful performance measures

VOL 12 2 4879

R0058172

relate to the achievement of local objectives that are not mandated by standards or permits. The distinction between regulatory requirements and locally defined objectives may not always be clear. Nevertheless, it is a useful distinction for local officials responsible for planning and implementing water quality improvement programs.

Work Group and Focus Group participants repeatedly spoke of the site specific nature of CSO control and offered examples of the resulting benefits: water bodies avoided by the public before controls were implemented are transformed into popular greenways; water-based recreation activity increases; blighted urban waterfront areas become valuable sites for residential or commercial redevelopment. In these and other examples, elimination of odors or nuisances and improvement of water quality and habitat enhanced the desirability of the water and shoreline for public use and enjoyment. Compliance with regulatory requirements helps to create the conditions for increased recreational or economic activity.

Achievement of locally defined objectives may be measured in terms of fishing, swimming or boating person-days; increased waterfront property values; development and use of shoreline trails; or other measures of activity or economic value. Regulations and permits contain standards that define a level of water quality sufficient to support designated uses. But permits do not specify the level of an activity that should actually take place after standards are met. Objectives of this type, and performance measures to document their achievement, are a matter of local discretion.

There are two reasons for considering performance measures related to locally defined objectives before and after implementing CSO controls. First, identifying local objectives for CSO-impacted water bodies during the planning process can produce better outcomes. If project objectives are seen as broader than compliance with regulations, opportunities may be found for enhancing project benefits. For example, trails and shoreline access points can be designed in conjunction with CSO piping and control structures. Waterfront sites suitable for public or private redevelopment can be acquired as part of CSO control projects.

Second, locally defined objectives are helpful in communication with the public. People can understand and support a goal of turning an urban stream from an open sewer into a scenic greenway. By formulating a vision for the future of receiving waters and adjacent lands, and then measuring success, local officials can assure ratepayers that their money is being spent wisely in the public interest.

3.2.5 Watershed Approach

Because of the broad variety of pollution sources affecting urban waters, the Work Group found that CSO control should be viewed in the context of watershed management. In particular, many of the receiving water measures and ecological, human health and resource use measures quantify impacts or effects that are often governed by sources beyond CSOs. Attaining water quality standards and meeting designated uses in most urban waters can only be accomplished through a concerted effort to limit all sources of

VOL 12 2 4880

R0058173

pollutants. This method of assessment and management is commonly referred to as the "Watershed Approach."

The Watershed Approach is built on three main principles. First, the target watersheds should be those where pollution poses the greatest risk to human health, ecological resources, desirable use of the water, or a combination of these. Second, all parties with a stake in the watershed should participate in the analysis of problems and the creation of solutions. Third, the actions undertaken should draw upon the full range of methods and tools available, integrating them into a coordinated, multiorganization attack on the problems. Other attributes of the Watershed Approach are that it provides a geographic focus for environmental management; it encourages the prioritization of objectives; and it fortifies partnerships and the development of integrated solutions. Because of the broad geographic areas covered, and the variety of pollution sources considered, state or regional agencies typically take an active leadership role in watershed studies. CSO communities typically participate as one of the stakeholders.

The importance of the Watershed Approach is clearly recognized in the CSO Policy where it is stated that:

> ***"Permitting authorities are encouraged to evaluate water pollution control needs on a watershed management basis and coordinate CSO control with other point and nonpoint source activities." (Section I.B.)***

The discussion of the "Demonstration Approach" in the CSO Policy also directly addresses watershed issues in discussing the need to allocate pollution among all sources:

> ***"Where water quality standards and designated uses are not met in part because of natural background conditions or pollution sources other than CSOs, a total maximum daily load (TMDL) including a wasteload allocation and a load allocation, or other means, should be employed to apportion pollution loads". (Section II.C.4.b)***

In recognition of the importance of the watershed approach, the Work Group identified performance measures that were particularly suitable for tracking environmental change on a watershed basis. However, many receiving water and ecological measures require expertise and an investment in staff and resources that go beyond the capabilities typically found in CSO communities. Therefore, it may be advantageous to share and coordinate monitoring targeted at watershed issues among involved federal, state, regional and local government agencies so that the appropriate expertise is utilized, and the cost burden to the CSO community is limited.

VOL 12 2 4881
R0058174

3.2.6 Cost Considerations

The Work Group found that cost is an important factor in the consideration of performance measures. In particular:

- The cost of obtaining data for the performance measures should be commensurate with the usefulness of the data.
- The cost of obtaining data for the performance measures should not represent an extra burden to CSO communities beyond what was stated or intended in the CSO Policy. (*Note: CSO communities may want to voluntarily take on added costs to track important measures associated with locally defined objectives.*)
- The cost of CSO control is not a performance measure per se, but should be tracked to put the economic investment of CSO control into context. CSO communities are encouraged to identify the relative cost of management and control alternatives in order to determine whether or not program activities are cost-effective.

3.3 RECOMMENDED PERFORMANCE MEASURES

3.3.1 Overview

The Work Group identified and recommended twenty-four individual performance measures to be used to track and quantify the results of CSO control. These recommended performance measures are summarized in Table 3-1. As shown, all four categories of performance measures are represented: administrative measures; end-of-pipe measures; receiving water measures; and ecological/human health/resource use measures. The end-of-pipe category is divided into two subcategories: measures of flow; and measures of pollutant load reduction. These performance measures are considered to be the ones that will generally be most useful for CSO communities. Other performance measures not included within these recommendations may also be appropriate. A discussion of performance measures and environmental indicators from other national programs is presented in Section 5.0

All twenty-four of the performance measures were considered to be *Appropriate for General Use* by CSO communities. Four of the performance measures were identified as *Appropriate for National Tracking*. The performance measures recommended as appropriate for national tracking represent a limited group of measures that would be particularly useful in tracking the overall status of the CSO Control Program, and reduction in the occurrence of CSO discharges to receiving waters. These measures are generally well understood by CSO communities, they can be monitored and tracked in a consistent manner across the nation, and they can be aggregated on an annual basis for simple trend analysis.

R0058176

NOV 12 2 5884

As shown in Table 3-1, the recommended performance measures are arrayed in a menu-like framework. This format is intended to present the performance measures in a manner that encourages CSO communities to select the most appropriate performance measures to meet their needs. The LTCP and local knowledge of the CSS, receiving waters, and impacts should be used to guide CSO communities in the selection of a subset of performance measures that will demonstrate the results of CSO control.

Many of the performance measures will not be appropriate for all CSO communities. For example, tracking beach closures is not warranted where there are no beaches. Similarly, tracking nutrient load reduction may not be warranted in CSO communities where the nutrient load associated with CSOs is not considered to be a problem. Common sense, local conditions, and cost-effectiveness should drive the selection of performance measures.

The relationship of the performance measures to the NMCs and the LTCP is presented in a generalized manner in Table 3-2. As shown, several of the NMCs are given special attention as individual performance measures. These are waste reduction, floatables, and dry weather overflows (DWOs). These measures might be useful on a case-by-case basis for CSO communities where special emphasis on these controls would be particularly valuable and consistent with the LTCP.

3.3.2 Technical Considerations

The primary purpose of collecting data on performance measures is to develop sufficient information so that meaningful yet simple trends can be developed. The time period of interest extends from baseline or pre-control conditions to full implementation of the LTCP, and beyond. Most of the performance measures require quantification on an annual or per year basis. Year-to-year differences and changes are targeted for tracking and trend analysis. Data collection should therefore be as consistent as possible from year-to-year.

The collection and examination of rainfall data is a major element of sewer system characterization. Rainfall data is also essential to the operation and management of most CSSs, and an important component in the assessment of several performance measures. With the exception of snowmelt conditions, the occurrence of CSO events is directly related to the frequency, duration, intensity and magnitude of rainfall. Changes in the performance of the CSS will also be directly related to the variability of rainfall from year-to-year. Therefore, several of the performance measures will require some "normalization" in order to make the results comparable from one year to the next. The simplest method of normalization is to divide the results (e.g., number of overflow events per year) by a normalization ratio calculated by dividing the annual rainfall received within a given year by long term average annual rainfall. The normalization ratio in this approach weights the results from one year to the next according to the annual rainfall or precipitation total for each year. Other more complex normalization methods based upon

3.3.3 Description of Performance Measures and Profile Sheets

A two-page summary for each performance measure is provided (see Table 3-3 for page locations). This includes:

- A **Description** for each performance measure with a general discussion about the expected results for each measure, the conditions that are appropriate for its use, and why the data is important. Examples and anecdotal information from CSO communities and federal and state programs have been provided where available.

- A single-page **Profile Sheet** for each performance measure that provides a readily available visual reference for managers that will be helpful in selection of the most appropriate performance measures. Each Profile Sheet contains a definition of the performance measure, and addresses applicability and use, advantages and disadvantages, units of measurement, probable reporting agency, potential data sources, cost of data collection, and a reference for additional information.

A qualitative assessment of each performance measure with regard to the attributes listed below is also contained in the Profile Sheets:

- Relationship to CSO discharge.
- Ability to be quantified for trend analysis.
- Usefulness relative to the cost of data collection.
- Flexibility with respect to local objectives and conditions.
- Ability to be understood by the general public.
- Relationship to environmental improvement.
- Applicability in a watershed context.

Attributes are rated as high, medium or low. The attributes are generally consistent with the selection criteria applied by the Work Group to screen potential performance measures.

The relative information provided on the cost of data collection and attributes are not provided as conclusions, but are presented as general considerations to be used in the comparison of performance measures.

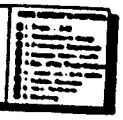
CSO Performance Measure Description
Documented Implementation of the Nine Minimum Controls



This administrative measure gauges how individual CSO communities and groups of CSO communities are progressing with implementation of the Nine Minimum Controls (see Table 1-1). As identified in the CSO Policy, the Nine Minimum Controls represent technology-based controls that can produce substantial environmental improvement at relatively low cost. At the local level, this measure is a simple yes or no, or a listing of the minimum controls implemented to date. At the state or national level, this measure represents the cumulative number of CSO communities where it has been documented that the Nine Minimum Controls are in place.

All CSO communities are expected to implement the Nine Minimum Controls by January 1, 1997. Documentation should include the alternatives considered, actions taken, scheduled actions to be taken in the future, and an assessment of the effectiveness of the controls in reducing or eliminating water quality impacts. Documentation that the Nine Minimum Controls are in place can come in many forms including facility plans, inspection and maintenance reports, public notices, and other technical studies. The Nine Minimum Controls are operating practices that are intended to be sustained over time, so documentation should be a continuing or periodic process. Specific guidance on documentation for each of the controls is discussed in EPA's *Guidance for Nine Minimum Controls* (U.S. EPA, 1995b).

While this measure does not directly measure receiving water or environmental results, it nevertheless provides a strong measure of progress in the reduction of CSOs at the source. It is therefore recommended as a performance measure that may be used for national tracking of activities and results related to CSO control.

Example

An informal survey of several dozen CSO communities in New England and the Midwest during May and June of 1995 revealed that nearly all CSO communities believed they had implemented or were in the process of implementing most of the Nine Minimum Controls. The control of solid and floatable material appears to present the largest challenge.

CSO Performance Measure Profile Sheet
Documented Implementation of the Nine Minimum Controls

Category: **Administrative**

Description:
The cumulative number of CSO communities with Nine Minimum Controls in place (# of CSO communities). For CSO communities, a description of progress in implementing the Nine Minimum Controls would be appropriate.

Applicability and Use:
Implementation of the Nine Minimum Controls is a requirement for all CSO communities under the CSO Policy. This performance measure is therefore appropriate for most CSO communities. Locally, it will be useful for CSO communities to demonstrate compliance with requirements established under the CSO Policy. At the state and federal level, this performance measures will be useful in tracking the implementation of the Nine Minimum Controls.

Advantages of Measure:
- Potentially includes all or most CSO communities in the nation.
- Largely based upon documentation of standard operating procedures for a CSS.
- Cost is relatively small.
- Shows progress of implementation at the state and national levels.

Disadvantages of Measure:
- Documentation may be inconsistent from community to community and state to state.
- Not a measure of environmental results.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Nine Minimum Controls.* EPA 832-B-95-003.

Units of Measurement:
Number of CSO communities.

Probable Reporting Agency:
CSO communities and Federal/State Regulatory Agencies.

Potential Data Sources:
Documentation Reports from CSO communities.

Cost of Data Collection:
Low. Information should be available. Documentation costs should be substantially less than implementation costs.

VOL 12 2 4890
R0058183

CSO Performance Measure Description
Status of Long-Term Control Plans (LTCPs)

This administrative measure assesses how individual CSO communities and groups of CSO communities are progressing with regard to the development and implementation of LTCPs. As described in the CSO Policy, the nine elements of the LTCP are:

1. Characterization, monitoring and modeling activities.
2. Public participation.
3. Consideration of sensitive areas.
4. Evaluation of alternatives.
5. Cost/performance considerations.
6. Operational plan revisions.
7. Maximization of treatment at the existing POTW for wet weather flows.
8. Implementation schedule.
9. Post-construction compliance monitoring program.

At the local level, this measure is a simple determination of the status of the LTCP with regard to the nine elements above covering the initiation of planning, system characterization, the evaluation of alternatives, and implementation. At the state or national level, this measure represents the cumulative number of CSO communities with LTCPs in development, being implemented, and completed.

While this measure is not a direct measure of receiving water or environmental results, it nevertheless provides a strong measure of progress in the development and implementation of LTCPs focused on reducing the frequency and volume of CSOs. It is therefore recommended as a performance measure that may be used for national tracking of activities and results related to CSO control.

Example

There are 117 CSO communities in New England. EPA Region I reports that 38 have LTCPs in development, 30 are implementing LTCPs, and 17 have completed implementation.

Source: U.S. EPA Region I, Boston, MA.

VOL 12 2 4891

R0058184

CSO Performance Measure Profile Sheet
Status of Long-Term CSO Control Plans

Category: **Administrative**

Description:
The number of CSO communities with LTCPs in development, being implemented, and completed (# of CSO communities). For CSO communities, a description of the status of the LTCP would be appropriate.

Applicability and Use:
This performance measure is appropriate for most CSO communities. LTCPs are intended to be water quality-based control plans that are technically feasible, affordable and consistent with the CSO Policy. At the local level this measure will have some value for elected officials and the general public as an indication of the status of required planning and implementation. At the state and federal levels, the aggregate numbers provide a snapshot of compliance with programmatic requirements.

Advantages of Measure:
- Potentially includes all or most CSO communities in the nation.
- LTCPs recognize the site specific nature of CSOs and their impacts on receiving waters.
- LTCPs provide a consistent way for state and federal agencies to track programmatic requirements.
- No additional costs are required to track this measure.

Disadvantages of Measure:
- Not a measure of environmental results.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Long-Term Control Plan.* EPA 832-B-95-002.

Units of Measurement:
Number of CSO communities.

Probable Reporting Agency:
CSO communities and Federal/State Regulatory Agencies.

Potential Data Sources:
- Long Term Control Plans.
- Implementation schedules.

Cost of Data Collection:
Low. Information should be available.

Attributes:

* Linkage to CSO discharge	●
* Quantifiable for trend analysis	○
* Usefulness relative to the cost of data collection	●

VOL 12 2 4892

R0058185

CSO Performance Measure Description
Waste Reduction

This administrative measure provides a quantification of the success of pollution prevention and other activities in reducing the amount of solids and floatables entering the CSS. Waste reduction is the volume of waste material prevented from entering the CSS from pollution prevention activities and catch basin cleaning. The units for this measure are cubic yards, pounds or tons per year.

Pollution prevention activities include street sweeping, solid waste collection, recycling, product bans, and household hazardous waste disposal. These activities control dissolved pollutants as well as solids and floatables. Modification of catch basins and routine catch basin cleaning are important elements of preventing waste material from entering the collection system. The stenciling of catch basins at the inlet to warn against dumping and disposal of motor oil, anti-freeze and other hazardous materials is an effective measure. However, the results of some activities such as stenciling and product bans are not readily quantifiable.

All CSO communities are required to implement pollution prevention programs to reduce contaminants in CSOs as part of the Nine Minimum Controls. Waste reduction is easily understood by the general public. It is considered as a separate performance measure because waste reduction is emphasized in some CSO communities, and the tracking of individual elements of waste reduction can be used as a measure of program success.

Example

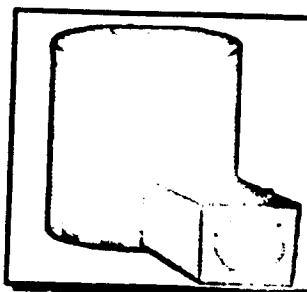
The King County Department of Metropolitan Services in Seattle, Washington has implemented a comprehensive program to reduce waste from entering the CSS. This program requests businesses and households to be careful not to let pollutants enter storm drains, and to maintain catch basins. The major elements of this program are as follows:

- ***Practice Good Housekeeping*** by keeping parking lots and walkways clean, cleaning up spills, keeping dumpsters covered and secure, storing chemicals properly, covering bare ground to prevent erosion, and keeping pet waste out of storm drains.
- ***Trap Pollutants*** by using a drip pan when transferring liquids from one container to another, and using a tarp to catch paint chips and wood and metal shavings when blasting, grinding, or sanding.
- ***Watch Your Washwater*** when washing your car or cleaning shop floors and divert oil, detergents and trace metals away from storm drain.
- ***Maintain Your Catch Basins*** through regular inspection and maintenance, cleaning, proper disposal of solids, and stenciling to reduce waste dumping.

Source: King County Department of Metropolitan Services, Seattle, WA.

VOL 12 2 4893

R0058186



CSO Performance Measure Profile Sheet

Waste Reduction

Category: **Administrative**

Description:
Trend of the volume of waste material prevented from entering the combined sewer system from pollution prevention activities and catch basin cleaning.

Applicability and Use:
Pollution prevention is one of the Nine Minimum Controls. Waste Reduction may be particularly useful as a performance measure in CSO communities where pollution prevention is emphasized. Increases in waste reduction volumes will generally indicate improvement in a combination of pollution prevention activities.

Advantages of Measure:
- Data for catch basin cleaning, street sweeping, recycling and other pollution prevention activities are available in many CSO communities.
- Many elements of waste reduction are understood by the public.

Disadvantages of Measure:
- Many types of pollution prevention activities are difficult to measure.
- Data for the combined and separate portions of the sewer system may be difficult to break out.
- The linkage between waste reduction and environmental improvement is weak.
- Trend analysis may be highly influenced by the frequency of maintenance activities and the success of recycling and other pollution prevention activities. These activities can work in different directions and be difficult to interpret, (i.e., more recycling may mean less waste removed from catch basins).

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Nine Minimum Controls.* EPA 832-B-95-003.

Units of Measurement:
Cubic yards, pounds or tons per year.

Probable Reporting Agency:
CSO Communities.

Potential Data Sources:
- Maintenance records.
- Tipping fees.
- Recycling records.

Cost of Data Collection:
Low to Medium. Cost to gather existing data is low. The cost of initiating new data collection activities may be low to medium.

Attributes:

* Linkage to CSO discharge	◗
* Quantifiable for trend analysis	○
* Usefulness relative to the cost of data collection	◗
* Flexibility with respect to local objectives and conditions	●
* Understandable to the public	◗
* Relationship to environmental improvement	○

VOL 12 2 4894
R0058187

CSO Performance Measure Description
Wet Weather Flow Budget

This measure quantifies the volume of wet weather flow within the CSS and how it is allocated. The appropriate components of the wet weather flow budget will vary from community to community depending on the design and configuration of the collection system, the capacity of the POTW, and the control alternatives selected for implementation. The wet weather flow budget may include the following components:

- Flow eliminated due to sewer separation.
- Flow diverted prior to the CSS (e.g., down spout diversion).
- Flow receiving primary or the equivalent of primary treatment.
- Flow receiving secondary or greater treatment at the POTW.
- Flow receiving no treatment.

The units for this measure are millions of gallons per year (MG/year). The use of flow meters strategically located within the CSS to measure the wet weather flow budget is ideal, but may be too costly or impractical in many CSO communities. The use of collection system models, supplemented with a continuing field validation program, will suffice in most instances. Some normalization of the components of the wet weather flow budget may be required to account for year-to-year differences in precipitation.

Example

The City of South Portland, ME combines real time flow measurements with model-based estimates to compute a wet weather flow budget. The wet weather flow budget for 1995 is illustrated in this example.

Wet Weather Flow Budget: 1995

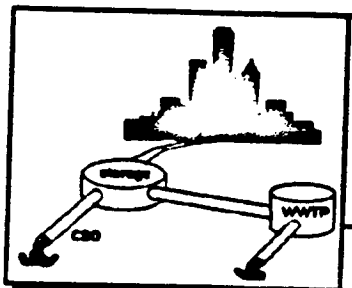
Flow eliminated due to separation:		184 MG
Flow diverted from CSS:		
Redirection of roof drains	6 MG	
Redirection of sump pump discharges	52 MG	
Flow slipping (1)	12 MG	
Subtotal Diverted:		70 MG
Flow receiving primary or equivalent treatment		2 MG
Flow receiving secondary or greater treatment		2,018 MG
Flow receiving no treatment		32 MG

(1) Flow slipping is the placement of solid covers on select catch basins to divert flow away from the CSS.

Source: City of South Portland, ME.

VOL 12 2 4895

R0058188



CSO Performance Measure Profile Sheet

Wet Weather Flow Budget

Category: **End-Of-Pipe**

Description:
Trend of the volume of wet weather flow:
a. Eliminated due to separation.
a. Diverted from CSS (e.g., down spout diversion).
b. Receiving primary or the equivalent of primary treatment.
c. Receiving secondary or greater treatment.
d. Receiving no treatment.

Applicability and Use:
Measuring and accounting for the volume of wet weather flow is a fundamental element of the proper operation and management of a CSS. Establishing a wet weather flow budget may be very valuable in CSO communities where reductions in wet weather flow and diversion within the CSS are important elements of the LTCP.

Advantages of Measure:
- Flow is a well understood unit of measurement, and many control practices are aimed at flow reduction or flow diversion.
- The use of flow meters and models to measure and estimate flow volumes and the flow budget is a common practice in most CSSs.

Disadvantages of Measure:
- The installation and operation of flow meters can be expensive.
- The comparison of wet vs. dry years may be difficult unless normalization procedures are applied.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Long-Term Control Plan.* EPA 832-B-95-002.

Units of Measurement:
MG per year.

Probable Reporting Agency:
CSO Communities.

Potential Data Sources:
- Flow meters.
- Collection system modeling.

Cost of Data Collection:
Variable. Use of existing computer models is a relatively low cost. Metering of CSS is a relatively high cost.

Attributes:

VOL 12 2 4896

R0058189

CSO Performance Measure Description
CSO Frequency

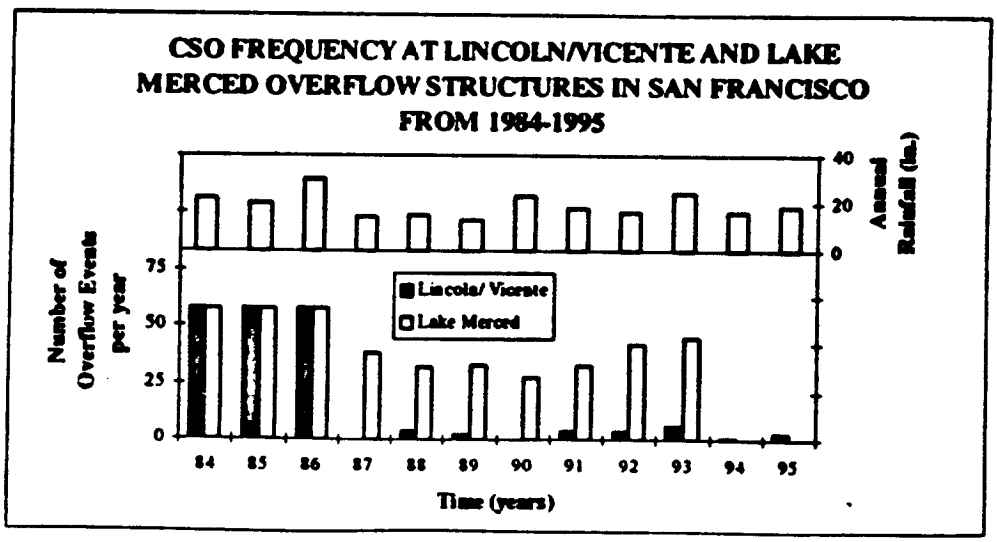
This end-of pipe measure tells us if the frequency of CSO discharge events is changing over time. CSO frequency is a quantification of the frequency of overflow events on an annual basis. The units of measurement are number of overflow events per year. Reducing the frequency of CSOs discharging to surface waters is one of the major goals of the CSO Policy. CSO frequency is therefore recommended as a performance measure that may be used for national tracking of activities and results related to CSO control.

An overflow event is defined as ***one or more overflows from a CSS as the result of a precipitation event that do not receive the minimum treatment specified.*** CSO frequency is particularly important for CSO communities interested in the "presumption" approach under which a total of no more than four overflow events per year is presumed to provide an adequate level of control.

The use of flow meters within the CSS is the ideal method of measurement, but can be very costly. Simpler methods including automatic water level recorders, block tests, and other mechanical devices may be appropriate. The use of collection system models, supplemented with a continuing field validation program, will suffice in most instances. Some normalization of annual CSO frequency values might be helpful in long term trend analysis to account for year-to-year differences in precipitation.

Example

The City of San Francisco has implemented CSO controls and reduced CSO frequency at major outfalls as illustrated in this example. Results are not normalized.



Source: San Francisco Department of Public Works, San Francisco, CA.

VOL 12 2 4897

R0058190

CSO Performance Measure Profile Sheet

CSO Frequency

Category: **End-Of-Pipe**

Description:
Trend of the frequency of overflow events per year from the CSS (number of overflow events per year normalized for precipitation). An overflow event is defined as *one or more overflows from a CSS as the result of a precipitation event that do not receive the minimum treatment specified.*

Applicability and Use:
Quantification of the occurrence and frequency of overflows is basic to the operation and management of combined sewer systems. Reducing the occurrence of CSOs is a primary objective of CSO control. CSO frequency is particularly appropriate for CSO communities considering the Presumption Approach and the option to reduce the frequency of overflows to no more than an average of four overflow events per year. This performance measure is recommended for national tracking of activities and results related to CSO control.

Advantages of Measure:
- Consistent with the *Presumption Approach* in the CSO Policy.
- Can be measured or modeled in a variety of ways with a fairly high level of precision.
- Provides an understandable measure of control effectiveness.

Disadvantages of Measure:
- Comparison of wet and dry years may be difficult unless the data is normalized.
- The cost and effort to install and maintain meters and to develop a model of the CSS can be substantial.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Long-Term Control Plan.* EPA 832-B-95-002.

Units of Measurement:
Number of overflow events per year.

Probable Reporting Agency:
CSO Communities.

Potential Data Sources:
- Flow meters.
- Collection system modeling.

Cost of Data Collection:
Variable. Use of existing computer models is a relatively low cost. Metering of CSS is a relatively high cost.

Attributes:

R0058191

VOL 12 2 4898

CSO Performance Measure Description
CSO Frequency in Sensitive Areas

This end-of-pipe measure quantifies the frequency of overflow events into sensitive areas on an annual basis. The units are number of overflows per year. Under the CSO Policy, CSO communities are expected to give the highest priority to controlling overflows to sensitive areas in the development of LTCPs. As a minimum, sensitive areas include designated Outstanding National Resource Waters, National Marine Sanctuaries, waters with threatened or endangered species and their habitat, waters with primary contact recreation (e.g., bathing beaches, etc.), public drinking water intakes or their designated protection areas, and shellfish beds. CSO frequency in sensitive areas is recommended as a performance measure that may be used for national tracking of activities and results related to CSO control.

An overflow event is defined as ***one or more overflows from a CSS as the result of a precipitation event that do not receive the minimum treatment specified.***

The use of flow meters within the CSS is the ideal method of measurement, but can be very costly. Simpler methods including automatic water level recorders, block tests, and other mechanical devices may be appropriate. The use of collection system models will suffice in most instances. Some normalization of annual totals for CSO frequency in sensitive areas might be helpful in long term trend analysis to account for year-to-year differences in precipitation.

Example

The Massachusetts Water Resources Authority's LTCP for the Boston Harbor area includes the elimination of CSO discharges to "critical use areas." Swimming and shellfishing are considered to be critical uses. As illustrated in this example, the frequency of CSO discharges to these critical use areas is expected to decrease to zero as the LTCP including sewer separation and relocation to less sensitive areas is implemented.

Critical Use		CSO Frequency for a Typical Year (#/YR)	
Areas	**Activities**	**Baseline**	**Projected in LTCP**
North Dorchester Bay	swimming, shellfishing	78	0
South Dorchester Bay(1)	swimming, shellfishing	22	0
Neponset River	shellfishing	17	0
Constitution Beach(1)	swimming, shellfishing	16	0
(1) Baseline includes partial treatment.	**Totals:**	133	0

Source: Massachusetts Water Resources Authority, Boston, MA.

VOL 12 2 4899

CSO Performance Measure Profile Sheet
CSO Frequency in Sensitive Areas

Category: **End-Of-Pipe**

Description:
Trend of the frequency of overflow events per year from the CSS with discharges to sensitive areas (number of overflow events per year). An overflow event is defined as *one or more overflows from a CSS as a result of a precipitation event that do not receive the minimum treatment specified.*

Applicability and Use:
Municipalities are expected to give the highest priority to the control of CSOs discharging to sensitive areas. Sensitive areas include marine sanctuaries, water with threatened or endangered species, beaches, shellfish beds, and waters designated for water supply use. This performance measure is appropriate for all CSO communities with discharges to sensitive areas. It is also recommended for national tracking of activities and results related to CSO control.

Advantages of Measure:
- High priority within the CSO Policy.
- Can be measured or modeled in a variety of ways with a fairly high level of precision.
- Relationship to environmental improvement is not direct but could be substantial.

Disadvantages of Measure:
- Comparison of wet and dry years may be difficult unless the data is normalized.
- The cost and effort to install and maintain meters and to develop a model of the CSS can be substantial.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Long-Term Control Plan.* EPA 832-B-95-002.

Units of Measurement:
Number of overflow events per year to sensitive areas.

Probable Reporting Agency:
CSO Communities.

Potential Data Sources:
- Flow meters.
- Mechanical devices.
- Collection system modeling.

Cost of Data Collection:
Variable. Metering of CSS is a relatively high cost. Mechanical devices are low in cost.

VOL 12 2 4900
R0058193

CSO Performance Measure Description
CSO Volume

This end-of-pipe measure tracks the volume of CSO discharge over time. It represents a quantification of the volume of overflows from a CSS on an annual basis. The units are millions of gallons per year (MG/year). CSO volume represents a potentially important performance measure for CSO communities interested in the "presumption" approach within their LTCP. Under the presumption approach, the elimination or capture for treatment of no less than 85% by volume of the combined sewage collected in the CSS on an annual average basis may be presumed to provide an adequate level of control.

Volume is best measured with metering systems that continuously record water level and/or velocity at outfalls within the CSS. Block tests or other simple mechanical devices that might be appropriate for measurement of the occurrence of an overflow event are not appropriate for the measurement of volume. The use of collection system models will suffice in most instances. Some normalization of the annual CSO volume might be helpful in long term trend analysis to account for year-to-year differences in precipitation.

Example

In 1992 the City of South Portland, ME installed a sophisticated yet cost-effective network of flow meters to measure real time flows within their CSS. Installation coincided with the implantation of CSO controls. The trend of CSO volume with a simple example of normalization with precipitation data is illustrated in this example.

Year	CSO Volume MG/YR	Annual Precipitation Inches	Normalization Ratio (1)	Normalized CSO Volume MG/YR
Pre Control	528	44.34(2)	1.00	528
1992	105	38.51	0.87	121
1993	289	43.81	0.99	292
1994	195	43.98	0.99	197
1995	32	41.43	0.93	34

(1) This example illustrates a simple normalization ratio calculated by dividing annual precipitation by average annual precipitation, with annual volume divided by the ratio. Other more sophisticated normalization procedures may be appropriate where uncontrolled CSO volume can be correlated with precipitation.

(2) Average Annual precipitation is 44 34 inches

CSO Performance Measure Profile Sheet

CSO Volume

Category: **End-Of-Pipe**

Description:
Trend of the volume of water discharged from the combined sewer system over a year.

Applicability and Use:
Measuring CSO volume is fundamental to the characterization of CSSs and to the evaluation of control alternatives. This performance measure has general applicability for most CSO communities. CSO volume is particularly appropriate for CSO communities considering the *Presumption Approach* and the option to eliminate or capture for treatment of no less than 85% by volume of the combined sewage collected in the CSS.

Advantages of Measure:
- Consistent with the *Presumption Approach* in the CSO Policy.
- Can be measured or modeled in a variety of ways with a fairly high level of precision.
- Provides an understandable measure of control effectiveness.

Disadvantages of Measure:
- Comparison of wet and dry years may be difficult unless the data is normalized.
- The cost and effort to install and maintain meters and to develop a model of the CSS can be substantial.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Long-Term Control Plan.* EPA 832-B-95-002.

Units of Measurement:
MG per year.

Probable Reporting Agency:
CSO Communities.

Potential Data Sources:
- Flow meters.
- Collection system modeling.

Cost of Data Collection:
Variable. Use of existing computer models is a relatively low cost. Metering of CSS is a relatively high cost.

Attributes:

* Linkage to CSO discharge	●
* Quantifiable for trend analysis	●
* Usefulness relative to the cost of data collection	●

R0058195

CSO Performance Measure Description
CSO VOLUME IN SENSITIVE AREAS

This end-of-pipe measure tracks the CSO volume discharged in sensitive areas over time. It represents a quantification of the volume of overflows from a CSS discharged to sensitive areas on an annual basis. The units are millions of gallons per year (MG/year). Under the CSO Policy, CSO communities are expected to give the highest priority to controlling overflows to sensitive areas in the development of LTCPs. As a minimum, sensitive areas include designated Outstanding National Resource Waters, National Marine Sanctuaries, waters with threatened or endangered species and their habitat, waters with primary contact recreation (e.g., bathing beaches, etc.), public drinking water intakes or their designated protection areas, and shellfish beds. This measure may also be useful under the presumption approach, where the elimination or capture for treatment of no less than 85% by volume of the combined sewage collected in the CSS on an annual average basis might be presumed to provide an adequate level of control.

Volume is best measured with metering systems that continuously record water level and/or velocity at outfalls within the CSS. Block tests or other simple mechanical devices that might be appropriate for measurement of the occurrence of an overflow event are not appropriate for the measurement of volume. The use of collection system models will suffice in most instances. Some normalization of the annual CSO volume in sensitive areas might be helpful in long term trend analysis to account for year-to-year differences in precipitation.

Example

The City of San Francisco, CA has implemented CSO controls to reduce discharge volume in sensitive areas as illustrated in this example.

Sensitive Areas	Activities	Pre-Control Vol.(MG/YR)	Current 1995 Vol.(MG/YR)	Projected 1997(1) Vol.(MG/YR)
Sunnydale	shellfish beds windsurfing	645	10	10
Ocean Beach	swimming surfing	2,117	491	341
Baker Beach	swimming	529	123	85
Aquatic Park	swimming	570	57	57
	Totals:	**3,861**	**681**	**493**

(1) All discharges projected for 1997 will have received the minimum treatment required in the CSO Policy.

CSO Performance Measure Profile Sheet
CSO Volume in Sensitive Areas

Category: **End-Of-Pipe**

Description:
Trend of the volume of CSO discharged to sensitive areas.

Applicability and Use:
CSO communities are expected to give the highest priority to the control of CSOs discharging to sensitive areas. Sensitive areas include marine sanctuaries, water with threatened or endangered species, beaches, shellfish beds, and waters designated for water supply use. This performance measure has general applicability for all CSO communities with discharges to sensitive areas where the quantification of CSO volume is consistent with the LTCP.

Advantages of Measure:
- High priority within the CSO Control Policy.
- Can be measured or modeled in a variety of ways with a fairly high level of precision.
- Relationship to environmental improvement is not direct but could be substantial.

Disadvantages of Measure:
- Comparison of wet and dry years may be difficult unless the data is normalized.
- The cost and effort to install and maintain meters and to develop a model of the CSS can be substantial.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Long-Term Control Plan.* EPA 832-B-95-002.

R0058197

VOL 12 2 4904

CSO Performance Measure Description
Dry Weather Overflows

This end-of-pipe measure quantifies the number of dry weather overflows (DWOs) that have been observed or occurred over the course of a year. The elimination of DWOs during dry weather is a major objective of the CSO Policy, and one of the Nine Minimum Controls. Because dry weather overflows are prohibited under the Clean Water Act and the NPDES Program, DWOs are included as a separate performance measure.

Implementation of a performance measure for DWOs requires two elements:

- A system for detection and documentation of DWOs; and
- A method of quantification that is meaningful.

Detection methods can include operator inspection of regulators or outfalls at a set frequency, use of visual or mechanical detection devices, or continuous on-line monitoring. Inspection frequency and other technical issues are addressed in EPA's *Combined Sewer Overflows - Guidance Document for the Nine Minimum Controls* (U.S. EPA, 1995a).

Quantification should be consistent from year-to-year so that the measure can be trendable over time. Given the variety of DWO detection methods, quantification of flow volume or flow rate is not realistic for most CSO communities. However, potentially meaningful measures would be the number of DWO occurrences per year (with "occurrence" defined as a period of continuous overflow at an individual regulator or outfall), and the number of DWO-days per year (defined as the number of days of continuous overflow at a given structure per year). An alternative measure would be the number of DWO occurrences found per 100 inspections.

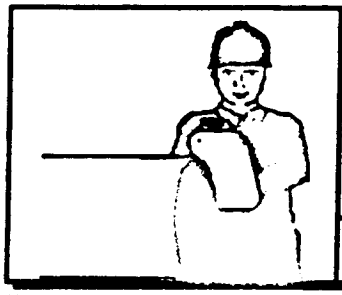
Example

An informal survey revealed that the occurrence of DWOs has not been tracked and quantified on a regular basis in most CSO communities. However, with the *elimination of CSOs during dry weather* as one of the NMCs, greater attention to detecting and documenting DWOs is anticipated. DWOs are particularly significant for the following reasons:

- Contaminants in DWOs, including pathogens, are undiluted compared with wet weather overflows.
- DWOs occur at a time when inclement weather would not discourage recreational contact with receiving waters, thus increasing public health risks.
- The presence of continuous or frequent DWOs could be indicative of more widespread operations and maintenance deficiencies.

VOL 12 2 4905

R0058198



CSO Performance Measure Profile Sheet

Dry Weather Overflows

Category: **End-Of-Pipe**

Description:
Trend of the number of dry weather overflows found per year within a combined sewer system (# per year or # days per year).

Applicability and Use:
The elimination of dry weather overflows is a major objective of the CSO Control Policy. It is also one of the Nine Minimum Controls, and subject to tracking and reporting requirements. Quantifying and tracking the number of dry weather overflows may be a useful performance measure in its own right for CSO communities where dry weather overflows are a recognized ongoing problem, and where the elimination of dry weather controls is emphasized within the LTCP. In these instances, additional effort may be required to quantify the occurrence of dry weather overflows in a meaningful, consistent and comprehensive manner.

Advantages of Measure:
- The elimination of dry weather overflows is a requirement for all CSO communities.
- Provides a measure of gross pollution and pollution abatement.
- Potentially applicable for all CSO communities.
- Overflows can be measured in several ways, including visual inspection.

Disadvantages of Measure:
- Consistency of measurement from system to system will vary greatly.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Nine Minimum Controls.* EPA 832-B-003.

Units of Measurement:
per year or # days per year.

Probable Reporting Agency:
CSO Communities.

Potential Data Sources:
- Flow meters.
- Inspection reports.
- Block tests or mechanical devices.

Cost of Data Collection:
Low. Should be part of proper Operation & Maintenance.

Attributes:

VOL 12 2 4906

R0058199

CSO Performance Measure Description
BOD Load

This end-of-pipe measure provides an estimate of the amount of oxygen demanding material discharged from the CSS to receiving waters over time. BOD load is the pounds of biochemical oxygen demand (BOD) in organic matter discharged from a CSS over the course of a year. The units for this measure are pounds per year of BOD. BOD_5, the amount of dissolved oxygen consumed in five days by biological processes, is commonly used as a measure of the strength or concentration of wastewater influent and effluent in mg/l. The BOD load from the CSS is the product of flow and concentration.

This measure may be important in those systems where the contribution of BOD from the CSS is a major cause of depressed dissolved oxygen, and where a reduction in the CSS contribution of BOD is an integral part of the LTCP. Tracking the trend of BOD load reductions over time in these systems should correlate with improved dissolved oxygen levels in impacted receiving waters. In general, changes in BOD load over time will typically be due to changes in CSO volume. However, the average concentration of BOD_5 in CSO discharges could be reduced over time due to the implementation of certain control technology such as swirl concentrators or other practices to reduce solids and first flush effects. Automated samplers could be used to monitor flow and BOD_5 concentrations for load calculation. The use of collection system models to estimate BOD load will suffice in most instances. Normalization of the annual BOD load might be helpful in long term trend analysis to account for year-to-year differences in precipitation.

Example

The Narragansett Bay Commission operates and maintains combined sewer interceptors and POTWs serving ten communities in north central Rhode Island including Providence, Central Falls and Pawtucket. The CSS includes 85 overflow structures that discharge to several rivers tributary to upper Narragansett Bay.

A conceptual design for the LTCP was completed in 1993 that includes recommendations for the construction of both near surface storage facilities and deep tunnels. Flows captured within these facilities will be pumped back to the interceptor system following storms, and will receive secondary treatment.

It is anticipated that implementation of the LTCP will result in an 86 percent reduction in the BOD load from the CSS. BOD loads can be tracked on an annual basis through a combination of direct measurement and model-based estimates. However, earlier studies had shown that bacterial contamination and floatables represent the two most important impacts associated with CSO discharges. A watershed-based comparison of BOD loading sources indicated that CSOs represent only 15 percent of the annual BOD load to the upper Bay. POTWs and upstream watershed sources represent 44 and 41 percent of the BOD load, respectively. BOD loads from the CSS are therefore not a major concern, and the Narragansett Bay Commission will utilize other performance measures more applicable for the upper Bay to track performance. This example is intended to illustrate the point that CSO communities should focus on those performance measures that are most applicable for their site-specific situation.

CSO Performance Measure Profile Sheet

BOD Load

Category: **End-Of-Pipe**

Description:
Trend of the pounds of BOD discharged from the combined sewer system (lbs per year normalized for precipitation).

Applicability and Use:
The BOD load in CSO discharge can be an important source of organic material in some receiving waters. BOD load potentially impacts water quality and habitat. The quantification of BOD load has general applicability where BOD is contributing to depressed dissolved oxygen conditions, or to the buildup of organic deposits in bottom sediments. It can be used by CSO communities to document reductions in BOD load where this is targeted in the LTCP. Quantifying BOD load also has significance at the watershed level where cause and effect relationships and tradeoffs among control options are examined.

Advantages of Measure:
- A variety of approaches can be used to quantify BOD load including direct measurement and application of models with varying levels of sophistication.
- BOD is a conventional pollutant that is relatively easy to measure and model.
- BOD load reduction has been a major element of waste water control at POTWs, and it is well understood by managers.

Disadvantages of Measure:
- Comparison of wet and dry years may be difficult unless the data is normalized.
- Load by itself is not a direct measure of environmental conditions.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Long-Term Control Plan.* EPA 832-B-95-002.

Units of Measurement:
Pounds of BOD per year.

Probable Reporting Agency:
CSO Communities.

Potential Data Sources:
- Automated monitoring.
- Model-based estimates.

Cost of Data Collection:
Low to Medium. Use of existing computer models periodically validated with BOD concentrations at the outfalls is appropriate.

VOL 12 2 4908

R0058201

CSO Performance Measure Description
TSS Load

This end-of-pipe measure provides an estimate of the amount of TSS (total suspended solids) discharged from the CSS to receiving waters over time. TSS load is the pounds of TSS discharged from a CSS over the course of a year. The units for this measure are pounds per year of TSS. TSS is commonly used as a measure of the strength or concentration of wastewater influent and effluent in mg/l. The TSS load from the CSS is the product of flow and concentration.

This measure may be important in those systems where the contribution of suspended solids from the CSS is a major cause of turbidity and associated receiving water impacts, and where a reduction in the CSS contribution of TSS is an integral part of the LTCP. In general, changes in TSS load over time will typically be due to changes in CSO volume. However, the average concentration of TSS in CSO discharges could be reduced over time due to the implementation of certain control technology such as swirl concentrators or other practices to reduce solids and first flush effects. Automated samplers could be used to monitor flow and TSS concentrations for load calculation. The use of collection system models to estimate TSS load will suffice in most instances. Normalization of the annual TSS load might be helpful in long term trend analysis to account for year-to-year differences in precipitation.

Example

The Columbus Water Works in Columbus, Georgia operates and maintains a sewer collection system and POTW with a service area of over 26,000 acres. The Long Term Control Plan (LTCP) initially identified 5,132 acres in the CSS. This initial phase of the CSO program allowed 2,520 acres to be separated from the CSS via installation of a single interceptor sewer. The remaining CSS covers 2,612 acres and includes 16 CSOs: 15 discharging to the Chattahoochee River, and one to Werecoba Creek.

Columbus initiated designs for sewer separation and for CSO conveyance and treatment in 1992. Two CSO treatment facilities were completed in late 1995 that include coarse screening, vortex separation, disinfection, degritting of vortex underflow, and secondary vortex. An EPA funded Demonstration Project testing the cost effectiveness of several treatment processes including high rate filtration and ultra violet disinfection is also underway with construction scheduled for completion in May 1996. A two year testing program will identify the applicability of these processes to CSO treatment.

It is anticipated that implementation of the LTCP will result in an 85 percent reduction in the TSS load from the CSS. TSS loads can be tracked on an annual basis through a combination of direct measurement and model-based estimates. However, earlier studies had shown that bacterial contamination and floatables represent the two most important impacts associated with CSO discharges. Columbus may elect to monitor and track annual TSS loads once the CSO demonstration project has been completed, but TSS is not a major concern. TSS and fecal coliform measurements will be made on the influent and effluent of both treatment facilities as well as up and downstream of the plant outfalls. However, other performance measures included in the NPDES permit and more applicable to site specific conditions in Columbus will probably be utilized to track performance.

CSO Performance Measure Profile Sheet

TSS Load

Category: **End-Of-Pipe**

Description:
Trend of the pounds of TSS discharged from the combined sewer system (lbs per year normalized for precipitation).

Applicability and Use:
The reduction of TSS loads to receiving waters is a major element in CSO control. The quantification of TSS load has general applicability where TSS is contributing to water quality problems or habitat impairment. It can be used by CSO communities to document reduction in TSS where this is targeted in the LTCP. The quantification of TSS load can be important in receiving waters where the accumulation of CSO solids in bottom sediments represents a persistent problem. It is also valuable in watershed studies where multiple sources of TSS have been identified as contributing to problems on a watershed scale.

Advantages of Measure:
- A variety of approaches can be used to quantify TSS load including direct measurement and application of models with varying levels of sophistication.
- TSS is a conventional pollutant that is relatively easy to measure and model.
- TSS load reduction has been a major element of waste water control at POTWs, and it is well understood by managers.

Disadvantages of Measure:
- Comparison of wet and dry years may be difficult unless the data is normalized.
- Load by itself is not a direct measure of environmental conditions.

For More Information:

VOL 12 2 4910
R0058203

CSO Performance Measure Description
Nutrient Load

This end-of-pipe measure provides an estimate of the amount of nutrients discharged from the CSS to receiving waters over time. Nutrient load is the pounds of total nitrogen (TN) and/or the pounds of total phosphorus (TP) discharged from a CSS over the course of a year. The units for this measure are pounds per year of TN and/or TP. Nutrient load from the CSS is the product of flow and concentration.

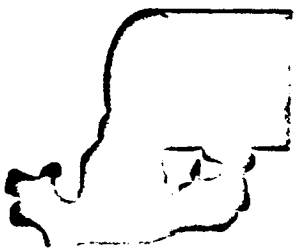
This measure may be important in those systems where the discharge of nutrients from the CSS contributes to eutrophication and associated impacts, and where a reduction in the CSS contribution of nutrients is an integral part of the LTCP. The targeted nutrient load may be TN, TP or both, depending on which is considered to be the nutrient that is limiting the growth of algae or other nuisance aquatic plants. In general, changes in nutrient load over time will typically be due to changes in CSO volume. However, pollution prevention and other nonstructural controls can reduce the concentration of nutrients in CSOs. Automated samplers could be used to monitor flow and nutrient concentrations for load calculation. The use of collection system models to estimate nutrient load will suffice in most instances. Normalization of the annual TSS load might be helpful in long term trend analysis to account for year-to-year differences in precipitation.

Example

No specific examples of CSO communities quantifying and tracking nutrient loads on an annual basis were found. The nutrient component of CSO loads is usually small relative to other sources including agricultural runoff, urban runoff and point sources. Nevertheless, nutrient load might be an appropriate performance measure where CSOs discharge to eutrophic lakes, estuaries or coastal waters, and where nutrients removed through CSO control can be credited toward targeted nutrient load reductions on a watershed basis.

R0058204

VOL 12 2 491 1 1



CSO Performance Measure Profile Sheet

Nutrient Load

Category: **End-Of-Pipe**

Description:
Trend of the pounds of nutrients discharged from the combined sewer system (lbs per year normalized for precipitation).

Applicability and Use:
The phosphorus and nitrogen loads in CSO discharges can be a source of nutrient enrichment in receiving waters. The quantification of nutrient load has limited applicability where the CSO contribution of nutrients to receiving waters is substantial, and where tracking nutrient load reduction is targeted in the LTCP. Evaluations of nutrient enrichment require site-specific consideration of existing and historical eutrophication conditions, water uses, and relevant standards and criteria.

Advantages of Measure:
- A variety of approaches can be used to quantify nutrient load including direct measurement and application of models with varying levels of sophistication.
- Nutrient load reduction has been a major element of waste water control at POTWs, and it is well understood by managers.
- Nutrient reduction from all sources is becoming increasingly important in some watersheds.

Disadvantages of Measure:
- The comparison of wet and dry years may be difficult unless normalization procedures are applied.
- The CSO component of nutrient loads on a watershed basis is typically small relative to point and agricultural sources.
- Load by itself is not a direct measure of environmental conditions.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Long-Term Control Plan.* EPA 832-B-95-002.

Units of Measurement:
Pounds of nutrients per year.

Probable Reporting Agency:
CSO Communities.

Potential Data Sources:
- Automated monitoring.
- Model-based estimates.

VOL 12 2 4912

R0058205

CSO Performance Measure Description
Floatables

This end-of-pipe measure quantifies the amount of solids and floatables captured within the combined sewer system. The units for this measure are cubic yards, pounds or tons per year. The methods utilized to remove solids and floatables from combined sewage within the CSS include baffles, screens, and trash racks. End-of-pipe methods include nets and outfall booms.

All CSO communities are required to control solid and floatable materials in CSOs as part of the Nine Minimum Controls. Quantification of the volume of solids and floatables controlled on an annual basis is a measure that would be understood by the general public, and it is considered to have value as a separate performance measure on a site-specific basis. This measure may be important in those systems where the discharge of solids and floatable material produces substantial aesthetic and public health impacts, and where the control of solid and floatable materials is an integral part of the LTCP.

Example

The City of Newark, NJ has thirty CSO outfalls. The New Jersey General Permit for CSSs requires the capture of all floatables greater than one-half inch in diameter from CSO discharges. A CSO Floatable Reduction Demonstration Project was carried out in Newark with an EPA grant during 1994. The demonstration focused upon the effectiveness of rigid frame netting technology to capture floatables at two outfalls. The results of the study indicated that the Trash Trap™ system incorporating a series of nets supported by pontoon structures was very effective, capturing over 95 percent of the floatables present. Further, the technology was reliable and reasonable with regard to capital cost, operation and maintenance costs, and cost per pound of floatable captured.

The composition of CSO Floatables from two separate outfalls is as follows:

Item	% Volume	% Weight
Plastic/paper bags	12 - 26	7 - 15
Plastic bottles	10 - 19	6 - 7
Straws	0 - 2	0 - 1
Cans	< 1	0 - 1
Styrofoam	14 - 20	3 - 5
Glass bottles	3 - 4	3 - 6
Wood	3	3
Medical waste	<1	<1
Misc. solids, leaves	38 - 45	66 - 73
Other(1)	0 - 1	0 - 2

(1) Most common items are other plastics, condoms, shoes and bottle caps.

R0058206

CSO Performance Measure Profile Sheet

Floatables

Category: **End-Of-Pipe**

Description:
Trend of the volume of floatables captured within the combined sewer system (cubic yards, pounds or tons per year normalized for precipitation).

Applicability and Use:
Floatables captured within the CSS are solids and other materials prevented from being discharged to a receiving water. This measure will be particularly useful in CSO communities where there is a heightened awareness of floatables as an aesthetic nuisance, a cause of beach closures, or a contributing factor to other environmental and health problems.

Advantages of Measure:
- Floatables are highly visible and understandable by the public.
- Floatables control is one of the Nine Minimum Controls.
- Quantification of floatables captured provides a positive measure for the general public of constructive action.
- Floatables control may be cost effective.

Disadvantages of Measure:
- End-of-Pipe technologies are relatively new and untested, and may be expensive or difficult to adapt to many CSSs.
- Results may be difficult to interpret due to initiatives in other areas such as pollution prevention, catch basin cleaning, etc.
- Involves construction, operation and maintenance costs.

For More Information :
U.S. EPA. 1995. *CSOs: Guidance for Nine Minimum Controls.* EPA 832-B-95-003.

Units of Measurement:
Cubic yards, pounds or tons per year.

Probable Reporting Agency:
CSO Communities.

Potential Data Sources:
- In system screens/racks.
- End-of-pipe nets and booms.

Cost of Data Collection:
Medium to High. Requires capital costs as well as ongoing Operation and Maintenance costs.

R0058207

VOL 12 2 4914

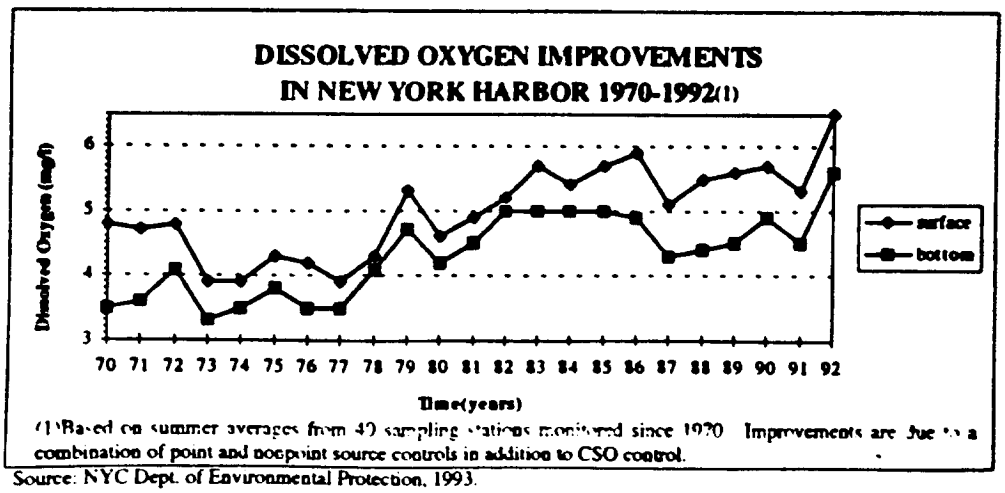
CSO Performance Measure Description
Dissolved Oxygen Trend

This receiving water measure describes the dissolved oxygen condition of impacted receiving waters over time. The dissolved oxygen trend is a time plot of the concentration of dissolved oxygen over time. The units are mg/l of dissolved oxygen.

Dissolved oxygen is vital to fish and other aquatic life, and for the prevention of odors. The level of dissolved oxygen is viewed as one of the most important indicators of a water body's ability to support desirable aquatic life. Dissolved oxygen concentration is widely applied to gauge attainment of designated uses and water quality standards. This measure may be important in those systems where the contribution of oxygen demanding material (the BOD load) from the CSS is a major cause of depressed dissolved oxygen in receiving waters, and where improvement of dissolved oxygen is a major objective of the LTCP. Tracking the trend in dissolved oxygen in impacted receiving waters may be appropriate for systems where the demonstration approach is utilized to show the adequacy of the LTCP with regard to criteria related to designated uses and water quality standards. Attainment of water quality standards is assessed by superimposing the dissolved oxygen standard on the time plot. Because of the variety of pollutant sources potentially affecting the dissolved oxygen balance in urban waters, this performance measure is well-suited for tracking improvement on a watershed scale.

The measurement of dissolved oxygen should be performed in waters that are known to be impacted by CSOs so that improvement can be tracked over time as controls are implemented. Continuous automated sampling provides the best record of wet weather impacts. Grab samples will suffice in most instances if the data reflect wet weather or impacted conditions.

Example



(1) Based on summer averages from 40 sampling stations monitored since 1970. Improvements are due to a combination of point and nonpoint source controls in addition to CSO control.

Dissolved Oxygen Trend

Category: **Receiving Water**

Description:
Trend of dissolved oxygen in CSO impacted receiving water (time plot or trend analysis of dissolved oxygen in mg/l).

Applicability and Use:
The dissolved oxygen concentration of receiving waters is a widely used measure of water quality conditions. This receiving water measure has general applicability for receiving waters where it is consistent with the LTCP. It is most applicable in those situations where depressed dissolved oxygen conditions occur and are caused in part by CSO loadings and/or sediment oxygen demand originating from CSO solids.

Advantages of Measure:
- Dissolved oxygen can be monitored in the field with simple inexpensive equipment.
- Dissolved oxygen can be monitored continuously making it possible to record trends over time.
- Dissolved oxygen has value at the local and watershed levels.
- Historical records are available in many receiving waters.

Disadvantages of Measure:
- Impacts can be transferred downstream and away from CSO outfalls in some systems.
- It may be difficult to associate change over time with CSO reductions because of other watershed sources.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Long-Term Control Plan.* EPA 832-B-95-002.

Units of Measurement:
Milligrams per liter (mg/l) of DO.

Probable Reporting Agency:
CSO Communities.
State and Federal Agencies.

Potential Data Sources:
- Water quality surveys.
- Continuous samplers.

Cost of Data Collection:
Medium to High. Requires long term commitment to consistent monitoring during wet weather events.

Attributes:

• Linkage to CSO discharge	◗
• Quantifiable for trend analysis	●
• Usefulness relative to the cost of data collection	◗
• Flexibility with respect to local objectives and conditions	◗
• Understandable to the public	◗
• Relationship to environmental improvement	●

VOL 12 2 4916
R0058209

CSO Performance Measure Description
Fecal Coliform Trend

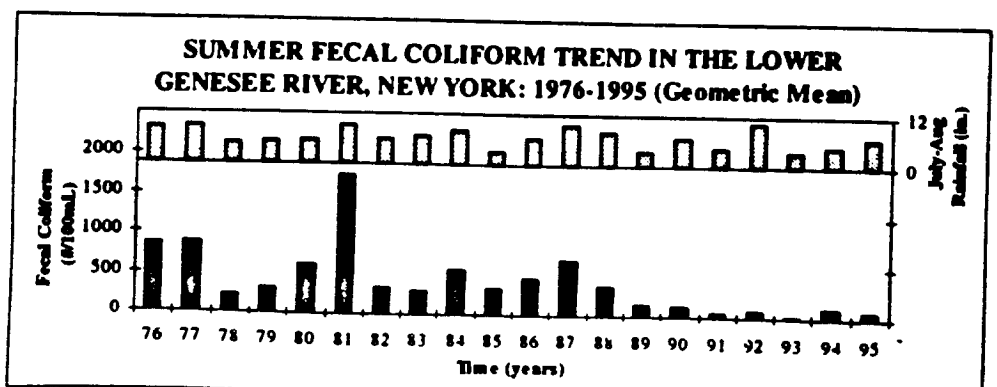
This receiving water measure describes the bacterial condition of impacted waters over time. Fecal coliform is a bacteria found in the intestinal tracts of mammals. Its presence in receiving waters indicates pollution and possible contamination by pathogens. The fecal coliform trend is a time plot of fecal coliform bacteria levels in impacted receiving waters. The units are the number of fecal coliforms per 100 ml.

Fecal coliform is the most widely used measure of the bacteriological condition of receiving waters. Urban waters typically have elevated fecal coliform levels during and following wet weather periods caused by a variety of sources including CSOs, storm water, agricultural runoff, failed septic systems, and marine discharges. This measure may be important in those systems where bacteria from the CSS contributes to elevated bacterial conditions in receiving waters, and where reducing bacterial contamination in receiving waters is a major objective of the LTCP. Tracking the trend of fecal coliform in impacted receiving waters may be appropriate for systems where the demonstration approach is utilized to show the adequacy of the LTCP with regard to criteria related to designated uses and water quality standards. Because of the variety of fecal coliform sources potentially affecting urban waters, this performance measure is well-suited for tracking improvement on a watershed scale.

Fecal coliform should be measured in waters that are known to be impacted by CSOs so that improvement can be tracked over time as controls are implemented. Grab samples will be adequate in most instances if the data reflect wet weather or impacted conditions. Use of other indicator organisms such as total coliform (*Escherichia coli*) or fecal streptococci (enterococci) may be appropriate where applicable.

Example

Monroe County, New York, which includes the city of Rochester, has implemented CSO controls including Best Management Practices and construction of expanded conveyance capacity that have substantially reduced fecal coliform levels in the lower Genesee River.



Source: Monroe County Health Department, Environmental Health Laboratory, NY.

VOL 12 2 4 9 1 7

CSO Performance Measure Profile Sheet

Fecal Coliform Trend

Category: **Receiving Water**

Description:
Trend of the wet weather concentration of fecal coliform or other bacterial indicator concentrations in CSO-impacted receiving waters (time plot or trend analysis of fecal coliform in #/100 ml in receiving water).

Applicability and Use:
The level of fecal coliform in receiving waters is a widely used measure of water quality conditions. Bacterial contamination is one of the major pollutants of concern discharged from CSOs. High bacterial levels can affect shellfishing, swimming, and other designated uses. Measuring the trend of fecal coliform can be a useful way for many CSO communities to assess the effectiveness of CSO control measures.

Advantages of Measure:
- Widely applied to gauge attainment of designated uses and water quality standards.
- Historical records are available in many receiving waters.

Disadvantages of Measure:
- Cannot be continuously monitored, making it difficult to obtain wet weather samples during and following overflow events.
- It may be difficult to associate change over time with CSO control because of other watershed sources of contaminants and management activities.

For More Information:
APHA, AWWA, WEF. 1995. *Standard Methods For the Examination of Water and Wastewater, 19th Edition.*

Units of Measurement:
per 100 ml or other appropriate units.

Probable Reporting Agency:

VOL 12 2 4 9 1 8

CSO Performance Measure Description
Floatables Trend

This receiving water measure quantifies the amount of floatable debris collected annually from clean up programs in CSO-impacted receiving waters including beach and shoreline surveys. The amount of floatables collected by skimmer boats in harbors could also be used to quantify a floatables trend. The units for this measure are cubic yards, pounds or tons per year. The number of items collected may also be appropriate.

Floatables in receiving waters represent an aesthetic nuisance and a potential public health problem. The wash-up of floatable sanitary and medical waste can result in beach closures. Floatables can also cause significant damage to wildlife and habitat. Floatables trend may be an important measure in CSO communities where there is a heightened awareness of floatables as a health hazard, aesthetic detraction, or environmental problem. Floatables are tangible and usually understood by the public.

The use of this performance measure presents several challenges. Street litter is a primary source of floatables. With the exception of certain personal hygiene products, it is often difficult to distinguish the origin of floatables (e.g., CSO vs. urban stormwater). Clean up programs including beach and shoreline surveys are usually dependent on volunteers, and the quantification of floatables is often not precise. Weather, the number of people involved, and other factors affect the total volume collected. Consequently, the linkage of trend analysis to CSO control is difficult to establish.

Example

Floatables control is a top priority of the New York City Department of Environmental Protection's CSO Abatement Program. Floatables have contributed to several problems in New York Harbor including beach closing, interference with navigation, and entanglement of wildlife. It is estimated that 85 percent of floatables in the Harbor originate from CSOs and separate storm sewers conveying street litter.

In addition to enhanced street sweeping, catch basin modifications, public education, and hydraulic control, New York City has aggressively studied and pursued floatables containment and removal. The principal controls include end-of-pipe nets, booms, and marine vessels that skim floatables from the water. From June 1994 through May 1995, 150,000 pounds of trash were boomed and skimmed. Since 1989, the capture of floatables from CSOs has increased from 30 to 70 percent.

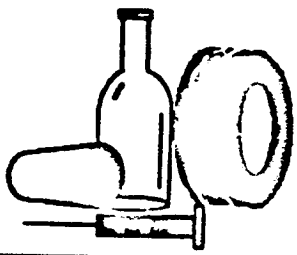
R0058212



CSO Performance Measure Profile Sheet

Floatables Trend

Category: **Receiving Water**

Description:
Trend of floatables measured or collected from receiving water cleanup programs or beach surveys (cubic yards, pounds or tons per year).

Applicability and Use:
Floatables are one of the major pollutants of concern discharged from CSOs. CSO communities are expected to control floatables as one of the Nine Minimum Controls. Tracking the trend of floatables collected in key use areas can be a useful performance measure for some CSO communities where it is consistent with the LTCP. Floatables trend represents an alternative to the end-of-pipe capture and measurement of floatables.

Advantages of Measure:
- Understandable to the public.
- Can be targeted at key problem areas to reduce cost and effort.
- Can help to determine the CSO contribution to debris problems.

Disadvantages of Measure:
- May be difficult to detect trend as volume of floatables may be highly variable.
- Non-CSO sources may still be a problem following CSO control.

For More Information:
U.S. EPA. 1995. *CSOs: Guidance for Nine Minimum Controls.* EPA 832-B-95-003.

Units of Measurement:
Cubic yards, pounds, tons per year or number of items collected.

Probable Reporting Agency:
CSO Communities.
Environmental Agencies.
Volunteers.

Potential Data Sources:
- Monthy or annual survey.
- Cleanup program records.

Cost of Data Collection:
Variable. Use of volunteers is low. Use of equipment intensive methods such as skimmer boats is high.

Attributes:

* Linkage to CSO discharge	◗
* Quantifiable for trend analysis	◗
* Usefulness relative to the cost of data collection	◗
* Flexibility with respect to local objectives and conditions	●

VOL 12 2 4920
R0058213

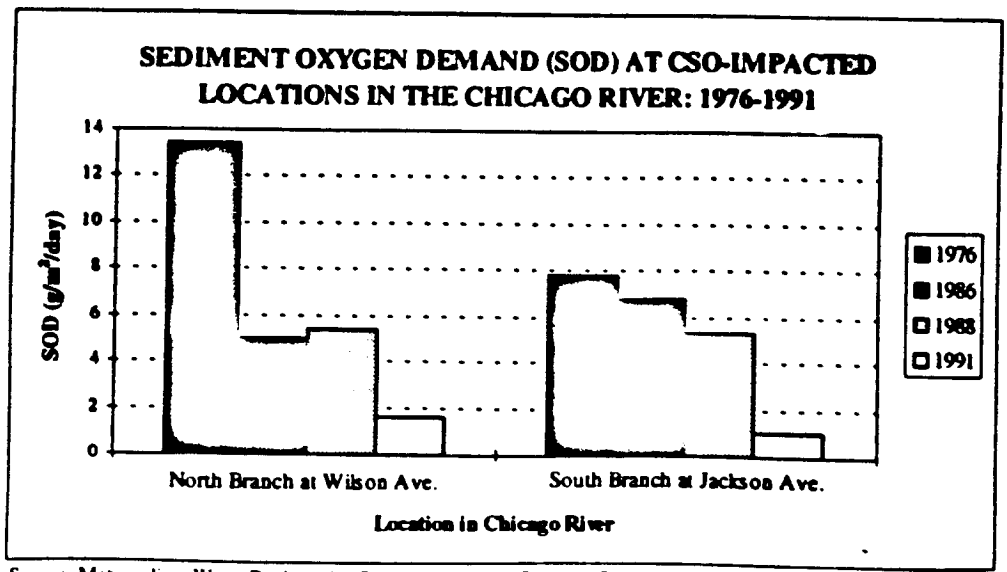
CSO Performance Measure Description
Sediment Oxygen Demand Trend

Sediment oxygen demand (SOD) is a measure of the potential of bottom deposits of organic material to decay and continuously remove oxygen from the overlying waters. SOD exerts its impact on receiving waters by reducing the dissolved oxygen concentration. The SOD trend is a time series of SOD measurements. The units of measurement are grams of oxygen (O_2) in meters squared per day.

SOD can be an important component of the dissolved oxygen balance in receiving waters that receive substantial organic loadings. It is particularly important in slow moving streams, estuaries and harbors where organic material accumulates in bottom sediments, and where scouring is minimal or infrequent. BOD and TSS loads discharged from CSSs can contribute to the accumulation of bottom deposits and to SOD. This measure may be important in those systems where dissolved oxygen impacts have been observed, and where SOD is known to be an important component of dissolved oxygen depression. Where applicable, use of this receiving water measure may provide an indication of whether or not the LTCP is having any influence on the SOD component of the dissolved oxygen balance. Because of the variety of pollutant sources potentially affecting SOD, this performance measure is well-suited for tracking improvement on a watershed scale.

Specialized skills are required for the measurement of SOD. Measurement once per year at impacted sites may be appropriate. Consistency in location and analytical technique from one year to the next is essential for the results to be meaningful.

Example



Source: Metropolitan Water Reclamation District of Greater Chicago, Chicago, IL.

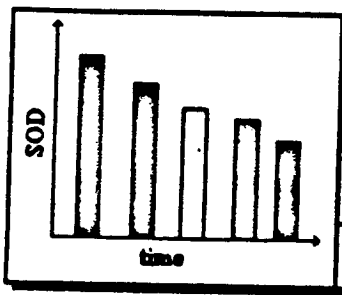
R0058214



CSO Performance Measure Profile Sheet

Sediment Oxygen Demand Trend

Category: **Receiving Water**

Description:
Trend of sediment oxygen demand in CSO-impacted receiving waters (time plot of sediment oxygen demand).

Applicability and Use:
Sediment Oxygen Demand (SOD) is a measure of the capacity of bottom sediments to remove oxygen from overlying waters. The performance measure may be useful in receiving waters where dissolved oxygen levels are continuously depressed, and where CSOs have been identified as contributing substantially to organic loadings. Tracking SOD over time may be an effective way to quantify long-term improvements due in part to CSO control.

Advantages of Measure:
- Trend can be linked to CSO control in some CSO communities.
- Measurement once per year should be sufficient.

Disadvantages of Measure:
- Requires high skill level to measure Sediment Oxygen Demand properly.
- Sediment Oxygen Demand is not widely understood.
- Sediment Oxygen Demand is not necessarily meaningful in itself. Its importance varies with its contribution to the overall dissolved oxygen budget of receiving water.

For More Information:
APHA, AWWA, WEF. 1995. *Standard Methods For the Examination of Water and Wastewater, 19th Edition.*

Units of Measurement:
Grams of O_2 in meters squared/day.

VOL 12 2 4922
R0058215

CSO Performance Measure Description
Trend of Metals in Bottom Sediments

This performance measure tracks the trend of select metals in bottom sediments. The principal metals of interest are the six metals most commonly found in urban runoff as reported in the Nationwide Urban Runoff Program (U.S. EPA, 1983). These are: cadmium, chromium, copper, lead, nickel, and zinc. Other metals may be important in some CSO communities. The trend of metals in bottom sediments is a time series of the concentration of individual metals in bottom sediments. The appropriate units of measurement are mg/kg.

The potential sources of metals in urban waters include municipal and industrial wastewater, urban runoff, industrial storm water, and other nonpoint sources. CSO discharges may represent a source in some CSO communities. Elevated metals concentrations in bottom sediment may cause adverse ecological and human health effects. This measure may be important in those systems where contaminated sediments are a recognized problem, and where the reduction in metals from the CSS is an objective of the LTCP. Because of the variety of sources potentially contributing to metals in bottom sediments, this performance measure is well-suited for tracking improvement on a watershed scale.

Specialized skills are required for the measurement of metals in bottom sediments. Measurement once per year at impacted sites may be appropriate. Consistency in location and analytical technique from one year to the next is essential for the results to be meaningful.

Example

Sediment quality monitoring is an ongoing part of the CSO control program being implemented by the King County Department of Metropolitan Services in Seattle, WA. The Denny Way CSO featured in this example is the largest in the CSS. Construction of a storage/treatment tunnel and relocation of the outfall to deeper waters will eventually eliminate CSO impacts at this site. Prior to control, a clean sand cap was applied to bottom sediments. The accumulation and concentration of metals in bottom sediments within this cap prior to control is illustrated. Monitoring will continue following the implementation of controls, and it is expected that concentrations will decrease over time. However, metals can have a long residence time in bottom sediments, and commitment to long term monitoring is needed for this performance measure.

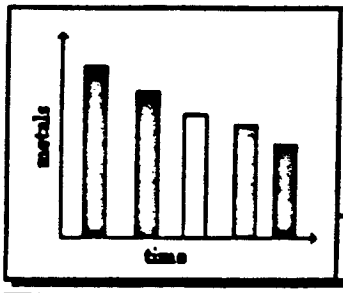
R0058216



CSO Performance Measure Profile Sheet

Trend of Metals in Bottom Sediments

Category: **Receiving Water**

Description:
Trend of the concentration of selected metals in bottom sediments (time plot of metals in mg/kg).

Applicability and Use:
Elevated metals concentration in bottom sediments may cause human health and ecological impacts. This performance measure may be useful in areas where sediment contamination is present, and where the reduction of metals load from the CSS is a goal of the LTCP.

Advantages of Measure:
- Trend can be linked to CSO control in some CSO communities.
- Measurement once per year should be sufficient.

Disadvantages of Measure:
- Requires a high skill level to measure metals in bottom sediment properly.
- Non-CSO sources of metals contamination are typically dominant in most areas.
- It may be difficult to associate change over time with CSO control because of other watershed sources of pollution.

For More Information:
APHA, AWWA, WEF. 1995. *Standard Methods For the Examination of Water and Wastewater, 19th Edition.*

VOL 12 2 4924

R0058217

CSO Performance Measure Description
Shellfish Bed Closures

This resource use measure quantifies the extent of shellfish bed closures from year-to-year. Shellfish beds are used for both recreational and commercial harvesting. Shellfish tend to accumulate pathogens and other toxic material in their tissue. Bacteriological contamination in receiving waters is the principal reason for shellfish bed closures. The recommended unit of measurement is acre days closed per year. Insofar as it is possible, the number of shellfish bed closures attributable to CSOs provides an even better measure if cause and effect can be distinguished. Other alternative units may be appropriate where there is a history of use and they are readily understood

Shellfishing is a major commercial and recreational activity in many receiving waters. The closure of shellfish beds represents non-attainment of a designated use. Shellfish beds are closed in order to protect human health. The sources of pollution that are usually responsible for shellfish bed closures include agricultural runoff, urban runoff, failed septic systems, and CSO discharges. This measure may be important in those systems where shellfish bed closures are limiting commercial and recreational activities, and where the reduction in shellfish bed closures is consistent with the objectives of the LTCP. Because of the variety of sources potentially contributing to shellfish bed closures, this performance measure is well-suited for tracking improvement on a watershed scale.

Example

The Rhode Island Department of Environmental Management has a Shellfish Growing Area Monitoring Program. Seventeen separate growing areas are covered with from nine to thirty-nine stations in each area. The result of this monitoring aggregated to the state level as reported in biennial 305(b) reports are presented below. The units are percent of growing area in acres, not the recommended acre-days. As shown, no major changes have occurred over the past decade.

CSO Performance Measure Profile Sheet

Shellfish Bed Closures

Category: **Ecological/Human Health/ Resource Use**

Description:
Extent of shellfish bed closures attributed to CSO discharges (acre/days closed per year).

Applicability and Use:
Shellfish bed closures pose a serious impact to commercial and recreational activities. Shellfish bed closures are based upon bacterial levels. Bacterial contamination is one of the major pollutants of concern discharged from CSOs. This performance measure may be appropriate for CSO communities where shellfish bed closures are a problem, and where CSO sources contribute to the problem.

Advantages of Measure:
- Widely used and understood by the public.
- Represents a direct measure of a designated use.
- Historical records are available in many receiving waters.

Disadvantages of Measure:
- It may be difficult to associate change over time with CSO control because of other watershed sources of pollution and management activities.

VOL 12 2 4926
R0058219

CSO Performance Measure Description
Benthic Organism Index

This ecological measure provides an estimate of the aquatic health of impacted waters. The benthic organism index is a measure of the diversity of macro-invertebrates within the benthic zone at the interface of bottom sediment with overlying waters. Benthic macroinvertebrates act as an in-place indicator of the quality of aquatic habitat. The abundance and diversity of species present as well as the ratio of pollution sensitive to pollution tolerant species are important indicators of current conditions.

Improvements in the aquatic health of receiving waters are anticipated as CSO controls are implemented. This measure may be important in those systems where aquatic habitat is impaired, and where improvement of the aquatic health of receiving waters is consistent with the LTCP Because of the variety of pollutant sources potentially affecting the macroinvertebrate community in urban waters, this performance measure is well-suited for tracking improvement on a watershed scale.

Specialized skills are required to conduct macroinvertebrate surveys. Many indices or protocols can be used, such as the Rapid Bioassessment Protocol, the Hilsenhoff Biotic Index, and the Invertebrate Community Index. Comparison with results from similar but relatively unimpacted reference sites is usually required. The units of measurement are typically in index-specific metrics. These indices and protocols are appropriate for most streams. Other comparable measures for deeper rivers, lakes, estuaries and coastal situations are under development by the EPA.

Example

The Macroinvertebrate Biotic Index (MBI) is used extensively in Illinois for biomonitoring. The MBI ranges from 11 to 1, with 11 representing the highest pollution tolerance, and, generally speaking, the most degraded water quality and habitat. The MBI is derived from the number of species collected and their pollution tolerance rating. In this example from the Chicago Sanitary & Ship Canal at Lockport, IL, the MBI trend over the period 1978 through 1991 is illustrated. The improvement over time at this site (decreasing MBI values) is the result of the cumulative effect of many water pollution control activities including CSO control and improved levels of municipal and industrial wastewater treatment. Note that data is not available for each year.

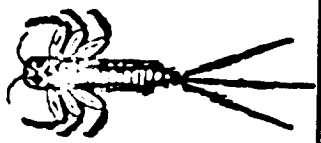
VOL 12 2 4927

R0058220



CSO Performance Measure Profile Sheet

Benthic Organism Index

Category: **Ecological/Human Health/ Resource Use**

Description:
Annual survey of macroinvertebrates in CSO receiving waters (e.g., Rapid Bioassessment Protocols (RBP), Macroinvertebrates Biotic Index (MBI), or Invertebrate Community Index (ICI)).

Applicability and Use:
The use of benthic organism indices as a measure of the health of aquatic systems in rising. Biological measures are being integrated with and in some instances replacing traditional water quality measures. This performance measure may be applicable in impaired water where CSO control and other environmental management activities are expected to improve aquatic habitat over time.

Advantages of Measure:
- Provides a direct measure of ecological results.
- Measurement once per year should be sufficient, if performed during the same season each year. Longer intervals may be acceptable.

Disadvantages of Measure:
- Requires high skill level to measure properly.
- Results are not readily understandable to the public, or even to environmental professionals other than specialized biologists.

For More Information:
U.S. EPA. 1989. *Rapid Bioassessment Protocols (RBP) for Use in Streams and Rivers - Benthic Macroinvertebrates and Fish.* EPA 440-4-89-001.

VOL 12 2 4928

R0058221

CSO Performance Measure Description
Biological Diversity Index

This ecological measure provides a broad assessment of the health of receiving waters by assessing habitat and the abundance and diversity of multiple organisms in receiving waters. Use of a composite biological diversity index provides a comprehensive evaluation of the aquatic community. This performance measure relates to the "Fishable" goal of the CWA. Appropriate measures include the Index of Biologic Integrity (IBI), the Rapid Bioassessment Protocol (RBP), and the Index of Well Being (I_{wb}).

Improvements in the aquatic health of receiving waters are anticipated as CSO controls are implemented. This measure may be important in those systems where aquatic habitat is impaired, and where improvement of the aquatic health of receiving waters is consistent with the LTCP. Because of the variety of pollutant sources potentially affecting the aquatic community in urban waters, this performance measure is well-suited for tracking improvement on a watershed scale.

Specialized skills are required to conduct biological surveys. Comparison with results from comparable but relatively unimpacted reference sites is usually required. The units are typically in index-specific metrics. These indices and protocols are most appropriate for shallow streams. Other comparable measures for deeper streams, lakes and coastal situations are under development by the EPA.

Example

The Bloomington and Normal Water Reclamation District in Illinois conducts annual biosurveys along Sugar Creek to evaluate the health of fish populations and potential impacts from agricultural runoff, urban runoff, CSOs, and point source discharges. An Alternate Index of Biotic Integrity (AIBI) is one of several measures used. The results at a CSO-impacted site (Biological Sampling Site No. 9) are presented below to illustrate the use of this performance measure. While some CSO control has been implemented, other factors appear to influence biological diversity. For example, 1987, 1988 and 1989 were drought years with intermittent flows. In addition, natural habitat is also limited in this channelized urban waterway. The value of the annual AIBI surveys is that they serve as a barometer of current aquatic conditions relative to the past, and as a baseline reference for the future.

R0058223

CSO Performance Measure Description
Beach Closures

Beach closures are one of the most obvious and understandable measures of the impacts of pollution. This measure of resource use represents the incidence of the closure of beaches for swimming or other contact recreation because of elevated bacterial concentrations that are indicative of potential public health problems and waterborne illness. This performance measure relates directly to the "swimable" goal of the CWA. The simplest unit of measurement is the number of beach closures per year. Insofar as it is possible, the number of beach closures attributable to CSOs provides an even better measure if cause and effect can be distinguished.

Contact recreation, including swimming, is an important designated use in many receiving waters. This measure may be important in those systems where there are beaches, and where implementation of the LTCP may be expected to contribute to a reduction in beach closures. Because of the variety of pollutant sources potentially contributing to beach closures, this performance measure is well-suited for tracking improvement on a watershed scale.

Example

The major causes of beach closures across the United States during 1994 are presented below. As shown, it is reported that CSOs were the major cause of 17 percent of beach closures and advisories. Although this example does not illustrate a trend for CSOs, follow-up surveys after the implementation of CSO controls would show change over time.

VOL 12 2 4932
R0058225

CSO Performance Measure Description
Recreational Activities

This measure provides a quantitative assessment of the number of individuals participating in recreational activities on or adjacent to impacted receiving waters. It is intended to measure participation in water-oriented recreation activities. The units of measurement would have to be determined locally but could include boat rentals, fishing days, the number of swimmers, or other quantification of recreational activities on an annual basis. Any measure of recreation activities or events that bring people back to impacted receiving waters or adjacent public areas for recreational purposes would probably be acceptable.

It is anticipated that recreational activities will increase substantially in urban waters as CSO controls are implemented. This measure may be appropriate for CSO communities that have identified increased recreational use as a locally defined objective. This performance measure is well-suited for tracking improvement on a watershed scale.

Example

The Metropolitan Water Reclamation District of Greater Chicago is responsible for a CSS with a service area of 375 square miles. TARP, an ambitious Tunnel and Reservoir Plan initiated during the 1970s, is the principal CSO control. CSOs are diverted to the deep tunnels for storage during wet weather events, and later pumped to POTWs for treatment. TARP phase I is nearing completion, and the majority of CSO discharges have been or soon will be eliminated.

The Chicago River has been an important beneficiary of TARP implementation. Flowing through the heart of the city, the Chicago River is reported to be cleaner now than it has been in over a century. In spite of its industrial character, this urban river is rapidly becoming a major recreational resource within the Chicago metropolitan area. Fishing is back as the number of species present has doubled and tripled at many locations over the past twenty years. Canoeing and other recreational boating is resurging in areas where this was previously unthinkable. The river banks are approachable and frequented more than ever for a variety of diverse recreational activities. The Chicago River is healing itself, and CSO control is a major factor in this process. The quantification of new recreational activities on the river and along its banks can be an important measure of the success of CSO control and investment in TARP.

CSO Performance Measure Profile Sheet

Recreational Activities

Category: **Ecological/Human Health/ Resource Use**

Description:
Quantification of water oriented recreation on an annual basis (e.g., user days, boat rental, etc. per year).

Applicability and Use:
Recreational activities covers a wide range of passive and active water oriented activities. This performance measure attempts to quantify real use attainment that may be linked to CSO control. It takes activities and benefits into account that might otherwise be overlooked. The use of recreational activities as a performance measure may be appropriate for CSO communities where implementation of the LTCP and other environmental management activities are expected to result in increased recreational use of impacted waters.

Advantages of Measure:
- Understandable to the public.
- Directly linked to designated uses.
- Data collection can be built-in to concession and resource management activities.

Disadvantages of Measure:
- It may be difficult to associate change over time with CSO control because of other watershed sources of pollution and management activities.
- Recreational interests of the public may change for reasons totally unrelated to water quality.

For More Information:
Coast Alliance. 1995. *State of the Coast.*

Units of Measurement:
Activity measure.

Probable Reporting Agency:
Chamber of Commerce.

Potential Data Sources:
- Local records.

Cost of Data Collection:
Variable. Information for some activities such as fishing licenses, boat rentals, etc. should available. Other activities may require new surveys or new quantification techniques.

Attributes:

* Linkage to CSO discharge	◗
* Quantifiable for trend analysis	●
* Usefulness relative to the cost of data collection	●
* Flexibility with respect to local objectives and conditions	●
* Understandable to the public	●
* Relationship to environmental improvement	◗
* Watershed Context	●

KEY
● High ◗ Moderate ○ Low

VOL 12 2 4934

CSO Performance Measure Description
Commercial Activities

This resource use measure provides an economic indicator of the value of commercial activities in receiving waters and waterfront areas. It is intended to measure economic activity related to CSO-impacted activities. Its use is intended to provide a barometer of business activity that is spawned by CSO control and other waterfront cleanup activities. Potential measurement units include the dock-side value of commercial fishing and shellfishing activities, revenues from waterfront concessions, real estate values, rental values, business tax revenues, tourism, and other indicators of commercial and economic activity that can be quantified and tracked.

Commercial development focused on previously polluted and underutilized urban receiving waters has been successfully implemented in many cities across the nation. This measure may be appropriate for CSO communities that have identified increased commercial activity as a locally defined objective. Because of the variety of pollutant sources potentially limiting commercial development and economic activities, this performance measure is well-suited for tracking improvement on a watershed scale.

Example

Casco Bay is an important receiving water along the south coast of Maine. CSOs form several Maine communities as well as other point and nonpoint sources affect water quality and habitat within Casco Bay. As these sources are controlled, the value of commercial activities associated with the Bay is expected to increase. Several economic indicators for Casco Bay are described to illustrate the use and importance of commercial activities as a performance measure.

As reported in the Draft Casco Bay Plan, *the species and ecosystems of Casco Bay provide a valuable economic resource for the region.*

- The value of the fisheries industry within Casco Bay is estimated to be $102 million per year. The soft-shell clam industry alone provides full or partial employment for approximately 300 people.
- The value of tourism and recreation in Casco Bay is estimated to be $250 million per year.
- Waterfront property along Casco Bay is estimated to be up to four times as valuable as similar property not located on the water.

It is often inappropriate to associate trends in commercial activity solely on the basis of CSO control as many other many other factors are involved. However, investment in CSO control is one element of environmental management and stewardship intended to improve water quality and habitat in impacted waters. The enhanced economic vitality of water bodies like Casco Bay due to this investment could be linked with measures of commercial activity.

CSO Performance Measure Profile Sheet

Commercial Activities

Category: **Ecological/Human Health/ Resource Use**

Description:
The value of commercial activities in receiving waters and waterfront areas.

Applicability and Use:
Commercial activities cover a wide range of water-oriented activities. This performance attempts to quantify the amount and value of commercial activities in receiving waters and adjacent waterfront areas. The use of commercial activities as a performance measure may be appropriate for CSO communities where implementation of the LTCP and other restoration activities are expected to result in increased commercial activities.

Advantages of Measure:
- Understandable to the public.
- Data collection consists of compiling existing information in most instances.

Disadvantages of Measure:
- It may be difficult to associate change over time with CSO control because of other watershed sources of pollution and management activities, as well as economic factors wholly unrelated to water quality.

For More Information:
Coast Alliance. 1995. *State of the Coast.*

Units of Measurement:
Dollars per year.

Probable Reporting Agency:
Chamber of Commerce.
Department of Commerce.

Potential Data Sources:
- Local records.

Cost of Data Collection:
Variable. Economic indicators related to fisheries, waterfront property values, tourism, etc. may be readily available in some CSO communities.

Attributes:

* Linkage to CSO discharge	◗
* Quantifiable for trend analysis	◗
* Usefulness relative to the cost of data collection	●
* Flexibility with respect to local objectives and conditions	●
* Understandable to the public	●
* Relationship to environmental improvement	◗
* Watershed Context	●

4.0 RECOMMENDATIONS FOR IMPLEMENTATION

4.1 INTRODUCTION

CSO control is ideally a coordinated effort among CSO communities, the federal government, states, and the public. All of these parties want CSO control to be successful, and all have a stake in the results. CSO communities, NPDES permitting authorities, and state water quality standards authorities are expected to undertake specific actions that are described in the CSO Policy. These include implementation of the NMCs, development and implementation of LTCPs, and regulatory review, support and oversight. Assessment of the effectiveness of control practices and measuring improvement in receiving waters is a major part of CSO control. The need to implement a program to track results and change over time is essential. The first step toward this end is the identification and selection of individual performance measures that are consistent with the LTCP and other locally defined objectives. The second step is the implementation of data collection and reporting for specific performance measures. These two steps are described in more detail below. In addition, potential federal and state use of performance measures is also discussed.

4.2 IDENTIFICATION AND SELECTION OF PERFORMANCE MEASURES

Identification begins with the CSO community and the local agency or department in charge of CSO control. The identification and selection of performance measures are undertaken as part of planning associated with implementation of the NMCs, and development and implementation of the LTCP. In fact, the identification of measures to meet CSO control goals and the implementation of post construction compliance monitoring are technical activities under the LTCP. CSO Communities should consider the identification and use of performance measures in relationship to the LTCP and other locally defined objectives. The major elements of identification are as follows:

- Characterize the CSS and baseline conditions.
- Identify the impact of CSOs in local receiving waters.
- Identify the CSO and water quality problems with the highest public interest through public participation.
- Identify local responsibilities under the CSO Policy, and other state policies and regulations where applicable.
- Identify what implementation of the LTCP is trying to accomplish and improve, particularly environmental results.
- Identify CSO control goals, water quality goals, and other locally defined objectives for the impacted waters and affected shorelines.
- Identify local financial capability and resources.
- Visit the menu-like framework (Table 3-1) and determine what performance measures will be most appropriate to meet local needs.
- Identify the agencies and programs that will collect data for individual performance measures.

VOL 12 2 4931

R0058230

- Identify the agency or program that will have overall responsibility for data management, coordination and reporting.
- Coordinate and negotiate with the NPDES permitting authority regarding data collection, reporting and compliance monitoring needs.

4.3 IMPLEMENTATION OF DATA COLLECTION AND REPORTING

Data collection and reporting are carried out as part of implementation of the NMCs, and development and implementation of the LTCP. The major elements of implementation are as follows:

- Confirm data management, coordination, and data collection responsibilities.
- Enlist the public and local environmental and civic groups as participants.
- Coordinate the selection of performance measures with the state authorities and the permitting agency. Consider parallel monitoring needs for storm water, SSO and other NPDES programs.
- Coordinate activities with local watershed and estuary programs where applicable.
- Coordinate activities with the U.S. Geological Survey and other agencies and institutions to identify cooperative efforts and cost-sharing opportunities.
- Encourage citizen volunteer monitoring where it fits in with the identified performance measures.
- Develop a central data base for storing and tracking data collected on performance measures.
- Produce regular reports on results.
- Coordinate results with state 305(b) programs.
- Review the data and results on a regular basis and use the information to guide CSO management activities.
- Coordinate data collection with NPDES permit monitoring and reporting requirements.
- Share data and information with the public and other CSO communities.

4.4 FEDERAL AND STATE USE OF PERFORMANCE MEASURES

The development of performance measures that would be useful for CSO communities was emphasized within this study. However, it was recognized that federal and state agencies, including permitting authorities, have a vested interest in the successful implementation and use of performance measures. In addition, it was recognized that the performance measures would provide useful information for state and federal programs. Therefore, the potential use of performance measures by state and federal agencies is described.

VOL 12 2 4938

R0058231

At the federal level, EPA should select a small number of performance measures that could be used to track programmatic results at the national level. Four specific performance measures considered in this study are recommended as appropriate for national tracking. These are:

- Documented Implementation of the NMCs.
- Status of LTCPs.
- CSO Frequency.
- CSO Frequency in Sensitive Areas.

The data for these measures should be collected primarily from the EPA Regional Offices and/or directly from state CSO program offices. In general, it is believed that information for these performance measures can be collected in a consistent manner, and that aggregation at the national level would produce a meaningful quantification of the results of CSO control efforts. Close coordidnation among EPA, the states and CSO communities is required.

At the state level, consideration of the following will increase the usefulness of data collection for performance measures:

- States should coordinate performance measures on a state wide basis that recognizes the site-specific nature of CSOs and their impacts.
- States should identify a small number of performance measures that can be used to track programmatic results at the state level. These measures should be carefully selected and defined so that they pose little if any additional administrative burden on CSO communities. Consideration of the performance measures recommended as appropriate for national tracking and noted above would be useful.
- States should provide assistance and field support for monitoring receiving water and ecological measures, particularly where diverse watershed sources are thought to be the cause of impacts.

VOL 12 2 4939

R0058232

5.0 RELATIONSHIP TO OTHER NATIONAL PROGRAMS

CSO performance measures can be related to other ongoing national programs including wet weather program efforts such as the urban wet weather and stormwater activities, the establishment of national environmental goals and environmental indicators to measure them, and the revitalization of water quality monitoring. Most of these efforts are conducted in partnership by EPA and other federal agencies, states, tribes, local governments, and private entities. The purpose of this section is to describe the principal national programs and relevant projects related to goals, environmental indicators, and performance measures.

Government Performance and Results Act (GPRA)

One overall effort at the federal level is the Government Performance and Results Act of 1993. This act requires all federal agencies to have a strategic planning process by September, 1997 which identifies key stakeholder's expectations and priorities, agency missions, high-priority long-term objectives, strategies and resources needed to achieve objectives, and types of information that can be used to measure, or indicate progress toward the long-term objectives. Following the establishment of a strategic plan, agencies will need to produce annual performance plans and reports. The annual performance plan will identify program performance indicators, annual performance goals, and processes and resources needed to achieve goals. The annual performance reporting will compare actual progress with the goals, explain why any performance goals were not met, and communicate the value of effective programs.

In the environmental indicator development process, national and international organizations are using various conceptual frameworks to present the data needed and the relationships among the types of measures. One of the most widely used is the Pressure-State-Response (PSR) framework. As explained by the World Resource Institute, (WRI, 1995), pressure indicators measure the pressures on the environment caused by human activities; state indicators measure changes in the physical or biological condition of the natural world; and response indicators measure what society is doing to address environmental change and problems. As shown below, the categories of performance measures utilized in the development of CSO performance measures generally fit within the PSR framework.

Direct Pressure (P)	State (S) or Condition	Societal Response (R)
End-of Pipe Measures	Receiving Water Measures Ecological Measures Human Health Measures Resource Use Measures	Administrative Measures

VOL 12 2 4940

R0058233

National Environmental Goals Project

EPA is in the process of establishing long-range environmental goals with ambitious but realistic milestones for measuring progress toward these goals by the year 2005. The milestones are measured by data from environmental indicators. These goals and the milestones which will mark measured improvement in or alleviation of pressures to the environment will be presented in an EPA report being prepared for review in 1996.

The proposed topics to be covered in the report include clean water and safe drinking water goals. The clean water goal states that:

> *All waters will support healthy communities of fish, plants, and other aquatic life. Surface waters will be safe for fishing and swimming and for sources of drinking water. Ground waters will be safe for intended uses. Remaining wetlands will be protected and many that have been lost will be restored.*

The safe drinking water goal states that:

> *Every public water system will consistently provide water that is safe to drink.*

Environmental Indicators

Environmental indicators are being used to support planning efforts in many programs. As reported by the Intergovernmental Task Force on Monitoring Water Quality (ITFM), "indicators are measurable features which singly or in combination provide managerially and scientifically useful evidence of environmental and ecosystem quality, or reliable evidence of trends in quality" (ITFM, 1994). EPA's Office of Water is leading an effort to develop national water environmental indicators in collaboration with other public and private partners. The development and reporting of national water environmental indicators feeds the activities of the GPRA and the National Environmental Goals Project. Within EPA, the main purposes for having national water environmental indicators include:

- Showing the condition of our nation's waters over time.
- Measuring progress towards national water goals.
- Measuring the effectiveness of national water programs.

EPA has selected and is proposing to report on 16 water environmental indicators. The relationship of the proposed EPA Office of Water indicators to the recommended CSO performance measures developed in this study is presented in Table 5-1. A more complete description of these proposed indicators is located in Appendix C.

VOL 12 2 4941

R0058234

Table 5-1. Relationship of the Office of Water Environmental Indicators to CSO Performance Measures Developed in this Study

OFFICE OF WATER INDICATORS	CSO PERFORMANCE MEASURES
HUMAN HEALTH	
♦ Violations of drinking water standards.	
♦ Drinking water systems not meeting filtration requirements.	
♦ Lead levels in public drinking water systems.	
♦ Source water protection for ground water.	
♦ Waters meeting drinking water designated uses.	
♦ Fish consumption advisories.	
♦ Shellfish bed closures.	♦ Shellfish Bed Closures, Commercial Activities.
♦ Waters meeting fish and shellfish consumption designated uses.	
♦ Waters meeting recreation designated use.	♦ Beach Closures, Recreational Activities.
ECOSYSTEM HEALTH	
♦ Biological integrity of the water.	♦ Benthic Organism Index, Biological Diversity Index.
♦ Species at risk.	♦ CSO Frequency in Sensitive Areas, CSO Volume in Sensitive Areas, Benthic Organism Index, Biological Diversity Index.
♦ Wetland acreage.	
♦ Waters meeting aquatic life designated uses.	♦ Benthic Organism Index, Biological Diversity Index.
DESIGNATED USES	
♦ Human health and ecosystem health.	
CONSERVE OR IMPROVE AMBIENT CONDITIONS	
♦ Selected surface water quality pollutants.	♦ Dissolved Oxygen Trend, Fecal Coliform Trend, Floatables Trend.
♦ Selected ground water quality pollutants.	
♦ Contaminated sediments.	♦ Sediment Oxygen Demand Trend, Trend of Metals in Bottom Sediments.
PREVENT OR REDUCE POLLUTANT LOADINGS	
♦ Point source loadings to surface and ground water.	♦ Wet Weather Flow Budget, CSO Frequency, CSO Volume, BOD Load, TSS Load, Nutrient Load, Floatables.
♦ NPS loadings to surface and ground water.	
♦ Marine Debris.	♦ Floatables, Floatables Trend.

VOL 12 2 4942

R0058235

Environmental indicators at the national level emphasize measurements related to the goals of the national CWA and Safe Drinking Water Act and the following objectives:

- Conserving and enhancing public health.
- Conserving and enhancing aquatic ecosystems.
- Supporting water uses designated by States.
- Conserving and improving ambient conditions.
- Preventing or reducing pollutant loadings.

These objectives support one another and are illustrated in a hierarchical order as illustrated in Figure 5-1. These overall indicators provide the framework for additional indicators and measurements made at the specific program level, such as the performance measures for the National CSO Control Program recommended in this study.

Wet Weather Programs

EPA's National Water Program Agenda for the Future, issued by the EPA's Assistant Administrator for Water on December 30, 1994, identified the improvement in wet weather flow controls as one of two programmatic priorities for EPA's Office of Water. The Agenda also discussed issues associated with improving control of wet weather flows.

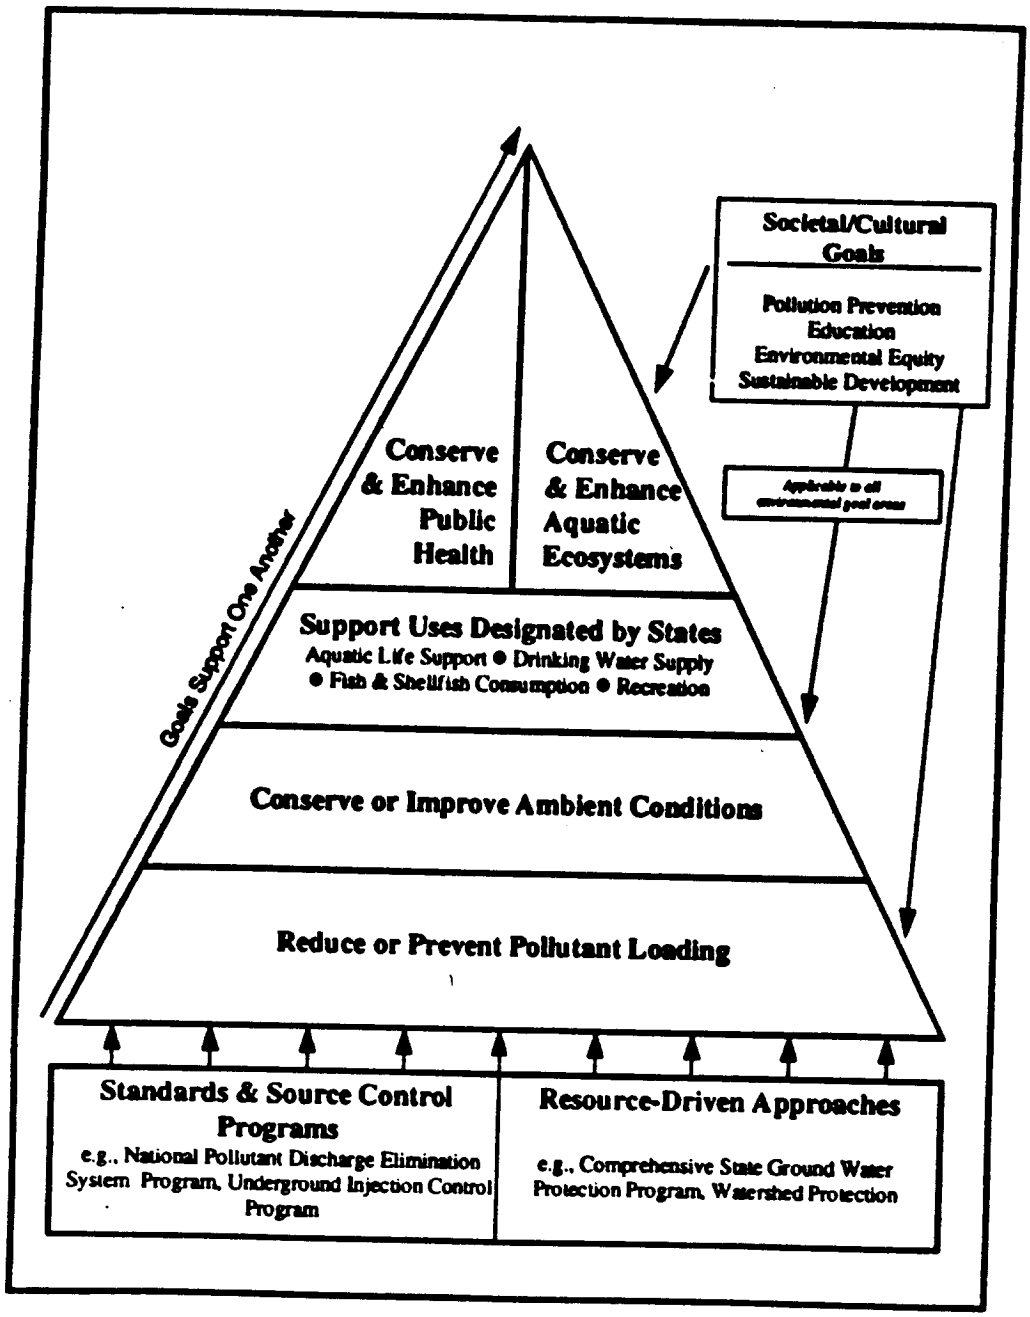
EPA formed the Urban Wet Weather Flows Advisory Committee in the spring of 1995. The Committee's purpose is to address issues associated with water quality impacts from urban wet weather flows and other storm water discharges under Section 402(p)(6) of the CWA. The Committee's mission is to provide a forum to develop recommendations on wet weather discharges (including CSOs) in an innovative and cost-effective manner. The Committee formed a Watershed Work Group whose mission is to recommend to the Committee how comprehensive watershed management can best contribute to meeting human health, ecological health and water quality goals when dealing with problems caused by wet weather flows in urban areas. One of the recommendations to be developed by this workgroup will identify appropriate measures of success for documenting the effectiveness of controlling urban wet weather flows. The performance measures identified in this report should be useful to the Watershed Work Group in the identification of measures to evaluate the impacts of urban wet weather flows on receiving water bodies.

EPA's Office of Wastewater Management is also supporting a multitask project to develop and implement storm water environmental indicators. Municipalities and other storm water dischargers will use the identified indicators to assess the effectiveness of storm water control efforts, and provide data for a national storm water indicators tracking system. At the time of this writing (January, 1996), Phase I of the storm water project is nearly complete, and two documents are in draft form. The first document describes recent efforts to develop and implement environmental indicators and techniques for assessing the effectiveness of municipal storm water management programs. The

VOL 12 2 4943

R0058236

Figure 5.1 National Goals: Clean Waters and Safe Drinking Water



VOL 12 2 4944

R0058237

identified indicators are grouped into seven broad categories: water quality indicators, physical and hydrological indicators, biological indicators, whole watershed indicators, social indicators, programmatic indicators, and site indicators. The second report contains profile sheets on the indicators that were identified in each of the seven broad categories. It also presents a framework for using the identified indicators and a methodology for establishing an indicator monitoring program. These reports should be available in 1996.

There are commonalities between the storm water indicators and the CSO performance measures. Communities with both combined and separate storm sewer systems should explore these commonalties before deciding on operating separate programs to measure the effectiveness of their control programs. An integrated program would in most cases be more cost-effective

Revitalizing Monitoring

Indicators are only as good as the data to report on them, so it is critical to support the indicators efforts with strong monitoring and data programs. Several major efforts are underway to revitalize monitoring which will, among other things, provide good data for indicators.

The Intergovernmental Task Force on Monitoring Water Quality - The ITFM was formed in early 1992 to design a nationwide water monitoring strategy for the collection of water quality data within all public and private sectors. The Task Force is a partnership that includes representatives from 20 federal, state, tribal, and interstate organizations. EPA chairs the ITFM, and the U.S. Geological Survey (USGS) has lead-agency responsibility for water information coordination. In addition to the 20 officially designated ITFM representatives, more than 150 individuals in federal and state agencies have participated in nine working groups to provide additional perspective and technical expertise on specific issues. Private sector organizations also participate in the process through the Federal Advisory Committee on Water Data for Public Use, public meetings announced in the *Federal Register*, and an initiative to promote coordination of ambient and compliance monitoring. The National Strategy is available from the USGS Office of Water Data Coordination (703 648-5023), or through the Internet at http://h2o.usgs.gov.

Pilot Programs - EPA is sponsoring pilot programs in eight states to test the implementation of the sixteen national indicators at the state and watershed level. One important objective of these pilot programs is to determine which of the indicators are best suited for use as measures of program effectiveness at the state level. A second group of pilot programs, undertaken in conjunction with the ITFM, is testing how to better integrate the use of ambient and compliance monitoring information in priority watersheds. The main objective of these pilot programs is to determine the most effective ways to integrate this information among all public and private stakeholders.

VOL 12 2 4945

R0058238

State and Tribe Monitoring Strategies - To facilitate efficient monitoring programs, the EPA is working closely with states and tribes to help them develop multi-year monitoring strategies to comprehensively assess the waters within their boundaries on a five-year cycle using a variety of monitoring techniques according to the condition of and goals for the waters. Guidance to develop these strategies parallels that agreed to by the ITFM. These comprehensive monitoring efforts in coordination with the individual program performance measures will aid in evaluating both program effectiveness and the condition of the nation's waters.

GLOSSARY

AMSA	The Association of Metropolitan Sewerage Agencies.
BOD	Biochemical Oxygen Demand: a measure of the amount of oxygen consumed in the biological processes that break down organic matter in water.
Catch basin	A chamber usually built at the curbline of a street, which admits surface water for discharge into a storm drain.
Combined sewer	A sewer designed to carry wastewater and stormwater runoff.
CSO	Combined Sewer Overflow: The term CSO can be used to mean either (1) the portion of flow from a combined sewer system (CSS) which discharges into a water body from an outfall located upstream of the headworks of a POTW, usually during a rainfall event; or (2) the outfall pipe which carries this discharge.
CSO Event	One or more overflows from a CSS as a result of a precipitation event that do not receive the minimum treatment specified.
CSO Policy	The Combined Sewer Overflow (CSO) Policy, April, 1994.
CSS	Combined Sewer System: a wastewater collection systems designed to carry sanitary sewage (consisting of domestic, commercial, and industrial wastewater) and storm water (surface drainage from rainfall or snowmelt) in a single pipe to a treatment facility.
CWA	The Clean Water Act of 1972 and its Amendments.
Dissolved oxygen	The oxygen freely available in water. Dissolved oxygen is vital to fish and other aquatic life and for the prevention of odors. Traditionally, the level of dissolved oxygen has been accepted as the single most important indicator of a water body's ability to support desirable aquatic life.
DWO	Dry Weather Overflow: a combined sewer overflow that occurs during dry weather flow conditions.
Fecal coliform	A bacteria found in the intestinal tracts of mammals. The presence of fecal coliform in water is an indicator of pollution and possible contamination by pathogens.

VOL 12 2 4949

R0058242

Floatables	Solid or semi-solid materials discharged from a combined sewer that represent an aesthetic nuisance, a threat to wildlife, and a pubic health problem.
LTCP	Long Term Control Plan.
MG	Million Gallons.
NPDES	National Pollutant Discharge Elimination System: a provision of the Clean Water Act which prohibits discharge of pollutants into waters of the United States unless a special permit is issued by EPA, a state, or (where delegated) a tribal authority.
NMC	Nine Minimum Controls.
POTW	Publicly Owned Treatment Works: a waste-treatment works owned by a state, a utility, a unit of local government, or a tribe designed to treat domestic wastewaters.
PSR	Pressure - State - Response framework.
Sensitive areas	Areas of particular environmental significance or sensitivity that could be adversely affected by a CSO, including Outstanding National Resources Waters, National Marine Sanctuaries, water with threatened or endangered species, waters with primary contact recreation, public drinking water intakes, shellfish beds, and other areas identified by the permittee or NPDES permitting authority, in coordination with the appropriate State or Federal agencies.
Sewage overflow	Bypassed or inadequately treated sewage.
SOD	Sediment Oxygen Demand: a measure of the capacity of bottom sediments to remove oxygen from overlying waters.
SSO	Sanitary Sewer Overflow.
TSS	Total suspended solids: a standard measure of the concentration of particulate matter in wastewater, effluent or receiving waters.

APPENDIX B

SUMMARY OF FOCUS GROUP RANKINGS OF THE FIRST-CUT PERFORMANCE MEASURES DEVELOPED BY THE WORK GROUP

A total of forty-eight potential or first-cut performance measures were identified in a brainstorming session by the Work Group. These measures were subsequently distributed at six regional Focus Group meetings in New England and Kentucky where the participants ranked the measures according to their usefulness to quantify and track change and improvement associated with CSO control. The results of this ranking are presented in the following table.

Separate rankings were developed for performance measures in four categories:

- Administrative Measures;
- End-of-Pipe Measures;
- Receiving Water measures; and
- Ecological, Human Health and Resource Use Measures.

Ranks were determined using 1 as the best performance measure, 2 as the second best measure, etc. Individual rankings and totals are presented for each Focus Group meeting, where

- Environ. Rank is the ranking of the environmental Focus Group;
- Reg. Rank is the ranking of the regulatory Focus Group; and
- CSO Rank is the ranking of the CSO communities.

A composite overall rank that includes the results of all six Focus Group meetings is provided in the rightmost column.

APPENDIX C

LIST OF EPA WATER ENVIRONMENTAL INDICATORS

VOL 12 2 4958

R0058251

LIST OF EPA WATER ENVIRONMENTAL INDICATORS(1)

Human Health	1. Violations of drinking water standards. Population provided drinking water by community water systems reporting one or more violations of maximum contaminant levels or treatment techniques. 2. Drinking water systems not meeting filtration requirements. Number of systems and population served by water systems that have not met the requirements of the Surface Water Treatment Rule. 3. Lead levels in public drinking water systems. This will report the population served by public drinking water systems that exceed the lead in drinking water action level (more than 10 percent of the lead samples exceed 15 parts per million, grouped to the 90th percentile). It would measure the lead in distribution systems, not ambient conditions. 4. Source water protection for ground water. Initially, number of source water protection programs for groundwater used as drinking water. 5. Waters meeting safe drinking water designated uses. Number of surveyed waterbodies that can support safe drinking water supply. 6. Fish consumption advisories. Percentage of river miles and lake acres for which States have issued fish consumption advisories for particular chemical contaminants (mercury, metals, dioxin, chlordane, PCBs, DDT, Other). 7. Shellfish bed closures. Presents the classification status of the nation's shellfish harvest areas for human consumption using NOAA survey data. 8. Waters meeting fish and shellfish consumption designated uses. Number of surveyed waterbodies that can support fish and shellfish consumption. 9. Waters meeting recreation designated uses. Number of surveyed waterbodies that can support safe recreation.
Ecosystem Health	10. Biological integrity of the water. The number of waters that meet the biological integrity objective of the Clean Water Act, as determined by States working with EPA to ascertain which waters are similar to regional reference conditions selected by States as goals for their waters. 11. Species at risk. Depicts the status of aquatic plants and animals in five categories: extinct, critically imperiled, imperiled, vulnerable, apparently secure, or demonstrably secure using criteria that includes distributional range and extent of appropriate habitat, population and range, threats, fragility or susceptibility to threats. 12. Wetland acreage. Loss of acres of wetland from 1780 to present. 13. Waters meeting aquatic life designated uses. Number of surveyed waterbodies that can support healthy aquatic life.
Designated Uses	States and tribes designated uses for their waterbodies that include safe drinking water supply (indicator 1), fish and shellfish consumption (indicator 6), recreation (indicator 9), and healthy aquatic life (indicator 13). Although this is a separate and important objective, the designated use indicators are discussed under the related objectives.
Ambient Conditions	14. Selected surface water quality parameters. The parameters that are chosen as loadings indicators will be tracked in the ambient environment 15. Selected ground water quality parameters. The parameters chosen to track contaminants in ground water will be measured in the ambient environment for ground water systems that do not violate drinking water use. 16. Contaminated sediments. Reports sediment toxicity in the sites sampled for EPA's Contaminated Sediment Inventory. Data collected on pesticides, halogens, metals, organics (C, H, O and N, S, P), PAHs, and PCBs as well as total phosphorus, total nitrogen, sediment oxygen demand, pathogens, TRI chemicals (PS; organics, metals & pesticides (NPS), total organic carbon and acid volatile sulfide.
Loadings	17. Point source loadings to surface and ground water. Reduction in loads of specific pollutants. 18. Nonpoint Source loadings to surface and ground water. NPS loadings are difficult to identify and track. The 1995 report will focus on soil loss and may add nutrients and pesticides. 19. Marine Debris. Pounds of trash collected during annual beach cleanup sponsored by Center for Marine Conservation (CMC), EPA, NOAA and others.

(1)This list of water environmental indicators will be published by the Environmental Protection Agency and its Federal, State, and Tribal Partners in the first national water indicators report in 1996.

Acknowledgments

Sacramento County would like to thank the parent corporations, owners/operators, and station managers from Arco, Chevron, and Shell for their participation in this study. Their cooperation and assistance is greatly appreciated.

The County also wishes to acknowledge the assistance of the staff and member companies of the Western States Petroleum Association, who helped identify suitable stations for the study, and facilitated their participation.

The County would also like to thank Mr. Mark McIntyre of Easy-Clean Systems for donating mobile cleaning services including the use of the Vacu-boom.

Funding for this project was provided by a grant from the U. S. Environmental Protection Agency through the San Francisco Estuary Project, with additional funding from the Sacramento County Water Resources Division.

Executive Summary

This report summarizes the findings of the Demonstration of Gasoline Fueling Station Best Management Practices project. The project is an "Action Plan Demonstration Project" (APDP) funded in part by a grant awarded by the U. S. Environmental Protection Agency (U.S. EPA) through the San Francisco Estuary Project to the County of Sacramento (County). The purposes of the study were to characterize storm water runoff from gasoline fueling stations, demonstrate the effectiveness of pollution prevention technologies or best management practices (BMPs) in reducing pollutant loadings from gasoline fueling station runoff, and to disseminate information on effectiveness and costs to a wide audience.

The basic project design involved a two year study in which:

- during the first wet season (1992/93), samples of sheet flow runoff from three gas stations were collected prior to BMP implementation and analyzed in the laboratory for a variety of pollutants (Phase 1);
- best management practices were developed and implemented during the following dry season (Phase 1); and
- the following wet season (1993/94), after BMP implementation, runoff samples were collected and analyzed for the purpose of comparing pre-BMP data to post-BMP data for a quantitative evaluation of BMP effectiveness (Phase 2).

The growing body of published studies and storm water monitoring data continues to indicate that vehicles are one of the most significant sources of storm water pollutants and that areas where service of vehicles is conducted may be of particular concern. Fueling station discharges may be regulated in the future, so cost-effective BMPs will be very important not only in pollution reduction, but regulatory compliance as well.

The initial work on Phase 1 included the selection of three representative gasoline fueling stations whose owners/operators were willing to participate in the BMP demonstration program. Runoff samples from six storms were collected at each of the three stations during the 1992/93 wet season. Multiple samples were collected manually from sheet flow to represent a flow-weighted composite sample of approximately the first 0.30 inch of rainfall. Climatological data were also compiled

VOL 12 2 4963

R0058256

throughout the first wet season to aid in interpreting the storm water runoff results. The major classes of constituents analyzed in Phase 1 were:

Oil & Grease,
Total suspended solids,
Heavy metals (thirteen priority pollutant metals, aluminum, and iron),
Polycyclic aromatic hydrocarbons, and
Petroleum hydrocarbons.

After the first three storms, constituents not found in detectable concentrations or those found significantly below levels of concern were no longer included in the analyses, thereby allowing the analyses to focus on indicator pollutants. These pollutants were present in relatively high concentrations and were thought to be representative of the other pollutants on-site. The following pollutants were selected as indicators:

Oil & Grease,
Total suspended solids, and
Heavy metals (cadmium, chromium, copper, lead, and zinc)

Runoff water quality data from the first wet season of this study appeared comparable to results from recent related studies. Regressions of the pre-BMP data versus four rainfall parameters were performed: rainfall intensity during the period of sampling, cumulative precipitation to date, days since last storm of 0.10 inch or greater, and days since last storm of 0.25 inch or greater. This was done for each station individually and for the pooled data set. Overall, the regressions of pre-BMP runoff concentrations versus rainfall parameters showed the most consistent relationship to be between log concentration and days since last storm >0.25 inch, particularly for zinc. This result indicated that pollutant buildup occurs during dry periods, and runoff concentrations reflect the length of the buildup period.

The selection process for best management practices included all the potential BMPs applicable to the stations given the physical limitations of the sites. Off-site BMPs (e.g., detention pond, wetlands) were not considered because the scope and budget did not allow for these to be tested. Best management practices were selected using a semi-quantitative scoring method based on cost and perceived effectiveness in reducing pollutants. A suite of BMPs was selected to implement at each station that focuses on the areas with the greatest potential to generate pollutants (e.g., air/water supply area, fueling area, drive through area) as opposed to areas with less pollution potential (e.g., roof drains).

VOL 12 2 4964

R0058257

The following BMPs were selected for implementation at each station:

- Mobile Cleaning,
- Litter Control,
- Public Notices,
- Storm Drain Stenciling,
- Spill Cleanup Materials, and
- Employee Training.

The selected BMPs were implemented in the summer of 1993. Post-BMP runoff samples from the 1993-94 wet season were collected and analyzed to compare pre-BMP data to post-BMP data for a quantitative evaluation of BMP effectiveness.

Based on observations by project personnel and best professional judgment about the efficacy of source controls, it is highly likely that of the six BMPs implemented at the gas stations, the one BMP with the most significant chance to affect runoff quality was mobile high pressure water cleaning. The combined effect of the other five source controls was not likely to have a significant impact on the sources of pollution at the stations, namely, high volume vehicle traffic and leaks and spills of vehicle fluids. Consequently, the study can be considered in large part a pilot test of mobile cleaning as a best management practice.

When all the data from the pre-BMP condition is combined and compared against all the post-BMP condition data, the only statistically significant difference in the pre- to post-BMP concentrations was for oil and grease, and it was higher after the BMPs were implemented. For the event mass loading comparisons, no statistically significant differences were found between the pre- and post-BMP data. This indicates that, generally speaking, gas station runoff quality was not significantly different before and after implementation of BMPs.

Although visual observations by the field crew confirmed that a significant amount of pollutants were removed with each cleaning, it is likely that the cleanings may have made more pollutants "available" for washoff in the next event, either storm or cleaning, by freeing up pollutants and allowing them to redeposit on the pavement surface. Potential reasons for this observation include:

- High pollutant deposition
- Rough surface texture
- Heavy pollutant buildup
- Incomplete washoff after cleaning

VOL 12 2 4965

R0058258

All-in-all, it appears that this pilot test of mobile cleaning asphalt surfaces, at high sales volume gas stations, near busy intersections on major streets, was probably a worst case scenario for this potential best management practice. The cost of mobile cleaning the fueling stations used for this study was estimated to be about $600 per station washdown which is equivalent to $1,300 per acre of paved surface. Therefore, the cost of mobile cleaning a significant amount of the areas in a watershed exposed to vehicle traffic, on a regular basis, would be quite high.

Since the results were inconclusive, this study cannot recommend the implementation of the mobile cleaning BMP on a large scale. However, field observations and study results seem to indicate that, given the right conditions, mobile cleaning may have the potential to remove sources of storm water pollution. It is clear from this study and others that it is not just gas station runoff, but runoff from any area where vehicles travel, park, or are serviced that is of concern. Recommendations are made for further investigation of BMPs for impervious areas exposed to vehicle traffic.

1.0 Introduction

1.1 Purpose and Scope

This report summarizes the findings of the Demonstration of Gasoline Fueling Station Best Management Practices project. The project is an "Action Plan Demonstration Project" (APDP) funded in part by a grant awarded by the U. S. Environmental Protection Agency (U.S. EPA) through the San Francisco Estuary Project to the County of Sacramento (County). The purposes of the study were to characterize storm water runoff from gasoline fueling stations, demonstrate the effectiveness of pollution prevention technologies or best management practices (BMPs) in reducing pollutant loadings from gasoline fueling station runoff, and to disseminate information on effectiveness and costs to a wide audience.

The basic project design involved a two year study in which:

- during the first wet season (1992/93), samples of runoff were collected prior to BMP implementation and analyzed in the laboratory for a variety of pollutants (Phase 1);
- best management practices were developed and implemented during the following dry season (Phase 1); and
- the following wet season (1993/94), after BMP implementation, runoff samples were collected and analyzed for the purpose of comparing pre-BMP data to post-BMP data for a quantitative evaluation of BMP effectiveness (Phase 2).

The scope of study was developed after a review of previous studies of storm water runoff. Information was obtained from a literature review and from discussions with researchers at agencies and in academia. Although no study was found that focused solely on runoff from gasoline fueling stations, several studies provided guidance for sample collection methodology and described pollutants typically found at gas stations.

1.2 Project Strategy

Approach

The project was conducted in two phases. The work in Phase 1 (first wet and dry seasons) consisted of identifying the pollutant loading from three representative

VOL 12 2 4971

R0058264

gasoline fueling stations by collecting and analyzing runoff samples. Additionally, Phase 1 included selecting and implementing BMPs at the gas stations with the intent of reducing those pollutants found in the runoff water samples.

Specific tasks in Phase 1 included a literature review, gas station selection, sampling design, water quality monitoring and analysis, BMP selection and implementation, and public participation. This phase of the work culminated with the development of a Phase 1 Report (Sacramento County, 1993a) summarizing the completed tasks and associated findings.

The work in Phase 2 (second wet season) consisted of determining the effectiveness of the implemented BMPs in reducing pollutant loading by re-sampling the selected gas stations after BMP implementation and analyzing the results. The Phase 2 work culminates with the development of this comprehensive final report summarizing all the completed tasks, associated findings, results, and cost estimates to implement the BMPs on a basinwide scale.

Applied Science

As the term "Action Plan Demonstration Project" implies, this study was conducted as an applied science project, as opposed to a basic research project. This is an important distinction to make, because it influenced the project study design. The primary goal of this project was to demonstrate the effectiveness of BMPs in reducing storm water pollutants generated at gas stations. The most critical factor in demonstrating BMP effectiveness is the need to establish a sufficient database to show statistically significant differences between the pre- and post-control measure implementation. Without this, any conclusions will be judged and received with some hesitation. Such a database is difficult to develop because of the variability among storms (quantity, duration, intensity, etc.) and the variability among sites (runoff characteristics, activities located on-site, etc.).

The ability to discern statistically significant differences between two data sets hinges not only on the variability within each of the two data sets, but also on the number of data points in each set. When data variability is likely to be high, as in this case, it is necessary to have either correspondingly large data sets or a relatively large difference in their average values to demonstrate a statistically significant difference. The project team therefore advocated an approach that emphasized maximum production of useful data.

VOL 12 2 4972

R0058265

In practical terms, this approach meant the collection and analysis of samples from the maximum number of storms in each of the two wet seasons. To accomplish this within the available budget, it was necessary to focus the analyses on indicator pollutants. These pollutants were known or expected to be present in relatively high concentrations, and to be representative of the other pollutants on-site. By focusing on a subset of the expected pollutants, money was spent where it could produce the most useful data. As discussed more specifically in section 4, Monitoring, the selection of indicator pollutants was based on both the literature review and the sample results from the first three storms.

Another way to maximize the statistical validity of pre- and post-BMP comparisons is to maximize the difference in the pre- and post-BMP data. To effect this, the project team implemented a full suite of BMPs at each station, as opposed to implementing one BMP at each station. The presumption was that the combined effect of the suite of best management practices would increase the likelihood of reducing pollutants, thereby producing more statistically significant results.

Characterization of gas station runoff was also a goal of the project. Given the applied science emphasis and practical constraints on project funding, a detailed, comprehensive characterization of all possible constituents in gas station runoff was not feasible. The runoff characterization therefore also focused on a limited list of key constituents.

VOL 12 2 4913

R0058266

2.0 *Background*

This section describes the scientific and regulatory background to the project.

2.1 Literature Review

The objective of the literature review was to collect, compile, and review the existing information on toxic pollutant loads associated with storm water runoff from gas stations. This information was used to support subsequent project tasks. Two independent approaches were used to conduct the review: on-line database searching on DIALOG to find published information, and telephone contacts to find any additional published information. The on-line database search showed that very little had been published on the topic of storm water runoff from service stations. The most closely related studies were conducted in Europe, but most of these efforts studied wastewater, and none focused strictly on storm water. However, valuable information was obtained through discussions with researchers (Sacramento County, 1992a).

2.2 Regulatory Impetus

As a result of published studies and monitoring data from municipalities, there is growing support for regulation of fueling station discharges, both sanitary as well as storm water. The growing body of storm water monitoring data continues to indicate that vehicles are one of the most significant sources of storm water pollutants and that areas where service of vehicles is conducted may be of particular concern. In fact, several agencies, including the City of Palo Alto Regional Water Quality Control Plant (RWQCP) and the County of Orange Environmental Management Agency, have recently passed new ordinances that regulate discharges from vehicle service facilities, including fueling stations (Palo Alto RWQCP, 1993; County of Orange, 1993). These agencies require the implementation of BMPs such as secondary containment, spill controls, and employee training, to comply with their ordinances.

At the national level, bills drafted to reauthorize the Clean Water Act are focusing on vehicle service facility discharges, particularly storm water runoff. In addition, U.S. EPA has been developing options for Phase II of the federal storm water regulations, that generally include increased regulation of vehicle service facilities, including fueling stations. The overall impression from this evidence is that fueling station discharges

VOL 12 2 4974

R0058267

will be regulated, and so cost-effective BMPs will be very important in not just pollution reduction, but regulatory compliance as well.

VOL 12 2 4975

3.0 *Monitoring Plan*

This section describes issues related to the constituents that were analyzed, the quality assurance and quality control aspects of the study design, and the sampling site selection process, including gasoline fueling station selection and sampling point determination. In addition, the sampling program design is provided, including weather monitoring, storm selection, sample collection, and sample handling procedures.

3.1 Constituents

The identification of constituents to analyze focused on the constituents generally thought to be present at fueling stations. Information on the likely pollutants from vehicles and vehicle traffic were obtained from a number of sources (Shaheen, 1975; Federal Highway Administration, 1984; City of Puyallup, 1988; Pitt and Field, 1990; Sacramento County, 1992b; Washington Department of Ecology, 1992; Wisconsin Department of Natural Resources, 1992). Based on a review of these studies, the major classes of constituents analyzed in the pre-BMP phase were:

Oil & Grease,
Total suspended solids,
Heavy metals,
Polycyclic aromatic hydrocarbons, and
Petroleum hydrocarbons.

For each constituent analyzed (see Table 3.1), the EPA test method, detection limit, sample type, sample bottle, maximum holding times, and preservative are listed. Samples were not filtered before analysis.

Based on the results from the first three storms of Phase 1, constituents not found in detectable concentrations or those found significantly below levels of concern were no longer included in the analyses after the third storm, thereby allowing the analyses to focus on pollutants regularly found in significant concentrations (i.e., indicators). This action was consistent with the project's applied science approach (see section 1, Introduction).

VOL 12 2 4977

R0058270

The following pollutants were selected as indicators and were analyzed in samples from all twelve storms (6 pre- and 6 post-BMP):

Oil & Grease;
Total suspended solids; and
Heavy metals -
Cadmium,
Chromium,
Copper,
Lead, and
Zinc.

The same suite of parameters that were analyzed in the environmental samples were also analyzed in the Quality Control (QC) samples (field duplicate, field blank, laboratory duplicate, matrix spike and matrix spike duplicate samples).

3.2 Quality Assurance / Quality Control

A Quality Assurance Project Plan (QAPP) (Sacramento County, 1993b) was prepared for the project using guidance from the *Interim Guidelines and Specifications for Preparing Quality Assurance Project Plans*, (U.S. EPA, 1983). The QAPP presented specific information including data quality objectives, data use objectives, procedures, organization, functional activities, and specific quality assurance (QA) and quality control activities for the project.

QA/QC Sample Collection and Handling

Strict adherence to the sampling protocols described in section 3.4 is the most important QA/QC measure to be followed in the field. Documentation of consistency in sampling and analytical procedures is important for the validation of any sampling effort. As a part of field QA/QC, the chain-of-custody for each sample was strictly maintained. Sampling points for both Field QC samples and Laboratory QC samples were located at the same point that environmental sample collection took place.

Field QC Samples

Two types of field QC samples were used for Phase 1 and 2: field duplicate samples (duplicates) and field bottle blank samples (blanks). The objective of collecting duplicates was to obtain a check on sampling and analytical precision. The objective of collecting blanks was to check for cross-contamination during sample collection, shipment, and laboratory handling.

VOL 12 2 4978

R0058271

Field duplicate samples were collected in the field using the same sample collection methodology and sampling procedures as those used for collecting environmental samples. The procedure consisted of filling two 5 liter composite sample bottles, one for the environmental sample and one for the duplicate. Each time a 1 liter aliquot was collected and poured into the first 5 liter composite bottle, a second 1 liter aliquot was collected immediately thereafter and poured into the second 5 liter composite bottle. Both composite bottles remained on ice and were covered with screw-on caps, except during sample introduction. A discussion of sampling procedures is presented in section 3.4.

Blanks were collected concurrently with the environmental samples. Contaminant free water sufficient for the specified QA/QC analyses, a separate 1 liter glass bottle, and a separate 5 liter composite bottle were brought into the field along with the environmental sample containers. Each time a runoff sample was collected at the sampling point, an aliquot of contaminant-free water was poured into the separate 1 liter bottle and then into the separate 5 liter composite bottle. Both 5 liter bottles (environmental and blank composites) remained on ice and were covered with screw-on caps, except during sample introduction.

Both duplicates and blanks were labeled, packaged and sealed in the same manner as the environmental samples. The duplicate and blank samples were submitted blind to the laboratory along with the environmental samples. Because one environmental composite sample from each gas station was collected and delivered to the laboratory for each storm event, the sample was uniquely identified by station name and date. The identity of blank and duplicate samples was disguised.

Laboratory QC Samples

Matrix spike and matrix spike duplicate analyses of field samples were conducted as a quality control check. In addition, laboratory duplicates and method blanks were analyzed as part of the laboratory's routine in-house protocols. A complete discussion of the laboratory QA/QC program is provided in the QAPP (Sacramento County, 1993b).

QA/QC Sample Collection and Analysis Frequency

Due to the unpredictable and uncontrollable nature of storms, the frequency of collecting QA/QC samples deviated from the recommended U.S. EPA (1980) collection frequency for duplicates of "one sample per week or 10% of all field samples, whichever

VOL 12 2 4979

R0058272

is greater," and for blanks "one blank per day." The collection frequency for this particular project was driven by storm events. Thus, QA/QC samples were collected on an event basis for each storm sampled. One field duplicate and one field blank were collected and analyzed for each event. One matrix spike, one matrix spike duplicate, and one laboratory duplicate was collected and analyzed for each event. QA/QC samples were collected at each of the three gas stations on a rotating basis.

3.3 Sampling Site Selection

The selection of sampling sites was a two step, sequential process. The first step was identifying three gas stations with appropriate characteristics whose owners/operators were willing to participate in the study. After the sites were identified, the actual sampling points were selected.

Station Selection

The goal of the site selection process was to select three representative gasoline fueling stations whose owner/operators were willing to participate in the BMP demonstration program. The following general principles were followed in this process:

- Maximize statistical validity of pre- and post-BMP comparisons.
- Select stations that are representative of those in Sacramento County.
- Select similar sites; minimize variability that may confound pre-and post-BMP comparisons.

As noted above, one of the guiding principles in site selection was to select sites that enhanced the ability to distinguish between pre- and post-BMP implementation. To this end, the project team originally expected to select stations that have automotive service bays. During the course of the site selection process, however, it became apparent that the major oil companies are phasing out the traditional service stations that provide a mix of gasoline sales and automotive repair services, and replacing them with the modern self service/convenience store facility.

The site selection process also strove to identify stations that are representative of gasoline service stations in Sacramento County. Lists of existing retail gasoline operations in Sacramento County were obtained from the records of public agencies during the site selection phase of the project. The major oil companies operating retail gasoline outlets in Sacramento were contacted individually. A meeting of the Western

VOL 12 2 4980
R0058273

States Petroleum Association's (WSPA) Environmental Management Subcommittee was attended by a member of the consultant team. From these contacts, information was obtained regarding the types of stations which represent typical gasoline stations currently in operation in Sacramento County. This information was used in the selection of gas station sites.

The typical station is now a self service gasoline retailer with a convenience market and without automobile repair service bays. Furthermore, older stations providing repair services are being renovated and converted to the self service/convenience market type of station. This type of station was therefore selected as most representative of gasoline retail stations in Sacramento County, and the selected gas stations all conform to this set of characteristics.

Given the ongoing changes in the oil industry, it was also considered important to select stations operating under companies that appear to be stable in the Sacramento market, to provide some security that the selected stations would still be in operation at the conclusion of the project. The project team selected one station from each of the three leading gasoline retailers in Sacramento County. This decision increased the representativeness of the program and added credibility to the results.

The three selected stations were located in fairly close geographical proximity to one another (2 miles) (see Figure 3.1), and all receive an average of 19 to 20 inches of annual rainfall. The stations were located in the suburban Citrus Heights / Fair Oaks area of northeastern Sacramento County. The sites are within the Arcade Creek watershed, a 25,000 acre mixed use watershed which drains to the Sacramento River via the Natomas East Main Drainage Canal, and then into the San Francisco Bay Delta/Estuary.

All three stations were high volume gasoline retailers (over 200,000 gallons per month) that emphasized self service gasoline sales. All three stations were situated at busy, signalized intersections along major arterial roadways. Station X was the parent oil company's highest volume retail station in Sacramento County. All three stations had convenience markets; none provided automotive repair services or had automobile service bays. Station Z had a car wash, but most of the runoff from this activity flowed away from the sample collection point. Figures 3.2, 3.3, and 3.4. show the facility layout for each of the three stations.

Besides the representativeness of the selected stations, the other key selection criteria involved the selection of similar stations, to minimize station-to-station variability in the

VOL 12 2 4981
R0058274

runoff chemistry data and maximize the statistical validity of the pre- and post-BMP comparison. The selected stations had the following characteristics in common:

- Geographic location (similar precipitation and atmospheric deposition)
- Local setting (land uses, traffic patterns)
- Quantity of gasoline sold (high volume sales)
- Station layout and design
- Mix of services (e.g., convenience store)
- Existing BMPs and on-site treatment

Stations also were chosen where samples could be collected effectively, safely, and securely, and where the collected runoff would include only runoff from the gasoline station, uncomplicated by runoff from off-site. Finally, and in practical terms most importantly, stations were selected where the owner/operator has pledged their full cooperation.

Sampling Points

In essentially all cases, collection of storm water runoff that includes only service station runoff requires collection of samples on the service station property. Therefore, oil company approval was required before physical modifications could be made to the site to accommodate sample collection. The WSPA members, representing the three gasoline station retail outlets, agreed to allow these physical modifications to be made.

Statistical techniques were used to determine the number of sampling locations and storm events that should be included in the project, subject to the project's budgetary, logistic, and practical constraints. The statistical methods included an ANOVA model used in conjunction with statistical power analysis, a sampling plan design tool (Cohen, 1988). This analysis concluded that a 50% change in runoff concentrations due to BMP implementation would produce a statistically significant difference in pre- and post-BMP runoff characteristics, assuming three gas stations with one sampling point and six storms each for both the pre- and post-BMP sampling.

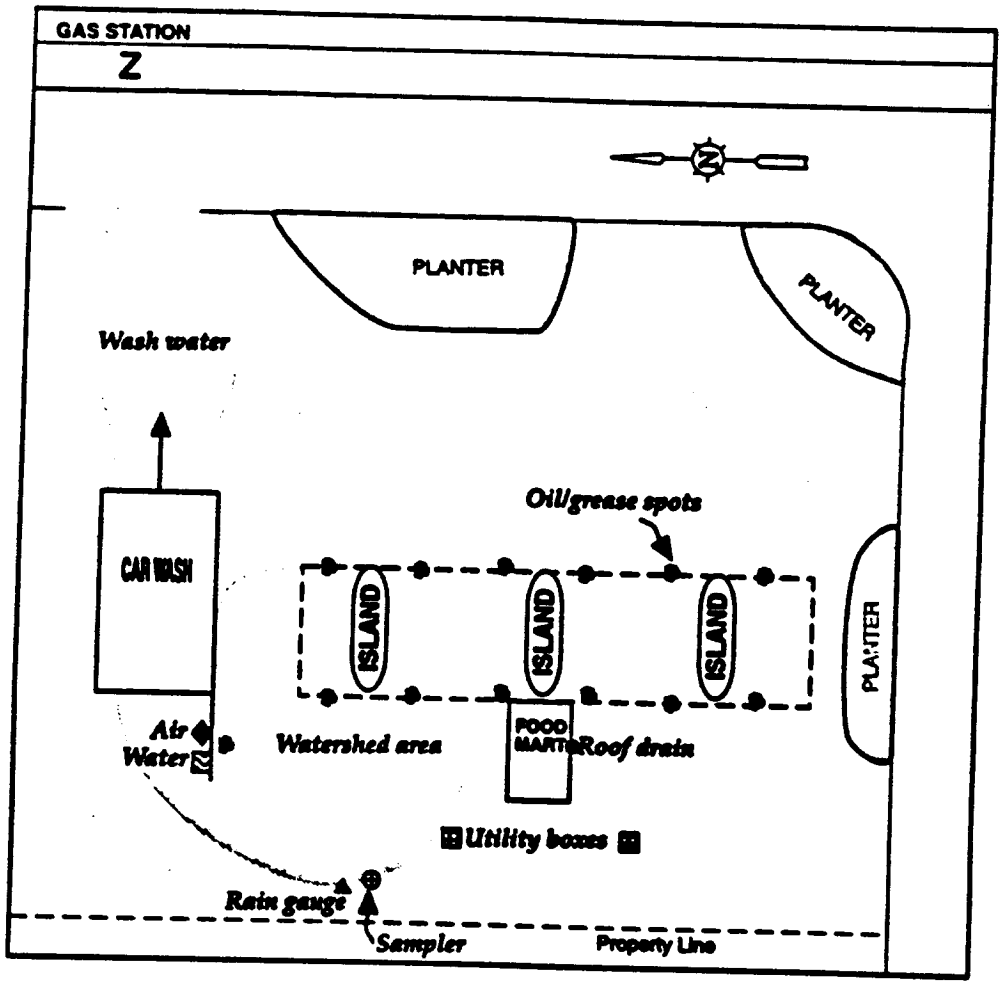
Figure 3.4



R0058279

VOL 12 2 4986

Given the expressed wish of the participating oil companies for the project to have a minimal impact on station operations (i.e., no interference with traffic flow or services), and the project's budgetary constraints (the cost of sampling manpower and monitoring station installation); the selection of one representative sampling point at each gas station was considered adequate. Safety of field sampling personnel was also a factor in sampling point selection. Sampling points were chosen based on the following criteria:

- Minimum intrusion of off-site runoff co-mingling with the sample
- Minimum interruption of station operation
- Maximum safety for sampling crews
- Consistency among gas stations
- Locations receiving runoff representative of gasoline fueling stations, including runoff from fueling areas and air and water supply service areas

At each of the three gas stations, a sampling point was selected where station runoff left the property, where the runoff stream at the sampling point drained a significant portion of the property, and where the runoff stream at the sampling point included drainage from fueling areas and auxiliary services (especially air and water supply areas). These sampling points were selected after careful site inspection and dry weather flow testing (observation of drainage patterns by allowing water to flow from a garden hose onto the areas of interest). Subsequent storm sampling experience at the gas stations confirmed that the sampling points received runoff representative of the gas stations.

Samples were collected at each of the three selected gas stations from the sampling points indicated in Figures 3.2, 3.3, and 3.4.

3.4 Sampling Program Design

Weather Monitoring

Weather was monitored during this project to maximize the likelihood of "capturing" six storms each season, to minimize false starts, and to ensure that the sampling equipment and team was prepared in sufficient time to collect runoff samples. The incoming storms were monitored using the Weather Network on-line weather database system, as well as direct telephone contacts with Weather Network and National Weather Service forecasters. The project team accessed Weathernet's on-line database via modem through an account established for this project, thereby providing live access to Weather Network forecasters available around the clock during-impending storm events.

VOL 12 2 4987

R0058280

Storm Selection

Using Weathernet information and a "phone tree," the Field Sampling Coordinator kept the project team informed as to the likelihood of sampling. As a storm approached, the Field Sampling Coordinator made a recommendation to the rest of the project team as to whether the storm was likely to be large enough for the purposes of this study. Only storms predicted to provide sufficient runoff to be sampled were selected.

Storm Events

Storm water monitoring programs in Sacramento County typically have restricted sampling events to storms expected to produce over 0.5 inch of rainfall within a 24-hour period, to achieve sufficient runoff to collect adequate samples. This guideline was adopted for the current project as well. In an average rainfall year, Sacramento County receives approximately 19-20 inches of precipitation in the area of the selected gas stations. In recent drought years (1986/87-1991/92), the annual rainfall has totaled significantly less. Given that some precipitation will occur during storms which do not meet the 0.5 inch / 24-hour intensity criteria, and given that it was not possible to predict the annual precipitation in advance, six was considered to be the number of storms that could reasonably be expected to be sampled within a wet season.

Sample Collection

Sheet flow samples were collected manually (without the use of sampling equipment) by placing a 1 liter glass bottle below grade at a sampling point (monitoring station). As shown in Figure 3.5, the monitoring station consisted of a 12 inch inside diameter by 18 inch deep reinforced concrete pipe (RCP) placed in the pavement at each location. A 3/8 inch aluminum plate was bolted in-place over the hole when sampling was not taking place. The plate was removed before sampling began.

At each station a 1 liter glass sample bottle was used to collect water for all the constituent analyses, and a 5 liter borosilicate glass bottle was used for compositing the 1 liter aliquots. During sampling, sheet flow runoff flowed over the lip of the RCP and was collected directly into the 1 liter sampling bottle. Continuous bailing was performed to keep the water level in the hole sufficiently below the mouth of the bottle to prevent cross-contamination of the collected sample. The individual 1 liter sample aliquots were composited immediately into the 5 liter borosilicate glass bottle.

R0058282

Samples were flow weighted by collection at intervals based on a pre-determined increment of rainfall volume, equal to 0.05 inches. To accomplish this, rain gauges were used to measure rainfall volume during storm sampling. The same type of gauge was placed at each of the three stations during the sampling period to provide site-specific data. The gauges were placed in an open area on-site, away from the influence of structures or trees. The rain gauges were checked periodically, depending on the rainfall intensity, and the amount of rain in each gauge was recorded during the sampling period to yield rate information as well as total rainfall data. Upon initiation of runoff sufficient to permit sample collection, a 1 liter sample was collected every 0.05 inches of measured rainfall until the composite bottle contained 5 liters of sample.

Sample collection was initiated by the Field Sampling Coordinator. Each station had dedicated staff who covered that station for the duration of the sampling period. All field observations were recorded, including storm characteristics, runoff characteristics, activities on-site, irregularities or difficulties in the sampling procedure, the time each grab sample was taken, and unusual qualities of the runoff sample.

Sample Handling

The composite container was field preserved at approximately 4° Centigrade by storage in a cooler containing ice. The filled composite sample containers were maintained on ice until delivery to the analytical laboratory. Delivery to the lab occurred within 24 hours of the completion of sampling. The composite containers remained closed with a screw on cover containing a Teflon Seal. Upon delivery to the lab, the composite was split by laboratory personnel into aliquots for the specified analyses, and preserved accordingly (see Table 3.1). Prior to pouring off aliquots from the composite for analyses, the composite sample was thoroughly shaken to ensure that representative samples were obtained.

Rainfall Monitoring

In addition to the on-site rain gauges used to measure rainfall during the sample collections, rainfall data were accessed from the closest Sacramento County ALERT system rain gauges. Figure 3.6 shows the location of three ALERT rain gauges in the vicinity of the three gas stations. The gauges are designated by numbers and nearby street names.

R0058284

4.0 *Best Management Practices (BMPs)*

This section describes the selection and implementation of best management practices designed to reduce gas station runoff pollution.

4.1 Selection

The selection of best management practices was based on a review of appropriate BMPs described and used elsewhere for vehicle-related activities (SCVNPSPCP, 1992; U.S. EPA, 1992; Palo Alto RWQCP, 1993; California SWQTF, 1993; County of Orange, 1993). As part of Phase 1, BMPs were selected based on their effectiveness, practicality, and cost by using a semi-quantitative scoring method (Sacramento County, 1993a). The following six BMPs were selected and implemented:

- Mobile High Pressure Water Cleaning
- Public Notices
- Litter Control
- Storm Drain Stenciling
- Spill Cleanup Materials
- Employee Awareness

The above list includes all of the BMPs applicable to the stations given the physical limitations of the sites. The selected best management practices were either low in cost, and/or high in perceived effectiveness in reducing pollutants. A "potential for disruption" criterion helped guide the selection toward BMPs that were acceptable to the station owners/operators. The BMPs tended to focus on the areas of the stations with the greatest potential to generate pollutants (e.g., air/water supply area, fueling area, drive through area) as opposed to areas with less pollution potential (e.g., roof drains, landscaping). On-site treatment control BMPs were not selected because of their high relative cost and disruption to operations. Off-site BMPs (e.g., detention pond, wetlands) were not considered because the scope and budget did not allow for these to be tested. Therefore, all of the best management practices selected for implementation were source controls.

One way to maximize the statistical validity of pre- and post-BMP comparisons is to maximize the difference in the pre- and post-BMP data. To effect this, the project team implemented the full suite of BMPs at each station, as opposed to implementing one

VOL 12 2 4992

R0058285

BMP at each station. The presumption was that the combined effect of the suite of best management practices would increase the likelihood of reducing pollutants, thereby producing more statistically significant results. The need to implement a suite of BMPs is especially important with source controls, because there are a variety of pollutant sources, each requiring a best management practice. If treatment controls had been a more viable approach, it's possible that fewer BMPs would have been necessary to produce a reduction in pollutants.

4.2 Implementation

Having selected the BMPs, the project team worked with the station owners/operators to gain their final approval and to implement the BMPs. The following discussions provide some detail on the actual implementation of each of the selected best management practices.

Mobile High Pressure Water Cleaning - The entire drainage area used in Phase 1, particularly the air/water supply, fueling, and drive through areas, was cleaned an average of about twice per month using a high pressure (3,000 psi) and high temperature (210°F) mobile cleaning unit (Figure 4.1). The wash water generated was collected using a "Vacu-boom," a portable, runoff collection system (Figures 4.2 and 4.3). The "Vacu-boom" includes a hollow, flexible snake that is connected to a high power wet vacuum unit. The apparatus enables sheet flow to be captured and conveyed to a sanitary sewer inlet.

Several concerns were identified and resolved before using the mobile cleaning system including: 1) potential asphalt erosion caused by the high temperature of the water, 2) wash water disposal, 3) safety of the cleaning operator and the equipment, and 4) disruption of normal station operations. To reduce the potential for erosion of the asphalt, the operator avoided persistent spraying in one area to avoid heating up the asphalt surface. Wash water disposal was handled by discharging into the sanitary sewer system via a cleanout or rest room connection. The safety and disruption issues were addressed by conducting cleaning operations late at night during slower business hours and by supplying the operator and assistant with safety orange cones and an orange vest for increased visibility.

VOL 12 2 4993

R0058286

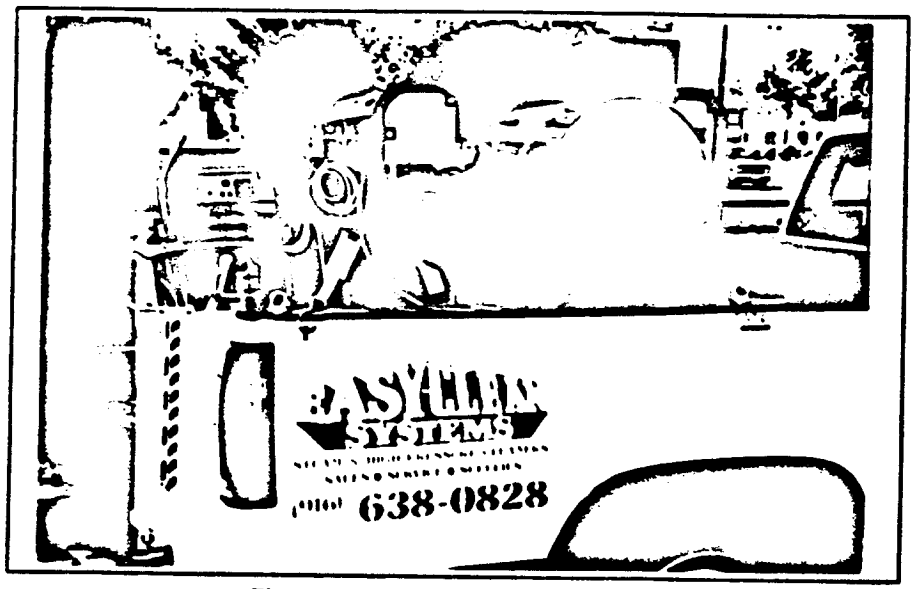

Figure 4.1 Mobile Cleaning System

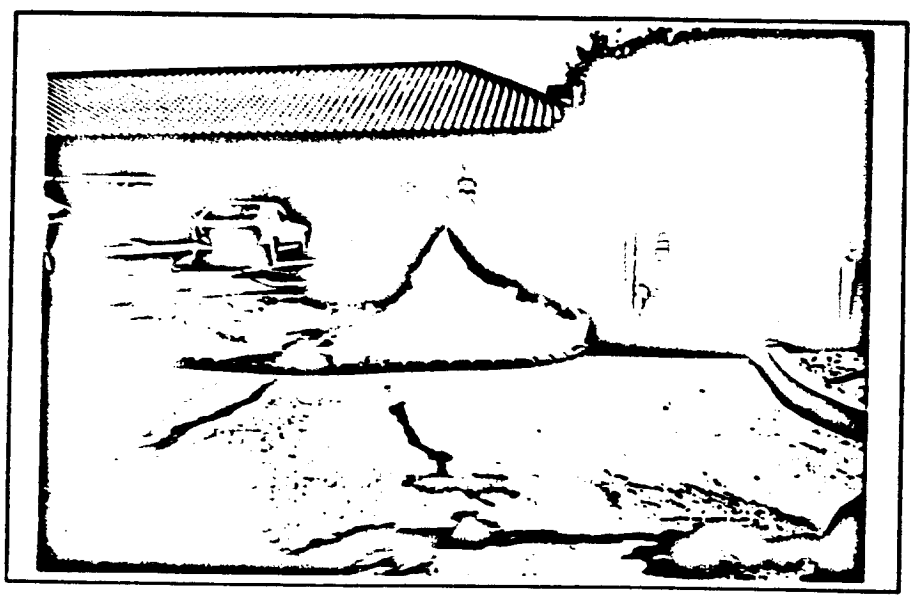

Figure 4.2 Vacu-boom

VOL 12 2 4994

R0058287

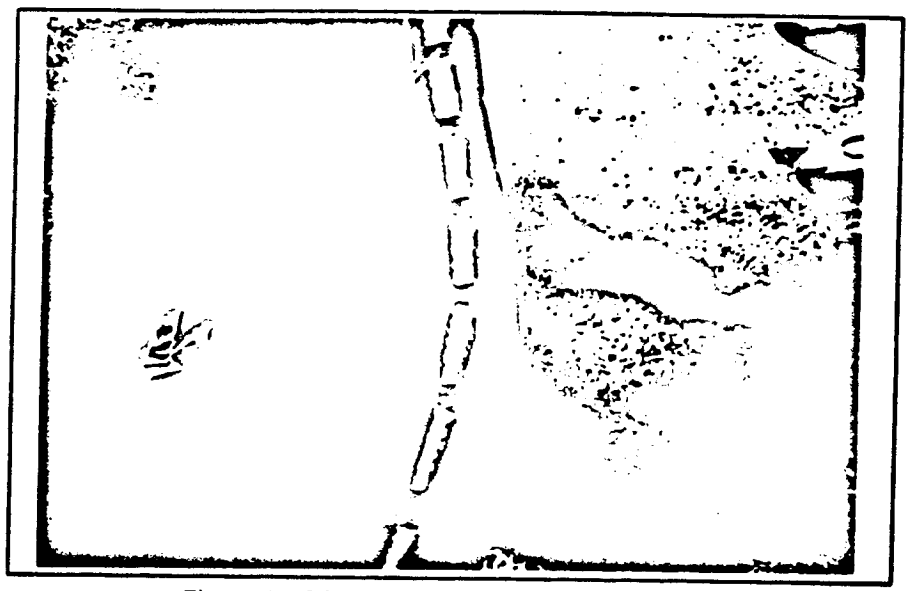

Figure 4.3 Wash water collected by Vacu-boom

The objective of the mobile cleaning BMP was to free the pollutants from the asphalt surface using high temperature and high pressure water and to transport the pollutants, in water suspension, to the Vacu-boom apparatus. The method of application that appeared to be the most effective was to initially wet the asphalt surface over the entire drainage area to the point of saturation without creating any significant runoff. The mobile cleaning took place starting from the furthest upstream point in the drainage area and working down in a back and forth line to the furthest downstream point. By initially wetting the surface, the waste stream from the mobile cleaning was able to freely travel down to the Vacu-boom without the water being "used up" in the wetting of dry asphalt. Water quality samples of the waste stream were originally going to be taken to determine the type and amount of pollutants being removed in the mobile cleaning BMP. However, since the Vacu-boom wet vacuum contained copper and brass fittings and components, project staff decided that the results would not be reliable and therefore abandoned the idea.

Table 4.1 presents data on the mobile cleanings performed during the project. The information presented in Table 4.1 relates the mobile cleaning number, dates of mobile cleaning, the stations cleaned, and the days since the previous cleaning with the storm number, the storm date, the number of days since the last cleaning, and the number of cleanings since the last storm sampled. The drainage areas at the three stations were mobile cleaned a total of ten times between late October 1993 and late March 1994.

VOL 12 2 4995

R0058288

To further explain Table 4.1, starting with the first column, the first cleaning occurred on 10/27/93 for stations Y and Z, and on 11/4/93 for station X. The second cleaning occurred on 11/9/93 for all three stations which resulted in 5 days since the last cleaning for station X and 13 days since the last cleaning for stations Y and Z (fourth column). The first storm (fifth column) was sampled on 11/29/93 (sixth column) which was 20 days since the last cleaning (seventh column) that was done on 11/9/93. The drainage areas at all the stations were mobile cleaned twice prior to this storm (eighth column).

Table 4.1 Mobile Cleaning/Sampled Storm Information

Mobile Cleaning Data				Sampled Storm Data			
Mobile Cleaning Number	Date of Mobile Cleaning	Station(s)	Days Since Previous Cleaning	Storm Number	Storm Date	Number of Days Since Last Cleaning	Cleanings Since Last Storm Sampled

VOL 12 2 4996

R0058289

Public Notices - Signs educating the public about good housekeeping practices and what to do in the event of a spill were displayed in the air/water supply area. One sign requested that the gas station attendant be notified should a spill occur and the other sign requested that litter be properly disposed (Figure 4.4).

Litter Control - To supplement the litter control sign, the project team monitored the presence of trash receptacles in the air/water supply area (Figure 4.4).

Storm Drain Stenciling - The public is usually unaware that storm drains flow directly to a creek, river, or a bay. Storm drain stenciling conveys the message that the water that flows into the catch basin goes directly to the local rivers. The on-site, and nearby off-site storm drain inlets were stenciled to increase public awareness (Figure 4.5).

Spill Cleanup Materials - To ensure that spilled fluids are promptly removed, cleanup materials must be readily available. All three stations keep spill cleanup materials on-site. The station managers were also encouraged to, not only keep the spill materials readily available, but also to train employees in the proper use of the spill materials.

Employee Awareness - All three stations and their parent corporations have employee training programs that include material and waste management practices. This training was supplemented, as necessary, to assist the project team in understanding the conditions at each station. Because the team could not be at each of the stations most of the time, the employees were encouraged to use log sheets to record significant events (e.g., spills) that could help to interpret study results. However, the use of log sheets to monitor spills outside the fueling areas was difficult to implement because the limited staff found at these type of stations usually did not have the time to make observations.

5.0 Results

This section describes the results of the first (pre-BMP) and second (post-BMP) year's wet season's measurements, including drainage area estimates, climatological data, runoff sample analyses, and graphs.

5.1 Drainage Area Estimates

For each of the stations, the area draining to the collection point was less than the total area of the station (see Figures 4.2-4.4). Measurements of the drainage area to the sample collection point were made based on site plans provided by the County of Sacramento and field measurements, including field flow (hose) trials, made by the project team. A planimeter was used to determine the watershed areas depicted in Figure 3.2 through 3.4. The estimated dimensions of the drainage areas are provided in Table 5.1.

As shown in Table 5.1, there are several ways to calculate the area draining to the sample collection point. The project team is using the exposed paved area plus the roof drainage area (row 6 in Table 5.1) to represent the "sample area," or area draining to the collection point. This area excludes the *covered* paved drainage area because runoff normally does not flow through this area. One difference between the stations is the percent of roof area draining to the collection point, with station X having significantly more roof drainage area (29%) than either of the other two stations (Y = 4% and Z = 0%).

5.2 Sampling Results

Climatological Results

Climatological data were compiled throughout both wet seasons to aid in interpreting the storm water runoff results. These data included areawide rainfall totals from Sacramento County ALERT system rain gauges, inter-event times (time between significant storms), and rainfall intensity data recorded during sampling. Rainfall data collected at the three ALERT gauges were used to calculate the cumulative precipitation for the 1992-93 (Figure 5.1) and 1993-94 wet seasons (see Figure 5.3). Figures 5.2 and 5.4 show the daily precipitation totals for the 1992-93 and 1993-94 wet seasons, respectively.

VOL 12 2 4999

R0058292

Table 5.1 Drainage Area Estimates

	Area		Station X (sq. ft.)	Station Y (sq. ft.)	Station Z (sq. ft.)
1	Exposed Paved Drainage Area		2,826	3,794	2,844
2	Covered Paved Drainage Area (1)	+	222	149	887
3	Total Paved Drainage Area (2)	=	3,048	3,943	3,731
4	Roof Drainage Area	+	1,150	168	0
5	Total Paved + Roof Drainage Area	=	4,198	4,111	3,731
6	Exposed Paved + Roof Drainage Area (3) = Sample Area (Row 1 + Row 4)		3,976	3,962	2,844
7	Roof Drainage as Percent of Sample Area		29%	4%	0%
8	Area of Gas Station (4)		20,809	18,358	30,423
9	Sample Area as Percent of Gas Station Area		19%	22%	9%

(1) Covered paved drainage area is a potential source of pollutants but runoff normally does not flow through this area.

(2) Total paved drainage area is the sum of the exposed drainage area and the covered drainage are (covered by an overhang).

(3) Excludes covered paved drainage area.

(4) Area of gas station includes buildings, landscaping, and other facilities but excludes adjacent streets and sidewalks.

All four plots of precipitation data show when the six pre-BMP and six post-BMP sampling events took place.

Once collected, the ALERT system rainfall data allowed for the calculation of the time between sampled storms (inter-event time). The determination of inter-event time depends on the definition of a "significant" storm. Consistent with U.S. EPA storm water regulations (40 CFR 122.26), the project team used 0.10 inches of rain as the significant storm threshold. Table 5.2 presents the inter-event data for both wet seasons.

* = Weighted average of three closest rain gauges
** = Average of Chicago and Van Maren Cripple rain gauges

Because 1992-93 (pre-BMP) was a relatively wet year in California, with frequent storms occurring on a regular basis throughout the winter, the inter-event times were fairly short, ranging from 2 to 9 days. In 1993-94 (post-BMP), about half as much rain fell as compared to 1992-93 (approx. 13 inches versus approx. 26 inches). The inter-event times in 1993-94 reflected the drier winter, ranging from 0 up to 33 days. Because a 0.10 inch storm does not always produce a significant volume of runoff (depending on duration and intensity), inter-event times based on the previous storm of 0.25 inches or greater were also evaluated for both years.

As discussed in section 3.4, Sampling Program Design, rain gauges were used to measure rainfall volume at the three gas stations during storm sampling. The same type of gauge was placed at each of the three stations during the sampling period to give site-specific data. The gauges were placed in an open area on-site, away from the influence of structures or trees. The rain gauges were checked periodically, depending on the rainfall intensity, and the amount of rain in each gauge was recorded during the sampling period to yield rate information as well as total rainfall data.

VOL 12 2 5005

R0058298

Table 5.3 presents information for both wet seasons on observed rainfall and the period of observation as recorded during sample collection, and the calculated rainfall intensity. The intensity shown is simply the quotient of the measured rainfall divided by the total time of observation, which corresponds to the amount of time required to collect the composite sample. For the most part, the differences in the rainfall intensities represent the inherent variability caused by the geographic separation of the stations.

Runoff Water Quality Results

QA/QC Evaluation

On a quarterly basis, a review of the QA/QC program was conducted, fulfilling the requirement for such a review as described in the Quality Assurance Project Plan (Sacramento County, 1993b). The quality control data from the storms indicated that the data quality objectives, as measured by the project specific numerical goals (Sacramento County, 1993b), were generally met during the second wet season. Specifically, precision, expressed as relative percent difference, was within the goals of +/- 20% for oil & grease and metals, and within +/- 10% for TSS, except for one storm (February 17 = +11%). Percent spike recovery values were all within the 80-120% accuracy goal for metals, and 70-130% for oil & grease. In addition, the collection of samples from all six storms exceeded the completeness goal of four storms for the season.

The qualitative system audits performed during this period indicated that the measurement systems were used appropriately and that the sampling and analysis activities matched those presented in the QAPP. The performance audit data described above indicate that data of known and defensible quality were produced. During the second wet season, there was one analytical result from a field duplicate in the third storm that did not match well with its corresponding environmental sample. With this exception, no other significant QA problems occurred during the 1993-94 monitoring.

Runoff Water Quality Data

Table 5.4 presents the pre-BMP (1992-93) runoff data for analytes detected in at least 75% of analyzed samples (i.e., indicators, nickel, aluminum, and iron). Table 5.5 presents the post-BMP (1993-94) data for the indicator analytes. As expected for storm

For both data sets (1992-93 and 1993-94) and for nearly all of these analytes, the number of samples was equal to or greater than five, except for chromium at station Z (n = 4) in 1992-93, and chromium at station Y (n = 3) in 1993-94. In order to increase the statistical validity of the chromium results, a distributional method was used to establish a maximum likelihood value for the non-detect results. The method used is outlined in Appendix A.

For example, the calculated values for the 1992-93 non-detected chromium values were 1.02 ug/L and 1.67 ug/L. These values were higher than the analytical detection limit, indicating a data gap between the detected values and the non-detected values. Given that the chromium values calculated to replace the non-detected values were actually slightly greater than the detection limit, it was concluded that it would be reasonable to replace the two non-detected values with the detection limit (1.0 ug/L).

VOL 12 2 5010

R0058303

Also for the 1992-93 data set, this same method was used to determine values for non-detect results on oil & grease (December 10 storm) and chromium (January 6 storm) at station X. In both cases, the values calculated to replace the non-detected values were actually slightly greater than the detection limit. So it was deemed reasonable to replace the two non-detected values with their respective detection limits (0.5 mg/L - oil & grease; 1.0 ug/L - chromium).

Appendix B presents plots of pollutant concentrations versus station for all six post-BMP storms. Where applicable, the plots include water quality objectives (SWRCB, 1991) for comparison. This comparison is very conservative because it does not consider the fate of the pollutants (e.g., adsorption) and the fact that the samples were collected upstream of the storm drain system, as well as the receiving waters for which these objectives are developed (SWRCB, 1991).

Appendix B also presents plots of post-BMP pollutant concentrations versus storm for the three stations. As in the case with the previous plots, where applicable, the plots include water quality objectives (SWRCB, 1991) for comparison. Again, this comparison is very conservative because of the reasons outlined above. As was the case with the first year's data, pooled mean concentrations of copper, lead, and zinc (Table 5.5) exceeded California Inland Surface Waters Plan water quality objectives based on a Sacramento River hardness value of 59 mg/L as $CaCo_3$.

Comparison to Related Studies

Table 5.6 presents some of the pre-BMP runoff water quality data from this study along with data from recent characterization studies. These studies have focused in whole or in part on vehicle-related sources. The studies vary in sample size (n=4 to 18), sample type (composite, grab), waste stream type (sheet flow runoff, simulated runoff, oil/grit separator water), and activity area (gas stations, fueling islands, oil/grit separators, parking, streets, vehicle service, driveways). So direct comparisons among studies is not possible. However, it does appear that the pre-BMP results from this study are comparable to results from other studies.

6.0 *Data Analysis*

This section describes the first and second year's data analysis, including a determination of which distribution plots (normal or log-normal) best fit the data, estimation of mass loads, analysis of station-to-station and pre- to post-BMP differences, evaluation of seasonal trends, and evaluation of high pressure water cleaning.

6.1 Descriptive Statistics

Descriptive statistics (mean, median and standard deviation) for each year for each constituent, for each station individually, and for all three stations combined, are presented in Table 6.1.

Table 6.1 Descriptive Statistics

Pre- and Post-BMP Data Combined

	TSS	O&G	O&G w/ NDs	Cd	Cr	Cr w/ NDs	Cu	Pb	Zn

6.2 Determination of Best Fit Distributions

The initial data analysis step involved testing the runoff water quality data to determine whether the data better fit a normal or log-normal distribution. The data were plotted using both a normal scale and a log scale for the y-axis, in each case plotted with a normal probability distribution for the x-axis. By fitting a regression line to the data

R0058306

VOL 12 2 5013

plot, it can be determined how well the data fit a normal or log-normal distribution. Only those constituents with four or more detected values at each station were included in this analysis. Those constituents were total suspended solids, oil & grease, cadmium, chromium, copper, lead, and zinc. The analysis was completed for each year of data separately for each gas station, and then for the data from all three stations combined.

As discussed in section 5.2, Sampling Results, non-detected data were replaced with the appropriate values before plotting so that the true number of data points could be used on each plot. In each case the curve-fitting function in Kaleidagraph™ was used to determine the equation of the line that fit the data most closely. Kaleidagraph™ reports an "R" value, which is an indication of how well the line approximates the actual data. Curves with "R" values close to 1.0 fit best.

Plots for Data Grouped by Constituent and Station

For the pre-BMP condition, the log-normal distribution fit the majority of the data best for the individual stations. In the case of cadmium and lead, the log-normal plots had higher "R" values than the normal plots for each sampling location, indicating that the log-normal curves fit best. In the case of chromium, copper, total suspended solids, and zinc, the station Y and Z curves fit best on the log-normal plot, but the curves for X fit slightly better on the normal plot. The station X and Y curves for oil and grease also fit best on the normal plot.

Plots for Data Grouped by Constituent Only (All Stations Combined)

For the pre-BMP data, for each of the seven constituents evaluated, when the data from all three stations were combined, the log-normal curves fit best. Each of the "R" values was greater than 0.93, indicating that the curves fit the data fairly well.

For the post-BMP data, log-normal distributions provided the best curve fits for the combined data sets for all constituents tested.

Assumption of Log-normal Distribution

Based upon the preceding analysis of the distributional characteristics of the data, the log-normal curves best fit the data overall for the constituents examined in this study. The regression analysis (sections 6.5 and 6.6) therefore assumes that the data are generally log-normally distributed. The distribution plots are shown in Appendix C.

VOL 12 2 5014

R0058307

6.3 Estimation of Event Mass Loads

For each constituent and station, event mass loads (EMLs) were estimated for each storm event monitored. The EMLs were calculated from the product of the measured pollutant concentration and the estimated runoff flow volume through the gas station monitoring site drainage area. The runoff flow volume for each storm was calculated from the estimated surface area draining to the monitoring site (as described in section 5.1), and the rainfall volume measured at the ALERT system rain gauge nearest the site. The estimated mass loads for the pre-BMP and post-BMP storm events are shown in Tables 6.2 and 6.3.

6.4 Analysis of Station-to-Station Differences and Pre- to Post-BMP Differences

Statistical analyses were conducted to determine whether runoff water quality differed from station-to-station during the study, and whether post-BMP runoff quality differed from pre-BMP runoff quality.

T-tests were used to evaluate the differences in gas station runoff water quality among the stations in each of the two years of the project, and also to evaluate the differences in runoff quality between the pre-BMP and post-BMP conditions. For the station-to-station comparisons, the tests were done by pairs of stations (X:Y, Y:Z, X:Z). A robust form of the paired, two-tailed Student's t-test was used. This test compares the means of two data sets, but does not assume that the variances of the populations from which the data sets are drawn are equal. The paired sample test is appropriate for data sets where the observations are in paired sets, as in this study.

The t-test evaluates the relative difference in mean values between two data sets. The test is set up to test what is called the "null hypothesis"; that is, the hypothesis that there is no significant difference between the two data sets. Technically, the t-test determines the probability of error associated with rejecting the null hypothesis. This is essentially equivalent to the probability of error (known as the "p" value) associated with accepting the hypothesis that there is a significant difference between two data sets.

The key measure produced by the t-test is the probability (p) value. A significant difference is considered to exist between the data sets when the p-value is less than or equal to 0.05, which indicates that the probability of error associated with rejecting the null hypothesis (or with accepting the alternative hypothesis that the data sets are different) is less than five percent.

Station-to-Station Differences - Pre-BMP Monitoring

The t-test p-values produced by the station-to-station comparisons of runoff pollutant concentrations for the pre-BMP condition (1992-93 monitoring) are shown in Table 6.4. In two instances, the p-value was small enough (<0.05) to warrant further investigation. The variances for these two instances were very large in comparison to the means, however, which indicates that the difference was likely an artifact rather than a significant difference. All of the other values indicate no statistically significant differences among the gas stations for the baseline monitoring, using the log-transformed values. These results allowed the data to be "pooled" or combined into a larger data set for evaluations of rainfall-related effects, and allowed the pooling of the data from the three stations in the pre-BMP analyses.

Table 6.4 p-Value Matrix; Paired t-tests
Pre-BMP (1992/93) Concentration Data

	Station Group		
Constituent	X/Y	Y/Z	X/Z
Total suspended solids	0.542	0.434	0.101
Oil & grease	0.232	0.936	0.112
Cadmium	0.349	0.345	0.155
Chromium	0.938	0.029	0.365
Copper	0.116	0.960	0.423
Lead	0.259	0.328	0.865
Zinc	0.002	0.329	0.884

Station-to-Station Differences - Post-BMP Monitoring

The t-test p-values produced by the station-to-station comparisons of runoff pollutant concentrations for the post-BMP condition (1993-94 monitoring) are shown in Table 6.5. As with the pre-BMP monitoring data, the t-test results indicate that no significant differences can be determined in post-BMP runoff water quality from one station to another. No p-values below 0.05 were obtained from the comparisons of the various station pairs. These results allowed the data to be "pooled" or combined into a larger data set for evaluations of rainfall-related effects, and allowed the pooling of the data from the three stations in the post-BMP analyses.

VOL 12 2 5018
R0058311

For the post-BMP monitoring, the EMLs were also tested for station-to-station differences. Significant differences were observed both between stations X and Y, and between stations Y and Z, for chromium, zinc, and oil and grease (see Table 6.6).

Pre-BMP to Post-BMP Differences

The lack of statistically significant differences in pollutant concentration data among the three stations for both years permits grouping of the data from the three stations in the pre- and post-BMP analyses, as well as use of the combined data sets in evaluations of rainfall-related effects for each year.

T-tests were again used to compare the pre-BMP monitoring results to those of the post-BMP conditions. The tests were run for each station individually and for data from the three stations combined, in each case comparing the pre-BMP data to the post-BMP data. The comparisons were done for both concentrations and mass loadings.

The results of the concentration data comparisons are shown in Table 6.7. A significance level of p=0.05 was again used to determine whether statistically significant differences exist. The only statistically significant difference in the pre- to post-BMP comparisons was found in the combined stations data sets for oil and grease. For the EML comparisons (Table 6.8), no statistically significant differences were found between the pre- and post-BMP data. This indicates that, generally speaking, gas station runoff quality was not significantly different before and after implementation of BMPs. A complete set of the paired t-test results is presented in Appendix D.

Table 6.8 p-Values; Paired t-tests

6.5 Evaluation of Seasonal Trends

Regression analysis was used to evaluate the effects of precipitation patterns on gas station runoff chemistry for each of the two study years. A regression analysis provides an evaluation of the best-fit line drawn through a data plot. The "p" value indicates the likelihood that the observed relationship is due to chance. A p-value of ≤ 0.05 is generally considered to indicate a statistically significant relationship. The "r" value indicates the relative "goodness of fit", or strength of the relationship. An r value of 1 equals a perfect positive correlation between the data points; -1 equals a perfect negative correlation.

For the pre-BMP data, regressions were performed on the runoff concentration data vs. four rainfall parameters: rainfall intensity during the period of sampling, cumulative precipitation to date, days since last storm of 0.1" or greater, and days since last storm of 0.25" or greater.

For the post-BMP runoff concentration data, additional precipitation parameters were added: sampled storm depth (volume), intensity of storm (overall intensity during the entire storm event, from the ALERT rain gauge data), and elapsed rainfall before start of sampling. For the post-BMP event mass data, regressions were run on a smaller subset of precipitation parameters: cumulative precipitation to date, and days since last storm of 0.25" or greater.

The regressions were run for each station individually and for the combined stations data set. The log-transformed pollutant concentration values were used in all cases.

Pre-BMP Concentration Data

The statistically significant regression relationships for the pre-BMP data are shown in Table 6.9. The highest number of statistically significant regression relationships ($p \leq 0.05$) was found with the "days since last storm >0.25 inch" parameter. Four different constituents at station Y (chromium, lead, zinc, and TSS) and one constituent at station Z (zinc) were significantly correlated with this parameter. For the pooled data set (all stations combined), chromium and zinc were again significantly correlated with this parameter, although the r values were relatively low.

For the "days since last storm >0.10 inch" parameter, the station X regression of cadmium concentration was statistically significant, and had a fair r value, but the slope is negative, indicating that cadmium concentration decreases as the inter-event time gets longer, which is counterintuitive. It is likely that this result was an artifact due to

VOL 12 2 5020
R0058313

chance. The pooled zinc data set was positively correlated with days since last storm >0.10 inch, although the r value was marginal.

At station Z, cadmium, lead, and zinc showed decreasing concentrations in relation to increasing rainfall intensity, which is plausible due to the diluting effect of more intense rainfall. For the pooled data set, oil and grease showed a similar inverse relationship to intensity, but the r value was weak.

Overall, the regressions of pre-BMP runoff concentrations versus rainfall parameters indicated that zinc (and possibly other metals) appeared to exhibit a build-up effect during dry periods at the fueling stations. Zinc concentration tended to decrease as the inter-event time decreased.

Post-BMP Concentration Data

The regression results for the concentration data are shown in Table 6.10. The statistically significant regression relationships are indicated by shading. Plots of the significant regressions are presented in Appendix E. There were several significant relationships but, as was the case with the pre-BMP data, the highest number of statistically significant regression relationships ($p \leq 0.05$) was found with the "days since last storm >0.25 inch" parameter. All five metal constituents and oil & grease, both at station Z and for the pooled data set (all stations combined), were significantly correlated with this parameter. Only TSS did not show any significant correlation with the "days since last storm >0.25 inch" parameter.

Concentrations of three of the five metals and oil & grease, in the pooled data set, were also significantly correlated with the "days since last storm >0.10 inch" parameter. Pooled data set concentrations of TSS showed statistically significant regression relationships with two parameters, elapsed rainfall before start of sampling and sampled storm depth. Both these parameters relate to volume of the sampled storm.

Post-BMP Event Mass Load Data

The regression results for the event mass load data are shown in Table 6.11. The statistically significant regression relationships are indicated by shading. Plots of the significant regressions are presented in Appendix F. In contrast to the post-BMP concentration data, there were no statistically significant regression relationships with the parameter "days since last storm of 0.25" or greater."

6.6 Evaluation of Effects of Mobile Cleaning

Despite the result, discussed in pre- to post-BMP Differences (section 6.4) that, overall, gas station runoff quality was not significantly different after implementation of BMPs, there were statistically significant regression relationships ($p \leq 0.05$) between both the post-BMP concentration and event mass load data, and the "days since last cleaning" parameter. The pooled concentration data set for two metals, cadmium and lead, showed a significant correlation with "days since last cleaning." The event mass load data showed a number of statistically significant regression relationships with the "days since last cleaning" parameter. The pooled data sets for three metals (cadmium, chromium, and zinc) and oil & grease showed that the event mass loads of these constituents decreased with decreasing number of days since last cleaning.

7.0 *Discussion and Recommendations*

This section discusses the results of Phase 1 and Phase 2 and makes recommendations for further research.

7.1 Discussion

One of the goals of the project was to compare pre-BMP data to post-BMP data for a quantitative evaluation of BMP effectiveness. As discussed in section 4, Best Management Practices, the project team implemented the full suite of BMPs at each station, as opposed to implementing one BMP at each station. The presumption was that the combined effect of the suite of best management practices would increase the likelihood of reducing pollutants, thereby producing more statistically significant results.

Based on observations by project personnel and best professional judgment about the efficacy of source controls, it is highly likely that of the six BMPs implemented at the gas stations, the one BMP with the most significant chance to affect runoff quality was mobile high pressure water cleaning. The combined effect of the other five source controls:

- public notices,
- litter control,
- storm drain stenciling,
- spill cleanup materials, and
- employee awareness,

seems likely to have a much less significant impact on the primary sources of pollution at the stations, namely, high volume vehicle traffic and leaks and spills of vehicle fluids. In addition, some of the other source controls (litter control, spill cleanup, and employee training) were in place, to some extent, during the pre-BMP period. Consequently, the study can be considered in large part a pilot test of mobile cleaning as a best management practice. The discussion of BMP effectiveness therefore focuses on mobile cleaning.

VOL 12 2 5025
R0058318

Climatological Differences

In discussing the differences between the pre-BMP and post-BMP data, it is important to note the large difference in the climatology of the two wet seasons. In 1993-94 (post-BMP), about half as much rain fell compared to the pre-BMP wet season (1992-93) (approx. 13 inches versus approx. 26 inches). Because 1992-93 (pre-BMP) was a relatively wet year in California, with frequent storms occurring on a regular basis throughout the winter, the inter-event times were fairly short, ranging from 1 to 8 days. The inter-event times in 1993-94 reflected the drier winter, ranging from 1 to 34 days. Average inter-event time for pre-BMP sampling events was four days, compared to over nine days for post-BMP samples. As discussed below, both pre-BMP and post-BMP runoff quality was significantly affected by the inter-event time period (number of days since last storm).

Research by others including Pitt (1987), indicates that rain depth and intensity significantly affect particulate residue washoff from impervious surfaces. Normal rains, up to about one inch, typically remove only about 10-20 percent of the particulate residue on a surface. So it is possible that during the post-BMP wet season, when total rainfall was one-half of the pre-BMP wet season, that relatively less particulate residue was washed off the asphalt surfaces at the gas stations by storm events.

Summary of Pre-BMP to Post-BMP Differences

When all the data from the pre-BMP condition is combined and compared against all the post-BMP condition data, the only statistically significant difference in the pre- to post-BMP concentrations was for oil and grease, and it was higher after the BMPs were implemented. For the event mass loading comparisons, no statistically significant differences were found between the pre- and post-BMP data. This indicates that, generally speaking, gas station runoff quality was not significantly different before and after implementation of BMPs.

However, these results must be interpreted in light of the sample size data variability and climatological effects, as follows:

1. Although the sample size for both years (n=18, 3 stations x 6 storms) is reasonable, given the logistical challenges of storm water monitoring; statistically, it is a relatively small sample size, particularly considering the inherently large variability in storm water data.

VOL 12 2 5026

R0058319

2. A review of the data from both years (Tables 5.4 and 5.5) confirms the high degree of variability in the pooled data. Standard deviations were generally as large as the means.

Effects of Climatology on Pre-BMP and Post-BMP Concentration Data

Overall, the regressions of pre-BMP runoff concentrations versus rainfall parameters indicated that zinc (and possibly other metals) appeared to exhibit a buildup effect during dry periods at the fueling stations. Zinc concentration tended to decrease as the inter-event time decreased. Similarly, for post-BMP data, the highest number of statistically significant regression relationships ($p \leq 0.05$) was found with the "days since last storm >0.25 inch" parameter (all five metal constituents and oil & grease), and with the "days since last storm >0.10 inch" parameter (three of the five metals and oil & grease).

This buildup or accumulation effect has been documented in other studies (U.S. EPA, 1979; U.S. EPA, 1985; Pitt and McLean, 1986) for particulates. It appears from this study that many of the heavy metals and oil & grease exhibit a similar effect. These data also seem to indicate that the accumulation of these pollutants translates into higher concentrations in the runoff, that is, that what accumulates tends to wash off.

For the post-BMP data, the only constituent that did not show any significant correlation with either of the "days since last storm" parameters was TSS. The concentration of total suspended solids in runoff did not increase with increasing time between significant storms. The potential explanations for this result are discussed below in relation to the effects of mobile cleaning.

Effects of Mobile Cleaning on Concentration and Mass Load Data

Although overall gas station runoff quality was not significantly different after implementation of BMPs, the length of time between cleanings and sampled storm events seems to have affected runoff quality. There were statistically significant regression relationships ($p \leq 0.05$) between both the post-BMP concentration and event mass load data for some metals and oil & grease, and the "days since last cleaning" parameter. This result appears to parallel the correlations found between the post-BMP concentration data and the "days since last storm" parameters. It seems that, in general, measured runoff concentrations for some metals and oil & grease increase with increasing time since the previous "washoff" event, whether that event was natural (storm) or artificial (cleaning).

VOL 12 2 5027

R0058320

In contrast to metals and oil & grease, the post-BMP concentrations and event mass loads of total suspended solids in runoff did not increase with increasing time between cleanings. Again, this result appears to parallel the correlations found between the post-BMP TSS concentration and load data and the "days since last storm" parameters. There are a couple of potential explanations for these results in relation to the effects of mobile cleaning.

One potential reason that post-BMP TSS concentrations and loads did not increase with increasing time between either storms or cleanings is that the cleanings were effective at removing available particulate residue and possibly even reducing the total residue lodged in the spaces of the asphalt surface. It is possible that the cleanings were much more effective at removing TSS, which did not exhibit a buildup effect, than in removing oil & grease and heavy metals, which did show an accumulation effect. It is likely that oil & grease have a strong affinity for asphalt surfaces because of the similarities in their chemical composition. This affinity would make the separation of oil & grease from asphalt difficult, even under the high pressure and temperature conditions created by the cleanings. As for the heavy metals, although they have been shown to be bound to particulates, it is likely that a significant amount of metals are also bound to oil & grease.

Another potential reason that post-BMP TSS data did not correlate with the "days since last ..." parameters may relate to the fact that the post-BMP concentrations of TSS showed statistically significant regression relationships with two completely different parameters than the other constituents: elapsed rainfall before start of sampling and sampled storm depth. Both these parameters relate to volume of the sampled storm. This result is consistent with the research of Pitt (1987), discussed previously, that indicates that rain depth and intensity significantly affect residue washoff from impervious surfaces, and that the accumulation of particulates on paved surfaces does not necessarily translate into those particulates being washed off by storm runoff. This study's results may indicate that, when total rainfall was significantly reduced during the post-BMP wet season, very little particulate residue was washed off the asphalt surfaces at the gas stations by storm events.

The point could be made that although total rainfall was significantly reduced during the post-BMP wet season, it would seem that the ten mobile cleanings that took place during this time would have, in a sense, "made up for" the lower frequency and volume of storms, and washed off much of the particulates. However, the timing of the cleanings was such that they may have had little impact on TSS buildup. Although the

VOL 12 2 5028

R0058321

mobile cleanings occurred interspersed throughout the wet season (see Figure 5.4), only the last two mobile cleanings occurred after a significant storm (greater than 0.1 inch) and before the sampled storm (#6), and therefore, shortened the number of days, and presumably the TSS accumulation, since a significant event, either storm or cleaning.

Effectiveness of Mobile Cleaning

Although visual observations (see Figure 4.3) confirmed that a significant amount of pollutants were removed with each cleaning, it is likely that the cleanings may have made more pollutants, particularly oil & grease, "available" for washoff in the next event, either storm or cleaning, by freeing up pollutants and allowing them to redeposit on the pavement surface. There are several reasons for this observation.

1. Pollutant deposition - The asphalt at gas stations, particularly the high sales volume stations used in this study, is subject to very high pollutant deposition rates. The sources include not only the vehicles themselves traveling over the surface for routine services (e.g., fueling), but episodic sources like fluid spills in the air/water supply area, and local sources like the resuspension and deposition of airborne pollutants from vehicles stopping at the intersections and traveling on the major streets adjacent to the stations. The net effect is an essentially continuous deposition of pollutants at such locations. The cleaning effort may not have been sufficient for the level of pollutant deposition occurring at the gas stations.

2. Surface texture - Asphalt is a relatively rough and porous surface. Because of its texture, it has innumerable miniature storage spaces that receive and detain pollutants as they are deposited on its surface. These spaces act as pollutant sources when it rains or when the surface is cleaned. The ability of high pressure cleaning to efficiently remove pollutants from porous surfaces is questionable.

3. Pollutant buildup - A relatively long-term buildup of pollutants may have occurred on the outside pavement surfaces of these stations because of the significantly reduced volumes of rain that fell during the six year drought period preceding the study. In addition, because of drought restrictions, the use of water to clean asphalt surfaces at these stations was prohibited by local ordinance during much of this period. The high pressure cleanings may have loosened up the long-term buildup of pollutants which otherwise would not have been available for washoff during normal rainfall conditions.

VOL 12 2 5029

R0058322

4. Water accumulation before runoff - Because of the innumerable miniature storage spaces in asphalt, a significant amount of water must fall, in the case of a storm, or be applied, in the case of a cleaning, before these spaces are "filled" and runoff occurs. Observations by the mobile cleaning crew confirmed that the asphalt had to be wetted first before actual cleaning could start. This phenomena means that when cleaning time is restricted, as it was at the stations because of high traffic volumes, it is difficult to tell if the spray application rate is sufficient to overcome the necessary wetting and create a constant sheet flow toward the wash water collection device.

5. Incomplete washoff after cleaning - The mobile cleaning crew reported that although visual observations indicated that the cleanings removed a significant amount of pollutants, they also probably left behind a significant amount for a couple of reasons:
   a) The asphalt seemed to contain more pollution than the crew had time to remove.
   b) The limited coverage of the cleaning wand meant that even when the crew was able to remove significant quantities of the pollutants from the asphalt and suspend them in the sheet flow, as soon as the wand was moved to another area, pollutants started settling out of the sheet flow back into the asphalt, resulting in a redistribution rather than removal of some pollutants.

   It's likely that some of the pollutants left behind or redistributed were previously not available to be washed off, but were made available by mobile cleaning to be washed off in the next significant storm.

All-in-all, it appears that this pilot test of mobile cleaning asphalt surfaces, at high sales volume gas stations, near busy intersections on major streets, was probably a worst case scenario for this potential best management practice. The cost of mobile cleaning used by the fueling stations for this study was estimated to be about $600 per station per wash down, which is equivalent to $1,300 per acre of paved surface. Therefore, the cost of mobile cleaning a significant portion of the areas in a watershed exposed to vehicle traffic, on a regular basis, would be quite high.

Because the results were inconclusive, this study cannot recommend the implementation of the mobile cleaning BMP on a large scale. However, field observations and study results seem to indicate that, given the right conditions, mobile cleaning may have the potential to remove sources of storm water pollution. The discussion below provides some ideas on the focus of future studies.

VOL 12 2 5030

R0058323

7.2 Recommendations for Conduct of Future Studies

Monitoring results for the pre- and post-BMP study showed that constituent concentrations in runoff from the fueling stations are similar to those found in storm water monitoring data on streets, parking lots, driveways, oil/grit separators, and other areas that have significant exposure to vehicle traffic. In this study, the potential for interference with gas station activities and the resulting disruption to business constrained implementation of mobile cleaning. Because runoff from other areas significantly exposed to vehicles is likely to be representative of gas stations, it may be more appropriate to conduct future investigations of source control effectiveness on paved surfaces exposed to vehicle traffic that are not subject to the logistical constraints at high volume fueling stations. The discussion below is intended to provide insight on how to improve investigations of BMP effectiveness.

Existing Source Controls

Because existing source controls such as spill cleanup, litter control ,and employee education were being implemented at the fueling stations on a regular basis in the pre- and post-BMP study periods, their effectiveness could not be quantified. However, their ability to prevent potential sources of contamination is high and should be emphasized in all commercial and industrial areas where outdoor spills may occur.

New Construction Source Controls

Methods of source control not used in this study because of the high costs of retrofit include those that could normally be built as part of new facility construction. These BMPs include isolating runoff, redirecting runoff from areas with high pollution potential, or substituting cement for asphalt because it is easier to clean. Many of these best management practices may be cost-effective over the long-term in reducing storm water pollution.

Further Study of Mobile Cleaning

In this study, the potential for interference with gas station activities precluded extensive quantitative monitoring of the mobile cleaning method itself. Application rates varied over the drainage areas because of traffic, operator judgment, and time constraints. To reduce variability, a controlled application could be done by monitoring the amount and rate of application of high pressure/high temperature water. Other

VOL 12 2 5031

R0058324

parameters to monitor might be use of soaps and detergents, use of different cleaning apparatus, and application on different pavement surfaces (e.g., cement concrete).

Because of the high cost of mobile cleaning, its practical use may be limited to spot cleaning specific areas with evidence of spills or staining such as behind restaurants, around vehicle service areas, and on heavily stained areas of parking lots. The important elements of mobile cleaning are that it be preventative and that the wash water be collected and disposed of properly.

Improvement in Pre- and Post-BMP Study Design

One of the advantages of this study's two-year time frame was that it allowed ample time after the pre-BMP monitoring to select and implement best management practices before the post-BMP monitoring began. The disadvantages of this time span were that climatological and site conditions changed between the pre-BMP and post-BMP monitoring. One alternative to this method is to conduct the study in the same wet season by monitoring a large number of vehicle traveled areas and service facilities of similar characteristics for the first few storms to verify that the data can be pooled, and then to implement the BMPs at some sites for the remaining storms to achieve a direct comparison on a per storm basis. This method may reduce climatological differences and differences in sites that occur from year to year. However, it would be necessary to statistically account for the effects of seasonal variation on runoff quality.

Use of Larger Watershed Treatment Controls

This study has attempted to demonstrate the effectiveness of BMPs, and source controls in particular, in reducing pollutant loadings from gasoline fueling station runoff. It is clear from this study and others that it is not just gas station runoff, but runoff from any area where vehicles travel, park, or are serviced that is of concern. Unfortunately, this description includes most of the area in urban watersheds and much of the area in suburban watersheds. The success and the practicality of implementing all but the most restrictive source controls (e.g., product reformulations - unleaded gasoline) over such a large area is questionable. In addition, measuring the effectiveness of less restrictive source controls is complicated by the inherent variability in runoff data. As a result, regional treatment such as detention basins, which have been used successfully elsewhere, may warrant a closer look in California.

8.0 *Public Participation*

This section describes the public participation process for the project. One of the goals of the project is to disseminate the results to a wide audience. To effect this goal, three presentations were made as part of the Phase 1 effort. The first presentation was an open house hosted by Sacramento County, a second presentation was made to WSPA at the beginning of the project, and, near the end of Phase 1, a third presentation was made to the American Public Works Association (APWA) California Stormwater Quality Task Force, a consensus building group of about 100 representatives from regulatory agencies, municipalities, industry, construction, and consulting firms.

A final presentation was made after Phase 2, also to the APWA California Stormwater Quality Task Force. Members of the project team presented preliminary results from the analysis of the post-BMP data as part of a larger presentation on monitoring results from a number of projects statewide, including the WSPA study of gas stations and parking lots (WSPA, 1993).

Distributional Method to Determine Non-detect Values

R0058330

Distributional Method to Determine Non-detect Values

Example: Chromium concentration at station Z, December 10, 1992 and January 6, 1993.

1. Assign ranks to each of the results in ascending order of concentration, beginning with the two non-detected values. The first non-detected value was rank one and the greatest concentration (7.4 ug/L) was assigned a rank of 6.

2. Assign probabilities to each value in the data set using the Hazen (1930) method:

   $p_i = (i - 0.5 / n) * 100\%$

   where i is the rank of the given data point, p_i is the probability assigned to the ith data point, and n is the number of data points.

3. Create a probability plot with the percent probability along the x-axis and the concentration on a log scale along the y-axis.

4. Using the curve fitting function of Kaleidagraph™, generate an exponential curve that closely matches the actual data curve:

   concentration = $2.6757e^{0.69726z}$

   where z is the standard normal deviate, or Z-statistic, corresponding to the specific cumulative probability (in percent).

5. Use the equation just derived, calculate values for the same probabilities as the original data points. The points with 8.33% and 25.00% probability correspond to the on-detected values.

6. The calculated values for the non-detects were 1.02 ug/L and 1.67 ug/L. These values were higher than the analytical detection limit, indicating a data gap between the detected values and the non-detected values.

7. Replace the non-detected values with the detection limit. (1.0 ug/L) since the values calculated to replace the non-detected values were actually slightly greater than the detection limit.

EXECUTIVE SUMMARY

This document details the Drainage Area Management Plan (DAMP) to be implemented by the Cities and the County of Orange and the Orange County Flood Control District. Orange County's Drainage Area Management Plan was prepared in compliance with the specific requirements of NPDES Stormwater Permits No. CA 8000180 and No. CA 0108740.

This baseline DAMP is presented as the first step of a comprehensive planning process rather than the culmination. The plan will therefore undergo revision as new information, particularly water quality data, becomes available.

The County and many of the cities have already been performing practices and procedures which protect the quality of stormwater runoff, such as monitoring to identify problems, implementing construction site and agriculture erosion and sediment control programs, implementing a watershed sediment control program on San Diego Creek and Upper Newport Bay, sweeping streets, managing solid waste, initiating residential recycling programs, maintaining storm drains and catch basins, enforcing prohibitions on illegal discharges, controlling spills, supervising industrial waste discharges through permitting, and enforcing ordinances prohibiting certain discharges. Through this DAMP, the co-permittees intend to improve existing stormwater quality management practices and, where necessary, to address identified problems and to implement new practices.

This DAMP has been formulated with the following objectives in mind:

- Meet the requirements of NPDES stormwater permits CA 0108740 and CA 8000180;
- Insure effective public participation and support;
- Focus on problems identified through monitoring;
- Utilize available resources effectively;
- Implement public education BMPs early;
- Detect and eliminate illegal discharges;
- Evaluate opportunities for retrofitting existing structures;
- Verify Best Management Practices (BMPs) designs through experience; and
- Develop plans on a watershed basis.

Private and public sector representatives participated in developing the storm water pollutant control programs described within this DAMP. Throughout the DAMP's evolution, the document will be available for public review and comment. Overall program guidance will be provided by the NPDES Co-permittees.

VOL 12 2 5 1 1 1

1. 0 INTRODUCTION

This document outlines Orange County's Drainage Area Management Plan to be implemented by the cities of Anaheim, Brea, Buena Park, Costa Mesa, Cypress, Dana Point, Fountain Valley, Fullerton, Garden Grove, Huntington Beach, Irvine, Laguna Beach, Laguna Hills, Laguna Niguel, La Habra, Lake Forest, La Palma, Los Alamitos, Mission Viejo, Newport Beach, Orange, Placentia, San Clemente, San Juan Capistrano, Santa Ana, Seal Beach, Stanton, Tustin, Villa Park, Westminster, and Yorba Linda, the County of Orange; and the Orange County Flood Control District within the Orange County storm water drainage system. Newly incorporated cities and other agencies will be included in the implementation process if they choose to participate in the National Pollutant Discharge Elimination System (NPDES) storm water program.

The stormwater pollution control effort, of which this DAMP is a part, is the result of twenty years of legislative effort beginning with the 1972 Water Pollution Control Act, subsequently known as the Clean Water Act. The Clean Water Act established the NPDES and required the Environmental Protection Agency (EPA) to issue regulations to be effective by 1983, that include stormwater runoff from rainfall. The program was called the National Pollutant Discharge Elimination System (NPDES).

As a result of concerns that urban stormwater runoff can carry pollutants from diverse sources, Congress passed the Water Quality Act of 1987 which required EPA to bring stormwater discharges into the NPDES program. These regulations were issued on November 16, 1990.

1. 1 Objectives of the Drainage Area Management Plan

The immediate objective of this DAMP is to fulfill the commitment of the co-permittees to present a plan that satisfies NPDES requirements. In addition, however, there are a number of important public policy issues which have influenced the co-permittees in framing this plan and which consequently define the objectives of the DAMP. Resources, both public and private, are limited. Public support is essential. In implementing this program it is the intent of the co-permittees to proceed in a measured, deliberate way designed to obtain the maximum benefit for the resources expended and to secure maximum public awareness, understanding, and support.

The co-permittees intend to proceed with the public participation, education, and information program immediately to raise the level of public awareness and at the same time improve the protection of runoff water quality. It is therefore an objective to develop and implement a countywide program of educational BMPs as an early priority.

The co-permittees want a stormwater quality management program which focuses resources on water quality problems, wherever identified within the County. They also intend to have a priority system to assure that water quality problems receive the available resources and attention. It is therefore planned to analyze and evaluate the existing and future monitoring data to identify those

VOL 12 2 5 1 1 2

R0058405

watersheds exhibiting the most urgent need for attention.

The co-permittees are aware that a successful stormwater quality management program will depend on the awareness, commitment, cooperation, and support of the various segments of the public, including businesses, industry, development, utilities, environmental groups, institutions, homeowners, and the general public. Accordingly, it is an objective of this plan to assure an open planning process, with ample opportunity for public participation and meaningful consideration of the input obtained. Accomplishment of this objective will be furthered by the management structure provided herein and by public meetings, hearings, and workshops as part of the planning and decision-making process.

The co-permittees presently own and operate an extensive system of flood control, drainage, recreational, habitat, and greenbelt corridor facilities. Some of these have already been modified to yield regional water quality benefits while still safely and reliably performing their primary function. It is the intent of the co-permittees to evaluate opportunities to incorporate stormwater quality features into existing flood control structures in each Orange County watershed.

The co-permittees have considerable experience and expertise in the planning, design and operation of flood control and drainage systems. They are familiar with the regional watershed approach to drainage planning and they are aware of the economic benefit of regional flood control facilities. The co-permittees therefore intend to approach the runoff water quality management program on the same regional watershed basis, guided by the priorities identified through the monitoring program.

Research, technical, and engineering design data indicate that source term quantification and design parameters are still in a developmental phase. "This finding tends to support the need for local data before making what may be far-reaching and expensive water quality management decisions."[1] The co-permittees intend to investigate the relative cost-effectiveness of the various structural BMP designs through a program of experimental construction and observation.

It is an objective of the co-permittees to vigorously detect and eliminate illegal discharges into the storm drain system. The co-permittees are committed to the pursuit of equity in distributing the cost of implementating of this program.

Orange County's Drainage Area Management Plan was prepared in compliance with the specific requirements of NPDES Stormwater Permits (No. CA 8000180 and No. CA 0108740). The plan proposes a wide range of Best Management Practices (BMPs) and control techniques which will be implemented over the term of the current permits. For planning purposes, these Best Management Practices are organized into seven program components. The goals of these seven components are:

---

[1] Stormwater Detention for Drainage, Water Quality, and CSO Management, Peter Stahre & Ben Urbonas, Prentice-Hall, 1990

VOL 12 2 5 1 1 3

R0058406

1. Public Agency Activities (Section 5.0)

Improve existing city and county pollution prevention activities and implement appropriate new practices to further reduce the amount of pollutants entering the storm drain system. Municipal government activities include housekeeping practices such as hazardous materials management in maintenance yards/facilities and community services such as street-sweeping, facility maintenance, trash removal, waste-oil disposal, and spill response and enforcement activities.

Implement the steps described in this DAMP:

- Initiate educational BMPs throughout the County;
- Detect and eliminate illegal discharges;
- Conduct stormwater monitoring program;
- Priortize watersheds based on evaluation of monitoring data;
- Evaluate the possibility of modifying existing stormwater facilities and/or stormwater maintenance programs to reduce pollutants in stormwater discharges.
- Evaluate appropriate BMP candidates; and
- Implement proven cost-effective BMPs.

2. Public Education (Section 6.0)

Educate the public about the issue of nonpoint source pollution and the practices they can adopt that will assist in pollution prevention.

3. New Development Controls (Section 7.0)

Ensure that all new development incorporates appropriate postconstruction nonstructural and structural BMPs, and equitably participates in the implementation of watershed structural BMPs as described herein.

4. Construction Site Controls (Section 8.0)

Ensure that construction sites implement pollutant-control practices that address control of construction-related pollutants including erosion control and on-site hazardous materials management.

VOL 12 2 5114

R0058407

5. Industrial Discharger Identification (Section 9.0)

Develop identification records of industrial dischargers in Orange County.

6. Illicit Discharge/Connection Identification and Elimination (Section 10.0)

Identify and eliminate non-permitted discharges and illicit connections to the storm drain system.

7. Monitoring (Section 11.0)

Conduct water quality monitoring county-wide to identify areas with particular water-quality problems to assist in the prioritization of watersheds for analysis and planning, and to assist in the prioritization of pollutants to facilitate the development of specific controls to address these problems.

Each of the seven program components is an integral part of the Drainage Area Management Plan. The success of the overall program will therefore reflect the combined impact of all program components.

1.2 "Maximum Extent Practicable"

The federal regulations indicate that proposed management programs such as this DAMP "shall include a comprehensive planning process which involves public participation and where necessary intergovernmental coordination, to reduce the discharge of pollutants to the maximum extent practicable using management practices, control techniques and systems, design and engineering methods, and such other provisions which are appriopriate."

The Permit defines "maximum extent practicable" as follows: "Maximum extent practicable (MEP) means to the maximum extent possible, taking into account equitable considerations of synergistic, additive, and competing factors, including but not limited to, gravity of the problem, fiscal feasiblity, public health risks, societal concern, and social benefits." Its presence places upon the co-permittees the responsibility of weighing economic, societal, and equity issues as they define the policies and standards to be employed in implementing the program.

1.3 Description of Drainage Area and Climate

Orange County has an area of 500,000 acres, beginning on a coastal plain and rising to an elevation of over 5,000 feet in the Puente Hills and Santa Ana Mountains to the north and east. Before urbanization which began in the early 1950's, Orange County was drained by ephemeral streams and agricultural drainage ditches which were dry most of the year and carried measurable flow primarily during short duration flash floods and longer duration general winter storms.

As urbanization progressed, man-made agricultural drainage ditches were enlarged to flood

VOL 12 2 5 1 1 5

R0058408

control channels and the few natural streams such as Santa Ana River and San Juan Creek were constrained within levees to provide flood protection. Ephemeral flows in some of the man-made and natural channels have been replaced with continuous low flows from urban and agricultural irrigation.

Orange County's climate has hot dry summers and mild winters. Nearly all the annual precipitation falls in only a few storm events between November and May. During times of drought, it is not unusual for years to pass between major rainfalls. Precipitation results from three distinct mechanisms. The most important is the convergence mechanism associated with general winter storms originating in Alaska and picking up moisture as they travel south and east. The second major precipitation mechanism is orographic lifting where moist air masses are deflected upward by local mountains, releasing rain. Orographic rainfall is also associated with winter rainfall. The third precipitation mechanism, which can cause extremely intense local precipitation, is the convective thunderstorm. One of the most intense convective rainfall events of record in Southern California dropped 11 inches of rainfall in about 80 minutes. On occasion, unstable tropical air masses move in from the south and produce rainfall. These tropical air masses combine convergence mechanisms with convective mechanisms to produce intense thunderstorms.

It is common for successive storms of varying durations and intensities to compound their effects, with the heavy rainfall of the second or third storm creating the most severe flood conditions. Regardless of the source of precipitation, rainfall in Orange County is a rare event. The present urban and former agricultural lifestyles are made possible only by large quantities of water imported from the Colorado River and Northern California.

1. 4 Implementation of the Drainage Area Management Plan

The Co-permittees will gather information from the monitoring program and other sources to identify the source of pollutants for each identified problem. The purpose of this effort is to assist in the investigation and development of funding souces which equitably assess existing communities and areas of new development in proportion to their relative contribution to the problem. Such a policy is essential to the establishment and maintenance of a broad base of community support for the program.

Since existing developed areas are on the tax rolls, any implementation program for financing improvements and activities assessable to developed areas will consider allocating a portion of the ad valorem tax revenue and other municipal and County revenues for program support. Should program requirements exceed available revenues from these sources the co-permittees will investigate other funding mechanisms.

BMPs will be required for both existing developed areas and areas of new development. The co-permittees will consider such options and will conduct public discussions to hear the views of various members of the community. There is ample precedent for the determination of a particular development's share of public plan facilities, such as sewer capacity, roads, and parks. These

VOL 12 2 5116

R0058409

precedents will be considered by the TAC in its development of the appropriate mechanism for implementing the program on a fair share basis in areas of new development.

The non-topographic boundary between Orange and adjoining Counties could result in certain co-permittees to the Stormwater Permit Implementation Agreement being subjected to flows originating from areas that are subject to NPDES municipal stormwater permits issued by Regional Water Quality Control Boards not a part of this DAMP. This DAMP is applicable only to stormwater permits issued by the San Diego and Santa Ana Regional Water Quality Control Boards, although Section 2.2.8 of DAMP acknowledges the fact that certain co-permittees could be impacted adversely by flows from drainage areas outside the two stormwater permit areas of the San Diego and Santa Ana Regions.

VOL 12 2 5117

R0058410

2.0 PROGRAM MANAGEMENT

2.1 Introduction

The management activities for the municipal stormwater program include providing administrative and technical support for the NPDES Co-permittees and their Technical Advisory Committee (TAC); developing and executing inter-governmental agreements necessary for program implementation,developing reports and other materials required by NPDES permits; developing budgets and fiscal analyses; reviewing and developing policy positions and representing the Program before appropriate agencies; developing Best Management Practices (BMPs); planning activities needed to direct the program; and program coordination with all affected local government agencies.

A more detailed discussion of these management tasks is provided below.

2.2 Major Management Activities

2.2.1 Decision Making

As noted in the Executive Summary, overall program guidance (including votes where necessary) will be provided by the NPDES Co-permittees.

The advisory group for program development and implementation is the NPDES Technical Advisory Committee (TAC). The TAC comprises one City Engineer, or selected representative, from each of the County Supervisorial Districts and a representative from the County of Orange Environmental Management Agency.

Administrative support for this committee includes maintenance of mailing lists of participating and interested parties, reserving meeting venues, preparing agendas and notifying participants, that public noticing required by law, and preparation of minutes.

The County has established a Stormwater Section to coordinate countywide compliance activities and submittals to the Regional Water Quality Control Boards under policy direction of the Co-permittees.

2.2.2 Agreement for Program Implementation

The agreement (see Appendices C and D) underpinning County and city cooperation is the NPDES Storm Water Permit Implementation Agreement which establishes the responsibilities of each party (County, Flood Control District, and cities) with respect to compliance with the NPDES Storm Water Permits issued by the Regional Water Quality Control Boards (RWQCBs). This Agreement also establishes a funding mechanism for the shared costs of the Program based on each municipality's area and resident population.

VOL 12 2 5 1 1 8

R0058411

Specific program responsibilities are as follows:

The CITIES shall, to the maximum extent practicable:

- Implement a facility inspection program in accordance with the uniform criteria developed by the DISTRICT and recommended by the Co-permittees, for all municipal separate storm sewers as defined by the stormwater permit and within the jurisdictional boundaries of that city.
- Submit storm drain maps to the COUNTY.
- Prepare watershed characterizations, including:

  a. Zoning designations and

  b. Identification of areas where hazardous materials are stored, manufactured or disposed of.
- Review approve, and implement system-wide BMP's.
- Eliminate or have eliminated, illegal/illicit connections to the storm drain system.
- Identify the legal authority for control of discharges to the storm drain system.
- Provide the COUNTY with annual reports and any other information needed to satisfy NPDES permit reporting requirements.
- Evaluate existing water pollution control ordinances, which prohibit non NPDES permitted discharges to the municipal separate storm sewer system. If legal counsel determines that new or amended ordinances are needed, submit these in acccordance with each co-permitee's procedures.

The COUNTY and the DISTRICT shall be responsible for:

- Functioning as the principal permittees responsible for overall program management.
- Preparing implementation and annual operating budgets.
- Preparing compliance reports to the Regional Water Quality Control Boards (RWQCBs).
- Preparing a draft system-wide BMP Program Report.

VOL 12 2 5 1 1 9

R0058412

- o Monitoring the implementation of system-wide BMP's, to evaluate structural and procedural BMP's and preparation of an annual report detailing results for presentation to the RWQCB.

- o Performing the water quality and hydrographic monitoring for permit compliance.

- o Administering the water pollution control program.

- o Developing uniform criteria for annual inspection of drainage facilities.

In addition, the COUNTY will also undertake, in the unincorporated areas, all the activities required of the cities.

The DISTRICT will also perform inspections, at no cost to the cities or the county, on those facilities owned by the District and on municipal separate storm sewers in unincorporated County. Contracts for such inspections within the cities may be undertaken at the sole expense of the requesting city (See Appendix C and Appendix D).

2. 2. 3 NPDES Permit Reporting Requirements

The following reports will be produced under the auspices of the NPDES Technical Advisory Committee and submitted to the Boards. The report submittal dates are the dates that the compliance reports are due at the Boards.

TABLE 1

NPDES PERMIT PROGRESS REPORT SCHEDULE
PROGRAM REPORT SUBMITTAL

Water Quality Monitoring	Annually 11/30
Reconnaissance Survey	Annually 1/31
Drainage Area Management Plan Status	Annually 8/31
Fiscal Analysis	Annually 8/31
Data Analysis	Annually 1/31
Program Analysis	Annually 3/31

2.2.4 DAMP Implementation And reporting Schedule

The reports and tasks required by this DAMP are listed in Appendix A (See Appendix B for Co-Permittee Implementation Plan).

VOL 12 2 5120

R0058413

2.2.5 Budget

The County will be responsible for preparing draft annual budgets for shared program costs, to be approved by the Co-permittees. In addition, the County will track shared program cost expenditures and prepare financial reports which will be distributed to all the co-permittees.

2.2.6 Program Representation

The County is a member of the State Water Resources Control Board Storm Water Quality Task Force which assists the SWRCB in developing the NPDES Storm Water Permit Program. The County will continue participating in the Task Force and will report activities to the co-permittees on a regular basis.

2.2.7 Planning

In accordance with the Implementation Agreement the County will administer and coordinate Program Planning and Development.

2.2.8 Co-Permittees having Watershed Boundaries Outside Those Covered By Sanat Ana And San Diego region NPDES Permits

Those co-permittees in compliance with a stormwater permit issued by either the Santa Ana or San Diego Regional Water Quality Control Boards shall be deemed in compliance with this DAMP even though portions of their drainage boundaries extend to other Regional Water Quality Control Board jurisdictions.

VOL 12 2 5121

R0058414

3.0 PLAN DEVELOPMENT

3.1 Regulatory Requirements

Section 101-Declaration of Goals and Policy-of the Clean Water Act, as amended by the Water Quality Act of 1987 states:

"It is the national policy that programs for the control of nonpoint source pollution be developed and implemented in an expeditious manner so as to enable the goals of this Act to be met through the control of both point and nonpoint sources of pollution."

EPA regulations require that storm water quality management plans include programs that address four types of pollutant sources (1) Runoff from commercial and residential areas; (2) Runoff from industrial sites; (3) Runoff from construction sites; and (4) Non-storm water discharges.

According to the regulations, an overall drainage area management program shall include a comprehensive planning process incorporating public participation and intergovernmental cooperation. The drainage area management program shall also meet the "Maximum Extent Practicable" (MEP) standard of pollutant control. The proposed program shall also describe priorities for implementing controls on a system wide basis, a watershed basis, a jurisdiction basis, or on individual outfalls.

The regulations also identify specific elements for addressing runoff from commercial and residential areas. These elements are:

- A program for maintenance activities for structural controls.
- Planning procedures to assess stormwater quality and to implement appropriate controls to reduce pollutant discharges from areas of new development and significant redevelopment.
- Planning procedures to assess flood water management project impacts on the water quality of receiving water bodies.
- A program to evaluate the possibility of modifying existing stormwater facilities and/or stormwater maintenance programs to reduce pollutants in stormwater discharges.
- A program to monitor runoff from municipal waste treatment, storage, and disposal facilities.
- A program to monitor municipal storm drain water quality.

VOL 12 2 5122

R0058415

- o A program to reduce pollution associated with the application of pesticides and fertilizer

The NPDES permits require development and implementation of best management practices to control the discharge of pollutants to waters of the United States. The vehicle for this BMP implementation is the Drainage Area Management Plan (DAMP) which shall include modifications to existing BMPs and other storm water system management programs to reduce pollutants in the storm water discharges from industrial, commercial, and residential areas to the maximum extent practicable. Specific requirements are:

- o Structural controls.
- o Nonstructural controls such as education programs, management practices, and regulatory approaches.
- o Enforcement programs.

In addition, an implementation plan is required in the DAMP for site specific structural and non-structural BMPs at construction sites (Commercial/Industrial construction sites disturbing one acre or more of total land area and residential construction sites disturbing 5 acres or more). An implementation plan is also required to assure that runoff from all new development or significant re-development is appropriately managed to the maximum extent practicable. NOTE: Both plans were completed early in 1993.

3.2 Plan Development

3.2.1 Approach To Plan Development

This DAMP has been developed to accomplish the objectives summarized in the Executive Summary and in Section 1.1.

The DAMP elements fall in to two general categories: prevention of pollutant introduction into the drainage system and removal of pollutants from the drainage system. The prevention-oriented elements include identification and elimination of illegal discharges, continued supervision of permitted industrial discharges, the early implementation of non-structural BMPs throughout the County in new developments and existing communities, and the continued use of structural and non-structural on-site BMPs for construction projects.

The removal-oriented element is a watershed planning program for structural BMPs. Water quality problems will be identified through the monitoring program. Watersheds will be considered using the principles of MEP. Watersheds determined to require additional BMPs will be surveyed for potential retrofitting. Existing flood control, retarding, sediment control, water conservation, recreation, habitat, and greenbelt facilities

VOL 12 2 5123

R0058416

will be evaluated in terms of their potential for modification to provide water quality benefits. Where retrofitting opportunities are not found, new structural BMPs will be considered, using the principles of MEP.

New structural BMPs will be selected from candidate BMPs which have been field-tested and evaluated as to their pollutant removal efficiency and cost effectiveness. New structural BMPs will be planned and located to maximize their cost-effectiveness.

Structural BMP program costs will be distributed among existing developed communities and newly developing areas in proportion to their responsibility for the recognized water quality problem, as far as possible. This is not intended to preclude the use of structural BMP's within new developments to address problems identified in the watershed planning process.

3.2.2 BMP Selection

Candidate non point source (NPS) control measures will be selected from review of technical literature, review of existing NPS control programs, and input from consulting firms and municipalities already involved in NPS control program implementation.

A summary of existing BMPs within Orange County is presented in Table 2. Collectively these existing BMPs provide a significant level of control for the target NPS pollutants identified in the federal regulations and the Region 9 NPDES permit. Furthermore, these existing BMPs include the permit-required structural and non-structural controls and function as pollutant controls in industrial, commercial and residential areas. The DAMP focuses on improving these BMPs and setting out a timetable for countywide implementation (see Section 5.0). The DAMP also considers new residential and commercial/industrial sites (Section 7.0) and construction sites (Section 8.0). Recognizing the need for a coordinated effort to insure the successful implementation of structural controls for storm water quality management, Sections 7.0 and 8.0 have provided for BMP development under the guidance of steering groups that included both public and private sector representation.

3.2.3 Plan revision

The NPDES Technical Advisory Committee will review, and submit to the Co-permittees for local approval, the DAMP and amendments to the DAMP. The documents will then be submitted to the Regional Water Quality Control Boards.

3.2.4 Public Participation

Public participation in the preparation and amendment of the DAMP will be encouraged in accordance with the NPDES Stormwater Permits.

VOL 12 2 5124

R0058417

3.3 Financing

3.3.1 Watershed Structural BMPs

Financial requirements for construction, operation and maintenance of watershed structural BMPs will be studied. Appropriate financing programs will be proposed, including consideration of means to assure appropriate participation by land developers and project proponents.

3.3.2 Operation And Maintenance

Those structural BMPs which are retrofitted onto existing structures will continue to be operated and maintained by the present owners. The planning process will include consideration and determination of maintenance responsibility for each new structure. A funding source for the operation and maintenance will be developed by the TAC with the support and discussion of the Co-permittees.

92-52

NOV 12

4.0 EXISTING LEGAL AUTHORITY

4.1 Introduction

The NPDES Storm Water Permits require implementation of a program to reduce pollutants in storm water discharges from commercial, industrial, and residential areas to the "maximum extent practicable." Central to this program is the establishment, by each municipality, of adequate legal authority to regulate the discharge of pollutants to the municipal separatestorm sewer.

4.2 Regulatory Requirements

Section 402(p) of the Federal Water Pollution Control Act, as amended by the Water Quality Act of 1987, requires that municipal NPDES Storm Water Permit include:

1. A requirement to effectively prohibit non-storm water discharges into the storm sewer.

2. Controls to reduce the discharge of pollutants to the maximum extent practicable, including management practices, control techniques and system, design and engineering methods and such other provisions as the Administrator or the State determines appropriate for the control of such pollutants.

Regulations, promulgated by EPA on November 16, 1990 (40 CFR 122.26 (d)(2)) require municipal NPDES Storm Water Permit applicants to demonstrate that they have adequate legal authority.

4.3 Authority To Control Pollutant Discharge

The County of Orange obtains its authority to control pollutants in storm water discharges, to prohibit illegal discharges, to control spills, and carry out flood control facility inspections from the Orange County Flood Control Act and the County's Water Pollution Ordinance.

The Orange County Water Pollution Ordinance regulates discharges associated with industrial activity by prohibiting the dumping or discharge of "industrial waste" by any individual in a manner that "will or may cause or result in the pollution of any underground or surface waters..." The ordinance also establishes the requirement for an industry to obtain a permit from the County if it intends to discharge. A permit may be issued if it is found that discharges will not result in pollution of ground or surface waters if it is found necessary to dispose of wastes in such a manner.

The County has the authority to enforce and to administer the provisions contained in the ordinance, including the authority to inspect any violation. The County also has the right to revoke a permit if it sees fit. Of the County's twenty-nine constituent cities, eighteen have adopted a similar or share the same water pollution ordinance.

VOL 12 2 5127

R0058420

In addition to the Water Pollution Ordinance, the Orange County Code establishes its authority to regulate various discharges in other ordinances.

- The County Solid Waste Management Ordinance (or comparable City ordinances) regulates where solid and liquid wastes, including hazardous and industrial wastes may and may not be deposited or discharged.
- The Harbor Sanitation Ordinance prohibits discharge of any refuse matter of any description from shore or sea into the "navigable waters of a harbor."
- The Uniform Fire Code prohibits the discharge of any waste liquid containing crude petroleum or its products "into or upon" any drainage canal or ditch, storm drain, sewer, ... or upon the ground."

4.4 Summary

Under existing codes, Orange County and twenty of the thirty-one cities have adequate legal authority to regulate (control, inspect, and enforce) discharges of pollutants to the municipal storm drains. The County's Water Pollution Ordinance, in particular, establishes authority of the County of Orange to inspect any violations. It is however intended that a Model Ordinance be developed to bring regulatory language "up to date".

4.5 Recommendations

Prepare a study for review and consideration by the NPDES TAC and Co-permittees which:

- Details existing legal authority of each co-permittee.
- Drafts amendments to existing regulations, if necessary, to adequately regulate and control pollutants in stormwater discharges as required by NPDES regulations.

After review and consideration of existing legal authority, the TAC will make recommendations to Co-permittees regarding necessary actions they must take to comply with NPDES regulations.

A committment has been made to retaining consultant services geared to developing a new Model Ordinance for water quality protection, which will be presented to all municipal Co-permittees for consideration as to adoption. The Water Pollution Enforcement Implementation Plan (See Appendix E) also provides considerably more detail on the possible scope of revised regulatory authority as an Appendix to this Drainage Area Management Plan.

4.6 Implementation Schedule

- Select consultant to complete study by July 1, 1992.

VOL 12 2 5128

R0058421

- Submit Water Pollution Enforcement Implementation Plan by October 1, 1992.
- TAC recommendations to Co-permittees by July 1993.

VOL 12 2 5129

R0058422

5.0 PUBLIC AGENCY ACTIVITIES

5.1 Introduction

All of the municipal NPDES Storm Water Permit co-permittees routinely conduct preventive maintenance activities that are widely recognized as effective Best Management Practices for nonpoint source pollutant control. These activities are detailed in Table 2 and include street sweeping, litter control, and catchbasin/drainage facility maintenance. One objective of this component of the Drainage Area Management Plan is to evaluate these existing public agency activities and, where necessary, implement improvements or new practices to reduce the amount of pollutants entering the storm drain system to the maximum extent practicable within financial and staffing constraints.

Initially this evaluation will require documentation of selected maintenance activities by the co-permittees. Data generated by this documentation process will be analyzed by County staff as lead agency for the program. Where differences in water quality can be directly attributed to the presence, absence, particular methodology, or frequency of a maintenance activity, the most effective strategy will be used as the basis for specific activity guidelines which will be developed by the County for consideration by the co-permittees. In addition, the County will undertake a number of site specific investigations to generate additional data for the purposes of evaluating an activity (e.g. Sec. 5.2.5).

Other objectives are set forth in Section 1 including implementing the steps described herein leading to development and implementation of priority watershed plans, and operating and maintaining the watershed plan structures.

5.2 Existing Municipal Government Activities

5.2.1. Litter Control

Litter control is an important element in the diversion of trash and other materials from the storm drain system.

1. Recommendations

   - o Evaluate the need for litter control regulation amongst co-permittees and propose draft ordinance or changes to existing ordinances if necessary (to be performed by the County as part of the legal authority review).

2. Schedule

   - o Report existing litter control regulations and describe existing municipal litter control programs by July 31, 1993.

VOL 12 2 5130

R0058423

5.2.2 Recycling

Community programs for collection and recycling of non-hazardous solid wastes have already been initiated statewide in response to the California Integrated Waste Management Act of 1989.

Municipal programs to collect recyclable materials are currently conducted in twenty-seven of Orange County's twenty-nine cities. In addition, collection centers, as required by California Law, are operated countywide in public places such as shopping centers so that recyclables can be deposited on a daily basis.

No improvements to these programs are proposed as part of the Drainage Area Management Plan. A reporting procedure will be implemented so that the volume of potential pollutants diverted from the storm drain system can be recorded. The specific information to be recorded, will be in accordance with the existing requirements of AB 939.

1. Recommendations

   - o Identify constituent materials (Article 2, Section 41030).
     - Volume
     - % by weight or volume
     - Material type
     - Source of generation (residential, commercial, industrial etc.)
   - o Describe methods used to determine the amount and categories of solid wastes (Article 4, Section 41071).

2. Schedule

   - o Submit a copy of the information required for AB939 (and a brief description of the programs). Include any public education fliers. Submit this information by July 31, 1993 and every year thereafter for use in the annual Progress Reports.

5.2.3 Drainage Facility Maintenance

All of the Orange County co-permittees clean out the storm drain inlets, catchbasins, and lines within their jurisdictions. Generally this work is performed on an as-needed basis.

1. Recommendations

VOL 12 2 5 1 3 1

R0058424

- o Inspect facilities regularly to determine if service is required.

  - Open Channels: Inspect annually* before storm season, remove debris as necessary.
  - Underground facilities 39" and larger diameter: Inspect every two years*.
  - All facilities: Remove debris and sediment either manually or by mechanical methods, use flushing in emergency situations only.

  * Inspection frequencies will be re-evaluated after one complete system inspection.

- o Special catch basins and other storm drain inlets.

  - Refer to Section 5.2.4.

2. Schedule

- o Co-permittees are to provide sample copies of inspection and maintenance logs. Submit by July 1, 1992. Logs are to include a description of the total volume of material, and estimates of the percentage of paper, plastic material, vegetation, soil and "other" materials.

- o Submit data tables that document the number of catchbasins and drains and length of channel/pipe cleaned per year by July 31, 1993 and every year thereafter for the annual Program Report.

- o Provide specific information on any facility where evidence of chemical contaminants are found. Include the nature and extent of the contaminants, and the location.

5.2.4 Catch Basin Stenciling

The goal of the stenciling program is to label and subsequently maintain labels on stormdrain inlets throughout Orange County. Initially the label will comprise NO DUMPING - DRAINS TO OCEAN written in 3" black letters on either the top of the curb or the curb face adjacent to the inlet. Each co-permittee, however, may implement its own variation of this catchbasin stenciling program.

1. Establish stenciling program and complete by 1995.

2. Schedule

VOL 12 2 5132

R0058425

- Complete catchbasin stenciling by the end of the permit in 1995. Submit number of catchbasins stenciled to date on July 31, 1993 and every year thereafter for the annual progress reports.

5.2.5 Street Sweeping

Currently, all the Orange County co-permittees maintain street-cleaning programs which sweep residential, commercial and industrial areas at least once a month. Most sweep on a weekly basis using rotating brush sweepers.

A method for evaluating the effectiveness of street sweeping county-wide is not currently available. It is recommended that such a procedure be developed.

1. Recommendations

- Obtain the schedule of all street sweeping operations.
- Consider vacuum sweepers when purchasing new equipment because they are more efficient at fine particle removal and can additionally be used for leaf collection and catch basin maintenance.
- Review, implement and enforce parking controls to coincide with sweeper schedule.
- Develop a system for spot testing the amount of loose debris on street surface, and the heavy metal content, as a function of time between sweepings (County as lead agency).

2. Schedule

- Submit the street sweeping schedule by July 31, 1993
- Submit sample copies of any log sheets used for internal documentation of the program.
- Develop and perform feasibility testing on a system for collecting and testing loose debris on street surfaces, and report results by July 31, 1993, for incorporation into the annual Program Report.

5.2.6 Hazardous Materials Management

The activities at various City and County facilities involve the use of hazardous materials and the generation of hazardous wastes. These materials include paints, solvents,

VOL 12 2 5133

R0058426

pesticides, fertilizers and motor oil As a matter of policy, used motor oil and motor oil filters will be recycled or managed as hazardous waste.

All municipalities will review and where appropriate implement improvements to hazardous materials management practices. These practices may be structural, such as covering storage/transfer areas and construction of secondary containment structures, and non-structural such as improved inspection procedures.

1. Schedule

   - o Prepare a list of improvements made to public facility hazardous material storage sites (defined as sites at which there are hazardous materials stored in quantities greater than or equal to 55 gallons, 500 lbs., or 200 cu. ft.) to reduce potential discharge of pollutants to the stormdrain. Submit updated list by July 31, 1993 and every year thereafter for the annual Progress Reports.

5.2.7 Household Hazardous Waste Collection

Orange County has an effective household hazardous waste collection program administered by the Integrated Waste Management Department. Refer to Section 6.3.2 for a detailed description of this program.

1. Recommendation

   - o Provide data to demonstrate the effectiveness of the program.

2. Schedule

   - o Provide, by July 31, 1993, and every year thereafter, a summary of information on toxic roundups and materials collected, plus data generated by the Integrated Waste Management Program.

5.2.8 Emergency Spill Response

The Orange County Hazardous Materials Area Plan has been adopted by nineteen County municipalities. For these, planned responses to a hazardous materials emergency specify the:

1) Incident command during the post emergency period of hazardous materials releases into the county flood control system, spills in public facilities and releases into county tidelands and harbors.

VOL 12 2 5134

R0058427

2) Participation in unified command during the emergency and post emergency period for incidents which threaten surface or groundwaters and releases in public facilities.

3) Direction and monitoring of clean-up activities where municipal jurisdiction and public facilities are involved.

The non-participating municipalities can be expected to develop one or more of their own programs, along similar lines. The Water Pollution Enforcement Plan, also prepared in permit compliance, will specify a schedule for city adoption of a revised ordinance, with criteria for an independent city spill response program, including clear assignment of support function responsibilities.

1. Schedule

- o Identify spill response staff and resources (physical and financial) for each Co-permittee by April, 1993
- o Undertake staff training by June, 1993.
- o Program implementation - June, 1993.

5.2.9 Fertilizer Management

Fertilizer management is the most effective means of controlling nutrient loss from landscaped areas. The development of a proper fertilizer management program (See Appendix F) is thus an important element of the Drainage Area Management Plan. Specific recommendations focus on the implementation of guidelines for public agency activities.

1. Recommendations

- o Establish guidelines for fertilizer application and landscape maintenance.

  - Specify the appropriate type and amount of fertilizer by using soil testing or other techniques.
  - Apply only what is needed or appropriate for the type of plants being grown.
  - To minimize surface runoff incorporate fertilizer into the soil and do not overwater after application
  - Use compost, peat, or mulch where applicable to increases soil porosity and thus water retention
  - Immediately clean up any fertilizer spilled on roads or sidewalks

VOL 12 2 5135

R0058428

- To measure program effectiveness monitor usage rates by chemical category, and presence of fertilizer residues in Receiving Waters.

2. Schedule

- Submit by July 31, 1992 Fertilizer Management Guidelines which would include application frequencies, types of fertilizer used, and concentration per unit area and location of sites where fertilizer is applied (See Appendix F).

- Report by July 31, 1993 and every year thereafter, the amounts of fertilizer used each year, by chemical category.

5.2.10 Pesticide Management

A Pesticide Management Plan will be developed. This plan will address both acute toxicity concerns and chronic exposure concerns associated with all insecticides, rodenticides and herbicides.

1. Acute toxicity problems normally occur when concentrated pesticides are being improperly stored, transported or mixed. Specific management procedures that address acute toxicity concerns are:

- Secure pesticides and application equipment to prevent tipping or excess jarring. Carry these materials in a part of the vehicle totally isolated from people, food and clothing during transportation.

- Bring to the work site only the amount of pesticide needed for the days use.

- Inspect daily for leaks, equipment used to store, transport, mix, or apply pesticides.

- Do accident pre-planning. In the unlikely event of a spill, take the following immediate actions:

  - Stop the spill
  - Warn others
  - Isolate the area
  - Minimize your own and others' risk
  - Contact the designated city/county department for further management and disposal

VOL 12 2 5136

R0058429

2. Consideration of long term chronic toxicity requires much broader program evaluation. OCEMA Public Works Operations, for example, uses new equipment and careful scheduling to maximize the Pacific Flyover habitat value of the Santa Ana River. The framework for that evaluation is detailed below and will be applied in this DAMP:

- o Maintain a list of pesticides and their specific uses. This information should already be documented through Hazardous Material Disclosure Requirements.

- o Establish proper application methods and procedures.

  - Always follow label instructions.
  - Note hazards related to the physical form of pesticide (dust, granular, spray).
  - Apply pesticides in the quantities and frequencies recommended.
  - Maintain application equipment.
  - Consider factors that may influence the type and amount of pesticide used, such as weather/soil conditions, area drainage patterns, and non-target organisms.

- o Establish controls to prevent surface and groundwater contamination.

  - Use only what is needed to prevent excess runoff.
  - Equipment and containers should be cleaned only in areas registered for use of pesticide and where accidental spills will not pollute water resources or contaminate the soil. Water used for cleaning equipment and triple-rinsing pesticide containers should be collected and used to dilute the next pesticide mixture. Triple-rinsed containers can be disposed of as trash.

- o Establish storage and disposal procedures.

- o Evaluate less toxic alternatives to pesticides (eliminate carcinogens, teratogens).

- o Consider whether broad spectrum or single specific use materials might be more appropriate in a given situation.

- o Consider pesticides that degrade more quickly, bind more strongly to soil particles, and have low water solubility.

- o Pesticide use must be supervised or performed by an individual with a California Pesticide Applicators Certificate.

- o A pest control advisor must provide a signed recommendation to an applicator describing the proper methods (e.g., - application rate) for using a specific pesticide or herbicide.

VOL 12 2 5137

R0058430

- Each co-permittee should review State (CCR Title 26) and Federal (40 CFR 162-180) pesticide storage and labeling requirements.

3. Schedule

- Submit a model Pesticide Management Plan incorporating the BMPs by July 31, 1992.

- Report progress on plan implementation by July 31, 1993 and every year thereafter.

VOL 12 2 5138

R0058431

6.0 PUBLIC INFORMATION

6.1 Introduction

Public education is an essential part of a BMP program Developing programs to inform and involve the public can be an effective method for controlling nonpoint source pollution. When a community has a clear idea where the pollution comes from, how it can affect them and what they can do to prevent those affects, it will be more willing to support and participate in program implementation.

6.2 Regulatory Requirements

The federal regulations specifically require, as part of the drainage area management plan, a description of educational activities, public information activities, and other appropriate activities to facilitate the proper management and disposal of used oil and toxic materials (Federal Register/Vol. 55, No. 222, p. 48071).

In addition, the regulations also specify education programs for construction site operators and a program to facilitate public reporting of illicit discharges.

The NPDES permits similarly follow federal requirements and specify as a component of the Drainage Area Management Plan education programs to educate the public on proper disposal of hazardous/toxic wastes. These may include public workshops, meetings notifications by mail, collection programs for household hazardous wastes.

6.3 Public Information And Education

The primary goal of the public education programs is to inform the community about the origins and causes of nonpoint source pollution and to constructively involve the public, municipalities, businesses, industries and development community in the Storm Water Program's objective of controlling nonpoint source pollution at its source. Achievement of this goal will require development of materials to explain the nature of nonpoint source pollution and its significant contribution to water quality impairment and to identify and promote behavioral changes that will contribute to controlling pollutants at the source.

In addition, the program will coordinate activities with other agencies running public information programs such as water districts, sanitation districts, fire departments and community and environmental groups.

6.3.1 Nonpoint Source Pollution Awareness

Raising public awareness of nonpoint source pollution and Orange County's stormwater program will entail development of informational materials aimed at local officials, public

VOL 12 2 5139

R0058432

agency personnel and the general public.

The County of Orange will coordinate a County-wide public awareness program for the benefit of all co-permittees. This will be a regional public outreach program addressing storm water quality problems and solutions applicable to all co-permittees. Individual co-permittees, at their option and expense, may choose to enhance the regional information to address specific storm water quality problems.

The County-wide public awareness program will include placing storm water quality articles in EMA's existing Flood Awareness program newsletters, preparing and distributing a stormwater pollution brochure and poster; and incorporating a storm water pollution features into EMA's County fair booth, community fair booths, and speaking engagements.

Regional public information materials will be distributed to each of the co-permittees who will in turn make the materials available at the Orange County, community and industrial fairs, disaster preparedness fairs, community facilities, and public libraries.

6.3.2 Household Hazardous Waste Collection

Orange County has an active and effective household hazardous waste collection program. This program is administered by the Orange County Integrated Waste Management Department. The goals of the program are to educate residents about household hazardous materials, influence buying habits to decrease the amount of hazardous materials used, and offer a safe and proper method to dispose of hazardous materials.

The program consists of four fixed collection sites and a Community Awareness Program (CAP). The CAP has made numerous public presentations, by staff and trained volunteers, to schools, civic organizations, and private industries. A "Healthy Home" video and a 24-hour hotline are used to promote program awareness.

In addition, many public information strategies are used to inform the public of the availability of household hazardous materials collection centers. These strategies include fact sheets in utility bills, radio and television public service announcements, and newspaper advertisements.

The existing household hazardous materials program fulfills NPDES requirements.

VOL 12 2 5140

R0058433

7.0 NEW DEVELOPMENT

7.1 Regulatory Requirements

The federal regulations specify that drainage area management programs include "a description of planning procedures including a comprehensive master plan to develop, implement, and enforce controls to reduce the discharge of pollutants from areas of new development and significant redevelopment."

The RWQCBs have indicated that the need for individual storm water quality management plans applies equally to private and public works projects. Transportation corridors, schools, parks, flood control projects and other public facilities will thus be subject to the same requirements as planned communities and mini-malls.

The California Government Code prevents city/county regulation of other public entities such as school, sanitation, and water districts. The NDPES permits, however, identify these entities as potential dischargers of storm water to the Orange County drainage area and the expectation is that these entities will work cooperatively with the co-permittees to manage urban Storm Water runoff. These entities include: Caltrans, Universities and Colleges, Metropolitan Water District, Department of Defense, School Districts, Sanitation Districts, Water Districts, and Railroads.

7.2 Program Development

The program will be developed using the principle of Maximum Extent Practicable, and the following application of BMPs.

Each new development will be required to implement appropriate non-structural BMPs in keeping with the size and type of development, to minimize the introduction of pollutants into the drainage system.

Each new development will also be required to implement appropriate "routine" structural BMPs in keeping with the size and type of development. "Routine" structural BMPs are economical, practicable, small scale-measures which can be feasibly applied at the smallest unit of development. Routine structural BMPs may function either to minimize the introduction of pollutants into the drainage system or to remove pollutants from the drainage system. Routine structural BMPs are intended to address drainage water quality impacts inherent in development, and need not be related to any identified water quality problem.

"Special" structural BMPs will be installed in new development to address specific water quality problems identified in the watershed planning process. This requirement may be addressed by providing an on-site "special" structural BMP, or by contributing to the implementation of a structural BMP specified in the watershed plan. "Special" structural

VOL 12 2 5141

R0058434

BMPs are engineered facilities designed to address specific pollutant problems identified in the watershed planning process, runoff management plan, CEQA process, or similar watershed planning. However, it is not the intent of this program to restrict city or county planning commissions or their governing bodies from imposing additional stormwater management requirements as a condition of development.

Compliance with these requirements necessitated development of a program to ensure that storm water quality management is considered during a project's planning phase, implemented during construction, and ultimately maintained for the life of the project. In addition, the program must be adopted and uniformly enforced by all municipalities.

As described in Section 1.0, this DAMP is comprised of preventive and corrective (removal) measures. Applying this concept to new development, it is intended that each new development will implement an approved program of BMPs to minimize the amount of pollution entering the drainage system. The New Development Task Force has developed guidelines for approval and use by Co-permittees and developers. These guidelines include conditions of approval, ongoing land use conditions, covenants, and restrictions, and user education and information.

7.3 Program Planning

The requirement for a post construction storm water quality management plan will be specified in each co-permittee's standard conditions of approval. These conditions will require project proponents to submit for approval a proposal identifying the BMPs that will be incorporated into the project to control non-point source pollutants after construction. Standard Conditions of Approval will be developed and implemented countywide as particular areas of concern are identified. Specific conditions will also be developed, with industry involvement, for certain types of new development such as gas stations, automotive centers, and food outlets.

In order to process storm water pollutant control proposals, planning approval procedures will have to be modified to ensure that these proposals represent "maximum extent practicable" levels of implementation. This modification may include formulation of procedures and guidelines for staff review of submittals, creation of guidance documents or checklists for the reviewing staff, and development of a program to communicate municipal control plan expectations to contractors and developers requiring guidance.

The final planning phase consideration is education, specifically the need to inform developers and contractors of pollutant control requirements for construction of all new developments irrespective of size.

7.4 Program Financing

Each developer will finance and implement the construction site controls specified in this program and will institute the appropriate development BMPs. To the extent the completed area

VOL 12
2
5142
R0058435

of new development even with non- structural BMPs in place can reasonably be expected to contribute to a watershed problem identified in the monitoring and watershed prioritization programs, the developer will also be required to contribute to the watershed program. This could be accomplished by establishing for each watershed a drainage water quality plan and funding program.

7.5 Program Implementation

- Refer to New Development Program Schedule in Figure 1.
- Establish a New Developments Task Force representing Co-Permittees and the BIA to provide program guidance in all aspects of its development and county-wide implementation.
- Develop and implement "non-structural" BMPs and submit initial report.
- Develop and implement "routine" structural BMPs and submit initial report.
- Finalize standard conditions of approval.
- Develop evaluate, and implement cost-effective "special" structural BMPs as indicated by the watershed planning process.
- Develop and adopt site specific conditions of approval for special developments such as gas stations, automotive repair facilities, food outlets, and other potentially significant sources of urban pollutants.
- Develop a guidance document to ensure the uniform processing of storm water quality control plan proposals. This could be modified by individual co-permittees to the extent needed to fit into their permit processing and issuance systems (See Appendix G).
- Develop an education program for developers and contractors. Educational materials and program may include:

  - Brochures
  - Ongoing coordination with construction and development organizations such as the BIA.
  - Providing speakers for seminars and conferences.

VOL 12

5143

R0058436

8.0 CONSTRUCTION

8.1 Introduction

Concern over construction sites as a major source of sediment and other pollutants is addressed in the federal regulations, which require a description of a program to implement and maintain structural and nonstructural BMPs to reduce pollutants in storm water runoff from construction sites. Specific components of the program are to include a description of procedures for site planning that incorporate consideration of potential water-quality impacts; a description of requirements for nonstructural and structural BMPs, a description of procedures for identifying priorities for inspecting sites and enforcing control measures that consider the nature of the construction activity, topography, and the characteristics of soils and receiving water quality; and a description of appropriate educational and training measures.

In addition to sediment, construction sites may be a source of pollutants such as paints, lacquers, and primers; herbicides and pesticides; landscaping and soil stabilization residues; soaps and detergents; wood preservatives; equipment fuels, lubricants, coolants, and hydraulic fluids; and cleaning solvents.

These pollutants can leak from heavy equipment, be spilled, or can be eroded by rain from exposed stockpiles. Once released, they may adsorb onto sediment particles and can be transported into the aquatic environment, where they may become available to enter aquatic food chains, cause fish toxicity problems, contribute to algal blooms, impair recreational uses, and degrade the water as a drinking source.

Sediment controls for construction activity directly impacting a watercourse should address sediment transport issues in the watercourse so that the natural quantity of sediment is not significantly changed. Contaminated sediment must be prevented from reaching the watercourse.

8.2 Regulatory Requirements

The municipal NPDES permits state that ... "industrial/commercial construction operations that result in a disturbance of one acre or more of total land area...and residential construction sites that result in the disturbance of five acres or more...shall be required to develop and implement BMPs...to control erosion and siltation and contaminated runoff from the construction sites."

Construction activities disturbing five acres or more of land will also be required to comply with a general Construction NPDES Storm Water Permit from the State Water Resources Control Board. In an April 2, 1992 ruling by the U.S. District Ninth Circuit Court of Appeal, the Court invalidated the exemption granted by USEPA for construction activity on less than five (5) acres, and remanded to EPA for further action. This Permit may be re-opened, as necessary, to accomodate any consequent changes to the definition of construction activity.

VOL 12 2 5144

R0058437

8.3 Existing Construction Practices

All public works construction contracts administered by the co-permittees are governed by "Standard Specifications for Public Works Construction" (the "Green Book"). Green Book Section 7 - "Responsibilities of the Contractor" imposes specific construction practices which are hereby included as Best Management Practices for public works construction. In general, the Green Book requires the Contractor to keep informed of, and at all times observe and comply with, State and National laws and County and Municipal ordinances and regulations.

The Green Book requires contractors, among other things, to: keep equipment in good condition (i.e., no fluid leaks) and insure that equipment and facilities meet requirements of ordinances and laws, keep the work site clean and free from rubbish and debris; use a street sweeper to keep paved areas clean; clear the work site of equipment and unused materials; prevent spillage on haul routes, and immediately remove spillage and clean the area; remove excavated material from catch basins or similar structures; comply with air pollution regulations; provide sanitation and control wastewater; provide water pollution, mud, and silt control to protect channels, storm drains, and bodies of water; and maintain drainage within and through the work site.

In addition, certain public works construction contracts administered by the co-permittees may include Special provisions and approved Standard Plans. Applicable Special Provisions and Standard Plans are hereby included as Best Management Practices for public works construction.

8.4 Existing Sediment Control Programs

8.4.1 Grading Codes

The co-permittees enforce strict grading codes designed to protect slopes from erosion and failure. These codes are also designed to protect watercourses and adjacent property from the effects of eroded soil or blowing dust.

8.4.2 "208" Program

The 208 Areawide Waste Treatment Management Plan, mandated by Section 208 of the Clean Water Act of 1972, was prepared by the Southern California Association of Governments (SCAG), eight participating local agencies, and the Los Angeles, Santa Ana, and San Diego Regional Water Quality Control Boards. The 208 Plan was adopted in 1979 as a management plan for nonpoint source waste and associated water quality degradation.

The Plan addressed nonpoint sources of waste associated with urban, agricultural and construction activities. Agriculture and construction activities were identified as significant sources of sediment to the Upper Newport Bay through direct rainfall and

VOL 12 2 5145

R0058438

drainage across such lands and established drainage channels.

As part of the 208 Plan, the Water Quality Action Plan gives priority to the restoration and protection of the Newport Bay The Action Plan consists of land management practices to reduce sediment at its source and structural measures to localize sediment deposition and facilitate its removal This is proposed through channel stabilization and use of retarding basins. Sediment control activities continue in the Newport Bay Watershed, together with a sediment monitoring program.

8.4.3 Agricultural Best Management Practices

The purpose of the Agricultural Best Management Practices (AgBMP) Program is to reduce the rate of sedimentation in Upper Newport Bay using erosion control measures within the agricultural areas of the San Diego Creek Watershed.

The role of the Orange County Environmental Management Agency (OCEMA), in the AgBMP Program, is to ensure the voluntary implementation of erosion control measures, based on AgBMPs, by The Irvine Company (TIC), the major agricultural land owner, and to report to the Regional Water Quality Control Board (RWQCB).

This role is defined in a Memorandum of Agreement (MOA), of June 1983, between Orange County and the RWQCB. The MOA obliges OCEMA to request landowners in the unincorporated areas of the watershed to develop and implement Resources Conservation Plans. OCEMA is also obliged to submit tri-annual reports, to the RWQCB, detailing the status of AgBMP implementation.

Since the inception of the AgBMP Program, OCEMA has been fulfilling its obligations, under the MOA, with technical assistance from the Riverside-Corona Resource Conservation District.

8.5 Program Development

The problem of construction site erosion and sediment loss has long been recognized by the Co-permittees. Consequently City and County grading ordinances and codes, the Green Book, and Public Works construction specifications already contain adequate requirements for construction practices for erosion control.

Full compliance with NPDES permit requirements, however, will require changes in grading practices to recognize sediment balance concepts, control of regulated materials used on the job site, and control of sediments polluted by contaminants.

Control of stormwater pollution associated with construction will be handled through the existing grading, building permit, and public works contracting process.

VOL 12
2
5146
R0058439

8.6 Program Implementation

- Refer to Construction Program Schedule in Figure 2.
- Establish a Construction Site Task Force under the direction of the NPDES Technical Advisory Committee to provide program guidance in all aspects of implementing a construction stormwater pollution program (See Appendix H).
- Verify to what extent existing codes, ordinances, and public works construction specifications can be applied to stormwater pollution problems. Refer to Section 4 0 for a detailed description of existing legal authority and actions to be taken to comply with Federal regulations.

8.7 Enforcement

Municipal grading and building inspectors will insure compliance with NPDES regulations as part of their present jobs. Inspection program elements specifically addressing stormwater pollution will include:

- Inspection at the beginning of construction to verify that required nonstructural or structural stormwater pollution control measures are in place.
- Inspection during storm events.
- Inspection shortly before notice of completion is filed.

8.8 Stormwater Pollutant Control Plan

Preparation of a stormwater pollutant control plan will be the responsibility of the project proponent. The stormwater pollutant control plan may be incorporated into the erosion control plan. The proponent may delegate the authority to prepare the plan to the contractor. The plan will include those elements specified by terms of the General State Permit, such as:

- Limits of disturbance (e.g. grading, clearing and grubbing, or pavement removal limits).
- An description of sources and nature of stormwater pollutants. On large projects, hydrologic routing of stormwater runoff may be required.
- For construction affecting a natural or unlined watercourse, a description of sediment or other controls to prevent erosion or silting of the watercourse.
- Appropriate Best Management Practices to reduce stormwater pollutants to the maximum extent practicable.

VOL 12 2 5147

R0058440

- Describing non-storm water discharges that can be anticipated.

9.0 INDUSTRIAL DISCHARGER IDENTIFICATION

9.1 Introduction

The objective of the Industrial Discharger Identification Program is to identify industrial stormwater dischargers in Orange County and notify them of State industrial stormwater permitting requirements This program is designed to provide coordination between the co-permittees and industrial dischargers in order to comply with the separate requirements of municipal and industrial stormwater discharger regulations.

9.2 Regulatory Requirements

Code of Federal Regulations Part 40 Section 122.26 (a) (4) requires industrial stormwater dischargers to notify operators of municipal storm drain systems receiving industrial stormwater discharges. Industrial stormwater dischargers will notify the co-permittee owning the storm drain into which the industrial stormwater flows. Municipal storm water permits issued by the San Diego (No. CA 0108740) and Santa Ana (No. CA 8000180) Regional Water Quality Boards state that industrial dischargers are required to cooperate with the County, and are further required to obtain individual industrial stormwater discharge permits from the Regional Boards.

Regulations proposed after the municipal storm water permits were issued will require industries to apply for coverage under a general regulatory permit issued by the State Water Resources Control Board.

In either case, the regulatory intent is for the co-permittees to maintain records of notifications submitted by industrial dischargers. Regulation of industrial discharges will be a Region or State responsibility.

9.3 Program Development

A central database will be developed which will consolidate the 40 CFR 122.26 (a) (4) notifications, the current NPDES permit holders, and industries whose SIC codes are identified by the State Water Resources Control Board as requiring coverage under the State's General Industrial NPDES Storm Water Permit. The database will provide the basis for a single notification to all the identified industrial facilities informing facilities' staff of the existence of the NPDES storm water program and possible state general permit application requirements. This countywide notification will be undertaken by county staff on behalf of all the co-permittees.

9.4 Program Implementation

- Define and compile database.
- Prepare information pack for industry (See Appendix I).

VOL 12 2 5150

R0058443

- Complete one-time distribution of information materials by July 1992.

VOL 12 2 5151

R0058444

10.0 ILLICIT CONNECTION/DISCHARGE IDENTIFICATION AND ELIMINATION

10.1 Introduction

Major sources of contamination in urban and stormwater runoff are illicit connections and illegal discharges. An example of an illicit connection is any intentional discharge to a municipal separate storm sewer that is not composed entirely of stormwater and that is not covered by an NPDES permit. The discharge does not have to contain particular constituents to be considered illicit. Such an illicit connection becomes illegal when the discharger is notified of the illicit connection and continues the discharge without having obtained an NPDES permit.

The NPDES permits require that the permittees shall effectively eliminate all identified illegal discharges/illicit connections in the shortest time practicable, and in no case later than July 1, 1995. In order to reduce the pollutant load from these sources, a facility inspection and documentation program has been developed by the Co-permittees.

10.2 Regulatory Requirements

The Orange County NPDES Permits, as mandated by Federal regulation, require a reconnaissance survey be conducted to identify illicit connections and illegal discharges to the storm drain systems. On January 31, 1991, a proposed field manual was submitted to the Santa Ana and San Diego Regional Water Quality Control Boards outlining general procedures for inspecting the drainage facilities and detecting contamination. The permits also include requirements for:

- Ordinances prohibiting illegal drainage entries and improper disposal (see Section 4.0).
- An implementation plan for prosecuting violators and eliminating illegal discharges, to be submitted by January 31, 1992 (see Appendix E).

10.3 Program Development

Draft inspection procedures were prepared by the Orange County Environmental Management Agency/Public Works Department and presented to the co-permittees for review (See Appendix J). The proposal submitted to the Water Quality Control Boards establishes facility inspection frequencies, documentation requirements, and pollution reporting procedures.

Open storm channels, retention basins and other above ground facilities will be inspected on an annual basis. Underground storm drains with diameters of 39 inches or greater will be inspected biennually. Facility inspection frequencies will be re-evaluated in cooperation with the Cities and the RWQCB's after all co-permittees have completed the first round of inspections. Based on this review, the frequencies may be modified.

VOL 12 2 5152

R0058445

Inspectors will be responsible for maintaining the proper program documentation Any suspected illegal discharge discovered during inspections must be recorded on a field log and reported to the appropriate water pollution response/enforcement agency for further investigation. All undocumented drainage entries will also be logged, identified on a map and forwarded to the appropriate local agency for verification of permit status. Action will be taken to approve undocumented connections into the municipal storm drain system by permitting or pursue abatement of those entries if determined to be illegal.

10.4 Program Implementation

The County and the City of Huntington Beach have implemented facility inspection programs The remaining Cities will be submitting implementation schedules to be included in the January 31, 1992 Reconnaissance Survey progress report. The progress report will also contain the following information:

- Analysis of the inspection results.
- Information used to identify illegal discharges/illicit connections (i.e., - visual observations, land use).
- A list of identified or suspected illegal dischargers.
- Identify large industrial facilities where hazardous/toxic substances are stored and/or used.
- Provide a list of local landfills, hazardous waste disposal, treatment, and recovery facilities and any known spills, leaks or other problems in the area.
- A discussion on all activities, related to the survey, conducted during the past year.

VOL 12 2 5153

R0058446

11.0 WATER QUALITY MONITORING PROGRAM

11.1 Introduction

A water monitoring program (See Appendix K) has been developed and implemented to aid in the detection and control of illicit/illegal discharges to municipal separate storm drain systems. The Co-permittees will utilize information from the monitoring program and other sources to identify the source(s) of pollution for each identified problem. The monitoring program includes field screening, storm sampling and; dry-weather sampling to identify sources and concentrations of pollutants.

The identification of sources which contribute pollutants to storm sewers is a critical step in characterizing the nature and extent of pollutants in discharges and in developing appropriate control measures.

11.2 Regulatory Requirements

Federal regulations require operators of municipal storm sewers to develop a "proposed monitoring program for representative data collection for the term of the permit that describes the location of outfalls or field screening points to be sampled (or the location of instream stations), why the location is representative, the frequency of sampling, parameters to be sampled, and a description of sampling equipment."

The objectives of the monitoring program as stated in the Permit are:

- To define the type, magnitude (concentration and mass load) and sources of pollutants in the storm water system discharges within each permittees respective jurisdiction so that appropriate pollution prevention and correction measures can be identified;
- To evaluate the effectiveness of pollution prevention and correction measures; and
- To evaluate the compliance with water quality objectives established for the storm water system or its components.

11.3 Program Development

From 1973 to 1990, the Environmental Resources Division of the County of Orange Environmental Management Agency conducted routine water quality monitoring on drainage facilities which are tributary to water bodies identified as waters of the state by the San Diego and Santa Ana Regional Quality Control Boards. The receiving waters were also monitored routinely to assess the chronic effects on established beneficial uses.

When the storm channel monitoring program was initiated in 1973, monthly nutrient and trace

VOL 12 2 5154

R0058447

element sampling was performed at several locations Sediment samples were collected semiannually to assess the impact of contaminant deposition and adsorption Additional constituents such as mercury, selenium, DDT, PCBs and radioactivity were also evaluated on a semiannual basis to address public concerns regarding the pollution threat from these constituents.

In order to bring the existing program in full compliance with new federal NPDES regulations, field screening to detect gross contamination was added to the program. The number of sampling sites in the channels and receiving waters were also increased in order to better assess the amount and type of contamination in storm water and urban runoff.

In addition, it is proposed that the program assess the impact of selected, permitted NPDES discharges including the runoff from nurseries in the San Diego Creek watershed. Information gathered during the life of the permit will be used in developing future monitoring programs.

11.4 Program Implementation

The monitoring program for storm channels and receiving waters consists of field screening (channels only); dry-weather, flow-composite, sampling; and storm sampling.

Field screening will be used to detect gross contamination which may be indicative of illegal disposal of pollutants. Monitoring locations were sited on channels which have drainage areas greater than one square mile or which have industrial (manufacturing) land uses in the drainage areas. Reports exhibiting elevated concentrations of field-screening constituents will be referred to the EMA Water Pollution Section for further investigation.

Data from dry-weather and storm sampling will be used to estimate the total annual volume of contaminants discharged by each monitored channel. These monitoring locations will be in channels which are identified in the permits as "Waters of the State", or will be in major tributaries to "Waters of the State".

Monitoring locations include 90 field screening stations, 34 channel sampling stations, and 20 sampling stations within the harbors and bays throughout the County.

Storm monitoring of channels will also be used to evaluate the level of contamination during and after storm events. Samples will be analyzed from the first 4 hours of the storm (first flush), the next 20 hours, and from two consecutive 36 hour periods (after the first day). These data will be used to compute four-day average, contaminant concentrations.

The receiving water monitoring program includes stations in the Huntington Harbor; Sunset, Anaheim, and Bolsa Bays; Upper and Lower Newport Bays; and Dana Point Harbor. These stations will also be monitored during and subsequent to storms for the same contaminants as in the channel monitoring program.

VOL 12 2 5155

R0058448

In the channel and receiving water monitoring programs semiannual sampling of bed sediment will also be conducted to determine the chronic effects of storm water runoff.

Annual Reporting Forms and Procedures

R0058452

RECONNAISSANCE SURVEY PROGRESS REPORT

Annual Reporting Forms and Procedures

1 0 INTRODUCTION

As detailed in the DAMP Implementation Plan, an annual report of progress made toward implementation of a drainage facilities inspection program is required of each co-permittee for inclusion in the annual Reconnaissance Survey Progress Report, due to the Regional Water Quality Control Boards annually by January 31.

2.0 PURPOSE OF THE REPORT

The Reconnaissance Survey Progress Report is intended to reflect co-permittee action toward eliminating illegal discharges into municipal storm drain systems. For the cities, this includes (1) an inventory of all above ground storm drain facilities and all below ground facilities greater than 39 inches, (2) a report of facilities inspection progress, and (3) a report of investigations of potential sources of illegal discharges (i.e. undocumented connections and updated lists of landfills and hazardous materials facilities within co-permittee jurisdiction).

3.0 PROCEDURES

Co-permittees must complete two reports -- a Reconnaissance Survey Summary Chart and a Suspected Illegal Discharges Report -- and submit them to County Stormwater Staff by December 15 of each year. A brief discussion of reconnaissance survey activities, to be completed through questionnaire, should also be included. A further explanation of how to complete these reports follows:

3.1 Reconnaissance Survey Summary

Co-permittees must report reconnaissance survey activities for all above ground drainage facilities and all below ground facilities greater than 39 inches in diameter. For these, co-permittees must report (1) the total miles of facilities in their jurisdiction, (2) the miles of facility inspections completed in the previous year, (3) the date that the current cycle of inspections began and the miles and percentage of total miles inspected in the cycle, (4) the number of suspected and/or actual illegal dischargers found in the previous year and (5) the number of undocumented connections found in the previous year.

Notes on Completing the Reconnaissance Survey Summary:

1.) According to the DAMP, co-permittees are required to complete inspection of all facilities every two years. A "cycle" (as referred to above) refers to a completion of inspections.

2.) "Total Miles of Facilities Inspected" and "Percentage of Facilities Inspected" both refer to facilities inspected since the last report, not a cumulative total.

VOL 12 2 5160

3) Undocumented connections are not to be considered "potential" illegal discharges

4) Under "Comments," be certain to characterize the origins or suspected origins of the undocumented connections found by facility inspection crews as being residential, commercial or industrial. For example, a statement such as "The majority of the 35 undocumented connections found originated from residential area swimming pools" would suffice

5) All suspected and actual illegal discharges reported in this summary chart must be completed on the Illegal Discharges Report.

6.) Do not report the results of routine inspections on the summary chart; if submitted, these should be included as an addendum to the report.

3.2 Suspected Illegal Discharges Report

Co-permittees must complete a list of all suspected and actual illegal discharges into city storm drain systems identified in the previous year. In keeping with the requirements of the permits, this list must include (1) the channel into which the discharge occurred, (2) the major adjacent land uses served by the channel (residential, commercial or industrial), (3) identification of suspected illegal dischargers, (4) the date of discharge, (5) visual observations of discharges (color, turbidity, etc.) and (6) the main water body receiving flow from the drainage facility. This information should have been compiled through the implementation of the Reconnaissance Survey Field Inspection and Documentation Manual, distributed to co-permittees in 1991.

Note that illegal discharges are considered "suspected" until they have been resolved through the proper authoritative channels.

3.3 Reconnaissance Survey Questionnaire

Co-permittees must include a brief discussion of the programs implemented in each calendar year related to the Reconnaissance Survey and their effectiveness in identifying and eliminating illegal discharges and illicit connections to the storm drain systems within their jurisdiction. A questionnaire has been developed and will be updated as needed for each annual report.

Reconnaissance Survey Questionnaire

City of _____

Your responses to the following questionnaire will assist in completion of the 1994 Reconnaissance Survey Progress Report, due to the Regional Water Boards by January 31, 1993 Please complete and return to the County Stormwater Program **no later than December 15, 1993**, to assure timely submittal of the report.

1.0 The Reconnaissance Survey Summary Chart

1. If your City has not completed one full "cycle" of facility inspections (including both above and below ground inspections), when do you expect to complete one cycle?

   Date _____

2. a. Do your facility inspectors use the standardized form included in the Reconnaissance Survey Field Manual for reporting conditions found during routine inspections?

   _____ Yes _____ No

   b. If not, do they use a form developed by the City?

   _____ Yes _____ No

   c. If so, please submit a copy of the documentation form developed by your City with this report.

   d. If no documentation of facility inspections has been undertaken, when does your City intend to begin documentation?

   Date _____

3. a. Has your city used video cameras for underground inspections?

   _____ Yes _____ No

   b. If not, what inspection method does your City use?

   c. If your City has not begun underground inspections, what method do you intend to use?

VOL 12 2 5164

VOL 12

2.0 Illegal Discharges/Illicit Connections

1 If your facility inspectors have discovered illegal discharges to the storm drain system, are steps being taken by your City to investigate and eliminate them, as specified in the NPDES permits?

____ Yes ____ No

If so, describe the steps being taken (attach a separate sheet, if necessary).

2. If any illicit connections were discovered to the storm drain system, were steps taken (or are being taken) to bring them into compliance with local requirements?

____ Yes ____ No

If so, describe the steps being taken.

2

5165

3. If any undocumented connections were discovered, please characterize the land use of the surrounding areas as residential, industrial or commercial below. If records have not been kept concerning land use surrounding the location of undocumented connections, please estimate the percentages (i.e. "about 50 percent residential, 25 percent industrial," etc.).

Undocumented Connections

Residential	Industrial	Commercial

3.0 Other Reconnaissance Survey Data

1 a. A computer database was made available to co-permittees in 1993 for documenting illegal discharges and illicit connections Was this database utilized by your City?

_____ Yes _____ No

b Does your City maintain its own computer database for documenting illegal discharges and illicit connections?

_____ Yes _____ No

c. Is your City considering such a database?

_____ Yes _____ No

2. a. Does your City conduct its own facility inspections or is the work contracted?

_____ Yes _____ No

b. If the work is contracted, who is performing the inspections?

_____

3. a. The County held a reconnaissance survey workshop for drainage facility inspectors August 1992. Have your City inspectors participated in any further training for facility inspections?

_____ Yes _____ No

b. If so, please describe this training (sponsored by, when, where, etc.).

c. Is there a need for further County-sponsored training programs?

_____ Yes _____ No

4. Other than the programs mentioned in this questionnaire, has your City initiated any other programs to identify and eliminate illegal discharges and illicit connections to the storm drain system?

_____ Yes _____ No

If so, please describe.

Drainage Area Management Plan Status Report

Annual Reporting Questionnaire

R0058460

DRAINAGE AREA MANAGEMENT PLAN

Annual Status Report

City of _____

I. DAMP Section 4, Legal Authority

1. Has the City adopted an ordinance to provide adequate legal authority to regulate discharges to municipal storm drain systems and to implement the programs of the DAMP? If so, when?

Yes _____ No _____

II. DAMP Section 5, Public Agency Activities

(If a specific section of the DAMP has not been completed or is in the process of being completed, please indicate progress toward implementation or the status of the program under "comments." Attach a separate sheet, if necessary.)

1. Attach a report or existing litter control regulations with a description of existing litter control programs (Section 5.2.1)?

Comments on litter control program effectiveness and future plans.

2. Attach a copy of the recycling information required for AB 939 (Article 2, Section 41030), a brief description of the programs and any public education material developed or distributed by the City (Section 5.2.2).

Comments on recycling program effectiveness and future plans.

3. Regarding the facility maintenance program, please attach the following (Section 5.2.3):

   A. Copies of facility inspection and maintenance logs detailing total volume of material removed from city drainage facilities since the last report and estimating the percentage of paper, plastic, vegetation, soil and "other" materials.

   B. Data tables that document the number of drains and length of channel/pipe cleaned since the last report.

   C. Any specific information on facilities where evidence of chemical contaminants have been found since the last report, including the nature, extent and location of the contamination identified.

Comments on drainage facility maintenance program effectiveness and future plans.

VOL 12 2 5168

4. How many catchbasins have been stenciled with the phrase "NO DUMPING -- DRAINS TO OCEAN" or with a variation on the phrase (Section 5.2.4)?

Phrase Used _____

Number of Catchbasins Stenciled _____

Comments on catchbasin stenciling program.

5. Attach copies of street sweeping schedules and sample log sheets used for internal documentation of the street sweeping program (Section 5.2.5).

Comments on street sweeping program effectiveness and future plans.

6. Attach an updated list of improvements made to public facilities for storage of hazardous materials, as defined in the DAMP Section 5.2.6.

Comments on hazardous materials management program effectiveness and future plans.

7. Submit a summary of any information or data gathered from toxic roundups and household hazardous waste collections in the last year (Section 5.2.7). Include quantities and materials collected, public education/information materials distributed and data generated by the Integrated Waste Management Program.

Comments on household hazardous waste collection effectiveness and future plans.

8. A. Have emergency spill response staff and resources been identified (Section 5.2.8)?

Yes _____ No _____

B. If so, has the staff identified undertaken training to implement the County emergency spill response program (Section 5.2.8)?

Yes _____ No _____

Comments on emergency spill response program effectiveness and future plans.

VOL 12 2 5169

9 Complete the attached Annual Progress Report for Fertilizer and Pesticide Management.

Comments on fertilizer/pesticide management program effectiveness and future plans.

III. DAMP Section 6, Public Education/Information

1. Describe steps taken by the City in the last year to further public education pertaining to stormwater quality, including materials developed or distributed, events/workshops/ activities attended or coordinated or any other relevant actions taken (Section 6.3). Attach a separate sheet, if necessary.

Comments on public education/information program effectiveness and future plans.

IV. DAMP Section 7, New Development

1. In its standard conditions for project approval, has the City required that developers provide post-construction stormwater management plans to control nonpoint sources of pollution (Sections 7.1 and 7.2)?

Yes _____ No _____

Comments.

2. Has the City participated in the distribution of educational materials to developers and contractors to make them more aware of stormwater quality issues and requirements (Section 7.2)?

Yes _____ No _____

Comments.

3. Has the City adopted the Best Management Practices (BMPs) developed by the County's New Development and Construction Task Force to be recommended at the planning stages for specific types of new development, such as gas stations, automotive centers and fast-food outlets (Section 7.3)?

Yes _____ No _____

Comments.

VOL 12 2 5170

V. DAMP Section 8, Construction

1 Has the City ensured that construction projects affecting more than five acres within its jurisdiction have obtained Statewide General Construction Permit coverage prior to issuance of grading, grubbing clearing, surface mining or paving permits (Section 8 2)?

Yes _____ No _____

Comments.

2. Do City grading and building inspectors regularly ensure compliance with NPDES regulations (Section 8.7) through:

A. Inspection at the beginning of construction to verify that required stormwater pollution control measures are in place?

Yes _____ No _____

B. Inspection during storm events?

Yes _____ No _____

C. Inspection shortly before notice of completion is filed?

Yes _____ No _____

Comments on construction inspection program.

I, _____, as a duly designated representative for the City of _____, hereby certify under penalty of perjury that the materials and information presented in this report represent a true and faithful response in accordance with the terms of the co-permittees' NPDES permit.

FERTILIZER AND PESTICIDE MANAGEMENT

Annual Progress Report

City of _____

I. **Fertilizer Management**

1 Were any soils in your jurisdiction tested for compatibility with the fertilizers being used (Section 2.3.1)?

Yes ____ No ____

2. Were qualified fertilizer specialists consulted regarding:

A. fertilizer application rates or timing (Sections 2.3.2 and 2.3.3)?

Yes ____ No ____

B. storage of fertilizers (Section 2.5)?

Yes ____ No ____

C. handling of fertilizers (Section 2.5)?

Yes ____ No ____

3. Were organic or slow release fertilizers used to a greater extent than in previous years (Section 2.2.2)?

Yes ____ No ____

4. Was it necessary to upgrade fertilizer storage facilities to meet the recommendations of the Fertilizer Management Guidelines (Section 2.2.2)?

Yes ____ No ____

If so, how?

5. Did you have any spills of fertilizers in your jurisdiction in the last year?

Yes ____ No ____

If yes, explain the circumstances and the steps taken to mitigate the situation (attach a separate sheet, if necessary, or a copy of the incident report).

6. In the course of the last year, over how many acres of land did your jurisdiction apply fertilizers? _____ acres

VOL 12 2 5113

R0058466

7 Attach a complete list of the fertilizers used in your jurisdiction in the last year, and note any changes in the list from the previous year.

II. Pesticide Management

1. Have all of your pest control personnel (applicators) obtained Qualified Applicators Licenses from the state?

Yes _____ No _____

If no, have they completed the County's equivalent training program (Section 3.3.2)?

Yes _____ No _____

2. Did you test any soils for compatibility with pesticides in the last year (Section 3.3.7)?

Yes _____ No _____

3. Were the recommended inspections conducted, as referenced in the Pesticide Management guidelines, for the following?

A. inspection of pesticide application equipment (Section 3.3.6)?

Yes _____ No _____

B. inspection of contracted and/or in-house pest control crew activities (Section 3.4.1)?

Yes _____ No _____

C. inspection of pesticide storage facilities (Section 3.5)?

Yes _____ No _____

If not, explain.

4. Were the appropriate measures completed for the following, as recommended in the Pesticide Management program?

A. transportation of pesticides (Section 3.5)?

Yes _____ No _____

B. disposal of pesticides (Section 3.5)?

Yes _____ No _____

If not, explain.

VOL 12 2 5174

5 In the course of the last year, to how many acres of land did your jurisdiction apply pesticides? _____ acres

6. Have you had any spills or other releases of pesticides in your jurisdiction in the last year?

Yes ____ No ____

If yes, explain the circumstances and the steps taken to mitigate the situation (attach a separate sheet, if necessary, or a copy of the incident report).

7. Submit a complete list of the pesticides you have used in the last year, noting any changes in the list from the previous year (indicate which pesticides contain restricted or Category One chemicals).

III. Integrated Pest Management

1. Does your jurisdiction currently implement Integrated Pest Management (IPM) techniques as recommended in the Management Guidelines for Use of Fertilizers and Pesticides?

Yes ____ No ____

2. If any, list the specific alternatives to pesticides that were employed by your pest control crews in the last year.

3. Have your work crews reduced the number of pesticides in use in your jurisdiction in the last year as a result of IPM?

If yes, quantify the reduction. Yes ____ No ____

ORIGINAL
CLERK OF THE BOARD
ORANGE COUNTY

VOL 12 2 5183

National Pollutant Discharge Elimination System
Stormwater Permit Implementation Agreement
Santa Ana/San Diego Regions

- This AGREEMENT entered into as of this 18th day of December, 1990 by the County of Orange, (herein called the COUNTY), the Orange County Flood Control District (herein called the DISTRICT and the Cities of Anaheim, Brea, Buena Park, Costa Mesa, Cypress, Dana Point, Fountain Valley, Fullerton, Garden Grove, Huntington Beach, Irvine, Laguna Beach, Laguna Niguel, La Habra, La Palma, Los Alamitos, Mission Viejo, Newport Beach, Orange, Placentia, San Clemente, San Juan Capistrano, Santa Ana, Seal Beach, Stanton, Tustin, Villa Park, Westminster, and Yorba Linda (herein called the CITIES) establishes the responsibilities of each party with respect to compliance with National Pollutant Discharge Elimination System (NPDES) Stormwater regulations administered by the United States Environmental Protection Agency (EPA) under the authority granted by the Clean Water Act (CWA) and its 1987 amendments, the Water Quality Act (WQA).

RECITALS

Whereas

Congress in 1987 amended Section 402 of the Federal Clean Water Act (33 U.S.C.A. 1342(p)) to require the federal Environmental Protection Agency to promulgate regulations for applications for permits for stormwater discharges; and

Whereas

These permit regulations will require the control of pollutants from stormwater discharges by requiring a National Pollutant Discharge Elimination System permit which would allow the lawful discharge of stormwaters into waters of the United States; and

Whereas

These EPA regulations will require NPDES permits for discharges from municipal storm sewers on a system-wide or jurisdiction-wide basis; and

Whereas

The Legislature, in enacting the Orange County Flood Control Act, created the Orange County Flood Control District to provide for the control of flood and storm waters; and

Whereas

The powers granted to the DISTRICT include carrying on technical and other investigations, examinations, or tests of all kinds, making measurements, collecting data, and making analyses, studies, and inspections pertaining to water supply, control of floods, use of water, water quality, nuisance, pollution, waste, and contamination of water, both within and without the DISTRICT; and

RECEIVED
SEP 10 1990

R0058476

Whereas
The CITIES, the COUNTY and the DISTRICT desire to develop an integrated stormwater discharge management program with the objective of improving water quality in the County of Orange; and

Whereas
The California State Water Resources Control Board (CSWRCB) as designee of the EPA has delegated authority to the Regional Water Quality Control Boards-Santa Ana Region (RWQCB-SAR) and San Diego Region (RWQCB-SDR) for administration of the NPDES Storm Water permit application process within the boundaries of their Regions; and

Whereas
The COUNTY, DISTRICT and CITIES have been designated as co-permittees by the RWQCBs; and

Whereas
The COUNTY has been designated as the lead Agency on the permits; and

Whereas
Cooperation between the CITIES, the COUNTY and the DISTRICT to jointly file applications for NPDES Stormwater permits is in the best interests of the CITIES, the COUNTY and the DISTRICT; and

Whereas
The COUNTY is willing to share the expertise of its staff with the CITIES so that they can join in seeking and implementing certain requirements of the NPDES Stormwater permits; and

NOW THEREFORE: The parties hereto do mutually agree as follows:

I. Filing Status. The COUNTY, DISTRICT and CITIES will file the applications for stormwater permits as co-permittees. The COUNTY, the DISTRICT and each individual city will be a co-permittee.

II. Incorporation of Federal Guidelines. The terms of all applicable Federal and State guidelines, as presently written or as changed during the life of this agreement are hereby incorporated by reference and made a part of this AGREEMENT and take precedence over any inconsistent terms of this agreement. Inconsistencies between the terms of the permit and final federal regulations are not applicable unless mandated by court order.

III. Delegation of Responsibilities. The responsibilities of each of the parties shall be as follows:

A. The COUNTY, on a cost-shared basis, shall administer system compliance by

VOL 12 2 5184

R0058477

1. Preparing implementation and annual operating budgets. The budget year shall coincide with the fiscal year of the COUNTY, July 1 - June 30.

   a. The participants shall be permitted to review and approve the annual operating budget for the forthcoming year. Criteria for approval shall be affirmative responses from a majority of the co-permittees which represent a majority of the percentage contribution as described in Section IV. The COUNTY and the DISTRICT will represent one voting co-permittee with their percentage contribution equal to the total of the COUNTY and the DISTRICT as described in Section IV. The review period shall be from November 1 to November 30 of each year with approval of the final budget to be completed by December 15.

   b. The annual operating budget shall not be exceeded without prior consent of the majority of the co-permittees which represent a majority of the percentage contribution.

2. Preparing compliance reports to the Regional Board and providing copies to the co-permittees.

3. Preparing a draft system-wide Best Management Practices (BMP) Program report.

4. Monitoring the implementation and ensuring the effectiveness of system-wide BMPs. This will include field reconnaissance to evaluate structural and procedural BMPs. An annual report to the RWQCB will be prepared presenting the results of these evaluations.

B. The DISTRICT shall, to the maximum extent practicable and on a cost-shared basis except in paragraph 4 below,

1. Perform the water quality and hydrographic monitoring for permit compliance.

2. Administer the water pollution control program by enforcing the Orange County Water Pollution Ordinance.

3. Develop uniform criteria for annual

VOL 12 2 5185

R0058478

inspection of drainage facilities.

4. Perform inspections, at no cost to the CITIES or the COUNTY, on these facilities owned by the DISTRICT and on municipal separate storm sewers in unincorporated County. Contracts, for such inspections within CITIES may be undertaken at the sole expense of the requesting city.

C. The CITIES shall, to the maximum extent practicable and at no cost to COUNTY or DISTRICT,

1. Implement a facility inspection program in accordance with the uniform criteria developed by the DISTRICT, for all municipal separate storm sewers as defined by the stormwater permit and within the jurisdictional boundaries of that city.

2. Submit to the COUNTY, storm drain maps with periodic revisions which reflect the modifications that were made to the storm drain system.

3. Prepare watershed characterizations, including:

a. Zoning designations and

b. Identification of areas where hazardous materials presently are or are suspected to have been stored, manufactured or disposed of. This shall include sites at which a hazardous material spill has occurred.

4. Review, approve, and implement system-wide BMPs.

5. Eliminate or have eliminated, illegal/illicit connections to the storm drain system.

6. Identify the legal authority for control of discharges to the storm drain system.

7. Provide to the COUNTY annual reports (on forms provided by the COUNTY) and any other information needed to satisfy annual reporting requirements of the RWQCBs.

8. Adopt and enforce, or name DISTRICT as enforcer of a water pollution control ordinance, which prohibits non-NPDES permitted discharges to the municipal

VOL 12 2 5186

R0058479

separate storm sewer system.

D. The COUNTY shall, to the maximum extent practicable and at no cost to the CITIES or the DISTRICT, undertake in the unincorporated areas of the COUNTY, all activities required above of the CITIES that are not responsibilities of the DISTRICT as outlined in Section III. B.

IV. Program Costs. The responsibilities for payment of all shared costs of equipment, services, contracted analytical services, and the cost of the Regional Board permits, shall be distributed among the DISTRICT, COUNTY and CITIES as follows:

Participant	Percentage Contribution
DISTRICT	5
CITIES + COUNTY	95

The individual percentage contributions from each city and the COUNTY shall be functions of their respective areas and populations relative to those of the entire County. Each shall be calculated as one half of the sum of the area and population fractions, multiplied by 95. Excluded are national forests, state parks, airports, landfills, oceans, harbors, tidal bays and military installations. The contribution of the COUNTY shall be calculated from unincorporated areas and their respective populations.

$$\text{Share in percent for City \# 1} = \frac{\left[\frac{x_1}{x_{tot}}\right] + \left[\frac{y_1}{y_{tot}}\right]}{2} (95)$$

x = area
y = population
tot = total population or area
95 = total percentage excluding Flood Control District contribution

The percentage shares shall be calculated by the COUNTY EMA Environmental Resources Division from population and area data. These calculations shall be completed by November 1 of each year and shall be included in the annual budget proposal. The initial percentage shares are presented in Attachment 1.

The total of shared costs shall not exceed $1,000,000 for the first year of the program. A deposit which constitutes a share percentage of the total anticipated first year costs shall be required of each city. The

VOL 12 2 5187

R0058480

COUNTY shall send invoices for these deposits to the CITIES within 15 days of the signing of this AGREEMENT by the Board of Supervisors. Each city shall pay the deposit within 45 days of the date of the invoice.

If at any time during a given fiscal year the program costs exceed the sum of the deposits, the COUNTY shall submit invoices to the CITIES to recover the deficit. The share for each city shall be prorated according to the formula above. Each city shall pay the invoice within 45 days of the billing date.

The COUNTY shall prepare a fiscal year end accounting within 60 days of the end of the fiscal year. If the fiscal year end accounting results in costs (net of interest earnings) exceeding the sum of the deposits, the COUNTY shall invoice each city for its prorated share of the excess cost. Each city shall pay the billing within 45 days of the date of the invoice. If the fiscal year end accounting results in the sum of the deposits exceeding costs (net of interest earnings), the excess deposits will carry forward to reduce the billings for the following year.

After the initial billing for the program, the COUNTY shall invoice each city for its annual deposit at the beginning (July 1) of each fiscal year. Each city shall pay the deposit within 45 days of the date of the invoice. Each city's deposit shall be based on their prorated share of the approved annual budget, reduced for any surplus identified in the prior fiscal year end accounting.

Interest earned on the CITIES deposits will not be paid to the CITIES, but will be credited against the CITIES share of the program costs.

Upon termination of the program a final accounting shall be performed by the COUNTY. If costs (net of interest earnings) exceed the sum of the deposits, the COUNTY shall invoice each city for its prorated share of the excess. Each city shall pay the invoice within 45 days of the date of the invoice. If the sum of the deposits exceeds the costs, the COUNTY shall reimburse to each city its prorated share of the excess, within 45 days of the final accounting. Interest earnings are used to offset the CITIES share of program costs and will not be refunded to the CITIES.

Each city and the COUNTY shall bear the financial responsibility for implementing the Program, within its jurisdictional boundaries, as outlined in Section III. C. and D.

The filing fees for the Permits shall be included in

VOL 12 2 5188

R0058481

the first year costs.

V. Life of the AGREEMENT. The life of the AGREEMENT shall be indefinite or as long as the WQA mandates compliance.

VI. Additional Parties. Any city which becomes signatory to this AGREEMENT after the applications for the initial NPDES Stormwater permits have been approved and any city which becomes incorporated shall become a co-permittee on the NPDES Stormwater permit issued by its respective RWQCB and shall comply with all of the provisions of this AGREEMENT. The date of initiation, for determining participant costs for newly incorporated CITIES shall be the date of incorporation, and for a city signing after NPDES Stormwater permit approval it shall be the date of the initial application for the NPDES Stormwater permit. The costs for adding the additional parties to the program, including additional permit and processing fees, shall be paid by the added party. Monies to be reimbursed to the existing co-permittees shall be credited to their respective annual program operating fees for the following budget year.

VII. Withdrawal from the AGREEMENT. A participant may withdraw from the AGREEMENT 60 days subsequent to written notice to the COUNTY. The COUNTY will notify the remaining co-permittees within 10 business days of receipt of the withdrawal notice. The withdrawing participant shall agree to file for a separate permit and to comply with all of the requirements established by the RWQCB(s). In addition, withdrawal shall constitute forfeiture of the withdrawing participant's deposit for the budget year of withdrawal. The withdrawing participant shall be responsible for all lawfully assessed penalties as a consequence of withdrawal. The cost allocations to the remaining members will be recalculated in the following budget year.

VIII. Non-compliance with Permit Requirements. Any participant found in non-compliance with the conditions of the permit within their jurisdictional responsibilities shall be solely liable for any lawfully assessed penalties, pursuant to Section 13385 of the Water Code. Common penalties shall be calculated according to the formula outlined in Section IV.

IX. Legal Action/Costs/Attorney Fees. Where any legal action is necessary to enforce any provision hereof for damages by reason of an alleged breach of any provisions of this AGREEMENT, the prevailing party shall be entitled to receive from the losing party all

VOL 12 2 5189

R0058482

litigation and collection expenses, administrative costs, witness fees and court costs.

X. **Amendments to the AGREEMENT.** This AGREEMENT may be amended by consent of a majority of the co-permittees which represent a majority of the percentage contributions as described in Section IV. The COUNTY and the DISTRICT will represent one voting co-permittee with a percentage contribution equal to the sum of the individual contributions of the COUNTY and DISTRICT as described in Section IV. No amendment to this AGREEMENT shall be effective unless it is in writing and signed by the duly authorized representatives of the majority of co-permittees.

XI. **Authorized Signatories.** The County Director of Public Works and the respective City Engineers or Directors of Public Works, shall be authorized to execute the application(s) for NPDES Stormwater permit(s) and take all other procedural steps necessary to file the application(s) for NPDES Stormwater permit(s).

XII. **Notices.** All notices shall be deemed duly given if delivered by hand; or three (3) days after deposit in the U.S. Mail, postage prepaid.

XIII. **Governing Law.** This AGREEMENT will be governed and construed in accordance with laws of the State of California. If any provision or provisions of this AGREEMENT shall be held to be invalid, illegal or unenforceable, the validity, legality and enforceability of the remaining provisions shall not in any way be affected or impaired hereby.

XIV. **Consent to Breach not Waiver.** No term or provision hereof shall be deemed waived and no breach excused, unless such waiver or consent shall be in writing and signed by the co-permittee to have waived or consented. Any consent by any co-permittee to, or waiver of, a breach by the other, whether express or implied, shall not constitute a consent to, waiver of, or excuse for any other different or subsequent breach.

XV. **Applicability of Prior Agreements.** This document constitutes the entire AGREEMENT between the co-permittees with respect to the subject matter; all prior agreements, representations, statements, negotiations and undertakings are superseded hereby.

XVI. **Execution of the AGREEMENT.** This AGREEMENT may be executed in counterpart and the signed counterparts shall constitute a single instrument.

REQUEST FOR CITY COUNCIL ACTION

Date: October 1, 1990

APPROVED BY CITY COUNCIL
_____ 19__
_____
City Clerk

Submitted to: Honorable Mayor and City Council

Submitted by: Michael T Uberuaga, City Administrator

Prepared by: Louis F Sandoval, Director of Public Works

Subject: ENVIRONMENTAL PROTECTION AGENCY - NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM (NPDES)

Consistent with Council Policy? [X] Yes [ ] New Policy or Exception

Statement of Issue, Recommendation, Analysis, Funding Source, Alternative Actions, Attachments

STATEMENT OF ISSUE:

As part of the U S Clean Water Act, the EPA has initiated a program to clean up our storm waters The program is called the National Pollutant Discharge Elimination System (NPDES) To bring about a more organized and efficient approach to this program, the County of Orange (EMA and Flood Control) and all of the cities in the county have developed a unified program The county has the expertise to do much of the needed investigation and storm water testing throughout the entire county (they have already a limited program in place) and is willing to be the lead agency A committee comprised of the county and all of the cities has developed an implementation agreement to be executed by all of the agencies.

RECOMMENDATION:

Authorize the Mayor, the City Administrator, the Director of Public Works and the City Clerk to execute the National Pollutant Discharge Elimination System Storm Water Permit Implementation Agreement.

ANALYSIS:

At the meeting of May 7, 1990, the City Council authorized the City to be a co-permittee on the application for the permit. The permit was subsequently submitted to the Santa Ana Regional Water Quality Control Board and approved by that body

We have received the final draft of the implementation agreement from the county It is imperative that the agreement be executed at this time in order to begin implementation of our program prior to receipt of the final EPA rules and guidelines scheduled to come out in late October.

The county-wide committee, not knowing the exact cost for the first year of implementation has prepared a first year program budget of $1,000,000 As identified in the attached agreement, the Huntington Beach share of the program is 5 80% or $58,090 78 for that first year. The $58,090 78 is included in the current budget of $105,000.

FUNDING SOURCE:

Included in the 1990/91 budget (Flood Fund) is $105,000 for an NPDES inspector position and the first year program costs.

R0058499

FISCAL ANALYSIS REPORT

Annual Reporting Forms and Procedures

1.0 SCHEDULE

As detailed in the DAMP Implementation Plan, financial reports are required from each co-permittee by July 15 of each year for inclusion in the annual Program Fiscal Analysis, which is prepared by the Orange County Stormwater Section and is due to the Regional Water Quality Control Boards annually by August 31.

2.0 PURPOSE OF THE REPORT

The Fiscal Analysis is intended to depict, as accurately as possible, all NPDES-related costs for each co-permittee. For the cities, this includes costs for (1) city operations, (2) contracted services and (3) functions financed by other means. Estimates should be used where accounting systems do not provide sufficient information.

Do not include NPDES permit costs or shared costs, which constitute contributions to activities performed by the County on behalf of the co-permittees rather than direct city expenditures for DAMP programs. This information is evaluated separately.

3.0 PROCEDURES

The NPDES permits specifically require separate input for Capital, Operations and Maintenance expenditures, which are defined as follows:

- "Capital Costs" refer to expenditures for capital equipment and facilities;
- "Operations Costs" refer to normal costs of operation, less maintenance costs.
- "Maintenance Costs" refer to the cost of maintaining equipment and facilities in working order.

These costs are to be reported on the three attached forms attached. The forms are set in the same format for reporting (1) *actual* expenditures for DAMP programs in the previous fiscal year and (2) *projected* expenditures for the coming fiscal year. These expenditure columns are further subdivided into costs for the programs already in place before DAMP implementation and for programs specifically implemented to comply with the DAMP. Procedures for completing the forms are as follows:

1.) Under the "Existing Program" column, list the costs of those pre-existing programs which contribute to pollution control and were generally in place prior to the advent of NPDES requirements.

2.) Under "DAMP Portion" column, list any additional cost for each program, beyond "Existing Program" costs, required to meet DAMP specifications. If no program existed

VOL 12 2 5207

previous to DAMP implementation, list the total cost under this column.

3.) Do not combine costs for two or more DAMP Cost Elements in a single line. For example, do not count the same cost figures for a hazardous waste contractor under both Hazardous Materials Management and Household Hazardous Waste Collection. Break up the costs appropriately (estimate if necessary, qualifying estimates under Comments.

4.) Where accounting systems do not separate Maintenance Costs from Operations Costs, estimate using a percentage factor to split the two, and so note under Comments.

5.) Show actual costs for the previous fiscal year and projected costs for the next. Where funding is expected but not approved, use your best estimate, noting so under Comments.

6.) List the costs for contracted operations under Operations Costs, and note under Comments that the item was contracted. Do not attempt to break out Capital or Maintenance cost elements from such contracted items.

7.) Tasks performed by volunteer organizations or inmates for which there is no direct charge *should be included as program costs.* Although they do not present an immediate cost to the program, these services should be listed according to their estimated dollar value under the appropriate category because they do represent a potential cost to the NPDES program in future years. A note should be placed in the Comments column stating who performed the effort and that there was no actual cost to the city.

4.0 NOTES ON TABLE HEADINGS

- **Hazardous Materials Management** -- Under "DAMP Portion," include the cost of any facilities improvements needed to meet DAMP requirements.
- **Public Property and Street Chemical Spill Response** -- This section refers to actions of the Fire Department and others in response to calls for assistance.
- **Pesticide and Fertilizer Management** -- Under "DAMP Portion," include the fiscal impact from implementing the Management Guidelines for Use of Fertilizers and Pesticides developed by the County for the cities.
- **New Development and Construction** -- Under "DAMP Portion," include the fiscal impact of implementing new programs to meet DAMP requirements.
- **Illicit Connections/Discharge Identification & Elimination** -- This element refers to Reconnaissance Survey activities. The sub-element under this titled "Other Efforts to Identify and Eliminate Illicit Connections/Discharges" refers to follow-up activities resulting from facility inspection findings. This could include the cost of an investigation or legal proceeding related to an identified illegal discharge.

VOL 12 2 5208

1.0 INTRODUCTION

To comply with federal regulations, the City of _____ must develop and implement various nonpoint source pollutant control programs according to the requirements of their National Pollutant Discharge Elimination System (NPDES) Stormwater Permits issued by the Santa Ana and San Diego Regional Water Quality Control Boards. The Orange County Flood Control District, the County of Orange and its incorporated cities are co-permittees in these permits.

The County of Orange, as lead agency, has developed a Drainage Area Management Plan (DAMP) that will meet permit requirements to be implemented by each city. The purpose of the DAMP is to help the cities implement Best Management Practices (BMPs) in accordance with the specific requirements of the NPDES permits. DAMP implementation involves controlling runoff from commercial, residential, industrial and construction sites and controlling pollutant sources such as illegal discharges and illicit connections to storm drain systems.

This Implementation Plan was designed to outline the actions that need to be taken by each co-permittee, a time frame to complete those actions and when specific information must be submitted to the County Stormwater Program for annual reporting to the Regional Boards.

2.0 PROGRAM MANAGEMENT – COMPLIANCE REPORTING

Under the co-permittees' NPDES Storm Water Permit Implementation Agreement, the County of Orange was designated to coordinate countywide compliance with the NPDES permits. In accordance with this responsibility, the County must prepare a number of progress reports on the status of the program for annual submittal to the Regional Boards. These reports are described as follows:

2.1 Reconnaissance Survey Progress Report

Description:
Report to show evidence of implementation of a plan to detect and eliminate illegal discharges to the stormwater conveyance systems and to show the resulting reduction in loadings of pollutants in receiving waters. All illegal/illicit discharges must be eliminated by July 16, 1995. Those identified after that date must be eliminated in the shortest time practicable.

This progress report is due to the Regional Boards annually by January 31.

Action Required:
Cities must report progress toward implementation of the Reconnaissance Survey Field Manual to County Stormwater Staff by December 15 annually, including:

- a listing of identified or suspected illegal discharges and undocumented connections discovered as a result of reconnaissance survey implementation, including names, locations and types of facilities, name of stormwater conveyance systems and the name of the waters receiving nonstormwater discharge;

- a report of the *total miles* of above ground and below ground (greater than 39 inches in diameter) stormwater conveyance system facilities under city jurisdiction and the *total miles of those facilities that were inspected* in the previous year;

- other information that could lead to the identification of illegal/illicit discharges to the storm drain system, such as visual observations or major land use activity changes, and

- any changes to the proposed implementation plan, including time schedule for prosecution of violators and elimination of illegal discharges to the storm drain systems.

Refer to Attachment 1 for the appropriate annual reporting forms, which should be completed and returned to County Stormwater Staff.

VOL 12 2 5211

R0058504

2.2 Data Analysis Report

Description:
The results of the chemical analysis and quantitative data (such as flow, precipitation and water level) will be compiled for each sampling of the drainage area and storm event and for different times during the same storm event. Mass loadings for pollutants of concern will be calculated and the impact of stormwater discharge will be discussed starting with the most significantly impacted receiving waters.

The Data Analysis is due to the Regional Boards annually by January 31.

Action Required:
No action is required of the cities for this report.

2.3 Program Analysis Report

Description:
As lead agency for the co-permittees, the County must prepare an analysis of the effectiveness of the stormwater management program. If the water quality objectives for receiving waters are violated, the County must identify proposed programs that will result in the attainment of the objectives and a time table for implementing new programs. This analysis is to be completed by the County based on the performance of the co-permittees in meeting the requirements of their NPDES permits during the previous year.

The Program Analysis is due to the Regional Boards annually by March 31.

Action Required:
No action is required of the cities.

2.4 Drainage Area Management Plan Status Report

Description:
Co-permittees must complete an annual progress report assessing the reduction of pollutants discharged to local receiving waters and evaluating the effectiveness of BMPs developed to improve the quality of stormwater and urban runoff. The report should further recommend BMP modifications and include a schedule for implementation to achieve compliance with any water quality objectives not attained.

The report will include (1) existing BMPs accepted by the Cities, and (2) proposed changes to BMPs for reducing pollutants in stormwater and urban runoff, including proposed structural and nonstructural controls.

The Drainage Area Management Plan Status Report is due to the Regional Boards annually by July 31.

Action Required:
Cities must submit to the County annually by June 15 a report summarizing progress toward implementation of the DAMP. Because of overlapping information required for other annual

VOL 12 2 5212

R0058505

reports, the necessary information should focus largely on DAMP Sections 5 0 through 8 0 (refer to Attachment 2).

The County, as lead agency, will assess the reduction of pollutants to local receiving waters and evaluate the effectiveness of the BMPs implemented through the DAMP, as required under the NPDES permits.

Section 3.0 details the cities responsibilities toward completing this permit requirement, and Attachment 2 details the information that must be submitted to County Stormwater Staff to complete the annual report.

2.5 Fiscal Analysis Report

Description:

Co-permittees must complete an annual report of all capital, maintenance and operations expenditures incurred in the previous fiscal year to implement the programs necessary under the NPDES permits. The County, as lead agency for the co-permittees, will compile this information and analyze the data.

The Fiscal Analysis is due to the Regional Boards annually by August 31.

Action Required:

Annually, no later than July 15, cities must complete a breakdown of costs and projected costs for the current and coming fiscal year and report any other information relative to the fiscal status of the NPDES program.

Refer to Attachment 4 for the appropriate annual reporting forms and instructions on how to complete them.

2.6 Water Quality Monitoring Progress Report

Description:

The County water quality monitoring program has been in effect since 1973. Additional sampling stations have been added to comply with the NPDES permits.

The Water Quality Monitoring Progress Report is due to the Regional Boards annually by November 30.

Action Required:

No action is required of the cities.

VOL 12 2 5213

R0058506

3.0 DAMP IMPLEMENTATION – PROGRAM REPORTING

3.1 Legal Authority

Description:
The County obtains its authority to control pollutants in stormwater discharges, to prohibit illegal discharges, to control spills and to carry out flood control facility inspections from the Orange County Flood Control Act and the County Water Pollution Control Ordinance.

The County has the authority to enforce and administer the ordinance, including the authority to inspect any violation. The County also has the right to revoke any discharge permit granted under the ordinance if it sees fit.

Action Required:
All co-permittees must demonstrate adequate legal authority to implement the programs of the DAMP (i.e. to regulate the discharge of pollutants to municipal separate storm drain systems).

To accomplish this, in December 1992, the co-permittees initiated a process to develop a model water quality ordinance, an enforcement consistency guide and an enforcement training program. The ordinance is intended to serve as a model for each individual co-permittee to adopt in order to provide adequate legal authority (1) to regulate the discharge of pollutants to municipal separate storm drain systems in Orange County and (2) to implement pollution control programs. **Implementation is set for December 1993.**

3.2 Public Agency Activities

Cities must report their progress toward implementation of each of the Public Agency Activities detailed in this section of the DAMP to the County Stormwater Staff **no later than June 15, 1993** and annually thereafter. This information will be used in the DAMP Status Report, due to the Regional Boards annually by July 31 (refer to Attachments 2 and 3 for the annual reporting forms for each subsection).

3.2.1 Litter Control (DAMP Section 5.2.1)

Description:
Litter control is an important element in the diversion of trash and other materials from the storm drain system.

Action Required:
Cities must examine their individual municipal litter control regulations and provide the County with a description of existing programs. This report must be submitted **no later than June 15, 1993**. The need to propose a draft ordinance or changes to existing regulations will be evaluated as part of the legal authority review detailed Section 4 of the DAMP.

VOL 12 2 5214
R0058507

3.2.2 *Recycling (DAMP Section 5.2.2)*

Description:
Community programs for collection and recycling of nonhazardous solid wastes have already been initiated in most Orange County municipalities in response to the California Integrated Waste Management Act of 1989 (AB 939). No improvements to these programs are proposed as part of the DAMP, but a reporting procedure will need to be implemented to document the volume of potential pollutants diverted from the storm drain systems.

Action Required:
Cities must submit copies of the information required for AB 939 by June 15, 1993, and every year thereafter. Specifically, this means identifying constituent materials by:

(1) volume
(2) percentage by weight
(3) material type
(4) source of generation (residential, commercial, industrial, etc.).

Cities must also submit a brief description of city recycling programs, the methods used to determine the amount and categories of solid wastes recycled and any public education material developed or distributed since the last annual report.

3.2.3 *Drainage Facility Maintenance (DAMP Section 5.2.3)*

Description:
All Orange County co-permittees clean out storm drain inlets, catchbasins and lines within their jurisdiction on an as-needed basis. Some of this information is included in the Reconnaissance Survey Progress Report, due to the Regional Boards annually by February 1.

Action Required:
As required for Reconnaissance Survey activities, Cities must complete the necessary cleaning of drainage facilities on a regular basis. Specifically, cities must:

- inspect all open channels annually before storm season and remove debris as necessary;
- inspect underground facilities of 39" in diameter and larger every two years;
- remove debris and sediment manually or by mechanical methods, using flushing only in emergency situations.

Additionally, to complete this section of the DAMP, Cities must provide the County Stormwater Staff annually, **no later than June 15** and every year thereafter, with:

- copies of facility inspection and maintenance logs that include a description of total volume of materials/debris removed from drainage facilities and estimates of the percentage of paper, plastic material, vegetation, soil and "other" materials;

VOL 12 2 5215

R0058508

- data tables that document the number of drains and the length of channel/pipe cleaned in the previous year, and

- specific information on any facility where evidence of chemical contaminants has been found in the previous year, including the nature, extent and location of the contamination identified.

3.2.4 Catchbasin Stenciling (DAMP Section 5.2.4)

Description:
To alert the public to the issue of nonpoint source pollution and the fact that stormwater is not treated, catchbasins in Orange County are to be stenciled with the phrase "No Dumping -- Drains to Ocean," or a similar variation.

Action Required:
Cities must document the number of catchbasins stenciled by **June 15, 1993** and every year thereafter. The catchbasin stenciling program must be completed by 1995. (This program could be completed as part of a community or volunteer program.)

3.2.5 Street Sweeping (DAMP Section 5.2.5)

Description:
All cities currently have at least monthly street-cleaning programs for residential, commercial and industrial areas.

Action Required:
Cities must submit street sweeping schedules to County Stormwater Staff by **June 15, 1993.**

3.2.6 Hazardous Materials Management (DAMP Section 5.2.6)

Description:
Various city activities involve the use of hazardous materials and the generation of hazardous wastes, including paints, solvents, pesticides, fertilizers and motor oil. As a matter of policy, used motor oil and motor oil filters will be recycled or managed as hazardous waste.

Co-permittees will review and, where appropriate, implement structural or nonstructural improvements to public agency hazardous materials management practices and facilities.

Action Required:
Cities must submit a list of improvements made to public facilities for storage of hazardous materials (defined as sites at which there are aggregate quantities greater than 55 gallons, 500 lbs. or 200 cu. ft.) by **June 15, 1993** and every year thereafter.

VOL 12 2 5216

R0058509

3.2.7 *Household Hazardous Waste Collection (DAMP Section 5.2.7)*

Description:
Orange County has an effective household hazardous waste collection program administered by the Integrated Waste Management Department.

Action Required:
Cities must submit to the County a summary of information on toxic roundups and materials collected by **June 15, 1993** and every year thereafter.

3.2.8 *Emergency Spill Response (DAMP Section 5.2.8)*

Description:
The Orange County Hazardous Materials Area Plan has been adopted by most of the cities. The plan is a set of planned responses to hazardous materials emergencies, addressing chain-of-command, public agency participation and jurisdictional authority.

Action Required:
Cities that do not adopt the countywide plan are expected to develop one of their own. Cities must identify spill response staff and resources by April 1993 and undertake staff training and program implementation by December 1993. Progress toward this implementation must be reported to County Stormwater Staff annually by **June 15.**

3.2.9 *Fertilizer and Pesticide Management (DAMP Sections 5.2.9 and 5.2.10)*

Description:
The proposed Guidelines for Use of Fertilizers and Pesticides was developed as a model for cities to follow in their vegetation management practices.

The guidelines recommend steps for the safest application, storage, transportation, handling and disposal of fertilizers and pesticides that will avoid nutrient loss into and chemical contamination of County storm drain systems. The guidelines specifically address appropriate application methods for fertilizers and pesticides, surface runoff minimization, accident mitigation and Integrated Pest Management (IPM).

Action Required:
Cities are expected to have adopted the Management Guidelines for Use of Fertilizers and Pesticides developed by the County, or a similar plan of their own, by February 1993.

Cities must report by **June 15, 1993**, and every year thereafter, on progress toward implementation of the management guidelines, including the amounts of fertilizers and pesticides used in their jurisdiction, the locations and frequencies of application and steps taken to implement IPM techniques. Refer to Attachment 3 for the details of annual reporting.

VOL 12 2 52117

R0058510

3.3 Public Information

Description:
The co-permittees need to take an active role in educating the public about the issue of nonpoint source pollution and the practices people can adopt to assist in pollution prevention. Educational BMPs will target local officials, public agency personnel and the general public, and they will include developing brochures for distribution, organizing educational workshops and providing speakers for seminars and conferences.

The DAMP specifies education programs (BMPs) for industrial and construction site operations, and programs to facilitate public reporting of illegal discharges. Also, wherever possible, co-permittees will coordinate activities with other agencies running public information programs, such as water and sanitation districts, fire departments and environmental groups.

The County will take the lead in coordinating a countywide public awareness program for the benefit of all co-permittees and will develop regional public information materials to be distributed locally by the co-permittees.

Action Required:
Cities must make public information materials developed by the County available to their local communities. This may be done through homeowners' associations, at County, community and industrial fairs, at community facilities or at public libraries. Individual co-permittees, at their option and expense, may choose to enhance the regional information to address their own specific storm water quality problems.

Co-permittees must report to County Stormwater Staff annually by June 15 on steps taken to further public education and disseminate information pertaining to stormwater quality. Refer to the information requested in Attachment 2.

3.4 New Development

Description:
The DAMP requires that each new development be required to implement appropriate nonstructural, "routine" structural and "special" BMPs as identified by the New Development/Construction Task Force. These measures will be implemented specific to the proposed size, location and type of development in order to minimize pollutant discharge into the drainage system.

The Task Force has completed a BMP plan and Standard Conditions of Approval that, when finalized, will be available for co-permittees to distribute to developers. The plan will provide definitions of BMPs and make recommendations for those that are appropriate for different types of development.

Action Required:
Cities must require that developers complete post-construction stormwater quality management plans, including BMPs to control nonpoint sources of pollution. The County will take the lead in

VOL 12 2 5218

R0058511

developing an educational program for developers and contractors, and cities should help in the local distribution of these materials.

Cities must report annually to the County Stormwater Staff by June 15 the steps taken toward meeting these obligations of the DAMP. Refer to Attachment 2 for the appropriate reporting information.

3.5 Construction

Description:
BMPs that address control of building site-related pollutants must be implemented for construction operations that disturb one acre or more of total land area for an industrial/commercial activity and residential construction sites that disturb five acres or more These BMPs must address erosion control, on-site hazardous materials management and contaminated runoff.

Specifically, stormwater pollution control BMPs must:

- describe site planning procedures that address water quality impact;
- describe the requirements for structural and nonstructural BMPs;
- identify the priorities for inspecting and enforcing pollution control measures; and
- incorporate appropriate educational and training measures for construction site operators.

All programs must consider the nature of the construction, site-specific topography and the characteristics of the soils and receiving waters.

Construction activities disturbing five acres or more of land are also required to comply with the Statewide General Construction Permit.

Action Required:
Prior to issuance of grading, grubbing clearing, surface mining or paving permits for all public or private projects of more than five acres, cities must assure that the project proponent (which may be themselves) has secured a Statewide General Construction Permit. For public works and commercial/industrial projects greater than five acres, cities must also assure compliance with the guidelines established by the co-permittees' New Development and Construction Task Force in Construction Activity Best Management Practices for Public Works (DAMP, Chapter 8 Addendum) before issuance of the appropriate permits to begin construction.

Also, for public works and commercial/industrial projects greater than one acre (but less than five acres), cities must assure compliance with the DAMP, Chapter 7 Addendum. Note that residential construction projects on less than five acres are not affected by this.

VOL 12 2 5219

R0058512

City grading and building inspectors must verify that appropriate NPDES stormwater pollution control measures are in place through inspections (1) at the beginning of construction, (2) during storm events and (3) shortly before a notice of completion is filed
Cities must report annually by June 15 on progress toward implementation of these requirements, on the incorporation of BMPs recommended in the Task Force guidelines into local standard conditions for approval and on the distribution of educational materials to developers.

Refer to Attachment 2 for the annual reporting information due annually to the County Stormwater regarding this program.

3.6 Industrial Discharger Information

Description:
The objective of this section of the DAMP is to identify industrial stormwater dischargers and notify them of the requirements of the Statewide General Industrial Permit. Cities need not retain records of Notices of Intention (NOIs) submitted by industrial dischargers within their jurisdiction. Record-keeping and enforcement responsibilities will be taken by the Region or by the State.

Action Required:
No action is required of the cities for this report.

3.7 Illicit Discharge/Illegal Connection Identification And Elimination

Description:
In order to reduce illegal discharges into storm drain systems, illicit connections will be identified in conjunction with regular storm drain inspections. Also, cities are obligated to implement a facility inspection program for all municipal separate storm sewers as defined by the NPDES permits and approve ordinances to prohibit illicit connections and illegal discharges to municipal storm drain systems.

An implementation schedule was submitted as of January 31, 1992 as part of the Reconnaissance Survey Progress Report, to be updated annually and to include (1) an analysis of inspection results and (2) a list of suspected illegal discharges and illicit connections.

Action Required:
The action required under this section of the DAMP is included in the Reconnaissance Survey Progress Report. Refer to Attachment 1 for the information required.

3.8 Water Quality Monitoring Program

Description:
The County water quality monitoring program has been in effect since 1973. Additional sampling stations have been added to comply with the NPDES permits, evaluating contamination levels before and after storm events. The program will evolve as more data is accumulated and analyzed.

VOL 12 2 5220

R0058513

The Water Quality Monitoring Progress Report, completed annually by November 30 and submitted to the Regional Water Boards for review, addresses the requirements of this section of the DAMP.

Action Required:
No action is required of the cities for this report.

APPENDIX D

R0058515

ORIGINAL
CLERK OF THE BOARD
ORANGE COUNTY

Amendment No. 1 to
National Pollutant Discharge Elimination System
Stormwater Permit Implementation Agreement
Santa Ana/San Diego Regions

This AMENDMENT entered into as of this 26th day of October, 1993 by the County of Orange, (herein called the COUNTY), the Orange County Flood Control District (herein called the DISTRICT), and the Cities of Anaheim, Brea, Buena Park, Costa Mesa, Cypress, Dana Point, Fountain Valley, Fullerton, Garden Grove, Huntington Beach, Irvine, Laguna Beach, Laguna Hills, Laguna Niguel, Lake Forest, La Habra, La Palma, Los Alamitos, Mission Viejo, Newport Beach, Orange, Placentia, San Clemente, San Juan Capistrano, Santa Ana, Seal Beach, Stanton, Tustin, Villa Park, Westminster, and Yorba Linda (herein called the CITIES) adds two additional co-permittees, provides revised participant share calculations, and establishes the NPDES Technical Advisory Committee.

RECITALS

WHEREAS, Section X of the Stormwater Permit Implementation Agreement (hereinafter, AGREEMENT) states that the Agreement may be amended by consent of a majority of the co-permittees which represent a majority of the percentage contributions as described in Section IV of the AGREEMENT; and

WHEREAS, Section VI of the AGREEMENT states that any city which becomes signatory to this AGREEMENT after the applications for the initial NPDES Stormwater permits have been approved shall comply with all of the provisions of this AGREEMENT; and,

WHEREAS, other government bodies or public agencies may request to become a co-permittee to the AGREEMENT.

WHEREAS, program costs and participant share calculations are based on the original 31 co-permittees and do not include calculations for additional co-permittees; and,

VOL 12 2 5223

R0058516

VOL 12

WHEREAS, administrative and technical tasks originally anticipated to be handled by the co-permittees are best handled by a Technical Advisory Committee; and

NOW THEREFORE: The parties hereto do mutually agree as follows:

1. Newly-incorporated co-permittees by their signatures hereon, are added as co-permittees to the AGREEMENT.

2. Participant share calculations shall be recomputed in accordance with the AGREEMENT, as amended, when additional co-permittees are added. Amended calculations and computation method are provided in Exhibit A.

3. The COUNTY as principal permittee may retain the services of professional consultants and may fund, or contribute to funding technical and/or economic studies conducted by professional organizations such as the American Public Works Association.

4. The co-permittees hereby establish a Technical Advisory Committee (herein called COMMITTEE) consisting of five members chosen by the Orange County City Engineers Association, and one member representing the County of Orange. The Committee shall prepare By-laws for Technical Advisory Committee and submit same to the co-permittees for approval. The Committee will act in an advisory role to the co-permittees and implement policy previously established by the co-permittees.

5. This AMENDMENT may be executed in counterpart and the signed counterparts shall constitute a single instrument.

6. This AMENDMENT incorporates the following Exhibits:

Exhibit A - Attachment 1 to Stormwater Permit Implementation Agreement: Revised Participant Share Calculations to account for additional co-permittees and current census data.

VOL 12 2 5259

R0058552

1.0 Introduction

1.1 Purpose

These Bylaws define the membership and authority of the National Pollutant Discharge Elimination System Technical Advisory Committee (hereinafter known as "Committee"). The purpose of the Committee is to serve the co-permittees of the Stormwater Permit Implementation Agreement between the County of Orange, the Orange County Flood Control District, and other participants (hereinafter, collectively known as "co-permittees") in an advisory capacity and help manage and implement the NPDES Permit Program.

1.2 Background

On July 13, 1990, the County of Orange and the Orange County Flood Control District (OCFCD), in cooperation with the Cities, obtained NPDES Permit Nos. CA 8000180 and CA 0108740 for areawide stormwater discharge permits under the National Pollutant Discharge Elimination System (NPDES).

The co-permittees believe the implementation of the stormwater discharge program will be implemented more efficiently and effectively through this Committee. Committee Members serving the Cities will be selected by the Orange County City Engineers Association.

1.3 Stormwater Permit Implementation Agreement

The Stormwater Permit Implementation Agreement (hereinafter known as "Agreement"), executed on December 18, 1990, governs the administration of the NPDES municipal stormwater permits. This Agreement identifies the County of Orange, the incorporated cities, other government entities and the Orange County Flood Control District collectively as co-permittees.

2.0 Technical Advisory Committee

2.1 Formation

The Stormwater Permit Implementation Agreement will be amended to create the Committee.

The Committee will be governed by these Bylaws.

2.2 General Tasks

The Committee will receive, review, recommend and take appropriate actions on all program related matters including financial reports on behalf of the co-permittees. The Committee will where appropriate seek co-permittees approval. The Committee will interpret and implement policy established by the co-permittees and advise co-permittees on matters relating to the program as required by the co-permittees.

The relationship between the Committee and other NPDES program participants is illustrated in Exhibit 1.

VOL 12 2 5260

2.3 Membership

The Committee will consist of six members: Five members each representing a supervisorial district and nominated by the Orange County City Engineers Association via the Orange County League of California Cities.

The sixth member will represent the Director, EMA.

Alternate representatives for appointed members will not be permitted.

2.3.1 Term of Membership

City members will serve three years on a staggered schedule as shown in Exhibit 2.

2.3.2 Committee Chairman

The Chairman will be elected annually by a majority vote of the Committee at its first meeting.

Exhibit 2 lists present and past members of the Committee.

2.4 Meeting Frequency

At least one meeting will be held each year. Additional meetings may be held as required.

2.5 Committee Support

Staff support to the Committee will be provided by EMA - Flood Program Division and Environmental Resources Division, and others as required. The Manager EMA-Flood Program Division or his designee will serve as the Secretary and keep minutes of meeting proceedings.

3.0 Delegated Authority

3.1 Annual Operating Budget

The Committee will formulate, review and recommend annual operating budgets to the co-permittees for approval in accordance with the Agreement and these Bylaws.

3.2 Submittals to Regulatory Authorities

The Committee will review all items submitted on behalf of co-permittees to the regulatory authorities as part of the Agreement.

3.2.1 Stormwater Permit Implementation Agreement

The Committee will review, and submit Stormwater Permit Implementation Agreement amendments to the co-permittees for approval.

VOL 12 2 5261

3.2.2 Drainage Area Management Plan

The Committee will review, and submit the Drainage Area Management Plan and amendments to this Plan to the co-permittees for approval.

3.2.3 NPDES Permits

The Committee will review, and submit new or amended NPDES Permits associated with the Municipal Stormwater discharge program to the co-permittees for approval.

3.2.4 Legislation

The Committee will review all proposed legislation relating to Stormwater Pollution (NPDES) and recommend appropriate action to co-permittees.

3.3 Consultant Selection

The Committee will review Scopes of Work, Requests for Proposals, and consultant slates for providing specialized services related to the NPDES program and make appropriate recommendations on these matters to co-permittees or the County as lead co-permittee.

3.4 Budgetary Items

All budgetary matters will be submitted with recommendations by the Committee for approval by the co-permittees. Budgetary items with recommended action will be submitted in writing to each co-permittee.

4.0 Communication with Others

The Committee may conduct informal communications as necessary with others on behalf of the co-permittees to carry out its delegated authority in implementing program.

EXECUTIVE SUMMARY

This report details a water pollution enforcement implementation program prepared in compliance with the requirements of Orange County's National Pollutant Discharge Elimination System (NPDES) municipal stormwater permits A review of Orange County's existing water pollution enforcement program identifies two areas requiring modification First, the ordinance underpinning the program does not meet current regulatory requirements and second, there is no uniform countywide water pollution enforcement program This program addresses these two issues by proposing development of a new ordinance, increased water pollution awareness amongst local agency staff involved in routine environmental compliance inspections, and the identification and training of enforcement staff to specified criteria (or delegation of enforcement authority to an existing County water pollution enforcement section).

VOL 12 2 5269

R0058562

1.0 INTRODUCTION

Orange County's municipal NPDES Stormwater Permits require the co-permittees to control the discharge of pollutants to waters of the United States through emergency spill response, source control measures, elimination of illegal discharges/illicit connections, and legal authority and its enforcement Source control measures are fully addressed in the Drainage Area Management Plan The County of Orange's planned response to a hazardous materials emergency is comprehensively detailed in the County of Orange Hazardous Materials Area Plan, one of the most sophisticated spill response programs in the nation Many elements of an effective enforcement program, such as the cooperative Orange County Hazardous Materials Strike Force and a water pollution ordinance are also long-established Full implementation of the permit compliance program will, however, require the limited development and implementation of new or modified program elements.

With respect to legal authority and enforcement, the focus of this report, there already exists, within Orange County, an effective and long established water pollution enforcement program. This report therefore proposes modifications to ensure that this program meets current NPDES regulatory requirements The objective of the proposed program is uniform countywide legal authority and enforcement utilizing a revised ordinance and existing environmental compliance programs.

2.0 BACKGROUND

The 1987 Water Quality Act required EPA to promulgate regulations establishing NPDES permit application requirements for stormwater discharges associated with industrial activity, discharges from large municipal storm drain systems (serving a population 250,000) and discharges from medium municipal storm drain systems (serving a population of 100,000 to 250,000). On March 15, 1990, Orange County's 29 constituent cities, in cooperation with the County of Orange and the County of Orange Flood Control District submitted NPDES applications to the Regional Water Quality Control Board (RWQCB) - Santa Ana Region and San Diego Region for area wide NPDES stormwater discharge permits. These applications resulted in the issuance of municipal NPDES stormwater permits in July, 1990.

These permits include requirements for:

- Field inspection and documentation of drainage systems.
- Detection procedures for illegal discharges/illicit connections.
- Ordinances prohibiting illegal discharges/illicit connections.
- An implementation plan for prosecuting violators and eliminating illegal discharges.

VOL 12 2 5270

3.0 REGULATORY REQUIREMENTS

3.1 Introduction

The parameters of a water pollution control program are specified in the municipal NPDES stormwater permits and in EPA regulations (40 CFR Parts 122, 123, and 124) It is appropriate to consider the latter since these regulations and supporting preamble define the nationwide intent of the program and may provide the basis of Orange County's municipal permits upon their renewal in July, 1995

3.2 Municipal NPDES Permit Requirements

NPDES Permits CA 0108740 and CA 8000180 impose two general requirements on the co-permittees, the prohibition of illegal discharges from entering into the municipal storm drain system and the development and implementation of pollutant controls, termed best management practices (BMPs) to the maximum extent practicable More specific requirements for an enforcement program are detailed in subsequent permit sections.

Section V.1 requires submittal, for Regional Board review, of an implementation plan for prosecuting violators and eliminating illegal discharges. Under V 4 this plan is to include a description of the legal authorities for prosecuting violators and eliminating or controlling illicit disposal practices/illegal discharges to the storm drain system, and a proposed time schedule for obtaining such legal authorities.

In V.6 the co-permittees are required to effectively eliminate all identified illegal discharges (i.e., non-stormwater discharges not specifically permitted) and illicit connections in the shortest time practicable, and in no case later than July 1, 1995. Illegal discharges/illicit connections identified after that date are required to be eliminated in the shortest time practicable.

Under the required elements of the co-permittees Drainage Area Management Plan (DAMP), enforcement programs are to include response to emergency incidents, field inspections, and identification and elimination of illegal discharges/illicit connections to the storm drain systems.

3.3 Federal Requirements

Since issuance of Orange County's "early" NPDES permit, EPA rules and regulations were promulgated (Federal Register November 16, 1990 Rules and Regulations, Page 48069). These will likely be the basis of any renewal of the Orange County municipal permits in 1995. Under these regulations the municipality is required to demonstrate "adequate legal authority" to:

- Control the contribution of pollutants to the municipal storm drain system by stormwater discharges associated with industrial activity.
- Prohibit illicit discharges to the municipal storm drain system.

VOL 12 2 5271

- Control spills, dumping or disposal of materials other than stormwater

- Control through interagency agreements amongst co-permittees the contribution of pollutants from one municipality into the common combined flood control/stormwater conveyance system managed by the Orange County Flood Control District.

- Require compliance with conditions in ordinances.

- Carry out all inspection, surveillance and monitoring procedures necessary to determine compliance and noncompliance with permit conditions, and effectively prohibit illicit discharge to the municipal storm drain system.

These federal regulations also require description of a system wide management program, including a schedule to detect and remove (or require the discharger to the municipal storm drain to obtain a separate NPDES permit for) illicit discharges and improper disposal into the storm drain. Specifically, this program is to address:

- Implementing (including inspections and enforcement) an ordinance to prevent illicit discharges to the storm drain system.

- Effective field screening activities.

- Investigating portions of the storm drain system that, based on field screening results or other information, indicate a reasonable potential of containing illicit discharges.

- Prevention, containment, and response to spills.

- Promoting, publicizing, and facilitating public reporting of illicit discharges.

Finally, municipalities are required, to monitor and control pollutants in stormwater discharges to municipal storm drain systems from municipal landfills, hazardous waste treatment, disposal, and recovery facilities, industrial facilities that are subject to Section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986 (SARA) and industrial facilities that are contributing a substantial pollutant loading to the storm drain system. Except for long inactive facilities, all of these also require individual NPDES permit coverage.

4.0 EXISTING PROGRAMS

4.1 Introduction

The elimination of non-stormwater discharges to the municipal storm drain system involves concurrent detection/investigation/enforcement and public education programs. The co-permittees already have programs that facilitate detection of non-stormwater discharges including: drainage facility inspection (Reconnaissance Survey), field screening for gross contamination, industrial facility inspection, and wide distribution of public education materials that provide phone numbers

VOL 12 2 5212

for reporting spills and dumpings

Enforcement requires underlying statutory authority and implementation procedures A water pollution ordinance administered by County staff exists for the unincorporated area, all Flood Control District properties, and most cities Prosecution is handled by the Orange County District Attorney As noted earlier, one element of NPDES compliance will be updating the language of this ordinance

4.2 Detection Programs

4.2.1 Industrial Facility Inspection

A number of different public agencies routinely conduct inspections of industrial facilities. The Orange County Health Care Agency regulates the storage and disposal of hazardous wastes through the Health and Safety Code (H&S Code 6 95 and California Code of Regulations Title 22) Approximately 5500 businesses are inspected annually to ensure proper hazardous waste management.

The Fire Departments in Orange County regulate the storage of hazardous materials through disclosure ordinances such as OCC Sec 4-3-200 to 300) and Article 80 of the Fire Code. This regulation involves facility inspection at over 7000 businesses.

Table 1 Disclosure Program: Businesses regulated by Fire Departments

Fire Department	Number of Businesses in Disclosure Program
Orange County	3,500
Anaheim	1,000
Brea	160
Buena Park	250
Fountain Valley	200
Garden Grove	340
Huntington Beach	500 (inc. 200 oil wells)
Newport Beach	140
Santa Ana	750

Agricultural chemicals, including pesticides and herbicides, are regulated by the Agriculture Commissioner through the State Agriculture Code (California Code of Regulations Title 3, Sec. 6000 et seq.). The Commissioner's office performs facility inspections and initiates enforcement action for non-compliance.

Solid waste disposal at landfills is regulated in the unincorporated areas by the Integrated Waste Management Department of the County of Orange through the County Code (Sec. 4-3-17 to 4-3-147). Waste collection services within the incorporated areas are administered by the individual cities.

VOL 12 2 5273

Discharges to the sanitary sewers are regulated by the County Sanitation Districts of Orange County (CSDOC) in north Orange County and the Aliso Water Management Agency and the South East Regional Reclamation Authority (AWMA/Serra) in the south. Both organizations conduct facility inspections

Municipal code compliance is administered by city and County code enforcement staff. This responsibility includes regulation of land use and land alteration through enforcement of zoning codes included in the Codified Ordinances of each co-permittee municipality Local Code Enforcement staff perform inspections in response to complaints and initiate enforcement actions for non-compliance

4.2.2 Drainage Facility Inspection

All the co-permittees are, under a separate NPDES permit requirement, conducting inspections of their drainage facilities Under the criteria established by the Stormwater Program, surface facilities will be inspected annually and below grade facilities (39" diameter) will be inspected every two yrs.

4.2.3 Field Screening

Field screening is conducted annually at 89 locations throughout the Orange County drainage system. The specific objective of this component of the water quality monitoring program is to detect gross contamination arising from illegal discharges, through analysis for phenols, cyanide, chlorine, copper, chromium, pH and conductivity.

4.2.4 Incident Reporting

The reporting of spills and dumpings is facilitated by the listing of City/County telephone numbers in materials produced and distributed by the Stormwater Program's public education activities. In addition, Orange County "white-page" telephone directories list the County's Water Pollution Section telephone number, while the County's quarterly "Hazardous Waste News" encourages people to report spills and dumpings by dialing 9-1-1.

4.3 Enforcement

4.3.1 Statutory Authority

Local statutory authority to control discharges is embodied in the Industrial Waste Disposal Ordinance, now more widely known as the Water Pollution Ordinance (OCC Sec. 4.3.148 to 190) which has been adopted by twenty Orange County cities and the County of Orange. This ordinance prohibits unpermitted discharges of industrial waste. Specifically, "No person, firm, or corporation shall discharge... any industrial waste in a manner which or may cause pollution of any underground or surface waters." The ordinance also details permitting for dischargers and businesses regulated by its provisions. In addition, city and county staff may variously cite other code sections from the Fish and Game Code, Water Code, Fire Code, and Penal Code, for

VOL 12 2 5274

controlling discharges

Specific limitations associated with the existing ordinance include its definition of regulated industrial waste (" any and all liquid or solid waste substance, not sewage, from any producing, manufacturing or processing operation of whatever nature) which appears to exclude wastes from a wide variety of non-manufacturing situations such as product dispensing operations and releases from vehicles

It is also believed that the following powers will ultimately be needed, none of which are clearly provided in the current language:

a To clean-up and abate illicit discharges, which could include physical removal and consequent expense-liening against title to discharger-owned properties, or in instances of spills in transit, to invoice responsible parties for costs, and pursue cost recovery legal action.

b To control the discharge to the municipal storm drain system of spills, dumping or disposal of materials other than stormwater.

c. To eliminate illicit physical discharge connections to the public storm drain system, and prohibit future connections except by permit or standing agreement.

d. To implement policy and provisions of the Orange County Drainage Area Management Plan, which may include required structural and non-structural controls over construction and new development, and required maintenance of same.

e. To administratively determine how enforcement efforts should be targeted. For example, municipalities may variously wish to conduct enforcement efforts on a prioritized watershed basis, on an area by area schedule, in conjunction with inspections for other purposes, or in response to complaints.

f. To utilize funds generated by all financing mechanism(s) in multi-jurisdiction projects and programs.

g. To control the water quality impacts of uses or activities (i.e., brush clearance, landscaping, paving, and outdoor material storage, for example) that may require no discretionary or ministerial permits.

h. To withhold municipal building and grading permits where other agencies (including state and federal) are prosecuting water resources/pollution violations for an uncorrected condition.

i. To issue correction or fee citations for observed violations.

VOL 12 2 5215

j To issue administrative orders to cease and desist illicit discharges and restrict physical access to public property for activities, operations or businesses that violate orders

k To carry out all inspections, surveillance and monitoring procedures necessary to determine compliance or non-compliance with approved discharge permit conditions or to discover illicit discharges to the storm drain system.

l To pursue retroactive cases (i e , to prosecute without having to prove a spill or discharge occurred after the effective Ordinance date)

m To establish optional alternative criminal/civil approaches to enforcement, including administrative civil penalty assessments.

n To seek public property trespass damages for physical damages caused.

o To establish strict liability for violators.

p In emergency situations, to suspend public or private operations or businesses, or elements of operations or businesses, that by their nature are discharging or threaten to discharge pollutants to the public storm drain system.

4.3.2 Enforcement

Enforcement is the process of effecting legal authority. Investigations of code violations pertaining to water pollution and hazardous materials management are routinely undertaken by various co-permittee agencies including Anaheim and Orange Fire Departments, Irvine and Newport Beach Police Departments, and EMA's Water Pollution Section. Although investigations may be unilateral efforts, more typically they are coordinated with other federal, state and local agencies through the Orange County Hazardous Materials Strike Force. The Strike Force is headed by the Orange County District Attorney's Office and includes representatives of a wide variety of local, regional, and state agencies including:

OCEMA/Water Pollution and Agricultural Commissioner OCHCA/Environmental Health
County and City Fire Departments County Counsel and City Attorneys
Sheriff and City Police Departments
Sanitation Districts and Water Districts
Orange County Integrated Waste Management
California Department of Fish and Game
Regional Water Quality Control Boards (RWQCB)

The agencies coordinate closely on individual cases, with each agency responsible for its own area of expertise. In issues of water pollution, enforcement is generally lead by those authorities with the strongest powers to cite for violations, i.e., California Department of Fish and Game, RWQCB, Coast Guard and EPA.

VOL 12 2 5276

5.0 ENFORCEMENT PROGRAM ELEMENTS

5.1 Introduction

The purpose of this section is to define the necessary elements of an effective water pollution enforcement program Based on the regulatory review in Section 3 0 and the limitations identified in Section 4 0, notably the need for revised legal authority and enforcement expertise, the following required program elements have been identified

5.2 Program Elements

Uniform Program Content - All co-permittees will implement a uniform program to eliminate illegal discharges to the municipal storm drain system The co-permittees collectively will adopt a uniform time schedule to identify and eliminate illegal discharges to the storm drain system

A uniform program throughout Orange County is consistent with the intent of the permits, the federal regulations, the Implementation Agreement, and with direction received from Regional Board Staff.

Adequate Legal Authority
All co-permittees will enact adequate statutory authority to enable them to control stormwater pollution including a prohibition on non-NPDES permitted discharges to the municipal stormdrain system. The establishment of adequate statutory authority is clearly identified in the NPDES permits and federal regulations as the responsibility of all co-permittees.

Assignment of Enforcement Responsibilities
All co-permittees will individually pursue enforcement actions to control storm water pollution or will delegate authority for enforcement to the Flood Control District. The NPDES permits identify the County, as principal permittee, and the cities, as co-permittees, as having responsibility for pursuing enforcement actions. The Implementation Agreement between the co-permittees allows the cities to "name the District as enforcer of a water pollution control ordinance."

It should be made clear that staff other than law enforcement officers or criminal investigators may become intimately involved in enforcement of this program. This is typically the case with local nuisance ordinances, building and zoning code violations, etc., where the bulk of "leg-work", due to practical limitations on the resources of police departments and municipal prosecutors, is borne by other municipal staff.

Special Facilities
All co-permittees will inspect, monitor, and control pollutants in stormwater discharges from landfills, hazardous waste treatment, disposal, and recovery facilities, industrial facilities subject to Section 313 of Title III of SARA, and industrial facilities located in their jurisdictions and determined to be significant sources of stormwater pollutants.

VOL 12 2 52717

Progress Reporting
All co-permittees will submit a progress report for each calendar year that evaluates their program of detecting and eliminating illegal discharges to the storm drain system

Information Systems
Central Reporting "Hot-Line" - The co-permittees will establish and publicize one countywide central phone number for the reporting of illegal discharges.

Listing of Permitted Discharges - The County on behalf of the co-permittees will maintain the list of permitted discharges

Field Inspections
All co-permittees will conduct field investigations of illegal discharges based on reports of spill incidents, determination of illegal connections, referrals from the public and other agencies and evidence of gross contamination from field screening data These activities are specified in the NPDES permits and federal regulations.

Definition of Staff Resources
Each co-permittee will identify staff assigned to perform investigations and admininstratively support those investigations.

Investigator Training Equipment
Co-permittee "investigators" will be trained and equipped to recognize and identify suspected illegal discharges; collect, preserve, and submit samples for analysis utilizing procedures defined in 40 CFR Part 136, SW846, and Standard Methods for the Analysis of Water and Wastewater; and to implement quality assurance/quality control protocols. Co-permittee staff investigators will be trained to collect evidence, utilize chain-of-evidence procedures, carry out surveillance of suspects releasing non-permitted discharges, photo document incidents, prepare reports and compile case submittals.

Investigator Role
Investigators will be available on a 24 hour basis to perform investigations. Criminal prosecution requires a high burden of proof. According to EPA this means that the prosecutor must prove every element of a crime beyond a reasonable doubt. The evidence collected at investigations should be adequate to support a criminal prosecution.

Co-permittee staff investigators may be required to provide both factual and "expert" testimony in hearings and trials per the judicial process to enforce the elimination of illegal discharges.

Finally, investigations of illegal discharges may result in findings that an emergency condition exists threatening life and property.

Staff investigators will be trained to recognize such conditions and to initiate an emergency response using the Orange County Hazardous Materials Area Plan, or

VOL 12 2 5278

equivalent City Plan

Administrative Support
Co-permittee staff will be provided to support all those actions/procedures to eliminate illegal discharges Co-permittee staff will coordinate actions with other agencies and participate in interagency meetings that pertain to the elimination of illegal discharges

6.0 PROGRAM IMPLEMENTATION

This Section details a schedule for implementing the previously described enforcement program elements Based on the regulatory requirements (Section 3 0), a review of existing programs (Section 4 0), and recognition of the need for specific program elements (Section 5 0), the following main areas of program modification are identified Adequate Legal Authority, Information Systems, Field Inspections, and Investigator Training.

6.1 Adequate Legal Authority

To address the issues of "adequate legal authority" a consultant (or the County Counsel) will be retained on behalf of the co-permittees to conduct a thorough review of existing city and county ordinances and to develop a new model Water Quality Ordinance that fulfills state and federal requirements for effective control of discharge to the storm drain system. The schedule for completing this work is detailed in the Drainage Area Management Plan.

- Prepare Request for Proposals (RFP) and Scope of Work - completed October, 1992.
- Recommend consultant to complete study - February 1993.
- Consultant recommendations to co-permittees - December 1993.
- Adoption and implementation by co-permittees - December 1993.

In the interim period, cities will be encouraged to adopt the existing Water Pollution Ordinance.

6.2 Information Systems

Extensive public education efforts already facilitate public reporting of spills or improper waste disposal. During 1992/93, creation of a water pollution telephone "hot-line" will be undertaken to further promote public awareness and program involvement.

- Develop, implement, and advertise water pollution telephone "hot-line" - July 1993 completion.

Information that has been collected identifying all permitted discharges from landfills, hazardous waste treatment, disposal, and recovery facilities, and industrial facilities will be shared so that co-permittee responsibilities for inspection, monitoring, and controlling discharge pollutants may

VOL 12 2 5279

R0058572

be carried out

- Distribute information on permitted discharges to co-permittees - May 1993 completion

6.3 Field Inspections

The industrial facility field inspection programs undertaken by co-permittee agencies other than the Environmental Resources Division of the County EMA are oriented to visual recognition of contamination rather than sources of stormwater pollution These agencies such as City Building, Business License, and Fire inspectors will be formally briefed on water quality protection concerns and provided with contacts to whom discharge information could be passed The schedule would be

- Develop handbook for use by co-permittee agencies (e g , municipal fire departments, inspectors and staff investigators, Orange County Health Care Agency, etc) - June 1993 completion
- Coordinate with other co-permittees - June 1993.
- Implement reporting of discharges - December 1993

Note: Reporting of discharges may be on an informal basis or formalized in Memoranda of Understanding between inspecting and enforcing agency(ies).

6.4 Investigator Training

It is recognized in Section 4.3 that Countywide there is neither uniform legal authority nor uniform water pollution enforcement. Currently, investigation is conducted primarily by EMA in accordance with the current Water Pollution Ordinance Co-permittees may take enforcement actions independently or may arrange for service through the County. Indeed, a number of cities do have effective independent enforcement programs Newport Beach and Irvine, for example, specifically assign police department staff to environmental crime investigations In Anaheim, Huntington Beach and Orange the fire department has primary responsibility.

Section 5.0 details the expertise necessary for staff to undertake effective enforcement. The primary rationale for the required expertise is that enforcement may in certain instances result in criminal prosecution Such prosecution requires a high burden of proof and thus a high degree of competency and technical understanding. This does not, however, preclude less highly trained staff from issuing citations for minor infractions, such an approach is envisioned as one element of the new ordinance.

In addition to designated enforcement staff with specific technical competency, effective enforcement will also require development of an enforcement response guide to ensure that Countywide, staff react in a consistent manner to similar instances of non-compliance.

VOL 12 2 5280

If staff follow documented enforcement procedures, dischargers will not view subsequent regulatory action as subjective, arbitrary or unreasonable. Indeed, the regulated community will recognize that certain violations will always bring a particular enforcement response. Although EPA's guidance manuals for POTW Pretreatment Program Development extensively address enforcement response plans, sanitary sewer protection programs and storm drain protection programs developed in compliance with NPDES Stormwater Permits are not directly analagous.

Consequently, a stormwater-specific enforcement response guide would be developed in conjunction with the proposed Water Quality Ordinance by the selected consultant.

The schedule for implementing an investigation program is clearly governed by the time frame over which legal authority is developed and adopted:

- Identify staff and resources (or delegate authority to EMA) - December 1993
- Develop enforcement response guide completion - December 1993
- Undertake staff training on enforcement guide - December 1993

Note: Investigators may also require training to meet Federal and State OSHA standards related to the variety of hazardous materials which may be encountered in field activities.

- Implementation - December 1993

6.5 Other (technical points)

The permits require annual reporting of progress with enforcement activities. The schedule for preparation of these reports is:

- Submittal of Co-permittee data to County - December 1992, 1993, 1994.
- Compilation of data by County into report form and submittal to Regional Boards - January 1993, 1994, 1995.

Annual Progress Report
For Fertilizer and Pesticide Management

VOL 12 2 5284

R0058577

EXECUTIVE SUMMARY

This document was prepared to fulfill the commitment in the Orange County Drainage Area Management Plan (DAMP), Sections 5 2 9 and 5 2 10, which requires that co-permittees establish guidelines for the management of fertilizers and pesticides

The main objective of these guidelines is to safeguard to "the maximum extent practicable" against unnecessary discharges of fertilizers and pesticides into surface and groundwater systems and to establish safe and reasonable standards for handling those materials The guidelines are based on state and federal laws, environmental policies and "best management practices" established by various public and private agencies

The County and many of the cities have already been following many of these guidelines. However, through this document, it is envisaged that these practices will be adopted by the County and all of the co-permittees to establish a set of uniform standards and procedures.

In addition to management guidelines, this document also includes a summary of the findings of the June 2 fertilizer and pesticide survey, specifically outlining and comparing different aspects of the policies and procedures of the co-permittees.

VOL 12 2 5285

R0058578

1.0 INTRODUCTION

1.1 Status of Fertilizer and Pesticide Use

Fertilizers and pesticides are primary tools of vegetation management Used properly, fertilizers provide important nutrient supplies for vegetation and agriculture, and pesticides help to protect those resources from potential harm.

Used improperly, fertilizers and pesticides can become an impairment to surface and groundwater supplies Careless application, mixing, transportation, storage and disposal allow chemicals to enter surface and groundwater through runoff and infiltration, the same handling problems endanger human health through exposure to toxic chemicals, soil degradation often results from overuse and misuse of pesticides and fertilizers Even under ideal conditions, there is still a high level of risk, and consequently, there is a need for considerable professional planning and management.

1.2 Management Options

Because of the risk involved in using fertilizers and pesticides, the development of management guidelines for use of fertilizers and pesticides is an essential element of the Drainage Area Management Plan (DAMP). These guidelines are designed not only to comply with National Pollutant Discharge Elimination System (NPDES) permitting, but also to minimize any threat to human health and environmental resources from improper use of fertilizers and pesticides. It is envisaged that consideration of these guidelines by the co-permittees will cause public agencies to re-evaluate their approach to using fertilizers and pesticides and move toward reducing dependence on them.

The guidelines that follow are intended for the use of the co-permittees, although they may ultimately be used on a broaderscale. They are based on the laws, management guidelines and "best management practices" established by other federal, state and local agencies. They recognize that the safe management of fertilizers and pesticides is a shared responsibility between the field worker and management. These guidelines address the concern for fertilizer and pesticide use at a basic level, and if followed, they should reasonably prevent environmental damage to the highest degree possible.

1.3 Definitions

For the purpose of these guidelines, fertilizers may be referred to as "nutrients" or "soil nutrients," and the term "pesticides" will encompass all herbicides, insecticides, fungicides and rodenticides. The California Food and Agricultural Code and the California Code of Regulations Title 3 (3 CCR) constitute the laws and regulations referenced in this plan. They are referenced often and usually referred to as the "State Code." Also, co-permittees in the NPDES permits shared by the County and its incorporated cities will be referred to as "public agencies," and employees working for these public agencies who handle fertilizers and pesticides will be referred to as "workers" or "public employees."

VOL 12 2 5286
R0058579

2.0 FERTILIZER MANAGEMENT

2.1 Definition and Scope of Guidelines

Fertilizers are nutrients applied to soil to provide a better growing environment for plants The fertilizers most commonly in use in Southern California today are nitrogen- and phosphorus-based Both leach into soils easily in the presence of water and have become a water quality concern, causing algal blooms and eutrophication and, in some cases, causing levels to exceed federal drinking water standards

However, fertilizers also play the important role of promoting vegetation growth that protects soil from erosion and enhances landscape aesthetics Because there is a necessity for soil nutrients and because there is a potential for adverse effects on local waterways due to the loss of these nutrients through runoff and infiltration, management guidelines are necessary as a means of reducing the loss of fertilizers into water supplies

2.2 General Considerations

2.2.1 State and Federal Law

Because most fertilizers are not as toxic as pesticides, state and federal lawmakers have not developed regulations for their use. Fertilizers are not usually considered an immediate danger to public health or safety. However, the California Fertilizer Association, a Sacramento-based organization, has developed complete management guidelines for fertilizer use and the State Department of Food and Agriculture has recommendations for use of nitrate-based fertilizers, both of which are available for consultation.

2.2.2 General Recommendations

1. Public agencies should periodically test soils before applying fertilizers to be certain that application is appropriate for and compatible with soil conditions. The samples should be analyzed by a qualified specialist, and workers should follow the recommendations for application.

2. Public agencies should choose to use organic fertilizers such as compost, peat and mulch wherever possible to increase soil porosity and water retention.

3. Workers should apply only the minimum amount of fertilizer needed and incorporate it directly into the soil around the plant where possible to minimize potential surface runoff.

4. Workers should not apply fertilizers in the rain or on the same day that rain is expected.

5. Workers should immediately cleanup any spill of fertilizers.

VOL 12 2 52871

R0058580

6 Storage facilities should be covered and have impermeable foundations so that potential spills don't have the opportunity to runoff into surface water or leach into groundwater systems

7 Fertilizers that may be carried by the wind should be stored in areas away from open loading spaces and entrances of storage warehouses.

8 Fertilizers should be securely covered in the vehicle before being taken to application sites so that none can spill or fly out during transport.

9 Use slow release fertilizers -- such as water soluble nitrogen fertilizers, coated fertilizers and fertilizers of limited solubility -- wherever possible to reduce the chances of leaching.

2.3 Planning for Use of Fertilizers

2.3.1 Soil Testing

Most fertilizers travel quickly through water. Therefore, fertilizers will leach through soil and potentially contaminate groundwater more quickly after excess watering or irrigation, after heavy rains and where the water table is high. For this reason, soil testing is an important management technique to determine the safest fertilizer application rate.

The California Landscape Contractors Association (CLCA) has a complete list of organizations in Southern California that offer soil testing and analyzing for fertilizer use. To get a copy of that list, CLCA can be contacted at (916) 448-2522. If a reliable soil analyst is not already known, it is advisable for public agencies to consult CLCA and research a specialist who can make recommendations for fertilizer use.

2.3.2 Application Rates

The amount of fertilizer needed for different applications depends on a number of factors. For specific recommendations, a qualified specialist should be consulted. However, some factors to be considered include:

- the vegetation's ability to use fertilizer;

- the amount of nutrients already in the soil, including fertilizer that may still be present from a previous application;

- the amount of soil nutrients that will or can be obtained from natural processes;

- expected loss of nutrients from the soil, and

- temperature at the time of application.

VOL 12 2 5288

R0058581

2.3 3 Timing

For vegetation with different growth patterns, fertilizers should be applied at different times and in different quantities The vegetation being managed should be researched and fertilizers applied only according to the recommended amounts and at the recommended time intervals so that waste of fertilizer and risk of water contamination are minimized This research should be incorporated in a recommendation from a qualified specialist for fertilizer applications.

2.4 Application Methods of Fertilizers

This section details the most common methods for application of fertilizers These are not the only acceptable methods of fertilizer application Every application has its own unique circumstances and variables to consider A qualified fertilizer specialist should be consulted to recommend the most appropriate application method.

2.4.1 Banding of Fertilizer

Probably the most common and safest application method, this involves physically working small amounts of fertilizer into the soil in a band beneath and around the sides of a seed. It allows new roots to efficiently use the nutrients and minimizes potential nutrient loss to surface runoff. However, given the labor involved, banding may not be practical for most public agency fertilizer applications.

2.4.2 Foliar Fertilization

This is fertilizer applied in solution form that is absorbed through leaves and stems. The method can reduce nutrient leaching into the soil when applied correctly and can be performed at the same time as pesticide applications to avoid spraying twice. In the latter case, the guidelines for pesticide use must also apply.

2.4.3 Broadcast Application

By this method, dry or liquid fertilizer is uniformly spread over the soil surface. This is often done mechanically, an example being the "drop spreader," which is usually an inverted triangle hopper. The simplest of mechanical applicators, the drop spreader is commonly mounted on wheels and pushed by hand or pulled by vehicle to drop fertilizer out the bottom of the triangle.

Other types of broadcast applicators include spray booms for liquid fertilizer or "spinning disks" mounted on a moving vehicle that throw dry fertilizer into the air. It should be noted that these latter methods do not offer much control over fertilizer drift in adverse weather conditions.

VOL 12 2 5289

2.4.4 Fertigation

Although not likely to be used by public agencies for fertilizer applications, this method is common among Californian farmers who incorporate fertilizers into irrigation water. The potential for nutrient leaching using this method, though, appears to be high.

2.5 Storage and Handling of Ferilizers

2.5.1 General Description

When stored and handled properly, fertilizers present no hazard to the users' health. Public employees responsible for storage and handling of fertilizers should be aware that some fertilizers have properties that can result in dangerous chemical reactions if mixed with other substances or under unusual conditions. For example, ammonium nitrate may become explosive if it becomes mixed in diesel fuel, a dehumidifier may be necessary for storage areas where sensitive fertilizers are stored. Also, because most fertilizers tend to be corrosive, concrete structures are preferred for fertilizer storage facilities.

2.5.2 Dry Fertilizer

In most cases, dry fertilizers are safe to store, transport and handle. However, because some fertilizers have unique, potentially dangerous properties, it is advisable for public agencies to consult a qualified fertilizer specialist for the safest storage and handling procedures for specific fertilizers.

2.5.3 Liquid Fertilizer

Fertilizers in liquid form are potentially more hazardous than dry fertilizer. Public employees responsible for storage and handling need to be aware of the specific properties of each liquid fertilizer in use, including corrosivity and tolerable temperature and pressure ranges. Protective equipment may be necessary for workers handling fertilizers such as sulfuric or phosphoric acid. A qualified fertilizer specialist should be consulted for recommending the safest handling and storage procedures for specific liquid fertilizers.

VOL 12 2 5290

R0058583

3.0 PESTICIDE MANAGEMENT

3.1 Definition and Scope of Guidelines

Pesticides are designed to kill or restrict the growth of plants and organisms, and thus, are potentially dangerous chemicals Increasing scientific concern for their safe use and heightened public awareness of health concerns has led to more and more regulations in the United States at both the state and federal level Pesticide use by public agencies often involves applications to keep flood control channels and roadways clear or to minimize health and safety hazards of disease-bearing rodents and insects -- any of these applications can drain into stormwater basins if not controlled properly. Although safety concerns and the cost of complying with new regulations have encouraged some public agencies to cut back on the use of pesticides, use is still common, and their management is therefore essential

3.2 General Considerations

3.2.1 State and Federal Law

The California Department of Food and Agriculture and the federal Toxic Substances Control Act (TSCA) have set forth extensive rules and regulations that must be met by all public agencies. At an absolute minimum, public agencies must comply with these laws or be subject to the penalties described in the statutes.

3.2.2 Chemical Labels and Materials Safety Data Sheets (MSDS)

1. Without exception, chemical labels provided by the manufacturer of each pesticide are the first source of recommendations and instructions for chemical use. Whenever a chemical is to be used by a worker or a contractor of a public agency, the user needs to be intimately familiar with the label instructions and requirements.

As described in the State Code (3 CCR, Ch. 2, Subch. 1, Art. 10), the label must appear on the immediate container of the chemical and include, in prominent, bold type, the appropriate warning or caution statement according to its toxicity classification. If a chemical is transferred to another container, a copy of the label should be transferred with it.

Workers should never handle a container that doesn't have a warning label attached, and the supervisor in charge should be immediately advised of the situation. If a label is badly damaged, it shall be replaced by the supervisor.

2. Workers using pesticides shall have readily available the Materials Safety Data Sheets (MSDS) for each chemical they are using Although the MSDS is a form that may vary in appearance for different chemicals, the information is the same, as required by law. Similar to the chemical labels, these sheets contain information necessary to handle each chemical safely, and all workers shall be familiar with the information.

VOL 12 2 5291

MSDS sheets include chemical identifications, hazardous ingredients, physical data, fire and explosion data, health hazards, reactivity data, spill or leak cleanup procedures, special protection and special precautions.

3.2.3 General Recommendations

1. Public agencies should maintain a complete list of all chemicals and their uses.

2. Public agencies should thoroughly investigate and consider all alternatives to pesticide use.

3. Workers shall use pesticides only according to label instructions.

4. Work crews should bring to the work site only the amount of chemical to be used during the application and use only the minimum amount of the chemical that is necessary.

5. Workers should consider weather conditions that could affect application (for example, they shouldn't spray when winds are exceeding 5 mph, when raining or when rain is likely).

6. Workers should consider area drainage patterns (for example, they shouldn't apply near wetlands, streams and lakes or ponds unless it is for an approved maintenance activity).

7. Workers should consider soil conditions before applying pesticides (for example, they shouldn't apply to bare or eroded ground).

8. Workers shall triple-rinse empty pesticide containers before disposal and use the leftover wash as spray.

9. Workers should never clean or rinse pesticide equipment and containers in the vicinity of storm drains.

10. Pesticides should only be stored in areas with cement floors and in areas insulated from temperature extremes.

11. Workers shall secure chemicals and equipment during transportation to prevent tipping or excess jarring in a part of the vehicle completely isolated from people, food and clothing.

12. Workers or their supervisors should inspect pesticide equipment, storage containers and transportation vehicles daily.

13. Public agencies should adopt a plan for dealing with potential accidents before they happen.

VOL 12 2 5292

R0058585

14 Workers should immediately clean up any chemical spill according to label instructions and notify the appropriate supervisors and agencies

3.3 Planning for the Use of Pesticides

3 3 1 Selection of Appropriate Pesticides

1 Pesticides are to be used only after recommendation from a state-licensed pest control advisor.

2. Public agencies should seek advice for appropriate pesticide use from the Orange County Agricultural Commission, from other professional pesticide handlers and/or through professional publications The County Agricultural Commission can be contacted at (714) 447-7100.

3 A special effort should be made to limit use of restricted pesticides and all other Category One pesticides.

3.3.2 Certification, Licensing and Permitting

1. Pesticides are only to be applied by or under the direct supervision of a state-licensed or certified pesticide applicator or by workers with equivalent training.

2. Chemicals listed as "restricted" in the State of California may be used only under a restricted materials permit (3 CCR Ch. 2, Subch. 4) to be issued by the Orange County Agricultural Commission. The permit must be renewed annually for continued use. For more information, contact the Commission at (714) 447-7100.

3. Other guidelines concerning permits, licensing and certification that need to be followed before pesticide application are detailed in the State Code (3 CCR, Ch. 3, Subch. 1).

3.3.3 Employee Training

1. Public agency employees must know the information on the chemical label and its MSDS before using pesticides in any capacity. In addition, they shall (a) know the immediate and long-term health hazards posed by chemicals to be used, the common symptoms of chemical poisoning and the ways poisoning could occur, and (b) know the safe work practices to be followed, including the appropriate protective clothing, equipment, mixing, transportation, storage, disposal and spill cleanup procedures that apply to the specific chemicals being used.

2. In addition to the training and annual continuing education required by State Law for licensing and certification (3 CCR, Ch. 3, Subch. 3, Art.2), public employees are

VOL 12 2 5293

encouraged to participate in continuing pesticide education programs whenever programs are available

3 3 4 Accident Mitigation

Public agencies using pesticides should have plans for dealing with potential accidents before they happen These plans should consider

1 Labels and MSDS Sheets -- All workers handling pesticides must be familiar with these instructions. The steps for accident mitigation are spelled out on chemical labels and MSDS sheets

2 Spill Cleanup Kits -- Any time pesticides are being handled, there should be a cleanup kit on hand in case of an accident This means there should always be a cleanup kit located in pesticide storage areas, on vehicles used to transport pesticides and on location where the chemicals are being applied Although these kits may vary in what they contain depending on the chemical type and the situation, at a minimum they should include:

- spill-control procedures;
- a five gallon drum with sealable lid;
- a dust pan and broom;
- a squeegee;
- a shovel;
- protective goggles, gloves, boots, coveralls;
- a tarp (for covering dry spills);
- detergent and water (check label or MSDS for proper use);
- barricade tape, florescent traffic safety cones or string to cordon off an area, and
- large sponges, containment booms or some other absorbent material.

3. Cleanup Procedures -- Spilled pesticides must be prevented from entering the local surface and/or groundwater supplies. Specific recommendations for spill cleanup should be available on each chemical label or MSDS. Specific recommendations for the sequence of procedures may also vary depending on the situation. However, generally, in case of a spill, the responsible worker(s) should:

EVALUATE the accident and quickly determine the most immediate concerns (medical and/or environmental).

CONTAIN OR CONTROL the spill.

NOTIFY the supervisor in charge who should, in turn, notify the proper authorities. If contact cannot be made, dial 911.

VOL 12 2 5294

R0058587

ISOLATE the area with fluorescent traffic safety cones, ropes or some other cordoning device to be sure that no one walks, wanders or drives through the spill area.

CLEAN UP the spill as best as possible following label instructions and using the appropriate spill cleanup kit.

EVALUATE any damage that may have occurred resulting from the spill (property damage, health damage, equipment damage, etc) and make notes on all relevant details and circumstances before leaving the scene.

PREPARE A COMPLETE REPORT detailing the incident immediately after leaving the scene upon returning to the work place and submit it to the immediate supervisor.

3.3.5 Emergency Medical Care

Accident situations requiring emergency medical care are likely to involve acute exposure to potentially toxic chemicals. Instructions for handling these exposures appear on the chemical label. Workers should:

1. Be aware of the symptoms of acute exposures for each chemical being used.

2. Have a predetermined strategy for dealing with exposure scenarios, including knowing (a) the label recommendations for dealing with acute exposures and (b) the nearest medical facility where emergency care is available.

3.3.6 Equipment and Equipment Maintenance

All equipment for the handling of pesticides should be inspected and cleaned by workers before each use to ensure that there are no problems that could lead to chemical leaks, spills or accidents during the day's work (3 CCR, Ch. 3, Subch. 3, Art. 2).

3.3.7 Groundwater and Surface Water Protection

Similar to the discussion of leaching in fertilizer management, the main factors determining the rate at which pesticides enter groundwater and surface water systems are chemical mobility, solubility and persistence and the soil type. For example, potentially dangerous chemicals are likely to have a high solubility and an extremely long half-life, and they are not likely to be easily absorbed into the soil. Therefore, chemicals that decompose rapidly may be preferred. However, note that to choose a chemical that may need to be applied two or three times as often may not make sense from a transportation and application risk standpoint.

VOL 12
2
52955

Because of these factors, regardless of the category of chemicals being used, pesticide advisors should periodically test the soil for compatibility with specific chemicals before recommending pesticides for a specific area

Furthermore, because the effect of these uses is not always immediately apparent, public agencies should periodically test areas that could be particularly vulnerable to contamination or deterioration The results of these tests should be kept on public record

3.4 Application of Pesticides

3.4.1 Supervision

1. In cases where supervision of pesticide applications is required by the State Code, supervision must be handled by a state-licensed or certified pesticide applicator For all other pesticides applications, supervision may be handled by workers with equivalent training.

2. Public agencies that contract for pesticide applications should periodically inspect contracted work crews to be certain that contractors are following proper management guidelines. Public agencies handling their own applications should likewise inspect their own work crews on a regular basis to ensure that safety standards are being met

3.4.2 Proper Techniques

1. Read the label carefully and follow application instructions Be absolutely certain that the right chemical is being used for the right job before applying.

2. To prevent potentially harmful runoff, only the absolute minimum amount of pesticides should be used to ensure vegetation safety.

3. Recommendations for best weather conditions to prevent pesticide spray drift are outlined in the State Code, Chapter 2, Subchapter 4, Article 2.

3.4.3 User Safety and Protection

1. Public agencies shall have on hand equipment for application of pesticides including eye protection, gloves, respiratory gear and impervious full-body, chemical resistant clothing when called for by the chemical label.

2. Even when wearing respiratory gear or masks, when dealing with spray applications of pesticides, workers should avoid directly inhaling in the spray mist.

3. Workers should avoid working alone, especially at night.

4. Workers should clean equipment, clothing and self thoroughly after each application.

VOL 12 2 5296

R0058589

5 State laws regarding re-entry into fields that have recently been treated with pesticides shall be followed (3 CCR, Ch 3, Subch 3, Art 3).

6 Public agencies are responsible for knowing and informing workers about the specific pesticides being used including how they are properly handled, the dangers involved and the proper training and safety procedures.

7 Public agencies are responsible for keeping updated records and a complete list of the pesticides being used in their jurisdiction This should include the chemicals, amount in storage, amount of applications, dates and location of applications and pests controlled with each application.

8 Public agencies shall keep all relevant label and MSDS information for each chemical updated and readily available at all times to workers handling the materials.

3.5 Storage, Disposal and Transportation

3.5.1 Proper Storage

1. Storage areas should be away from living areas and in a covered area that is well-insulated from temperature extremes; they should have a cement floor and good ventilation. Also, storage areas should be clearly marked according to state standards and be securely locked at all times when not in use.

2. Public agencies shall ensure that chemical labels on pesticides being stored or used are kept in good condition and attached to all containers holding pesticides (3 CCR, Ch. 3, Subch. 2, Art. 4).

3. Workers should ensure that storage equipment and containers are inspected daily for leaks or defects before being taken on the job. Containers should also be inspected and before storing at the end of the day.

3.5.2 Proper Disposal

1. Workers shall make certain that chemical containers are triple-rinsed before disposal (3 CCR, Ch. 3, Subch. 2, Art.

2. It is recommended that cleaned containers be sent back to the manufacturer for recycling whenever possible. However, once triple-rinsed, most haulers will take them to most landfills.

3. Workers should use left over rinse water as spray.

VOL 12

2

5297

4 Public agencies should ensure that surplus or out-of-date chemicals are given to a licensed hazardous waste hauler for disposal

3 5 3 Safe Transportation Methods

1. Before transporting pesticides, workers shall ensure that all pesticide containers are tightly sealed and secured from tipping or excess jarring (3 CCR, Ch. 3, Subch. 2, Art. 4)

2. Transportation compartments on vehicles shall be isolated from the compartment carrying people, food and clothing and should be securely locked (3 CCR, Ch. 3, Subch. 2, Art. 4).

3. Workers should transport only the amount of pesticide needed for the day to the site.

4. Workers should be certain that the appropriate chemical labels and MSDS sheets, a spill cleanup kit, the location of emergency medical care and a first aid kit are always brought along when transporting pesticides.

5. Public agencies should encourage all vehicles used for pesticide transportation to include radio communications for contacting help in case of a spill or some other emergency.

VOL 12 2 5298

R0058591

4.0 INTEGRATED PEST MANAGEMENT (IPM)

4.1 Background on Pesticide Use

For most of the last 50 years, the trend in vegetation management has been toward a greater reliance on pesticides The result has been not only an enormous increase in the use of many dangerous chemicals, but also an enormous increase in the number of pests that are resistant to the pesticides being produced -- in essence, as more pesticides have been produced, more resistent strains of pests have evolved Worse, recent studies have shown that the end result of this global trend has been no net gain in vegetation survival rates.

With these realizations becoming well-known, vegetation managers are now moving away from their reliance on pesticides and toward an integrated approach that combines limited pesticides use with more environmentally-friendly pest control techniches.

4.2 Scope of Guidelines

For public agencies in Orange County, IPM practices should be preferred to the sole use of pesticides as the primary means of vegetation management. These techniques are designed to prevent overuse and to reduce reliance on them. IPM should be considered by all public agencies or their contractors before intensive use of pesticides.

The goal of IPM is not to eliminate all pests, but to keep their populations at a manageable number. Pesticides are part of IPM techniques, but they are used in small quantities and only after all other alternatives have been reviewed.

4.3 Alternatives to Pesticides

Some of the alternatives to pesticides that may be considered as part of an IPM program include:

1. Introduction of natural predators such as ladybugs, lacewings, garter snakes and toads. Also, some bacteria, viruses and insect parasites may be preferable to pesticides.
2. Selected removal or rotation of vegetation habitat to eliminate the breeding places of specific pests.
3. Weeding, hoeing and trapping manually. Pruning and thinning of trees is also an effective means of preventing epidemic tree insects and diseases.

Also, at certain times of the year and under certain environmental conditions, certain pests can be expected. Therefore, timely planting or well-timed use of small quantities of pesticides may avoid the need for some chemical use.

VOL 12

2

52999

GLOSSARY

TERMS, ABBREVIATIONS, ACRONYMS

RELATED TO THE MANAGEMENT GUIDELINES FOR USE OF FERTILIZERS AND PESTICIDES

Best Management Practices (BMPs)
Schedules of activity, prohibitions of practices, maintenance procedures and other management practices to prevent or reduce the pollution of "waters of the United States." BMPs also include treatment requirements, operating procedures and practices to control plant site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.

California Code of Regulations Title 3, Division 6 (3 CCR)
The State of California code regulating pesticides and pest control operations.

California Fertilizer Association (CFA)
An organization promoting progress in the fertilizer industry in the interest of an efficient and profitable agricultural community. Activities of CFA include developing and disseminating new information to its members and others; supporting production-oriented research programs to identify maximum yield systems for farmers; promoting agronomic topics at our schools, colleges and universities; and maintaining open communications among the industry, universities and other state and federal agencies.

Chemical Labels
As required by federal law, manufacturers of pesticides must provide chemical labels on the containers of all pesticides distributed. These labels include all necessary information on the chemical constituents of the pesticide, including recommendations and instructions for use, toxicity classification and the appropriate warning statements and emergency procedures in case of acute exposures. As required by state law, labels must be kept in good, readable condition and be attached to all pesticide containers at all times.

Co-permittee
A permittee to an NPDES permit that is responsible for permit conditions relating to the discharge for which it is operator. As used in the Stormwater Permit Implementation Agreement, co-permittees are the County of Orange, its incorporated cities and the Orange County Flood Control District.

Drainage Area Management Plan (DAMP)
A document required under the municipal NPDES stormwater permits granted to the co-permittees by the Santa Ana and San Diego Regional Water Quality Control Boards.

VOL 12 2 5300

R0058593

Equivalent Training
A term referring to public agency employees dealing with the application of pesticides who have not received a qualified applicator's license (QAL) from the State of California but who has completed a training course in pesticide application offered by the County of Orange.

Eutrofication
A decrease of dissolved oxygen in a body of water to such an extreme extent that plant life is favored over animal life. For example, a lake that has been overgrown in algae on the surface is likely in a state of eutrofication.

Integrated Pest Management (IPM)
The trend in vegetation management which supports moving away from reliance on pesticides and toward an integrated approach of limited pesticide use with more environmentally-friendly pest control techniques.

Materials Safety Data Sheet (MSDS)
Similar to chemical labels and also required by federal law, these sheets contain all information necessary for the safe handling of pesticides. They include chemical identifications, hazardous ingredients, physical data, fire and explosion data, health hazards, reactivity data, spill or leak cleanup procedures, special protection and special precautions.

Maximum Extent Practicable (MEP)
MEP means taking into account equitable considerations of competing factors including, but not limited to, the gravity of the problem, fiscal feasibility, public health risks, societal concern and social benefits.

National Pollutant Discharge Elimination System (NPDES)
The national program under the Clean Water Act for controlling discharges from point source discharges directly into the waters of the U.S.

Pest Control Adviser (PCA)
Certification obtained from the State of California after demonstrating an adequate knowledge of pests, pesticides and the implications of pesticide use. A recommendation for pesticide use must be obtained from a PCA before public agencies may approve any pesticide applications.

Qualified Applicators License (QAL)
A license obtained from the State of California after demonstrating adequate knowledge of the proper techniques for handling, storing, transporting and applying pesticides. Workers must obtain a QAL before being permitted to apply or supervise application of Category One pesticides.

VOL 12 2 5301

Qualified Fertilizer Specialist
A person designated by the governing public agency who is knowledgeable of the proper techniques for handling, storing, transporting and applying fertilizers as defined in the Management Guidelines for Use of Fertilizers and Pesticides. This person shall be able to sample, inspect, test and make analyses of fertilizers that are in use or being considered for use in the agency's jurisdiction to such an extent that may be necessary to comply with the management guidelines.

Restricted Materials Permit
A permit that must be acquired by any public agency before application of any one of the pesticides listed as restricted by the State of California in the State Code of Regulations Title 3, Division 6. In Orange County, this permit must be obtained from the County Agricultural Commissioner.

State Code
In this report, referring to the State of California Code of Regulations Title 3, Division 6 and referenced as "3 CCR."

Storm Drain
Pipe or channel structure designed to convey only stormwater runoff for purposes of flood protection. Federal regulations use the term "storm sewer." Use of the word "sewer" for a stormwater conveyance structure should be discouraged, since the word "sewer" also includes sanitary sewers and combined sewers which carry human waste.

Toxicity Classification
Pesticides are grouped into three categories by the California Department of Food and Agriculture according to their toxicity or potential for causing injury to people. Category One pesticides are the most hazardous and their use is normally restricted, while Category Three pesticides are least toxic to people and are generally less hazardous.

APPENDIX I

Annual Progress Report
For Fertilizer and Pesticide Management

R0058598

APPENDIX 1
Annual Progress Report for Fertilizer and Pesticide Management

Pursuant to the Drainage Area Management Plan (DAMP), a report must be completed annually by July 31 on co-permittee progress toward implementation of a fertilizer and pesticide management plan Subsequently, this information will be included in the DAMP Progress Report which is required under the co-permittees' NPDES permits and is due to the Regional Water Quality Control Boards annually by July 31 The report will also include a Fertilizer and Pesticides Use Summary Chart similar to the one found in Attachment 1.

As lead agency for the co-permittees, the County is responsible for completing the progress report on the DAMP, and, therefore, each co-permittee must submit the attached annual progress report pertaining to the implementation of the fertilizer and pesticide management guidelines by June 15, 1993 and every year thereafter.

ANNUAL PROGRESS REPORT
FOR FERTILIZER AND PESTICIDE MANAGEMENT
City of _____

I. Fertilizer Management

1. Were any soils in your jurisdiction tested for compatibility with the fertilizers being used (Section 2.3.1)?

Yes ____ No ____

2. Was a qualified fertilizer specialist consulted regarding:

A. fertilizer application rates or timing (Sections 2.3.2 and 2.3.3)? Yes ____ No ____

B. storage of fertilizers (Section 2.5)? Yes ____ No ____

C. handling of fertilizers (Section 2.5)? Yes ____ No ____

3. Were organic or slow release fertilizers used to a greater extent than in previous years (Section 2.2.2)?

Yes ____ No ____

4. Was it necessary to upgrade fertilizer storage facilities to meet the recommendations of the Fertilizer Management Guidelines (Section 2.2.2)? Yes ____ No ____

If so, how?

5. Have you had any reported spills of fertilizers in your jurisdiction in the last year?

Yes ____ No ____

If yes, please explain the circumstances and the steps taken to mitigate the situation (attach a separate sheet, if necessary, or a copy of the incident report).

6. In the course of the last year, to how many acres of land did your jurisdiction apply fertilizers? _____ acres

7. Please attach a complete list of the fertilizers used in your jurisdiction in the last year, and note any changes in the list from the previous year.

VOL 12 2 5307

R0058600

II. Pesticide Management

1 Have all of your pest control personnel (applicators) obtained Qualified Applicators Licenses from the state?

Yes ____ No ____

If no, have they completed the County's equivalent training program (Section 3.3.2)?

Yes ____ No ____

2 Did you test any soils for compatibility with pesticides in the last year (Section 3.3.7)?

Yes ____ No ____

3 Were the recommended inspections conducted, as referenced in the Pesticide Management guidelines, for the following:

A. inspection of pesticide application equipment (Section 3.3.6)?

Yes ____ No ____

B. inspection of contracted and/or in-house pest control crews (Section 3.4.1)?

Yes ____ No ____

C. inspection of pesticide storage facilities (Section 3.5)?

Yes ____ No ____

4. Were the appropriate measures completed for the following, as recommended in the Pesticide Management program?

A. transportation of pesticides (Section 3.5)?

Yes ____ No ____

B. disposal of pesticides (Section 3.5)?

Yes ____ No ____

5. In the course of the last year, to how many acres of land did your jurisdiction apply pesticides? _____ acres

6. Have you had any reported spills or other releases of pesticides in your jurisdiction in the last year?

Yes ____ No ____

If yes, please explain the circumstances and the steps taken to mitigate the situation (attach a separate sheet, if necessary, or a copy of the incident report).

7. Please submit a complete list of the pesticides you have used in the last year, noting any changes in the list from the previous year (indicate which pesticides contain restricted or Category One chemicals).

VOL 12 2 5308

III. Integrated Pest Management

1 Does your jurisdiction currently implement Integrated Pest Management (IPM) techniques as recommended in the Management Guidelines for Use of Fertilizers and Pesticides?

Yes _____ No _____

2 If any, list the specific alternatives to pesticides that were employed by your pest control crews in the last year.

3 Have your work crews reduced the number of pesticides in use in your jurisdiction in the last year as a result of IPM?

Yes _____ No _____

If yes, please quantify the reduction.

1.0 INTRODUCTION

This Appendix was prepared by the New Development/Construction Task Force a group comprising County, City, Building Industry Association, Association of General Contractors, and Civil Engineers & Land Surveyors of California representatives with additional input from the Food Sanitation Advisory Council, Sanitation Districts, and the Western States Petroleum Association In accordance with Sections 7 5 and 8 6 of the DAMP it was reviewed by the Technical Advisory Committee (TAC) and submitted for Co-permittee implementation. Section 1-4 of the DAMP, in discussing Best Management Practices (BMPs) for existing developed areas and areas of new development, states that "The co-permittees will consider such options and will conduct public discussions to hear the views of various members of the community." The composition of the Task Force and the review process reflects such an approach.

The objective in preparing this Appendix was to identify relatively small-scale development source pollutant prevention and treatment measures that could be incorporated into new development. The New Development/Construction Task Force was identified in the DAMP as a program guidance body to recommend which BMPs should be required as standard practice (and when), and which should be viewed as solutions applicable only to special water quality problems, on a case by case basis.

The Drainage Area Management Plan does not specify a minimum development size to be considered for BMP applications, nor does it specify which land uses should receive the most attention. In general, BMPs are required on a wide variety of land uses, both residential and non-residential. BMPs should also be required on accessory uses of concern (such as outdoor material/equipment storage, vehicle/equipment fueling and service) and certain low intensity (but potentially high polluting) uses such as golf courses and plant nurseries.

2.0 REGULATORY REQUIREMENTS

Orange County's municipal NPDES permits require:

> "All new developments and existing facilities with significant redevelopment, irrespective of size, must develop individual, comprehensive, long-term post construction storm water management plans, incorporating structural and non-structural BMPs"; and
>
> "All industrial/commercial construction operations that result in a disturbance of one acre or more of total land area (or smaller parcel of land which is part of a large common development) and residential construction sites that result in a disturbance of five acres or more of total land area (or smaller parcel of land which is part of a larger common development) shall be required to develop and implement BMPs." (Order 90-71, pages 18 and 19).

The requirement for storm water quality management applies equally to private and public projects.

VOL 12 2 5313

R0058606

3.0 BMP SELECTION

Candidate non-point source (NPS) control measures have been selected from review of technical literature, review of existing NPS control programs, and input from consulting firms and municipalities already involved in NPS control program implementation. As required by terms of Orange County's municipal NPDES permits, consideration was given to:

Structural Controls: First flush diversion, detention/retention basins, infiltration trenches/basins, porous pavement, oil/grease separators, grass swales, swirl concentrators, and engineering and design modification of existing structures.

Non-structural Controls: Programs to educate the public on proper disposal of hazardous/toxic wastes, regulatory approaches, street sweeping and facility maintenance, and detection and elimination of illicit connections and illegal dumping.

Each new development will be required to implement appropriate non-structural BMPs in keeping with the size and type of development, to minimize the introduction of pollutants into the drainage system.

Each new development will also be required to implement appropriate "routine" structural BMPs in keeping with the size and type of development. "Routine" structural BMP's are economical, practicable, small scale-measures which can be feasibly applied at the smallest unit of development.

A wide variety of documents from other jurisdictions, including the State BMP Manuals, as well as a number of new development BMP plans approved in the unincorporated area (plus a number in Cities) have been reviewed. The measures identified in Tables 1 and 2 are to be deemed "standard practice" to be required on new developments, as specified.

Later, "special" structural BMPs may be installed to address specific water quality problems identified in the watershed planning process. "Special" structural BMPs are engineered facilities designed to address specific pollutant problems identified in the watershed planning process, runoff management plan, CEQA process, or similar watershed planning. Thus, there will be the future need to revisit these requirements at an as-yet unspecified date or frequency.

3.1 Non-structural Measures

N1. Education for Property Owners, Tenants and Occupants - For developments with no Property Owners Association (POA)[1] or with POAs of less than fifty (50) dwelling units, practical information materials will be provided to the first residents/occupants/tenants on

[1] The term "Property Owners' Association" or POA as used herein means a nonprofit corporation or unincorporated association created for the purpose of managing a common interest development [from California Civil Code Sec. 1351(a)].

VOL 12

2

5314

general good housekeeping practices that contribute to protection of storm water quality initially these materials will be provided by the developer Thereafter such materials will be available through the co-permittees' education program Different materials for residential, office commercial, retail commercial, vehicle-related commercial, and industrial uses will be involved

For developments with a POA and residential projects of more than fifty (50) dwelling units, project conditions of approval will require that the POA provide environmental awareness education materials, made available by the municipalities, to all members periodically Among other things, these materials will descnbe the use of chemicals (including household type) that should be limited to the property, with no discharge of specified wastes via hosing or other direct discharge to gutters, catch basins and storm drains.

N2. Activity Restrictions - If a POA is formed, conditions, covenants, and restrictions shall be prepared by the developer for the purpose of surface water quality protection. Alternatively, use restrictions may be developed by a building operator through lease terms, etc.

N3. Common Area Landscape Management - Ongoing maintenance consistent with County Water Conservation Resolution or city equivalent, plus fertilizer and pesticide usage consistent with County Management Guidelines for Use of Fertilizers and Pesticides, or city equivalent.

N4. BMP Maintenance - Identification of responsibility for implementation of each non-structural BMP and scheduled cleaning of all BMP structural facilities.

N5. Title 22 CCR Compliance - Compliance with Title 22 of the California Code of Regulations and relevant sections of the California Health & Safety Code regarding hazardous waste management, to be enforced by County Environmental Health on behalf of State.

N6. Local Industrial Permit Compliance - Provides for clean storm water discharges from fuel dispensing areas, and requires permission to discharge industrial wastes to public properties.

N7. Spill Contingency Plan - Prepared by building operator for use by specified types of building or suite occupancies (County Environmental Health has provided list to County Building Plan Check, as an example), and which mandates stockpiling of cleanup materials, notification of responsible agencies, disposal of cleanup materials, documentation, etc.

N8. Underground Storage Tank Compliance - Compliance with State regulations dealing with underground storage tanks, enforced by County Environmental Health on behalf of State.

VOL 12 2 5315

N9 Hazardous Materials Disclosure Compliance - Compliance with County and comparable City ordinances typically enforced by respective fire protection agency

N10 Uniform Fire Code Implementation - Compliance with Article 80 of the Uniform Fire Code enforced by fire protection agency

N11 Common Area Litter Control - For developments with POAs, the POA will be required to implement trash management and litter control procedures in the common areas aimed at reducing pollution of drainage water The Associations may contract with their landscape maintenance firms to provide this service during regularly scheduled maintenance, which should consist of litter patrol, emptying of trash receptacles in common areas, and noting trash disposal violations by homeowners or businesses and reporting the violations to the Association for investigation.

N12. Employee Training - Education program (see N1) as it would apply to future employees of individual businesses Developer either prepares manual(s) for initial purchasers of business site or for development that is constructed for an unspecified use makes commitment on behalf of POA to prepare.

N13. Housekeeping of Loading Docks - Loading docks for grocery, drug and discount stores and warehouse type commercial and industrial loading docks must be kept in a clean and orderly condition through a regular program of sweeping and litter control and immediate cleanup of spills and broken containers.

N14. Common Area Catch Basin Inspection - For developments with POAs and privately maintained drainage systems, require the Association to have privately owned catch basins inspected and, if necessary, cleaned prior to the storm season, no later than October 15th each year.

N15. Street Sweeping Private Streets and Parking Lots - For developments with POAs and privately owned streets and parking lots, require the streets and parking lots be swept prior to the storm season, no later than October 15th each year.

N16. Commercial Vehicle Washing - Vehicle exteriors may be washed with tap water or deionized water without the use of soaps or detergents and discharged to the storm drain system. Solvents/degreasers may be used on a spot basis but must be wiped off before the vehicle is rinsed.

VOL 12

2

5316

3.2 Routine Structural BMPs

S1. Filtration - Surface runoff shall be directed to landscaped areas wherever practicable and as recommended by the engineer of record.

S2. Common Area Efficient Irrigation - Physical implementation of landscape plan consistent with County Water Conservation Resolution or city equivalent, which may include provision of water sensors, programmable irrigation times (for short cycles), etc.

S3. Common Area Runoff-minimizing Landscape Design - Group plants with similar water requirements in order to reduce excess irrigation runoff and promote surface filtration.

S4. Community Car Wash Racks - In complexes larger than 100 units where car washing is allowed, a designated car wash area which does not drain to a storm drain system shall be provided for common usage. Wash waters from this area may be directed to the sanitary sewer (in accordance with Attachment A and with the prior approval of the sewering agency), to an engineered infiltration system, or to an equally effective alternative.

S5. Wash Water Controls for Food Preparation Areas - Food establishments (per State Health & Safety Code 27520) shall have either contained areas, sinks, each with sanitary sewer connections for disposal of wash waters containing kitchen and food wastes. If located outside, the contained areas, sinks shall also be structurally covered to prevent entry of stormwater.

S6. Trash Container (dumpster) Areas - Trash container (dumpster) areas to have drainage from adjoining roofs and pavements diverted around the area(s), and:

A. For trash container areas associated with fuel dispensing, vehicle repair/ maintenance, and industry, such areas are to be roofed over or drained to a water quality inlet (see S16), engineered infiltration/filtration system, or equally effective alternative.

B. For trash container areas associated with restaurants and warehouse/grocery operations such areas are to be screened or walled to prevent off-site transport of trash.

S7. Self-contained Areas for Washing/Steam Cleaning/Maintenance/Repair/ Material Processing - Self-contained areas are required for washing/steam cleaning, wet material processing, and maintenance activities, specifically:

A. For businesses where washing of vehicles without steam cleaning occurs, provide wash racks constructed in accordance with the guidelines in Attachment A and with the prior approval of the sewering agency (Note: Discharge monitoring may be required by the sewering agency). Alternatively, refer to N16.

VOL 12 2 5311

B. Where steam cleaning occurs, provide wash racks as in S7A. or structurally contain (with a cover for rain events) runoff from such areas on site for commercial waste removal.

C. Where wet material processing occurs (eg. electroplating), secondary containment structures (not double wall containers) shall be provided to hold spills resulting from accidents, leaking tanks or equipment, or any other unplanned releases (Note: If these are plumbed to the sanitary sewer, the structures and plumbing shall be in accordance with Attachment B and with the prior approval of the sewering agency). Also see N10.

D. Where vehicle repair/maintenance occurs, impermeable berms, drop inlets, trench catch basins, or overflow containment structures shall be provided around repair bays to prevent spilled materials and wash-down waters from entering the storm drain system.

S8 Outdoor Storage - Where a plan of development contemplates or building plans incorporate outdoor containers for oils, fuels, solvents, coolants, wastes, and other chemicals, these shall be protected by secondary containment structures (not double wall containers). Also see N10. For outdoor vehicle and equipment salvage yards, and outdoor recycling the entire storage area shall drain through water quality inlets (see S16.).

S9. Motor Fuel Concrete Dispensing Areas - Areas used for fuel dispensing shall be paved with concrete (no use of asphalt). Concrete surfacing to extend 6 1/2' from the corner of each fuel dispenser in any direction. This distance may be reduced to OR the maximum length that the fuel dispensing hose and nozzle assembly may be operated in any direction plus one (1) foot. In addition, the fuel dispensing area shall be graded and constructed so as to prevent drainage flow either through or from the fuel dispensing area (also see S11.).

S10. Motor Fuel Dispensing Area Canopy - All motor fuel concrete dispensing areas are to have a canopy structure for weather protection, extending over the motor fuel concrete fuel dispensing area as defined in No. 9.

S11. Motor Fuel Concrete Dispensing Area Interruptable Drainage - The concrete motor fuel dispensing area will be graded and constructed so as to drain to an underground clarifier/ sump/tank equipped with a shut-off valve that can stop the further draining of stormwater or spilled material therefrom into the street or storm drain system. Spills will be immediately cleaned up according to Spill Contingency Plan

S12. Energy Dissipaters - Energy dissipaters are to be installed at the outlets of new storm drains which enter unlined channels, in accordance with applicable agency specifications.

S13. Catch Basin Stenciling - Phrase "No Dumping - Drains to Ocean" or equally effective phrase to be stenciled on catch basins to alert the public to the destination of pollutants discharged into stormwater.

VOL 12

2

5318

R0058611

S14 Diversion of Loading Dock Drainage - Below grade loading docks for grocery stores and warehouse/distribution centers of fresh food items will drain through water quality inlets (see S16), or to an engineered infiltration system, or an equally effective alternative.

S15 Inlet trash racks - Where appropriate to reduce intake and transport through the storm drain system of large floatable debris, trash racks shall be provided where drainage from open areas enters storm drains (County EMA Standard Plan 1305 & 1327, CalTrans Standard Plan D96 & D98-C, or City equivalent)

S16 Water Quality Inlets - Water Quality Inlets designed to remove free phase liquid petroleum compounds, grease, floatable debris, and settleable solids can be used in the following applications: S6, S8, S14

4.0 CONSTRUCTION REGULATORY REQUIREMENTS

The municipal NPDES permits state that ... "industrial/commercial construction operations that result in a disturbance of one acre or more of total land area.. and residential construction sites that result in the disturbance of five acres or more...shall be required to develop and implement BMPs...to control erosion and siltation and contaminated runoff from the construction sites."

Construction activities disturbing five acres or more of land will be required to comply with a general Construction NPDES Storm Water Permit from the State Water Resources Control Board. The following is therefore required as a result of the wording of the NPDES permits and applies only to commercial/industrial operations disturbing land areas of one to five acres.

Co-permittees shall ensure that the following requirements are defined on permit plan cover sheets as either general or special notes.

1. Construction sites shall be maintained in such a condition that an anticipated storm does not carry wastes or pollutants off the site.

   Discharges of material other than stormwater are allowed only when necessary for performance and completion of construction practices and where they do not: cause or contribute to a violation of any water quality standard; cause or threaten to cause pollution, contamination, or nuisance; or contain a hazardous substance in a quantity reportable under Federal Regulations 40 CFR Parts 117 and 302.

   Potential pollutants include but are not limited to: solid or liquid chemical spills; wastes from paints, stains, sealants, glues, limes, pesticides, herbicides, wood preservatives and solvents; asbestos fibers, paint flakes or stucco fragments; fuels, oils, lubricants, and hydraulic, radiator or battery fluids; fertilizers, vehicle/equipment wash water and concrete wash water; concrete, detergent or floatable wastes; wastes from any engine/ equipment steam cleaning or chemical degreasing; and superchlorinated potable water line flushings.

VOL 12 2 5319

R0058612

During construction, disposal of such materials should occur in a specified and controlled temporary area on-site, physically separated from potential storm water run-off, with ultimate disposal in accordance with local, state and federal requirements

2 Dewatering of contaminated groundwater, or discharging contaminated soils via surface erosion is prohibited Dewatering of non-contaminated groundwater requires a National Pollutant Discharge Elimination System Permit from the respective State Regional Water Quality Control Board.

5.0 DEVELOPMENT PLANNING

Municipal Storm Water Permit compliance requires that storm water quality management is considered during a project's planning phase, implemented during construction, and ultimately maintained for the life of the project In addition, the program must be adopted and uniformly implemented by all municipalities.

Applying this concept to new development, it is intended that each new development will incorporate the approved program of BMPs to minimize the amount of pollution entering the drainage system.

Standard Conditions of Approval were developed to be implemented countywide to address land use areas of concern. The requirement for a post-construction storm water quality management plan will be specified in each co-permittee's standard conditions of approval. These conditions will require project proponents to submit for approval a proposal identifying the BMPs that will be incorporated into the project to control non-point source pollutants after construction.

Each municipality will require BMPs for specified new development through similar processes. The typical process is outlined as follows:

1. The present municipal procedure for approval of grading, building, and similar permits will be modified to include incorporation of the BMPs listed in Tables 1 and 2, as applicable.

2. Municipalities will make this Appendix, detailing implementation of BMPs, available to applicants through the permitting process. Applicants will be informed at the earliest possible point of processing of these requirements.

3. Applicants will be required to submit a Water Quality Management Plan (WQMP) at appropriate discretionary and ministerial permit issuance levels. The Plan shall include a description of the project and an outline of which BMPs apply to the project pursuant to this Appendix. A sample Plan outline is provided in Attachment C. The Plan shall also include a location map and a project map identifying storm drain facilities and receiving waters.

VOL 12 2 5320

As increasing detail concerning the nature of specific uses within the project becomes available, the WQMP shall be refined

4 Upon review of the WQMP, each municipality will require project incorporation of the identified routine structural and non-structural BMPs.

GENERAL CONDITIONS to be applied by municipalities

Upon discretionary actions that include a precise plan of development:

1. Prior to issuance of building permits, permit applicant shall submit for approval of City/EMA Official(s), a water quality management plan (WQMP) specifically identifying Best Management Practices (BMPs) that will be used on site to control predictable pollutant run-off.

   This WQMP shall identify the: structural and non-structural measures specified in this Appendix detailing implementation of BMPs whenever they are applicable to the project (when the project has a below grade loading dock, for example); the assignment of long-term maintenance responsibilities (specifying the developer, parcel owner, maintenance association, lessee, etc.), and, shall reference the location(s) of structural BMPs.

Upon Subdivisions of Land:

2. Prior to Recordation and if determined applicable by City/EMA Official(s), applicant shall submit a WQMP that identifies the application and incorporation of those routine structural and non-structural BMPs outlined in the Countywide NPDES Drainage Area Management Plan Appendix detailing implementation of BMPs not dependent on specific land uses, for approval of City/EMA Officials.

Upon projects whose discretionary or grading or surface mining or grubbing and clearing or paving approval could result in the surface disturbance of more than five (5) acres, or which is an integral part of an earlier such approval not yet fully implemented (for example, a development area, road, or channel being graded/improved in phases):

3. Prior to issuance of grading or grubbing and clearing or surface mining or paving permits, applicant shall obtain coverage under the NPDES Statewide Industrial Stormwater Permit for General Construction Activities from the State Water Resources Control Board. Evidence this has been attained shall be submitted to City/EMA Official(s).

All three conditions also functionally apply to public projects where the local jurisdiction technically chooses not to issue formal permits to themselves or hired-contractors, but nonetheless undertakes the work.

VOL 12 2 5321

R0058614

SPECIAL CONDITIONS

To address unusual situations, particularly when an unanticipated element of land use or occupancy is proposed after a basic building has already been completed, the County itself applies and recommends application of language similar to the following condition upon permit issuance decisions that involve projects constructed for an unspecified use.

> Prior to issuance of certificates of use and occupancy or building permits for individual tenant improvements or construction permits for a tank or pipeline, uses shall be identified and, for specified uses, the applicant shall propose plans and measures for chemical management (including, but not limited to, storage, emergency response employee training, spill contingencies and disposal) to the satisfaction of the EMA Official(s).
>
> Chemical management plans shall be approved by the EMA Official(s)and other specified agencies such as County Fire, the Health Care Agency, and sewering agencies to ensure implementation of each agency's respective requirements. Further, a copy of the approved "Chemical Management Plans" shall be furnished to the EMA Building Official, prior to the issuance of any certificates of use and occupancy.
>
> Certificates or permits may be ministerially withheld if features needed to properly manage chemicals cannot be incorporated into a previously completed building, center, or complex..

For the County, the Health Care Agency Environmental Health and Fire Department have provided a list of specified uses/occupancies of concern to Building Plan Check.

6.0 EDUCATIONAL PROGRAM FOR DEVELOPERS AND CONTRACTORS

The following defines the required educational program for developers and contractors per DAMP Section 7.3.

This Appendix with its attachments will contain the legal, administrative, and technical information needed to acquaint developers and contractors with the NPDES program. Orange County developers and contractors have been implementing erosion control plans for many years and are familiar with that portion of the program. New requirements resulting from the NPDES Permit and the DAMP are contained herein.

The Building Industry Association and the Associated General Contractors have been asked to assume responsibility for alerting their members of the information contained in this Appendix. The Appendix text will be made available by the County and Cities as part of the development review process.

VOL 12 2 5322

COUNTY SANITATION DISTRICTS OF ORANGE COUNTY

Guidelines For Preventing Sewer Discharge Of Surface Runoff Through wash Pads August 1992

Purpose And Scope

These guidelines are established pursuant to Section 203 of the Districts' Wastewater Discharge Regulations (Ordinance) as amended February 7, 1992. Section 203 provides that

> No person shall discharge groundwater, surface runoff, or subsurface drainage to the Districts' sewerage facilities except as provided herein Pursuant to section 305, et seq., the Districts may approve the discharge of such water only when no alternate method of disposal is reasonably available or to mitigate an environmental risk or health hazard.

The Guidelines presented herein are intended for the implementation of this policy as it applies to preventing surface runoff from entering the Districts' sewerage system through exposed wash pads.

Application

Two sources from which surface runoff can potentially enter the Districts' sewerage system are the exposed area around the wash pad and the wash pad itself.

Exposed Area Around the Wash Pad: Appropriate measures must be taken to insure that surface runoff from the exposed area around the wash pad (e.g. parking lot, storage areas) does not enter the sewer. Surface runoff must be directed away from the sewer. Appropriate measures include grading the open area to redirect surface runoff to the storm drain; berming around the wash pad; or trenching around the wash pad with grating over the trench, and directing the collected water to a storm drain in accordance with stormwater discharge requirements.

The Wash Pad: Appropriate measures must be taken to insur that surface runoff from the wash pad itself does not enter the sewer. Provided that local regulations are satisfied, roofing will be required for all exposed wash pads which have a total area exceeding 150 square feet. If the roof structure does not include walls, then the roof's overhang must extend a minimum of 20 percent of the roof's height. All roof drains must be routed to a storm drain.

Where roofing of exposed areas is infeasible or prohibited by local regulations, the Districts may accept the use of an automated surface runoff diversion system. [Note: This diversion system will not substitute for the appropriate measures cited above for surface runoff from the exposed area around the wash pad.] In cases where a diversion

VOL 12 2 5333
R0058616

system is installed, only the first 0 1 inch of rainwater will be allowed to enter the sewer After the first 0 1 inch of rainfall, excess rainwater must be diverted to an appropriate drainage system by use of an automated divrsion system The diversion system is subject to acceptance by the Districts Manual methods of diversion (e g manual gates, removable plugs) are not acceptable Companies are responsible for maintaining the automated diversion system in proper operating condition to ensure that no excess surface runoff from the wash pad is discharged to the sewer

VOL 12 2 5324

ATTACHMENT B

COUNTY SANITATION DISTRICTS OF ORANGE COUNTY

Minimum Requirements For Spill Containment

1. Elimination of all floor drains in the wet process area.

2 Installation of containment facilities to hold any drag-out process materials or spills resulting from employee accidents, leaking tanks or orher equipment, or any other accidental releases Installation of structures to seal the floor at any potential wastewater discharge points.

3. Provide direct plumbing of all overflow or final rinse tanks and concentrated waste/wastewater to the pretreatment system or holding tank. Regulated process wastewater may be plumbed to downstream of the pretreatment system, but upstream of the sample point, if it can be shown by sampling and analysis to meet permit limitations. An analysis report of these waste streams by-passing treatment must be submitted for Districts' approval.

4. Spill containment (SC) volume requirements:

   - o If the SC is inside (covered), the volume must be equal to 110% of the largest tank or 10% of the total process tank volume inside the bermed area (whichever is larger). An additional 1" of freeboard or height must be added.
   - o If SC is outside (outdoors), use the inside criteria plus capacity to hold a rainfall of 24 hours based on a 25 year storm. An additional 1" of freeboard or height must be added.
   - o Appropriate deductions to the spill containment volume shall be made for tanks and/or equipment occupying the same spill containment area.

5. Separation of incompatible chemicals with a berm or other impermeable barrier.

6. All berm penetrations or leaks must be sealed.

7. The floor and berm must be made or coated with material capable of withstanding spills of the chemicals being stored.

8. Spill containment is also required in the pretreatment system area to prevent hazardous chemicals used in the pretreatment system and untreated wastes from entering the sample point.

1.0 INTRODUCTION

This Appendix fulfills requirements of Section 8 6 2 of the Drainage Area Management Plan (DAMP) for developing a public works construction storm water pollution prevention program to regulate public works construction The requirements are modeled after the State General Construction Activity Storm Water Permit Federal and State regulations and related information are incorporated by reference A storm water pollution control program will be implemented to reduce pollutants in storm water run-off from construction sites to the maximum extent practicable. This Appendix provides guidance to co-permittees for uniform implementation of NPDES requirements and individual co-permittees will continue to retain the ability to add, amend, or delete specific requirements to reflect local conditions.

2.0 REGULATORY REQUIREMENTS

This Appendix applies only to co-permittee public works construction projects Public works construction projects shall comply with the State General Construction Activity Storm Water Permit (Construction Permit) where applicable. Co-permittees awarding a public works construction contract shall submit a Notice of Intent (NOI) to the State Water Resources Control Board.

3.0 BEST MANAGEMENT PRACTICES FOR PUBLIC WORKS CONSTRUCTION

3.1 General Criteria

Public works construction activities will implement non-structural (source control) and structural Best Management Practices (BMPs) to control contaminated storm water run-off to the maximum extent practicable (MEP), where MEP is defined in the NPDES permit as "...the maximum extent possible, taking into account equitable considerations of synergistic, additive, and competing factors, including but not limited to, gravity of the problem, fiscal feasibility, public health risks, societal concern, and social benefits."

BMPs selected are to be based on rational criteria including magnitude and type of potential pollutants, water quality objectives of receiving water bodies, and the principle of MEP. As a minimum, BMP selection shall be consistent with the State General Construction Activity Storm Water Permit. A BMP list with corresponding reference documents is provided for information purposes as Exhibit A.

Figure 15 from APWA's Special Report No. 61 "Water Quality: Urban Run-off Solutions", reproduced as Exhibit B, provides guidance on restrictions to BMP use.

Other sources for BMPs are found in co-permittee's approved standard plans and BMPs listed in the State General Construction Activity Storm Water Permit and other Environmental Protection Agency documents. Another reference on storm water retention for removal of pollutants other than sediment is found in "Methodology for Analysis of Detention Basins for Control of Urban Run-off Quality", EPA440/5-87-001.

VOL 12 2 5333

R0058626

3.2 Sediment and Erosion Control

Ordinances regulating sediment and erosion control are found with most if not all co-permittees In the absence of such ordinances, the County of Orange Grading and Excavation Code (Title 7, Division 1, Article 8 of the Codified Ordinances) and the County of Orange Grading Manual (Board of Supervisors Resolution No 81-1358) are considered as meeting the sediment and erosion control requirements Grading and excavation codes of co-permittees not inconsistent with the County codes considering local conditions, are also considered as BMPs meeting the sediment and erosion control requirements The State General Construction Activity Storm Water Permit BMPs are also considered as suitable for meeting the sediment and erosion control requirements.

Where desilting is found to be required for sediment control, appropriate BMPs such as the Orange County Environmental Management Agency Standard Plans 1326-Pipe Entrance to Earth Channel, 1327-Desilting Basin, 1328-Sandbag Velocity Reducer, 1329-Street Desilting Basin, and 1330-Temporary Drainage Inlet (attached as Exhibit C) are considered as meeting sediment control requirements. Similar or equivalent sediment control BMPs of other co-permittees, not inconsistent with the County Standard Plans, considering local conditions, are also considered as meeting the sediment control requirements.

3.3 Public Works Construction Practices

Public works construction practices from the latest edition of "Standard Specifications for Public Works Construction" (SSPWC) are considered as meeting the sediment, erosion, and pollutant control requirements in the Municipal NPDES permits.

The following specific construction practices for public works construction are found in SSPWC Section 7 - "Responsibilities of the Contractor", and will be followed by contractors working for co-permittees:

- **Cleanup and Dust Control**

  Throughout all phases of construction, including suspension of work, and until final acceptance of the project, work site shall be kept clean and free from rubbish and debris. Dust nuisance will be abated by cleaning, sweeping, and sprinkling with water, or other means as necessary. The use of water resulting in mud on public streets will not be permitted as a substitute for sweeping or other methods.

  Where appropriate and when required a self-loading motor sweeper with spray nozzles will be used at least once each working day to keep paved areas acceptably clean wherever construction, including restoration, is incomplete.

  Materials and equipment shall be removed from the site as soon as these are no longer necessary, and upon completion of the construction project, the site shall be cleared of

VOL 12 2 5334

equipment, unused materials, and rubbish so as to present a clean and neat appearance

Care shall be taken to prevent spillage of earth or construction materials offsite Any such spillage shall be removed immediately and the area cleaned

- Sanitation

All enclosed toilets for the use of employees at the construction site shall be maintained in a neat and sanitary condition These facilities shall comply with all applicable laws, ordinances, and regulations pertaining to the public health and sanitation of dwellings and camps.

Sanitary sewage flow shall not be interrupted. Should the Contractor disrupt existing sewer facilities, sewage shall be conveyed in closed conduits and disposed of in a sanitary sewer system Sewage shall not be permitted to flow in trenches or be covered by backfill

- Water Pollution Control

Construction activities will be conducted in a manner to protect channels, storm drains, and bodies of water from pollution. Also, the operations shall be scheduled so as to minimize or avoid muddying and silting of said channels, drains, and waters. Water pollution control work shall consist of constructing necessary facilities when required to provide prevention, control, and abatement of water pollution.

- Drainage Control

Drainage within and through the work areas will be maintained. Temporary dams of sandbags, asphaltic concrete, or other acceptable material will be used to protect the work site as appropriate. Such temporary dams shall be removed from the site as soon as their use is no longer necessary.

- Storage of Equipment and Materials in Public Streets

Construction materials shall not be stored in streets, roads, or highways for more than 5 days after unloading. All materials or equipment not installed or used in the construction within 5 days after unloading shall be stored elsewhere unless authorized additional storage time.

Excavated material, except that which is to be used as backfill in the adjacent trench, shall not be stored in public streets, roads, or highways unless otherwise permitted. After placing backfill, all excess material shall be removed immediately from the site.

- Special Hazardous Substances and Processes

VOL 12 2 5335

Material usage shall be accomplished with strict adherence to California Division of Industrial Safety requirements and all manufacturers' warnings and application instructions listed on the Material Safety Data Sheet and on the product container label

4.0 STORM WATER POLLUTION PREVENTION PLAN (SWPPP)

For public works construction activities that result in a disturbance of five acres or more of total land area (or a smaller construction site which is part of a larger common project), a Storm Water Pollution Prevention Plan (SWPPP) will be prepared and implemented The SWPPP shall be consistent with the State General Construction Activity Storm Water Permit and the provisions of this Chapter.

Public Works construction activities less than 5 acres are required by the DAMP to comply with appropriate pollution prevention control practices in accordance with the current edition of Standard Specifications for Public Works Construction, and the provisions of this Chapter

5.0 MONITORING PROGRAM AND REPORTING REQUIREMENTS

Public works construction activities requiring a SWPPP will also require preparation and administration of a storm water monitoring program. The monitoring program will be consistent with the State General Construction Activity Storm Water Permit.

5.1 Implementation

Each co-permittee will be responsible for implementing these requirements until construction activity is complete.

For ongoing construction activity involving a change in ownership of property covered by this Permit, each co-permittee will insure that the new owner implements the requirements of the Section concurrent with the change of ownership.

5.2 Site Inspections

The construction inspector, accompanied by the contractor will conduct inspections of the construction site prior to anticipated storm events and after actual storm events to identify areas contributing to a storm water discharge associated with construction activity and to evaluate whether measures to reduce pollutant loadings identified in the SWPPP are adequate and properly implemented in accordance with the terms of the Permit or whether additional control measures are needed. A record of the inspections will include the date of the inspection, the individual(s) who performed the inspection and the observations.

5.3 Non-compliance Reporting

Each co-permittee will notify the appropriate Regional Water Board if compliance cannot be certified and/or if there are other instances of non-compliance. The notifications will identify the

VOL 12 2 5336

type(s) of non-compliance, describe the actions necessary to achieve compliance, and include a time schedule, subject to the modifications by the Regional Water Board, indicating when compliance will be achieved Non-compliance notifications will be submitted within 30 days of identification of non-compliance

5.4 Monitoring Records

Each co-permittee will retain records of all inspections, compliance certifications, and non-compliance reporting for a period of at least three years With the exception of non-compliance reporting, these records need not be submitted to the State

For purposes of compliance with the Municipal NPDES permit, each Co-permittee will report instances of non-compliance in the annual reconnaissance report to the County, and will maintain the monitoring records in Co-permittee files on each public works project

6.0 TRAINING PROGRAM FOR PUBLIC AGENCY STAFFS

To insure uniform enforcement, all grading, building, and public works construction inspectors, and all other appropriate public agency staff members will be provided adequate training. A general training program will be developed by the Environmental Management Agency and be provided to all co-permittees The training objectives include but are not limited to.

- Historical background and Federal Acts
- EPA and State NPDES regulations - Construction and Industrial permits
- Municipal NPDES permits and storm water Permit Implementation Agreement
- Selection of BMPs for pollutant control
- Inspection of non-structural BMPs
- Monitoring requirements

7.0 EDUCATION PROGRAM FOR PUBLIC WORKS CONTRACTORS

Contractor training will be included as part of pre-job conferences, to address:

- Historical background, Federal, State, Municipal NPDES regulations.
- State General Construction Storm Water Permit
- Selection of BMPs for pollutant control
- Compliance with Municipal NPDES permit

APPENDIX I

R0058638

Did You Know You May Need a Storm Water Permit?

(whether or not you have materials that contact storm water)

What the Clean Water Act requires

In 1972, the Federal Water Pollution Control Act (also referred to as the Clean Water Act or CWA) was amended to provide that the discharge of pollutants to waters of the United States from any point source is effectively prohibited, unless the discharge is in compliance with a NPDES permit. The 1987 amendments to the CWA established a framework for regulating municipal and industrial storm water discharges under the NPDES program. On November 16, 1990, the Federal Environmental Protection Agency (EPA) published final regulations that establish application requirements for storm water permits. The regulations require specific categories of industrial facilities to obtain an NPDES permit.

The regulations allow authorized states to issue general permits or individual permits. The State Water Resources Control Board has elected to issue a statewide general permit that will apply to all dischargers, except those performing construction activities. There is a separate general permit for construction activities.

Coverage under the general permit requires that dischargers:

- Eliminate non-storm water discharges (including illicit connections) to storm water systems;
- Develop and implement a storm water pollution prevention plan; and,
- Monitor discharges to storm water systems.

VOL 12 2 5346

R0058639

Who must have a Permit

The permit extends to facilities described in the categories below, whether the activity is primary or auxiliary (a complete list of facilities is shown on the back page).

- Facilities subject to storm water effluent guidelines (40 CFR Subchapter N);
- Manufacturing facilities;
- Mining and oil and gas facilities;
- Hazardous waste treatment, storage, or disposal facilities;
- Landfills, land applications sites, and open dumps that receive industrial waste;
- Recycling facilities such as metal scrap yards, battery reclaimers, salvage yards, and automobile yards;
- Steam electric generating facilities;
- Transportation facilities;
- Sewage treatment plants; and,
- Any facilities where materials are exposed to storm water.

How to obtain Permit coverage

To obtain authorization for continued and future industrial storm water discharge, owners, or operators when the owners do not operate the facility, must submit a Notice of Intent Form (NOI) to be covered by the Permit. Certification of the NOI signifies that the discharger intends to comply with the provisions of the permit.

EPA's regulations exclude dischargers covered by a general permit from submitting individual permit applications. The NOI requirements are intended to establish a mechanism which can be used to obtain a clear accounting of the number of dischargers complying with the permit, their identities, the nature of operations at their facilities and the location of such facilities. A $250 annual fee is required for coverage under the general permit.

VOL 12 2 5341

Where to file for Permit coverage

The NOI, accompanied by the annual fee, should be sent to the following address:

State Water Resources Control Board
Division of Water Quality
PO Box 1977
Sacramento, CA 95812-1977
Attention: Storm Water Permit Section

The submittal of an NOI to the SWRCB is the initial step in the permit application process. By submitting the NOI, you are committing to several follow-up activities. These include preparation of a Stormwater Pollution Prevention Plan (SWPPP), establishment of an on-site monitoring program, implementing Best Management Practices (BMP's) and record retention/reporting activities.

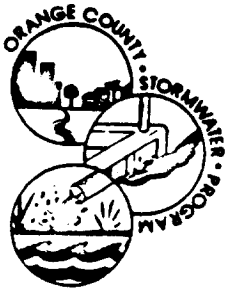
Facilities that discharge industrial storm water and do not obtain coverage under this Permit or by an individual permit will be in violation of the Clean Water Act and the California Water Code. There are substantial fines that can be pursued by the State or Regional Boards, EPA or by private citizens.

When to file for Permit coverage

A completed NOI must be filed no earlier than January 15, 1992 and no later than March 30, 1992. Facilities beginning operations after March 30 must submit an NOI 30 days prior to the beginning of operations.

Who to call for more information

The State Water Resources Control Board Water Quality Order No. 91-13-DWQ, "Waste Discharge Requirements for Discharges of Storm Water Associated with Industrial Activities Excluding Construction Activities," plus a related fact sheet and NOI, can be obtained by calling Jesse M. Diaz, 916/657-0756; Archie Mathews, 916/657-1110; Don Perrin, 916/657-1288; or Leo Cosentini, 916/657-1009. State Board staff can also answer any questions you may have regarding the Permit.



This newsletter has been prepared by the Orange County Storm Water Program, a cooperative project of the Orange County Flood Control District, the County of Orange and its incorporated cities, in compliance with its municipal NPDES Permit.

VOL 12 2 5348

R0058641

Facilities Covered By the General Permit

Industrial facilities include Federal, State, municipally owned, and private facilities from the following categories:

Facilities subject to storm water effluent guideline limitations: Includes categories of facilities specified in 40 CFR* Subchapter N. Currently, these are cement manufacturing (40 CFR 411), feedlots (40 CFR 412), fertilizer manufacturing (40 CFR 418), petroleum refining (40 CFR 419), phosphate manufacturing (40 CFR 422), steam electric (40 CFR 423), coal mining (40 CFR 434), mineral mining and processing (40 CFR 436), ore mining and dressing (40 CFR 440) and asphalt emulsion (40 CFR 443).

Manufacturing facilities: Standard industrial classifications (SICs*) 24 (except 2411 and 2434), 26 (except 265 and 267), 28 (except 283), 29, 311, 32 (except 323), 33, 3441 and 373.

Oil and gas/mining facilities: SICs 10 through 14 including active or inactive mining operations (except for areas of coal mining operations meeting the definition of a reclamation area under 40 CFR 434.11(l) because of performance bond issued to the facility by the appropriate Surface Mining Control and Reclamation Act (SMCRA) authority has been released, or except for area of non-coal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990 and oil and gas exploration, production, processing or treatment operations or transmission facilities that discharge stormwater contaminated by contact with or that has come into contact with any overburden, raw material, intermediate products, finished products, by-products or waste products located on the site of such operations. Inactive mining operations are mined sites that are not being actively mined, but which have an identifiable owner/operator. Inactive mining sites do not include sites where mining claims are being maintained prior to disturbances associated with the extraction, beneficiation or processing of mined material, nor sites where minimal activities are undertaken for the sole purpose of maintaining a mining claim.

Hazardous waste treatment, storage or disposal facilities: Includes those operating under interim status or a permit under Subtitle C of the Resource Conservation and Recovery Act (RCRA).

Landfills, land application sites and open dumps: Sites that receive or have received industrial waste from any of the facilities covered by this permit, sites subject to regulation under Subtitle D of RCRAs and sites that have accepted wastes from construction activities (construction activities include any clearing, grading or excavation that results in disturbance of five acres or more).

Recycling facilities: SICs 5015 and 5093. These codes include metal scrapyards, battery reclaimers, salvage yards and automobile junkyards.

Steam electric power generating facilities: Includes coal handling sites.

Transportation facilities: SICs 40, 41, 42 (except 4221-25), 43, 44, 45 and 5171 which have vehicle maintenance shops, equipment cleaning operations or airport deicing operations. Only those portions of the facility involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling and lubrication) or other operations identified herein that are associated with industrial activity.

Sewage or wastewater treatment works: Facilities used in the storage, treatment, recycling and reclamation of municipal or domestic sewage, including land dedicated to the disposal of sewage sludge that are located within the confines of the facility, with a design flow of one million gallons per day or more, or required to have an approved pretreatment program under 40 CFR Part 403. Not included are farm lands, domestic gardens or lands used for sludge management where sludge is beneficially reused and which are not physically located in the confines of the facility, or areas that are in compliance with Section 405 of the CWA.

Manufacturing facilities where materials are *exposed* to stormwater: SICs 20, 21, 22, 23, 2434, 25, 265, 267, 27, 283, 285, 30, 31 (except 311), 323, 34 (except 3441), 35, 36, 37 (except 373), 38, 39 and 4221-4225.

*CFR refers to the Code of Federal Regulations available at major libraries. SIC code descriptions are in the Standard Industrial Classification Manual prepared by the Executive Office of the President, Office of Management and Budget, available at most libraries.

R0058642

State to Regulate Construction Discharges

Sites Greater Than Five Acres May Need a Storm Water Permit

Who Needs a Construction Permit

If your construction project involves five acres of land area or more, you probably need coverage under the State of California's new General Construction Activity Storm Water Permit. The Permit, adopted by the State Water Resources Control Board (State Water Board), is part of the federal National Pollution Discharge Elimination System (NPDES) storm water program that regulates pollutants in municipal and industrial discharges, including both private and public sector construction activity.

Under the General Construction Permit, "construction" is defined as site activity that involves any clearing, grading or excavation, or site activity subject to water quality certification for dredging and filling that is not already regulated by the Army Corps of Engineers. Construction sites that are less than five acres but are part of a larger, common development plan must also obtain coverage under the Permit.

Construction projects that are exempt from this criteria include routine maintenance activities such as maintaining original line and grade, hydraulic capacity and the original purpose of the facility, or emergency construction that is necessary to protect public health and safety. If uncertain, operators of facilities should confirm with their local Regional Water Quality Control Board (in Orange County, the Santa Ana or San Diego Regional Water Boards) whether specific maintenance activities qualify under this exemption.

What Does the Permit Require

Under the General Construction Storm Water Permit, operators of affected construction projects commit to:

- eliminating or reducing non-storm water discharge into storm water systems;
- developing and implementing a Storm Water Pollution Prevention Plan; and
- performing inspections of storm water control structures and pollution prevention measures.

To meet these goals, construction site operators will need to implement Best Management Practices (BMPs) for the control of pollutant discharges in their storm water, establish an on-site inspection program for water quality monitoring and report noncompliance to their Regional Water Board. Records need to be kept for at least three years.

When construction is complete or ownership transferred, operators must notify the State Water Board to indicate that all Permit requirements have been met.

VOL 12 2 5350

How to Comply with the Permit

Before construction may begin, owners or operators of affected construction sites need to submit a certified Notice of Intention (NOI) and a check for the appropriate annual fee (currently $250 for construction sites in Orange County) to the State Water Board. Completing an NOI signifies an intent to comply with the terms of the General Construction Storm Water Permit. The NOI is also meant to identify the location and scope of operations of proposed construction that could adversely affect storm water systems, as well as to clearly identify the responsible parties for construction activities.

In Orange County, the Permit is to be implemented and enforced by the Santa Ana and San Diego Regional Water Boards. Dischargers who do not submit an NOI and do not obtain Permit coverage will be in violation of the Clean Water Act and the California Water Code. There are substantial fines that can be pursued by the State for noncompliance of up to $25,000 per day for each violation.

When and Where to Apply for Coverage Under the Permit

Affected ongoing construction projects must submit an NOI by September 30, 1992. Those commencing after that date must submit before construction may begin.

The NOI (Form NOI-2) can be obtained from the State Water Board and, with the $250 fee, must be sent to:

State Water Resources Control Board
Division of Water Quality
Storm Water Permit Unit
P.O. Box 1977
Sacramento, CA 95812-1977

Realizing that the deadline for ongoing construction has come about relatively quickly, the State Water Board has indicated that it will not penalize NOIs submitted within a reasonable time frame after September 30, 1992.

For More Information

This flyer is meant to notify as many affected businesses and individuals as possible of the General Construction Storm Water Permit and to briefly explain what needs to be done to comply. Some important aspects are not fully addressed, such as the Storm Water Pollution Prevention Plan, record-keeping and monitoring procedures, and potential follow-up legislation.

Affected owners and operators who have questions regarding their obligations are urged to contact the State Water Board for a copy of the Permit, the NOI form and a related fact sheet. This information can be obtained through the State Water Board's Construction Storm Water Information Line at 916/657-1146. State Water Board staff can also answer questions regarding the Permit.

This Flyer was prepared by the Orange County Stormwater Program, a cooperative effort of the Orange County Flood Control District, the County of Orange and its incorporated cities, in compliance with its municipal NPDES Permit.

1.0 INTRODUCTION

The Clean Water Act of 1987 requires municipalities to apply for NPDES (National Pollutant Discharge Elimination System) permits for controlling urban stormwater runoff. The issued permits include requirements for:

- field inspection and documentation of drainage systems
- detection procedures for illegal discharges/illicit connections
- ordinances prohibiting illegal discharges/illicit connections
- an implementation plan for prosecuting violators and eliminating illegal discharges

The facility inspection and documentation manual was prepared by the County as lead agency in cooperation with the cities.

The Porter-Cologne Water Quality Act (California State Law) authorizes the State Water Resources Control Board through its Regional Water Quality Control Boards (RWQCBs) to enforce the federal Clean Water Act and regulate stormwater discharges. The Orange County NPDES permits were issued in July 1990 by the Santa Ana and San Diego RWQCBs to the County and the twenty-nine incorporated cities. The County of Orange is the lead agency in the development and implementation of the Stormwater Permit Programs.

This Facility Inspection and Documentation Manual has been prepared in order to comply with the NPDES permit requirements. The purpose of the manual is twofold:

- to assist in the identification and elimination of illegal discharges and illicit connections
- to document the storm drain systems

This Facility Inspection and Documentation Proposal will serve as a guideline to ensure consistency between county and city programs. Each city will be responsible for inspecting and documenting their own drainage facilities.

2.0 INSPECTION PROCEDURES

All open drainage facilities and underground drainage facilities (39 inches and larger) under the jurisdiction of the Local Agency will be inspected to identify pollutant discharges and to regulate undocumented and illegal drainage entries into said facilities.

2.1 Inspection Frequencies

Open storm drains, retention basins and other above ground facilities will be inspected on an annual basis. Underground storm drains with diameters of 39 inches or greater will be inspected biannually. Facility inspection frequencies will be re-evaluated in cooperation with cities and the RWQCBs after the first round of inspections. Based on this review, the frequencies may be modified.

VOL 12 2 5355

2.2 Documenting Facility Inspections

A. Each facility surveyed will be documented by filling out a Field Inspection Log (refer to Section 3.0) Information will include facility, location and land use

B Inspectors will be responsible for filling out log sheets, updating maps and completing reports

C All new stormwater discharges to the municipal storm drain system not shown on current maps will be transferred onto local and Orange County drainage maps and/or submitted to EMA/Environmental Resources This information will be compiled and provided to the RWQCBs.

D. Updating drainage maps will be an ongoing task of each co-permittee. Permanent changes will be made after completion of the biannual inspections.

2.3 Illegal Discharges/Illicit Connections

A. Any suspected illegal discharge discovered during inspections must be documented on the Field Log and reported to the appropriate water pollution response/enforcement agency for further investigation.

B. All undocumented entries will be logged and forwarded to the appropriate local agency for verification of permit status.

C. Appropriate actions will be taken to approve undocumented stormwater discharge entries into the municipal storm drain system by permit procedure and/or pursue abatement of those entries that are determined to be illegal/illicit connections and not in compliance with the local agency standards.

2.4 Safety

The inspection of underground facilities will be performed in compliance with appropriate safety standards. The use of video technology is encouraged.

2.5 Implementation

Each city must provide implementation schedules for fiscal year 91/92 for submittal to the Regional Water Quality Control Boards. The RWQCBs will provide a letter establishing a date for submitting these implementation schedules.

Inspection of County drainage facilities is currently being implemented. Surveying for illegal discharges/illicit connections began on a part time basis in August 1989. To date, approximately 200 miles of above ground facilities have been inspected. Approximately 103 miles of underground inspection has been completed. Reconnaissance is due to begin on a full-time basis in

VOL 12 2 5356

March 1991, so it is expected that the first round of inspections will be completed by June 1991 Due to the lack of a road drainage facility inventory, a time table for inspection at these facilities has not been established An inventory is currently being prepared

2.6 Estimated Costs

County Public Works has provided a breakdown of costs for one year of inspection for a crew working full-time (10 hrs/day, 40 hrs/week):

ABOVE GROUND FACILITIES (approx. 260 miles)

	Hourly Rate	Over Head	TOTAL COST
1 Maintenance Technician	$19.36	$17.77	$38.92
1 Pickup Truck			$3.80
			$42.72/hour

UNDERGROUND FACILITIES (approx. 240 miles)

	Hourly Rate	Over Head	TOTAL COST
3 Maintenance Technicians	$60.57	$53.19	$116.76
2 Maintenance Workers	$26.92	$23.64	$ 50.56
Equipment Truck			$8.75
1-Ton Utility			$4.80
Pickup Truck			$3.80
			$181.67/hour

TOTAL PROGRAM COST/YEAR: $466,731.20

EXECUTIVE SUMMARY

The following report was prepared in response to the requirements contained in Stormwater and Urban Runoff Permits issued to the County of Orange and the cities of Orange County These permits, prepared by the Santa Ana and San Diego Regional Water Quality Control Boards, required that proposals for water quality monitoring programs be submitted to the Boards by November 30, 1990 The report was submitted and approved by the Regional Boards in 1991

The monitoring program for storm channels and receiving waters consists of field screening (channels only), dry-weather, flow-composite sampling, and storm sampling.

Field screening is used to detect gross contamination which may be indicative of illegal disposal of pollutants. Monitoring locations are sited on channels which have drainage areas greater than one square mile or which have industrial (manufacturing) land uses in the drainage areas. Reports exhibiting elevated concentrations of field-screened constituents are to be referred to the EMA Water Pollution Section for further investigation.

Data from dry-weather and storm sampling are used to estimate the total annual volume of contaminants discharged by each monitored channel. These monitoring locations are in channels which are identified in the permits as "Waters of the State" or are in major tributaries to "Waters of the State".

Storm monitoring of channels is performed to evaluate the level of contamination during and after storm events. Samples are analyzed from two consecutive 48 hours periods of a storm. These data are used to compute four-day average, contaminant concentrations.

The receiving water monitoring program includes stations in the Huntington Harbour; Sunset, Anaheim, and Bolsa Bays; Upper and Lower Newport Bays; and Dana Point Harbor. These stations are monitored during and subsequent to storms for the same contaminants as in the channel monitoring program.

In the channel and receiving water monitoring programs, semiannual sampling of bed sediment is conducted to determine the chronic effects of stormwater runoff.

The permits are renewable and have a term of five years. They were issued in July of 1990. The water quality monitoring programs were initiated in February of 1991.

VOL 12 2 5363

1.0 INTRODUCTION

To comply with Order Nos 90-71 (NPDES No CA 8000180) and 90-38 (NPDES No CA 0108740), Stormwater and Urban Runoff Management Permits issued by the Santa Ana and San Diego California Regional Water Quality Control Boards (RWQCB), the following water quality monitoring program was prepared.

The water quality monitoring is conducted by the County of Orange Environmental Management Agency (EMA) by the authority granted by California Assembly Bill No. 3664 which amended the Orange County Flood Control Act. The amended Act gives EMA (formerly the Orange County Flood Control District) the legal authority to "carry on technical and other investigations, examinations, or tests of all kinds, making measurements, collecting data, and making analyses, studies, and inspections pertaining to water supply, control of floods, use of water, water quality, nuisance, pollution, waste, and contamination of water both within and without the District."

The monitoring program is funded through a cooperative agreement (Stormwater Permit Implementation Agreement) between the County and the cities of Orange County.

This monitoring program was prepared with the following considerations:

1. Program objectives established in the permit;
2. Funding available for personnel, equipment and analytical services;
3. Present and proposed equipment and staffing;
4. Safety during storm monitoring;
5. Existing data;
6. Historical annual frequency of representative storms; and
7. Tidal influences on the collection of representative samples.

The Receiving Water and Stormwater System Monitoring Programs have been combined in this document.

2.0 OBJECTIVES

The objectives of the monitoring program as stated in the Santa Ana RWQCB Permit are:

1. To define the type, magnitude (concentration and mass load*[1]) and sources of pollutants in the stormwater system discharges within each permittees respective

[1] Terms marked with an asterisk are defined in the glossary.

VOL 12 2 5364

R0058657

jurisdiction so that appropriate pollution prevention and correction measures can be identified.

2. To evaluate the effectiveness of pollution prevention and correction measures, and

3. To evaluate the compliance with water quality objectives established for the stormwater system or its components

In addition, the program is designed to assess the impacts of selected, permitted, NPDES discharges on the discharges of the Municipal Separate Storm Sewer System These NPDES discharges include the runoff from nurseries in the San Diego Creek watershed Information gathered during the life of the permit (FYs 90-95) will be used in developing future monitoring programs.

2.1 Discussion

Objective 1.

To define the mass load of pollutants from the stormwater system is a substantial undertaking. The degree of accuracy in determining this quantity is a function of the available equipment, manpower and funds (for analytical services). The program concentrates on the major regional* facilities which discharge directly to large receiving water bodies (Pacific Ocean; Huntington Harbour/Sunset, Anaheim and Bolsa Bays; Upper Newport Bay; Dana Point Harbor; Santa Ana and San Gabriel Rivers; and San Juan Creek).

To calculate the mass load from major regional facilities requires a representative sampling of these outfalls throughout the year. This representative sampling entails flow-weighted* automatic sample collection during storms and the dry season. Equipment required includes automatic wastewater samplers with toxics (synthetic organic compounds) sampling capabilities and continuous water discharge recorders. The proposed monitoring program reflects the current and proposed availability of this required equipment.

To assist in the development of the appropriate pollution prevention and correction measures (generally water pollution enforcement activities) a field screening program is performed. The intent of the program is to detect gross contamination by illegal/illicit* connections.

Objective 2

To assume that the water quality benefit from each Best Management Practice (BMP) could be measured by water quality monitoring is very presumptuous. The only BMPs which may result in any statistically significant change in water quality would be water quality structures such as basins where the water quality benefit would be determined by monitoring the quality of inflow and outflow; or the elimination through enforcement activities of a significant (high mass load relative to ambient) illegal/illicit connection. The San Diego Creek Sediment Monitoring Program – a cooperative project of the County of Orange, the Irvine Company and the cities of Irvine,

VOL 12 2 5365

R0058658

Tustin and Newport Beach -- assesses the sediment trapping efficiency of in-channel basins in San Diego Creek Much of the contaminants found in stormwater discharge are adsorbed onto these sediments.

Assessing the effectiveness of some BMP programs can be conducted by monitoring the volume of collected material (recycled oil, street sweepings etc) which may have otherwise entered the storm sewer system This assessment approach will be developed in subsequent compliance program documents

The water quality monitoring program is designed to identify trends in the receiving water quality which result from the entire BMP program.

Objective 3

Both Regional Boards have adopted as a general objective, the State Water Resources Control Board Resolution No 68-16, the policy of nondegradation of the waters of the State of California. In this resolution it is stated that "it is the policy of the State that the granting of permits and licenses for unappropriated water and the disposal of wastes into the waters of the state shall be so regulated as to achieve highest water quality consistent with maximum benefit to the people of the State and shall be controlled so as to promote the peace, health, safety and welfare of the people of the State; and ..."

Water quality objectives (limiting concentrations) have been adopted by each RWQCB, in their respective Basin Plans, to protect the waters with specific beneficial uses. Most of these objectives are applicable only to waters designated as Municipal Water Supply (MUN) and would not be appropriate for channels which are primarily stormwater conveyances. Other objectives were developed to protect freshwater and marine habitats.

The monitoring program for the Stormwater Permit only evaluates the types of contamination which significantly affect the existing or intended beneficial uses of the receiving waters. The following is a list of chemical characteristics which were considered in developing the monitoring programs.

1. Biostimulatory substances (compounds of nitrogen and phosphorus) can lead to nuisance growths of plants and algae.

2. The illegal introduction of acidic or alkaline substances to the stormdrain system can alter the pH and create chronic or acute toxicity problems for the indigenous biota.

3. Discharges of waters with high temperature can be harmful or lethal to aquatic life in the receiving water.

4. Unionized ammonia* can be toxic to aquatic life. The concentration of this contaminant is a function of the pH and the temperature.

VOL 12 2 5366

R0058659

5 Depressed dissolved oxygen levels can result from inputs of substances which impart a high biochemical (BOD) or chemical (COD) oxygen demand on the receiving waters. Stormwaters typically have elevated BODs and CODs

6 Trace elements* at high concentrations can be toxic to aquatic life. These can be introduced into the system by illegal discharges from plating or integrated circuit board companies.

7. The toxicity of trace elements is inversely proportional to the hardness*

8 PCBs, organochlorine pesticides and herbicides (PHP)* are toxic to aquatic life and have been detected in several channels and receiving waters in the the Toxic Substance Monitoring Program (TSMP) and the State Mussel Watch Program (SMW).

9. Many organic and inorganic contaminants are adsorbed onto settleable and suspended solids. Settleable solids can deposit in the receiving waters reducing circulation and impacting navigation. Contaminated settleable solids introduce toxics at the bottom of the food chain. These toxic compounds can be concentrated at higher levels of the food chain.

3.0 EQUIPMENT INVENTORY

The County's Environmental Resources Division currently maintains a large inventory of water quality and hydrographic monitoring equipment. These include automatic wastewater samplers, portable and laboratory diagnostic equipment, fluvial* and bed sediment samplers, streamgages, a fleet of vehicles, and a boat. Table 1a is a list of the laboratory and transportable field equipment. Table 1b is a list of the equipment currently in the field at streamgaging stations near the proposed sampling locations. This hydrographic monitoring equipment includes water level sensors (mechanical floats or manometers), graphic analog recorders, and transmitting dataloggers. The information is transmitted (by radio frequency) to the County's ALERT Flood Warning System. The system is capable of converting the water level information into discharge rates so that flow compositing of discrete samples can be conducted in the laboratory.

Flow-weighting* of composite samples is dependent on the availability of necessary equipment and the desired analyses. To collect samples for full-spectrum analyses (organic and inorganic), the wetted components of the automatic sampler must be composed of inert materials. Presently EMA has 18 such samplers, including two ISCO model 2700s and 16 ISCO model 3700s. The Model 3700 allows a more accurate flow compositing (when integrated with a flowmeter) because it is capable of maintaining a uniform sample volume whereas the model 2700, which operates on a timed collection cycle and sample volume is influenced by the level of water in the channel, does not.

VOL 12 2 5367

R0058660

The current sampler inventory also includes seven older model ISCO samplers (1680) which have only inorganic sampling capabilities (nutrients and trace elements) These also can be integrated with a flowmeter to obtain a reasonable flow-weighted sample A Manning Model 4500T automatic sampler is also available This unit can collect representative samples which are high in suspended or settleable solids Its vacuum collection system (versus ISCO's peristaltic* pump) provides a higher sample transport velocity with less settling of solids in the collection line The model 4500T also can ensure uniform sample volumes but does not have toxics (organic) monitoring capability In order to collect flow-weighted composites, it requires a compatible flowmeter or must be used in channels with continuous water level recorders.

VOL 12 2 5368

4.0 FIELD SCREENING PROGRAM

This program is designed to detect gross contamination of regional flood control facilities by illegal/illicit discharges. Monitoring involves one dry season (two samplings at least four hours apart) and one storm sampling of the facilities listed in Table 2. A map with these locations can be found in the Appendices. The criteria for channel selection were drainage area size and/or presence of industrial land uses in the corresponding watershed. Those channels with drainage areas greater than one square mile and smaller conduits with industrialized watersheds are included. Also included are retention/detention basins with detention times greater than 24 hours.

The monitoring parameters are those listed on the attached Field Screening Information sheet (Figure 1). This information includes channel configuration, discharge rate (measured if pollution observed, otherwise estimated), instrumental determinations of physical conditions, visual and olfactory observations, and field chemical analyses and is consistent with the federal regulations. The chemical analyses are used as indicators of swimming pool (chlorine residual), illegal construction dewatering (total suspended and settleable solids), printed circuit board (copper), plating (chromium, cyanides), plastics manufacturing (phenols) and sewer line (MBAS, phenols) discharges. Although zinc is not usually a component of illegal discharges, it is found in relatively high concentrations in stormwater and numerical objectives are listed for it in the ISWP. Dissolved zinc concentrations from tire wear and corrosion of galvanized steel is measured during dry weather and storms. Samples for Chemical Oxygen Demand (COD) are collected and analyzed at the Environmental Resources Laboratory.

All of the chemical analyses from Figure 1 can all be performed in the field except for MBAS and suspended and settleable solids. Samples are collected for "laboratory" analyses if high silt-clay turbidity or foam are observed.

The in-situ chemical analyses are performed with a field uv-visible spectrophotometer* and pre-packaged, single analysis reagents. Information which indicates pollution is referred to the Water Pollution Section of the Environmental Resources Division. If the source is determined to be continuous and non-point, follow-up sampling is performed to assess the mass loading. Identified point sources will be issued a discharge permit or be eliminated through enforcement.

The stations in the field screening program are monitored each year according to the procedure outlined above. Additional channels will be added to the list if the land uses in the watersheds become industrial.

VOL 12 2 5369

R0058662

5.0 CHANNEL MONITORING PROGRAM

The channel monitoring program includes the streamcourses also identified in the permits as receiving waters In addition to these receiving water channels, five stations in the Huntington Harbour watershed, five stations in the Upper Newport Bay watershed and two quality control stations are included in the program Table 3 is a list of the sampling locations The sites can also be found on the map in the Appendices

5.1 Monitoring Locations

The rationale for selection of these monitoring locations included the existence of prior monitoring data, the proximity of existing, continuous discharge monitoring locations, and general compliance to the lists of "Waters of the State" in the permits. The additional stations were chosen because they were tributary to "Waters of the State" and, in some instances (Lane and Barranca Channels), have exhibited (in the current monitoring program) higher than system average concentrations of heavy metals.

Two quality control stations (upper San Juan Creek and Silverado Creek) are monitored to establish "no or limited urban impact" conditions to which the urban channels can be compared. These channels have also been designated as "Waters of the State" in the Stormwater Permits.

5.2 Monitoring Parameters

The selection of monitoring parameters was based on the analyses of past data from EMA, the RWQCB-SAR Toxic Substance Monitoring Program (TSMP) for Huntington Beach Channels and the State Mussel Watch Program (SMW).

A voluminous amount of data has been collected during dry weather conditions. Both the TSMP and EMA data show that aqueous concentrations of organochlorine pesticides and trace metals (except for rare instances) have been low or below the detection limits of the laboratory. Sediment samples collected from the channel bottoms have exhibited higher relative concentrations of these contaminants. This is a logical observation since these contaminants tend to be adsorbed onto silt and clay particles which deposit onto the channel bottom when water velocities decrease after storms. Shellfish collected in the SMW have also shown bioaccumulation of these substances.

5.2.1 Dry-weather

The constituents monitored during dry weather conditions include biostimulatory substances (nutrients*) which tend to be found in the dissolved form. This nutrient sampling should be conducted in channels which have historically produced high (greater than 20 ppm as NO3) mean nitrate concentrations or are directly tributary to major waters of the state (Pacific Ocean, Sunset/Bolsa Bay, and Upper Newport Bay). These stations

VOL 12 2 5370

R0058663

include those in the upper San Diego Creek watershed, San Juan Creek, Aliso Creek, Prima Deschecha, Segunda Deschecha, Bolsa Chica and East Garden Grove-Wintersburg Channels.

Stations which have exhibited high (relative to system average) dry-weather trace element concentrations, such as Lane and Barranca Channels in the San Diego Creek watershed, will be sampled for these contaminants.

Bed sediment sampling of channels, designated as "Waters of the State", is used to assess the magnitude of pollutant (trace elements, PHP, Polynuclear Aromatic Hydrocarbons* [PAH]) deposition PAHs include the byproducts of combustion (automotive emissions) and are washed into the system during storms. This sampling will also be conducted in Lane and Barranca Channels to evaluate the potential for pollutant discharges to San Diego Creek during high water velocities (scouring) Samples will be collected in specially prepared glass containers with Teflon caps The bed material will be sampled as close to midchannel as possible This type of sampling, however, will not be conducted in channels which are concrete-lined.

5.2.2 Storms

Storm monitoring includes collection of samples for nutrients and trace metals. The mean values (event mean concentration) of the storm data are assumed representative of all storms for that channel. These mean values are used in computing the annual mass pollutant load from those channels. During the first 48 hours of each monitored storm, samples are collected for both nutrients and trace metals. Two additional samples from the subsequent 48 hour period are analyzed.

Storm samples may be analyzed for particle size distribution to correlate the level of contamination to the concentrations of transported silts and clays. If a significant correlation can be developed between silt/clay and pollutant concentrations, the former analyses are used to supplement the chemical concentration data used in mass load calculations.

These particle size distribution analyses are much less expensive than chemical analyses. They can be performed in the Environmental Resources Laboratory. Grab samples of fluvial (transported) sediment can be collected during storm sampling with equipment currently available.

Initially this correlation analysis will be attempted for stations which are presently monitored in the San Diego Creek sediment transport study. If a significant correlation is identified, the sampling will be expanded to other stations.

VOL 12 2 5371

R0058664

5.3 Monitoring Frequency

The frequency must be developed so that the program is cost effective and produces data which can be used to address the program objectives. An initial frequency has been be proposed and may be modified according to analysis of the collected data

For example, if after two years of representative storm sampling (5-10 storms) no (below detection limit) trace element contamination is detected, the monitoring frequency for those parameters will be reduced upon approval by the Regional Boards. If the standard deviation of the mean concentration is low the same reduction will be implemented. If however, a mean concentration of a contaminant exceeds a water quality standard but the standard deviation of that mean is high, the sampling frequency for that contaminant will be increased to more accurately assess the mass loading.

The current initial frequency is outlined in Table 3a.

5.3.1 Dry-weather

The present frequency for dry weather monitoring for nutrients and trace elements is monthly. This frequency is based on the present equipment, staffing, the analytical services budget, and the past observed seasonal variations in concentrations and water discharges. Nutrient monitoring is conducted using the entire inventory of automatic samplers. Sites without continuous water level recorders are sampled with automatic samplers and compatible flowmeters. Field determinations of dissolved oxygen, electrical conductance*, pH and temperature are made at the time of sampler collection.

Semiannual sediment sampling is conducted before the storm season to assess the magnitude of dry season, pollutant deposition and after the storm season to assess the deposition and/or removal (due to channel scouring) as a result of storms.

5.3.2 Storms

The period designated as the official storm season by EMA is October 15 to April 15 of each year. This period was established from storm frequency analysis.

The automatic sampling equipment is left in the field (on storm activation mode) during this period and will be serviced weekly (battery changes, sample line/strainer inspection and operational checks). Since the number of storm samplings is a function of the number of representative storms*, the available staff and equipment, an annual frequency can only be estimated. Three to five samplings per year will be attempted.

The data from storm sampling are used to characterize the distribution of pollutants during and after storm events. Prior to a storm, an automatic sampler is programmed to activate when the water level in the channel is indicative of a storm. The level of activation is

VOL 12 2 5 3 7 2

above the maximum observed (from discharge hydrograph analysis) diurnal water surface elevation. Once activated, 24 discrete, bi-hourly samples are collected. The time of activation is determined from the the memory on the sampler or remotely from the ALERT water level sensor records.

Samples collected by the samplers are composited according to water level records. All samples comprising the storm are composited together. If the storm lasts more than the sampled period, the samples are composited in two groups of 12. If no water level information is available, electrical conductivities of each sample are measured. The series of samples with similar conductivities comprise the first composite. If there is a significant change in conductivity from one sample to that which was subsequently collected, the later is first sample of the second composite.

A second 48-hour sampling (24 discrete samples: one collected every two hours) is initiated within 12 hours of cessation of the first 48-hour sampling. The samples are composited in a manner similar to that used for the first 48-hour sampling. In addition to determining the degree of contamination during and after the storm, the data are used to determine four-day average concentrations of the monitored substances.

Since there are fewer automatic samplers than monitoring locations, the samplers cannot be permanently assigned to a site. During the storm season, a sampler remains at a monitoring site until at least three complete 96-hour samplings have been completed.

Operational problems at some stations in the Upper Newport Bay watershed, specifically San Diego Creek and Big Canyon Wash, and vandalism at Hicks Canyon Wash have prevented complete samplings with automatic samplers. Grab samples will be collected at these locations performing other functions in the watershed such as field screening and fluvial sediment monitoring. If more than one sample is collected at each station during the storm evaluations of water quality relative to the ISWP objectives can be made. This grab sampling method will be used until the operational problems with the sampling locations are resolved.

VOL 12 2 5313

6.0 RECEIVING WATER PROGRAM

6.1 Monitoring Locations

The waterbodies that are monitored in the Receiving Water Program include the Huntington Harbour/Anaheim, Sunset, Bolsa Bay complex; the Upper and Lower Newport Bay; Dana Point Harbor; the Santa Ana River; San Diego and San Juan Creeks. The last three waterbodies are included in the Channel Monitoring Program as are many of the other channels designated as "Waters of the State".

The monitoring locations were chosen on the basis of the existence of past data and the proximity of tributary inputs. The locations are listed in Table 4 and maps are in the appendices. As in the Channel Monitoring Program, quality control (assumed to be limitedly affected) stations at the Harbor entrances are also monitored.

6.2 Monitoring Parameters

6.2.1 Dry-weather

Dry season sampling includes semiannual sediment analyses for organic and trace element concentrations as well as nutrient evaluations of the water.

6.2.2 Storms

These locations are sampled during storms for the same contaminants monitored in the channel program (storms). Samples representative of the entire water column are collected with a USGS depth integrating sampler which has been coated with trace metal (epoxy) paint. The depth and velocity of the fresh water lens* are also noted. Field readings of dissolved oxygen, electrical conductivity, pH and temperature are made throughout the water column at the time of sampling. The Hydrolab with datalogger enables the operator to make these measurements quickly.

6.3 Monitoring Frequency

The proposed frequencies for Harbor/Bay monitoring are outlined in Table 4b.

6.3.1 Dry-weather

Dry weather monitoring is conducted monthly (to monitor the influences of tributary inflows and tidal flushing) in the Upper Newport Bay and semiannually (pre and post storm season) at other locations (unless designated storm only in Table 4). Monthly nutrient samplings are conducted in the Upper Newport Bay on the days subsequent to the period during which the automatic samplers were used in the watershed. The nutrient

VOL 12

2 5374

content of the tributary discharges are assumed to be seasonally influenced, monthly sampling allows three determinations per season.

Control stations at the Harbor entrances are sampled during storms (if safe to do so); problems with rapid currents, depth to bottom, and boat traffic make semiannual benthic sediment sampling impractical at these sites.

6.3.2 Storms

The storm monitoring frequency is dependent on the weather and is limited by the amount of equipment (one boat) and available manpower. Storms greater than 0.5 inches in magnitude are monitored. This volume of rainfall usually is great enough to generate rainfall which shows a significant impact in these receiving waters. Two followup samplings, 48 and 96 hours from the initial storm sampling, are conducted to assess the chronic and acute influences of the runoff on the receiving waters.

As in the channel monitoring program, the frequency will be modified according to the analyses of the data.

VOL 12 2 5375

7.0 DATABASE MANAGEMENT

The water quality monitoring data are entered into the USEPA's national water quality database, located in Triangle Park, North Carolina. This database management system is known as STORET, an acronym meaning storage/retrieval. The data storage and retrieval process is performed by PC communication, via modem, with the system mainframe.

Chemical data from the contractor laboratory and field data collected by Enviromental Resources staff are tranformed into the proper computer format and are transmitted to the National Computer Center. After the transmitted data is integrated into the STORET database, the information is rechecked and edited, if necessary.

Retrievals of information can be in various forms including raw data, statistics, graphical displays and maps. These retrievals are also performed with the PC/modem link.

8.0 QUALITY ASSURANCE

All methods of analyses employed by the contractor laboratory shall be from 40 CFR Part 136, "Guidelines for Establishing Test Procedures for the Analyses of Pollutants Under the Clean Water Act". Included are the APHA-AWWA-WPCF Standard Methods for the Examination of Water and Wastewater, 18th Edition. Field, chemical test methods shall be EPA approved (if available).

Quality assurance of chemical analyses performed by the contractor laboratory is conducted by the contractor laboratory through its internal quality control program and by a blind, check-sample submittal program conducted by the County.

With every batch of samples submitted to the contractor laboratory, at least one synthetically prepared, spiked or replicate sample for each 10 samples is included. The synthetic or spiked samples containing trace elements or organic compounds will be prepared using aliquots of commercially or EPA prepared stock solutions. Quality assurance samples containing nutrients are prepared from aliquots of stock solutions prepared in the Environmental Resources laboratory. Replicate samples are splits of well-mixed samples. Both fractions are be sent to the laboratory to evaluate the precision of analyses.

The accuracy of analyses is evaluated from the results of the synthetic and spiked sample submittals. A deviation from the contract limits of error will result in a request to reanalyze the batch of samples containing the QC sample. Only that constituent which exhibits the discrepancy is reanalyzed in each sample.

9.0 PROGRAM COSTS

The costs for the sampling programs include manpower, equipment and contracted analytical services. Manpower includes sample collection / preparation, hydrographic monitoring and

VOL 12
2
5376

calculations, equipment maintenance, employee training, laboratory contract administration including quality control, database management and report preparation

9.1 Labor

9.1.1 Sampling/Water Quality Monitoring

A team of two people is required to conduct the water quality field sampling. This sampling includes field screening and channel/receiving water monitoring (storm and dry-weather). The time required includes transportation, sample collection, automatic sampler deployment, sample preparation (labeling, preservation, logging, laboratory submittal) and equipment maintenance. The annual required manpower is summarized in Table 5.

9.1.2 Hydrographic Monitoring

EMA conducts hydrographic monitoring to support its Public Works/Flood Control Design and Field Operations Divisions. Hydrographic monitoring for the Stormwater Program which exceeds these requirements is charged to the Program. This monitoring includes maintenance, stage-discharge calibration and preparation of annual discharge summaries for stations on receiving water channels which presently do not have (or were not previously scheduled to have) continuous water level recorders. Each new gaging station requires 120 manhours of maintenance annually. Calculations of precipitation intensities for stations in excess of the number in the present program is charged to the program. These calculations require 40 hours annually to complete.

9.1.3 Analytical Services Contract Administration

Contract administration includes quality control sample preparation, analytical report evaluation, and invoice processing. This requires approximately 20 hours per month or 240 hours annually.

9.1.4 Database Management

Database management as described in Section 10.0 requires approximately 20 hours monthly or 240 hours annually.

9.1.5 Report Writing

Compilation of data and report writing require approximately 400 hours annually. The reports include rainfall intensities at 23 existing EMA precipitation gages, discharge summaries for streamgages near water quality stations, calculations of the annual pollutant load from each monitored channel and a summary of the impacts of those discharged pollutants on the the water and bed sediment quality of each receiving water. The results

VOL 12 2 5377

R0058670

of the monitoring are to be used in the modification of existing BMPs or the implementation of new BMPs

The annual report is reviewed by the Copermittees before submittal to the Regional Water Quality Control Boards.

9 1 6 Training

Training must be completed by all staff throughout the life of the permit. This training includes OSHA-required hazardous material handling; equipment operation, new employee orientation, and computer software usage (STORET). Approximately 240 hours annually is devoted to training.

9 1.7 Labor Summary

The total annual manpower requirement is approximately 5424 hours (see Table 6). Most of the work is performed by Environmental Resources Specialist IIs who are presently compensated at an hourly rate (including overhead) of $23.79. The 5424 hours computes to approximately $129,000. Approximately half of the storm sampling, however, is conducted during non-working (overtime) hours. The total number of overtime hours required annually is 910. This computes to an additional $10,800 or a total of $139,900.

9.2 Analytical Services

The costs for analytical services were derived from the contract fee schedule from the current analytical services vendor, Brown and Caldwell Analytical Laboratories. The costs per analysis and the total annual costs are also outlined in Table 5.

9.3 Equipment Costs

Equipment required to supplement the existing inventory of EMA includes automatic samplers; flowmeters; field, diagnostic equipment and analytical reagents; and continuous water level recording gages.

Continuous water level recording gages will be installed at the urban channels which are identified as "Waters of the State" and currently lack this equipment. Eight stations currently fit this criteria. They are Serrano Creek; Segunda Deschecha, Prima Deschecha, Sand Canyon, and Bee Canyon Channels; and Rattlesnake Canyon, Hicks Canyon and Agua Chinon Washes. The cost of the equipment per station is approximately $7,500.

Four vehicles are used in the sampling program. Two of these were replaced FY 92/93 at a cost of $25,000 each.

VOL 12 2 5378

Miscellanous equipment expenditures (analytical reagents, automatic sampler, repair parts, field sampling equipment, etc) is approximately $5,000 annually

VOL 12 2 5379

R0058672

10.0 DEFINITION OF TERMS

Beneficial Uses - Categories into which specific Waters of the State have been assigned by the Regional Water Quality Control Board A listing of the present and intended beneficial uses of each Water of the State can be found in the respective Regional Water Quality Control Board Basin Plans.

Best Management Practices (BMPs) - Programs, procedures, or structural devices intended to reduce the impact of non-point source urban runoff on the receiving waters.

Electrical Conductance - also known as specific conductance or electrical conductivity. It is the numerical expression of ability of a solution to carry an electric current It is proportional to the concentration of dissolved ionic solids

Flow-weighted Sampling - Samples are collected in proportion to the volume of water passing the sampling point The composite of all samples collected is representative of the entire period of collection.

Fluvial - That sediment which is transported when water velocity increases as during storms.

Freshwater Lens - The layer of freshwater will flows over the more dense salt water layer. This situation occurs when the magnitude of the tributary discharge into the saline receiving water is great, as in a storm.

Hardness - The amount of calcium and magnesium measured as calcium carbonate.

Illegal/illicit - When referring to discharges an illicit connection is an undocumented or unpermitted conduit. An illegal discharge is one which is in direct violation of an ordinance.

Mass Load - The annual total mass (pounds or tons) discharged from a tributary stream into a receiving water.

Nutrients - The physical or chemical characteristics from the following list.

- nitrate + nitrite
- ammonia
- Total Kjeldahl Nitrogen (TKN)
- total phosphate
- total suspended solids (TSS)
- volatile suspended solids (VSS)
- pH
- dissolved oxygen
- specific conductance
- turbidity

VOL 12 2 5380

R0058673

Polynuclear Aromatic Hydrocarbons (PAHs) - Those organic compounds from the following list

Acenaphthene	Chrysene
Acenaphthylene	Dibenzo(a.h)anthracene
Anthracene	Fluoranthene
Benzo(a)anthracene	Fluorene
Benzo(a)pyrene	Indeno(1.2.3-cd)pyrene
Benzo(b)fluoranthene	Naphthalene
Benzo(ghi)perylene	Phenanthrene
Benzo(k)flouranthene	Pyrene

PCB - Polychlorinated biphenyls Those analyzed by EMA include:

Aroclor 1016	Aroclor 1221	Aroclor 1232
Aroclor 1242	Aroclor 1248	Aroclor 1254
Aroclor 1260	Aroclor 1262	

Peristaltic - When describing a pump, it is fluid transport in a tubing when a rotating pinch roller assembly compresses the tubing in the pump housing. The fluid moves in the direction of rotation.

PHP - Pesticides, herbicides and PCBs.

Aldrin	2,4-D
Dieldrin	2,4,5-TP Silvex
Chlordane	Malathion
Endosulfan I	Methoxychlor
Endosulfan II	Ethyl Parathion
Endosulfan sulfate	Perthane
Endrin	Simazine
Heptachlor epoxide	p,p' DDD
Heptachlor	p,p' DDE
alpha BHC	p,p' DDT
beta BHC	Toxaphene
delta BHC	PCBs from above
gamma BHC (lindane)	

Regional Facilities - Flood control channels with drainage areas greater than one square mile. Designated by a letter followed by two numeric characters (e.g. C02 - Bolsa Chica Channel).

Representative Storms - Those storm events during which at least 0.1 inch of rain falls and which were preceded by at least 96 hours of dryness.

VOL 12 2 5381

R0058674

Spectrophotometer - An instrument used in colorometric analysis A solution containing an unknown concentration of a substance is treated with reagents to form a colorometric complex The intensity of the color of this complex is measured against that of a complexed solution of known concentration

Stormwater - as defined by the EPA means storm water runoff, snow melt runoff, surface runoff, street cleaning or maintenance, runoff from fire fighting, infiltration (other than infiltration contaminated by seepage from sanitary sewers or by other discharges) and drainage. Included is runoff from residential car washing and irrigation.

Trace Elements - Those elements from the following list:

copper lead zinc nickel chromium cadmium silver

Unionized Ammonia - Dissolved gaseous ammonia.

9.0 SWMP IMPLEMENTATION PLAN

The Storm Water Management Plan (SWMP) Implementation Plan summarizes major activities to be accomplished during the period June of 1995 through June of 2000. The approach emphasized by the Program is to establish greater clarity of Program mission, goals, and objectives while encouraging continuous improvement through an adaptive management implementation strategy. This SWMP seeks to focus on shared co-permittee commitment, implementation consistency and effectiveness, greater regional coordination through the Bay Area Stormwater Management Agencies Association (BASMAA), improved integration of the various Program elements, simplification of annual reporting for routine activities and linkage of the SWMP to the Program's annual reporting, work plan preparation, and budgeting processes.

To implement the continuous improvement strategy, the Program is committed to maintaining the SWMP as an up-to-date and living document by linking it to the Program's annual reporting process. In contrast to the Program's first SWMP, this plan includes less specific detail but a greater emphasis on commitment to the accomplishment of overall Program goals. Some Program elements include three alternative implementation strategies which have been designed to reflect co-permittee characteristics summarized in Appendix A. This approach is reflected in the Program's Mission Statement, which is presented in the SWMP Preface. The goals of the overall Program are presented in Chapter 3 while the particular goals and objectives of the SWMP are presented in Chapter 1.

9.1 Program Commitment to SWMP Implementation

The Program's Mission Statement states, in part: *The 15 co-permittees of the Santa Clara Valley Nonpoint Source Pollution Control Program are committed to a cooperative program of pollution prevention and control measure activities which reduce or eliminate pollutants in storm water to the maximum extent practicable.* All co-permittees have committed to follow the general approach and activities of the implementation plan presented in this chapter. The specific details of year to year implementation of tasks, the evaluation of those tasks, and any deviation from the tasks or time schedule contained in the SWMP Implementation Plan will be reported in the detailed annual work plans and the Annual Report.

9.2 Ongoing Coordination with Regional Board and Interested Citizens

The Program invites and encourages Regional Board staff, interested citizens, and representatives of public interest groups to attend its monthly Management Committee meetings and other Program Subcommittee meetings in order to directly participate in key Program discussions and decisions. In addition, Program staff at SCVWD are committed to periodic meetings with Regional Board staff to ensure effective communication and cooperation.

R0058690

VOL 12 2 5397 F

9.3 Program Management, Roles, and Responsibilities

The Program's organization, administration, management, internal and external coordination, co-permittee and committee roles and responsibilities, and institutional arrangements are presented in Chapter 6. Key documents which define roles and responsibilities include the Program's Memorandum of Agreement, Bylaws, and NPDES permit, and the March 1994 South Bay Copper Reduction Memorandum of Understanding. The SWMP is intended to serve as a Program policy document and five year plan rather than a detailed description of Program management. Thus, Program Management activities include only those new tasks aimed at improving the effectiveness of the existing Program management.

9.4 Annual Reporting, Evaluation, and SWMP Update

The Program's purposes and the process of annual reporting and evaluation, the roles and responsibilities of the Program and its co-permittees, and the linkage of this process to the update of the SWMP are described in Chapter 7. Emphasis is placed on continuous improvement of control measure effectiveness and cost effectiveness, streamlining and simplifying annual reporting of routine ongoing activities, and the use of new information from monitoring, special studies, pilot projects, or other sources as it becomes available. If necessary, the SWMP will be updated each year following submittal of the Annual Report. Program and co-permittee work plan and budget planning processes will be initiated annually following the update of the SWMP and will use current information for budget planning and decision making. The annual reporting process also serves as the mechanism for accountability for regulatory compliance.

9.5 Implementation Plan Elements and Time Schedules

Because this is the Program's second Storm Water Management Plan, it includes significant changes to the document's organization, format, and update process based upon experience gained during implementation the first SWMP. In addition, details on the development of the SWMP and its elements have not been included because the Program's co-permittees and Regional Board staff are familiar with the Program. Additional Program elements such as Program Management, Metals Control Measures, and Watershed Management have been added to the Implementation Plan for purposes of defining Program policy and strategy, and to provide a-sufficient statement of commitment for purposes of regulatory compliance. A summary of Program elements of the implementation plan is presented below.

PM - Program Management
RPT - Annual Reporting and Evaluation
MON - Monitoring
PAA - Public Agency Activities
PIP - Public Information and Participation
MET - Metals Control Measures

VOL 12 2 5398

R0058691

WMM - Watershed Management Measures
ICID - Illicit Connection/Illegal Dumping
IND - Industrial and Commercial Dischargers
NDC - New Development and Construction

9.6 Demonstration/Pilot Projects and Control Measure Activities

The Demonstration and Pilot Projects currently underway or planned listed in Table 5.2-2 are intended to facilitate the development of BMPs for control measures, improve the efficiency and/or effectiveness of existing control measures, or to evaluate the effectiveness (and quantify pollutant reduction) of control measures. Each of the projects will potentially affect one or more of the control measure activities in the implementation plan. The control measure activities which could be affected by each project are presented in Table 9.6-1.

Table 9.6-2 lists the demonstration/pilot projects, any currently scheduled project or study completion date, and the anticipated usefulness or product expected from the project. For example, the Parking Lot BMP Development project is scheduled for completion in December 1995. The product of this study will be a manual of low cost new and retrofit BMPs for urban parking lots, such as malls, convenience stores, and municipal lots. The reproduction of the manual for co-permittees use and distribution is anticipated to take until March 1996, at which time the manual will be ready for widespread distribution. It is expected that the co-permittees can implement appropriate BMPs at municipally-owned lots fairly rapidly. However, referring to control measure IND-2.8, a strategy which includes inventory, outreach, and enforcement is needed for application of the manual to commercial and industrial facilities.

VOL 12 2 5401

9.7 Format of Implementation Plan

This section describes, in summary form, each of the Program's elements, activities, and tasks, the relevant roles and responsibilities of the Program and its co-permittees, and the corresponding implementation time schedules. The tasks and time schedules will be updated as necessary in conjunction with the annual reporting process.

Each Program element is designated by a character abbreviation as summarized in Section 9.5. Activities within a Program element are designated by the addition of a number to the character abbreviation. Thus, the Public Information and Participation element is designated as PIP and the first activity within this element (General Outreach) is designated as PIP-1.

The approach used in the Implementation Plan consists of providing a uniform plan, with some Program elements having a single strategy. Other elements have alternative implementation strategies, which will apply to all 15 co-permittees except as specifically noted and explained by the co-permittees in the individual work plans to be submitted as an appendix to the SWMP and the application for NPDES permit renewal. This approach is being proposed to achieve the SWMP goals of Chapter 1. The focus is placed on defining the goals to be achieved, facilitating consistent implementation, and making the SWMP a true policy and planning document rather than a detailed list of specific activities which quickly become outdated.

Tables 9-7.1 through 9-7.10 provide information on the roles and responsibilities of the Program, its subcommittees, each co-permittee and other involved parties related to performing activities with Program elements. An organization taking a lead role with respect to a task or activity is designated with an "L." A lead role is defined as actual performance of or full financial support for all or part of an activity. It is possible to have more than one lead organization per activity. A supporting role with respect to a task or activity is designated with an "S." Supporting organizations provide financial or technical assistance to lead organizations. If the Program is noted as a lead or supporting entity, all co-permittees are considered to support this activity by definition, however this support is not additionally noted. If an individual co-permittee also provides financial or technical assistance to the Program for an activity, a support role is noted. For example, the SCVWD supports the Program's watershed management activities by providing technical assistance through its Coyote Creek Watershed Planning effort.

General scheduling information is also provided in Tables 9-7.1 through 9-7.10. Estimated project completion dates (by fiscal year) are noted for new tasks. Projected implementation dates are noted for new activities. Completed tasks are denoted by the word "Done," followed by the fiscal year of completion. On-going activities or tasks are designated "OG." The status of new tasks or activities which are dependent on on-going or future analysis or studies and cannot yet be accurately scheduled are denoted "TBC," (to be considered).

VOL 12 2 5402

R0058695

More detailed information on strategy and role selection and scheduling is included in the individual agency work plans.

PM—Program Management

PM GOALS AND OBJECTIVES

The goal of Program Management (PM) is to effectively and efficiently plan and implement the various activities of the Program elements, leading to cost effective achievement of the Program's stated goals and compliance with the NPDES permit and other regulatory requirements.

PM IMPLEMENTATION

Program Management is carried out through a combination of Program staff, provided by the Santa Clara Valley Water District, and by the Management Committee, Steering Committee, and the subcommittees. The Program Manager has overall responsibility for implementation of the area-wide activities of the Program and receives general policy direction from the Management Committee. Additional discussion of Program Management, including roles and responsibilities of co-permittees and committees, is provided in Chapter 6.

COORDINATION AND INTEGRATION WITH OTHER ACTIVITIES

Program Management embraces and is integrated with all Program elements because of the budget and regulatory compliance issues and objectives. In accordance with the Memorandum of Agreement, the Program Manager, in consultation with the Budget Subcommittee, prepares the proposed Program budget for review and approval by the Management Committee and reports at least quarterly on the status of budget execution. Program compliance issues are discussed within the NPDES Permit Subcommittee and general policy direction is provided by the Management Committee.

EFFECTIVENESS EVALUATION

Program Management is evaluated by the Management Committee through ongoing discussion and through the annual reporting process.

PM ACTIVITIES

PM-1 Program Policy, Administration, and Management

The purpose of this activity is to clarify the missions, roles, and responsibilities of the Management Committee, subcommittees, their chairs and members and to improve integration and coordination of Program policies and activities by establishing a Steering Committee.

VOL 12 2 5403

R0058696

Task 1: Develop Management Committee/Subcommittee mission statements.
Task 2: Establish a Steering Committee to address policy, administrative, and strategic issues.
Task 3: Amend Program Bylaws to enact recommendations from the Steering Committee.

PM-2 Improve Institutional Arrangements to Meet Program Goals

The objective of this activity is to identify opportunities to improve the Program's internal (area-wide) and external (regional, state, and national) institutional arrangements in order to more effectively and efficiently meet the Program's overall goals. These activities are discussed in detail in Chapter 6. Institutional arrangements to facilitate effective watershed management are included in WMM-1.

Task 1: Increase the Program-level staffing at the District to improve effectiveness.
Task 2: Review and assess the strengths and weaknesses of the Program's MOA.
Task 3: Amend the Program's MOA if recommended in Task 2.
Task 4: Identification of new internal Program arrangements to facilitate or improve PM, WMM, MET, PAA, PIP, IND, ICID and NDC elements.
Task 5: Identification of new external arrangements to encourage or support regional, state, or national coordination and collaboration (CalTrans).
Task 6: Implement recommendations in Tasks 4 and 5.

RPT—ANNUAL REPORTING AND EVALUATION

RPT GOALS AND OBJECTIVES

The goals and historical evolution of annual reporting are discussed in detail in Chapter 7. The principal goal of annual reporting and evaluation is to demonstrate to the Regional Board the co-permittees compliance with their NPDES permit. The secondary goal, which is of greatest value to the Program, is to: (1) annually assess the progress and effectiveness to date, (2) serve as a forum for co-permittee sharing of information and results in order to continuously improve effectiveness and efficiency, and (3) serve as a mechanism to update the Storm Water Management Plan. An important objective of the Program in this SWMP is to reduce the administrative burden of annual reporting by streamlining and simplifying the reporting requirements of routine ongoing activities.

RPT IMPLEMENTATION

There is a single implementation approach for this element which all co-permittees must follow. Program staff take the lead on providing guidance in annual reporting based upon discussion and recommendations by the Program's Subcommittees and Management Committee and in compiling, filing, and distributing the Annual Report.

INTEGRATION AND COORDINATION WITH OTHER PROGRAM ELEMENTS

The Annual Report integrates all Program elements by providing a status report and proposing changes to the Program's Storm Water Management Plan subject to review and approval by the Regional Board.

RPT EFFECTIVENESS EVALUATION

Program participants continuously evaluate both the effectiveness of the various Program elements as well as the annual reporting and evaluation process itself. An important objective stated above is to streamline and simplify the reporting requirements for routine or ongoing activities. This is proposed in order to improve Program and co-permittee efficiency and to focus on new management measures, activities, and special study results.

RPT ACTIVITIES

RPT-1 Continuously Improve Annual Reporting and Evaluation

The purpose of this ongoing activity is to continuously improve the quality, value, and efficiency of the Program's Annual Reporting and Evaluation process.

Task 1: Evaluate the recent reporting process and identify areas needing improvement.

R0058699

VOL 12 2 5406

Task 2: Identify and develop minimum performance standards for activities which can be reported in a check list format.
Task 3: Submit proposed changes to Regional Board for review and approval.
Task 4: Develop and implement annual co-permittee performance evaluation plan.

MON—MONITORING PROGRAM

MON GOALS AND OBJECTIVES

The overall goal of monitoring is to obtain adequate information to characterize and define problems, and in turn implement and assess the effectiveness of management measures which are designed to provide reasonable protection of resources and beneficial uses. The monitoring program's specific objectives, major findings, and plan summary are discussed in detail in Chapter 8.

MON IMPLEMENTATION

Monitoring activities are implemented at the regional, area-wide, and community-specific (co-permittee) levels. Regional monitoring of the San Francisco Bay Delta Estuary is implemented by the San Francisco Estuary Institute for the Regional Board. Regional research and monitoring is a program area identified in the San Francisco Estuary Project's June 1993 Comprehensive Conservation and Management Plan. The Program annually funds

VOL 12 2 5407
R0058700

a proportionate share of the cost of the Regional Monitoring Plan and uses information reported by this activity to adjust control measure activities.

Area-wide monitoring activities are implemented by Program staff on behalf of all co-permittees in order to comply with the Program's NPDES permit, identify sources, and assess the effectiveness of control measures. Key objectives of Program monitoring include comparison of storm water discharges with water quality criteria, identifying sources of pollutants and toxicity, evaluating effectiveness of control measures, and providing direction to the overall Program based upon an ongoing definition and characterization of problems.

Community-specific or targeted monitoring may be implemented by co-permittees as a tool to assist in identifying special problems, illicit connections, or illegal dumping problems. At the co-permittee level, monitoring is one of many tools that may be used to assist in local activities.

INTEGRATION AND COORDINATION WITH OTHER ACTIVITIES

Monitoring activities are coordinated and integrated with many other activities of the Program. Information obtained from the Regional Monitoring Plan and the Program's monitoring activities is used to direct future Program activities and make decisions regarding problem characterization, source identification, effectiveness of control measures, and Program priorities. Thus the knowledge gained through this Program element is used as input to the overall Program direction as well as other Program elements.

MON EFFECTIVENESS EVALUATION

One of the objectives of the Program's monitoring activities is to assess effectiveness of control measures of other Program elements. The best measure of effectiveness evaluation of the monitoring program itself is an ongoing assessment of whether it is providing useful information to help direct and prioritize future Program activities. The Program's objective is to propose modifications to the monitoring plan as needed to provide information necessary to address evolving issues and questions.

MON ACTIVITIES

MON-1 Participate in the Regional Monitoring Plan

The objective of this activity is to support and participate in the Regional Monitoring Plan (RMP) in order to obtain the greatest value of resulting information at the most reasonable public cost.

Task 1: Fund the Program's appropriate share of the RMP.
Task 2: Participate in the policy and technical committees of the RMP.
Task 3: Use RMP findings to assist in setting future direction of the Program.

R0058701

VOL 12 2 5408

MON-2 Implement and Evaluate the Program's Monitoring Plan

Five specific objectives of this activity are described in Chapter 8. Increased emphasis will be placed on integrated watershed based monitoring of water quality, sediment, soil, and biological resources.

- Task 1: Report and describe findings through the Program's annual reporting process.
- Task 2: Identify and propose changes to the Plan to improve its effectiveness.
- Task 3: Develop and implement annual control measure effectiveness evaluation plan.
- Task 4: Coordinate regionally through BASMAA in order to share information.
- Task 5: Develop and implement additional monitoring activities designed to meet the goals of the Watershed Management Measures (WMM).
- Task 6: Conduct a pilot project to evaluate the use of a watershed monitoring approach.

PAA—PUBLIC AGENCY ACTIVITIES

PAA GOALS AND OBJECTIVES

Control measures under the Public Agency Activities (PAA) element have the goal of reducing or eliminating adverse water quality impacts due to construction, operations, and maintenance actions by municipalities of the Program. Successful implementation of PAA activities is particularly important since agencies in the Program should serve as good examples to the community.

PAA IMPLEMENTATION

With the exception of effectiveness evaluation development or special studies, the PAA element is implemented at the agency-specific level; there are no Program-wide or regional level implementation activities. Related elements such as PIP and New Development and Construction may consist of Program level activities in response to PAA needs or outputs. There is a single implementation strategy for this element which all co-permittees must follow, if the specific activity or issue area is applicable. Detailed information regarding implementation of these activities is included in the individual co-permittee work plans.

INTEGRATION AND COORDINATION WITH OTHER PROGRAM ELEMENTS

Public Agency Activities should be closely coordinated with the PIP element (with municipal employees as the target audience) and with the NDC element. Municipal staff education and training needs should be outputs of the PAA element which serve as inputs to the PIP element. Those municipal activities such as planning, design, and construction of public agency projects should be closely coordinated and integrated with the NDC element to assure implementation of public projects is consistent with those of the private sector.

PAA EFFECTIVENESS EVALUATION

Intrinsic to implementation of PAA element activities is an iterative process of effectiveness evaluation leading to BMP refinement. This process includes six components:

1. Inventory public agency operations and maintenance (O&M) activities
2. Assess and prioritize the pollution potential of O & M activities
3. Evaluate potential BMPs
4. Select and implement BMPs
5. Evaluate the effectiveness of the BMPs selected and report results
6. Refine/revise BMP implementation

Eventually, as PAA BMPs are selected and refined, co-permittees will concentrate on steps 5 and 6.

R0058704

VOL 12 2 5411

Mechanisms to determine and track effectiveness of the PAA activities will be developed and implemented, where feasible, as part of this element.

PAA ACTIVITIES

The following is an outline of PAA activities and tasks.

PAA-1 Municipal Corporation Yards

Task 1: Prepare Storm Water Pollution Prevention Plans (SWPPPs).
Task 2: Implement SWPPPs.

PAA-2 Parks and Recreation

Task 1: BMPs for storage and application of fertilizers and pesticides.
Task 2: Implement equipment wash water BMPs.
Task 3: Implement maintenance activities BMPs.
Task 4: Implement swimming pool BMPs.

PAA-3 Storm Drain System Operation & Maintenance

Task 1: Perform inlet maintenance.
Task 2: Perform line maintenance.
Task 3: Perform solid waste management.
Task 4: Perform debris basin maintenance.
Task 5: Research and incorporate structural retrofits.

PAA-4 Streets and Roads

Task 1: Perform street sweeping/cleaning.
Task 2. Implement practices to improve street sweeping effectiveness.
Task 3: Implement pavement washing BMP (sidewalks, plazas, parking lots, etc.).
Task 4: Implement saw cut slurry management BMPs.
Task 5: Implement paving BMPs.
Task 6: Inventory median irrigation and pesticide use practices and implement appropriate BMPs.

R0058705

VOL 12 2 5412

PAA-5 Flood Control

Task 1: Coordinate project planning with NDC element activities.
Task 2: Conduct an inventory of all key operations and maintenance activities.
Task 3: Evaluate and implement opportunities to reduce the use of pesticides.
Task 4: Evaluate and implement opportunities for sediment management.
Task 5: Evaluate and implement opportunities for vegetation protection and restoration.
Task 6: Evaluate and implement opportunities for improved fisheries management.

PAA-6 Water Utility Operations

Task 1: Coordinate project planning with NDC element activities.
Task 2: Conduct an inventory of all key operations and maintenance activities.
Task 3: Identify all routine & unplanned non-stormwater discharges.
Task 4: Identify discharges to receiving waters of all chemical additives.
Task 5: Develop management plan to reduce/eliminate discharges of concern.
Task 6: Implement the discharge management plan.
Task 7: Evaluate impacts of ongoing O&M activities from Task 2.
Task 8: Develop a plan to reduce/eliminate O&M impacts of concern.
Task 9: Implement the O&M impacts management plan.

PAA-7 Public Facilities

Task 1: Implement parking lot BMPs.
Task 2: Implement BMPs to reduce pollutant loading from golf courses.
Task 3: Implement BMPs to reduce pollutant loading from hospital sites.
Task 4: Implement BMPs to reduce pollutant loading from public buildings, plazas, landscaping, etc.

PAA-8 Ponds, Fountains, & other Public Water Bodies

Task 1: Implement BMPs to control algae.
Task 2: Implement BMPs to control chlorine/pollutant discharges.

PIP- PUBLIC INFORMATION AND PARTICIPATION

PIP GOALS AND OBJECTIVES

Public Information and Participation (PIP) has the dual goals of (1) changing specific behaviors that adversely impact the water quality of streams and the Bay and (2) increasing the understanding and appreciation of streams and the Bay. The second PIP goal may eventually lead to a change in values by individuals and society as a whole. These two PIP goals can be achieved through the implementation of the following PIP programmatic activities: (1) general outreach, (2) targeted outreach, (3) educational programs, and (4) citizen participation.

PIP IMPLEMENTATION

PIP activities are implemented at the regional, Program-wide, and community-specific (co-permittee) levels. Regional activities and tasks are implemented in cooperation with or through the Bay Area Stormwater Management Agencies Association (BASMAA). Program-wide activities are implemented uniformly throughout the Santa Clara Valley by the Program staff or contractors. Community-specific activities are implemented by each co-permittee and are reflective of the characteristics of the co-permittee's jurisdiction.

There are three implementation strategies presented for the PIP Targeted Outreach activity in order to accommodate the variation in co-permittee characteristics. All co-permittees must select one of the Targeted Outreach strategies. Each co-permittee must provide an explanation of the qualifying conditions or criteria on which their strategy selection is based in their individual work plans.

Each of the PIP Targeted Outreach activities defines a list of required tasks and the bases and standards for evaluation. All co-permittees must provide an explanation for any of the tasks within applicable activities that are proposed to be eliminated or modified, and the co-permittees must also prepare a time schedule indicating the target completion date for each activity. Detailed information on the progress and success of each individual task within a PIP activity will be reported by each co-permittee in their detailed work plans and/or the Program's Annual Report. Regional and Program level activities will be reported by the Program.

COORDINATION AND INTEGRATION WITH OTHER ACTIVITIES

Because some PIP goals and objectives are directly related to and driven by other Program elements, many specific needs and tasks will be identified within those other Program elements. The PIP Targeted Outreach needs will be defined through other Program elements, such as the IND, ICID or PAA elements. Specific products, outreach strategies, distribution methods, and evaluation techniques will be defined to meet those identified needs and developed at the Program level in close cooperation with the PIP Subcommittee and

VOL 12 2 5422

R0058715

members of the originating Subcommittee(s). Upon completion of products or materials, actual implementation may be at the co-permittee level, Program-wide, or regional depending on the outreach strategy. Other PIP activities, such as General Outreach and Education, will be implemented at the Program and regional levels and will be considered a voluntary activity for co-permittees' community specific actions.

PIP EFFECTIVENESS EVALUATION

Perhaps one of the most difficult aspects of the PIP element is assessing its effectiveness. The Program's strategy to determine effectiveness will be to evaluate specific PIP activities which are most suitable for evaluation, rather than to attempt to evaluate PIP as a whole. To the extent feasible, effectiveness measures will be defined at the time of initial product development and outreach strategy definition. The focus will be on measuring actual behavior and attitude changes rather than measuring the quantity of the outreach messages or materials.

PIP-1 Develop a Program PIP Strategy and Plan for the Years 1995-2000

This activity will be conducted by the Program in close cooperation with the PIP Subcommittee, co-permittees, and BASMAA. Target completion date is July 1, 1995. The objectives of the PIP strategy are to clearly state PIP goals based upon and consistent with overall Program goals and objectives, distinguish and coordinate activities to be implemented at the regional versus Program-wide and co-permittee level, develop and implement a PIP effectiveness assessment strategy, establish well-defined criteria for PIP priorities, establish criteria which define the best level of PIP outreach method (region, Program, or local), coordinate and integrate PIP with all other Program elements, identify marketing or market research needs, and develop sound evaluation techniques.

Task 1: Develop/Refine Program-wide PIP goals and objectives.
Task 2: Determine and prioritize Targeted Outreach needs based on PIP goals.
Task 3: Develop a three level outreach strategy: regional, Program ,city.
Task 4: Develop PIP coordination and support plan.
Task 5: Define near term tasks within PIP activities and budget estimates.
Task 6: Develop a standard process for product development, outreach strategy, and effectiveness measurement.

PIP-2 General Outreach

This activity will be conducted at the regional and Program levels. Co-permittees may add general outreach to their community-specific activities on a voluntary basis. The objective of this activity is to increase the general public awareness and appreciation of water quality issues in streams and the Bay and the importance of protecting beneficial uses. Other goals include establishing consistency with the Public Involvement and Education objectives of the San Francisco Estuary Project.

VOL 12
2
5423
R0058716

Task 1: Distribute existing materials.
Task 2: Participate in a BASMAA regional advertising campaign.
Task 3: Develop and distribute general information written materials.
Task 4: Develop and broadcast general information audio materials.
Task 5: Develop and broadcast general information video materials.
Task 6: Develop material and an outreach strategy to support the WMM element.

PIP-3 Targeted Outreach

This activity will be conducted primarily at the Co-permittee level, but will also be conducted at the Program and regional levels, as appropriate, based upon overall Program and PIP goals and outreach strategies. The objective of this activity is to change those specific behaviors which are known to adversely impact water quality in streams and the Bay or impact beneficial uses. This activity consists of three Co-permittee level implementation strategies. All co-permittees must select one of the strategies and provide an explanation of the qualifying conditions in their work plans and/or the Annual Report.

STRATEGY 1

Qualifying Conditions:

Primarily residential communities-limited commercial activity.

Activities/Tasks:

Task 1: Develop outreach materials for residential education.
Task 2: Implement residential outreach.
Task 3: Implement commercial outreach, as determined by PAA, IND and ICID element activities.
Task 4: Implement outreach to the development community, as determined by NDC element activities.
Task 5: Educate/train public employees.
Task 6: Modify outreach and educational efforts as new materials/information become available.

Reporting and Evaluation Criteria:

Written outreach strategy and distribution plans. Annual summary of products developed/distributed and training activities. Annual revision of outreach plans. Evaluation of response to identified needs by appropriate co-permittee departments or subcommittee.

R0058717

VOL 12 2 5424

STRATEGY 2

Qualifying Conditions:

Moderate amount of commercial areas and some light industrial development in the form of modern industrial parks.

Activities/Tasks:

Task 1: Develop outreach materials for residential education.
Task 2: Implement residential outreach.
Task 3: Implement commercial/light industrial outreach, as determined by PAA, IND, ICID and MET element activities.
Task 4: Implement outreach to the development community, as determined by NDC element activities.
Task 5: Educate/train public employees.
Task 6: Modify outreach and educational efforts as new materials/information become available.

Reporting and Evaluation Criteria:

Written outreach strategy and distribution plans. Annual summary of products developed/distributed and training activities. Annual revision of outreach plans. Evaluation of response to identified needs by appropriate co-permittee department or subcommittee. Analysis of trends in observed pollution problems.

STRATEGY 3

Qualifying Conditions:

Older business districts and/or some relatively heavy industrial areas.

Activities/Tasks:

Task 1: Develop outreach materials for residential education.
Task 2: Implement residential outreach.
Task 3: Implement outreach commercial/industrial outreach, as determined by PAA, IND, ICID and MET element activities.
Task 4: Implement outreach to facilities regulated by the State NPDES General Industrial permit.

R0058718

VOL 12 2 5425

Task 5: Implement outreach to the development community, as determined by NDC element activities.
Task 6: Incorporate and coordinate educational outreach into ongoing inspection activities.
Task 7: Develop and implement outreach to meet goals of the WMM element.
Task 8: Educate/train public employees.
Task 9: Modify outreach and educational efforts as new materials/information become available.

Reporting and Evaluation Criteria:

Written outreach strategy and distribution plans. Annual summary of products developed/distributed and training activities. Annual revision of outreach plans. Evaluation of response to identified needs by appropriate co-permittee department or subcommittee. Analysis of trends in observed pollution problems. Analysis of inspections and use of educational materials by facilities to comply with nonpoint source reductions.

PIP-4 Education Programs

This activity will be conducted primarily at the Program level. It will be implemented at the co-permittee level as a voluntary measure. The objective of this activity is to change peoples' values through education and understanding of the importance of water quality and beneficial uses in streams and the Bay. Because values change very slowly and over the long term, it is important to incorporate the needed education into the curriculum at various points (e.g. K-12, college, post educational). Educational programs directed at public employees or other specifically targeted groups will be implemented through the PIP Targeted Outreach activity and closely coordinated with the appropriate Program element and subcommittee.

Task 1: Develop and implement school education programs.
Task 2: Develop and implement general public programs.

PIP-5 Citizen Participation

This activity will be conducted primarily at the co-permittee level since individual co-permittees are best suited to enlist and engage their local citizens and organized citizen groups. Some tasks within this activity, such as Streamkeepers Pilot Implementation and Watershed Monitoring Strategy development, will be conducted at the Program level. The objective of this activity builds upon the objectives of (1) general outreach, (2) targeted outreach, and (3) education programs, in that it seeks to inform and engage citizens through direct participation and in such a way as to (1) increase their awareness and appreciation of the functions and values of streams and the Bay, (2) modify behaviors which they may have exhibited which adversely affected water quality or compromised beneficial uses,

VOL 12 2 5426
R0058719

(3) influence a positive change in their values toward a deeper appreciation of streams and the Bay, and (4) motivate them to become participants of a community creek watch.

Task 1: Complete Pilot Streamkeepers Program.
Task 2: Support Citizen Monitoring through implementation of Streamkeepers.
Task 3: Coordinate with Streamkeepers to respond to citizen reports of pollution problems.
Task 4: Identify other opportunities for citizen participation.

MET—METALS CONTROL MEASURES

MET GOALS AND OBJECTIVES

The goal of the Program's Metals Control Measures (MET) is to reduce metals concentrations in Santa Clara Valley streams and loads to the South Bay for those metals which have been found to be regularly present in detectable quantities in storm water and are of environmental concern. A process for assigning priority to metals reduction is provided in Chapter 4. Priority is given to reducing copper loads in order to implement the March 1994 Copper Reduction MOU, meet the requirements of the December 1993 Cease and Desist Order, and attain the goals of the CCMP mass emissions strategy.

MET IMPLEMENTATION

This Program element is implemented at the Program level in terms of coordinating, tracking and reporting the progress, and at the co-permittee level in terms of implementing specific control measure activities. Control measures for metals reduction generally fall into other Program elements and take a watershed approach to implementation. Emphasis will be given to those metals for which a waste load allocation is pending or has been adopted (e.g., copper), and those metals known to be of urban origin and present in storm water (copper, cadmium, lead).

COORDINATION AND INTEGRATION WITH OTHER ACTIVITIES

Metals control measure activities fall into other Program elements but are grouped together in this element for purposes of regulatory compliance, quantification of load reduction, annual reporting, accountability, and logical organization of a group of targeted control measures. Each control measure action within a particular task will be cross referenced to the Program element and activity in which it is located as part of the annual reporting process.

MET EFFECTIVENESS EVALUATION

The regulatory mandates for the heavy metals, and copper in particular, are such that source identification and quantification of control measure effectiveness is probably the most advanced of any activities of the Program. Effectiveness is measured through special studies, pilot projects, and ongoing evaluation and reporting.

MET ACTIVITIES

MET-1 Copper Load Reduction

The principal purpose of this activity is to meet the commitments of the March 1994 Copper Reduction MOU and the regulatory requirements in Provision B of the December 1993 Cease

VOL 12 2 5437

R0058730

and Desist Order. Other objectives include consolidation of the efforts contained in other Program elements into a single area in the annual reporting process.

Task 1: Estimate and assign Caltrans metal load reduction responsibilities.
Task 2: Define and implement short term copper reduction measures and quantify their credits.
Task 3: Develop implementation plan for long term copper reduction measures and strategies per MOU.
Task 4: Quantification & evaluation per MOU through annual reporting process.
Task 5: Report on effectiveness of various pilot projects.
Task 6: Assess progress and potential need for additional measures.

MET-2 Other Heavy Metals Reduction

The purpose of this activity is to meet the requirements of Provision A in the December 1993 Cease and Desist Order which requires identification and implementation of control measures for heavy metals. Chapter 4 contains a method for determining the priorities of heavy metals reduction.

Task 1: Determine reductions of other metals associated with copper control measures.
Task 2: Develop and implement control measures for priority metals.
Task 3: Quantify reduction estimates.

WMM—WATERSHED MANAGEMENT MEASURES

WMM GOALS AND OBJECTIVES

In the broadest sense, the principal goal of watershed management is to protect the beneficial uses of Santa Clara Valley streams and the South Bay. The key SWMP purpose is to facilitate this goal. Secondary goals include protecting surface and groundwater drinking water supplies, increasing community awareness and appreciation of the importance of watersheds and water resources, and engaging the community in watershed protection. This element also meets the requirements of Provision D of the December 1993 Cease and Desist Order, the watershed planning and classification measures of the March 1994 Copper Reduction MOU, and the spirit of the San Francisco Estuary Project CCMP and the Coastal Zone Act and Reauthorization Amendments. Watershed Management recognizes the watershed specific goals, values, problems, and solutions.

WMM IMPLEMENTATION

This Program element is coordinated and managed at the Program level but specific activities are implemented at the co-permittee level. A phased approach to implementation is proposed. Certain activities such as the development of watershed monitoring goals and protocols are proposed to be implemented at the regional level through BASMAA and with assistance from the San Francisco Estuary Institute. Other activities such as the development of a pilot watershed management Plan will be initiated by the Program with SCVWD as the lead agency, and expanded to a Program-wide effort as it matures. Cities and the county play the key role in land use planning and implementation of New Development control measures.

INTEGRATION AND COORDINATION WITH OTHER PROGRAM ELEMENTS

Watershed Management is an approach to comprehensive pollutant reduction and natural resource management which seeks to coordinate and integrate many goals, objectives, and activities in such a way as to provide maximum overall benefits at the minimum overall cost to the community. Watershed Management embraces many specific activities of other Program elements, especially those within the NDC element, and includes a Program and regional level approach to coordination and integration. The Watershed Management Measures also seek to meet the intent of the San Francisco Estuary Project, the Coastal Zone Act and Reauthorization Amendments, and Regional Board staff guidance for new development (see Chapter 5).

WMM EFFECTIVENESS EVALUATION

Watershed management involves the effective coordination of many different activities in order to achieve watershed specific goals and priorities. Thus, watershed management effectiveness can be measured indirectly through an evaluation of the success in coordination

R0058734

VOL 12 2 5441

of Program and related activities. Other success criteria will need to be defined as a clearer purpose is established and watershed specific goals, problems, and solutions are defined.

WMM ACTIVITIES

WMM-1 Improve Institutional Arrangements

This activity emphasizes first establishing the specific goals and objectives for the overall Program to undertake in a watershed management approach and then identify opportunities to achieve these objectives through impro ement of existing or new institutional arrangements. In contrast to activity PM-2, the objectives of WMM-1 are specific to watershed protection.

Task 1: Define the Program's goals and objectives of watershed management.
Task 2: Review CONCUR/PERC paper and identify opportunities.
Task 3: Develop new institutional arrangements (including goals).

WMM-2 Develop Watershed Monitoring Plan and Protocols

The purpose of this activity is to define a uniform watershed monitoring framework for the Bay Area. This activity will be carried out in coordination with BASMAA, the San Francisco Estuary Institute, and the Regional Board.

Task 1: Define Goals and Objectives of watershed monitoring.
Task 2: Establish monitoring sampling design, protocols, and data management plan.
Task 3: Define linkage to WMM-3, Watershed Classification.
Task 4: Initiate pilot watershed monitoring (see WMM-4).

WMM-3 Implement Watershed Classification

The purpose of this activity is to meet commitments of the March 1994 Copper Reduction MOU and develop an approach to watershed classification that maximizes cost effectiveness of pollutant reduction measures and protection of natural resources and beneficial uses.

Task 1: Review CONCUR Watershed Classification paper.
Task 2: Identify opportunities to use CONCUR paper concepts.
Task 3; Define linkage to watershed monitoring (WMM-2).
Task 4: Classify and prioritize watersheds.

WMM-4 Develop a Pilot Watershed Plan

The objective of this activity is to initiate watershed management through the development of a pilot watershed plan. The results of the pilot effort will be used to direct other watershed planning activities to be implemented under WMM-5. While SCVWD will take the lead on

R0058735

VOL 12 2 5442

many PAA efforts in the pilot, cities and counties will play key roles in land use management.

Task 1: Coordinate with SCVWD Coyote Watershed Planning effort.
Task 2: Evaluate the Pilot project process and results.
Task 3: Recommendations for future plans.
Task 4: Develop model watershed plan.

WMM-5 Implement Area-Wide Watershed Management

This is the final activity under the Watershed Management Measures and represents full implementation of the WMM element. The objective is phased implementation of institutional arrangements (WMM-1), watershed monitoring (WMM-2), watershed classification (WMM-3), and a pilot watershed planning effort (WMM-4), leading to full implementation.

Task 1: Develop an area-wide watershed management strategy and plan.
Task 2: Implement the watershed management strategy.

ICID—ILLICIT CONNECTION AND ILLEGAL DUMPING IDENTIFICATION AND ELIMINATION ACTIVITIES

ICID GOALS AND OBJECTIVES

Control measures under the ICID element have the goal of identifying and eliminating non-permissible non-storm water discharges associated with either illegal dumping or illicit connections between sanitary/process water lines and storm drains.

ICID IMPLEMENTATION

This program element is implemented at the co-permittee level with Program support provided in developing guidance and policies for permissible and non-permissible non-storm water discharges and alternative disposal methods. These control measures include inspections. Co-permittees may enter into cooperative agreements with other co-permittees or agencies (e.g., sanitation districts) to assist in inspections. There are three strategies designed to accommodate differences in the co-permittee community characteristics: co-permittees which are primarily residential Strategy 1), co-permittees that have moderate amounts of commercial and light industry and reasonably new storm drain systems (Strategy 2), and co-permittees which have a moderate amount of heavy industry or business districts served by older storm drain systems. The strategies are intended to build on each other, and therefore co-permittees which qualify for Strategy 2 are required to implement activities under Strategy 1. Implementation will take into account and build on past accomplishments of the first permit period.

COORDINATION WITH OTHER PROGRAM ELEMENTS

PIP Element: For successful implementation of the illegal dumping/illicit connection identification and elimination program element, coordination will be required with the PIP program element which will provide focused outreach materials for educating target audiences about specific non-permissible non-storm water discharges (e.g, pool/spa discharges, restaurant practices).

IND Element: The illicit connection/illegal dumping program element will be integrated into the industrial control program as inspection for storm water discharges as well as non-storm water discharges can be conducted simultaneously.

Regional Board: This element should be coordinated with the Regional Board who issues NPDES waste discharge permits for cleanup operations that often discharge into storm channels or storm drain systems.

R0058741

VOL 12 2 5448

EFFECTIVENESS EVALUATION

Measures of effectiveness will be tailored to reflect the conditions and community characteristics of each co-permittee and will differ as described under each strategy. Overall, the evaluation of effectiveness will focus on the number of connections and dumping incidents identified and eliminated each year for a given level of effort (e.g., problems identified per 100 inspections). Ideally, the success of the program would be reflected in a reduction of problems for a given level of effort with each succeeding year.

STRATEGY 1

Qualifying Conditions:

Primarily Residential Communities

Activities:

The primary causes of illegal discharges in residential communities stems from homeowner misunderstanding of what materials are permitted to enter the storm drain system; therefore key elements in the strategy are coordinating with PIP element activities to conduct homeowner education through public outreach and responding to citizen complaints. The technical basis for residential outreach is primarily the Program's list of permissible and non-permissible non-storm water discharges. Co-permittees will review this list in the context of their jurisdiction and develop a list of homeowner activities (e.g., illicit pool and spa connections, dumping of used motor oil, mobile cleaner discharges) which are potentially the primary causes of non-permissible non-storm water discharges. Based on this list, the co-permittee will develop and implement a focused outreach program coordinating with other agencies (e.g., County Health) as appropriate. In addition to these activities, illicit connection identification activities are coordinated with public agency element activities.

Specific tasks to be accomplished will vary depending on the jurisdiction and previous related efforts of the first SWMP. The following are recommended tasks that may be tailored and modified for each co-permittee:

ICID-1 Residential Illegal Discharge Elimination

- Task 1: Prioritize non-storm water discharges of concern (target audience identification).
- Task 2: Coordinate with PIP element activities to develop residential outreach materials.
- Task 3: Implement incident response plan and update as necessary.
- Task 4: Conduct illegal dumping/illicit connection inspections/surveys in response to citizen complaints and in coordination with PAA element activities.

VOL 12 2 5449

R0058742

Reporting and Evaluation Criteria:

The co-permittees will annually document the number and type of incidents identified, addressed, and resolved or non-resolved; coordination with other co-permittees or agencies including MOUs and agreements; and the number of complaints received. It is anticipated that the number of complaints will increase in the early years of implementation as citizens become more aware of problems, and gradually decrease as education efforts begin to create a permanently aware population.

STRATEGY 2

Qualifying Condition:

Jurisdiction contains moderate amount of commercial areas (e.g., malls, commercial strip development) and/or light industrial development most of which is in the form of relatively modern industrial parks.

Activities:

Commercial and light industrial areas constitute an additional source of illegal dumping and illicit connections and warrant additional activities beyond those specified in Strategy 1. The public outreach target audience should be expanded to address commercial and light industrial activities. A sustained illegal dumping identification and illicit connection elimination program consisting of education, coordinated inspections, spill response, complaint response, alternative disposal guidance, enforcement, and reporting should be developed and implemented. Implementation should be conducted through the most cost-effective means and, in most municipalities, will be integrated with IND and PAA element activities. Inspection and enforcement coordination will likely be required with maintenance staff, HAZMAT and pretreatment industrial inspectors, and health inspectors, among others.

Specific, *in addition to those under Strategy 1*, are:

ICID-2 Illegal Discharge Elimination for Commercial and Light Industrial Facilities

Task 1: Prioritize inventory of facilities developed in the IND element.
Task 2: Coordinate with PIP element activities to develop appropriate outreach materials and strategy.
Task 3: Establish system of receiving, responding, and tracking response to citizen complaints.
Task 4: Coordinate with other agencies to develop agreements for alternative disposal options.
Task 5: Evaluate and obtain enforcement authority and develop enforcement procedures.

R0058743

Task 6: Develop illicit connection survey plan.
Task 7: Perform illegal dumping/illicit connection inspections in conjunction with IND element activities.

Reporting and Evaluation Criteria:

Written illegal dumping identification and elimination strategy that includes criteria for selection of high priority activities and areas, inventory of commercial/industrial businesses in high priority activities and areas, inspection methods, enforcement authority, and coordination of implementation with other agencies. Annual reporting will include type and extent of inspections, the number and type of problems encountered, actions taken, and status of resolution. The primary evaluation criteria for effectiveness will be number and type of incidents identified and eliminated and the type and extent of inspections.

STRATEGY 3

Qualifying Conditions:

Jurisdiction that contains older business districts and/or some relatively heavy industrial areas.

Activities:

Older business districts and/or older industries are often served by older storm drain and sanitary sewer systems that may potentially contain more cross connections than is found with more recent construction. *In addition to implementing activities identified under Strategies 1 and 2,* jurisdictions containing such areas should develop and implement an outreach strategy for older non-residential areas and develop and implement a plan for routine surveillance for illicit connections. The surveillance plan should build on relevant information obtained from activities conducted during implementation of the first SWMP.

Specific tasks are:

ICID-3 Illegal Discharge Elimination for Older Business and Heavy Industrial Areas

Task 1: Coordinate with PIP element activities to develop appropriate outreach materials and strategy for older business districts and heavy industrial facilities, as appropriate.
Task 2: Develop system surveillance plan which includes prioritization of non-residential areas to be inspected.
Task 3: Conduct routine system surveillance of storm drains.

R0058744

VOL 12 2 5451

Reporting and Evaluation Criteria:

Written outreach strategy and surveillance plan. Annual report to include the type and extent of surveys conducted, survey methods and schedule, training and staffing information, problems encountered, actions taken, and status of resolution of problems.

R0058749

IND—INDUSTRIAL AND COMMERCIAL DISCHARGERS CONTROL PROGRAM ELEMENT

IND GOALS AND OBJECTIVES

The goals and objectives of the industrial and commercial discharger's program element is to control storm water discharges associated with industrial and commercial activities into municipal storm drain systems.

IND IMPLEMENTATION

This program element is implemented at the co-permittee level with Program support in developing BMP guidance and PIP materials that may be useful in educating target audiences. Implementation strategies are developed for three land use conditions so that co-permittees can select the most appropriate strategy for their community characteristics.

INTEGRATION AND COORDINATION WITH OTHER PROGRAM ELEMENTS

PIP Element: Various activities will require targeted commercial and industrial educational materials (eg, BMP guidance) to be developed through the PIP program element.

ICID Element: Many activities in the IND program element can be cost-effectively coordinated with the illicit connection and illegal dumping identification and elimination program element. The Program has facilitated this coordination by creating a joint subcommittee responsible for assisting in the implementation of both elements.

Regional Board: This element should be coordinated with the Regional Board which regulates certain industries that are covered by the State General Industrial Permit.

Other Inspection Agencies: This element should be coordinated with HAZMAT, POTW pretreatment, County Department of Health, and other agencies with inspection responsibilities to minimize the number of inspections at a given facility and to provide more cost effective programs.

IND EFFECTIVENESS EVALUATION

Effectiveness evaluation criteria will be tailored to co-permittee community characteristics. Recommended criteria include the number of problems identified and resolved relative to a given level of effort (e.g., number of inspections) and the percentage of significant sources inspected per year. Yearly progress would show a decrease in problems for a given level of implementation.

VOL 12 2 5457

R0058750

VOL 12 2 5458

STRATEGY 1

Qualifying Conditions:

Primarily residential communities with limited commercial or industrial uses.

Activities:

For jurisdictions in this category there are very few commercial areas and likely to be no industrial facilities. In this case, co-permittees will identify and inspect all commercial facilities that handle pollutants of concern and may have exposure to storm water, follow up with educational assistance and, if necessary, take enforcement action. Co-permittees will also assist facilities to comply with General Industrial permit, as appropriate.

Recommended Tasks are:

IND-1 Commercial/Industrial Inspection and Outreach (Few Facilities)

Task 1: List all commercial/industrial facilities.
Task 2: Identify which facilities have exposure and are potential sources of pollutants of concern.
Task 3: Conduct inspections and provide outreach.

Reporting and Evaluation Criteria:

Report on number of facilities inspected, any problems or enforcement actions taken and their resolution.

STRATEGY 2

Qualifying Conditions:

Jurisdictions which contain moderate amount of commercial land use and/or light industrial development.

Activities:

Jurisdictions in this category will focus source control efforts on specific commercial facilities that are potential storm water pollutant sources (e.g., restaurants, gas stations, automotive repair shops). A secondary focus will be to address treatment options for sources common to various facilities (e.g., parking lots). Activities shall include targeted outreach to these facilities using BMP guidance and PIP materials developed by the Program and/or the local co-permittee. If the jurisdiction contains a sufficient

R0058751

number of facilities, a commercial/industrial data base will be developed in order to support inspection, enforcement, and reporting functions. Facilities may be ranked in terms of potential for exposure and materials handled using guidance contained in the Program's Source Identification Report or other information. An inspection program will be implemented using co-permittee resources, Program resources, and/or other agencies resources such as the sanitary district, HAZMAT, or County Environmental Health. The inspection program results will be used to update the data base and refine the scope and necessity of continued inspections. The co-permittee will consider the feasibility of developing a commercial awards program to recognize cooperating facilities.

Specific tasks that the local agencies may tailor or modify for their community characteristics are:

IND-2 Commercial/Light Industrial Inspections

Task 1: Identify and prioritize commercial and industrial sources.
Task 2: Develop a commercial/industrial data base for tracking progress, reporting.
Task 3: Coordinate with PIP element activities to develop commercial/industrial BMP guidance materials.
Task 4: Develop and implement inspector training program.
Task 5: Conduct inspections in cooperation with other agencies.
Task 6: Develop cooperative agreements with other agencies to coordinate inspections.
Task 7: Evaluate feasibility of commercial awards program.
Task 8: Develop parking lot BMPs and a control strategy based on Program/USEPA pilot project.
Task 9: Implement parking lot control strategy.

Reporting and Evaluation Criteria:

Number and comprehensiveness of inspections conducted and percentage of important sources inspected per year. Number of problems resolved. Year to year progress in reducing problems and the number of facilities which require inspections due to compliance.

STRATEGY 3

Qualifying Conditions:

Jurisdictions which contain older business districts and/or heavy industries.

R0058752

VOL 12 2 5459

Activities:

Monitoring data indicate that the quality of storm water runoff is poorer from catchments which have significant industrial sources. For jurisdictions in this category, there is the need to assist industries to comply with the State's General Industrial Permit and to assist other industries (who are not covered by the permit but constitute an important source of pollutants, e.g., auto repair) to comply with local requirements. If useful, enter into agreement with Regional Board on coordinating inspections, reporting, and referrals of problems. Outreach should be conducted utilizing existing BMP and PIP materials developed (or in the process of being developed) by the Program and by co-permittees. An inspection program similar to that outlined in the above strategy should be developed and implemented with additional consideration for assisting industries with General Permit compliance. Jurisdictions in this category may also have industrial clean-up operations ongoing where treated groundwater is discharged (under permit from the Regional Board) to the jurisdiction's storm drain system or local streams. In this case, the co-permittee should work with the Regional Board and these businesses to ensure that storm water and non-storm water discharge issues are addressed.

Additional specific tasks beyond those identified in Strategy 2 are:

IND-3 Older Business Districts and Heavy Industrial Area Inspections

Task 1: Identify industries regulated by the State NPDES General Industrial permit.
Task 2: Develop and implement outreach strategy and inspection plan to assist regulated industries in complying with NPDES General Industrial permit (non-compliance problems to be reported to the Regional Board).
Task 3: Coordinate with PIP element activities to develop outreach materials to assist permitted and non-permitted industries to comply with State and local requirements, as applicable, and enforce compliance where necessary.
Task 4: Develop MOU with Regional Board to coordinate inspection and enforcement activities for permitted facilities.

Reporting and Evaluation Criteria:

Similar to Strategy 2 but with additional focus on industrial facilities and coordination with the Regional Board.

R0058757

NDC—NEW DEVELOPMENT AND CONSTRUCTION ACTIVITIES CONTROL MEASURES

NDC GOALS AND OBJECTIVES

The goal of new development and construction activities control measures is to minimize the adverse effects on urban runoff from new and redevelopment both during and after construction. Activities contained within this element apply to private development and to public agency construction projects.

NDC IMPLEMENTATION

This program element is implemented primarily at the co-permittee level. Significant effort will be put toward integrating Program, CZARA and CCMP goals into project planning and design, strengthening current project approval and inspection procedures, and evaluating BMPs. Program support is provided in developing BMP selection guidance and modifications to CEQA language to incorporate storm water quality issues. Regional level coordination is provided through the Program's participation in the BASMAA New Development Subcommittee.

INTEGRATION AND COORDINATION WITH OTHER PROGRAM ELEMENTS

PAA element: Planning, design and construction of public agency projects shall be conducted to comply with the NDC element. In addition, for consistency of approach, long-term maintenance issues related to the selection of post-construction storm water BMPs for private developments need to be coordinated with the PAA element.

PIP Element: The new development and construction activities control element coordinates with the PIP element to develop and up date focused outreach materials for contractors, developers, engineers and municipal staff. These materials include general construction-related manuals and BMP brochures for specific construction trades.

MET element: The erosion control activities of the new development and construction activities control element may be effective metal control measures. Erosion control activities will be analyzed for load reduction potential as part of the Program's pilot sedimentation study.

WMM element: An outcome of the Coyote Creek pilot watershed management plan will be development of model watershed protection policies and ordinances. These model policies will incorporate the provisions of the Regional Board's *Staff Recommendations for New and Redevelopment Controls for Storm Water Programs* related to the siting, design, and construction of new development. Area-wide watershed management implementation will follow recommendations of the pilot watershed plan (see WMM-4 and WMM-5).

VOL 12 2 5465

R0058758

IND element: New and redevelopment proposals for regulated industries are to be advised of the need to comply with the Regional Board's NPDES General Industrial Storm Water Discharge Permit as part of the project approval process.

Regional Board: This element should be coordinated with the Regional Board who regulate construction projects disturbing five or more acres of land area through NPDES General Construction Activities Storm Water Discharge permits.

Local Flood Control Agencies: Aspects of this element related to post-construction structural water quality controls should be coordinated with the Santa Clara Valley Water District Flood Control Department and/or the local agency having flood control design and maintenance responsibilities.

NDC EFFECTIVENESS EVALUATION

Effectiveness evaluation criteria will be based on implementation of the Regional Board *Staff Recommendations for New and Redevelopment Controls for Storm Water Programs* as applicable to each co-permittee's physical, economic and demographic conditions. Progress would be indicated by improvements in project approval and inspection procedures, incorporation of permanent storm water BMPs into project designs, and by implementation of watershed protection policies and storm water master planning related to controlling storm water quality from development sites.

NDC ACTIVITIES

NDC-1 Planning Procedures

Task 1:	Integrate Program, CZARA and CCMP goals into private and public project planning and design.
Task 2:	Revise project approval procedures to incorporate review for storm water quality issues.
Task 3:	Prepare and analyze development potential (available sites, development potential, General Plan projections).
Task 4:	Incorporate storm water quality issues into General Plan policies, goals and objectives.
Task 5:	Incorporate storm water quality issues into environmental review processes (CEQA, NEPA).
Task 6:	Utilize model watershed management plan prepared in WMM element to develop and/or revise policies, ordinances and design criteria.
Task 7:	Investigate the use of new BMPs for public agency projects.

R0058759

VOL 12 2 5466

NDC-2 Permitting/Design

Task 1: Establish minimum standards and BMPs for both construction and post-construction storm water quality controls, including erosion and sediment controls.

Task 2: Review and revise existing permit requirements to require incorporation of storm water BMPs and related information into project plans, specifications and permits.

Task 3: Require all projects regulated by the State NPDES General Construction Activities Storm Water Discharge permit to file for coverage under this permit as a condition of local agency construction permit approval.

Task 4: Coordinate storm water BMP requirements with other agency permitting requirements (e.g. zoning, design criteria, Hazmat, fire safety).

NDC-3 Education and Outreach

Task 1: Coordinate with PIP element activities to provide public agency training (Planning, Building, Public Works staff).

Task 2: Develop outreach materials for contractors, developers and designers on construction and new development BMPs and compliance with State NPDES General Construction permit.

NDC-4 Construction Control Activities

Task 1: Adopt inspection procedures (checklists, enforcement, reporting) consistent with the State NPDES General Construction Activities Storm Water Discharge permit and existing inspection programs.

Task 2: Require the use and/or construction of BMPs through inspection and enforcement.

NDC-5 Post-Construction Control Activities

Task 1: Develop and implement procedures for coordinating with the local flood control agency on issues related to applicable post-construction BMPs.

Task 2: Develop an operations and maintenance program to guarantee on-going responsibility of post-construction BMPs.

Task 3: Implement program for operation and maintenance of post-construction BMPs.

1.0 SUMMARY OF FINDINGS

This Retail Gasoline Outlet Storm Water Runoff Study identifies and quantifies chemical constituents detected in simulated storm water runoff from concrete and asphalt pavement at five preselected retail gasoline outlets (RGOs). The RGOs were selected to represent geographical areas, varying population densities, and different types of RGOs operating in California. Rainfall typical for California was simulated at each of the five RGOs. Runoff generated during the tests was collected and analyzed to identify and quantify chemical constituents that may have been present.

Metals.

The study analyzed metals in the first 15-minute sample (first flush) of runoff from the RGO pump island area. The concentrations reported in the data are below minimum analytical detection limits with the exceptions of barium, copper, and zinc. The GTEL Environmental Laboratory, Inc. (GTEL) analytical data sheets indicate that the maximum detection limit was increased for some samples due to a foaming effect noted in these samples.

The analytical results for metals demonstrate that the maximum concentrations of most constituents detected in the runoff water samples are lower than current United States Environmental Protection Agency (EPA) primary and secondary drinking water maximum contaminant levels (MCLs). The exceptions are antimony, arsenic, beryllium, cadmium, and lead, where the concentration cannot be compared to the drinking water MCLs because the minimum analytical detection limits are higher than the drinking water MCLs.

Volatile Organic Compounds.

The data collected during this study indicate that all VOC concentrations found in the storm water runoff from the pavement at RGOs are below the EPA MCLs. The concentrations of metals and VOCs detected during this study represent normal conditions at RGOs where the RGOs maintain effective housekeeping practices and cleanup of incidental spills.

At each RGO, nine samples of runoff water were obtained to be analyzed for the volatile organic compounds benzene, toluene, ethylbenzene and total xylenes (BTEX). Forty-five samples were collected from the five RGOs for analysis of volatile organic compound (VOC) content. Of 45 samples, 27 of the samples were below analytical detection limits (reported as ND, not detected). In the remaining 18 samples, VOCs were detected in the

R0058771

VOL 12 2 5478

runoff water at concentrations below the respective EPA MCLs. Out of the 45 samples, all were below the EPA MCLs.

2.0 PROJECT PROCEDURES

The simulated storm water runoff tests were conducted to identify and quantify chemical constituents in runoff at the five selected RGOs. The findings presented in this report identify the levels of chemicals commonly present in the runoff from typical RGOs in California. The data are presented as a comparison between each RGO and EPA primary and secondary drinking water MCLs.

Representatives of the Western States Petroleum Association (WSPA) selected RGO categories to represent the various geographical areas, varying population densities and types of RGOs located in California. The storm water runoff sampling was conducted at the five Southern California RGOs selected by the WSPA representatives.

Rainfall was simulated in the same manner at both the pump island (automotive refueling areas) and the driveway approach areas at each RGO (See Figure 1); samples were collected in the same manner at each RGO; sampling equipment was properly cleaned between each round of sampling. The only notable difference in the testing methodologies at the five RGOs occurred at the Category 5 RGO. One quart of gasoline was "spilled" at the pump island of the Category 5 RGO and cleaned up with absorbent material prior to the rainfall simulation. The "spill" was simulated at the pump island area only.

Tables 1 through 5 identify the sample source, collection time, date, weather conditions, and the specified analyses for each of the samples collected at the five RGOs.

The rainfall simulation was designed to represent the light, medium, and heavy rainfall regions of California. This report compares and documents the analytical data obtained from these tests. The test data quantify the concentrations of storm water constituents in runoff at the RGO pump islands and in driveway approaches to the RGO and pump islands. The analytical data for the samples collected at the five selected RGOs are summarized in Tables 6 through 9. The GTEL analytical data sheets are presented in Appendix A.

A comparison of average RGO runoff concentrations with water quality criteria and typical urban runoff are presented in Tables 10 through 14.

R0058772

VOL 12 2 5479

3.0 LITERATURE SEARCH

Initially a computerized literature file search was conducted to assess whether other similar studies had been performed which contained scientific information that may contribute to this storm water runoff project. The computerized literature file search did not disclose a previous RGO storm water study. Key literature abstracts relating to storm water runoff or other related information is included in Appendix B.

The computerized literature file search was conducted using the Dialog Information Database. The search was conducted of the following files:

NTIS (National Technical Information) - File 6;
COMPENDEX (Engineering Information Inc., NY, NY) - File 8;
APILIT (American Petroleum Institute) - File 354;
Pollution Abstracts/Cambridge Scientific Abstracts - File 41;
Water Resources Abstracts - File 117;
WATERNET (American Water Works Association,) - File 245; and
CA SEARCH (Chemical Abstracts , Columbus, OH) - File 399.

4.0 TECHNICAL APPROACH

The technical approach for this project included:

Developing site selection criteria and selecting representative RGOs;
Conducting preliminary field testing to establish test procedures; and
Determining sampling and analytical procedures.

These topics are described in detail in the following sections.

4.1 Selection of Retail Gasoline Outlets

The selection of the RGOs for this study was based on a cross section of the various populated and geographic areas in California and used the following criteria:

Anticipated refueling frequencies and anticipated ages of vehicles expected to frequent the RGOs.

Anticipated commercial use, based on the RGO's location.

The RGO's age and general appearance.

R0058773

VOL 12 2 5480

The construction class of the RGO including fuel islands, mechanics' bays, car washes and convenience stores.

The topography around the RGO including the drainage pattern and adjacent property use.

The WSPA members provided RGOs to represent differing examples of the above-listed categories. The RGOs selected for each category are located in the following cities in California:

Trabuco Canyon
Apple Valley
San Diego
Rancho Cucamonga
Los Angeles

Using the criteria previously mentioned, the RGOs which were selected had the following characteristics:

Category 1

Throughput greater than 250,000 gallons per month
Urban location, little or no commercial use
New facility, clean appearance
Covered fuel islands; carwash; no mechanics' bays
Hilly area, runoff to the east and west; facility is bermed[1]; shopping center adjacent to RGO

The Category One RGO was observed to have minimal staining on the ground surface around the pump islands. The pump island and driveway approach areas are concrete. The driveway approach area was observed to be relatively clean and free of oil and grease stains.

R0058774

VOL 12 2 5481

Category 2

Throughput greater than 250,000 gallons per month
Urban location, little or no commercial use
New facility, clean appearance
Covered fuel islands; carwash; convenience store; no mechanic's bays
Flat area, runoff to the west; facility is bermed; fast food adjacent to RGO

The Category Two RGO was observed to have minimal staining on the ground surface around the pump islands. The pump island and driveway approach areas are concrete. The driveway approach area is concrete and was observed to have oil and grease stains.

(1) - refers to concrete curbs (present at the category 1 and 2 RGOs) which direct the flow of storm water to on-site surface storm drains. At the RGOs without berming, rainfall on the RGO lot flows into surface storm drains on-site or off of the RGO into the street adjacent the RGO.

Category 3

Throughput of 150,000 to 250,000 gallons per month
Inner city, light commercial use
Older facility, stained and degraded concrete and asphalt
Covered fuel islands; mechanic's bays
Flat area, runoff to the south; facility is not bermed; residential and retail adjacent to RGO

The Category Three RGO was observed to have dark oil and grease stains on the ground surface around the pump islands and in the driveway approach areas. The pump island areas are concrete. The asphalt in the driveway approach areas was observed to be in poor condition, or degraded.

Category 4

Throughput of 150,000 to 250,000 gallons per month
Urban location, light commercial use
Older facility, stained and degraded concrete and asphalt
Covered fuel islands; mechanic's bays
Area sloped to the south; runoff to the south; facility is not bermed; shopping center adjacent to RGO

The Category Four RGO was observed to have oil and grease stains on the ground surface around the pump islands. The pump island areas are concrete. The asphalt in the driveway approach areas was observed to be in good condition.

VOL 12
2
5482

VOL 12 2 5483

Category 5

Throughput less than 150,000 gallons per month
Inner city, high commercial use
Older facility, stained and degraded concrete and asphalt
Covered fuel islands with mechanic's bays
Flat area, runoff to the north and south; facility is not bermed; industrial and retail adjacent to RGO

The Category Five RGO was observed to have oil and grease stains on the ground surface around the pump islands. The pump island areas are concrete. The asphalt in the driveway approach areas was observed to be degraded.

4.2 Preliminary Field Testing

Two days of preliminary field testing were conducted prior to initiating the on-site RGO storm water evaluation (discussed in further detail in Appendix C - Preliminary Field Testing). The preliminary field testing was performed at an abandoned RGO in Westminster, California.

The preliminary field testing was conducted to achieve the following objectives:

Develop the simulated rainfall distribution system;

Determine the minimum rainfall rate necessary to create sheet flow;

Test the containment berms and collection apparatus for performance and effectiveness;

Determine a method to contain water generated during rainfall simulation; and

Develop safety protocol to ensure that RGO personnel and customers were not exposed to hazards during the testing period.

R0058776

VOL 12 2 5484

4.3 Water Application

The test was designed to simulate a significant storm as defined by the National Oceanic and Atmospheric Administration (NOAA). A significant storm is defined as a continuous discharge of storm water for a minimum of one hour, or intermittent discharges of storm water for a minimum of three hours, in a 12-hour period.

During the test, potable water was distributed over the pump island and the driveway approach areas at a rate sufficient to provide adequate coverage of the test zone and develop sheet flow.

The test area evaluated at each RGO was approximately 400 square feet. The volume of water required to attain adequate sheet flow across each test area was determined to occur at a flow rate of about 2.0 gallons per minute (gpm). Based on this flow rate, the test was designed to run for a duration of 45 minutes. The 45-minute test was divided into three, 15-minute periods.

A flow rate of 2.0 gpm was dispensed over the 400 square-foot test area (See Figure 1) for a total of 45 minutes. This flow rate was determined to be appropriate for the test area size and functional operation of the water dispensing equipment. The flow rate of 2.0 gpm was sufficient to generate sheetflow within the test area.

Water distributed at the constant flow rate of 2.0 gpm distributed approximately 0.125 inches of "rain" over the test area in the first 15-minute period (33 gallons over 400 square feet). After 30 minutes, 0.250 inches of "rain" was distributed over the test area (66 gallons over 400 square feet). After 45 minutes, 0.375 inches of "rain" was distributed over the test area (100 gallons over 400 square feet).

4.4 Water Dispensing System

The water dispensing system was comprised of a supply line (a flexible hose), a flow meter with an on/off valve and 1 inch diameter, schedule 80 polyvinyl chloride (PVC) pipe. One end of the supply line was attached to the source water (the RGO hose bib). The other end of the supply line was attached to the flow meter. The flow meter was attached to the network of PVC pipes. The PVC pipes were perforated at 8 to 12 inch intervals with 3/64 inch holes (See Figure 2).

At each RGO, the network of pipes was set up so that the water would cover an area approximately 20 feet x 20 feet. The location of the water

R0058777

dispensing equipment was positioned at each RGO depending on the physical layout and the slope of the RGO. The volume of water was regulated by a shut-off valve and monitored by the flow meter. The water was dispensed through the network of PVC pipe.

4.5 Water Collection Apparatus

The containment berms consisted of sand-filled polyethylene tubing. The berms were constructed of 5-foot-long tubes and placed into position around the test area. The containment berms were used to channel the runoff water to the collection point. A stainless steel collection trough was placed at the lowest point of the test area and incorporated into the containment berms (See Figures 2 and 3).

At the end of each 15 minute period, an electric pump was used to pump the collected water into a 55-gallon steel drum. The 55-gallon drum was lined with a polypropylene liner. A new liner was used for each test to ensure the composite samples were representative of the test area being sampled. The electric water pump and sampling scoop were properly cleaned between sampling rounds using a solution of deionized water and alconox and then rinsed with deionized water.

4.6 Staged Spill and Cleanup Sampling Event

A staged spill was conducted at the Category 5 RGO. The RGO was randomly picked from the five categories. The spill was conducted to simulate the type of spill that would occur at the pump island if a motorist were to drop the pump nozzle while in the process of fueling an automobile. No cleanup or sweeping was performed prior to conducting the spill.

To simulate the spill the pump nozzle was used to dispense one quart of regular unleaded gasoline onto the ground. The gasoline was allowed to spread out naturally. After one minute, absorbent material was applied to the spill area and allowed to soak up the gasoline. When the absorbent material appeared saturated and the gasoline appeared to be completely soaked up, the absorbent was swept up.

After sweeping up the absorbent, the water dispensing equipment was set up and the storm water runoff test begun. The spill was conducted at the pump island area only.

R0058778

VOL 12 2 5485

5.0 SAMPLE COLLECTION

A total of 28 samples were collected at each RGO. Tables 1 through 5 identify the site-specific conditions for each round of samples collected at the five RGOs. The sample source, collection time, date, weather conditions, and the specified analyses for the samples are listed in the tables.

Appendix E lists rainfall dates and amounts prior to the simulated rainfall runoff testing. Appendix F contains volume calculations of the simulated runoff at each RGO.

5.1 Sampling Procedures

Sampling procedures followed strict sampling protocol established by SW846, "Test Methods for Evaluating Solid Waste" (including surface and groundwater). Samples were obtained using cleaned sampling equipment and placed into laboratory supplied and certified "clean" sample containers. The samples were kept at or below 4 degrees Celsius.

Prior to starting each test, a background sample was collected from the RGO's potable water at the end of the supply line used to deliver water to the network of PVC pipes, this sample was the Round 1 sample. After the simulation started, the predetermined flow rate was adjusted and three successive samples were collected from the collection trough at 15-minute intervals.

Trip blanks are sent along with field samples as a measure of quality assurance. Trip blanks are used to ensure that the field samples represent the material sampled and not material or chemicals introduced during transport. The trip blanks were analyzed to verify that contamination was not introduced to the samples while they are in transit between point of collection and the laboratory.

For the RGO runoff sampling the same type of vials were used for the trip blanks as were used to collect the water samples at the RGOs. The vials were filled with purified water and handled in the same manner as the other samples, which were analyzed for VOCs and TPH. One trip blank was stored in each cooler together with the field samples. See Appendix D - Sampling Procedures for detailed sampling procedures followed for this study.

R0058779

VOL 12 2 5486

5.2 *Sample Time and Location*

At each RGO the following samples were obtained:

One background sample from the RGO potable water source;

Three discrete grab samples of runoff from the pump island area collected at 15-minute intervals;

One composite sample of total runoff from the 55-gallon drum collected from the pump island area over the 45-minute test duration;

Three discrete grab samples of runoff from the driveway approach area collected at 15-minute intervals;

One composite sample of total runoff from the 55-gallon drum collected from the driveway approach area over the 45-minute test duration; and

One trip blank sample for quality assurance was filled with deionized water prior to arriving at the RGO for the sampling event.

See Figure 2 for sample time, location and sample round numbers.

5.3 *Sample Analytical Methods*

The samples were analyzed by the methods listed below.

Volatile Organic Compounds -	EPA method 8020
Total Petroleum Hydrocarbons -	EPA method 8015
Total Suspended Solids -	EPA method 160.2
Total Recoverable Oil and Grease -	EPA method 413.2
Title 26 Metals -	EPA method 6010 and EPA method 7470

VOL 12 2 5487

R0058780

6.0 RESULTS AND DISCUSSION

6.1 Physical Condition of Retail Gasoline Outlets

The laboratory test results indicate that the physical condition of the RGO did not influence the concentrations of chemicals detected in the storm water at the pump island areas and the driveway approach areas. This was for both asphalt and concrete ground surfaces.

The analytical data for the samples collected at the five selected RGOs are summarized in Tables 6 through 9. The GTEL analytical data sheets are presented in Appendix A.

6.2 Volatile Organic Compounds and Total Petroleum Hydrocarbons

All samples were determined to be below the EPA MCLs for the VOCs (benzene, toluene, ethylbenzene and total xylenes). Data presented in Table 6 indicates that most concentrations of VOCs in the runoff samples are below analytical detection limits. Some samples had detectable concentrations of VOCs, but the concentrations were below the EPA MCLs. The only clear pattern emerging from the data is that total xylenes are the most prevalent VOC to be detected; this pattern is logical due to total xylenes having a lower vapor pressure (i.e., lesser tendency to volatilize) compared to benzene, toluene, and ethylbenzene.

The EPA MCLs for the BTEX compounds are as follows:

Compound	EPA MCLs
benzene	5 μg/L
toluene	1,000 μg/L
ethylbenzene	700 μg/L
total xylenes	10,000 μg/L

At the Category 1 RGO, concentrations of VOCs were detected in each sample of runoff from the pump island area. Toluene was detected at a maximum of 0.8 micrograms per liter (μg/L) and total xylenes were detected at a maximum of 1.4 μg/L. The VOCs were not detected in the runoff samples from the driveway approach area.

R0058781

VOL 12 2 5488

At the Category 2 RGO, VOCs were not detected in the samples from the pump island area. VOCs were detected in the samples from the driveway approach area. Benzene was detected at 1.5 µg/L in the 15-minute sample (the first flush) from the driveway approach area and at 0.4 µg/L in the composite sample from the driveway approach area. Toluene was detected in the trip blank that was sent along with the samples from this RGO at 0.5 µg/L. (See Trip Blank section)

At the Category 3 RGO, the highest concentrations of VOCs were detected in the 15-minute sample from the pump island area and the 45-minute runoff sample from the driveway approach area. Toluene was detected at 7.9 µg/L and total xylenes were detected at 20 µg/L in runoff from the pump island area. Benzene was detected at 0.5 µg/L, toluene at 4.5 µg/L, ethylbenzene at 1.1 µg/L and total xylenes at 12 µg/L in the runoff from the driveway approach area.

At the Category 4 RGO, the highest concentrations of VOCs were detected in the source water and in the last runoff sample from the pump island. The application water was determined to have toluene at 0.3 µg/L and total xylenes at 7.1 µg/L. Toluene was detected at 0.4 µg/L and total xylenes were detected at 1.5 µg/L in the last runoff sample. Toluene was detected in the trip blank that was sent along with the samples from this RGO at 0.7 µg/L. (See Trip Blank section)

At the Category 5 RGO, VOCs were detected in the runoff from the pump island following the spill and cleanup of one quart of gasoline. The highest concentrations of VOCs detected at this RGO were benzene at 1.0 µg/L, toluene at 14 µg/L, ethylbenzene at 6.3 µg/L and total xylenes at 41 µg/L. VOC concentrations were below detection limits in the runoff samples from the driveway approach area.

6.3 Suspended Solids

The analytical results for total suspended solids are presented in Table 7. Most of the results are below analytical detection limits. Total Suspended Solids were not detected at the Category 1 and 2 RGOs. Total Suspended Solids were detected in the application water at the Category 3 and 4 RGOs at 11 and 14 mg/L, respectively. These results were slightly above the detection limit of 10 mg/L. These levels were reflected in the runoff data. At the Category 5 RGO, the 45-minute sample from the driveway approach

R0058782

VOL 12 2 5489

area had 13 milligrams per liter of total suspended solids, slightly above the detection limit of 10 mg/L.

6.4 Metals

The analytical results for the metals are presented in Table 8. The data represent the metal concentrations in the 15-minute sample from the pump island area at each of the RGOs. Subsequent samples were not analyzed for metals. All of the concentrations reported in the data are below analytical detection limits with the exceptions of barium, copper and zinc.

The EPA MCLs and detection limits for barium, copper and zinc are listed below:

element	EPA MCL	Detection Limit
barium	1,000 µg/L	20 µg/L
copper	1,000 µg/L	200 µg/L
zinc	5,000 µg/L	100 µg/L

At the Category 1 RGO, barium was detected at 130 µg/L.

At the Category 2 RGO, all metals analyzed for were ND, not detected.

At the Category 3 RGO, barium was detected at 60 µg/L and zinc at 200 µg/L.

At the Category 4 RGO, barium was detected at 60 µg/L and zinc at 200 µg/L.

At the Category 5 RGO, barium was detected at 80 µg/L, copper at 200 µg/L and zinc at 600 µg/L.

R0058783

VOL 12 2 5490

6.5 Recoverable Oil and Grease

The analytical results for total recoverable oil and grease are listed in Table 9. The detection limit for the oil and grease test was 1 mg/L. The highest detected concentration of oil and grease was 34 mg/L.

At the Category 1 RGO, total recoverable oil and grease was at the detection limit in the 15-minute sample and the 45-minute sample from the pump island area. In the driveway approach area, the 15-minute sample and the 45-minute sample had oil and grease concentrations of 2 mg/L.

At the Category 2 RGO, total recoverable oil and grease was at the detection limit in the 15-minute sample from the driveway approach area and composite sample from the driveway approach area.

At the Category 3 RGO, the highest total recoverable oil and grease was detected at 8 mg/L in the 15-minute sample from the pump island area. The subsequent samples in the pump island area for the 30, 45-minute and composite samples were 3, 2 and 3 mg/L, respectively.

At the Category 4 RGO, an unexpected result in the analytical data is reported. A 15 mg/L concentration of total recoverable oil and grease is reported in the source water. The 15 mg/L concentration in the background sample is higher than the 4, 2, and 8 mg/L concentrations reported in the 15, 30, and 45-minute runoff water samples collected.
At the Category 5 RGO, the total recoverable oil and grease concentrations detected were the highest among the RGOs. The composite sample at the pump island area had a concentration of 34 mg/L. The composite sample at the driveway approach area had a concentration of 29 mg/L.

6.6 Trip Blanks

Toluene was detected in the quality control trip blanks that were sent with the runoff samples from the Category 2 and 4 RGOs at concentrations of 0.5 µg/L and 0.7 µg/L, respectively. These concentrations are slightly above the analytical detection limit of 0.3 µg/L. The laboratory did not provide the trip blanks used for this test. The trip blanks were filled with bottled water prior to arriving at each RGO from different bottles of purified water. In the two trip blanks with detectable levels of toluene, the concentrations of toluene were higher than the levels detected in the runoff

R0058784

VOL 12 2 5491

water. Contamination was not introduced through sample handling or transportation because toluene was not detected in the other samples from this site.

The GTEL laboratory director, Ms. Joan Greenwood, indicated that GTEL has detected toluene in batches of purified bottled water. At our request, Ms. Greenwood prepared a letter to explain their findings. The letter is included in Appendix H. The letter states that GTEL has detected toluene in bottles of "pure" water from commercial bottled water companies. Water in glass containers has frequently contained toluene in concentrations up to 2 μg/L. GTEL found plastic containers to contain toluene in even higher concentrations.

7.0 WATER QUALITY COMPARISON

The average concentrations for the chemical compounds studied during the runoff test are compared to water quality criteria and typical urban runoff in Tables 10 through 14.

7.1 EPA MCLs

The data indicate that the average concentrations observed at the five RGOs are lower than the current EPA primary and secondary drinking water MCLs with a few exceptions. The exceptions are antimony, arsenic, beryllium, cadmium, and lead. These exceptions exist because laboratory analytical detection limits are higher than the drinking water MCLs.

We note here that this study illustrates a problem typical of many water quality studies; the analyses employed in the study were performed using standard methods approved by regulatory agencies. However, the detection limits inherent to the standard methods are higher than current and proposed water quality criteria identified in the CA Draft Freshwater and Saltwater Aquatic Life Water Quality Objectives. Achieving lower detection limits requires specialized and expensive analytical techniques sometimes by non-standard research-oriented methods.

7.2 Federal Freshwater and Marine Aquatic Life

The EPA has published chronic exposure water quality criteria for freshwater and marine aquatic life. Concentrations from the RGO runoff which exceed these criteria are copper and zinc. Many of the EPA freshwater and marine aquatic life criteria are below the analytical detection

VOL 12 2 5492

R0058785

limits attainable by laboratory methods employed for sample analysis in this study.

7.3 Draft California Freshwater/Saltwater Aquatic Life Water Quality

The State of California is proposing water quality objectives for freshwater and saltwater aquatic life. Comparisons of the RGO runoff with the proposed four-day exposure freshwater aquatic life objectives are difficult because many of the objectives must be calculated by use of the hardness concentrations in the aquatic environment. With respect to the proposed four-day exposure marine chronic objectives, the standards are set below the analytical detection limits attainable by the laboratory methods employed for this study except for chromium and selenium; neither of which were detected in the runoff in concentrations above the proposed objectives.

7.4 Range of Concentrations Typical in Urban Runoff

Tables 10 through 14 also list ranges of chemical concentrations typical of urban runoff as reported in the EPA's Nationwide Urban Runoff Program (NURP). Comparison of the analytical data obtained from the runoff at the five RGOs represented by this study show the chemical concentrations from runoff water are similar to the ranges reported by NURP. The data from this study showed slightly higher concentrations of toluene and copper. The data produced by this study are in the lower ranges of many of the concentrations reported in the NURP, for example, benzene and total suspended solids.

8.0 CONCLUSION

All volatile organic compound concentrations detected in the samples of runoff water were below EPA MCLs. More testing will be necessary to determine the levels of gasoline constituents present in stormwater.

The results of the incidental spill performed at the Category 5 RGO indicate that good housekeeping practices minimize the amount of gasoline constituents present on the RGO ground surface. By minimizing the gasoline constituents present on the ground surface, minimal gasoline constituents will be available to be washed away with the runoff water from the RGO surface during a storm event.

VOL 12 2 5 5 1 5

Mr. John Netherwood
Hart Crowser
1 World Trade Center
Long Beach, CA 90831

Dear Mr. Netherwood,

This report replaces the original report, dated September 22, 1992, which is being reissued due to GTEL's inadvertant ommission of information pertaining to this project. Enclosed please find the analytical results for the samples received by GTEL Environmental Laboratories, Inc. on 9/4/92.

A formal Quality Assurance/Quality Control (QA/QC) program is maintained by GTEL, which is designed to meet or exceed the EPA requirements. Analytical work for this project met QA/QC criteria unless otherwise stated in the footnotes.

GTEL is certified by the state of California under Certification #1123.

If you have any questions concerning this analysis or if we can be of further assistance, please call our Customer Service Representative.

Sincerely,

GTEL Environmental Laboratories, Inc.

for JG

Joan Greenwood
Laboratory Director

Mr. John Netherwood
Hart Crowser
1 World Trade Center
Long Beach, CA 90831

Dear Mr. Netherwood,

Enclosed please find the analytical results for the samples received by GTEL Environmental Laboratories, Inc. on 9-11-92

A formal Quality Assurance/Quality Control (QA/QC) program is maintained by GTEL, which is designed to meet or exceed the EPA requirements. Analytical work for this project met QA/QC criteria unless otherwise stated in the footnotes.

GTEL is certified by the state of California under Certification #E721.

If you have any questions concerning this analysis or if we can be of further assistance, please call our Customer Service Representative.

Sincerely,

GTEL Environmental Laboratories, Inc.

Minsoon Song
Laboratory Director

cc: Allison Fong

Mr. John Netherwood
Hart Crowser
1 World Trade Center
Long Beach, CA 90831

Dear Mr. Netherwood,

Enclosed please find the analytical results for the samples received by GTEL Environmental Laboratories, Inc. on 9/4/92.

A formal Quality Assurance/Quality Control (QA/QC) program is maintained by GTEL, which is designed to meet or exceed the EPA requirements. Analytical work for this project met QA/QC criteria unless otherwise stated in the footnotes.

GTEL is certified by the state of California under Certification #1723.

If you have any questions concerning this analysis or if we can be of further assistance, please call our Customer Service Representative.

Sincerely,

GTEL Environmental Laboratories, Inc.

Minsoon Song
Laboratory Director

VOL 12 2 5562

Mr. John Netherwood
Hart Crowser
1 World Trade Center
Long Beach, CA 90831

Dear Mr. Netherwood,

Enclosed please find the analytical results for the samples received by GTEL Environmental Laboratories, Inc. on 9-10-92.

A formal Quality Assurance/Quality Control (QA/QC) program is maintained by GTEL, which is designed to meet or exceed the EPA requirements. Analytical work for this project met QA/QC criteria unless otherwise stated in the footnotes.

GTEL is certified by the state of California under Certification #E723.

If you have any questions concerning this analysis or if we can be of further assistance, please call our Customer Service Representative.

Sincerely,

GTEL Environmental Laboratories, Inc.

Minsoon Song
Laboratory Director

Mr. John Netherwood
Hart Crowser
1 World Trade Center
Long Beach, CA 90831-2300

Dear Mr. Netherwood,

This report replaces the previous report issued on 10-2-92 due to a typographical error in the dilution multiplier on page 2. Enclosed please find the analytical results for the samples received by GTEL Environmental Laboratories, Inc. on 9-18-92.

A formal Quality Assurance/Quality Control (QA/QC) program is maintained by GTEL, which is designed to meet or exceed the EPA requirements. Analytical work for this project met QA/QC criteria unless otherwise stated in the footnotes.

GTEL is certified by the state of California under Certification #E723.

If you have any questions concerning this analysis or if we can be of further assistance, please call our Customer Service Representative.

Sincerely,

GTEL Environmental Laboratories, Inc.

Minsoon Song
Laboratory Director

a. Test Methods for Evaluating Solid Waste, SW-846, Third Edition, Revision 0, US EPA November 1986. Modification for TPH as gasoline as per California State Water Resources Board LUFT Manual procedures.

b. Indicates the adjustments made for sample dilution.

c. TFT surrogate recovery acceptability limits of 72.8-123% are derived from the 99% confidence interval of all samples during the previous quarter. Expected surrogate value is 100 ug/L.

* Detection limit increased due to matrix effect (foaming)

Main Title	Contributions of Urban Roadway Usage to Water Pollution
Personal Author	Shaheen., Donald G.;
Corporate Author	Biospherics, Inc., Rockville, Md.;Environmental Protection Agency. Washington, D.C. Office of Research an Development.
Year Published	1975
Call Number	PB-245 854
Report Number	EPA-68-01-0197; EPA-ROAP-21ASY-005; EPA/600/2-75-004;
Abstract	Street surface contaminants are deposited on roadways from many sources within an urban area. Industrial operations, land use activities, fallout of air pollutants, roadway usage and other activities contribute to the loading of particulates on urban roadways. These materials are then carried into receiving waters by storm runoff where they constitute a substantial portion of the overall water pollution problems of cities. Metropolitan Washington, D.C., with its low background of industrial emissions, was the area chosen for study of contributions of motor vehicle usage to urban roadway loading factors. Specific roadway study sites within this area were selected so as to provide minimal interference from nontraffic-related land use activities and thus isolate, as much as possible, the traffic-related depositions.

Main Title	Toxicants in Urban Runoff: Metro Toxicant Program Report Number 2.
Personal Author	Galvin, D.V.; Moore, R.K.;
Corporate Author	Municipality of Metropolitan Seattle-METRO,WA. Water Quality Div.
Year Published	1982
Call Number	PB84-104124
Report Number	MMS/WOR-8210; EPA-P-000161-01:
Abstract	As part of the U.S. Environmental Protection Agency's Nationwide Urban Runoff Program, the Municipality of Metropolitan Seattle (METRO) studied the sources and presence of toxic substances in urban stormwater runoff, as well as their potential adverse effects on local freshwater receiving environments. Sampling and analysis were designed to provide concentration data for the Clean Water Act's priority pollutant metals and organics. Sampling of potential sources to stormwater runoff included airborne particles, street dust, and catchbasin sediments. Both urban control environmental samples were taken from interstitial streamwaters, stream sediments, and Lake Washington bottom sediments. Evaluations of toxicant control measures focuses on currently available removal techniques, such as street sweeping, detention basins, and oil separators. The report incorporates a thorough literature review and includes an extensive bibliography.

Abstract	This summary report consolidates the major findings and conclusions of several individual studies, which included: Tests conducted to contrast the biological and chemical conditions in an urban creek with a rural creek; Monitoring urban runoff quality and quantity from 3 urban areas; Analysis of many source area, urban runoff, and creek samples for metallic and organic priority pollutants; Sampling of urban stormwater and base flows rom 2 residential areas. Collection of street dirt samples and evaluation of effects of street cleaning and catchbasin cleaning on improvement of urban runoff quality.

Abstract:	In an effort to provide a better understanding of the sources of petroleum hydrocarbons in urban runoff, petroleum products as well as probable source materials were analyzed for hydrocarbons and trace metals and then compared to urban runoff samples from four different land use areas. The petroleum products considered were No.2 and No.6 fuel oil, used and virgin crankcase oils, and gasoline. Source materials included street dust, roadside soil, roadside vegetation, and atmospheric fallout; and the land use categories were commercial, residential, interstate highway, and industrial areas. The samples were compared on the basis of hydrocarbon (saturated and aromatic) and trace metal (Cd, Pb, Mn, Cu, Fe, Zn) loadings and distributions. Results indicated that the hydrocarbon content in runoff at all four land use sites originated primarily from used crankcase oil, with a small amount of No. 2 fuel oil detected at the industrial site. Only a small portion of the crankcase oil component came from the sources surveyed, and the majority of this oil probably came from: (1) oil drops within the driving lanes on the road surfaces or deposits in parking areas, and/or (2) direct dumping of waste crankcase oil down storm drains. Abstract: Waste-to-energy resource recovery facilities fall into two major categories: mass burn and RDF (refuse-derived fuel). Site design considerations presented here are applicable to both categories; however, layout and system description used is for mass-burn facilities. The project site is identified through a complex screening process that includes issues such as environmental compatibility and public sentiment. This paper considers the design within the selected site. Site layout and aesthetics of the facility are of utmost importance to win public support. Traffic congestion is an issue which may be of particular concern to residents in the area of the project; therefore, it is essential that sufficient on-site truck queuing space is provided to avoid traffic spillover onto public streets. Storm-water drainage system must be designed to prevent water pollution during the construction, and in many instances it must be designed to maintain predevelopment runoff rate from the site. Last is the economic consideration: Site must be designed to minimize the capital cost and cost of maintenance. (Edited author abstract)

The Science of the Total Environment STENDL, Vol. 93, p 419-431, April 1990. 6 tab, 12 ref.,
Journal Announcement: SWRA2402
Investigations were performed in the Federal Republic of Germany to determine pollutant concentrations in rainwater in order to obtain a comprehensive picture of the pollution caused by precipitation runoff. Influencing parameters included: exhaust gases, tire abrasion particles, brake lining abrasion dust, leakage of hydrocarbons, and winter street cleaning activities. The analysis of these factors was complemented by the determination of detection limits. After an assessment of all possibilities, 30 substances remained, and 22 were analyzed. Lead, chromium, copper, nickel, and zinc are the elements commonly found in the emissions/particles of the aforementioned parameters. (Stoehr-PTT)

Journal Announcement: SWRA2204
Data were collected as part of the National Urban Runoff Program to characterize urban runoff in Fresno, California. Rainfall-runoff quantity and quality data are included along with atmospheric dry-deposition and street-surface particulate quality data. The data are presented in figures, and tables that reflect four land uses: industrial, single-dwelling residential, multiple-dwelling residential, and commercial. A Total of 255 storms were monitored for rainfall and runoff quantity. Runoff samples from 112 of these storms were analyzed for physical, organic, inorganic, and biological constituents. The majority of the remaining storms have pH and specific conductance data only. Ninety-two composite rain samples were collected. Of these, 63 were analyzed for physical, inorganic and (or) organic constituents. The remaining rainfall samples have pH and specific conductance data only. Nineteen atmospheric deposition and 21 street-particulate samples were collected and analyzed for inorganic and organic constituents. The report also details equipment utilization and operation, and discusses data collection methods. (USGS)

Oil and Grease in Stormwater Runoff
Stenstrom, M. K.; Silverman, G.; Bursztynsky, T.A.; Zarzana, A.L.; Salarz, S.E.
California Univ., Los Angeles, Dept. of Engineering Systems Report, February 1982. Association of Bay Area Governments, Berkeley, California. 241 p., 41 Fig., 44 Tab., 158 Ref., 3 Append.,
Journal Announcement: SWRA1511
The objective of this project was to determine the environmental effects of oil and grease in urban stormwater on marine environments in San Francisco Bay and to recommend suitable control measures. Studies show that there are significant effects of low level oil/grease pollution and that continuous pollution from urban stormwater can change the ecology of a marine environment. Five field sampling stations were selected in a stormwater basis in Richmond, CA to determine oil/grease pollution by land-use type. Samples were taken from the mouth of the watershed, a parking lot, a commercial street, a residential area, and from a light industrial facility. Land-use strongly affects oil/grease in stormwater. The major contributing factor is motor vehicles. Areas with the most auto traffic had the highest concentration of oil/grease in stormwater and the highest hydrocarbon load factor. Mean oil/grease concentration in runoff flow ranged from 4.13 mg/l in an upstream residential area to 15.25 mg/l in a parking lot. A strong correlation exists between total rainfall and total mass of oil/grease pollution--contamination is higher at the beginning of a storm than at the end. Nine control techniques showed promise. Three non-structural techniques were to recycle used crankcase oil, reduce auto emissions through better inspections, and improve standards. Six structural techniques were to improve street/parking lot cleaning, sorption systems for manhole and gutter intakes, porous pavement, greenbelts around parking lots, dispersion devices, and wetlands or marshes to trap pollutants. These are site-specific techniques but it was recommended they be developed further. (Atkins-Omniplan)

Constituents of Highway Runoff: Volume I, State-of-the-Art Report
Gupta, M.K.; Agnew, R.W.; Kobriger, N.P.
Envirex Inc., Milwaukee, WI.
Available from the National Technical Information Service, Springfield, VA 22161 as PB881-241895, Price codes: A06 in paper copy, A01 in microfiche. Federal Highway Administration Report No. FHWA/RD-81/042, February, 1981. 121 p., 16 Fig., 37 Tab., 169 Ref., DOT-FH-11-8600.
Journal Announcement: SWRA1510
The factors which most affect quantity and quality of highway runoff are traffic volume, rainfall intensity and pattern, highway drainage characteristics, operation and maintenance characteristics and degree of imperviousness of the drainage area. Maintenance of adequate drainage is one of the most important aspects of highway design. Highway runoff characteristics are similar to those of urban runoff and may exert significant shock pollutional loads on receiving waters. The weighted average of total solids accumulations between successive street cleanings, a period of 2 to 12 days, for eight cities was found to be 1400 lb/curb mile. A high percentage of street surface pollutants are associated with very fine dust and dirt particles. Substantial quantities of toxic materials, such as heavy metals and pesticides, are present in street surface contaminants with the amounts varying considerably from site to site. Because of the consistent presence of heavy metals in amounts large enough to interfere with BOD5 measurements, COD is considered to be a better parameter for measuring the oxygen demand potential of highway runoff. Highway salting rates usually range from 400 to 1200 lbs per two-lane mile. Over the winter season, a typical multiple lane highway may use 100 tons or more of salt per mile. Significant amounts of vehicle released airborne matter are settled out and washed off the road surface during rainstorms. (Moore-SRC)

Water Quality Patterns During A Storm On a Mall Parking Lot
Black, P.E.
State Univ. of New York at Syracuse, Coll. of Environmental Science and Forestry.
Water Resources Bulletin, Vol 16, No. 4, p. 615-620, August, 1980, 6 Fig. 2 Tab., 13 Ref.
Journal Announcement: SWRA1510
Rainfall, surface runoff, and subsurface drainage plus streamflow upstream and downstream of a suburban New York mall parking lot were intensively sampled during and after a thunderstorm on June 18, 1978. Prior to the 11.4mm which fell within less than 1.5 hours, no rain had fallen for 4 days. Ammonia-N concentrations were high (up to 2.5mg per liter) in parking lot runoff, a result of precipitation which contained up to 2.0mg per liter ammonia-N. Surface runoff had a peak in conductivity during the rainfall and returned to prestorm levels by the end of the study period. Initial runoff appeared gray and nearly opaque. Nine constituents (K, Mn, Fe, P, Pb, Zn, Mg, Ca, and Na) showed a peak in surface runoff between 45 and 60 min after the rain started, declined to a low at 75 min, and returned to prestorm values by 105 min. Drainage from subsurface drains was brown in color and had a strong odor. In the receiving stream, water temperature increased and conductivity decreased during the beginning of the storm and returned to prestorm levels after 5 hours. (Cassar-FRC)

The Distribution of Heavy Metals and Petroleum Residues in the Soil from Urban Surface Runoff
Owe, M.
State Univ. of New York at Syracuse. Coll. of Environmental Science and Forestry.
PhD Thesis, January, 1981, 197 p., 56 Fig., 22 Tab., 100 Ref., University Microfilms International, Ann Arbor, MI; Order No. GAX81-18121.,
Journal Announcement: SWRA1509

The soil is thought to possess an enormous capacity for immobilizing environmental contaminants, especially those typically contained in urban surface runoff. The profiles of two common area soil, a sandy, porous Arkport and a dense clayey Dunkirk, were reconstructed in 14 cm by 80cm columns in the laboratory. The design was intended to simulate a collection basin, one fourth the surface area of the test basin. Surface runoff was sampled and collected from a heavy used shopping center parking lot. Treatments simulated actual precipitation-runoff event frequency and volume occurring during the study period. The profiles were subsequently analyzed at predetermined increments for zinc, lead, cadmium, copper and petroleum residues. An overall increase in total cation and petroleum concentration was noticed with an increase in treatment concentration. A positive relationship between contaminant concentration in the soil and treatment level, exchange capacity, final soil pH and percent organic matter was realized. A negative correlation was noticed between contaminant concentration and bulk density. Treatment level and final soil pH recovered totals far below the input amounts, consistently lower hydrocarbon totals were recovered from the Arkport. This indicates the possibility of a higher rate of petroleum residue decomposition in the more porous, better aerated Arkport soil. (Sinha-OEIS)

PRELIMINARY FIELD TESTING PROCEDURES AND FINDINGS

2

R0058899

Preliminary Field Testing Procedures and Findings

The preliminary field testing was successful in determining that a constant flow rate was needed to achieve uniform distribution of the application water over the selected area. The preliminary field testing of various distribution systems identified that a cascading flow of potable water dispersed through perforated Polyvinyl Chloride (PVC) pipe and measured by an accumulating water meter achieved the desired results. The flow rate was measured by a Rotameter with a scale of 0 through 10 gallons per minute. A stainless steel water collection trough was designed and constructed (Figure C-1) to function as a sampling point and accumulation sump to capture the applied water. It was determined that the leading edge of the stainless steel trough needed a flexible edge to conform to the irregular surface of the concrete and asphalt. A length of polypropylene tubing was cut and slipped over the leading edge of the trough for this purpose.

The captured water was pumped from the collection sump into a plastic-lined metal 55-gallon drum. Four-foot-long containment berms were used to contain the water flow. The berms were constructed from 6 millimeter clear polypropylene tubing, 4 inches in diameter, and filled with clean sand. The non-porous polypropylene and sand filled berms contained the water flow and diverted it to a preselected collection point at the lowest area of the sampling site.

Safety precautions included placing cones around the active test area and meeting with the station attendant to discuss the activities that were going to be conducted.

I

SAMPLING PROCEDURES

The water dispensing equipment was set up at each location using the PVC pipe apparatus to cover an area approximately 20 feet x 20 feet. The location of the equipment was determined at each station depending on the physical layout and the slope of the station island. The containment equipment was then placed into position around the area. The containment berms were used to channel the runoff water to the collection point. A stainless steel collection trough was placed at the lowest point of the test area and incorporated into the network berms.

Tables 1 through 5 list each sample round, the sample point or time and the analyses run on the samples collected during that round:

The first round of samples was collected from the source water. The source water sample was submitted for testing with the site samples. The predetermined flow rate was adjusted when the water flow was started. The second round of samples was taken 15 minutes into the water dispensing. A plastic scoop was used to fill the sample bottles from water in the collection trough.

After the second round of samples the water in the collection basin was pumped into a 55-gallon drum using an electric pump. The 55-gallon drum was lined with polypropylene that was changed between the pump island test location and the driveway approach test location at each station. The electric water pump and scoop were decontaminated between sample rounds using a solution of deionized water and alconox, followed by two rinses with deionized water.

For quality control one trip blank was filled with deionized water and stored in each cooler together with the field samples. The trip blank insures that the data obtained from the site testing represents the pollutants collected from the site surface and does not represent contaminates introduced during transport.

A background sample was collected from the service station's potable water at the end of the supply line that was used to produce the simulated rain. The sampling and analysis keys used for this project list the sample identification, station category, location, time interval and weather for each sampling event. The keys are presented in Tables 1 through 5.

At the Category 5 station an incidental spill evaluation was conducted at the pump island prior to conducting the runoff test. The incidental spill test was conducted using one-quart of gasoline. The staged spill of fuel was collected in absorbent that was applied to the spill and picked up prior to the application of the test water.

Grab samples were drawn from the collected water and caution was used to insure that the 40 ml vials for BTEX did not contain any head space. The samples were transported to GTEL Environmental Laboratories, Inc. in an ice chest maintained at 4 degrees Celcius where the samples were analyzed for the specified chemical compounds in the sampling protocol. The analytical data are intended to represent an estimate of the water quality from a storm event equivalent to the flow represented.

VOL 12

2

5609

SAMPLING PROCEDURES (Continued)

(Round 2 at 15 minutes, Round 3 at 30 minutes, and Round 4 at 45 minutes in the pump island area and Round 6 at 15 minutes, Round 7 at 30 minutes, and Round 8 at 45 minutes in the driveway approach area). At the end of each 15-minute interval, the water in the collection trough was pumped into a 55-gallon drum using an electric pump. Upon completion of the simulation, a composite sample was collected from the 55-gallon drum (Round 5 for the pump island area and Round 9 for the driveway approach area).

Trip blanks were used to ensure that the sample obtained from a site represented the material sampled and its constituents not material or chemicals introduced during transport. Trip blanks are sent along with field samples as a measure of quality assurance. The trip blanks are analyzed to verify that contamination is not introduced to the samples while they are in transit between the point of collection and the laboratory.

RE: Toluene in Trip Blank

Dear Mr. Darrow:

Recently, GTEL's Torrance Laboratory investigated several commercial sources of "pure" water for use as trip blanks. It was our experiance that water sold in glass containers frequently contained up to 2 parts per billion (ppb) Toluene. Water from plastic containers tended to have even higher concentrations of Toluene due to leaching. As a result of our study, we now verify purity of every trip blank prior to sending it out to Clients.

Another source of Toluene contamination in Trip Blanks is the sample container. As part of GTEL's Total Quality Management Program, evaluation of several vendors' products were conducted. One supplier's glass VOA vials consistently showed several ppb Toluene. GTEL's now purchases sample containers from a single source and receives a Certificate of Analysis with each shipment to ensure that the containers meet our specifications.

I strongly recommend that in the future, Trip Blanks be ordered directly from the Laboratory at the time the project is scheduled. It is very difficult for a consultant to make his/her own Toluene-free Trip Blanks.

If I can be of further assistance, please do not hesitate to contact me.

Very truly yours,
GTEL Environmental Laboratories, Inc.

Joan V. Greenwood
Laboratory Director

INTRODUCTION:

Storm Water Pollution Control for Industrial Facilities

Storm water pollution is the major source of contamination affecting local creeks and the San Francisco Bay. Storm drains carry excess water from streets, urban centers, industrial sites, and open spaces. In Alameda County, contamination of storm water is largely due to urban runoff pollution, which occurs when contaminants from industrial, commercial, and residental areas are picked up by runoff water and carried into the storm drain. In Alameda County alone, more than 85 billion gallons of untreated water and debris pass through the storm drain systems each year and flow into the bay.

Industrial operations constitute only partly responsible for urban runoff pollution, but they are known to be a source of heavy metals, oily wastes, and other contaminants. Manufacturing, shipping, and storage operations that are exposed to storm water runoff are common contributors to storm water pollution.

Federal and state storm water regulations now require most industrial facilities to take steps to prevent such contamination. Your facility might need to be covered by the Regional Board's October 1992 Industrial Storm Water General Permit. If so, you must prepare a Storm Water Pollution Prevention Plan (SWPP) that incorporates a variety of Best Management Practices (BMPs) like the ones described in this manual. If your facility is not covered by the General Permit, you might still need to implement BMPs to comply with local pollution prevention requirements.

Unlike some pollution problems, storm water pollution cannot be covered by a single set of rules that applies to all industrial facilities. Regulated industrial facilities in Alameda County range from manufacturing facilities that occupy several square miles to storefront distributors. As a result, plants can have very different storm water quantities, flow patterns, and potential pollutants. Even different facilities within the same general industry might have to adopt different approaches to the prevention of storm water pollution.

The BMPs in this manual are recommended by the Alameda County Urban Runoff Clean Water Program to help you:

- *Prevent storm water pollution;*
- *Protect water quality in local creeks, groundwater basin and the bay; and*
- *Comply with storm water regulations.*

This manual is intended to help you identify and implement the BMPs that are necessary and economically feasible for your facility to prevent storm water pollution. The BMPs include both operating practices and structural controls designed to reduce the amount of pollutants entering the storm drain system. You will need to evaluate which apply to your facility and implement them as necessary. Specific regulations can vary from one municipality to another, so you should become familiar with local storm water ordinances in the communities in which you do business.

This manual consists of two parts. The recommended BMPs in Part 1 are basic everyday operational practices that can be very effective in preventing pollution and reducing potential pollutants at the source, with relatively minimal structural or equipment requirements.

In many industrial facilities, storm water pollution can be prevented with common-sense precautions and modest changes in routine operations or maintenance practices. The numbered sections are keyed to industrial operations that are common to many kinds of facility. For some industrial facilities, these practices alone might be sufficient to control storm water pollution.

In other cases, it will be necessary to establish new practices or build physical controls to prevent storm water pollution. Part 2 of this manual consists of "advanced management practices." The advanced BMPs require more costly or more intensive efforts to address pollutants that are not adequately controlled by the simpler operational BMPs.

R0058924

VOL 12 2 5631

PART 1

Recommended BMPs for Storm Water Pollution Prevention

Part 1 of this manual contains BMPs that are recommended to control storm water pollution from particular industrial activities. It is divided into numbered sections, describing activities common to many kinds of industrial facilities, and it contains BMPs tailored to each kind of industrial activity or operation.

The recommended BMPs are to be implemented on an ongoing basis for the indefinite future. Operators of commercial and industrial facilities in Alameda County should implement these BMPs or similar controls wherever they would be effective in preventing pollutants at the site from entering storm water runoff.

PREVENT WATER FROM CONTACTING WORKING AREAS.

Shipping areas, outdoor equipment, material storage areas, vehicle maintenance spaces, and working areas of all sorts are subject to contamination by raw material, process liquids, grease, oily wastes, heavy metals, and miscellaneous potential pollutants. If you prevent storm water, wash water, or water from other sources from contacting areas exposed to pollutants, you won't discharge pollutants into your storm drains. Following are measures you should take to prevent water from contacting exposed areas:

- Keep rainfall from directly contacting working areas by installing roofs or moving industrial operations indoors where possible.
- Prevent storm water *runoff* from flowing across industrial areas by using properly designed berms or grading.
- Avoid practices in which you use water that later enters the storm drains — for instance, washing in outdoor areas. Most of those practices, including many that were acceptable in the past, are now considered to be "illicit discharges" of nonstorm water to the storm drain.

KEEP POLLUTANTS OFF SURFACES THAT COME INTO CONTACT WITH WATER.

Evaluate your site carefully to identify all areas that are contacted by storm water, wash water, or other water that is discharged into the storm drain. Then take special care to keep pollutants off those surfaces. That means controlling minor leaks and spills you might otherwise overlook, and taking a close look at your operating routines and equipment to determine whether any substances are unnecessarily exposed to storm water.

MANAGE STORM WATER BEFORE IT IS DISCHARGED INTO THE STORM DRAIN.

If you cannot avoid adding pollutants to storm water, you might have to remove them before they are discharged. Storm water control regulations, and this manual, consider treatment to be a last resort and emphasize source control options, because they are usually less costly, and more effective in the long run. In this manual, treatment measures appear only under Advanced Management Practices.

VOL 12 2 5632

R0058925

1 TRAINING AND EDUCATION FOR EMPLOYEES AND CUSTOMERS

Successful storm water pollution control relies mostly on the proper training and education of employees. Many of the recommended BMPs in this part of the manual identify specific training needs for employees who conduct the activities.

Train employees in the BMPs, because an employee's mistake can lead to a costly pollution incident. Assign experienced workers to train new employees. Review procedures as a group at least once a year.

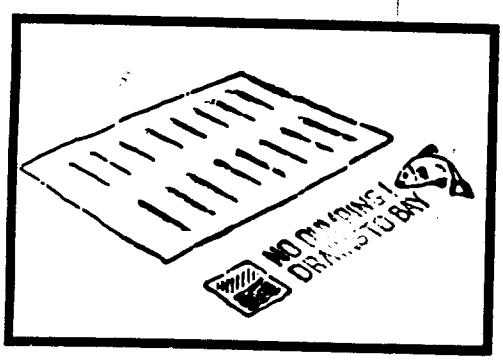
Periodically check employees' work practices to be sure the BMPs are implemented properly. Post informational signs, such as proper equipment washing procedures, at designated washing areas, and "Close the cover" signs at dumpsters and other storage areas. Stencil "NO DUMPING! — DRAINS TO BAY" messages at storm drains. (Stencils might be available from the Clean Water Program.)

Provide general information as well, because employees often respond best if they understand *why* they are being asked to conduct a new procedure. Employees' suggestions in return can help identify cost-effective storm water controls for your facility.

If you subcontract for small construction jobs or other work on your premises, include BMPs as conditions when writing contracts. Provide contractors with proper disposal options for wastes. Monitor contractors to be sure they comply with your BMPs.

If you serve customers at your facility, be aware of customer activities on-site. If they dispose of material improperly, *you* will be responsible for the violation. Ask your customers not to discard liquids into your trash cans or storm drains. If you have persistent problems, you might need to monitor your customers more carefully at trash cans, storm drains, and other potential disposal areas, on your property.

Let your customers know how you are minimizing wastes and recycling fluids to show that you are a "good neighbor," and encourage your customers to do the same. Showing clients what you are doing to protect the Bay is good public relations. Some businesses make the customer aware of their environmental requirements by including a modest environmental compliance fee, itemized on customers' billing statements, to cover handling and disposal costs for hazardous material.



Label storm drain inlets, so that employees do not dispose of waste there.

2 ELIMINATING IMPROPER DISCHARGES INTO STORM DRAINS

Local ordinances generally prohibit discharging *anything but storm water* into the storm drains. There are many ways in which nonstorm water from industrial plants can enter the storm drainage system. In most cases, those discharges are now illegal, even though they might have been permissible in the past. Industrial process water, building wastewater, and water from other sources are prohibited, with a few exceptions described in Table 1. Inspect your facility and yard to be sure no unauthorized discharges enter your storm drains.

Unauthorized discharges take two forms:

Illicit connections are improper permanent connections that allow wastewater to enter storm drains. Connections that allow sanitary or process wastewater to enter the storm drain are prohibited, including all storm drain connections from indoor drains or sinks. More information on identifying and removing illicit connections is available from your sanitary sewer district or municipality.

An **illicit discharge** is any nonstorm water discharged into the storm drainage system. Pollutants can be introduced into storm drains inadvertently by routine practices that discharge water outdoors or by routinely discharging wastes, wash water, and other material into storm drains, catch basins, and other conveyance facilities either on your property or in the street. A large part of this improper discharge results from employees' lack of understanding, coupled with a lack of readily available proper routes for the discharge.

You need to make a long-term ongoing effort to assure that no illegal discharges will occur. That requires continuing observation to identify potential sources of intentional or

VOL 12 2 5633 3

TABLE [redacted] PREFERRED DISPOSAL OPTIONS FOR WATER DISCHARGES [redacted]

WATER SOURCE	PREFERRED DISPOSAL OPTION	RESTRICTIONS OR PERMIT NEEDED	POSSIBLE OPTIONS FOR REUSE OR RECYCLING
Industrial process	**Sanitary sewer whenever possible**	**POTW permit**	**Reuse in-plant wastewater**
Noncontact cooling water	**On-site reuse**		**Reuse in closed-loop cooling system** *(cooling tower)*
• Uncontaminated*	• Storm drain if reuse is impossible	• Storm water NPDES permit	
• Contaminated	• Sanitary sewer	• POTW permit	• Treat and reuse
Industrial cooling equipment condensation		**Storm water NPDES permit**	**Hold and apply to landscape**
• Uncontaminated*	• Storm drain	• Must be tested and shown to be uncontaminated.	
• Contaminated	• Sanitary sewer	• POTW permit	
Building air conditioner condensation	**Storm drain (if city allows)**	**Some localities require discharge to POTW with permit**	
Building air conditioner coolant			**Reuse in-plant whenever possible**
• Uncontaminated*	• Storm drain	• Storm water NPDES permit	
• Contaminated	• Sanitary sewer	• POTW permit	
Storm water in outdoor secondary containment			
• Uncontaminated*	• Storm drain	• Test to determine contamination.	• Pump and apply to landscaping. (See Section 5)
• Contaminated	• Sanitary sewer	• POTW permit	
Storm water from outdoor material storage			
• Covered	• No discharge	• Zero contact with storm water.	
• Open	• Storm drain	• Water quality inlet or similar treatment. (See Section 20) Storm water NPDES permit	
Roof drain water	**Storm drain if no pollutants**	**Roof vents may be source of pollutants. See BAAQMD air emissions regulations and Section 4.**	
Industrial equipment wash water	**Sanitary sewer**	**POTW permit**	**Reuse in-plant whenever possible**
Vehicle maintenance wash water	**Sanitary sewer**	**POTW permit**	**Capture and reuse for washing**
Vehicle one-time wash water	**Storm drain (See Section 7)**	**Water only (no soap or solvents)**	**Minimize water; prevent flow across paved area**
Wash water from paved walkways in commercial and business districts	**Storm drain**	**Sweep sidewalks before washing. No cleaning chemicals may be used.**	**Minimize water use and direct to landscape.****
Commercial building exterior wash water	**Storm drain**	**Filter before it enters catch basin**	**Minimize water use and direct to landscape****
Landscape irrigation	**Storm drain**		**Minimize water so none runs off****
Potable water and potable line flushing	**Storm drain**	**Must be dechlorinated*****	
Fire-fighting flows	**Storm drain**	**Block downstream channels to detain for testing as hazardous waste**	

R0058927

VOL 12 2 5634

inadvertent improper discharges. Discontinue or reroute the water from those activities. Measures to help prevent illegal discharges include:

- Providing well-marked proper disposal or collection methods for wastewater wherever you frequently use wash water, discharge cooling water, or produce a liquid waste that might otherwise reach the storm drain.
- Employee training that especially emphasizes proper disposal of nonstorm water (see Section 1). Educate employees to understand that storm drains connect directly to streams and the bay without treatment.
- Labeling all storm drain inlets and catch basins "NO DUMPING! — DRAINS TO BAY," so that employees will know which inlets are part of the storm drain system.
- Periodically inspecting and maintaining storm drain inlets. Clean out catch basins so that accumulated pollutants do not wash down the storm drains.

Table 1 identifies some common sources in industrial plants of water that can enter storm drains. For each source, the table lists the preferred disposal option. For water that is allowable for discharge into the storm drain, Table 1 lists conditions or restrictions placed on the discharge.

Following are conditions or restrictions placed on a few categories of special interest:

- **Cooling tower condensate** for industrial process water must be discharged into the sanitary sewer. Permits are required.
- **Internal coolant** for refrigeration or building air conditioning must not be discharged into storm drains.
- **Building air conditioner condensate** may be discharged into the storm drain *only* if it is not treated with algae inhibitors, corrosion, control chemicals, or other additives.

Wipe up spills immediately with shop rags.

Source: Storm Water Industrial General Permit for the Santa Clara Valley, Regional Water Quality Control Board/S.F. Bay Region, January 1992.
POTW (Publicly Owned Treatment Works) permit: Permit to pretreat and discharge is required from your wastewater authority.
BAAQMD: Bay Area Air Quality Management District.
* Biocides, corrosion inhibitors, or other additives are contaminants from a storm water point of view.
** Must comply with local water use restrictions during drought conditions.
*** Potable water, swimming pool water, and other chlorinated sources must be dechlorinated by aeration, retention, or chemical additives to a "no measurable chlorine" standard before reaching receiving water. If the water is not dechlorinated, it must be discharged to the sanitary sewer under a POTW permit.

3 SPILL PREVENTION, CONTROL, AND CLEANUP

Small spills can have cumulative effects that add up to a significant source of potential pollutants in your storm water discharge. The best approach by far is to prevent spills and leaks. Maintain a regular inspection and repair schedule, and correct potential spill situations. Some prevention techniques are described in Sections 4, 5, and 6.

When a spill does occur, quick and effective response is the best way to prevent pollutants from reaching storm water. Prepare a set of well-defined procedures for responding to a spill of any liquids in an area that might be exposed to storm water. The procedures can be specific for your facility. They should take into consideration all circumstances, from small and minor releases that can be easily handled to a large emergency spill, and they should identify whom to call to respond to the situation before it gets out of hand. Train employees in the procedures (Section 1).

The basic procedures should emphasize that spills be cleaned up promptly and not allowed to evaporate. Otherwise, pollutants remain on the pavement and might be washed to the storm drains with the next rain, or they remain in the soil and become a possible groundwater pollutant. If the spill is on an unpaved surface, determine whether you need to remove the contaminated soil to prevent it from becoming a source of future storm water pollutants.

Also the standard procedures should specify cleaning up leaks, drips and other spills without water whenever possible. Do not use a hose or wet mop to clean up a spill area. Hosing might remove the spill from the immediate area, but does not keep the pollutant out of the environment. On the contrary, it

VOL 12 2 5635
R0058928

adds to the volume of the spill and spreads the spilled material around a larger area.

If you handle hazardous material, spill prevention and response procedures are described in your hazardous material management plan filed with your fire department or other hazardous material ("HazMat") authority (see Section 6). If a spill occurs, notify the authorities as required in your emergency response plan. Contain and collect the spilled substance, then dispose of the substances and any contaminated soil in compliance with hazardous materials regulations.

Small spills are those which can be wiped up with a shop rag. Do not put wet rags in the dumpster with the shop trash. Store them in a covered rag bin of the kind used at auto service stations. Avoid paper towels. You can avoid making this a waste stream by sending used rags to a professional cleaning service. (You must inform your cleaning service of what the shop rags have been used for.) Do not saturate rags with gasoline, solvents, or other volatile liquids.

Medium sized spills are too large to wipe up with a rag and require more attention. Contain and soak up the liquid, using dry absorbent material, such as vermiculite, specially prepared sawdust, or cat litter. Absorbent "snakes" may be used as temporary booms to contain and soak up the liquid. Sweep up the used absorbent material and snakes, and dispose of them appropriately, with the shop trash if nonhazardous, with the hazardous wastes if necessary. Another convenient option is to use a wet/dry shop vacuum cleaner to collect spills and dispose of the liquid with your liquid or hazardous wastes. *Do not* use vacuums for gasoline, solvents, or other volatile fluids because the enclosed vacuum could become an explosion hazard.

Larger spills must be contained then cleaned up. For spills of food waste or other nonhazardous liquid, take steps to contain and clean up the liquid and minimize the wash water used in cleanup. Shut off or plug storm drain inlets or sewer inlets where the spill can enter. If necessary, keep temporary plugs on hand to fit your inlets and train employees regarding when and how to use them. For hazardous material spills, implement your emergency procedures and alert your HazMat authority.

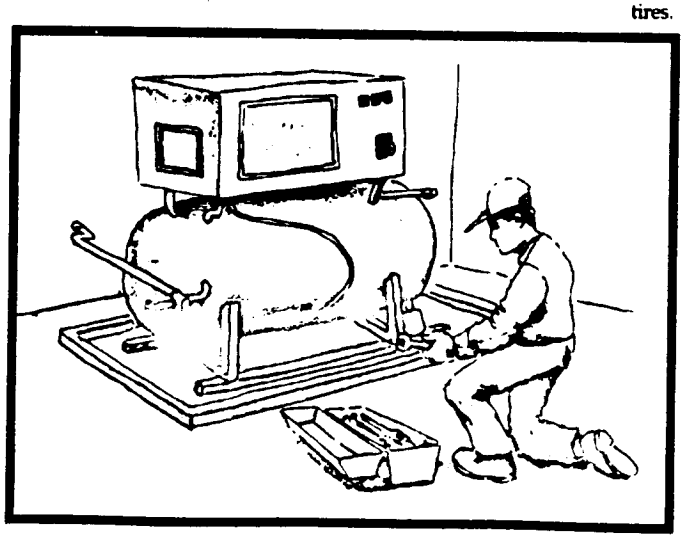
4 OUTDOOR EQUIPMENT OPERATIONS AND MAINTENANCE

Storm water from your site can accumulate pollutants by exposure to numerous small leaks, spills, and other discharges from outdoor equipment. Large equipment might require specially designed structural or advanced BMPs to reduce the potential for storm water to contact pollutants. Ordinary precautions, such as those described below, might suffice for smaller equipment.

As a first step, identify all equipment at your site that might be exposed to storm water or could discharge potential pollutants that could be exposed to storm water. Identify the kinds of pollutants each piece of equipment might generate—lubricants, coolants, and other leaks or discharges.

Be creative and thorough in developing your list. The inventory should include rooftop cooling towers or air conditioners; rooftop air vents for industrial equipment; outdoor air compressors and other service equipment; indoor wet processes where leaks or discharges might reach outdoor areas; and material transfer areas, such as loading areas where forklifts or trucks can carry pollutants outdoors on their tires.

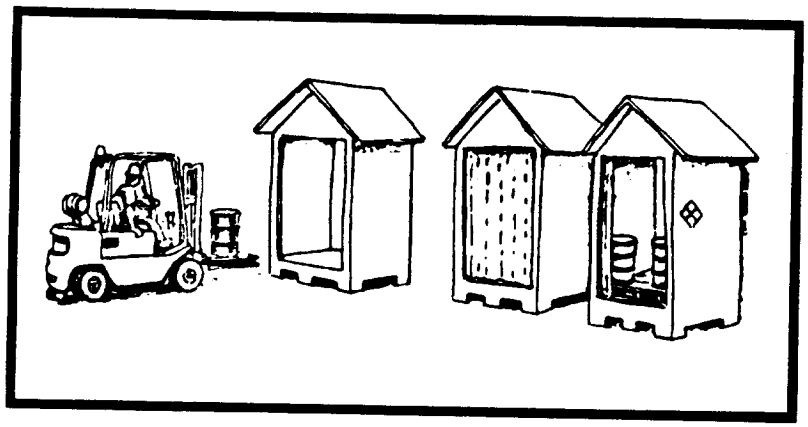
Using the equipment inventory, assign an employee to inspect each piece of equipment on a regular basis to see that it is functioning properly. The employee might be the person responsible for operating the equipment if it is used regularly, or a maintenance staff member for equipment on the roof or in seldom-seen places. Inspect for leaks, malfunctions, and staining on and around the equipment and other evidence of leaks and discharges. Assign to the inspecting person responsibility for reporting a spill.



Keep drip pans under outdoor equipment to contain drips and leaks, especially during maintenance.

VOL 12 2 5636

R0058929



A "Doghouse" shed is one way to keep storm water away from barrels and materials kept outdoors, and at the same time it provides spill control.

Develop a routine for taking actions on the report—cleaning up the spill and repairing the leak to prevent future spills.

Where possible, take the next step toward full pollution prevention and make modifications to prevent storm water from contacting the equipment or its discharges. Place equipment on an impermeable surface, or install a drip pan beneath potential leak points. To minimize the amount of rainwater that contacts the equipment, you might construct a simple roof and install a berm to prevent run-on and runoff. If the equipment requires a "wet" process—that is, if operation inevitably releases wash water or process liquids—place it on a paved surface and install a connection to the sanitary sewer. Check with your municipality or wastewater authority to identify appropriate permits.

Air compressors and other equipment sometimes produce small quantities of automatic blowdown water, which usually contains lubricating oil or other potential pollutants. The water may not be discharged into the storm drain. Connect the blowdown to the sanitary sewer with proper approval. Or if the compressor has a frequent small bleed, place a drip pan or catchment to collect the water—do not let it soak into unpaved surfaces or run off paved surfaces.

Condensate on exterior surfaces of compressors, building cooling equipment, and other machinery may be directed to the storm drain system or, preferably, to a landscaped area.

5 OUTDOOR MATERIALS STORAGE AND HANDLING

If you handle **bulk solid material** outdoors, keep them covered in appropriate containments and protected from storm water. Apply this policy to raw material, products, by-products, and construction materials or supplies.

Store the material in one of these ways:

- The preferred method is storage on a paved surface, with a roof or covering, so that no direct rainfall contacts them, and with appropriate berms or mounding to prevent run-on of storm water. Roofs are recommended by most municipalities for new facilities.
- Where a roof is not feasible, place the material on a paved surface and cover it with plastic sheeting or tarp secured with weighted tires or sand bags. If possible, choose a mounded or bermed area that will prevent run-on of storm water through the material.

Parking lots or other surfaces near bulk material storage facilities should be swept periodically to remove fines that wash out of the material and would otherwise wash away with storm water. Larger bulk material storage facilities need more extensive structural controls for the specific facility and material.

Hazardous material must be stored in accordance with federal, state, and local HazMat requirements. The requirements are generally more than adequate to prevent storm water pollution—for instance, a HazMat secondary containment might have no drain.

If you store **liquid containers**, implement a plan and a design to control unexpected leaks and spills so that the liquid does not reach storm drains or surfaces that will be exposed to storm water. If you store hazardous material, the spill prevention plans required by your HazMat authority are adequate to ensure storm water protection. Nonhazardous material storage should also incorporate spill control designs and procedures.

Select a storage method appropriate for the type of material. Keep liquid tanks in a designated area on a paved impermeable surface and within a berm or other secondary containment. Inspect containers regularly for damage or leaks, as described in Section 4. Clean up any leaks or spills immediately (using dry methods described in Section 3), and repair the leaks promptly.

For smaller storage tanks, storage in roofed areas can prevent all contact with storm water (in combination with well-designed spill control procedures). A possible option is the "doghouse" design used by some firms (see illustration). The roof and flooring prevent contact with direct rain or run-on storm water. Contact your local HazMat and fire authorities for specific requirements.

VOL 12 2 5631

R0058930

Storm water often accumulates in **secondary containment** areas. If this water is contaminated, it may not be discharged into the storm drain system.

You might wish to roof the containment to avoid this problem. If that is not possible, the liquids that accumulate in the containment *might*, with approval, be acceptable for discharge into the sanitary sewer. However, the area itself should have no direct connection, in case of spills. One common solution is a portable pumping system that can be moved to accommodate separate containment structures on your site. The equipment can pump water into a truck or portable temporary holding tank. The water then can be tested and disposed of according to whether any pollutants are present. Following are some disposal options:

- If the water meets criteria for hazardous waste, employ a certified hazardous waste hauler for disposal at a permitted hazardous waste facility.
- If it has constituents similar to process wastewater for which your on-site wastewater pretreatment facilities are designed, pretreat the water and discharge into the sanitary sewer.
- If it meets standards for your industrial discharge permit, discharge it into the sanitary sewer without pretreatment (if permitted by your wastewater authority).
- Reuse it on your site in an appropriate manner as industrial process water, equipment wash water, steam cleaning makeup, or another use where the water will eventually be discharged as industrial or sanitary wastewater. You might have to invest in a truck or plumbing to convey the water to its reuse location.
- If it is free of hazardous constituents, use it on your facility grounds for landscape watering. Do not apply the water to landscaping if hazardous pollutants are present—even if not concentrated enough to be hazardous waste—because the pollutants might accumulate in the soil or vegetation and eventually create a health hazard.

6 WASTE HANDLING AND DISPOSAL

Table 2 summarizes the preferred storage and disposal practices for some common industrial facility wastes. For many wastes, reusing or recycling is the most cost effective means to prevent potential pollution. Fluids that you hold for recycling are special categories of hazardous waste. You may store them on your site only for short periods in accordance with hazardous waste requirements, but they may be transported under somewhat less stringent requirements than other hazardous wastes. Many recycling services have special variances or permits, which reduce your paperwork requirements and allow shipping at reduced cost.

Keep general shop trash in a dumpster with the lid closed. Put the dumpster in a paved area, not on unpaved soil or your lawn. Keep the area clean by picking up dropped trash and sweeping the area regularly (perhaps once a week), but do not use a hose to clean up—keep water off the area. Nearly all dumpsters and trash compactors leak; keep liquid wastes out of them, and keep them closed to keep out storm water.

If you cannot prevent leakage from trash containers, install a roof or lean-to that keeps direct rainfall off them, and place asphalt curbing or berms around the dumpster to contain the leaks. (Check with your local agencies, and comply with fire codes and building permits.)

If you store **scrap metal** or other such material outdoors, keep it under a roof, cover, or tarpaulin. Keep scrap, parts or other used metals indoors. Oils and other potential pollutants can wash off long after you think the parts have been washed clean. Collect waste metal, such as used parts and metal lathe filings, for delivery to a scrap metal dealer.

If you store **empty drums** outdoors, do not hold them longer than necessary. Ship them to a drum reconditioner or another facility. Before shipping:

- Drain them completely to avoid spills.
- Seal them properly so that they are watertight, to keep storm water from entering; otherwise the water would become a process wastewater, and could not be dumped into the storm drain.

Store and handle **hazardous wastes** properly. Hazardous material or waste is not a storm water problem if they are handled in accord with state and federal regulations, and the requirements of your local HazMat control authority.

Keep hazardous waste and material indoors or under cover in a locked area, to keep nighttime trespassers away from them. Store them before disposal in special hazardous waste containers or in closed drums within a secondary containment that is approved by your HazMat authority.

In some cities of Alameda County, the municipal fire department is the HazMat authority that controls hazardous material storage, handling, and response. Other locales contract with the County Health Department. For information about handling solid wastes that might be controlled under hazardous waste regulations, contact the County's Environmental Health Department or Cal-EPA's Toxic Substances Control Division. (See the back cover for a list of regulatory agencies.)

Empty containers, such as storage barrels, oil cans, paint buckets, and aerosol cans are hazardous wastes if they once held hazardous material. You may not discard these with the regular trash. They must be stored properly so that they do not leak outdoors. Some drum suppliers accept empty drums for reuse under less stringent hazardous material recycling regulations.

VOL 12 2 5638

R0058931

TABLE 2 PREFERRED WASTE HANDLING & DISPOSAL METHODS

		RECOMMENDED STORAGE	PREFERRED DISPOSAL	HAZARDOUS WASTE?
General Plant Wastes	• Used parts—clean metal scrap	• Bin (covered or indoors)	• Scrap collector	No
	• Used oily parts—contaminated	• Drum	• Hazardous waste hauler	Yes
	• Metal shavings	• Bin (covered or indoors)	• Scrap collector	No
	• Used rags	• Rag bin with lid	• Rag laundry	*Possibly*
	• Soiled cleanup absorbent	• Drum	• Hazardous waste hauler	Yes
	• Coolant from air conditioner or refrigeration equipment	• Recycling machine	• Reuse in-house (HVAC service company)	No
Liquid Wastes	• Paints*	• Original container, with lid	• Hazardous waste hauler	Yes
	• Waste lubricating oil	• Drum (segregated)	• Oil recycler	*Special***
	• Solvents, thinners, and miscellaneous fluids*	• Tank ("hot" waste) *Segregate different fluids to make recycling possible*	• Solvent recycler (where possible) or waste hauler	*Possibly*
Liquid Containers	• Empty drums	• Indoors or under cover	• Drum reconditioner	
	• Empty cans, bottles, aerosol cans, etc.	• Drum	• Municipal trash or hazardous waste hauler	*Possibly*
Vehicle Wastes	• Waste motor oil	• Drum (segregated)	• Recycler	*Special***
	• Brake fluid, gear oil, hydraulic fluids, etc.*	• Bottle or tank ("hot" waste)		Yes
	• Antifreeze	• Tank (segregated)		*Special***
	• Batteries	• Open rack	• Battery supplier	*Special***
	• Tires	• Covered or indoors	• Tire hauler	No
	• Oil filters	• Drum (drain first)	• Oil recycler	*Special**

*Unused pure product may sometimes be returned to the vendor rather than disposed of as waste.

**Recyclable under special hazardous-materials restrictions.

Vehicle maintenance waste material often deserves special attention. Waste oil, antifreeze, spent solvents, and some other liquids can be recycled. Spent batteries may not be discarded with trash, but must be either disposed of as hazardous waste or returned for reclamation and reuse to the dealer from whom you purchased them. Guidance on handling vehicle wastes can be found in the Automotive Industries BMP manual which is available from your municipality.

7

EQUIPMENT WASHING AND STEAM CLEANING

Wash water for industrial equipment in most cases must be discharged as process wastewater into the sanitary sewer, and it is not allowed in storm drains. To clean dirty and/or greasy field equipment or trucks, you must install equipment to capture and pretreat the wash water for discharge into the sanitary sewer as industrial process waste. It may be less costly in the long run to locate a commercial car wash that has all the appropriate equipment and municipal permits, and to contract with them for washing services offsite.

If you wash vehicles or equipment on your site, you may do so only in a designated area, which must be designed and equipped as follows:

- Pave the area.
- Mark the area clearly as a wash area, and be sure all employees know that they may wash in this area only. Post instructional signs that prohibit changing vehicle oil, washing with solvents, and other such activities.
- Install sumps or drain lines to collect wash water for treatment and discharge into the sanitary sewer; reuse (for repeated washings); or recycle (for use elsewhere on-site).

VOL 12 2 5639

R0058932

- If the equipment is a continuing source of grease or heavy dirt, cover the area to prevent contact with rain water when not in use.
- Grade or berm the area to prevent storm water from running onto it.
- Wash inside a building designed for maintenance or equipment storage if possible. Ensure that all drains connect to the sanitary sewers.

Steam cleaning should be done on your site *only* if you are equipped to capture all the water and other wastes. All the washing requirements above apply to steam cleaning as well. Steam cleaning wash water is not allowed in storm drains unless you have a permit from your wastewater authority. Permit requirements include pretreatment with equipment such as an oil/water separator, which might have to be a hazardous waste unit. If you steam clean, do it indoors or in a specially prepared outdoor working area where you collect the wash water and treat it for discharge.

Storm water runoff from industrial roofs, trucks, parking lots, and yards flows into storm drains and directly into streams and the Bay. It never receives treatment that would remove pollutants.

8

TRUCKING AND SHIPPING/ RECEIVING

Truck loading and unloading are potential sources of pollutants when rainfall and run-on contact spilled raw material, dust, and motor fluids that accumulate in this heavy traffic area.

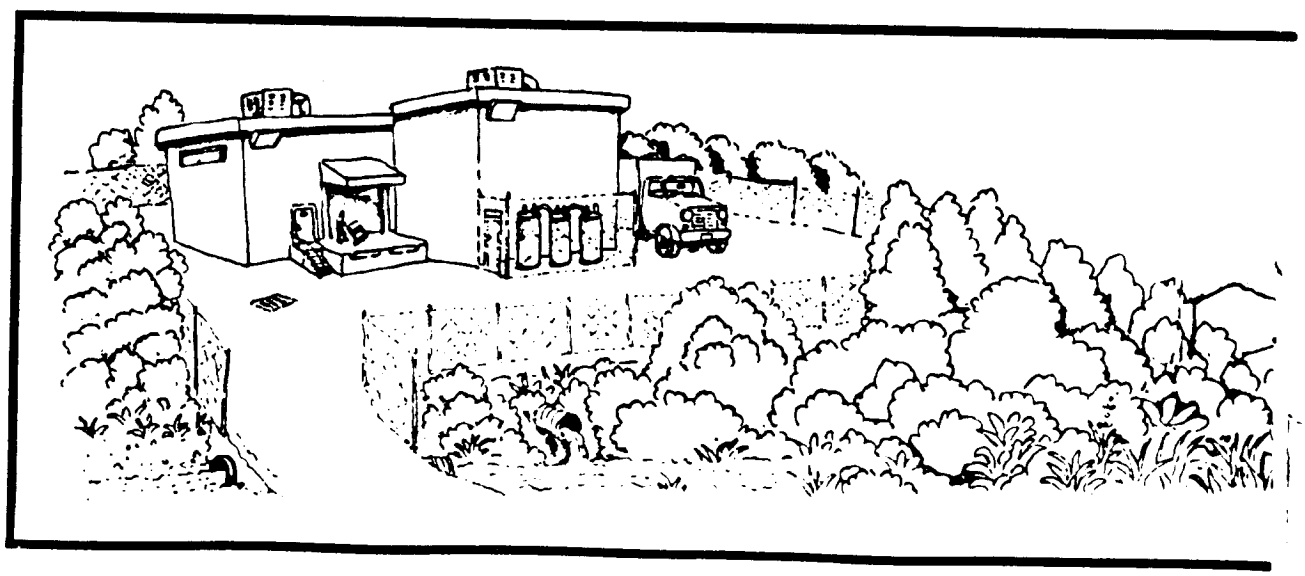
Load and unload raw material, products, and other material only at designated loading areas. In that way, you can isolate the potential source in areas that you can control, instead of in unspecified areas throughout your site. The best areas from a storm water point of view are indoor bays. For facilities that must use an outdoor loading dock, some operational BMPs and simple design features can control storm water pollution:

- Cover the loading dock area with a roof overhang, or use a door skirt that snugly fits both the building door and the truck door.
- Install curbs or berms around the loading area to prevent storm water from running onto it and any spilled material from running off it.
- Instruct the person who accepts the shipment, the truck driver, or someone else to check under the truck for leaked motor fluids, spilled matter, debris, and other foreign material.
- Develop a procedure requiring a maintenance crew to clean up spilled material promptly.

If you load or unload liquids, you need further operational precautions, and the loading dock should have additional design features. If you handle hazardous material, all the features you need are probably in place as part of a spill control and response plan. If they are not, you should select structural BMPs like those described in Section 13.

Parking lots and access roads are sources of potential pollutants from the trucks themselves and from possible spills or leaks of the material being transported. If you are regrading roads and parking lots, or if you transport materials that you expect to be significant sources of potential storm water pollutants, follow the structural BMPs recommended in Section 16. For existing facilities, especially smaller parking lots and short driveways where no hazardous material are transported, you can effectively prevent storm water pollution by implementing routine maintenance activities, such as:

- Regular visual inspection of your access roads and parking lots to identify and clean up spills.
- Removal of debris as soon as operations permit.



VOL 12 2 5640

R0058933

Conduct street sweeping style cleanups periodically to remove loose debris, small amounts of spilled raw material, road dust, and other potential pollutants:

- Smaller spaces can easily be swept by hand.
- Do not hose off paved surfaces.
- For larger spaces, use a vacuum truck or mechanical sweeper (one that collects solids, not just brushes them aside). Whenever possible, do not use a wet washing street sweeper unless you can collect the polluted wash water.
- Private companies can perform the work on a contract basis so that you need not purchase the truck.

During the dry weather season, the appropriate frequency of sweeping for your facility depends on how heavily the road is used and the kinds of material you transport. Following are signs that you need to sweep more frequently:

- Your trucks commonly spill or drip bulk material.
- Debris or other material accumulates on the access roads. The correct frequency is one that prevents unwanted material from accumulating.

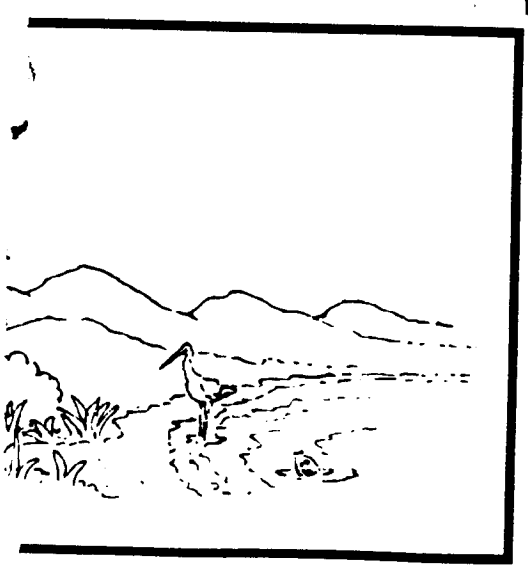
During the wet weather season, emphasize sweeping at times that will best prevent storm water from contacting potential pollutants:

- Clean the area once thoroughly before the wet weather season begins.
- After that, you may stay close to your dry season needs for debris removal, but add an additional thorough cleaning before a major rainfall (when half an inch or more is forecast).

Dispose of the cleaned-up material with your regular facility trash if there is no hazardous material. If you suspect it is hazardous — if you handle hazardous material, or if you know of a significant motor oil leak, for example — you should test the material or dispose of it with your facility's hazardous waste. You could face substantial penalties if you improperly dispose of hazardous waste.

If you **park trucks or heavy equipment** on-site, inspect the parking area for leaks of oil and motor fluids and design a procedure to report them, clean them up, and repair the leaking vehicle. Following are some practical techniques:

- Design consistent parking spots for each vehicle, so that if a leak is indicated on the ground the truck can be identified and repaired.
- Designate a person to be responsible for checking under a vehicle for leaks or spills. If you employ drivers, the driver could have the responsibility as part of a vehicle check conducted before driving.
- Clean up spills promptly, using dry cleanup procedures described in Section 3. Conduct the preferred cleanup procedures for unpaved, as well as paved, areas.
- Develop a reasonable procedure for identifying, reporting, repairing, and cleaning up leaking motor fluids and spilled material. Make sure employees are fully trained in the procedures and know who is responsible for checking each truck, who should be notified if there is a problem, and who should respond.



9 MAINTENANCE OF FLEET VEHICLES

The Automotive BMP manual prepared by the Alameda County Urban Runoff Clean Water Program addresses automotive and vehicle repair facilities. You should implement the BMPs in that manual if vehicle maintenance is a potentially significant source of pollutants on your site. Sections 9 and 10 of this manual summarize some of the appropriate BMPs for fleet maintenance at an industrial facility.

Whenever possible, perform vehicle maintenance in an indoor garage, not in outdoor parking areas. If you change oil and do other routine engine work outdoors, you should create a designated area for vehicle maintenance. Keep the area clean, as if it were part of your shop floor, and use dry cleanup practices. The area should incorporate some specific design features, such as those described in Sections 14 and 15. Some operational methods also can be successful in preventing storm water pollution at vehicle maintenance areas. A few suggestions:

- Keep equipment clean; do not allow buildup of grease and oil, which will wash away when the equipment is exposed to rain.
- If you work on vehicles outdoors, keep drip pans or containers under the vehicles at all times while you work on them — leaks and spills can occur unexpectedly. Place drip pans under vehicles as soon as you detect a leak.
- Drain fluids from any retired vehicles kept on-site for scrap or parts. Out-of-service vehicles you intend to restore and vehicles being held for resale should be checked periodically for leakage.

VOL 12 2 5641

R0058934

- Do not change motor oil or perform vehicle or equipment maintenance in the parking lot or storage yard; use the vehicle maintenance area. Do not allow customers or employees to change their personal vehicles' oil in your vehicle service areas.

Vehicle **parking or storage yards** need to be operated with similar precautions:

- Inspect equipment in the yard for fluid leaks regularly — perhaps with a walk-by inspection for ground staining every day, and a closer visual inspection once a week.
- Keep the equipment yard clean and clear of debris, using dry sweeping methods described in Section 8. Do not hose off the area or wash with water, because any runoff becomes an illegal discharge into the storm drain.
- Maintain the yard's storm drain inlet(s) with special care. Clean them on a regular schedule and also after large storms. Pay attention to the kinds of potential pollutants that accumulate, so that you can identify the sources and take measures to control the sources.

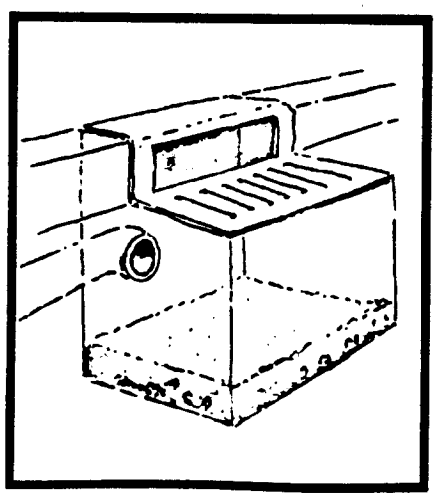
10 FUELING FLEET VEHICLES AND EQUIPMENT

If you have a vehicle fueling area, it should be designed and operated to minimize the contact of spilled fuel and leaked fluids with rain water. This section describes general principles, but simple operational controls might not be adequate for an industrial fueling facility. You might have to redesign your fueling area or install structural controls. Section 14 describes some general design approaches that can be useful in your eventual complete Storm Water Pollution Prevention Plan. Following are steps you can take for proper operation of a fueling area:

- Use a paved area or provide a concrete slab for the fueling area — never locate the area on open ground. Concrete is preferred because fuel and oils cause asphalt to deteriorate.
- Clean up gasoline overflows and spills, using dry methods described in Section 3. Do not allow spills to run off or evaporate, and do not flush the spill away with a hose. Spread absorbent material, sweep it up with a broom, and dispose of it as hazardous waste.
- Post signs that instruct pump operators not to "top off" or overfill gas tanks. Keep dry cleanup material in the fueling area, and instruct employees in the dry cleanup methods described in Section 3. Assign someone the responsibility of checking the area every day for gasoline, motor oil, or other fluids that have leaked.
- When you do routine cleaning, use a damp cloth on the pumps and a damp mop on the pavement, instead of spraying with a hose, to minimize the flow of cleaning water to the sump.

The main concept is to respond properly to fluid leaks in this spill-prone area. Even very small spills, when they happen every day, add up to a lot of fuel in the drainage system. This is an improper discharge that is illegal under the General Permit. Small spills do not present a problem if the fueling area is designed to handle spills — that is, if no storm water contacts it, and if it drains to a sump. But if the area drains to a valved-off storm drain or sewer connection, it must be pumped out before the valve may be opened during a rainfall.

A permit from the HazMat Authority is required for fuel tanks, including temporary ones. The authority will specify design features, such as the size of containments. Keep temporary fuel tanks in a bermed area that has an impervious lining, such as concrete or heavy-gauge plastic.



A catch basin helps keep debris and sediments out of the storm drain, but must be cleaned out periodically.

VOL 12 2 5642

R0058935

11 BUILDING AND GROUNDS MAINTENANCE

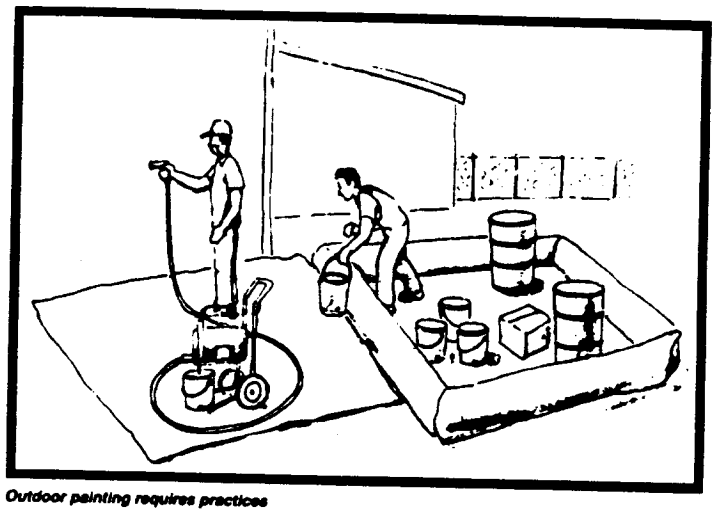
Building maintenance and general outdoor cleanup should be based on the same principles as parking lot cleanup and spill prevention: clean up without water, whenever possible, by sweeping or wiping; wash with as little water as possible; prevent and clean up spills; and clean up debris and solids, so that they do not reach the storm drains.

Maintain the **storm water conveyance system** on your property. The "conveyance system" might be as simple as roof downspouts and a gutter in your driveway or might be an extensive system of inlets, ditches, drainage channels, and underground lines. Keep all parts of the system clear of debris to avoid blockage that can cause storm water to back up. Remove from the system any spilled or leaked material that can be transported by storm water.

Clean the storm drain inlets to remove sediment and debris at least twice a year — late in the dry weather season before the first storm, and after the first major storm of the wet weather season. After each large storm, inspect the inlet; remove debris; and determine whether you need to remove sediment or do other maintenance.

The storm drain inlet might have a **catch basin**—a below-grade chamber where the storm drain pipe connects. Catch basins are intended to collect debris and sediment to prevent clogging the lines. Therefore the catch basins themselves must be cleaned out periodically to prevent flooding. If you clean catch basins annually, shortly before the wet weather season, you can keep them flowing freely and remove leaves, sediment, and other material that would otherwise be washed down the storm drain. Do not flush the catch basin with water; use a shovel or vacuum device to remove the material.

Other useful design features, such as vegetated ditches and water quality improvement inlets, are described in Sections 19, 20, and 21 as advanced BMPs.



Outdoor painting requires practices to prevent paint and dust from becoming storm water pollutants.

12 BUILDING REPAIR, REMODELING, AND CONSTRUCTION

This section describes some relatively simple BMPs that apply to minor building repairs, remodeling, and minor construction projects that involve "industrial activity exposed to storm water."

Large-scale projects, such as construction of new facilities, are covered under a separate General Permit for construction. They require more extensive storm water pollution prevention measures than described here. A manual developed by the state is available through the Clean Water Program. (See the back cover of this manual.)

The same practices are *recommended* for construction activities on industrial sites. Before you begin a construction or repair project, review the Construction BMP Manual to identify and implement the appropriate practices. If those BMPs do not apply, or are unduly elaborate for a simple construction activity that will be completed in a short time, consider the BMPs described in this section.

Store building materials under cover or in contained areas, using BMPs discussed in Section 5. For outdoor storage at a construction site, select a pollution prevention method such as:

- Putting an impermeable tarp over piles of wood, gravel or other material. Do not wait for forecasts of rain — do this every day, to avoid being caught unawares. Also it will keep material from blowing off the pile and contributing pollutants to runoff later.
- Keeping the working area clean every day for the same reason. Sweep up wood splinters, paint chips, and other residue every day, as well as thoroughly cleaning up at the end of the project.

Painting requires some basic procedures:

- Before you scrape to remove old paint, spread a ground cloth or tarpaulin to collect dust and paint chips. If the paint contains lead or tributyl tin, dispose of the paint chips as hazardous waste.
- Use impermeable ground cloths, such as plastic sheeting, while you paint. Place in-use paint buckets in a pan or on plastic sheets.

VOL 12 2 5643

R0058936

- At the end of the work day, store paint buckets and barrels of material away from contact with storm water.
- Treat a paint spill as a chemical spill. Capture it before it flows to the storm drain, and clean it up promptly using dry methods.

During **painting cleanup**, the following are important procedures:

- If you use water-based paint, clean brushes and equipment in a sink connected to the sanitary sewer.
- Clean up oil-based paint where you can collect the waste paint and solvents for handling as small-quantity hazardous waste — do not pour it into the sink or a storm drain.
- Keep leftover paint, solvents, and other supplies for a later use, or deliver them to a solvent recycler with other plant wastes when you ship a batch.
- Handle empty paint cans and other containers as described in Section 6. Containers might be small-quantity hazardous waste. Latex paint cans are not hazardous waste if the paint is dry.

Do not fall back on old cleanup practices from days when storm water pollution was not known to be a problem. Do not pour leftover paint down the storm drain or onto the ground. Do not clean brushes into the storm drain or pour buckets of cleanup water into the drain, or wash spilled paint down the storm drain with a hose. Those practices are now categorized as "illegal dumping." Do not wipe brushes onto old newspapers or pour leftover paint supplies into newspapers and discard the paper in the trash.

Spray painting requires a few extra precautions:

- Use temporary scaffolding to hang drop cloths or draperies to shield you from the wind and to collect overspray.
- Arrange the draperies to minimize the spreading of windblown materials.
- Be aware of air-quality restrictions on spray paints that use volatile chemicals. Consider a water-based spray paint for better air quality compliance.

Sand blasting can be controlled to keep particles off paved surfaces and out of storm drains. Ask your municipality whether building and construction codes place requirements on the size and type of blasting medium that is allowed. More complete instructions are available in the Construction BMP manual for full-sized jobs, but some basics should be applied for smaller projects as well:

- Place a tarpaulin or ground cloth beneath your work to capture the blasting medium and particles from the surface being cleaned.
- Hang tarps or drop cloths to enclose the area, using temporary scaffolding if necessary. Arrange the drop cloths to protect the work area from wind and to capture airborne particles.
- Curtail operations on a windy day.
- Clean up frequently; collect dust and particles from the drop cloths before you produce a pile that is too large to handle easily.

Wood preservatives, pavement seal coating, and other outdoor surface treatments commonly contain metals, pesticides, solvents, or polymers that are hazardous materials. Handle and dispose of them properly in the following ways:

- Apply only as much of the chemical as the wood can absorb or as needed to cover the paved area.
- Soak up excess chemicals with absorbent material or rags, instead of allowing them to flow to the storm drains or soak into the soil.
- If the chemicals spill, clean them up promptly using dry techniques (See Section 3).
- When sealing a sidewalk, prevent the sealant from reaching the gutters or drains.
- When treating a roof with wood preservative or sealant, line the gutters with rags. Dispose of the rags properly—with your hazardous waste if the substances you are using are hazardous.
- If you clean a roof or sidewalk before applying preservative, sweep thoroughly to remove loose particles, then wash with water if necessary.
- Collect wash water from down spouts or drains where possible, and remove particles.
- Avoid applying surface treatment chemicals during the wet weather season.

VOL 12 2 5644

R0058937

PART 2

Advanced BMPs and Structural Controls

Some industrial operations and plant situations require more extensive measures to control storm water pollution. Depending on your facility, and your success at eliminating potential sources of storm water pollution, your long-term implementation plan might need to contain some advanced BMPs. The BMPs include structural controls — storm water management measures that require the construction of new facilities or installation of new equipment.

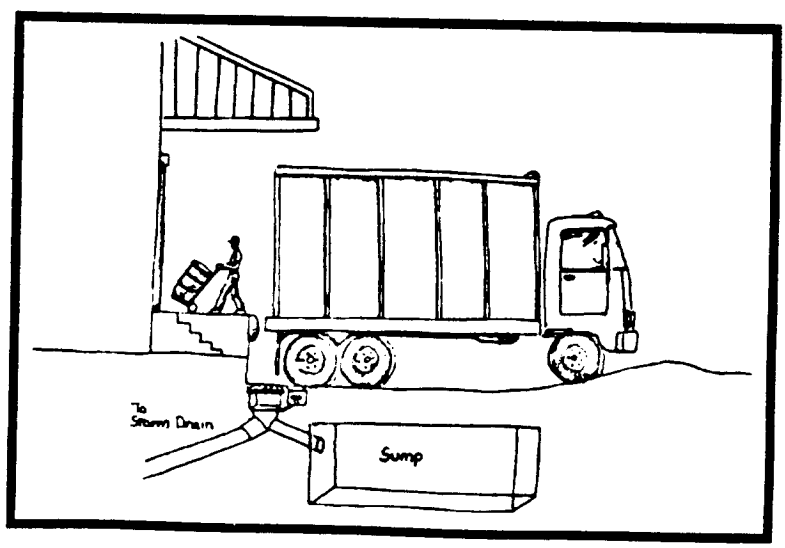
You will need to evaluate your own plant to determine which BMPs are applicable to your operations and which combination will be most effective at controlling the storm water pollutants that might run off from your site. You could find that you have a choice in selecting structural BMPs. Evaluate and select controls that are adequate and most cost-effective for your site.

The BMP descriptions in this section are not complete design standards, but describe the principles you need to consider in identifying and controlling storm water pollution. Design standards, performance specifications, and further discussion of the design and application of structural and treatment BMPs are contained in the State BMP Manual (available from the Clean Water Program).

Advanced pollution control practices take a number of forms, and might include solutions that are not listed here. If you conduct activities that are unavoidably exposed to storm water, you will need to develop more intensive source control and storm water management BMPs.

If you are renovating your shop or building a new facility, you should consider installing some of these structural controls. For example, if you regrade an equipment parking area, you should consider storm water design criteria. If you put off implementing the measures, more stringent requirements in the future could oblige you to retrofit the new or upgraded facility, which could be more costly than if you include the work in the construction or renovation.

A dead-end sump provides secure spill control, but any accumulated liquids need to be pumped out, tested, and properly disposed. Use berms or slopes to prevent run-on so storm water is not added to waste in the sump.



13 LOADING DOCK DESIGN FEATURES

Loading docks sometimes require more intensive pollution controls than the operational BMPs described in Section 8. That is especially true of areas where you load or unload liquids in containers. Bulk liquid transfers are a more intensive industrial operation that require specific control designs, and are not addressed in this manual.

Additional features of a properly designed loading dock including grading the loading area so that it is sloped or recessed to direct flow toward an inlet with a shutoff valve or toward a dead-end sump. Make sure the inlet includes a sump with enough capacity to hold a spill while the valve is closed. Keep the valve closed at all times, except when you need to release storm water or other liquids that are acceptable for discharge.

VOL 12 2 5645

R0058938

Preferably, the inlet should connect to a sanitary sewer instead of a storm drain. Check with your wastewater treatment authority for permit requirements. Consider completely preventing contact with storm water by using a roof and berms, as described in Section 8. This will avoid both washing potential pollutants into the drain and discharging clean storm water into the sanitary sewer.

If the inlet connects to a *storm drain*, accumulated liquid must be tested and found to contain no pollutants before the valve may be opened for discharge. If the liquid does contain pollutants, you must pump it from the sump and discharge it into your sanitary sewer, providing that the wastewater treatment authority agrees to accept it. (See the recommendation below.)

If the inlet connects to a *sanitary sewer*, accumulated liquid must be tested and found to be within the parameters specified in your wastewater discharge permit before the valve may be opened for discharge. If you cannot discharge into the sanitary sewer, you need to convey the liquid to a hazardous waste disposal facility.

14 EQUIPMENT YARD DESIGN FEATURES

Parking and storage yards for large vehicles and heavy equipment generally require site-specific structural and operational controls. Follow the operational BMPs for vehicles recommended in Sections 7, 8, 9, and 10. Also assess your equipment yard to determine if there are possible sources of pollutants, and install appropriate controls to keep potential pollutants out of the storm water. Following are some measures that might be included in the design:

- Grade the area to slope toward a longitudinal drain, or install curbs to direct all storm water to a storm drain in the yard. If your yard is not too large and is properly designed, it should drain to a single storm drain. Even a small yard should include a storm drain on your property and not rely on a city-operating drain in the street.
- If you determine that the equipment yard is a significant source of oily material in your storm water, consider fitting the inlet(s) with a sand filter (see Section 20) or removing oily pollutants (see Section 21).

Segregate the area where you service vehicles, and install special structural controls:

- If possible, perform all work indoors, or construct a roof over the specified area. That will require a building permit and compliance with appropriate fire codes.
- Pave the surface with concrete, not asphalt. Vehicle fluids can dissolve asphalt or be absorbed into the blacktop and released later.
- Drain the surface to a single drain, preferably one connected to a sanitary sewer. The drain will require an oil/water separator or oil/grease trap, and must be approved by your wastewater treatment authority.
- Grade the working area to be higher than the parking lot, or surround it with a berm, to prevent storm water run-on.
- Construct a special area in which to segregate your "dirtiest" equipment (roof tar equipment, asphalt paving equipment, etc.) Handle its discharges, leaks, and runoff separately. This approach could save you from the need to treat all the runoff from the equipment yard.

VOL 12 2 5646

R0058939

15 FLEET OR EQUIPMENT FUELING AREA DESIGN FEATURES

If your facility's vehicle fueling area is one of the significant sources you identify in your SWPP Plan, you might need more intensive BMPs than the operational efforts described in Section 10. Following are some design features to consider:

- Cover the fueling area to prevent rain from falling directly on the area. Install a roof over the fueling island, the area where vehicles park while fueling, and as much of the approach as practical. Leaked engine fluids and spilled fuel inevitably accumulate on the pavement in those heavy traffic areas.
- Storm drain and sewer inlets that drain the fueling area must be equipped with shutoff valves to keep fuel out of the drain in the event of a spill from the pumps. The valves should be kept closed at all times except during a rainfall.
- Curtail fueling activities when the valves must be open, or use extra precautions to capture any spilled fuel, such as a large drip pan under the vehicle.

A number of different approaches can serve as effective drainage design. The fueling area must be separated from the rest of the yard, both to contain any fuel spill and to prevent storm water from running onto the area. Select or adapt one of the following schemes:

- Grade the fueling area to be "mounded" or elevated. The Automotive Industries BMP manual includes a suggested mounded grading scheme.
- Install around the area berms that are high enough to redirect water from a large storm.
- Grade the entire fueling area to drain to a single inlet. You can accomplish this with longitudinal drains at the perimeter along the "downhill" side of the fueling area, or with a depression in the middle of the fueling area. Either way, be sure to design the grading to avoid run-on.
- Install at the inlet a sump from which you will pump any accumulated liquids. The sump or connection should be operated as suggested for a loading dock area in Section 13.

16 ACCESS ROADS AND RAIL CORRIDORS

Access roads and rail corridors can be significant sources of pollutants. In the General Permit, access roads and rail corridors are defined as "industrial activities exposed to storm water," which you must include when identifying potential sources and selecting BMPs for your SWPP Plan.

Maintenance and operational BMPs for access roads are the same as those described for vehicle access and parking areas under Section 9. Some structural BMPs are described below.

Proper drainage design is a good place to start. Generally, this means that the roads should be crowned and sloped outward and that storm water should not be allowed to drain across the road but be carried in ditches or culverts alongside the road. Grass lining the roadside ditches, can be an effective way to remove storm water pollutants — see Section 20. Maintain the ditch to make sure it does not clog or fill with sediments and cause storm water to overflow. Plant vegetation by the roadside to control erosion and promote rainwater infiltration.

If your site includes railroad access, preservatives on wooden railroad ties can become important pollutants. Use a less-toxic preservative. Avoid organic toxics, such as creosote and pentachlorophenol. Or use concrete ties or other nonwood ties.

Control spills and dust from railroad unloading. If your rail line delivers or picks up liquids in bulk or in containers, you might have to add spill control loading docks with shutoff valves. (See Section 3 for spill controls, and Section 13 for loading dock design features.) If parked railroad cars drip, install a drip pan at the loading dock between the rails.

R0058940

VOL 12 2 5647

17 ON-SITE STORM WATER MANAGEMENT

Some industrial facilities will have potential pollutants exposed to storm water even after implementing source control measures like the operational BMPs described in the first part of the manual and the structural source controls discussed in this part. Further structural controls can be used to manage the storm water itself, either to control the flow of the runoff (described in Section 19), to remove some of the pollutants in passive devices (Section 20), or to remove pollutants using specially designed equipment (Section 21).

The best way to avoid the need for storm water management or treatment is to use source controls, most likely in combination. The right combination for your facility will probably include conscientious implementation of BMPs such as those recommended in Sections 1 through 12 of this manual, attention to the sources of waste at your facility, and careful reduction of process wastes.

If you need to manage storm water on-site, the most important consideration is to minimize the quantity of storm water that contacts potential pollutants. For example, keep the area of industrial activities as small as possible, separate the area from parking lots to prevent run-on, and roof or enclose the area if possible.

Design your storm water conveyance system to *isolate* the areas where storm water contacts potential pollutants, and convey water from those areas separately from water that runs off of "clean" and nonindustrial parts of the site. That will allow you to control storm water with smaller and less costly hydraulic or water quality controls. Or, if you plan to discharge to your wastewater treatment authority (see Section 18), reducing the volume will reduce the discharge cost and increase the willingness of your wastewater authority to accept the discharge.

18 REDIRECT STORM WATER DISCHARGE FROM STORM DRAIN INTO SANITARY SEWER

If source control BMPs are not adequate to prevent discharging pollutants in storm water from your facility, you might have to cease discharging storm water that contacts those pollutants. One way to avoid discharging potential pollutants with storm water is to isolate runoff from that part of your facility where the pollutants are contacted and discharge the storm water into the sanitary sewer instead of a storm drain.

Installation of new connections and new piping can be quite costly, and the necessary permits could be a barrier. Also, a permit from your local wastewater authority will be required. The permit will specify the volume of water you may discharge, the kind of pretreatment equipment you might need to install and operate, and requirements for monitoring your discharge.

Redirecting discharge to the sanitary sewer might not be allowed in all localities — some wastewater authorities have sections in their local ordinances that prohibit the discharge of storm water into the sanitary sewer. Requirements might differ from one municipality to another, so contact the authority that serves your area for information. (See the list on the back cover.)

As a rule, your wastewater treatment authority would prefer to minimize the volume of storm water that passes through the treatment system. You should reduce the quantity of storm water you redirect, using techniques like those described in Section 17.

The wastewater authority might require temporary storage of your storm water on-site, to avoid overloading its facilities during a storm. Your authority is more likely to accept discharge of storm water that has contacted pollutants if you can store it temporarily and deliver it *after* the high flows from a storm.

19 STORM WATER MANAGEMENT: HYDRAULIC CONTROLS

Hydraulic controls are intended to control the *quantity* of storm water discharge, but can be useful for water *quality* as well by removing potential pollutants from storm water. BMPs of this type are widely used to control erosion of hillsides and to remove sediments from storm water runoff. Also hydraulic control BMPs can help to remove oils and heavy metals that adsorb to sediment particles in storm water.

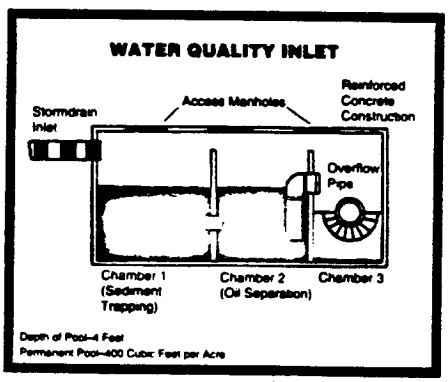
Design standards and operating information for hydraulic controls are available in a number of reference works. Design specifications for hydraulic controls are addressed in the State Industrial BMP manual. Many local and regional regulations that target erosion control provide specifications for hydraulic BMPs.

Hydraulic controls are designed for one of two purposes. One category controls the rate of peak flow, slowing the flow of water at the height of the storm to reduce its potential for carrying away soils and other contaminants. The other type reduces volume of runoff, generally by causing some storm water to *infiltrate* (or soak into the soil) instead of running off into storm drains, streets, or streams. Some approaches control both peak rate and volume.

VOL 12 2 5648

R0058941

Hydraulic controls for a site are most effective if the overall site design is considered. The first step generally is to modify the site layout to increase the water-permeable surface, thereby increasing infiltration and reducing runoff volume. If greater flow control is needed, the second step might be to strategically place *infiltration trenches* to intercept runoff and promote infiltration. (Infiltration is not permitted in some areas — see Section 20.) For large quantities of flow, on-site ponds can be designed either to slow the peak flow of storm water or to hold water on-site until it infiltrates or evaporates. They are known as *detention ponds* or *retention ponds*. A variation is the *storm water wetland*, which similarly controls flow while wetland vegetation helps remove pollutants.



An API separator is only partly effective in removing oily wastes, but is more effective than an ordinary catch basin in removing sediments.

20 STORM WATER MANAGEMENT: WATER QUALITY CONTROLS

A number of specific storm water management controls are better suited to water-quality control than hydraulic control. These features might be added to various parts of the storm water conveyance system on an industrial site to help control potential pollutants in the storm water before it leaves the site. They are, for the most part, passive design features instead of treatment devices in the usual sense. Information in existing references gives design parameters for those water-quality controls, so this section merely summarizes a few types of controls.

A simple technique is a **vegetated swale** or **channel**, a ditch that carries storm water in which plants are permitted to grow. The plants provide some peak flow control by slowing the water. They also remove some pollutants by encouraging the deposit of sediments and minor oily wastes. This control can be retrofitted to some existing storm water conveyance ditches simply by allowing grasses to grow, if it does not interfere with storm water drainage and cause water to back up onto the site.

A **water quality inlet** is a simple multi-purpose device. A storm drain inlet is fitted with an enlarged catch basin or grit chamber where solids and sediments settle out of the water. A baffle restricts the flow of surface-floating oil, which can be removed by hand later. Floatable debris also collects at the baffle. This type of inlet has, in the past, been used to help remove oily wastes, but is of limited effectiveness. Section 21 describes the inlet further, including maintenance requirements.

A **sand filter inlet** is a storm drain inlet that contains sand or another filter medium. The sand removes particulates and oily wastes from storm water as it enters the storm drain. An extension of the same concept is a **sand filter**, where storm water quality can be improved before discharge. Sand filters appear to be particularly effective if used in combination with detention or retention ponds because they divert the first-flush of runoff (often carrying the most pollutants) to the filter and route the remainder of the water to the pond.

VOL 12 2 5650

21 STORM WATER MANAGEMENT: REMOVING OILY POLLUTANTS

A simple technique for removing oils and grease from storm water uses **oil-absorbent materials** (or oleophilic materials), such as the booms used to contain oil spills. The absorbent material preferentially absorbs oil and does not fill with water, so it can be used on storm water with small concentrations of oily materials.

Some facilities that have a storm water conveyance ditch where water flows throughout the rainy season have found it convenient to install a permanent floating boom to control an occasional light surface sheen. When the boom is spent, it is full of oil and is visibly heavier, floating lower in the water. The booms are inexpensive enough to be easily replaced whenever the absorbent is saturated. Disposal is more costly, since they might be hazardous waste, unless an oil recycler can accept the material.

Oil/water separators comprise a broad category of devices that are intended to remove oily constituents. There are many varieties of oil/water separators, and the term is not used in the same way by all equipment vendors or design specifications.

For most applications, oil/water separators are *not recommended* as a storm water management strategy. Source control BMPs are strongly preferred. Oil/water separators are fairly costly, and most designs do not operate well at the low concentrations commonly present in storm water. A sand filter inlet is typically more effective, and less costly, for the small quantities and low concentrations of oils in routine storm water runoff — that is, runoff that has not directly contacted oily industrial activities.

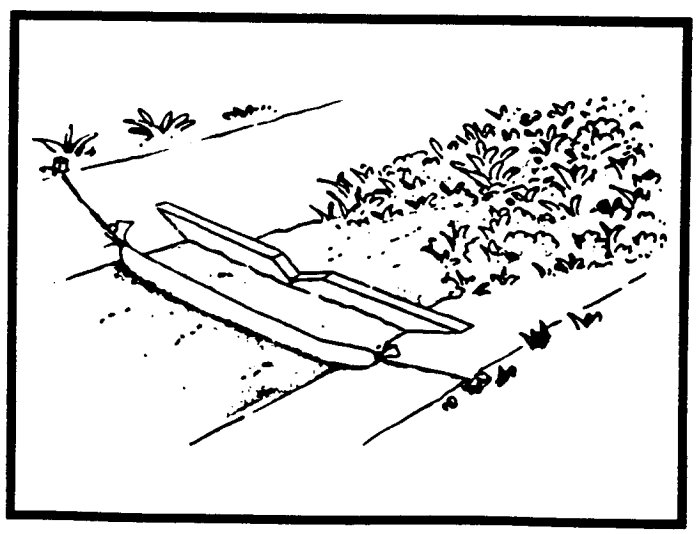
Separators can be useful in limited applications, such as for retrofitting to temporarily help a facility comply while it installs more effective source control BMPs. Another use is in spill control sumps, upstream of a treatment process. The advanced designs are sometimes used as treatment devices, discharging into a sanitary sewer storm water that contacts industrial activities in isolated areas where contact cannot be avoided.

The **API (American Petroleum Institute) oil/water separator** is a simple design. It is sometimes called an "oil and grease trap," to distinguish it from a true oil/water separator used for industrial wastewater. An API separator usually is a long basin with multiple chambers or vaults, typically installed below grade. It can be fitted to storm drains or storm water inlets in a variety of configurations — the water-quality inlet described in Section 20 is one form. The intent is to slow water and stratify the flow so that oil rises. The floating oil is then retained by one or more baffles in the chambers.

An API separator removes the bulk of floating oily wastes, especially if the oil is not well mixed but floats on top of the water. However, it is not very efficient, so storm water can still be polluted unacceptably even after it flows through the inlet. The separator works by concentrating oily wastes within the chamber, so some of the collected wastes are inevitably carried away during heavy storms. It can be made somewhat more effective at oil removal if it includes pads or pillows of oleophilic material at the water surface level.

If you install an **API separator**, *it must be maintained* regularly. It requires a standing pool of water, which should be pumped out periodically and replaced with clean water. To clean, remove oil floating on the standing pool and greasy matter collected at the baffle. Some commercial oil recyclers accept this material for recycling; otherwise, it must be handled as hazardous waste. If you install oil-absorbent pillows, they must be closely monitored and replaced when they are saturated, and must be disposed of either as hazardous waste or sent to a recycler. If the inlet includes a sediment trap, as in the water-quality inlet shown in Section 20, remove solids with a shovel between storms.

Develop a regular cleaning schedule. For inlets that don't carry much flow, three cleanings a year are sufficient— once before the rainy reason (mid-September) to remove materials that have accumulated; once after the first major storm; and then at the end of the rainy season to prevent slow loss or



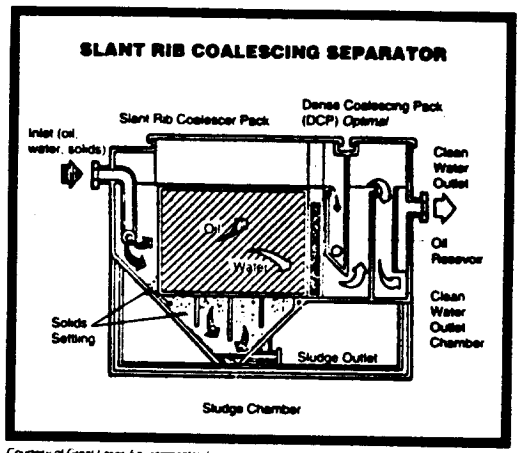
Oil-absorbent berms can remove oily sheen from storm water. Vegetation in an open ditch can slow the flow, helping sediments settle.

R0058943

evaporation of the collected oily wastes. If storm water flow is greater, the API separator might have to be cleaned monthly or periodically between storms. As another guideline, clean the separator before three inches of oil accumulate in the entry chamber.

The **CPI, or coalescing plate interceptor** oil/water separator, is a more advanced design. It is commonly used for treatment of oil-bearing industrial wastewater, but is less often cost-effective for storm water. The CPI separator generally achieves greater removal efficiency than an API type, but is more costly to purchase and operate. A CPI separator can attain a high removal efficiency and accommodate a fairly high flow rate, but at ever-increasing capital costs for the equipment because of the addition of more separator plates. Cost-effectiveness is generally optimal for relatively high concentrations of oil at low and constant flow rates.

A few design features can improve the effectiveness of an oil/water separator. Pollution removal is most effective if the concentration is high when the storm water enters the unit. Avoid diluting the water to be treated with water from other parts of the site where it does not contact the potential pollutants, both to save on the capital investment and to increase treatment effectiveness. For industrial process applications, an evaporator can be used to reduce the volume of water treated.



Courtesy of Great Lakes Environmental, Inc.

A CPI separator can be very effective in removing oil, but requires upstream sediment control and can be costly to maintain.

An oil/water separator works best if sediment is not present in the water — limit the water to be treated to isolated areas free of mud and soils if possible. Efficiency is highest with a fairly steady flow, so you might require upstream detention. Also, do not site the separator downstream of a pump, because the pump mixes the oil and water and partially emulsifies the oil, with the result that separators are less effective.

Storm water treatment generally is *not recommended* as a BMP. The State or your local wastewater authority might consider as treatment some of the devices described in Section 21, but that could open the door to some burdensome regulatory restrictions and permit requirements.

For most industrial facilities, the best advice about on-site storm water treatment is to avoid it, for a number of reasons. Most of the available treatment equipment is costly to purchase and to obtain permits for. Operational costs can also be significant — you must monitor the equipment to ensure continued effectiveness, and you might need to prepare and submit chemical analyses to demonstrate compliance.

The most troublesome permit procedures are for hazardous materials. Before installing any treatment equipment, determine whether your wastewater is hazardous. Cal-EPA/Toxics or the County Environmental Health Department will describe the necessary testing and approval procedures. If the wastewater that would enter the pretreatment equipment is considered to be hazardous you must obtain a permit from Cal-EPA/Toxics to operate a hazardous waste treatment facility. At present this might be true even for a simple water-quality inlet. If you determine that the waste stream is not hazardous, and do not apply for a hazardous waste treatment permit, keep your testing documentation on hand to show regulators.

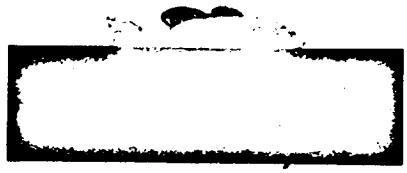
R0058947



In the Santa Clara Valley, all storm drains flow directly to local creeks and the San Francisco Bay, with no treatment. Stormwater pollution is a serious problem for wildlife dependent on our waterways, and for the people who live near polluted streams or baylands.

Food handling facilities such as restaurants, institutional cafeterias, grocery stores, bakeries, and delis, contribute to this stormwater pollution mainly through improper cleanup practices that allow food particles, oil, grease, and cleaning products to flow into a street, gutter, or storm drain.

All of the cities in the Valley are required by the Regional Water Quality Control Board to enforce local ordinances prohibiting the discharge of pollutants to storm drains or local creeks. Also, the California Department of Fish and Game forbids any discharge of materials that could pass into creeks, rivers, or the Bay that would be "deleterious to fish, plant life, or bird life."

In addition, the Santa Clara County Department of Environmental Health and local wastewater treatment plants require that all grease traps and other grease removal devices be cleaned as often as necessary to prevent overflow and to meet local grease and oil limits in wastewater. Check with these agencies to find out about other requirements — see phone numbers on page 12.

Following the practices in this manual will ensure compliance with ordinance requirements with respect to both the sanitary sewer and the storm drains, and will help contribute to a cleaner Bay. Please share this information with any contractors that you hire.

VOL 12 2 5655

R0058948

Food handling facilities sometimes discharge food waste, oil and grease, as well as toxic chemicals, such as cleaning products, disinfectants and pesticides, into the environment.

When cooking oil and grease is improperly disposed of into the sanitary sewer lines (indoor plumbing), the lines become plugged and back up. A sewer backup, especially in a food preparation area, presents a severe risk to the public health. Serious, even fatal diseases, can be caused by contact with raw sewage.

If cooking oil, grease, food wastes and washwater are dumped onto the street, gutter, parking lot, alley, or into a storm drain, they end up in local creeks and the San Francisco Bay, without being treated at a wastewater treatment plant. Even detergents labeled "biodegradable" contain harmful ingredients that are toxic to aquatic life. Soapy washwater that is dumped onto pavement finds its way to storm drains and into nearby creeks.

In addition to drawing flies, vermin, and creating odor and public health problems, decaying organic waste materials (primarily food and oil waste) use up the dissolved oxygen in streams and the Bay, stressing or killing aquatic animals.

Sanitary Sewer or Storm Drain?
How to Tell the Difference.

If you are not certain whether a drain leads to the storm drain or sanitary sewer, call your city's sewer department so that they can help you resolve the question. In general, drains inside the building are connected to the sanitary sewer, and outside drains (except for capped sanitary sewer "cleanouts") are connected to the storm drain system. Sanitary sewer cleanouts are usually 6 inches in diameter or smaller, storm drain inlets are larger – but there are exceptions. You need to know for sure!

VOL 12 2 5656

R0058949

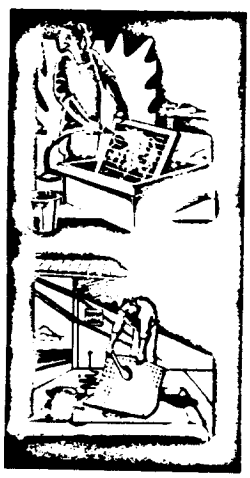
[redacted]

When cleaning floor mats, exhaust filters, garbage cans, carts, and tray racks — in order of preference:

1. Clean equipment in a designated indoor area, such as a mop sink, pot sink, or floor area with a drain connected to the sanitary sewer (indoor plumbing).

2. Clean equipment in a designated covered, bermed outdoor area with a drain connected to the sanitary sewer (indoor plumbing). This area should be isolated from the storm drain with a berm or other barrier. Don't allow food wastes to accumulate in this area. (Option 2 may not be permitted in certain cities. Check with your local planning department before installing an outside drain.)

[redacted]



- Consider installing anti-slip floors when you remodel.

- If possible, use floor mats that are small enough to be cleaned inside in a mop sink or near a floor drain.

- For hood filter cleaning companies, see "Restaurant Equipment Repairing and Servicing" in the yellow pages.

- Consider cleaning your filters in the dishwasher. Contact your local wastewater treatment plant or the County Department of Environmental Health for guidance and other cleaning options (see page 12).

- Remember that your facility is liable for the behavior of contractors that you hire. Be sure that you know how any contractor will be cleaning your equipment and disposing of washwater. No storm drain disposal is allowed!

VOL 12 2 5657

R0058950

When cleaning frying equipment, or when storing fat or grease for removal to a grease recycler or for waste grease disposal, follow these guidelines:

- Recycle used cooking oil, grease, and meat fat, whenever possible. See "Tallow" in the yellow pages for a list of recyclers.
- Do not contaminate the recyclable oils and grease in your tallow bin with the waste grease from your grease trap or grease interceptor.
- Inspect and clean all waste grease removal devices (grease traps and grease interceptors) regularly. For under-the-sink grease traps, we recommend skimming of the surface weekly and a more thorough cleaning quarterly. For the larger grease interceptors, we recommend pumping every 3 months (or more frequently as required to meet your local oil, fats, and grease limit). Check with your local wastewater treatment plant for guidelines.
- For disposal of waste grease from grease interceptors and traps, see "Grease Traps" and "Septic Tanks" in the yellow pages. Most landfills will not accept grease or other liquid waste from businesses. It is in your best interest to ensure that your waste grease is disposed of properly. Ask your waste grease hauler where your waste grease is disposed of.

VOL 12 2 5658

R0058951

VOL 12 2 5659

Whenever a spill occurs, and when cleaning dumpster areas, loading docks, and other paved surfaces:

Don't hose down the area!

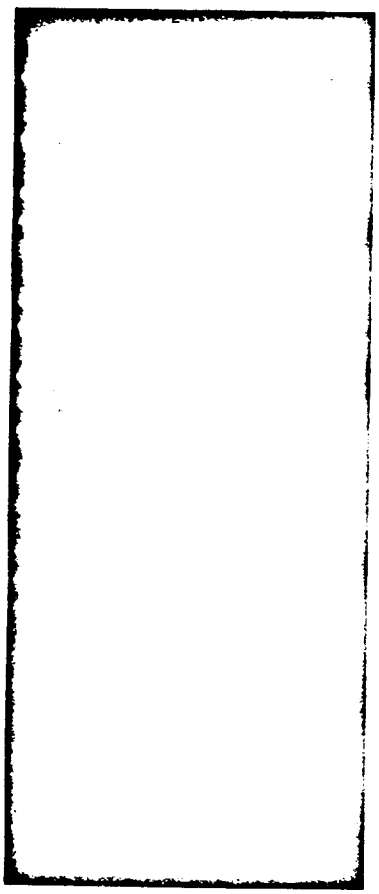
- First, stop any spill at its source.
- If the spill could enter a storm drain, block the flow with sandbags, absorbent, rags, or a pile of dirt. You can temporarily seal the storm drain with plastic sheeting.
- Dry sweep, as much as possible, using rags and granular absorbents (e.g. cat litter) to absorb the spill. Sweep and dispose of used absorbent in the garbage (if hazardous materials are not involved).

- If wet cleaning (including high-temperature or high-pressure washing) is required, dry clean first and then mop (or if it is absolutely necessary, wash) and collect water. Dispose of water in sink or other indoor drain, not the storm drain.
- If a final rinse is necessary for health reasons, collect the rinse-water and dispose to sink or indoor floor drain. If outdoors, block storm drain before applying water. Mop up or wet-vacuum water, and dispose to sink or indoor drain.
- Do not use bleach or disinfectants if there is a possibility that the rinsewater could flow to a street, gutter, or storm drain.

R0058952

- Keep dumpster lids closed to keep out rainwater.

- Keep dumpsters or the dumpster enclosure locked to prevent illegal dumping.



- Never place liquid waste or leaky garbage bags into a dumpster.

- Don't hose out dumpster interior. Apply absorbent over any fluids spilled in the dumpster. Absorbent and fluid will usually be knocked out when the dumpster is emptied.

- Leaking dumpsters and compactors, and dumpsters that need to be cleaned out, should be replaced by the dumpster leasing company.

- Make sure tallow bins (cooking oil/meat fat recycling bin), and any containers of waste grease are always tightly covered to prevent contamination of the grease and to prevent problems with rats and insects.

- Keep litter from accumulating around the loading docks by providing trash receptacles and encouraging employees to use them.

- Have spill cleanup materials handy near the dumpster and loading dock areas.

VOL 12 2 5660

R0058953

Please post the enclosed poster in the food handling area.

Copy and distribute the enclosed brochure to employees at your regular training meetings and to all new employees when they are first trained. Be sure all new employees are informed about these practices. Discuss good pollution control practices with all employees at least quarterly. The enclosed brochures have been translated into Spanish, Vietnamese, and Chinese. Call 800-794-2482 if additional originals are needed.

Stencil the storm drains in your parking lot with "No Dumping! Flows to Bay" to remind your employees that these drains flow directly to creeks and the Bay. Call 800-794-2482 for free stencils.

Post spill cleanup guidelines and the name of each shift's designated spill cleanup monitor in a visible location.

Complete the worksheet, located on pages 10-11, and share it with employees.

R0058964

Introduction

Stormwater pollution is rapidly growing in importance as a national environmental issue. In California, stormwater pollution is a major source of water pollution. To help combat the problems of stormwater pollution, federal and state governments have developed a program for monitoring and permitting discharges to municipal storm drain systems, creeks, and water bodies such as San Francisco Bay.

Municipalities in the Bay Area are required by the Clean Water Act to develop stormwater management programs that include requirements for construction activities. Your construction project will need to comply with local municipal requirements. If your construction activity will disturb five acres or more, you must also obtain coverage under the General Construction Activity Permit (see Requirements for Dischargers).

Blueprint for a Clean Bay is an introductory guide to stormwater quality control on construction sites. It contains several principles and techniques that you can use to help prevent stormwater pollution. BASMAA has developed this booklet as a resource for all general contractors, home builders, and subcontractors working on construction sites.

Blueprint for a Clean Bay is not a design manual or a Stormwater Pollution Prevention Plan (SWPPP) (see Requirements for Dischargers). For more information on the General Permit, designing stormwater quality controls, or producing a Stormwater Pollution Prevention Plan, please refer to the California Storm Water Best Management Practice Handbook for Construction Activity, or consult your local program or the SWRCB (see below). Please note that this booklet is concerned only with the management of construction sites and activities during construction.

Stormwater Pollution

Storm Drain System

Stormwater or runoff from sources like sprinklers and hoses flows over the ground into the storm drain system. In the San Francisco Bay Area, storm drain systems consist of gutters, storm drains, underground pipes, open channels, culverts, and creeks. Storm drain systems are designed to drain directly to the Bay, Delta, or Pacific Ocean with no treatment.

Pollution From Construction Sites

Stormwater runoff is part of a natural hydrologic process. However, land development and construction activities can significantly alter natural drainage patterns and pollute stormwater runoff. Runoff picks up pollutants as it flows stormwater runoff. Runoff picks up pollutants as it flows over the ground or paved areas and carries these pollutants into the storm drain system. Common sources of pollutants from construction sites include: sediments from soil erosion; construction materials and waste (e.g., paint, solvents, concrete, drywall); landscaping runoff containing fertilizers and pesticides; and spilled oil, fuel, and other fluids from construction vehicles and heavy equipment.

Adverse Effects from Stormwater Pollution

Stormwater pollution is a major source of water pollution in California. It can cause declines in fisheries, disrupt habitats, and limit water recreation activities. Even more importantly, stormwater pollution poses a serious threat to the overall health of the ecosystem.

For more information on stormwater requirements, call the State Water Resources Control Board's Stormwater Information Line at (916) 657-1146 or your local program.

VOL 12 2 5672

R0058965

Requirements for Dischargers

Municipal Stormwater Program

Municipalities in the Bay Area are required by federal regulations to develop programs to control the discharge of pollutants to the storm drain system, including the discharge of pollutants from construction sites and areas of new development or significant redevelopment. As a result, your development and construction projects may be subject to new requirements designed to improve stormwater quality such as, expanded plan check and review, new contract specifications, and increased site inspection. For more information on municipal requirements, please contact the municipal representative listed on the back cover of this booklet.

Projects Equal To Or Greater Than 5 Acres

If your construction activity will disturb five acres or more, you must obtain coverage under the General Construction Activity Storm Water Permit (General Construction Permit) issued by the State Water Resources Control Board (SWRCB) for stormwater discharges associated with construction activity. To obtain coverage under the General Permit, a Notice of Intent (NOI) must be filed with the SWRCB. The General Construction Permit requires you to prepare and carry out a "Stormwater Pollution Prevention Plan" or SWPPP. Your SWPPP must identify appropriate stormwater pollution prevention measures or best management practices (BMPs), like the ones described in this booklet, to reduce pollutants in stormwater discharges from the construction site both during and after construction is completed. A best management practice or BMP is defined as any program, technology, process, practice, operating method, measure, or device which controls, prevents, removes, or reduces pollution.

Projects Less Than 5 Acres

If your project is less than five acres, you may still need to use BMPs to comply with local municipal requirements. Check with the local planning or engineering department for details.

Best Management Practices

General Practices

The following are some general principles that can significantly reduce pollution from construction activity and help make compliance with stormwater regulations easy:

- Identify all storm drains, drainage swales and creeks located near the construction site and make sure all subcontractors are aware of their locations to prevent pollutants from entering them.
- Clean up leaks, drips, and other spills immediately so they do not contact stormwater.
- Refuel vehicles and heavy equipment in one designated location on the site and take care to clean up spills immediately.
- Wash vehicles at an appropriate off-site facility. If equipment must be washed on-site, do not use soaps, solvents, degreasers, or steam cleaning equipment, and prevent wash water from entering the storm drain. If possible, direct wash water to a low point where it can evaporate and/or infiltrate.
- Never wash down pavement or surfaces where materials have spilled. Use dry cleanup methods whenever possible.
- Avoid contaminating clean runoff from areas adjacent to your site by using berms and/or temporary or permanent drainage ditches to divert water flow around the site. Reduce stormwater runoff velocities by constructing temporary check dams and/or berms where appropriate.
- Protect all storm drain inlets using filter fabric cloth or other best management practices to prevent sediments from entering the storm drainage system during construction activities.
- Keep materials out of the rain — prevent runoff pollution at the source. Schedule clearing or heavy earth moving activities for periods of dry weather. Cover exposed piles of soil, construction materials and wastes with plastic sheeting or temporary roofs. Before it rains, sweep and remove materials from surfaces that drain to storm drains, creeks, or channels.

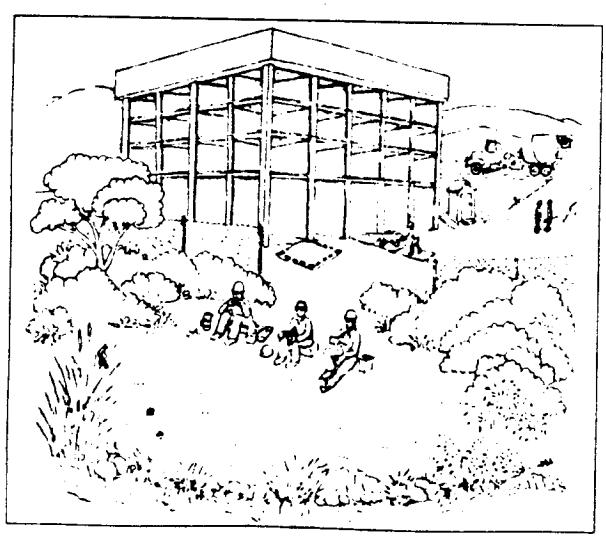
For more information on the General Permits, call the State Water Resources Control Board's Stormwater Information Line at (916) 657-1146 or your local program.

VOL 12 2 5673

R0058966

Best Management Practices

- ❑ Keep pollutants off exposed surfaces. Place trash cans around the site to reduce litter. Dispose of non-hazardous construction wastes in covered dumpsters or recycling receptacles.
- ❑ Practice source reduction — reduce waste by ordering only the amount you need to finish the job.
- ❑ Do not over-apply pesticides or fertilizers and follow manufacturers instructions for mixing and applying materials.
- ❑ Recycle leftover materials whenever possible. Materials such as concrete, asphalt, scrap metal, solvents, degreasers, cleared vegetation, paper, rock, and vehicle maintenance materials such as used oil, antifreeze, batteries, and tires are recyclable (See separate list of "Recyclers and Disposal Services" for more information).
- ❑ Dispose of all wastes properly. Materials that cannot be reused or recycled must be taken to an appropriate landfill or disposed of as hazardous waste. Never throw debris into channels, creeks or into wetland areas. Never store or leave debris in the street or near a creek where it may contact runoff.
- ❑ Illegal dumping is a violation subject to a fine and/or time in jail. Be sure that trailers carrying your materials are covered during transit. If not, the hauler may be cited and fined.
- ❑ Train your employees and inform subcontractors about the stormwater requirements and their own responsibilities.



Specific Practices

Following is a summary of specific best management practices for erosion and sediment control and contractor activities. For more information on erosion and sediment control BMPs and their design, please refer to the California Storm Water Best Management Practice Handbook for Construction Activity (March 1993) and the Association of Bay Area Governments (ABAG) Manual of Standards for Erosion & Sediment Control Measures (May 1995).

Erosion Prevention and Sediment Control

Prevent erosion

Soil erosion is the process by which soil particles are removed from the land surface, by wind, water and/or gravity. Soil particles removed by stormwater runoff are pollutants that when deposited in local creeks, lakes, Bay or Delta, can have negative impacts on aquatic habitat. Exposed soil after clearing, grading, or excavation is easily eroded by wind or water. The following practices will help prevent erosion from occurring on the construction site:

- ❑ Plan the development to fit the topography, soils, drainage pattern and natural vegetation of the site.
- ❑ Delineate clearing limits, easements, setbacks, sensitive or critical areas, trees, drainage courses, and buffer zones to prevent excessive or unnecessary disturbances and exposure.
- ❑ Phase grading operations to reduce disturbed areas and time of exposure.
- ❑ Avoid excavation and grading during wet weather.
- ❑ Limit on-site construction routes and stabilize construction entrance(s).
- ❑ Remove existing vegetation only when absolutely necessary.
- ❑ Construct diversion dikes and drainage swales to channel runoff around the site.
- ❑ Use berms and drainage ditches to divert runoff around exposed areas. Place diversion ditches across the top of cut slopes.

VOL 12 2 5674

R0058967

Best Management Practices

- ❑ Plant vegetation on exposed slopes. Where replanting is not feasible, use erosion control blankets (e.g., jute or straw matting, glass fiber or excelsior matting, mulch netting).
- ❑ Consider slope terracing with cross drains to increase soil stability.
- ❑ Cover stockpiled soil and landscaping materials with secured plastic sheeting and divert runoff around them.
- ❑ As a back-up measure, protect drainage courses, creeks, or catch basins with straw bales, silt fences and/or temporary drainage swales.
- ❑ Once grading is completed, stabilize the disturbed areas using permanent vegetation as soon as possible.
- ❑ Conduct routine inspections of erosion control measures especially before and immediately after rainstorms, and repair if necessary.

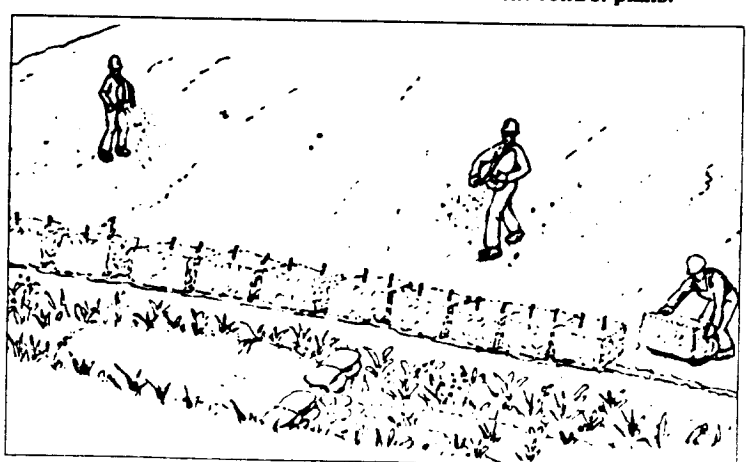
Control sediment

Sedimentation is defined as the process of depositing sediments picked up by runoff. Sediments consist of soil particles, clays, sands, and other minerals. The purpose of sediment control practices is to remove sediments from stormwater before they are transported off-site or reach a storm drain inlet or nearby creek. The most effective sediment control practices reduce runoff velocity and trap or detain runoff allowing sediments to settle out.

- ❑ Use terracing, rip rap, sand bags, rocks, straw bales, and/or temporary vegetation on slopes to reduce runoff velocity and trap sediments. Do not use asphalt rubble or other demolition debris for this purpose.
- ❑ Use check dams in temporary drains and swales to reduce runoff velocity and promote sedimentation.
- ❑ Protect storm drain inlets from sediment-laden runoff. Storm drain inlet protection devices include sand bag barriers, filter fabric fences, block and gravel filters, and excavated drop inlet sediment traps.
- ❑ Collect and detain sediment-laden runoff in sediment traps (an excavated or bermed area or constructed device) to allow sediments to settle out prior to discharge.
- ❑ Use sediment controls and filtration to remove sediments from water generated by dewatering.
- ❑ Prevent construction vehicle tires from tracking soil onto adjacent streets by constructing a temporary stone pad with a filter fabric underliner near the site exit where dirt and mud can be removed.
- ❑ When cleaning sediments from streets, driveways and paved areas on construction sites, use dry sweeping methods where possible. If water must be used to flush pavement, collect runoff to settle out sediments and protect storm drain inlets.

Note: Performance of erosion and sediment controls is dependent on proper installation, routine inspections and maintenance of the controls. Most of the BMPs described above are temporary and if left alone can quickly fall into disrepair and/or become ineffective. Routine inspections and maintenance, particularly before and after a storm event, must be part of any erosion and sediment control plan.

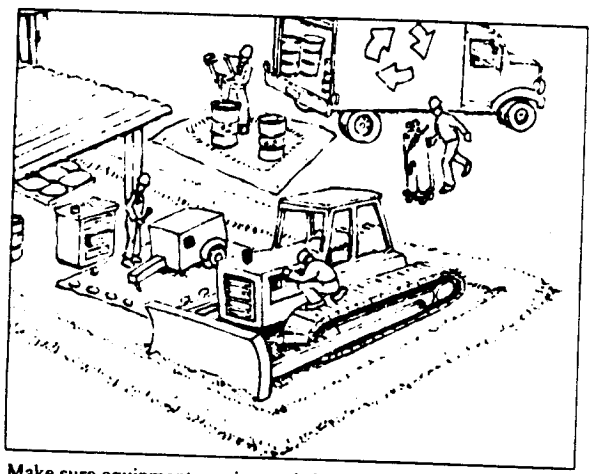
The California Storm Water Best Management Practices Handbook for Construction Activity and the Association of Bay Area Governments Manual of Standards for Erosion and Sediment Control provide specific details and design criteria for erosion and sediment control plans.



Drainage swales channel runoff around a construction site. Planting temporary vegetation on freshly graded areas, and trenching and staking straw bales and/or silt fences downslope are common techniques for preventing erosion and controlling sediment.

VOL 12 2 5675

R0058968



Make sure equipment repair area is bermed or well away from creeks and storm drains.

General Site Maintenance

Prevent spills and leaks

Poorly maintained vehicles and heavy equipment leaking fuel, oil, antifreeze, or other fluids on the construction site are common sources of stormwater pollution and soil contamination. Construction material spills can also cause serious problems. Careful site planning, preventive maintenance, and good materials handling practices can eliminate most spills and leaks.

- ❑ Maintain all vehicles and heavy equipment. Inspect frequently for and repair leaks.
- ❑ Designate specific areas of the construction site, well away from creeks or storm drain inlets, for auto and equipment parking and routine vehicle and equipment maintenance.
- ❑ Perform major maintenance, repair jobs and vehicle and equipment washing off-site when feasible, or in designated and controlled areas on-site.
- ❑ If you must drain and replace motor oil, radiator coolant, or other fluids on-site, use drip pans or drop cloths to catch drips and spills. Collect all spent fluids, store in labeled separate containers, and recycle whenever possible. Note that in order to be recyclable, such liquids must not be mixed with other fluids. Non-recycled fluids generally must be disposed of as hazardous wastes.

Clean up spills immediately after they happen

When vehicle fluids or materials such as paints or solvents are spilled, cleanup should be immediate, automatic, and routine.

- ❑ Sweep up spilled dry materials (e.g., cement, mortar, or fertilizer) immediately. Never attempt to "wash them away" with water, or bury them. Use only minimal water for dust control.
- ❑ Clean up liquid spills on paved or impermeable surfaces using "dry" cleanup methods (e.g., absorbent materials like cat litter, sand or rags).
- ❑ Clean up spills on dirt areas by digging up and properly disposing of the contaminated soil.

Clean up spills on dirt areas by removing contaminated soil.

- ❑ Report significant spills to the appropriate spill response agencies immediately (See reference list on the back cover of this booklet for more information).

Note: Used cleanup rags that have absorbed hazardous materials must either be sent to a certified industrial laundry or dry cleaner, or disposed of through a licensed hazardous waste disposal compay.

VOL 12 2 5676

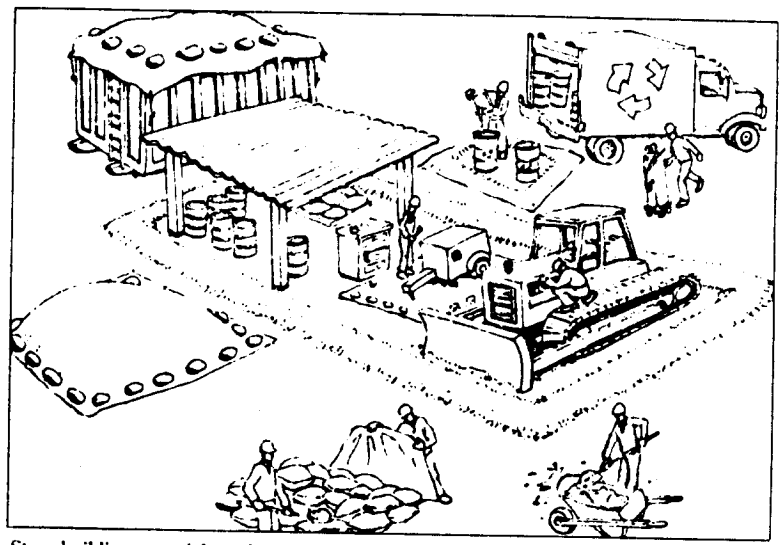
R0058969

Best Management Practices

Store materials under cover

Wet and dry building materials with the potential to pollute runoff should be stored under cover and/or surrounded by berms when rain is forecast or during wet weather.

- ❑ Store stockpiled materials and wastes under a temporary roof or secured plastic sheeting or tarp.
- ❑ Berm around storage areas to prevent contact with runoff.
- ❑ Plaster or other powders can create large quantities of suspended solids in runoff, which may be toxic to aquatic life and cause serious environmental harm even if the materials are inert. Store all such potentially polluting dry materials —especially open bags— under a temporary roof or inside a building, or cover securely with an impermeable tarp. By storing dry materials under a roof, you may also help protect air quality, as well as water quality.
- ❑ Store containers of paints, chemicals, solvents, and other hazardous materials in accordance with secondary containment regulations and under cover during rainy periods.



Store building materials under cover. Make sure dumpsters are properly covered to keep out rain.

Cover and maintain dumpsters

Open or leaking dumpsters can be a source of stormwater pollution.

- ❑ Cover open dumpsters with plastic sheeting or a tarp during rainy weather. Secure the sheeting or tarp around the outside of the dumpster. If your dumpster has a cover, close it.
- ❑ If a dumpster is leaking, contain and collect leaking material. Return the dumpster to the leasing company for repair/exchange.
- ❑ Do not clean dumpsters on-site. Return to leasing company for periodic cleaning, if necessary.

Collect and properly dispose of paint removal wastes

Paint removal wastes include chemical paint stripping residues, paint chips and dust, sand blasting material and wash water. These wastes contain chemicals that are harmful to the wildlife in our creeks and the water bodies they flow to. Keep all paint wastes away from the gutter, street, and storm drains.

- ❑ Non-hazardous paint chips and dust from dry stripping and sand blasting may be swept up or collected in plastic drop cloths and disposed of as trash. Chemical paint stripping residue and chips and dust from marine paints or paints containing lead or tributyl tin must be disposed of as a hazardous waste.
- ❑ When stripping or cleaning building exteriors with high-pressure water, cover or berm storm drain inlets. If possible (and allowed by your local wastewater treatment plant), collect (mop or vacuum) building cleaning water and discharge to the sanitary sewer. Alternatively, discharge non-contaminated wash water onto a dirt area and spade into the soil. Be sure to shovel or sweep up any debris that remains in the gutter and dispose of as garbage.

VOL 12 2 5677

R0058970

Clean up paints, solvents, adhesives, and cleaning solutions properly

Although many paint materials can and should be recycled, liquid residues from paints, thinners, solvents, glues, and cleaning fluids are hazardous wastes. When they are thoroughly dry, empty paint cans, used brushes, rags, absorbent materials, and drop cloths are no longer hazardous and may be disposed of as garbage.

- ❑ Never clean brushes or rinse paint containers into a street, gutter, storm drain, or creek.
- ❑ For water-based paints, paint out brushes to the extent possible and rinse to a drain leading to the sanitary sewer (i.e., indoor plumbing).
- ❑ For oil-based paints, paint out brushes to the extent possible, and filter and reuse thinners and solvents. Dispose of unusable thinners and residue as hazardous waste.
- ❑ Recycle, return to supplier or donate unwanted water-based (latex) paint. You may be able to recycle clean empty dry paint cans as metal (See separate list of "Recyclers and Disposal Services" for more information).
- ❑ Dried latex paint may be disposed of in the garbage.
- ❑ Unwanted paint (that is not recycled), thinners, and sludges must be disposed of as hazardous waste.
- ❑ More and more paint companies are recycling excess latex paint (See separate list of "Recyclers and Disposal Services" for more information).

Keep fresh concrete and cement mortars out of gutters, storm drains, and creeks

Concrete and cement-related mortars that wash into gutters and storm drains are toxic to fish and the aquatic environment.

- ❑ Avoid mixing excess amounts of fresh concrete or cement mortar on-site.
- ❑ Store dry and wet materials under cover, protected from rainfall and runoff.
- ❑ Wash out concrete transit mixers only in designated wash-out areas where the water will flow into settling ponds or onto dirt or stockpiles of aggregate base or sand. Pump water from settling ponds to the sanitary sewer, where allowed. Whenever possible, recycle washout by pumping back into mixers for reuse. Never dispose of washout into the street, storm drains, drainage ditches, or creeks.
- ❑ Whenever possible, return contents of mixer barrel to the yard for recycling. Dispose of small amounts of excess concrete, grout, and mortar in the trash.

Service and maintain portable toilets

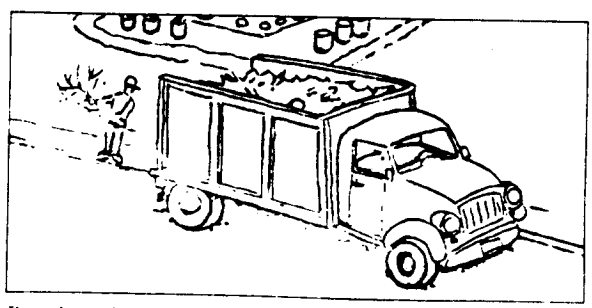
Leaking portable toilets are a potential health and environmental hazard.

- ❑ Inspect portable toilets for leaks.
- ❑ Be sure the leasing company adequately maintains, promptly repairs, and replaces units as needed.
- ❑ The leasing company must have a permit to dispose of waste to the sanitary sewer.

Dispose of cleared vegetation properly

Cleared vegetation, tree trimmings, and other plant material can cause environmental damage if it gets into creeks. Such "organic" material requires large quantities of oxygen to decompose, which reduces the oxygen available to fishes and other aquatic life.

- ❑ Do not dispose of plant material in a creek or drainage facility or leave it in a roadway where it can clog storm drain inlets.
- ❑ Avoid disposal of plant material in trash dumpsters or mixing it with other wastes. Compost plant material or take it to a landfill or other facility that composts yard waste (See separate list of "Recyclers and Disposal Services" for more information).



Recycle yard waste and tree prunings at a landfill that chips and composts plant material.

R0058971

VOL 12 2 5678

Demolition Waste Management

Make sure all demolition waste is properly disposed of

Demolition debris that is left in the street or pushed over a bank into a creek bed or drainage facility causes serious problems for flood control, storm drain maintenance, and the health of our environment. Different types of materials have different disposal requirements or recycling options.

- ❑ Materials that can be recycled from demolition projects include: metal framing, wood, concrete, asphalt, and plate glass.
- ❑ Materials that can be salvaged for reuse from old structures include: doors, banisters, floorboards, windows, 2x4s, and other old, dense lumber.
- ❑ Unusable, unrecycleable debris should be confined to dumpsters, covered at night and during wet weather, and taken to a landfill for disposal.
- ❑ Hazardous debris such as asbestos must be handled in accordance with specific laws and regulations and disposed of as a hazardous waste. For more information of asbestos handling and disposal regulations, contact the Bay Area Air Quality Management District.
- ❑ Arrange for an adequate debris disposal schedule to insure that dumpsters do not overflow.

Roadwork and Pavement Construction

Plan roadwork and pavement construction to avoid stormwater pollution

Road paving, surfacing, and asphalt removal happen right in the street, with numerous opportunities for stormwater pollution from the asphalt mix, saw-cut slurry, or excavated material. Properly proportioned asphalt mix and well-compacted pavement avoid a host of water pollution problems.

- ❑ Apply concrete, asphalt, and seal coat during dry weather to prevent contaminants from contacting stormwater runoff.
- ❑ Cover storm drain inlets and manholes when paving or applying seal coat, slurry seal, fog seal, etc.
- ❑ Always park paving machines over drip pans or absorbent materials, since they tend to drip continuously.
- ❑ When making saw-cuts in pavement, use as little water as possible. Cover each catch basin completely with filter fabric during the sawing operation and contain the slurry by placing straw bales, sand bags, or gravel dams around the catch basin. After the liquid drains or evaporates, shovel or vacuum the slurry residue from the pavement or gutter and remove from site.
- ❑ Wash down exposed aggregate concrete only when the wash water can: (1) flow onto a dirt area; (2) drain onto a bermed surface from which it can be pumped and disposed of properly; or (3) be vacuumed from a catchment created by blocking a storm drain inlet. If necessary, place straw bales downslope, or divert runoff with temporary berms. Make sure runoff does not reach gutters or storm drains.
- ❑ Allow aggregate rinse to settle, and pump the water to the sanitary sewer if allowed by your local wastewater authority.
- ❑ Never wash sweepings from exposed aggregate concrete into a street or storm drain. Collect and return to aggregate base stockpile, or dispose with trash.
- ❑ Recycle broken concrete and asphalt (See separate list of "Recyclers and Disposal Services" for more information).

VOL 12 2 5679

R0058972

Contaminated Ponded Stormwater, Groundwater, and Soil Guidance

Look for ponded stormwater, groundwater, and/or soil contamination

Ponded stormwater, groundwater and soil may become contaminated if exposed to hazardous materials. If any of the following conditions apply, contaminated ponded stormwater, groundwater, and/or soil may be present and pose a potential health and environmental hazard:

- ❑ The project site is in an area of previous commercial/industrial activity;
- ❑ There is a history of illegal dumping on the site or adjacent properties;
- ❑ The construction site is subject to a Superfund, state, or local cleanup order;
- ❑ Ponded stormwater, groundwater and/or water generated by dewatering exhibits an oily-sheen and/or smells of petroleum;
- ❑ Soil appears discolored, smells of petroleum and/or exhibits other unusual properties;
- ❑ Abandoned underground storage tanks, drums, or other buried debris are encountered during construction activities; or
- ❑ Spills have occurred on the site or adjacent properties involving pesticides and herbicides; fertilizers; detergents; plaster and other products; petroleum products such as fuel, oil, and grease; or other hazardous chemicals such as acids, lime, glues, paints, solvents, and curing compounds.

Take appropriate action

Ponded stormwater, groundwater, or water generated by dewatering that is contaminated cannot be discharged to a street, gutter, or storm drain. If contamination is suspected, the water should be contained and held for testing. Call the appropriate local agency and/or the Regional Water Quality Control Board for further guidance (See reference list on the back cover of this booklet for more information).

Remember: The property owner and the contractor share ultimate responsibility for the activities that occur on a construction site. You may be held responsible for any environmental damage caused by your subcontractors or employees.

Agencies to call in the event of a spill

You are required by law to report all significant releases or suspected significant releases of hazardous materials, including oil.

To report a spill, call the following agencies:

1. Dial 911 or your local emergency response number.
2. Call the Governor's Office of Emergency Services Warning Center, (800) 852-7550 (24 hours).

For spills of "Federal Reportable Quantities" of oil, chemicals, or other hazardous materials to land, air, or water, notify the National Response Center (800-424-8802). If you are not sure whether the spill is of a "reportable quantity," call the federal Environmental Protection Agency (800) 424-9346 for clarification.

For further information, see *California Hazardous Material Spill/ Release Notification Guidance* (State Office of Emergency Services, Hazardous Materials Division).

Acknowledgments

A business advisory group provided valuable ideas for the development of the Business Partners for Clean Water program and program manuals. A special thanks is extended to the following advisory group members:

Rod Bailey, Evergreen Services Corporation
Bruce Chattin, Washington Aggregate and Concrete Association
Jeff L. Davis, Cadman Premix Company, Inc.
James Edwards, Eastside Transmission
Debi Frausto, Terranomics Crossroads Associates
Steve Holzknecht, Parkwood Homes
Charles Hord, Restaurant Association of Washington
Bill Johnston, Safeway
Colin MacRae, Bellevue Public Schools, Operations and Maintenance
L. J. Matson, Len's Automotive
Wes Mitchell and Mike Mac, Servicemaster of Seattle
Robert Potts, NW Home Maintenance
Chuck Worthington, Eastgate Chevron

Thanks is also given to Sarah Hubbard-Gray and Wendy Skony, who provided project management for the City in the early stages of the project, and to the many people who provided information used in this manual.

How to Use This Manual

This manual will be used as a training tool at the Business Partners for Clean Water workshops for automotive-related services that are located or do work in the City of Bellevue. (The workshops are scheduled for 1990 and 1991.) It is also intended as a reference for owners and employees of automotive-related businesses and ideally will be part of any new-employee orientation.

This manual is divided into sections for easy use as follows:

SECTION 1 (Business Partners for Clean Water) is an introduction explaining the Business Partners for Clean Water Program.

SECTION 2 (Streams Are Our Business) is an overview of the surface water system, how it can be harmed, and why we should protect it.

SECTION 3 (Potential Pollutants) summarizes the major pollutants associated with automotive-related businesses and lists steps to keep those pollutants out of water.

SECTION 4 (Best Management Practices) describes in more detail the steps (called *best management practices* or BMPs) that owners and employees of automotive-related businesses can take to reduce pollution. You can go straight to Section 4's coverage of the best management practices associated with your business activities by using the following chart.

Activity	BMP #
Washing vehicles or mechanical systems by any method of cleaning with water	1,11
Fueling vehicles	2,11
Using parking lots or other outdoor areas for parking, repair work, or storage	3, 4, 5, 11
Sanding, blasting, and grinding materials	4, 11
Using liquids which can spill, including paints, solvents, oils, gasoline, detergent	6, 11
Producing or handling wastes such as paints, solvents, used oil, used gasoline or rags saturated with the above	7, 8, 9, 11
Being located by a stream	10

VOL 12
2
5866
R0058979

SECTION 5 (Water Quality Self-Assessment and Action Program) includes a self-assessment checklist so that business owners and employees can judge how well they currently keep pollutants from the water. It also shows businesses how to create an action program identifying steps to take to protect water quality.

APPENDIX A (Resources) provides directions for reporting problems, contacting agencies for help, and locating reference materials.

APPENDIX B (Regulatory Requirements) contains summaries of and excerpts from many environmental regulations.

APPENDIX C (Glossary) lists definitions for quick reference.

Note: This manual is not a substitute for keeping abreast of applicable regulations; regulations summarized in this manual are subject to change over time, and summaries can omit detail important to a given situation. This manual does not attempt to address each individual activity for every business, but it does provide sources of additional information.

Business Partners for Clean Water

R0058981

1 Business Partners for Clean Water

This Business Partners for Clean Water manual discusses why automotive businesses should keep pollutants out of our streams and lakes, and how this can be done. It is geared for owners and employees of gas stations, auto repair shops, auto body shops, dealerships, detailers, and mobile fleet washing businesses. Those in other auto-related businesses will also find this manual useful. The manual is geared for businesses working in the City of Bellevue, but much of the information applies to automotive services wherever they are located.

What is "Business Partners for Clean Water"?

Business Partners for Clean Water is a cooperative effort between the City of Bellevue Storm and Surface Water Utility (SSWU) and local businesses. The goal is to reduce pollution and stream corridor degradation by local businesses and to recognize businesses which take steps to protect the water.

The program was developed with the help of a business advisory group and is partially funded by a Centennial Clean Water Fund grant from the Washington State Department of Ecology.

Five different business categories are targeted:

- automotive businesses
- construction-related businesses
- building maintenance services
- landscaping, yard maintenance, and nursery businesses
- food-related industries

Businesses in each category can learn how to protect water quality by reviewing this manual and attending a workshop targeted for that category.

The workshops will occur in 1990 and 1991. (Additional workshops may occur in the future if funding is obtained.)

Each business that attends a program workshop and prepares a water quality protection action program (meeting minimum standards) will be publicly recognized as a Business Partner for Clean Water.

For more information about the program, call the Storm and Surface Water Utility at 451-4476.

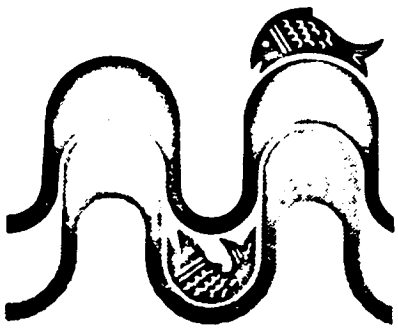
What is the Storm and Surface Water Utility?

The Storm and Surface Water Utility is a City of Bellevue department; its mission is to prevent flooding and protect water quality and aquatic wildlife habitat for the enjoyment of all citizens.

One of the first storm water utilities in the country, the SSWU is still recognized as a leader in surface water management. Initially, the SSWU focused on controlling flooding. That is still important; the SSWU protects streams and property by controlling storm water runoff and operating a number of City flood control facilities. Its water quality efforts include monitoring, inspecting the private and public drainage system, responding to water quality problems, and conducting public education.

VOL 12 2 5689

R0058982



Why a water quality program for businesses?

It is against state and local law to allow pollutants to enter streams and lakes. But businesses and residents don't always realize when they're polluting. For example, a business is polluting if it lets dirty wash water enter a storm drain or if it allows the rain to wash away spilled oil.

Pollution harms our environment. It also costs money, such as the costs of responding to and cleaning up problems and the increased maintenance costs that arise when pollutants such as sediment and grease are washed into the drainage system.

The Storm and Surface Water Utility believes education is important to protecting water quality and has been a leader in public education and outreach. Business Partners for Clean Water is SSWU's first program to focus entirely on the needs of businesses. The program exists because protecting water quality depends on everyone — including business owners and employees.

In addition, the program was prompted in part by changes in state and federal law. In 1987, a section was added to the federal Water Quality Act (formerly the Clean Water Act) that requires local jurisdictions such as Bellevue to obtain permits for discharging storm water into water bodies. These permits, called National Pollutant Discharge Elimination System (NPDES) permits, require the permittee to develop and implement storm water pollution control plans.

More than ever, the City of Bellevue will be responsible for the quality of its surface waters. To meet this obligation, the City will need to better enforce its existing water quality laws and may adopt additional controls on businesses. However, the SSWU prefers voluntary cooperation over enforcement actions and is therefore pursuing education programs such as this one as a first step.

Section 2
Streams Are Our Business

R0058984

2 Streams Are Our Business

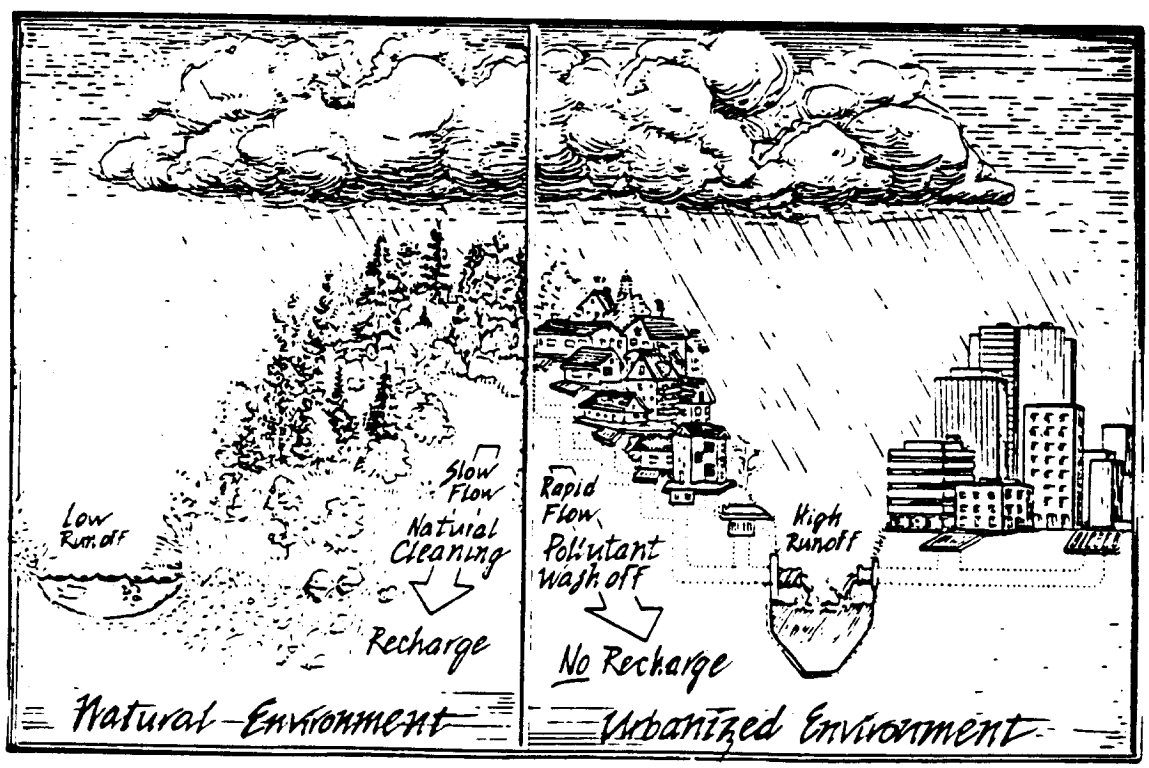
WATER
A Vital Resource

The quality of our water directly affects the quality of our lives. In the Puget Sound area, we depend on clean water for drinking, food sources, recreation, industry, aesthetics, and fish and wildlife habitat. Preserving the character of our region depends on preserving our streams, our lakes, and Puget Sound (into which our streams and rivers flow).

THE FLOW OF WATER
In a Forest Versus a City

The supply of water on earth is constant; water cycles endlessly between the sky and land, evaporating into the air and falling back to the land as rain or snow. When rain falls on undeveloped land, trees and shrubs intercept much of the water. What reaches the ground is taken up by the vegetation, collects in streams, or is absorbed into the ground where it replenishes the ground water.

In an urban area such as Bellevue, there are fewer trees and shrubs to intercept the rain. Water hits the hard surfaces of roofs, parking lots, and streets and is not absorbed into the ground. Instead, the water flows downhill until it enters a stream, wetland, lake or, more commonly, a pipe (a storm drain) which leads to a stream, wetland, or lake.



VOL 12
2
5692
R0058985

STORM WATER RUNOFF
Carrying Pollutants In Its Path

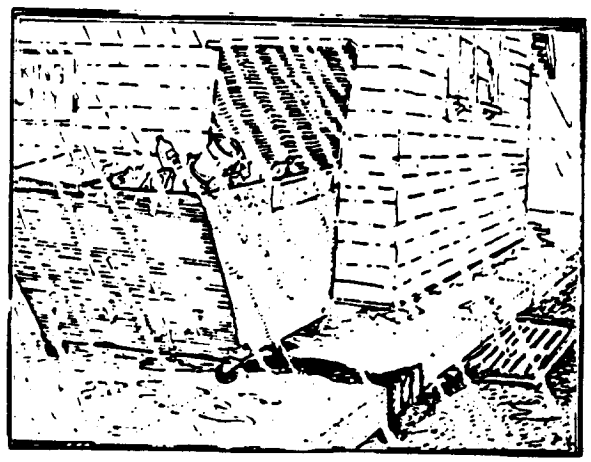
The water that flows across the land, called storm water runoff or urban runoff, collects pollutants as it travels. For example, runoff from streets and parking lots picks up oil and grease dripped from cars, asbestos worn from brake linings, and zinc from tires. Pesticides, herbicides, and fertilizers are collected from landscaped areas, and soil is washed from cleared land.

Any substance found on the ground can wind up in storm water runoff, including pollutants that settle out from the air, litter, and chemicals deliberately or inadvertently applied to the ground. Some pollutants result from everyday actions such as driving cars. Others result from harmful practices such as draining antifreeze onto streets, dumping used motor oil into storm drains, leaving soils exposed on construction sites, and applying too much fertilizer or pesticides. Because most of the pollution comes from dispersed or poorly defined sources rather than a single point such as an industrial outfall pipe, it is often called nonpoint source pollution.

POLLUTANTS
Many Different Kinds

Pollutants are substances that can render water harmful to people, fish, or wildlife or impair recreation or other beneficial uses of water.

Pollutants include *toxic* substances which are poisonous, carcinogenic (cancer causing), or otherwise harmful to people or other organisms during brief or prolonged exposure; example toxics include pesticides, solvents, preservatives, and cleaners, to name a few. *Metals* such as lead and mercury are a special category of toxic pollutants. *Oil and grease* can be toxic and can also coat fish gills (which suffocates the fish) and can block oxygen from entering water by forming a surface film or sheen.



Pollutants from leaky dumpsters can reach streams through nearby storm drains.

Other categories of pollutants include *nutrients* which are beneficial in small amounts but can be harmful in large quantities, and *oxygen demanding substances* (such as decaying plants) which use up dissolved oxygen through biological or chemical processes. (Aquatic organisms need minimum levels of dissolved oxygen to live.) Finally, *sediments* (such as soil particles) turn water cloudy, harm the aquatic habitat, and increase the cost of maintaining storm drainage facilities.

WATERSHEDS
Land Draining to Streams

Storm water runoff carries pollutants into streams and lakes and, as a result, water bodies are affected by activities far from their shores. Each stream and lake is affected by the activities within its watershed. A watershed is the geographic area from which all surface water flows to a given body of water. Because water flows downhill, watershed boundaries are ridges or high points.

The City of Bellevue includes all or parts of twelve watersheds which drain directly to Lake

VOL 12 2 5693
R0058986

Sammamish or Lake Washington or indirectly to one of these lakes via a stream.

THE DRAINAGE SYSTEM
Streams and Built Structures

Bellevue's streams carry storm water runoff and are the backbone of the City's drainage system. The drainage system also includes built structures such as storm drain inlets and pipes which lead to streams and to detention facilities.

Every activity in a watershed affects water quality.

Detention ponds and vaults are needed to control the increased runoff volume that results when vegetation is replaced by hard surfaces. Detention vaults store runoff and release it slowly so that it does not quickly enter streams and cause erosion and flooding. The City requires most developments to construct on-site detention ponds or vaults. The City has also constructed numerous neighborhood and regional detention ponds, some of which are part of the stream system.

Detention structures can be designed to help catch or filter out pollutants which would otherwise reach the streams. Other built drainage features such as grassy ditches (swales) or created wetlands can also help to filter or remove pollutants from urban storm water. The best way to keep Bellevue's water clean is to keep pollutants from entering runoff.

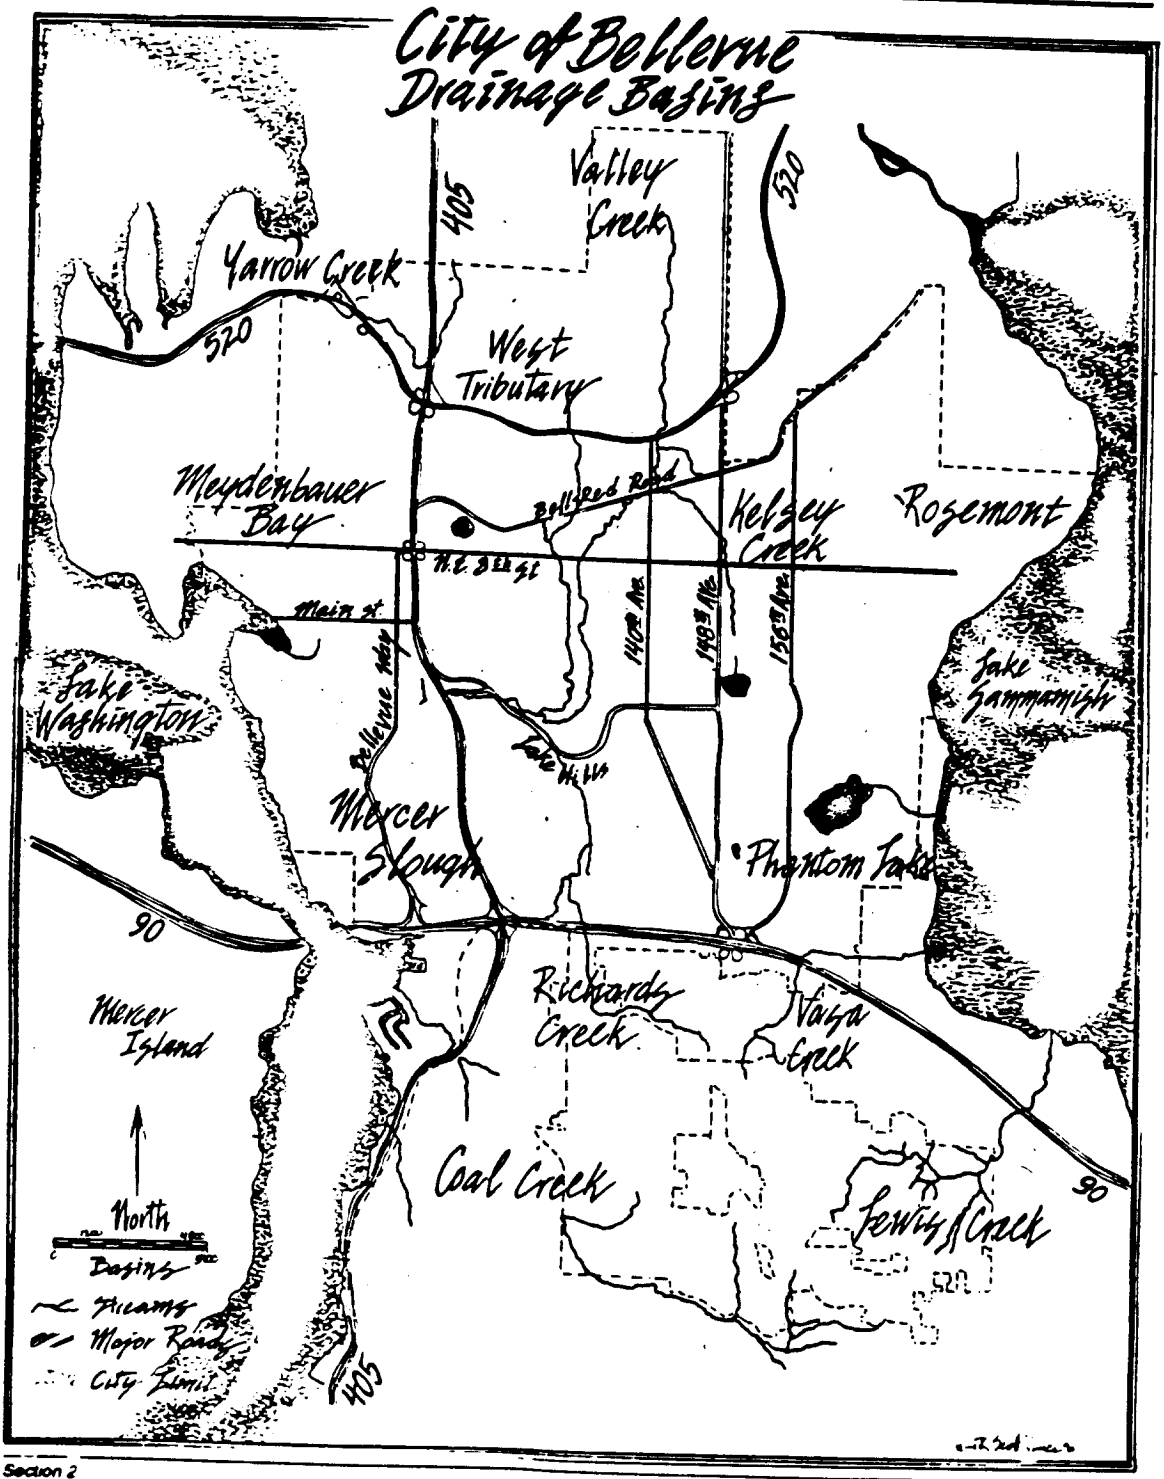
INDOOR DRAINS
Another Way to Puget Sound

Indoor drains aren't usually part of the storm drainage system (although buildings from the mid 1970s and before often had floor drains leading to the storm drainage system). But indoor drains are part of another system — the sanitary sewer system — that eventually leads to Puget Sound. Sanitary sewage is treated before it reaches the Sound, but the treatment process doesn't remove all pollutants. Therefore, the City of Bellevue and Metro (which operates the regional sewer system and treatment plants) regulate what can be discharged to the sanitary sewer. (See Appendix B2.)

BELLEVUE'S STREAMS
Sensitive Urban Oases

Bellevue's streams and the stream-side or riparian areas support fish and wildlife, provide open space, and serve as outdoor classrooms and wading areas for our children. Streams and wetlands also help

VOL 12 2 5694
R0058987



VOL 12 2 5695
R0058988

reduce flooding by "absorbing" or slowing runoff in their meandering channels, soils, and vegetation.

A number of Bellevue streams are healthy enough to support salmonid fish — primarily chinook and coho salmon and cutthroat trout. Salmonids need specific environmental conditions in order to reach their destinations as migratory fish and to have young that survive. For example, they need a specific temperature and oxygen range. Good water quality is vital because salmon eggs and young are especially vulnerable to pollutants.

Where water quality is degraded, more sensitive species such as salmon and some of the aquatic insects they feed on are replaced by more tolerant species. What remains is a less complex ecosystem with fewer species.

BELLEVUE'S WATER QUALITY
How Clean?

In general, Bellevue streams show signs of degradation; they have higher temperatures, greater nutrient concentrations, and more bacteria and sediment than streams from less developed watersheds.

Storm water runoff, which flows into the streams, can be quite polluted. For example:

- Toxic pollutants have been found in significant concentrations; a recent Metro study found 19 of the U.S. Environmental Protection Agency's 121 priority pollutants present in street runoff.
- A study by the Nationwide Urban Runoff Program (NURP) consistently found cadmium, chromium, copper, lead, and zinc in runoff from Bellevue's Lake Hills and Surrey Downs watersheds. Nickel was found in more than half the samples. Seven other metals were found in less than half the samples.
- Oil and grease concentrations in storm water from commercial and industrial areas often exceed the Washington Department of Ecology (WDOE) standard of 10 mg/L.

Sometimes neither the source of the pollution nor its effect in the water is readily apparent, but some problems are obvious. In 1989, the SSWU received 175 calls about observed water quality problems.

Some callers report problems in the water — such as discolored water, oil on the surface, or a fish kill — but don't know the source. Others report a source of pollution, such as a fuel spill, someone dumping waste down a storm drain, or a business which routinely allows pollutants to enter storm water runoff.

POLLUTING
Against the Law

Keeping pollutants out of the water isn't just a good idea; it's the law for business owners and employees. The *Washington State Water Pollution Control Law* (RCW 90.48) and the *Bellevue City Drainage Code* (BCC 24.06) prohibit people from allowing pollutants to enter the storm drainage system or surface waters (see Appendix B5). Violating Bellevue's code is a civil offense for which monetary penalties may be imposed. Violations of the State Water Pollution Control Law, such as discharging without a required permit, can lead to violation notices, injunctive actions, civil penalties with fines up to $5,000, or criminal proceedings.

Not only is it important to avoid dumping pollutants in the water, it is also important to properly dispose of hazardous and solid wastes. If solid waste is dumped without proper permits, the person and business can be guilty of a misdemeanor. Penalties for improperly disposing of hazardous waste can be more severe. They include a fine between $100 and $10,000 and/or imprisonment for not more than one year for each violation.

VOL 12 2 5696

R0058989

It is easier *not* to pollute than to be faced with an enforcement action. This is true for employees, not just business owners; both are liable for pollution they cause.

As stated in the Bellevue code, water pollution includes, but is not limited to, petroleum products, trash or debris, pet wastes, chemicals, paints, stream cleaning wastes, washing of fresh concrete for cleaning and/or finishing purposes or to expose aggregates, laundry wastes, soaps, pesticides, herbicides or fertilizers, sanitary sewage, heated water, chlorinated water or chlorine, degreasers and/or solvents, bark and other fibrous material, antifreeze or other automotive products, lawn clippings, leaves or branches, animal carcasses, silts, acids or alkalis, recreational vehicle wastes, dyes (without prior permission), and construction materials.

Polluting is against the law, regardless of the amount, because small amounts from lots of places add up to create a problem. (And small amounts of highly toxic pollutants are a problem in and of themselves.) In fact, the Environment 2010 report (sponsored by the State of Washington and the U.S. Environmental Protection Agency) ranked nonpoint source discharges to water — water pollution from dispersed sources — as a "priority level 1" environmental threat. (Only three of the 23 listed environmental threats were ranked as priority level 1.)

Business Partners for Clean Water is intended to make sure business owners and employees know how and why not to pollute and take steps to help keep our water clean.

R0058990

VOL 12 2 5698

Section 3
Potential Pollutants

R0058991

3 Potential Pollutants

With proper precautions, automotive businesses can minimize harm to water quality and the natural environment. However, automotive activities such as repairing engines, washing cars, or fueling vehicles are not always done in an environmentally sensitive manner.

This section describes pollutants that can result from automotive activities and why they are a problem. It also summarizes ways to prevent or reduce pollution. These steps, referred to as *best management practices*, are described more completely in Section 4 and may involve either changing or modifying practices, structural solutions, or both.

The most common pollutants from automotive businesses are oil and grease (hydraulic, gear, and engine), toxics (in brake fluid, antifreeze, battery acids, degreasers, and solvents), and metals (from sanding debris, brakes, oils, machining shavings, paints, tires, and fuels). Some automotive businesses also may generate nutrients (from detergents), oxygen-demanding substances (such as food scraps from an associated convenience store), and sediment (dust and debris from operations).

The following table shows pollutants associated with automotive activities and how to keep them from the water.

Automotive Services:
Potential Pollution Problems and How to Prevent Them

The Problem	The Solution
Oil and grease such as from steam cleaning, repairing engines, or storing a leaky engine	• Wash vehicles and engines in a designated area. • Keep oily parts, rags, and containers covered. • Properly dispose of or recycle wastes. • Cover and drain the fueling area to the sanitary sewer. • Install and maintain an oil/water separator.
Toxics such as found in antifreeze, brake fluid, battery acid, solvents, and paints	• Maintain a clean, organized work area. • Wash vehicles and parts in a designated area. • Properly store all materials and have a spill control plan. • Properly dispose of or recycle all materials.
Metals such as from repairing brakes and engines, rebuilding and painting auto bodies, and from fuel and waste oil	• Do not sand or grind outside, unless a tarp is placed on the ground. • Clean up metal shavings and dust from sanding and grinding. • Cover containers and materials. • Properly dispose of used oils and scraps. • Recycle metal shavings and large scraps.
Nutrients such as from vehicle washing detergents and exposed soils of unpaved lots	• Wash only in a designated area. • Plant vegetation on exposed soils.

VOL 12 2 5699
R0058992

OIL AND GREASE
A Harmful Film

Problem: Oil and grease contain a wide array of hydrocarbon compounds (compounds containing hydrogen and carbon), many of which can injure or kill aquatic life at low concentrations. Oil and grease coat fish gills and can block oxygen from entering the water.

Car lubricating agents are the major source of oil and grease found in urban runoff. Every car and car owner are potential contributors; oils and greases drip from leaks, are spilled from leaky containers or during transfer, and are dumped down storm drains.

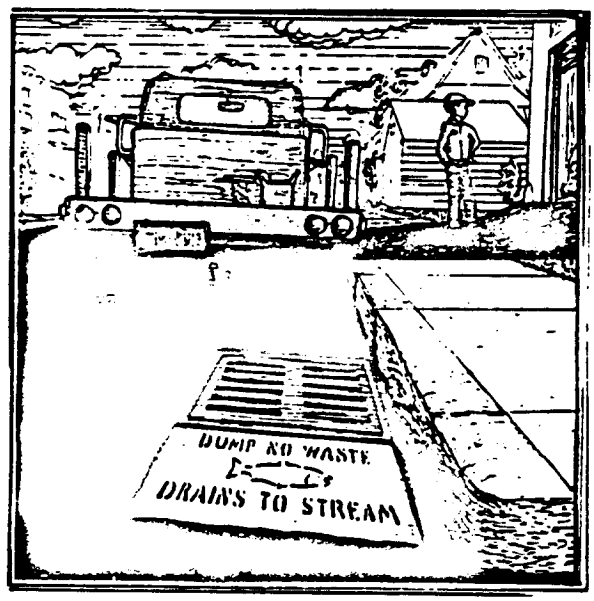
Because most automotive businesses handle oil and grease (for example, by steam cleaning or repairing engines, or simply by storing a leaky car or engine) they are potential sources of oil and grease in our streams.

Oil and grease on surfaces exposed to rain or vehicle wash water can be washed to the storm drain and ultimately the stream. This includes oil from wastes such as oil filters and soiled rags stored in uncovered or inadequate dumpsters.

At times, used oil has been deliberately poured down the storm drain. Even if the storm drain has an oil/water separator (which traps oils), it will not keep all oil out of the water, especially if pollutant concentrations are high or if the separator has not been maintained.

Solution: To minimize the amount of oil and grease that enters the stream system:

- Wash vehicles and engine parts only in a designated wash area properly connected to the sanitary sewer system with an appropriate oil/water separator.
- Keep oily parts, rags, and containers indoors or otherwise covered to prevent rain from washing the oil into the drainage system.
- Dispose of oil and grease wastes properly and recycle whenever possible; never dump them down storm drains or on the ground.
- Install and maintain an oil/water separator.



Many small releases of oil and grease from vehicles can add up to big problems in streams.

TOXICS
Poisonous to Life

Problem: Automotive businesses use or encounter a wide variety of materials toxic to the environment and sometimes also provide an avenue for such pollutants to enter the stream system. Selling gasoline; servicing engines, tires, mufflers, radiators, and batteries; and repairing and painting body chassis are among the automotive activities which generate toxic liquid and solid wastes.

VOL 12 2 5100
R0058993

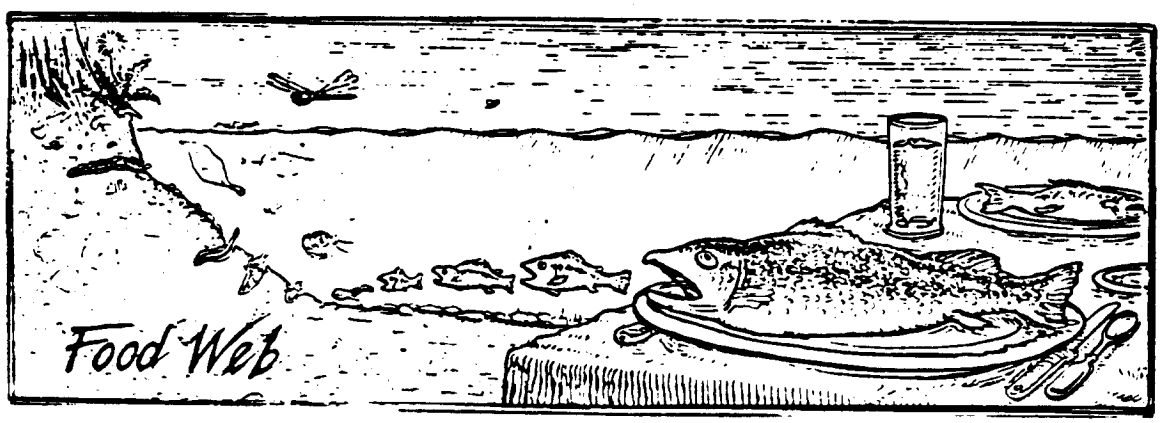
Toxic liquid wastes include used automotive products (such as antifreeze, brake fluid, radiator flush, and battery acid sludges), contaminated cleaners (such as solvents, mineral spirits, carburetor cleaners, paint thinner, and detergent wash water) and other chemicals (such as hydrochloric acid, hydrofluoric acid, hot-dip tank caustics, and naval jelly). Toxic liquid products become toxic pollutants when they leak from inadequate containers, spill during use or transfer, or are collected in wash water. Toxic liquid products also become toxic pollutants if they are deliberately poured down the storm drain or drained onto paved surfaces.

Solid waste materials (such as used batteries, empty contaminated containers, machining chips, and soiled rags) can also be a source of toxics entering lakes, wetlands, and streams. When solid wastes are stored, toxic pollutants can sometimes leak or be washed from the containers if the containers are not covered from the rain. Storm water and wind can also sweep away chips and dust created from sanding and machining automotive parts.

By definition, toxic pollutants are harmful to wildlife, people, or both. High concentrations of toxic materials can cause fish kills. In addition, some toxic pollutants accumulate in the environment; others concentrate in the food chain as one organism eats others which have been contaminated.

Solution: To minimize the release of toxic pollutants:

- Maintain a clean, organized work area.
- When washing vehicles and parts with water, only do so in a designated wash area connected to the sanitary sewer system.
- Properly store all materials and have a spill control plan.
- Dispose of all toxic materials properly and recycle whenever possible; never dump them down storm drains or on the ground.
- Cover the fueling area to keep rain from washing away leaked or spilled fuel, and drain it to the sanitary sewer.



Harmful pollutants can work their way up the food chain.

VOL 12 2 5101

R0058994

METALS
Toxic Pollutants

Problem: Many metals are toxic pollutants and are regulated. The Environmental Protection Agency (EPA) regulates the disposal of eight hazardous metals: arsenic, barium, cadmium, chromium, lead, mercury, selenium, and silver. They are commonly referred to as heavy metals and can cause injury, death, or damage, and can pollute land and water. The Washington State Department of Ecology regulates the levels of metals found in surface waters. These state regulations, called the Surface Water Quality Standards, cover the metals cadmium, chromium, copper, lead, mercury, nickel, selenium, silver, and zinc.

Such metals are present in various auto parts and can be released to the environment in activities such as repairing and maintaining brakes, transmissions, differentials, and engines as well as rebuilding and painting auto bodies. Leaded fuels, lead additives, and wastes such as used oil, fragments from machined metal parts, and dust from sanding or grinding painted surfaces are all sources of metals. Some metals are released to the environment slowly as they corrode or leach out of the source.

A large fraction (often over half) of the metals in urban runoff are attached to sediment and settle out of the water column, accumulating at the bottom where they can remain for a long time, potentially harming bottom-dwelling organisms. Metals that are more soluble, such as copper and zinc, remain in the water and may create toxic conditions for fish and other aquatic life.

Solution: The best management practices for metals are similar to those for toxics in general:

- Do not sand or grind painted surfaces or machine parts outside, unless a tarp is placed on the ground.
- Clean up metal shavings and dust from sanding and grinding.
- Cover containers and materials including batteries and waste parts.
- Properly dispose of used oils and paints.
- Recycle metal shavings and large scraps.

NUTRIENTS
Too Much Can Be a Problem

Problem: Nutrients are substances such as phosphorus and nitrogen that stimulate plant growth. Sources of nutrients from automotive activities include vehicle washing detergents and exposed soils of unpaved parking lots.

Nutrients such as phosphorus and nitrogen are needed by plants to grow, but high levels can harm water quality. Excess levels over-stimulate the growth of algae and other aquatic plants, potentially causing unpleasant tastes, odors, unsightly conditions, and lowered dissolved oxygen levels from plant decay. Nutrients are most likely to pose a problem in slow-moving water such as lakes or sluggish streams.

Solution: Management practices that minimize nutrient losses from automotive activities:

- Wash only in a designated wash area which drains to the sanitary sewer system.
- Plant vegetation on or pave exposed soils (depending on the use of the area).

Section 4
Best Management Practices

R0058996

4 Best Management Practices

By using *best management practices* (BMPs), you can help keep pollutants out of Bellevue's streams. Best management practices, devices or methods for reducing pollution, were introduced in Section 3 and are described more completely in this section. Some of these practices are operational whereas others are structural controls that are installed and maintained.

The following BMP categories are discussed here (they have been numbered for easy reference, not to indicate relative importance):

Best Management Practice Categories

BMP #1 *Designate Vehicle Wash Area*
BMP #2 *Cover and Drain Fueling Area*
BMP #3 *Treat Runoff with Oil/Water Separator*
BMP #4 *Keep Workplace Clean and Maintain Catch Basins*
BMP #5 *Cover Containers and Materials*
BMP #6 *Prepare for and Clean up Spills*
BMP #7 *Dispose of Wastes Properly*
BMP #8 *Minimize Wastes*
BMP #9 *Recycle Wastes*
BMP #10 *Preserve/Enhance Streams and Adjacent Vegetation*
BMP #11 *Educate Employees and Customers*

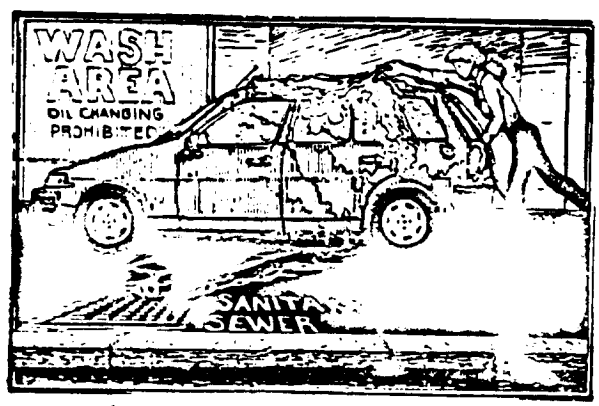
To identify best management practices appropriate for your job or business, locate the activities and corresponding BMP categories in the diagram on the following page. Then read the appropriate best management practice categories in this section.

BMP #1
Designate Vehicle Wash Area

Who: Any business that washes vehicles or mechanical systems by any method of cleaning with water — including low-pressure, high-pressure, and steam cleaning — should do so only in a designated area. This covers mobile washing services as well as business that wash on-site. Designating a wash area can involve facility changes which need to be approved by the business owner/manager. Employees who wash vehicles with water need to know the designated wash area and use it.

Why: If vehicles or mechanical equipment are washed outside a properly designed area, then oil and grease, suspended solids, heavy metals, and toxics can be washed into the drainage system in violation of state and local laws.

How: The designated wash area needs to have specific features including drainage to a sanitary sewer. Check the Bellevue Permit Center (462-2034) for permit requirements involved with any construction.



Send wash water to the sewer, not the storm drain — they're not the same thing.

VOL 12
2
5104
R0058997

Automotive Service Activities and BMPs

Activity	Best Management Practice	BMP Reference #	Pollutants Addressed
Washing vehicles or mechanical systems by any method of cleaning with water	• Designate a properly designed vehicle wash area. Make sure all employees know they should use the designated area.	BMP 1, 11	oil, grease, toxics, nutrients, metals
Fueling vehicles	• Pave fuel area with cement, cover it, drain it to the sanitary sewer, and keep cleanup materials for spills. • Make sure all employees know how to clean up spills.	BMP 2, 11	toxics, oil, grease, metals
Using parking lots or other outdoor areas for parking, engine storage, repair work, dumpster or material storage	• Install a new or locate an existing oil/water separator. Maintain it. • Sweep parking lot and dispose of sweepings. • Pick up litter and other wastes. • Drain fluids from old vehicles kept for parts. • Clean catch basins and other drainage facilities. • Cover waste containers, including dumpsters. • Cover used batteries. • Train all employees in the proper procedures.	BMP 3, 4, 5, 11	oil, grease, toxics, metals, potentially others
Sanding, blasting, grinding	• Use a tarp to cover the ground and dispose of the collected material in the garbage. • Clean all wastes such as remaining paint chips and sandings. • See that all workers follow proper practices.	BMP 4, 11	toxics, metals
Using liquids which can spill, including paints, solvents, oils, gasoline, detergents	• Handle materials carefully to avoid spills. • Prepare a cleanup plan and know how to follow it. • Immediately clean up any spills. • Ensure all workers know what to do in the event of spills.	BMP 6,11	toxics, metals, oils, nutrients
All activities producing or handling wastes such as paints, solvents, used oil, used gasoline, or rags saturated with the above	• Minimize wastes and properly dispose of or recycle all wastes. • Ensure all workers manage waste properly.	BMP 7, 8, 9, 11	toxics, metals, oil, grease
Being located by a stream	• Preserve the stream corridor and take steps to enhance it.	BMP 10	sediment

VOL 12 2 5705
R0058998

First, select a location for washing. To ensure proper wash water routing, washing can occur in the following areas:

- inside the business owner's building
- at a commercial washing business in which the washing occurs in an enclosure
- in a separate vehicle or equipment washing building, similar to a commercial car or truck washing business, in which all internal drains discharge to the sanitary sewer
- in an unenclosed wash area that is no bigger than 200 square feet and is designed to prevent storm water from running onto it.

Properly design and mark the wash area. Specifically, it must be:

- well marked as a wash area
- paved
- posted with signs (one that forbids the changing of oil and indicates the nearest oil recycling facility and another that forbids washing with solvents)
- drained by a system which leads to an oil/water separator and then is connected to the sanitary sewer (as described below)

Connecting a wash area's drain to the sanitary sewer requires a side sewer permit from the City Water and Sewer Utility. Refer to Appendix B2 for City regulations listing wastes prohibited from the sewer system and oil/water separator requirements.

If it is not possible to have the designated area discharge to a sanitary sewer, do one of the following:

- Place a temporary plug in the storm drain and pump the accumulated water to the nearest sanitary sewer.

- Wash vehicles with water only; do not use soaps, detergents, and cleaners. (If vehicle surfaces are greasy or oily, this method is not appropriate.)

BMP #2
Cover and Drain Fueling Area

Who: Any business that pumps gas or diesel fuel should cover and drain the fueling area. This can involve facility changes which need to be approved by the owner/manager. All employees who fuel vehicles need to know how to stop spills and clean them up.

Why: Gas and diesel spills are common when vehicles are fueled, and the cars being fueled can also drip oil. If the fueling area is improperly designed, oil and grease, metals, and toxics are washed to the drainage system in violation of state and local law.

How: The main steps are to cover the fueling area and to drain it to the sanitary sewer.

Specifically:

Cover the fuel island. This keeps rain from hitting the ground and washing away any spilled materials.

Drain the fuel area to the sanitary sewer. To do so, locate longitudinal drains at the perimeter along the "downhill" side of the island and connect them to the sanitary sewer. To comply with Metro requirements (summarized in Appendix B2) the drain should have a valve to allow shutoff in the event of a large fuel spill. Connecting to the sanitary sewer requires a side sewer permit from the City Water and Sewer Utility.

Pave the island using Portland cement concrete, not asphalt; fuel deteriorates asphalt.

Keep suitable cleanup materials on-site to allow prompt cleanup of any spill.

Post signs that instruct fuel pump operators not to overfill gas tanks; that causes spillage and vents gas fumes to the air.

Place any temporary fuel tank in a bermed, impervious area. The area should be large enough to contain 110 percent of the tank's total volume.

VOL 12 2 5706

R0058999

Impervious liners such as heavy mil plastic or Portland cement will work.

BMP #3
Treat Runoff with Oil/Water Separator

Who: All businesses with a parking lot for more than 20 vehicles should have an oil/water separator and maintain it.

Why: Parking lots are major sources of oil and grease to the drainage system.

For new construction, the City of Bellevue Development Standards require oil/water separation devices to be installed whenever parking space is provided for more than 20 vehicles or whenever paved parking or an access road is within one-quarter mile of any open waterway or stream.

Nearly all automotive businesses in Bellevue fall into one of these two categories; the City is considering requiring existing businesses in these two categories to install an oil/water separator if they don't already have one.

How: To treat the runoff from your site, be sure that an oil/water separator is installed and maintained.

Install a new or locate an existing oil/water separator.

Chances are you already have an oil/water separator, if your business is in the City and was built or substantially remodeled in the past ten years. To locate your separator, check the manholes on or near your business site or check the "as-built" building plans. The City of Bellevue has "as-built" plans for commercial facilities built in the last 10 years; you can call the City of Bellevue Permit Center at 462-2034 and ask the Storm and Surface Water Utility representative to locate the plans for your site.

If you have an oil/water separator or if you are going to install one, it is most likely an American Petroleum Institute (API) separator. The API separator, also known as a baffle-type separator is a long vault or basin with baffles to slow the water so that dispersed oil can be removed. The City of Bellevue has design plans for numerous oil/water separators in the City *Development Standards*.

Oil/water separators are installed by a private sewer contractor between an inlet and either a storm drain or a sewer pipe. If the separator is used to treat contaminated storm water from large parking lots, businesses, and streets, it will most likely be connected to a storm drain. The Department of Ecology (867-7000) must approve the installation of oil/water separators connected to storm drains. To protect the water, the Department of Ecology encourages all businesses to connect wash areas to the sewer system. Oil/water separators connected to the sewer system must be approved by Metro (684-2300) and the Bellevue Sewer Utility (462-2034) and must drain an area less than 200 square feet.

If the oil/water separator is connected to the storm drainage system, improve the effectiveness of the separator and allow the use of a smaller separator by not routing all drainage through it. Drainage from an impervious area that is not likely to be contaminated by oil, such as rooftops, can be diverted to the storm drains at a location "downstream" of the oil/water separator.

Maintain the oil/water separator.

An oil/water separator should be cleaned before three inches of oil accumulate in the entry chamber. Generally, oil/water separators need to be cleaned at least twice a year to keep accumulated oil from escaping during an extreme storm. The most appropriate times to clean an oil/water separator are by October 15th to remove material that has accumulated during the dry season and again after the first significant storm.

Separators must be cleaned by approved and environmentally safe methods, such as those used

VOL 12
2
5707
R0059000

by commercial tank-cleaning companies. You can find tank-cleaning services listed in the yellow pages of your telephone directory. These services will pump out the oil/water mixture and take it to a treatment facility, where the oil will be further separated for recycling. Do not use septic tank-cleaning services to clean your oil/water separator; there is no legal, environmentally safe way for them to dispose of oily wastes.

During the maintenance:

- Close the effluent shutoff valve.
- Replace oil absorbent pads.
- Test and dispose of waste oil and sludge in accordance with current Seattle-King County Health Department requirements. Call the Health Department at 296-4633 to determine which chemicals must be tested for. At a minimum they will require total petroleum testing, but they could also require a scan for solvents. Most businesses generate only a small amount of minimally contaminated sludge (residue that collects in the system); in that case, the sludge can be sealed in a container and disposed in the dumpster. If you generate a high volume (some separators can hold 20 cubic yards of dirt) of minimally contaminated sludge then you will have to arrange to have it hauled to the landfill. If the contaminants are unusually high and are above permitted levels, the sludge should be taken to a treatment, storage, and disposal facility. (See BMP #7.)
- Any standing water removed during the maintenance operation can be disposed to a sanitary sewer at an approved discharge location. This dirty standing water should be replaced with clean water to prevent oil from being washed out of the separator.

Eliminate oil sources to the maximum extent possible. Oil/water separators do not remove all oil and are not a substitute for keeping oil off the parking lot to the maximum extent possible. For example, do not store uncovered oily parts outdoors and keep business vehicles in tune.

BMP #4
Keep the Work Place Clean and Maintain Catch Basins

Who: It's up to all employees to help keep the workplace clean.

Why: Any residue (such as paint chips, metal shavings, and grease) on a surface that drains to a storm drain can be washed or blown to the City's streams and lakes, in violation of state and local laws (see Appendix B1). Messy work places increase the chance of spills.

How: Keep the work place organized and keep surfaces which drain to the City's drainage system clean. Maintain storm water facilities such as catch basins so that they serve their intended function. More specifically:

Pick up litter.

Sweep the parking lot. Dispose of the sweepings in the garbage.

Keep paint chips and metal shavings off the ground. Use a tarp to cover the ground when blasting, sanding, or grinding to catch chips and metal shavings, or do those activities inside. Call the Seattle-King County Health Department at 296-4633 to see if chips can be disposed of at a landfill.

Clean up all wastes at the work site. For instance, clean up remaining paint chips, dust, and sandings. If the wastes are wet, dry them before disposal.

Drain fluids from old vehicles kept for parts. This includes unused gas, transmission and hydraulic oil, and radiator coolant.

Cover exposed soils. Pave exposed soils on unpaved parking areas and plant vegetation on exposed soils not used for parking.

VOL 12
2
5708
R0059001

Clean the catch basin. A catch basin needs to be cleaned when deposits fill 60 percent of the catchment area. Generally, this will be every six months, but if woody debris accumulates it should be cleaned weekly.

Clean storm water basins. Regularly remove debris from basins used for either peak-rate control or storm water treatment. Clean the control structure if the distance between the sediment and the orifice plate is less than one-third the depth.

BMP #5
Cover Containers and Materials

Who: All employees should properly store materials so they don't become sources of pollution.

Why: Rain can wash pollutants from improperly stored materials into the drainage system, in violation of state and local laws. For example, a used engine stored outside may drip oil which is then washed to the stream system.

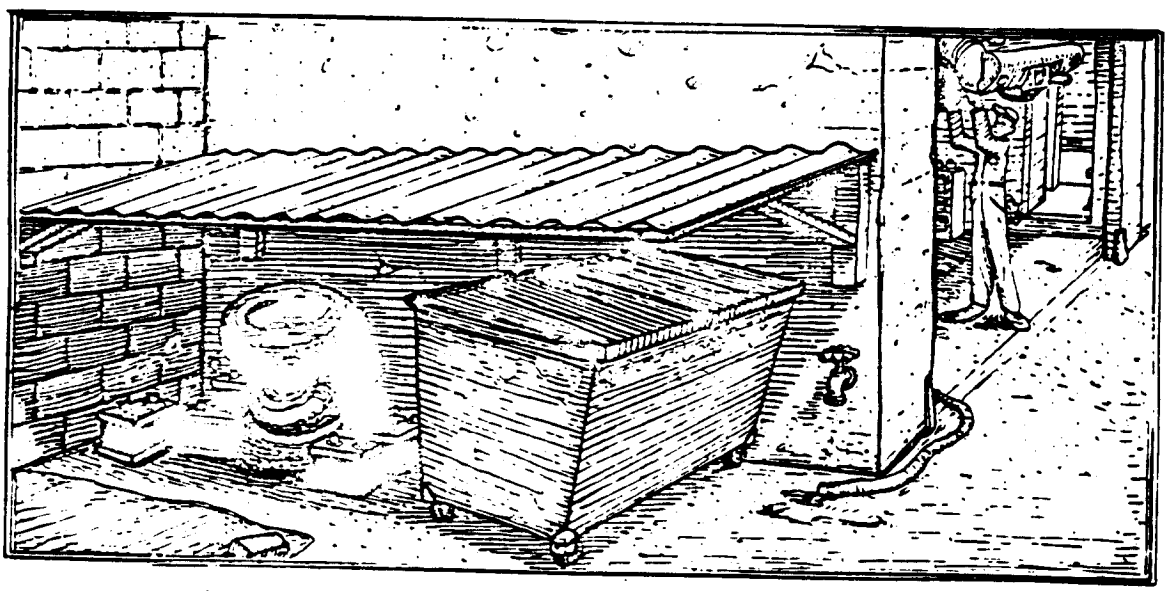
How: Raw materials, by-products, products, and their containers should be covered to keep rainfall from reaching them and washing out pollutants.

Cover all potentially polluting materials. This includes:

- dumpsters that store items awaiting final disposal such as used oil filters, cleaning rags, and food scraps
- waste-container drums, tanks, or boxes
- used batteries

Cover adequately. Several methods of covering are adequate; select one of the following methods most appropriate for the type of material. Be sure to meet the City of Bellevue *Fire Code* requirements summarized in Appendix B6.

- Store wastes inside a building.



A good storage area keeps materials covered so pollutants can't wash away.

VOL 12
2
5709
R0059002

- Store materials or containers inside the service bay.
- Place materials or container inside another container that has a tightly fitting cover.
- Build a covered area such as a lean-to, pave the surface area beneath, and prevent runoff from entering the area.
- Place temporary plastic sheeting over the material or containers and secure the cover with ties and weighted objects.
- For liquid products or wastes, surround the storage area with a curb or dike to provide volume to contain 10 percent of the volume of all the containers or 110 percent of the volume of the largest container, whichever, is greater. If the storage area is permanent, install a drain. For used oil or liquids controlled by the fire code the liquid should drain to a dead-end sump; otherwise connect it to the sanitary sewer. (Connecting to the sanitary sewer requires a side sewer permit from the City of Bellevue.)

BMP #6
Prepare for and Clean up Spills

Who: All automotive businesses that use paints, solvents, oils, gasoline or other materials which can spill should have a spill control plan. All employees should know what to do in the case of a spill.

Why: Spills can result in toxic pollutants reaching the drainage system and can cause acute problems such as fish kills.

State law requires owners of businesses that produce hazardous waste to have a spill cleanup plan. Federal law requires the owners of facilities which store, process, or refine oil and oil products to have a spill prevention and control plan. (See Appendix B3.)

How: There are three overall practices to minimize pollution from spills: handle materials carefully to avoid spills and leaks, prepare a cleanup plan, and immediately clean up any spills. The latter two are discussed below.

Prepare a cleanup plan. Generally, a cleanup plan includes the following steps:

- Establish who to notify in the event of a spill, such as the City of Bellevue, the Department of Ecology, and Metro for large spills. (See Appendix A1.)
- Provide specific cleanup instructions. General cleanup options are discussed later in the description of this best management practice.
- Assign a person to be in charge of cleanup.
- Prepare spill containment and cleanup kits which are easy to reach and use. Firms such as the following can provide cleanup materials:

Envirosorb Co. 8128 — 187th SW Edmonds, WA 98020 778-7485	CHEMPRO 2203 Airport Way S Seattle, WA 98134 1-800-228-7872

- Post a summary of the cleanup plan at appropriate locations.

Clean up spills immediately. If a liquid spill occurs, clean it up right away following the cleanup plan and safety requirements. If there is not a plan, take the following steps:

- Stop the source of the spill.
- Contain the liquid. If there is a chance the spill could enter the storm drain or sewer, close the storm drain inlet and turn off or divert any incoming water.
- Cover the spill with absorbent material. Use materials that can be swept or picked up such as kitty litter, sawdust, or vermiculite. Do not use straw, emulsifiers, or dispersants. If the spill is small and the listed absorbent materials

VOL 12
2
5710
R0059003

Kitty litter can be used to soak up small spills.

are not available, use rags or paper. If the spill involves battery acid, neutralize the acid with cement, lime, or bicarbonate (baking soda).

- Call the appropriate government agencies. In Bellevue, first call the City of Bellevue Storm and Surface Water Utility (455-7846, 24 hours). For large spills, call the Department of Ecology Regional Office (867-7000, 24 hours). If the spill could reach the sanitary sewer call Metro (684-2325).

- For larger spills, use the services of a private cleanup firm such as:

CHEMPRO
2203 Airport Way S
Seattle, WA 98134
1-800-228-7872

Global Diving and Salvage
2763 — 13th Ave. SW
Harbor Island
Seattle, WA 98134
623-0621

North American Environmental, Inc.
2432 E 11th St.
Tacoma, WA 98421
272-9988 (primarily PCB's)

Sol-Pro, Inc.
3401 Lincoln Rd.
Tacoma, WA 98421
627-4822

- Dispose of cleanup materials. Cleaning products used to absorb a hazardous waste (such as vermiculite used to soak up spilled degreasers) must be treated as hazardous waste. These hazardous-waste-soaked materials can not be put in the garbage. Instead, bag them or place them in a drum, label the container, and have them transported to a site authorized by the federal government.

- Oil is not generally considered hazardous unless it contains a high concentration of metals. For small oil spills, the absorber can be placed inside a sealed container — sealed plastic bags are fine — and put into the garbage can or dumpster.

BMP #7
Dispose of Wastes Properly

Who: All businesses and employees need to know how to properly dispose of waste.

Why: Proper disposal of wastes is extremely important to avoid both environmental and legal problems.

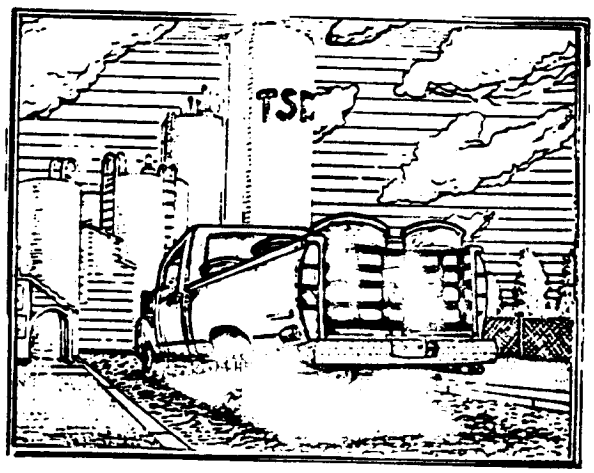
Businesses are financially and legally responsible for their waste disposal even if the waste is handled by a waste contractor. Improper disposal practices can lead to environmental contamination and the business risks losing the ability to get bank loans, to obtain or keep business insurance, and to sell the business or property; for some it can lead to a jail sentence. Recently, in Tacoma, the Hidden Valley Landfill was identified as a Superfund site;

VOL 12 2 5 7 1 1

R0059004

businesses who disposed of wastes there may have to pay a portion of the $24 million for cleanup.

According to Washington State law, "The owner, operator, or occupant of any premise, business establishment, or industry shall be responsible for the satisfactory and legal arrangement for the solid waste handling of all solid waste accumulated by them on the property" (WAC 173-302-190). Though the business owner has ultimate responsibility for the proper disposal of hazardous and solid waste, the employee is also legally liable. In fact, any person who violates the law by improperly disposing of hazardous waste or any person who knowingly aids another is guilty and could be fined or jailed for each separate violation. In case of a continuing violation, every day's violation is considered a separate and distinct offense (RCW 70.105.080-090).



Hazardous wastes need to be delivered to an approved TSD facility.

How: Proper waste disposal depends on both the properties and the amount of the waste. To dispose of waste, identify if it is hazardous, estimate the amount in pounds, determine the disposal method, and if necessary, contact a hazardous waste service. These steps are further explained below:

Identify whether your waste is considered hazardous. A hazardous waste is a solid or liquid material with certain properties that could pose dangers to human health, property, or the environment (see Appendix B4). Possible hazardous wastes often associated with automobile-related businesses include:

- paints, thinners, solvents, cleaning fluids, or coolants
- petroleum products or used oil contaminated with heavy metals
- used gasoline or other flammable materials
- rags saturated with gasoline or other hazardous materials

Other materials that burn or itch on contact with skin, that dissolve metals, wood, paper, or clothing, or that bubble or fume upon contact with water are also probably hazardous. Check shipping papers, labels, or material safety data sheets (MSDSs) which indicate if a product is hazardous. If you do not know whether a product or waste is hazardous, assume it is until you find out otherwise.

If wastes are hazardous, estimate the amount. Determine whether there is less than 220 pounds generated per month and whether there is less than 220 pounds accumulated at any time. This is approximately half of a 55-gallon drum. Businesses that generate more than this have different disposal requirements than those who generate less.

Stay under 220 pounds of hazardous waste produced per month and collected at your business site at any one time, and you will be considered a small-quantity generator (SQG). By state law, if you are a small-quantity generator you must identify your hazardous wastes and understand the required precautions necessary for handling and disposing of them. You must also dispose or recycle your wastes through a recycling firm, an approved landfill (the closest are in Idaho and Oregon), or send it to a treatment, storage, and disposal facility (TSD). King County Solid Waste Division is planning to operate a mobile hazardous

VOL 12 2 5712
R0059005

waste collection facility for small quantity generators starting sometime in 1991.

Accumulate 220 pounds — or more — of hazardous waste and you lose your small-quantity generator status. You must have the waste removed by a reliable hazardous waste service within 180 days. In addition, you must get a U.S. Environmental Protection Agency identification number from the Washington State Department of Ecology and follow additional reporting requirements. Refer to Appendix B4 for more information on the Department of Ecology regulations or call the Department at 867-7000.

Determine the best disposal method. Recycling or finding someone who can use the waste are preferred to disposal. Here are some suggested disposal methods for a variety of materials:

- **Oil Paints** (may be flammable and poisonous): Excess paint should be left with the property owner for touch-ups. Small amounts of excess paints (less than a quart) can be painted onto boards or left in cans, allowed to dry, and then thrown into covered dumpsters. Allow paint thinners to settle, then strain and re-use the liquid. Leftover paint thinner must go to a treatment, storage, and disposal facility.

- **Used Oils** such as hydraulic, gear, and engine (flammable and poisonous): Recycle oils. Do not dispose or spill on the ground (including as a dust suppressant); this is against the law. Never place used oil in a dumpster or pour down a storm drain.

- **Brake Fluid** (poisonous): Brake fluid must be disposed of through a TSD.

- **Tires** (produce poisonous leachate): King County landfills will accept four tires per load. Recycling is the best option. Check the recycling section.

- **Petroleum Products** such as gasoline, diesel, or kerosene (flammable): Petroleum products must be disposed of through a TSD.

- **Degreasers** such as solvents, mineral spirits, and paint thinners (may be flammable): Small parts can be cleaned with solvents which are distilled, re-used, or recycled. Allow paint thinners to settle, then strain and re-use the liquid. When the solvent can no longer be re-used, dispose of it through a TSD.

- **Batteries** (corrosive and poisonous): Recycle, do not dispose of. Within Washington State, no person may knowingly dispose of a vehicle battery except by delivery to: a person or entity selling lead acid batteries, a person or entity authorized by the Department of Ecology to accept the battery, or to a secondary lead smelter.

If necessary, use a reliable treatment, storage, and disposal facility. To do so, locate several, check up on them, interview them, and arrange for your wastes to be transported to the one you select. Keep copies of all your transactions. These steps are further explained below:

- Locate a TSD. There are a number of private treatment, storage, and disposal companies that operate in this area. The following is a partial list to help you get started; listing does not constitute a recommendation.

CHEMPRO
2203 Airport Way S
Suite 400
Seattle, WA 98155
1-800-228-7872

Northwest EnviroService, Inc.
1500 Airport Way S
Seattle, WA 98134
622-1090

Chem-Security
10602 NE 38th Place
Kirkland, WA 98033
827-0711

- Check up on the TSD. All waste should be delivered to a site authorized by the federal or state government. Call the Hazardous Substances Information Hotline, 1-800-633-7585, to find out if a TSD has an EPA identification number or has been cited for past violations. They can also give you a list of vendors who can transport your waste.

VOL 12
2
5713
R0059006

- Interview the TSD. Your business is responsible for what a TSD does with your waste. Ask the company for references and check them. Also ask if the company is properly insured, how it disposes of the wastes, how employees are trained, and if the company will reduce or recycle your waste before disposal. Depending on the waste, a TSD may treat it to make it less hazardous, incinerate it, or dispose of it at an authorized site.

- Arrange to transport your wastes. Large-quantity generators must have an authorized TSD transport their wastes, but small-quantity generators can choose to transport wastes themselves. The TSDs in the area operate differently in terms of services and costs. For example, as of June 1990, Chemical Processors (CHEMPRO) will only accept hazardous wastes from SQGs the last Tuesday of every month and requires little paperwork. Northwest Enviroservice, Inc. will accept it daily, but requires more paperwork. Both companies will come and pick up your wastes for $55-$77 per hour. They are willing to coordinate and combine loads, so businesses who generate small amounts of waste can develop a neighborhood "milk-run" route and share the transportation costs. This is a money-saving option for companies that generate small amounts of hazardous waste.

Get help if necessary. There are a number of organizations that can help you to determine if a substance is hazardous or how you should dispose of a material. Some of these numbers are:

Metro's Hazardous Waste Section 684-2300
Department of Ecology Hotline.....1-800-633-7585
King County Hazards Information 296-4692

If it is after business hours place the substance in a sealed container, label it, and store it in a safe place where no one can touch it.

BMP #8
Minimize Wastes

Who: All businesses and employees should look for ways to reduce waste.

Why: Like proper disposal, minimizing waste reduces the chance of associated pollutants entering the City's drainage system. Minimizing waste results in the greatest environmental benefits and is Washington State's top solid waste management priority. By reducing waste you can save the costs and regulatory process associated with proper disposal.

How: Wastes can be minimized through good housekeeping (for example, keeping products labeled and free of contaminants), separating different wastes, substituting non-hazardous materials for hazardous ones, and maintaining products. Reducing waste reduces potential sources of pollutants to the drainage system and also preserves natural resources.

Automotive businesses and employees can reduce waste in a number of ways. For example:

Use solvents more than once. Solvents such as MEK, methylene chloride, and trichloroethylene can be used more than once. Filter out the solids or let them settle before re-use. When solvents become too dirty to be used again, contact a hazardous waste treatment storage and disposal facility.

Buy the least toxic products available. Look for "non-toxic" on the label. Do not let the term "biodegradable" mislead you. Products labeled with these terms are not necessarily safe for the environment, particularly after they are used. For example, a "biodegradable" degreaser can become a hazardous waste after it is mixed with oil and solvent.

To substitute less hazardous materials and activities for more hazardous ones:

VOL 12 2 5714
R0059007

- Rather than detergents, use hot water/steam-cleaning methods for washing oil off metal parts such as engines, tools, and equipment.
- Use non-solvent cleaners.
- Use water-based materials rather than petroleum-based.
- Use non-chlorinated compounds, instead of chlorinated compounds; non-chlorinated compounds are less toxic and less expensive to dispose of.
- Use waterless hand cleaners.

Buy only what you need. Purchase products in amounts that can be used completely and maintain a good inventory control system to prevent unnecessary purchases. Consider waste management costs before buying new materials and equipment.

Use only what is needed. Twice as much does not mean twice the results. Follow the directions.

Purchase products that last longer (for example, good quality rather than poor quality tires) and recommend them for your customers.

See if others can use your waste. Use the services of the Industrial Materials Exchange (see the recycling section).

BMP #9
Recycle Wastes

Who: Any business or employee producing or handling waste — such as oil, tires, and batteries — should recycle whenever possible.

Why: Both recycling and proper disposal reduce the risk of wastes entering the City's drainage system. But recycling is preferred to disposal because of the overall environmental benefits. For example, recycling produces one gallon of oil for each gallon of used oil. On the other hand, to produce 2.5 quarts of new motor oil, 42 gallons of high quality crude oil must be "cracked."

Recycling is second to minimizing waste in the State of Washington's priorities for solid waste management. The State has a goal to achieve a fifty percent recycling rate by 1995. Bellevue's goal is a 65 percent reduction in the waste stream by 2000.

How: Ways to make recycling work are outlined below:

Purchase recycled products. By doing so, you help ensure a use for the recyclable materials that people collect and turn in.

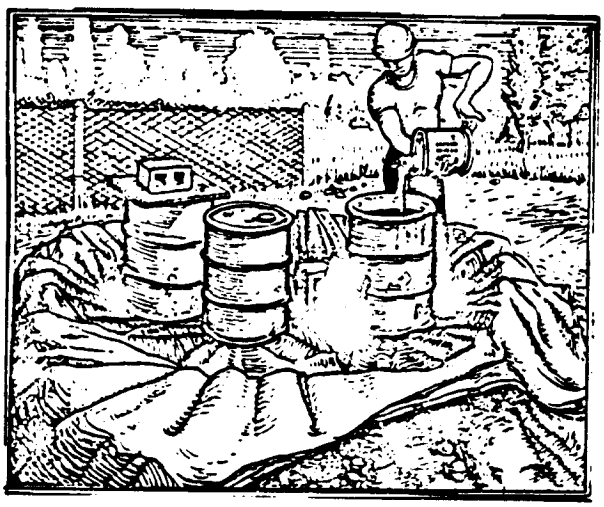
Separate wastes. Keep your wastes in separate containers according to the type of product and keep records of container contents (keep materials in the original container if possible). Do not mix oil, degreasers, solvents, antifreeze, or brake fluid. Combining different types of waste can prevent recycling and greatly increase disposal costs. For example, uncontaminated waste oil can be recycled, whereas waste oil mixed with solvents requires a much more complicated and expensive disposal process.

Avoid phenol. Avoid using products containing phenol compounds because they are more costly to recycle. You can find out which products you use that contain phenol compounds by asking your vendors.

Keep receipts. For documentation purposes, always keep receipts from the recycler showing the amount and specific types of wastes recycled.

Recycle what you can. Many materials are recyclable, and some private firms will pay you to let them pick up and recycle your wastes. Call recycling companies for details. Information on recycling specific items is included below (the list of private recycling agencies may not be complete and does not constitute a recommendation):

VOL 12 2 5715
R0059008



Recycle used oil; don't throw it away.

- **Used Antifreeze:**

  223-0500
  or, 1-800-228-7872

  Safety Kleen
  6303 212th SW
  Lynnwood, WA 98036
  775-7030

  Northwest EnviroService, Inc.
  1500 Airport Way S
  Seattle, WA 98134
  622-1090

  Petroleum Reclaiming Bus.
  3003 Taylor Way
  Tacoma, WA 98421
  383-4474

  Fuel Processors
  744 S Marsh Pt. Rd
  Anacortes, WA 98221
  225-6571

- Solvents: Solvents can be recycled on- or off-site. You can contract with a solvent tank maintenance service who will remove and replace your solvent regularly. Or your solvents can be sent off-site to be recycled and 70-80 percent returned. You can also purchase a commercial solvent recovery unit; the smallest unit available handles five gallons. Most recovery systems pay for themselves in less than two years.

  The following recyclers accept either degreasing agents or paint solvents:

  CHEMPRO
  2203 Airport Way S
  Seattle, WA 98134
  1-800-228-7872

  Northwest EnviroService
  1500 Airport Way S
  Seattle, WA 98134
  622-1090

  Sol-Pro, Inc.
  3401 Lincoln
  Tacoma, WA 98421
  627-4822

- **Paper:**

  Data Destruction
  P.O. Box 2265
  Kirkland, WA 98083
  828-4769

  Kirkland Recycling
  514 Central Way
  Kirkland, WA 98033

  Issaquah, WA
  392-5280

  Redmoor Resource Recovery
  6200 E Lake Sammamish Parkway SE
  Issaquah
  885-9416

- Other Materials: To recycle materials not listed here, call the Industrial Materials Exchange (IMEX) at 296-4899. IMEX, sponsored by the Seattle-King County Department of Public Health, is an information network that helps businesses find inexpensive sources or markets for hazardous or non-hazardous materials. IMEX publishes a directory six times a year listing available and wanted materials. It is distributed in the western United States, Alaska, Canada, and Pacific Rim Countries. Companies that supply materials save disposal costs, and the companies that use the wastes get the product free or at a reduced rate.

VOL 12 2 5711

R0059010

BMP #10
Preserve/Enhance Streams and Adjacent Vegetation

Who: Any business located by a stream should be aware of City of Bellevue codes requiring stream protection. In addition, stream-side businesses can take steps to improve or restore the stream if it is now degraded.

Why: Preserving and enhancing stream corridors helps aquatic and terrestrial wildlife, helps buffer the stream from the effects of development, and preserves important natural resources for our children. Preserving stream corridors is also required by City of Bellevue codes.

How: Protecting and improving the stream corridor are discussed separately below:

Protect streams. Stream protection is required by City of Bellevue codes. In addition, many properties developed since 1984 have native growth protection easements along the stream. Bellevue codes define streams and the adjacent land — called riparian corridors — as Type A, B, or C depending on their significance. To find out if a stream or drainage ditch near your property is considered a Type A, B, or C riparian corridor call the City of Bellevue Permit Center at 462-2034 and ask for the Storm and Surface Water Utility representative.

New development or vegetation clearing is generally prohibited within Type A and B riparian corridors, which extend 50 and 25 feet respectively from each stream bank. No clearing is allowed within the corridor boundaries unless permitted by a clearing and grading permit. New structures must

Vegetation planted along streams helps protect water quality and prevent erosion.

VOL 12
2 5118
R0059011

be set back an additional distance from the corridor boundaries. (Some Type A riparian corridors have a floodplain which extends beyond the riparian corridor and must also be protected.)

Type C riparian corridors are less protected and extend just to the top of the bank if the channel is open and to the sides of the pipe if its piped. (See Section 20.25H of the Bellevue *Land Use Code* and the *Clearing and Grading Code* for more information on riparian corridor regulations.)

Consider improving the stream corridor. First, you must first determine if the stream corridor is degraded. The stream is considered degraded if it does not provide optimum water quality or habitat — for example, if:

- the banks are eroding
- the banks have grass only or one or a very few native plants
- the banks have been artificially channeled
- the stream has been piped in places

You can help solve the first two problems listed above by planting native vegetation. Consult the *Streamside Revegetation Enhancement Criteria*, prepared by the Storm and Surface Water Utility in March, 1989. (Call 451-4476 or stop at the Permit Center for a copy). If you follow those criteria the City will waive the fee for the clearing and grading permit which is required for any work near streams, including enhancement. (If you work below the high water line, plan to fill or excavate, or are located in the City's shoreline district, you need additional permits; call the Permit Center at 462-2034 for more information.)

You can minimize costs of revegetation by planting with cuttings. For more information on the use of cuttings, call the Storm and Surface Water Utility at 451-4476 and ask for a copy of their *Bioengineering Construction Techniques*, March 1989.

If you want to do more than plant vegetation — for example, turn a straight channel into a natural meandering one — then it's best to hire a firm specializing in stream rehabilitation.

BMP #11
Educate Employees and Customers

Who: All employees need to know how and why to keep pollutants out of the water. Businesses can also raise customers' awareness of what the business is doing to preserve water quality and how they can help (for example, by fixing their car oil leaks).

Why: Many of the steps to prevent pollution are operational and need to be followed on a daily basis. Therefore, employee education is key. Showing customers what is being done to protect the water is good public relations; getting customers to take action (such as fixing an oil leak) can be good for business as well as the environment. Finally, preventing pollution is much cheaper than pollution cleanup.

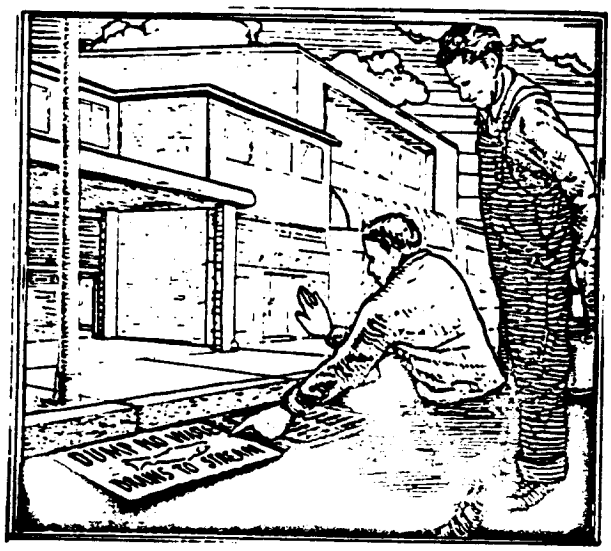
How: Educational opportunities for automotive businesses include:

Participate in workshops, courses, and knowledge transfer. For example:

- Attend the Business Partners for Clean Water workshops (scheduled for 1990 and 1991).
- Conduct annual water quality training sessions for all employees.
- Include water quality training in new-employee orientations and in written procedures.
- Provide educational materials to customers, for example listing motor oil collection centers and stressing the importance of fixing car oil leaks.
- Explain BMPs to peer businesses.

VOL 12 2 5719

R0059012



Employees can educate each other to help protect water quality.

Post signs and posters. For example:

- Stencil storm drains at workplace and construction sites. (The City of Bellevue provides stencils which say "Dump No Waste, Drains to Stream.")
- Post BMPs for employees and customers.
- Post the spill control plan.

Section 5
Water Quality Self-Assessment and Action Program

R0059014

5 Water Quality Self-Assessment and Action Program

STEPS:
1. Complete the following assessment to evaluate current work practices that affect water quality and identify areas of needed improvement.
2. Use the results of this assessment to develop a business action program for using water quality best management practices at your business/work place.
3. Submit your action program to the City of Bellevue Storm and Surface Water Utility to qualify as a recognized Business Partner for Clean Water.

The assessment is designed to be completed by either business owners or employees. However, the action program will require the agreement of the owner/manager.

Identify the locations of the storm drains which receive runoff from your property: _____

_____

_____

1. Is runoff from the site treated with an oil/water separator? (BMP #3)
   Yes_____ No_____

2. Is the fueling area covered and designed to drain to the sanitary sewer? (BMP #2)
   Yes_____ No_____ Not applicable_____

	always	sometimes	seldom/never	not applicable
3. The oil/water separator is cleaned as necessary. (BMP #3)	☐	☐	☐	☐
4. Washing vehicles or parts by any method with water is done in a properly designed designated area. (BMP #1)	☐	☐	☐	☐

If you answered yes to questions 1 and 2 (if #2 applies) and "always" to questions 3 and 4, that's great. If not, what changes are needed?

_____

_____

_____

_____

_____

C. General Housekeeping (BMP #4, 5, 6)

1. Surfaces which drain to the storm drainage system are swept clean and sweepings properly disposed. (BMP #4)	☐	☐	☐	☐
2. When sanding, grinding, or blasting, a tarp is used to cover the ground and catch chips and metal shavings. (BMP #4)	☐	☐	☐	☐
3. All wastes are cleaned up, such as remaining paint chips, dust, and sandings. (BMP #4)	☐	☐	☐	☐
4. When used cars or engines are saved for parts, they are drained of fluids and the fluids properly disposed. (BMP #4)	☐	☐	☐	☐
5. The catch basin is routinely inspected and cleaned when needed. (BMP #4)	☐	☐	☐	☐

VOL 12

2

5 7 2 3

R0059016

	always	sometimes	seldom/never	not applicable
6. Dumpsters, waste materials, and other containers and products from which pollutants can leak or be washed out are kept covered. (BMP #5)	☐	☐	☐	☐
7. The workplace is organized and materials are handled carefully to prevent spills. (BMP #6)	☐	☐	☐	☐
8. For each potentially harmful liquid which could spill (such as gasoline and oil) there is a spill control plan. (BMP #6)	☐	☐	☐	☐

If you answered "always" to all the preceding questions which apply, keep up a great job. If not, what changes are needed?

_____

_____

_____

D. Waste Management (BMP #7, 8 AND 9)

List the kinds of waste that your business produces (such as used antifreeze, used oil, solvents, and paint) and indicate whether or not it is hazardous and whether or not you recycle it. (See BMP #7 regarding hazardous waste.)

Waste	Check If Hazardous	Check If Recycled
_____	_____	_____
_____	_____	_____
_____	_____	_____
_____	_____	_____
_____	_____	_____
_____	_____	_____
_____	_____	_____
_____	_____	_____

VOL 12 2 5124

R0059017

1. Does your business produce more than 220 pounds of hazardous waste per month or at any one time?

   No_____

   Yes_____ If yes, the business is considered a large quantity generator and must have an ID. number from the Washington State Department of Ecology. (BMP #7)

	always	sometimes	seldom/never	not applicable
2. Hazardous wastes that are not recycled are disposed through a treatment, storage, or disposal facility. (BMP #7)	☐	☐	☐	☐
3. Non-hazardous wastes that are not recycled are properly disposed. (BMP #7)	☐	☐	☐	☐

If you did not answer "always" to the preceding questions (if they apply), then what do you need to do to correct the situation?

_____

_____

_____

You can do more to protect the environment by recycling and cutting back on waste whenever possible. Consider the following:

What additional wastes could be recycled? Recyclable materials include used antifreeze, tires, batteries, metals, oils, solvents, paper, pallets, and more. (See BMP #9.)

_____

_____

_____

How could you reduce the amount of your waste? (See BMP #8 for ideas.)

_____

_____

_____

Could you reduce the toxicity of any of your waste by using less toxic materials? If yes, what materials could be substituted?

_____

_____

_____

VOL 12

2

5125

R0059018

If you don't already, could you collect used oil or other automotive wastes from customers for recycling? _____

_____

_____

_____

E. Being Located near a Stream (BMP #10)

Complete this section if your business office/storage yard is within 70 feet of a stream.

What is the name of the stream?

_____

Assuming the stream is in Bellevue, check whether it is a Type A, B, or C (see BMP #10).

Type A_____ Type B_____ Type C_____

(Most of Bellevue's major streams — such as Kelsey Creek, Richards Creek, and Coal Creek — are Type A. To find out the stream type, call the City of Bellevue Permit Center at 462-2034 and ask for the Storm Surface Water Utility representative.)

	always	sometimes	seldom/never	not applicable
The applicable City of Bellevue regulations governing new development and clearing in riparian corridors are followed.	☐	☐	☐	☐

Is the stream corridor now degraded? Yes_____ No_____

For example:

- Are the banks eroding? Yes_____ No_____
- Is the adjacent vegetation just grass or limited to one or two species? Yes_____ No_____

If the stream corridor is on the business property and is now degraded, how could it be enhanced? (See BMP #11.)

_____

_____

_____

_____

_____

VOL 12 2 5126

R0059019

F. Education (BMP #11)

	always	sometimes	seldom/never	not applicable
1. New employees are trained in how their jobs can affect water quality and in the best management practices.	☐	☐	☐	☐
2. Employees attend workshops or have other continuing training in water quality.	☐	☐	☐	☐
3. Nearby storm drains are stenciled "Dump No Waste, Drains to Stream."	☐	☐	☐	☐
4. The spill control plan or other BMP's are posted.	☐	☐	☐	☐
5. The business publicizes its best management practices or suggests ways that customers can help protect water quality.	☐	☐	☐	☐

If you answered "never" or "seldom" to any of the above questions, then there are more ways the business can help raise employee and community understanding about protecting water quality. What else might you do?

_____

_____

_____

G. Other

Identify any of your business activities which could pollute the water even if all applicable practices outlined in this assessment were followed:

_____

_____

_____

What steps would prevent pollution from those activities? (If unsure, ask for help at the workshop, or call 451-4476.)

_____

_____

_____

_____

VOL 12 2 5727
R0059020

H. For Employees Only

What water quality best management practices apply to your job?_____

- ☐ BMP #1 *Designate Vehicle Wash Area*
- ☐ BMP #2 *Cover and Drain Fueling Area*
- ☐ BMP #3 *Treat Runoff with Oil/Water Separator*
- ☐ BMP #4 *Keep Workplace Clean and Maintain Catch Basins*
- ☐ BMP #5 *Cover Containers and Materials*
- ☐ BMP #6 *Prepare for and Clean up Spills*
- ☐ BMP #7 *Dispose of Wastes Properly*
- ☐ BMP #8 *Minimize Wastes*
- ☐ BMP #9 *Recycle Wastes*
- ☐ BMP #10 *Preserve/Enhance Streams and Adjacent Vegetation*
- ☐ BMP #11 *Educate Employees and Customers*

Based on this assessment, what changes can you make in carrying out your job to better protect water quality?

_____

_____

_____

VOL 12 2 5128
R0059021

I. Scoring the Assessment

If you'd like to score the assessment:

1. a. Add up all the questions to which you answered either "always," "sometimes," or "seldom/never." (Maximum possible: 18 if all the questions apply to your business).
   Total _____

   b. Multiply that by 5:
   (total answered) x 5 = _____

2. a. Add up all the questions which you answered "always."
   Total number of "always": _____

   b. Multiply that by 5:
   total number of "always" x 5 = _____

3. a. Add up all the questions which you answered "sometimes."
   Total number of "sometimes": _____

   b. Multiply that by 3:
   total number of "sometimes" x 3 = _____

4. You don't need to add up the number of "seldom or never." You don't get any points for those.

5. Add your answer to 2b and 3b and divide by your answer to 1b.

If your answer is 0.8 or greater, then good for you. You're definitely taking steps to protect the water. Spread the word to your peers.

If your answer is between 0.5 and 0.8, then you're doing some things right but there's more to be done. Emphasize the areas of needed improvement in your action program.

If your answer is below 0.5, then congratulations on taking this first step and evaluating your current practices. But you need to change those practices to better protect our water.

VOL 12 2 5729
R0059022

WATER QUALITY ACTION PROGRAM

Provide a brief description of the activities conducted by your business that could affect water quality (for example fueling, automotive repair, vehicle washing).

For each of the headings below, review the corresponding section in the self assessment and list the best management practices that apply to your business but are not currently followed. Identify when and by whom they will be started and how they will be maintained.

Example

Existing BMPs			How Maintained
Keep dumpster lid closed and check for leaks.			Posted at dumpster and reminded at meetings.
BMP to Be Implemented	**When to Initiate**	**By Whom**	**How Maintained**
Install an oil/water separator.	By 1993	Shop manager to oversee	Company hired to clean at least twice a year.

Appendix A
Resources

R0059026

A Resources

This appendix contains resources for the following:

A1 — Reporting Problems A-1
A2 — Contacting Agencies for Help A-3
A3 — Helpful Reference Materials A-6

A1 — REPORTING PROBLEMS

When you detect a problem in the stream or stream corridor, note the location, time of day, and other pertinent information and call the appropriate agency immediately. Please call the SSWU first at 455-7846 (24 hrs.) if the problem is in Bellevue, and the situation will be handled or referred to the appropriate agency. Inform the agency whether you have a crisis or non-crisis situation, and leave your name and phone number in case information needs to be verified.

Water quality trouble calls are divided into two categories: crisis and non-crisis. Examples of these calls are:

Crisis	Non-Crisis
fish and wildlife kills	dirty or turbid water
oil spills	minor erosion/sedimentation
hazardous chemical spills	algae blooms
sewage overflows	debris/litter problems
extreme erosion/sedimentation or flooding	animal waste
	request for information

The following is a list of potential types of crisis trouble calls and the appropriate agencies to notify. The agency contacts are listed in the order of importance for Bellevue problems.

Fish and Wildlife Kills

Contact: City of Bellevue Storm & Surface Water Utility ..... (24-hour number) 455-7846
Washington State Department of Ecology ..... (24-hour number) 867-7000

Information to give to agencies:
- location
- time of day observed
- duration
- number of fish or wildlife involved in kill
- any obvious cause of the kill

R0059027

VOL 12 2 5134

Oil Spills

Contact:
City of Bellevue Storm & Surface Water Utility ..... (24-hour number) 455-7846
Washington State Department of Ecology (freshwater or saltwater) . (24-hour number) 867-7000
U.S. Coast Guard (saltwater only) ..... (24-hour number) 1-800-424-8802

Information to give agencies:
- specific location: address, cross streets, or noticeable landmarks; if body of water involved, which one
- description of spill (heavy tar, colored sheen, etc.)
- approximate size or volume of spill
- vehicle, vessel(s), or probable sources
- time and frequency of spill

Hazardous Chemical Spills

Contact:
911 911
City of Bellevue Storm & Surface Water Utility ..... (24-hour number) 455-7846
Washington State Department of Ecology ..... (24-hour number) 867-7000
Metro — Water Quality Lab ..... (days) 684-2346
— Treatment Plant ..... (nights) 684-1801
*Stay clear of area — area should be blocked off from public. If possible, another person should stay nearby to make sure area stays clear.

Information to give to agencies:
- the body of water, if appropriate
- description including odor
- specific location
- probable source

Sewage Overflows

Contact:
*If risk to human health, immediately notify Seattle-King County Health Department . 587-4632
City of Bellevue — Public Works Maintenance Division ..... (days) 455-7840
— Storm & Surface Water Utility ..... (nights; 24-hour number) 455-7846
Metro Renton Treatment Plant ..... (24-hour number) 226-3680
Washington State Department of Ecology ..... (24-hour number) 867-7000

Information to give to agencies:
- location

Erosion or Flooding

Contact:
City of Bellevue Storm & Surface Water Utility ..... (24-hour number) 455-7846
For erosion — Washington Conservation District 226-4867
For flooding — King County Public Works (if in unincorporated King County) 1-800-527-6237
or 296-8100
Washington State Department of Ecology ..... (24-hour number) 867-7000

Information to give to agencies:
- location and/or landmarks near problem area

VOL 12 2 5735
R0059028

A2 — CONTACTING AGENCIES FOR HELP

Flammable Materials

City of Bellevue, Fire Protection Bureau, Fire Education Coordinator 587-3292
The Fire Protection Bureau enforces and provides information on the storage and handling of flammable, ignitable, and reactive materials.

Hazardous Products and Hazardous Waste

Seattle-King County, Department of Public Health 296-4692
The Hazard line provides information on the disposal of hazardous wastes and alternatives to hazardous products.

State of Washington, Department of Community Development 753-5255
or 1-800-526-6108
SARA: Emergency Planning and Community Right-to-Know Hotline 1-800-535-0202
RCRA and CERCLA 1-800-424-9346
These sources have information on RCRA, CERCLA (Superfund), and SARA regulations.

State of Washington, Department of Ecology, Hazardous Waste Program 1-800-633-7585
This hotline provides access to hazardous substance information.

State of Washington, Department of Labor and Industry — General 281-5447
— Safety and Health 1-800-423-7233
Call for information on the Hazard Communication Standard, Worker Right-To-Know law.

State of Washington, Department of Ecology, Northwest Regional Office 867-7000
This office enforces state regulations concerning hazardous waste.

U.S. Environmental Protection Agency, Chemical Emergency Preparedness Program 1-800-423-7233
Call for information regarding Title III, Emergency Planning, and Community Right-To-Know laws.

U.S. Environmental Protection Agency, Waste Management Branch 442-2777
or 1-800-368-5888
Call for technical information about federal environmental regulations that affect small businesses.

RCRA/Superfund Hotline 1-800-424-9346
This hotline answers general questions regarding the regulation of hazardous wastes under RCRA, CERCLA, and SARA. Answers are not legally binding and cannot be considered "official— agency policy; they are helpful in interpreting the regulations.

Other Wastes

Seattle-King County, Department of Public Health 296-4692
This agency provides specifications to ensure the integrity of containers.

King County, Solid Waste Division, Department of Public Works 296-6542
Call for information on what can be disposed at area landfills.

VOL 12 2 5136

R0059029

Washington Toxics Coalition **632-1545**
The Washington Toxics Coalition provides information on alternative products and proper use.

Sanitary Sewer System

City of Bellevue, Water and Sewer Utilities **453-2977**
or Permit Center **462-2034**
The Sewer Utility regulates discharges into the sewer system.

Municipality of Metropolitan Seattle (Metro), Industrial Waste Section **684-2325**
Metro regulates industrial discharge into the Metro sewer system.

State of Washington, Department of Ecology **867-7000**
Call for information regarding National Pollutant Discharge Elimination System (NPDES) permits.

State of Washington, Department of Health **464-7672**
This agency disperses information on public sewage related health issues and performs inspections of wells and surface water.

Storm Water Management

City of Bellevue, Storm and Surface Water Utility (SSWU) **451-4476**
or ..... **(24-hour number) 455-7846**
or Permit Center **462-2034**
The SSWU manages the storm and surface water system in Bellevue to maintain a hydrologic balance, prevent property damage, and protect water quality and aquatic wildlife habitat.

King County Public Works, Surface Water Management **296-6519**
This department manages and regulates surface water runoff (flooding, drainage, and erosion) in unincorporated King County.

King County Conservation District **226-4867**
Throughout the County the Conservation District advises on erosion control, construction-related water quality concepts, and agricultural runoff management. They have information on soils, standard erosion control practices, and seeding rates or varieties.

Waste Reduction and Recycling

City of Bellevue, Solid Waste Program **637-5217**
This is a local resource for waste reduction and recycling information.

King County Recycling Information Line **296-4466**
Call for county-wide information.

State of Washington, Department of Ecology **1-800-633-7585**
Call for information on waste reduction.

VOL 12
2
5713
7
R0059030

State of Washington, Department of Ecology 1-800-RECYCLE
Call for general recycling information such as where to recycle waste oil.

Industrial Materials Exchange 296-4899
IMEX is an information network that helps businesses find inexpensive sources or markets for materials.

Water Quality

City of Bellevue, Storm and Surface Water Utility (SSWU) 451-4476
or ..... (24-hour number) 455-7846
Among other tasks, the SSWU manages and regulates water quality.

Municipality of Metropolitan Seattle (Metro), Water Pollution Control Department, Water Resources Section 684-1233
Metro monitors water quality in area lakes, streams, and portions of Puget Sound; they also provide advice and assistance on the protection of water bodies.

Puget Sound Water Quality Authority (PSWQA) 464-7320
PSWQA provides general information about Puget Sound water quality and prepares the Puget Sound Water Quality Management Plan.

State of Washington, Department of Ecology, Northwest Regional Office 867-7000
Enforces state water quality standards and groundwater protection regulations.

U.S. Environmental Protection Agency (EPA), Region 10 Headquarters Water Division 442-1014
Public Information 442-1200
Publications 442-1519
Drinking Water Programs 442-1893
Office of Water Plan 442-2116
This division provides guidance and oversight of Nonpoint Source, State Water Quality Management, and Clean Lakes Programs, and water quality standards.

Wildlife and Habitat Protection

City of Bellevue, Parks and Recreation Department 455-6885
This department provides information on wildlife enhancement, coordinates volunteers for the wildlife volunteer program, and manages parks, open spaces, and recreational areas.

City of Bellevue, Storm and Surface Water Utility, Stream Team Program 451-4476
The Stream Team program is designed to increase awareness and involve citizens in the protection and enhancement of Bellevue's streams, fish, and wildlife.

Seattle Fisheries Patrol 464-7916
or ..... (24-hour number) 455-7700
This patrol enforces fish regulations.

VOL 12 2 5 7 1 3 8
R0059031

State of Washington, Department of Fisheries, Habitat Management Division, Regional Office 545-6582
The Department of Fisheries manages fish (commercial fish, food fish, and shellfish) and protects stream habitat in salmon streams.

State of Washington, Department of Fisheries, Habitat Management Division, Volunteer Fisheries Resource Program 753-4490
This program coordinates volunteer efforts in fisheries enhancement projects statewide.

State of Washington, Department of Wildlife, Region Four Office 775-1311
The Department of Wildlife manages game fish and wildlife in all inland waters, and protects their habitat.

Appendix B
Regulatory Requirements

R0059034

B Regulatory Requirements

Many of the regulatory requirements in this appendix are excerpted from the *Stormwater Management Manual for the Puget Sound Basin*, Technical Review Draft (June 1990). Because that manual is still in draft form, it is subject to revision.

This appendix contains regulatory requirements for the following:

B1 — Air Quality
(Puget Sound Air Pollution Control Agency) B-1
B2 — Discharge to Sanitary Sewers
(Metro, City of Bellevue, and Department of Ecology Regulations) B-2
B3 — Spill Cleanup
(United States Environmental Protection Agency and State Department of Ecology) B-4
B4 — Hazardous Waste
(Department of Ecology) B-4
B5 — Polluting Surface Waters
(City of Bellevue and Washington State Code) B-7
B6 — Storage of Materials
(City of Bellevue Fire Code and Seattle-King County Health Department) B-8

B1 — AIR QUALITY (PUGET SOUND AIR POLLUTION CONTROL AGENCY)

The Puget Sound region is under the jurisdiction of regional air quality authorities who in turn must function under Washington State and federal air quality regulations. The Puget Sound Air Pollution Control Agency (PSAPCA) covers Snohomish, King, and Pierce Counties. Two other regional air quality authorities cover the remaining Puget Sound counties.

Of direct interest to persons using this manual are air authority policies on fugitive dust and outside painting. All three air authorities in the Puget Sound region require that reasonable precautions be taken to prevent fugitive particulate material from becoming airborne when handling, loading, transporting, or storing particulate material. The Puget Sound Air Pollution Control Authority specifies that reasonable precautions include: the paving of parking lots and storage areas; housekeeping measures (for example, sweeping); minimization of the accumulation of mud and dust and preventing its tracking onto public roads; and stabilization of storage piles with water spray, chemical stabilizers, tarps, or enclosures.

PSAPCA requires abrasive blasting and spray painting operations to be performed inside a booth designed to capture the blast grit and overspray. Outdoor blasting or painting of structures or items too large to be handled indoors are to be enclosed with tarps.

VOL 12 2 5742
R0059035

PSAPCA requires reasonable precautions to prevent the tracking of material onto public roads. One precaution is wheel-washing of trucks.

Source: Adapted from *Stormwater Management Manual for the Puget Sound Basin*, Technical Review Draft (June 1990), Washington State Department of Ecology.

B2 — DISCHARGE TO SANITARY SEWERS (METRO, CITY OF BELLEVUE, AND DEPARTMENT OF ECOLOGY REGULATIONS)

To discharge storm water to a public sanitary sewer one must receive the approval of the local sewer authority, such as Metro and the City of Bellevue. If the site has not yet been assigned a sewer authority, the business or public agency wishing to discharge storm water to the sanitary sewer must obtain the approval of the Pretreatment Program administrator at the regional office of the Washington State Department of Ecology (Ecology).

Metro Requirements for Discharge to Sanitary Sewer

Storm water can not be discharged into a sanitary sewer unless specific conditions are met. For detailed information you should refer to Metro literature; Metro's telephone number is listed in Appendix A2 (the sanitary sewer system subsection). Generally, Metro's discharge requirements are as follows:

- If the discharge does not meet Ecology standards for receiving waters, it must be treated by all known and available technology, unless Ecology determines this will cause an unreasonable financial burden.
- The discharge must not exceed the hydraulic capacity of the collection system or the Metro treatment plant.
- The contaminants must not damage the collection system or the Metro treatment plant, impact the health and safety of Metro plant workers, pass through the treatment process, or limit use of Metro's sludge for land application.
- The storm water shall not have a pH less than 5.5 or contain any gas or substance which by itself or by interaction with other waste may cause corrosive damage to sewer works or treatment facilities.
- The storm water shall not contain heat in amounts that interfere with the treatment plant.
- The concentration of fats, oils and greases of animal or vegetable origin, petroleum oil, nonbiodegradable cutting oil or mineral oils shall not exceed 100 mg/l.
- Prohibited from discharge to the sanitary sewers are flammable or explosive materials including gasoline, kerosene, naphtha, benzene, toluene, xylene, ethers, alcohols, ketones, aldehydes, peroxides, chlorates, perchlorates, bromates, carbides, hydrides and sulfides, and any other substance which the City, State or EPA has indicated is a fire hazard.
- The following parameters shall not exceed the concentrations indicated: arsenic, 1 mg/l; cadmium, 3 mg/l; chromium, 6 mg/l; copper, 3 mg/l; lead, 3 mg/l; mercury, 0.1 mg/l; nickel, 6 mg/l; silver, 1 mg/l; zinc, 5 mg/l; and cyanide, 2 mg/l.

VOL 12
2
5143
R0059036

City of Bellevue Sewer Utility Requirements for Discharge to Sanitary Sewer

City of Bellevue Sewer Utility regulations specify a number of unauthorized wastes and substances which may not be discharged into any sewer within the Utility's service area:

- any wastes or substances prohibited by Metro regulations
- surface or underground waters from any source
- any liquid or vapor having a temperature higher than 150° F
- any garbage that has not been properly shredded
- any ashes, cinders, sand, mud, straw, hair, shavings, metal, glass, rags, feathers, tar, plastics, wood, paunch manure, hay, or other solid or substance capable of causing obstruction to the flow in sewers or improper operation of the sewage works
- any waste having a pH lower than 5.5 and higher than 8.5 or having any other corrosive property capable of causing damage or hazard to the structures, equipment, or personnel of the city
- any waste containing a toxic or poisonous substance in sufficient quantity to injure or interfere with any sewage treatment process
- any waste containing suspended solids of such character and quantity that unusual attention or expense is required to handle such materials in the public sewer system or at the sewage treatment plant

Department of Ecology Requirements for Discharge to Sanitary Sewer

In setting pretreatment requirements, the local sewer authority or the Washington State Department of Ecology must operate within State Regulations WAC 173-216 (State Waste Discharge Permit Program) which in turn must comply with Federal Regulations 40 CFR 403.5 (National Pretreatment). Specific prohibitions include:

- materials which pass through the municipal treatment plant untreated or interfere with its operation
- materials which create a fire or explosion hazard, create a public nuisance or hazard to life, prevent entry into the sewer for maintenance and repair or is injurious in any other way to the operation of the system or the operating personnel
- materials which have a pH less than 5.0 or greater than 11.0 or have any corrosive property capable of causing damage or hazard to the system, equipment, or personnel
- materials which will cause obstruction to flows
- materials which will cause the sewage temperature to exceed 40° C or will in any case interfere with the biological activity in the municipal treatment plant

VOL 12 2 5744

B3 — SPILL CLEANUP (UNITED STATES ENVIRONMENTAL PROTECTION AGENCY AND STATE DEPARTMENT OF ECOLOGY)

USEPA — SPCC Plans (40 CFR 112)

Federal regulations require that owners or operators of facilities engaged in drilling, producing, gathering, storing, processing, refining, transferring, or consuming oil and oil products are required to have a *spill prevention and control plan* (SPCC), provided that the facility is nontransportation related; and, that the above-ground storage of a single container is in excess of 660 gallons, or an aggregate capacity greater than 1,320 gallons, or a total below-ground capacity in excess of 42,000 gallons. Examples of oil products are petroleum, fuel oil, sludge, oil refuse, and oil mixed with wastes.

The Plan must:

- be well thought out in accordance with good engineering
- achieve three objectives: prevent spills, contain a spill that occurs, and clean up the spill
- identify the name, location, owner, and type of facility
- include the date of initial operation and oil spill history
- name the designated person responsible
- show evidence of approval and certification by the person in authority
- contain a facility analysis

Ecology — Dangerous Wastes (WAC 173-303-350)

Businesses classified as hazardous (dangerous) waste generators must have a *contingency plan* which includes:

- actions to be taken in the event of spill
- descriptions of arrangements with local agencies
- the name of the owner's Emergency Coordinator
- a list of emergency equipment available
- an evaluation plan for business personnel

Source: Excerpts from the *Stormwater Management Manual for the Puget Sound Basin*, Technical Review Draft (June 1990), Washington State Department of Ecology.

B4 — HAZARDOUS WASTE (DEPARTMENT OF ECOLOGY)

The State's *Dangerous Waste Regulations* (Chapter 173-303 WAC) cover accumulation, storage, transportation, treatment, and disposal of hazardous wastes. A hazardous waste is a solid or liquid material with certain properties that could pose dangers to human health, property, or the environment.

A dangerous waste is a hazardous waste that is regulated by state law. A waste is considered dangerous if it is on a list generated by the Environmental Protection Agency or if it has certain characteristics (such as whether the material is ignitable, corrosive, reactive, EP toxic, carcinogenic, persistent, or toxic as defined by the state). State

VOL 12 2 5745
R0059038

publications identify the 400 listed wastes and explain in detail the characteristics of dangerous waste. (See Appendices A2 and A3.) Under state law, the worst dangerous waste is referred to as extremely hazardous waste.

Following is a summary of the dangerous waste regulations pertinent for businesses or public agencies that periodically accumulate waste at their buildings. It includes aspects of the regulations that apply to waste generators and accumulation.

State regulations require generators of dangerous wastes to obtain a Washington State Department of Ecology (Ecology) identification number if they generate more than 220 pounds per month (2.2 pounds if the waste is defined as extremely hazardous).

In addition, under certain circumstances, as described below, the generator must obtain a permit to store dangerous wastes. Where storage permits are required, Ecology has the responsibility of ensuring that technical requirements are met.

Local governments must be concerned about situations where an Ecology storage permit is not required (less than 220 pounds per month). Although these generators still fall under Ecology regulations, the technical requirements are general. The first opportunity for local government to enforce the regulations is when a generator requests a building permit.

A storage permit is not required by Ecology under the following circumstances:

- if the business generates more than 2,200 pounds per month of dangerous waste but intends to store the accumulated material less than 90 days
- if the business generates between 220 and 2,200 pounds per month of dangerous waste but intends to store less than 180 days
- if the business produces less than 220 pounds per month regardless of the length of storage.

Generators that produce more than 220 pounds per month (see 1 and 2 above) and avoid the need for a permit must still fulfill these general regulations with regard to temporary storage:

<u>If Placed in Containers</u>:

- If the container is not in good condition (e.g., severe rusting, apparent structural defects) or if it begins to leak, the owner must replace the container.
- The container must be labeled as to its contents.
- The container must be lined with a material that does not react with the waste.
- The container must always be closed except when adding or removing waste.
- The container must not be opened, handled, or stored in a manner which may cause a rupture or leak.
- The containers must be examined for leakage at least weekly.
- Containers storing reactive or ignitable waste must meet requirements of the *Uniform Fire Code*.
- Incompatible wastes must be stored separately.

VOL 12 2 5746

R0059039

- Ecology may require secondary containment of the storage area. Specifically, the storage area must:
  - be capable of collecting and holding spills and leaks
  - if uncovered, be capable of handling a 25-year storm
  - have a base which is free of cracks or gaps and is sufficiently impervious to leaks, spills and rainfall
  - be sloped or designed such that liquids can drain to a point for removal
  - have positive drainage control (e.g., a valve) to insure containment until any liquid is removed. Removal must occur in a timely manner
  - have a holding capacity equal to 10 percent of the volume of all containers or 100 percent of the volume of the largest container whichever is greater
  - not allow runoff of rainfall from areas adjacent to the storage area

If the waste does not contain free liquids the above requirements need not be met provided that the area is sloped or the containers are elevated.

If Placed in Tanks:

- The tank must be lined with a material that does not react with the waste.
- The tank, tank area, and its ancillary equipment must be inspected regularly according to a posted schedule.
- If retired, the tank is to be cleaned of all contents. Any wash waters should be disposed of in a manner similar to the disposal of the actual wastes.
- Tanks storing reactive or ignitable waste must meet the *Uniform Fire Code* requirements.
- Incompatible wastes must be stored separately.

The above generators must also have a designated employee on site or on call with the responsibility for coordinating all emergency response measures. Any spills are to be contained and cleaned up as soon as practicable.

If the business produces less than 220 pounds per month (2.2 pounds, if the waste is defined as "extremely hazardous"), it need not comply with the above regulations. It need only dispose of the waste using one of the methods acceptable to the local health department, which are as follows:

- Dispose of the waste to a facility that is permitted to accept hazardous waste.
- Dispose of the material to a recycling facility.
- Dispose of the waste to a municipal or industrial landfill that is permitted to accept hazardous waste.
- Put the waste to a beneficial use, such as the use of sludge as fertilizer. This should be cleared with the local health department.

B5 — POLLUTING SURFACE WATERS (CITY OF BELLEVUE AND WASHINGTON STATE CODE)

City of Bellevue Code

Chapter 24.06 of the *Bellevue City Code*, known as the *Storm and Surface Water Utility Code*, provides for the regulation and management of the City's storm and surface water system. The code prohibits the discharge, by any manner, of any organic or inorganic matter that causes pollution in the City's natural waters. The code prohibits the disposal or spilling of these pollutants on virtually any land that potentially drains to a water body. Therefore, it is extremely important that potential pollutants be handled with care.

Pollutants include, but are not limited to the following:

- petroleum products, including but not limited to oil
- gasoline, grease, fuel oil, heating oil
- chemicals, acids or alkalis
- pesticides, herbicides or chlorine
- degreasers and/or solvents
- antifreeze and/or other automotive products
- dyes (without prior permission of the SSWU)
- paints
- pet wastes or animal carcasses
- recreational vehicle wastes
- steam cleaning wastes
- washing of fresh concrete for cleaning and/or finishing purposes or to expose aggregates
- laundry wastes or soaps
- trash or debris
- bark and other fibrous material
- lawn clippings, leaves, branches, or silt
- construction materials

Under Chapter 24.06.187 any person responsible for pollutant discharge into natural waters who fails to take remedial action at the SSWU director's request is responsible for the necessary expenses incurred by the City in pollutant abatement.

Revised Code of Washington

The *Revised Code of Washington* (RCW) has provisions regarding polluting matter in general and oil in particular. Oil is defined as oils, including gasoline, crude oil, fuel oil, diesel oil, lubricating oil, sludge, oil refuse, liquid natural gas, propane, butane, oils distilled for coal, and other liquid hydrocarbons regardless of specific gravity, or any other petroleum related product. Following are excerpts from the code that pertain to polluting matter and oil.

RCW 90.48.080: *Discharge of polluting matter in waters is prohibited. It shall be unlawful for any person to throw, drain, run, or otherwise discharge into any of the waters of this state, or to cause, permit or suffer to be thrown, run, drained, allowed to seep or otherwise discharged into such waters any organic or inorganic matter that shall cause or tend to cause pollution of such waters according to the determination of the Department of Ecology, as provided for in this chapter.*

VOL 12 2 5748

R0059041

RCW 90.48.320: *It shall be unlawful, except under the circumstances here after described in this section, for oil to enter the waters of the state from any ship or any fixed or mobile facility or installation located offshore or onshore whether publicly or privately operated, regardless of the cause of the entry or fault of the person having control over the oil, or regardless of whether it be the result of intentional or negligent conduct, accident or other cause. This section shall not apply to discharges of oil in the following circumstances:*

1. *The person discharging was expressly authorized to do so by the Department of Ecology prior to the entry of the oil into state waters.*

2. *The person discharging was authorized to do so by operation of law as provided in RCW 90.48.200.*

3. *The person having control over the oil can prove that a discharge was caused by:*
   a. *an act of war or sabotage*
   b. *negligence on the part of the United States government or the State of Washington.*

Sources: Summary of *Bellevue City Code* and excerpts from the *Revised Code of Washington.*

B6 — STORAGE OF MATERIALS (CITY OF BELLEVUE FIRE CODE AND SEATTLE-KING COUNTY HEALTH DEPARTMENT)

Generally, the storage of flammable materials is regulated by the *City of Bellevue Fire Code* and containers used for holding solid waste are regulated by the Seattle-King County Health Department.

City of Bellevue Code

Storage of flammable, ignitive, and reactive chemicals and materials must comply with the *City of Bellevue Fire Code*: Article 50, Storage of Raw Materials and Finished Products; Article 79, Storage of Flammable and Combustible Liquids; and Article 80, Storage Cabinets for Hazardous Materials.

- Storage of hazardous materials requires a permit from the fire department. In Bellevue, a fee of fifty dollars is charged for each item and each classification of hazardous materials. Any hazardous material with multiple classifications is charged only once.

- Flammable finished products and combustible liquids may be stored inside the manufacturing building as long as they are stored in a room separated from the processing area by a two-hour occupancy separation (the wall must be able to burn for two hours before a hole burns through the wall).

- Container and tank storage areas are to be protected against trespassers by fencing or other control measures. The area is to be kept free of weeds, debris, and other combustible materials.

- The storage area is to be graded to divert spills away from buildings or it shall be surrounded by a 6-inch curb. If a curb is used, a drain with a positive control valve shall be provided for draining of accumulations of rain water or spills.

- Combustible merchandise outside of buildings shall not be stored or displayed under sprinklered eaves, canopies, or other projections or overhangs of buildings which are protected by automatic sprinklers. Such

VOL 12 2 5749
R0059042

merchandise shall not be stored or displayed within ten feet of an exit doorway.

- The storage of Class I and Class II liquids in aboveground tanks outside of buildings is prohibited within the limits established by law as the limits of districts in which such storage is prohibited. Districts for which the prohibition applies includes areas zoned as other than LI (Light Industrial) and GC (General Commercial) as defined in the *City of Bellevue Land Use Code* and designated on the City's official zoning map.

- An operator or other trained personnel shall be in attendance at all times while a tank vehicle or tank car is discharging.

- The area surrounding a tank or group of tanks shall be provided with drainage or shall be diked to prevent an accidental discharge of liquid from endangering adjacent tanks, adjoining property or reaching waterways.

- The area within the dikes shall be sloped not less than 1 percent towards an impounding basin or an approved means of disposal.

- The volume of the diked area shall not be less than 100 percent of the volume of the largest tank.

- Drains shall be installed to remove excess water from the diked area. The drains shall not discharge to natural watercourses, public sewers or drainage channels unless a valve, operable from outside the dike, prevents the release of flammable or combustible liquids.

- Provision shall be made during loading and unloading to prevent liquids from entering drainage systems, public sewers, or natural waterways. Connections to such systems by which liquids might enter shall have separator boxes.

Seattle-King County Health Department Container Requirements

Rules and Regulations No. 8 of the *Minimum Functional Standards for Solid Waste Handling* specify the characteristics of containers to insure their integrity. The rule states:

> *Reusable containers, except for detachable containers, shall be: rigid and durable; corrosion resistant; nonabsorbent and water tight; rodent-proof and easily cleanable; equipped with a close fitting cover; suitable for handling with no sharp edges or other hazardous conditions...* (Part IV, Section 1.B)

Detachable containers are reusable containers that are mechanically loaded or handled such as a dumpster or drop box.

> *Detachable containers shall be durable, corrosion-resistant, nonabsorbent, nonleaking and having either a solid cover or screen cover to prevent littering.* (Part IV, Section 1.B)
>
> *All wastewater from container cleaning shall be disposed to a sanitary sewer unless otherwise authorized by the health officer.* (Part IV, Section 1.B)
>
> *All persons collecting or transporting solid wastes shall avoid littering, or the creation of other nuisances at the loading point...* (Part IV, Section 1.C)
>
> *...solid waste shall be moved in such a manner that the contents will not fall, leak in quantities to cause a*

VOL 12
2
5750

nuisance, or spill therefrom. Where such spillage or leakage does occur, the waste shall be picked up immediately... (Part IV, Section 1.C)

BUSINESS PARTNERS FOR Clean Water

Appendix C
Glossary

R0059045

C Glossary

Aquatic Habitat — A place in, on, or near water where organisms are normally found.

BMP (Best Management Practices) — A general name given to a variety of methods for controlling nonpoint source pollution.

Carcinogenic — A cancer-causing substance.

CERCLA (Comprehensive Environmental Response Compensation and Liability Act) — A federal regulation, commonly called Superfund, created to remedy hazardous waste problems.

Constructed Wetland — A wetland constructed by creating ponded areas and either planting aquatic plants or allowing them to colonize naturally, usually to perform water treatment and flood control.

Contaminant — A substance that is not naturally present in the environment or is present in amounts that can, in sufficient concentration, affect the environment.

Degradation — Being lowered in value, quality, etc.

Detention Pond (Vault) — A constructed pond (or vault) that temporarily stores storm water runoff and releases it at controlled rates.

Dissolved Oxygen — Oxygen which is present (dissolved) in water and available for use by fish and other aquatic animals. If the amount of dissolved oxygen in the water is too low, the aquatic animals will suffocate.

Diversion Channels — Waterways that collect storm water runoff and divert it away from an area of concern. For example, channels can divert storm water around exposed soils which would erode or around a source of pollution which would otherwise be washed into the drainage system.

Drainage Basin — See Watershed.

Drainage System — See Storm Drainage System.

Ecosystem (Ecological System) — A community of living things interacting with one another and with their physical environment, such as a rain forest, pond, or estuary. Damage to any part may affect the whole.

EPA (Environmental Protection Agency) — A federal agency with authority for enacting and enforcing many environmental laws.

Erosion — The wearing away of the land surface by running water, wind, ice, or other geological processes.

Filter Fabric Fence — A fence constructed of a small-mesh textile that allows storm water runoff to pass through while trapping sediments.

Ground Water — Underground water supplies, also called aquifers.

VOL 12
2
5 7 5 3
R0059046

Hazardous Waste — Any solid, liquid, or gaseous substance which, because of its source or measurable characteristics, is classified under state law as dangerous or federal law as hazardous and subject to special handling, shipping, storage, and disposal requirements. Washington State businesses are regulated for two categories of hazardous waste: Dangerous and Extremely Hazardous.

Herbicide — A chemical substance used for killing plants, especially weeds.

IMEX (Industrial Materials Exchange) — This agency is an information network sponsored by the Seattle-King County Department of Health that helps businesses find inexpensive sources or markets for materials.

Impermeable — Not permitting the passage of liquids or gasses.

Impervious Surface — Material which resists or blocks the passage of water.

Infiltration — The movement of water from the surface downward through the soil.

Leaching — To extract from some material, such as the washing of pollutants from a dumpster by storm water.

Metals (Heavy Metals) — Elements such as mercury, lead, nickel, zinc, and cadmium that are of environmental concern because they can accumulate in the food chain and, in high enough concentrations, can be toxic to life. Many are also necessary nutrients but in very low concentrations.

Metro (Municipality of Metropolitan Seattle) — A Puget Sound area agency that is responsible for waste water treatment and mass transit.

MSDS (Material Safety Data Sheets) — Information supplied by the manufacturer on the chemical properties, hazards, and special handling of a product.

NPDES (National Pollutant Discharge Elimination System) — A permitting process established by the Clean Water Act that regulates the release of pollutants to waters of the United States.

Nonpoint Source (NPS) Pollution — Pollution that comes from dispersed or poorly defined sources rather than a single point such as an industrial pipe.

Nutrients — Elements or substances, such as nitrogen or phosphorus, that are necessary for plant growth. Large amounts of these substances reaching water bodies can lead to reduced water quality and eutrophication by promoting excessive aquatic algae growth. Some nutrients can be toxic at high concentrations.

Pesticide — Any chemical agent used for control of specific organisms such as insecticides, herbicides, fungicides, etc.

Pollutants — See Water Pollutants.

RCRA (Resource Conservation and Recovery Act) — A federal regulation that addresses waste handling and disposal.

Retention — The process of storing runoff on a surface area or in a storage basin so it does not enter the drainage system at a destructive rate.

VOL 12 2 5754

R0059047

Riparian Corridor — A stream (either intermittent or year-round) and the lower and upper banks including associated vegetation which stabilizes the banks and maintains habitat.

Riprap — A facing layer or protective mound of stones placed to prevent erosion or sloughing of a stream bank or embankment.

Salmonid — Any species of fish in the salmon or trout family.

Sanitary Sewer System — A network of pipes for carrying sewage to a treatment facility.

SARA (Superfund Amendment and Reauthorization Act) — A reenactment of CERCLA with additional provisions.

Sediment — Particles from rocks, soil, or biological materials.

SSWU (Storm and Surface Water Utility) — A Bellevue utility that manages the City's storm and surface water system to maintain a hydrologic balance, prevent property damage, and protect water quality.

Storm Sewer — See Storm Drainage System.

Storm Drainage System — A network of pipes and channels for carrying storm and surface waters (not domestic, industrial, and commercial waste waters) to surface water bodies such as streams and lakes.

Storm Water Runoff — Precipitation excess that is not retained on the vegetation or surface depressions and is not lost by infiltration, and thereby is collected on the surface and runs off.

Stream Corridor — See Riparian Corridor.

Surface Roughening — Any practice that provides for rougher, more permeable surfaces that will slow runoff velocity and reduce erosion potential. Porous pavements, grassed, and gravel driveways are examples.

Surface Runoff — See Storm Water Runoff.

Swales — A grass lined ditch. More specifically, a natural or constructed waterway (usually broad and shallow covered with erosion resistant grasses) used to convey surface runoff.

TSD (Treatment, Storage and Disposal Facility) — A facility permitted by the Department of Ecology or the EPA to store, treat, or dispose of hazardous waste.

Urban Runoff — Storm water that passes through and out of developed area to a stream or other body of water. (See Storm Water Runoff.)

Water Pollutants — Substances which can render water harmful to people, fish, or wildlife or impair recreation or other beneficial uses of water.

Watershed — A geographic area within which all surface water drains into a particular body of water.

WDOE (Washington State Department of Ecology, also referred to as Ecology) — A state agency that enacts and enforces environmental laws.

VOL 12 2 5755

R0059048

Wetland — Lands where groundwater is usually at or near the surface, or where the land is covered by shallow water for all or part of the year. Wetlands are further defined as lands where the saturation with water is the dominant factor for determining the soil development and the types of plant and animal communities living in the soil or on its surface.

EXECUTIVE SUMMARY

This report summarizes and evaluates Best Management Practices (BMPs) that are potentially appropriate for Retail Gasoline Outlets (RGOs). This report also summarizes and evaluates several studies that characterized the chemical quality of storm water runoff from RGOs. These prior studies are important because they provide a basis for evaluating and recommending appropriate BMPs for RGO applications.

Based on the results of several storm water studies, it does not appear that the water quality of storm water runoff from properly operated and maintained RGOs is appreciably different than water quality from a number of other sources, including parking lots and roads. Additionally, in most cases, the mean concentrations of oil and grease, total suspended solids, and chemical oxygen demand are below the NPDES storm water permit limitations established by several states for vehicle-related activities.

Properly operated and maintained RGOs may currently be implementing a variety of BMPs to reduce storm water contaminant concentrations. Two basic categories of BMPs are presented in this paper. The first category consists of practical pollution prevention measures. These are the basic, common operational practices and relatively simple facility modifications that are effective in preventing storm water pollution. The second category consists of storm water treatment BMPs. These include structural controls that involve installation of equipment to reduce contaminant concentrations in storm water runoff.

Practical pollution prevention measures are appropriate for RGOs because they are simple, cost effective, and protective of storm water quality. In contrast, the storm water treatment BMPs are less appropriate for RGOs because they are ineffective or unproven for treatment of low contaminant concentrations and are relatively expensive to install and maintain.

STORM WATER BEST MANAGEMENT PRACTICES FOR RETAIL GASOLINE OUTLETS

SECTION 1.0 – INTRODUCTION

1.1 General

Storm water Best Management Practices (BMPs) are practices used to prevent or reduce the pollution of surface waters caused by storm water runoff. This report summarizes and evaluates BMPs that are potentially appropriate for Retail Gasoline Outlets (RGOs). This report also summarizes and evaluates several studies that characterized the chemical quality of storm water runoff from RGOs. These prior studies are important because they provide a basis for evaluating and recommending appropriate BMPs for RGO applications.

The Western States Petroleum Association (WSPA) commissioned this study in response to existing and anticipated regulation of storm water discharges from RGOs. In some cases, municipal ordinances require owners and operators of RGOs to implement BMPs that may not have beneficial effects on storm water quality. Additionally, the required BMPs may not be consistent between municipalities, causing compliance difficulties for RGO owners and operators. The information in this report is based on a variety of sources, including an extensive literature search and review; discussions with numerous researchers regarding on-going and unpublished studies; a review of local, state, and federal regulations; and a review of storm water BMPs currently utilized by WSPA members.

1.2 Background

In 1972, the Federal Water Pollution Control Act (also known as the Clean Water Act, or CWA) was amended to provide that any discharge of pollutants from a point source to waters of the United States is effectively prohibited unless it is in compliance with a National Pollutant Discharge Elimination System (NPDES) permit. Although this technically prohibits discharge of pollutants in storm water, the focus at that time was on the bigger problems of industrial waste and sewage treatment.

R0059056

As more significant sources of water pollution were brought under control, the impact of pollutants in storm water began to receive greater attention. Water quality studies conducted in the 1970s and 1980s identified urban runoff as a diffuse, or nonpoint, source of pollution. In response to these studies, the 1987 amendments to the Water Quality Act added Section 402(p). This section established a comprehensive, two-phased approach for the U.S. Environmental Protection Agency (EPA) to follow in addressing storm water discharges. Five types of storm water discharges are covered under the Phase I program. Dischargers within these five categories, listed below, were required to obtain permit coverage before October 1, 1992:

a. A discharge for which a permit has been issued prior to February 4, 1987.
b. A discharge associated with industrial activities.
c. A discharge from a municipal separate storm sewer system serving a population of 250,000 or more.
d. A discharge from a municipal separate storm sewer system serving a population of 100,000 or more, but less than 250,000.
e. A storm water discharge determined by the EPA Administrator or the State to contribute to a violation of a water quality standard or to be a significant contributor of pollutants to the Waters of the United States.

Storm water discharges from commercial facilities, such as RGOs and parking lots associated with other commercial operations, are not included under the Phase I regulations. However, Phase II regulations now being promulgated are expected to increase the number and type of dischargers required to obtain NPDES permit coverage for storm water discharges. EPA, in a draft Phase II report to Congress (EPA, 1993), identified several business categories that are not currently regulated by NPDES permits but are proposed for regulation in Phase II. Automotive service facilities, including RGOs, are included on EPA's list of potential Phase II permittees.

In addition to potential regulation under state and federal programs, RGOs are likely to be regulated by local municipalities. Municipalities, as part of their mandated storm water management programs, are required to monitor and control pollutants in storm water discharges from their municipal storm drainage systems. Methods of control may include regulating storm water discharges from facilities, including RGOs, that are identified by municipalities as contributors of pollutants to the municipal storm drain system.

1.3 Water Quality of Storm Water Discharges from RGOs

To evaluate the BMPs appropriate for use at RGOs, it is necessary to develop an understanding of the types and concentrations of chemicals typically found in storm water runoff from RGOs. For this reason, summaries of three recent studies that characterized the water quality of storm water discharges from RGOs are included in this report. These studies are described in the following subsections.

1.3.1 WSPA/API RGO AND COMMERCIAL PARKING LOT STUDY

A WSPA/API storm water runoff study (WSPA/API, 1994) was conducted on six retail gasoline outlets (RGOs) and four commercial parking lots. The objective of the study was to characterize simulated storm water runoff from RGOs and compare the results with simulated runoff from commercial parking lots and published urban "background" values. The analytical results from this study are presented in Table 1.

The WSPA/API study was conducted on RGOs that were "normally operated and maintained." For the purposes of that study, "normally operated and maintained" signifies that the RGOs utilize Best Management Practices (BMPs) to minimize the buildup of potential storm water contaminants on exposed areas. These BMPs include regular sweeping of exposed areas, regular site inspections, and standardized spill response procedures. All of the RGOs were high-volume retailers, and three conducted on-site vehicle maintenance or repair services.

The study demonstrates that for the constituents analyzed, median event mean concentrations (EMCs) of chemicals in storm water runoff from normally operated and maintained RGOs are no higher than those in runoff from commercial parking lots. Additionally, median EMCs of total suspended solids, copper, lead, and zinc in runoff from RGOs and parking lots are no higher than background levels present in urban runoff as established by the National Urban Runoff Program (NURP). Furthermore, for the constituents analyzed, no significant differences were found between median EMCs of runoff from RGO pump islands and driveways. These results indicate that fueling activities at normally operated and maintained RGOs do not contribute significant additional concentrations of chemical constituents to storm water runoff.

R0059058

VOL 12 2 5766

1.3.2 DISCRETE LAND USE TYPES STUDY

Another recent study (Shepp, 1995) investigated the petroleum hydrocarbons and general water quality characteristics associated with four discrete land uses in the Washington D.C. Metropolitan Area. The monitored sites included a parking lot where cars typically are parked for relatively long periods; a parking lot for a commercial convenience store, where short-term parking occurs; a street; and an RGO. Details were not provided regarding the throughput or BMPs used at the RGO monitored for the study, however; the station is described as a "gas and go" style facility, providing no automotive service or maintenance. Samples were collected from 26 storm events for the longer-term parking lot, 14 storm events for the short-term parking lot, 9 storm events for the street, and 13 storm events for the RGO. The mean results, which are summarized in Table 2, indicate that the mean hydrocarbon concentration in runoff from the convenience commercial store is substantially higher than the closely grouped mean values for the RGO, longer term parking lot, and street. Similar results were reported for the majority of the other parameters measured.

1.3.3 ACTION PLAN DEMONSTRATION PROJECT

Sacramento County's Action Plan Demonstration Project (Uribe and Associates, 1994) characterized storm water runoff from RGOs and evaluated the use of mobile high-pressure washing as a BMP. The report presents the analytical results of storm water samples collected over two consecutive wet seasons from three RGOs in Sacramento County.

The Sacramento County project selected high-volume (more than 200,000 gallons per month), self-service RGOs with convenience markets and without automobile repair service bays for the study.

The initial analytical program for the collected samples included analyses for oil and grease, total suspended solids, metals (13 EPA priority pollutant metals plus aluminum and iron), polycyclic aromatic hydrocarbons (PAHs), and petroleum hydrocarbons. However, some of the metals, petroleum hydrocarbons, and PAHs were consistently not detected in samples collected from the first three storm events. On the basis of these results, the following parameters were selected for the remainder of the study:

R0059059

VOL 12 2 5767

- oil and grease
- total suspended solids
- heavy metals (cadmium, chromium, copper, lead, and zinc)

The analytical results from the study are presented in Table 3. The results of the study indicated that regular high-pressure washing of pavement surfaces at RGOs actually caused an increase in the concentrations of certain pollutants in storm water discharges.

1.4 Evaluation of RGO Storm Water Runoff Studies

The results of the three RGO storm water runoff studies described in the preceding subsections are summarized in Table 4. For comparison, Table 4 also presents the effluent limitations contained within draft or final NPDES storm water permits from several states that have promulgated effluent limitations for industrial facilities engaged in vehicle-related activities. Also presented are the mean concentrations for residential and commercial land uses from NURP (1983), a comprehensive study conducted from 1978 through 1983 with funding and guidance provided by EPA. The results of NURP provide insight on what can be considered background levels for urban runoff.

As summarized in Table 4, the mean concentrations of total suspended solids, lead, copper, and zinc in runoff from RGOs are generally below the background levels established by the results of NURP. Additionally, in most cases, the mean concentrations of oil and grease, total suspended solids, and chemical oxygen demand are below the limitations established for a number of NPDES permits, including storm water discharge limitations established for transportation-related industrial facilities located in Missouri, Alabama, Oregon, and Louisiana. On this basis, it appears that the concentrations of chemical constituents in storm water discharges from properly operated and maintained RGOs are below background concentrations and are generally below levels that require additional controls or treatment, as established by the effluent limitations developed for storm water discharges from sites where vehicle fueling, maintenance, and repair occur.

R0059060

However, it should be noted that the preceding conclusions are based on the mean concentrations from samples collected from a total of ten RGOs. The analytical results for individual RGOs and storm events are variable, as would be expected based on typical variability in RGO age, construction, throughput, and management practices. The variability in analytical results for oil and grease and total suspended solids is illustrated on the histograms presented as Figure 1. In some cases, the results exceed the background concentrations established by NURP and/or the effluent limitations developed for vehicle-related sites. The variability in analytical results shown on this figure suggests that there may be cases where concentrations of specific chemical constituents in storm water discharges from RGOs are above levels where additional controls may be required. However, the histograms also indicate that the majority of the results are below concentrations where additional controls may be required, suggesting that, in most cases, the BMPs implemented at properly operated and maintained RGOs are effective and sufficient for preventing storm water pollution.

GEOMATRIX

SECTION 2.0 -- BEST MANAGEMENT PRACTICES FOR RGOs

2.1 General

As described in Section 1.4 of this report, storm water discharges from RGOs contain concentrations of oil and grease, total suspended solids, heavy metals, and other constituents. Although the concentrations of these constituents from properly operated and maintained RGOs are often no higher than from other land uses, such as parking lots and streets, there may be a requirement to minimize pollutant loading of storm water through implementation of BMPs.

Two basic categories of BMPs are described in this report. The first category consists of practical pollution prevention measures. These are the basic, everyday operational practices and relatively simple facility modifications that are effective in preventing storm water pollution. The second category consists of storm water treatment BMPs. These include structural controls that usually involve installation of equipment to treat storm water. The storm water treatment BMPs described in this report are limited to on-site treatment devices applicable to relatively small sites that lack the room necessary for traditional urban BMPs such as extended dry detention basins or wet ponds.

The first category of BMPs, pollution prevention measures, are preferred over storm water treatment BMPs because they are relatively simple and cost effective. The results of a recent survey of several WSPA/API member companies, representing several thousand RGOs across the western United States, indicated that the types of pollution prevention and source control practices that are described in this report are already being used at many RGOs. This approach for preventing pollution is endorsed by EPA as one of the best means of pollution control. In fact, the Pollution Prevention Act of 1990 set forth a national policy that:

> "...pollution should be prevented or reduced at the source whenever feasible; pollution that cannot be prevented should be recycled in an environmentally safe manner, whenever feasible; pollution that cannot be prevented or recycled should be treated in an environmentally safe manner whenever feasible; and disposal or other release into the environment should employed only as a last resort and should be conducted in an environmentally safe manner."

R0059063

VOL 12 2 5771

The second category of BMPs are storm water treatment measures. Storm water treatment may require a fairly significant capital outlay, along with operational and maintenance expenses, and may not result in an appreciable improvement in storm water quality. Treatment of storm water discharges from RGOs is problematic for two reasons. First, as characterized in Section 1.4 of this report, storm water discharges from RGOs typically carry relatively low concentrations of contaminants. The efficiency and removal rates for many structural BMPs at such low influent concentrations are questionable. Second, storms are often short-duration events with relatively high intensities. It is often difficult to effectively treat the necessary amount of rainfall that discharges from a 100 percent impervious RGO without storing a large volume of water. Creating on-site storage for the necessary volume of storm water runoff often is the most costly item in the overall BMP system (Bell & Nguyen, 1995). Nevertheless, structural BMPs may be required for sites where it has been demonstrated that operational practices are not sufficient to control pollutants. In addition, some municipalities require the installation of structural BMPs for new developments or significant remodels. The specific requirements vary greatly between jurisdictions, and it is recommended that owners and operators contact individual municipalities for specific requirements.

A description of practical pollution prevention measures and storm water treatment BMPs are described in the following sections.

2.2 Practical Pollution Prevention Measures Suitable for RGOs

The following are proactive practical pollution prevention measures that can be effective for all RGOs. The intent of these pollution prevention measures is to control pollutants to the extent that the treatment of storm water is unnecessary. A summary of these practical pollution prevention measures is presented in Table 5.

R0059064

VOL 12 2 5712

2.2.1 USING SPILL CONTAINMENT & OVERFILL PREVENTION EQUIPMENT

Using spill and overfill equipment for Underground Storage Tanks (USTs) can effectively reduce fuel spills during UST filling activities. Federal regulations have made installation of spill and overfill equipment mandatory for all RGO USTs installed after December 1988. For RGO USTs installed prior to December 1988, federal regulations will not require spill and overfill equipment until 1998; however, local and/or state regulations may require earlier installation. In addition, fuel pump shut-offs, including automatic shut-offs at each pump and a manual shut-off inside the building, are effective for preventing or minimizing the size of spills.

Proper maintenance of the spill containment equipment is required to ensure proper product delivery. The required maintenance includes regular removal of accumulated debris, water, and product.

2.2.2 POSTING SIGNS WARNING AGAINST "TOPPING OFF"

"Topping off" fuel tanks during fueling can lead to spills, which can potentially contribute hydrocarbon pollutants to storm water runoff. Posting high visibility signs, warning against "topping off" can be effective for minimizing these types of spills.

2.2.3 USING "HOLD OPEN" LATCHES ON DISPENSER NOZZLES

Proper use of "hold open" latches on dispenser nozzles can facilitate automated gasoline fueling and can minimize spills caused by improper fueling methods, including use of fixed objects such as gas caps, wallets, pieces of wood, etc., to keep dispenser latches open. It should be noted that "hold open" latches may not be allowed by local fire departments and may increase the potential for spills caused by customer drive-offs unless used in conjunction with break-away hoses.

R0059065

VOL 12 2 5773

2.2.4 PROVIDING CANOPIES AND USE OF CONCRETE FOR FUELING AREAS

Providing canopies over fueling areas can reduce storm water pollution caused by direct precipitation onto fueling areas. However, canopies may not be necessary for RGOs with effective good housekeeping and spill response procedures.

Portland Cement Concrete (PCC) can be used instead of asphaltic concrete in fuel areas. This is advantageous because asphalt soaks up fuel, or can be slowly dissolved by fuel, engine fluids, and other organic liquids. Over time, the asphalt itself can become a source of storm water pollutants.

2.2.5 AVOIDING STORM WATER RUNON

RGOs should be graded to prevent storm water runon to fuel islands and outdoor maintenance areas. Runon can also be prevented by installing berms, curbs, or valley gutters to redirect the runoff. It is also possible to redirect roof gutter downspouts so that they drain away from the fueling and maintenance areas.

2.2.6 MAINTENANCE PROCEDURES FOR EXISTING OIL & GREASE SEPARATORS AND OTHER TREATMENT BMPS

Any structural BMP, including oil and grease separators, drainage sumps, and catch basins, should be maintained regularly. This reduces the potential for re-suspension and transport of settled particulates, which can be a source of storm water pollutants. Proper maintenance of oil/grit separators includes periodic sediment clean out.

2.2.7 AVOIDING RGO WASH DOWNS

As described in Section 1.3.3 of this report, a study to evaluate the use of high-pressure washing as a storm water BMP was conducted for Sacramento County (Uribe and Associates, 1994). The results of the study indicated that regular high-pressure and high-temperature washing of pavement surfaces at RGOs can actually cause an increase in the concentrations of

R0059066

certain pollutants in storm water discharges. In addition, discharges to the street or storm drain system that result from RGO washdowns is prohibited by many municipalities. As an alternative, fuel dispensers should be regularly cleaned using a damp cloth or mop. Mop water should be discharged to a mop sink connected to the sanitary sewer. However, check with your local sewer authority regarding permitting or other requirements for mop water discharges to the sewer system.

2.2.8 SWEEPING EXPOSED AREAS

Regular sweeping of exposed areas, using hand brooms and/or vacuums, can be an effective storm water BMP. Sweeping may be most effective when conducted immediately prior to the wet season and forecasted rain events. Studies show that routine sweeping is effective in reducing concentrations of total suspended solids, particulate heavy metals, and hydrocarbons bound to particulates. In addition, pollutant removal rates are shown to vary directly with the frequency of sweeping. A street sweeping study in San Jose revealed approximate removal rates of 50 percent for heavy metals and total suspended solids when streets were swept once or twice a day (NVPDC, 1992). However, a significant reduction to less than 5 percent removal was observed when the frequency of sweeping dropped to once or twice a month (Pitt, 1979).

2.2.9 ELIMINATING NON-STORM WATER DISCHARGES AND ILLICIT CONNECTIONS

Non-storm water discharges and illicit connections are potentially significant sources of storm water pollution. An example of a non-storm water discharge is the wash water from vehicle or pavement washing that is discharged to the street or storm drain system. This type of discharge is prohibited by many municipalities. Examples of illicit connections are indoor drains or sinks that discharge to the storm drain instead of the sewer system. These illicit connections are also prohibited by most municipalities, and it is recommended that all RGOs be inspected to confirm that all illicit connections are eliminated.

VOL 12 2 5714

R0059067

VOL 12 2 5775

2.2.10 STANDARDIZING SPILL RESPONSE PLAN

A standardized spill response plan ensures that spills are promptly detected, contained as necessary, and properly cleaned up. An effective plan provides a well-defined set of spill response procedures and establishes a training program to educate all employees about the procedures. Typical spill response techniques at RGOs include using shop rags for small spills and using absorbent materials such as vermiculite, sawdust, or cat litter for larger spills. In addition, there are commercially available adsorbent materials that can be recycled. Used shop rags should be stored in a closed bin for recycling by a cleaning service. Separate wet/dry vacuums also can be used for larger motor oil and antifreeze spills. Due to their potential flammability, spilled gasoline, solvents, or other volatile liquids should be removed using absorbent materials. Depending on the type of spill, the used absorbent materials may have to be disposed of as a hazardous waste.

2.2.11 TRAINING EMPLOYEES

Employee training is a key component of pollution prevention. Routine employee training can take the form of distinct BMP training programs or incorporating BMP training into existing employee safety or other general training sessions. An effective training program emphasizes routine employee observations of product deliveries to USTs and frequent inspections of self-serve fueling areas and other customer-related operations. RGOs with maintenance and/or repair facilities should also emphasize routine employee shop inspection to ensure that operations do not adversely impact storm water.

2.2.12 PROVIDING OVERHEAD COVERAGE OF VEHICLE MAINTENANCE AND REPAIR AREAS

Conducting vehicle maintenance and repair activities under canopies or inside buildings is an effective pollution prevention measure. Overhead coverage includes use of temporary roofs, permanent roofs, sheds, or indoor facilities. Overhead coverage prevents direct storm water

R0059068

VOL 12 2 5716

contact with the maintenance area, which can potentially contribute automotive waste fluids to the storm water runoff.

2.2.13 PREVENTING DISCHARGES WHEN CHANGING FLUIDS

Preventing spills and other discharges in exposed maintenance and repair areas is an effective storm water BMP. A drip pan can be placed under a vehicle while disconnecting hoses, unscrewing filters, or removing other parts to capture the automotive fluids. However, if fluids are leaked onto exposed surfaces, proper spill response procedures should be performed, as described in Section 2.2.9 of this report.

2.2.14 USING PARTS CLEANING STATIONS

Using a self-contained parts cleaning station can prevent parts cleaning wash-off from contacting storm water. Parts cleaning wash-off can contain cleaning solvents, along with oil residues from the parts. Drip pans, drain boards, and drying racks can be installed as part of the cleaning station for drainage of parts cleaning wash-off into appropriate recycling or disposal equipment.

2.2.15 COLLECTING AND STORING FILTERS, WASTE OIL, AND OTHER FLUIDS

Proper collection and storage of oil filters, waste oil, and other fluids such as transmission fluid, degreasers, antifreeze, hydraulic fluid, and various cleaning solvents is an effective BMP. In addition, recycling these materials can significantly reduce the disposal costs associated with hazardous wastes. Many commercial recycling facilities pick up the wastes on site, but typically accept only separated wastes. Unseparated wastes are harder to recycle, and therefore, increase overall treatment costs. Used oil filters and fluids should be stored in covered drums. If the drums are stored in exposed areas, the drum exterior should be routinely checked for contaminants and wiped clean, if necessary.

R0059069

VOL 12 2 5777

2.3 Storm Water Treatment BMPs

In the event that the practical pollution prevention measures described above are determined to be insufficient, or in areas where additional controls are mandated, it may be necessary to install storm water treatment devices. Descriptions of the available treatment methods for RGO storm water runoff are provided in the following subsections. A summary of these treatment BMPs are included in Table 5. The BMPs described below are limited to those that can be used in urban areas where almost 100 percent of the surface is covered with structures or pavements, and where there is insufficient space available for relatively large structural storm water quality management facilities such as extended dry detention or wet ponds. The information presented is based on a review of published and unpublished studies, discussions with researchers with studies in progress, review of literature provided by manufacturers, and discussions with personnel from numerous regulatory agencies. The descriptions provide the approximate initial installation and yearly maintenance costs. Specific design information is not included in this report; however, references that provide sufficient design level information are cited and a list of useful references is attached to this report.

2.3.1 VEGETATIVE BUFFER AREAS

2.3.1.1 BMP Description

A vegetative buffer area (VBA), also referred to as a biofilter, is a nonstructural BMP designed to remove particulate pollutants by filtration through grass and infiltration through soil. According to U.S. EPA (1991), a VBA is designed as a permanent, maintained strip of planted or indigenous vegetation located between non-point sources of pollution and receiving water bodies to remove or mitigate the effects of non-point source pollutants such as nutrients, pesticides, sediments, and suspended solids. VBAs that are used as storm water conveyance systems usually are called grass swales. A schematic of a typical grass swale is presented as Figure 2.

R0059070

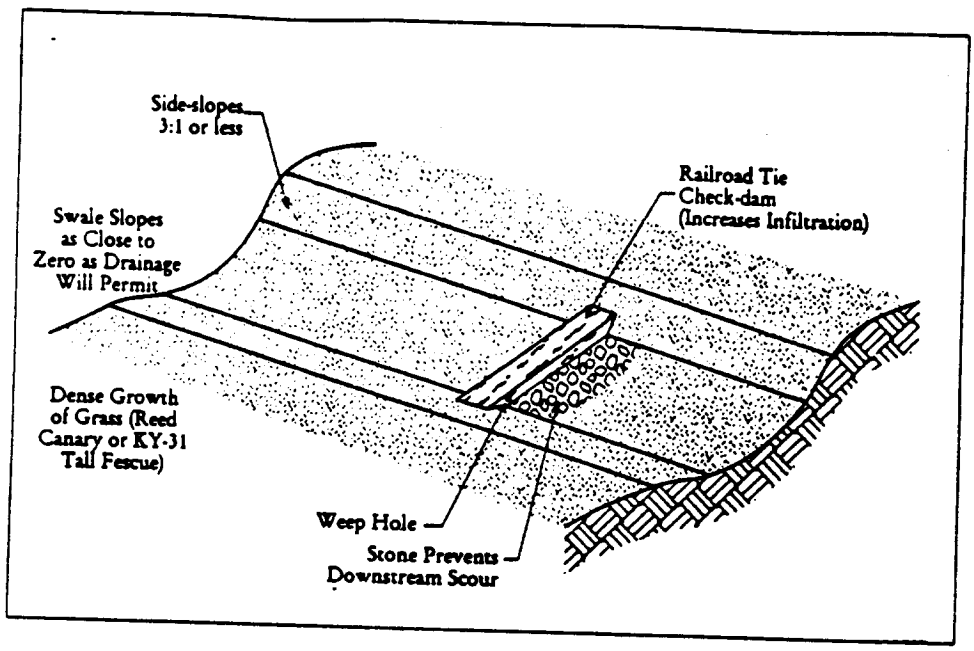

Figure 2 - Schematic of a Typical Grass Swale (MWCOG, 1987)

2.3.1.2 BMP Discussion

The vegetation in a VBA acts to filter and settle out particulate sediment and attached pollutants. The reduction in runoff velocity within the vegetated areas enhances the amount of settling and infiltration that occurs. Nutrient uptake, adsorption, and infiltration mechanisms may decrease the pollutant load entering the natural waterways. The reduced runoff velocity also lessens the potential for resuspension of particles as the flow travels toward the waterway (NVPDC, 1992). Results of modeling studies indicate that VBAs are somewhat effective in removing particulates, although settling is not optimized. VBAs are less effective in removing soluble nutrients (MWCOG, 1987).

Several methods have been proposed to size VBAs (Horner, 1988; FHWA, 1989; IEP, 1991; Tollner, et al., 1976). Using the method of Horner (1988) and assuming a 2-year event, a 3% slope, and a 4-inch grass height, the VBA area required to treat a 1/2 acre impervious site ranges between 400 and 650 square feet (Camp Dresser & McKee et. al., 1993). Typical design lengths for grass swales range from 100 to 200 feet (Horner, 1988). Studies have shown that

VOL 12 2 5718

R0059071

swales are most effectively used on sites with a minimal amount of impervious cover, where peak discharge is less than 5 cubic feet per second (cfs) and velocities are less than 5 feet per second (fps). For these reasons, VBAs may not be a practical on-site BMP for RGOs.

Because VBAs rely on infiltration, fuel leaks or spills may potentially contaminate subsurface soils and, in some cases, groundwater. Even if discharges from leaks and spills can be avoided, metals and other contaminants may accumulate in the subsoils. As with the other infiltration BMPs, there may be waste discharge permitting requirements for VBAs (Camp Dresser & McKee et. al., 1993).

2.3.1.3 Range of Costs

According to MWCOG (1992), construction costs for a typical grass swale may range from $5 to $15 per linear foot, depending on the swale dimensions, grass type, and other possible characteristics. Maintenance costs for swales are estimated to be fairly low. Typical maintenance includes replacement of non-vegetated areas, periodic sediment removal, routine inspections, mowing, watering, and chemical applications.

2.3.2 POROUS PAVEMENT

2.3.2.1 BMP Description

Porous pavements use infiltration to control storm water runoff. This BMP is applicable as a substitute for conventional asphalt pavement on parking areas and low-traffic-volume roads, provided that the grades, subsoil characteristics, and groundwater table conditions are suitable for such use. In general, the grades should be very gentle to flat, the subsoil should have at least moderate permeability ($f \geq 0.27$ in/hr), and the depth to groundwater should be 2 to 4 feet (State of Maryland Department of the Environment). As indicated on Figure 3, porous pavements usually are layered systems, consisting of a porous asphalt surface overlying two layers of aggregate base course. The upper base course layer is designed as a filter layer, and the lower layer serves as a reservoir. A typical porous pavement asphaltic concrete mixture has approximately 16 percent voids, as opposed to conventional asphaltic concrete, which has 3 to 5 percent voids (NVPDC, 1992). The design of the actual porous pavement system is a function of several factors, including the load-bearing capacity of the subgrade, the expected traffic

VOL 12 2 5719

R0059072

VOL 12 2 5780

volume, and the storage capacity of the reservoir course layer. In turn, the storage capacity of the reservoir course layer is designed with respect to the depth to bedrock and the high water table, design storm, design method, allowable detention time, and existing subsurface soil infiltration rates. For sites with relatively pervious subgrade conditions, a porous pavement may allow infiltration of approximately 60 to 90 percent of the storm water runoff, depending on the rainfall intensity, existing subsurface conditions, and the actual design method used (MWCOG, 1987).

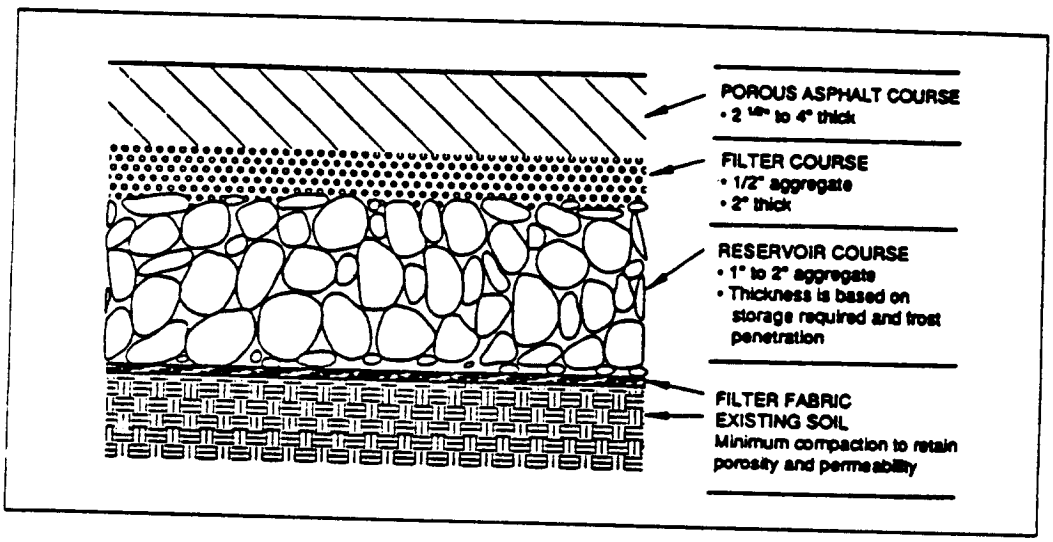

Figure 3 - Schematic of a Typical Porous Pavement (NVPDC, 1992)

2.3.2.2 BMP Discussion

Porous pavements may be an effective storm water BMP for some applications, however, because porous pavements are designed to allow rapid infiltration of storm water into subsurface soils, there is a significant potential for fuel leaks or spills to contaminate subsurface soils and, in some cases, groundwater. Also, depending on the types and concentrations of contaminants in the storm water discharge, metals and other contaminants may potentially accumulate in the subsoils. For these reasons, the use of porous pavements at RGOs is discouraged. Other problems associated with porous pavements are the high probability of pavement pore clogging from larger sized particulates and the absence of effective techniques to mitigate significant clogging that may occur. According to MWCOG (1992), 75 percent of all porous pavement

R0059073

VOL 12 2 5781

systems surveyed in Maryland have partially or totally clogged within five years. For this reason, pretreatment of storm water to remove particulates often is recommended. Other disadvantages of porous pavements include the high level of required construction workmanship, the reduced strength of the pavement system, and the necessity of frequent inspections and maintenance after construction. Also, waste discharge permits may be required for infiltration BMPs, including porous pavements (Camp Dresser & McKee et. al., 1993).

2.3.2.3 Range of Costs

In general, a porous asphalt system may cost as much as 50 percent more than a conventional asphalt section and the necessary materials may be difficult to obtain in some regions of the country. An average additional construction cost over conventional asphaltic pavement was calculated by MWCOG (1987) for a 1-acre porous pavement BMP parking lot, using an 18-inch-thick reservoir course. The calculated construction cost was $75,054 greater than the cost of a conventional pavement section. This estimate did not include costs for initial site testing or pretreatment structures. Routine maintenance of porous pavements may constitute one to two percent of the initial construction costs (MWCOG, 1992).

2.3.3 INFILTRATION TRENCHES

2.3.3.1 BMP Description

An infiltration trench is a shallow excavation filled with a coarse stone medium to create an underground reservoir. The infiltration trench is designed to collect, store, and slowly exfiltrate storm runoff, relying on native subsurface biological, chemical, and physical pollutant removal mechanisms for treatment. A schematic of a typical infiltration trench is presented as Figure 4. The depth of the trench typically ranges from 2 to 10 feet, and the stone medium typically consists of washed aggregate with diameters of 1.5 to 3 inches (State of Maryland Department of the Environment). Infiltration trenches are only suitable for sites with relatively permeable subsurface conditions. It usually is recommended that an infiltration trench be installed at sites in conjunction with a pretreatment device (such as a filter strip, sump basin, or oil/grit separator) to remove particulate matter.

R0059074

GEOMATRIX

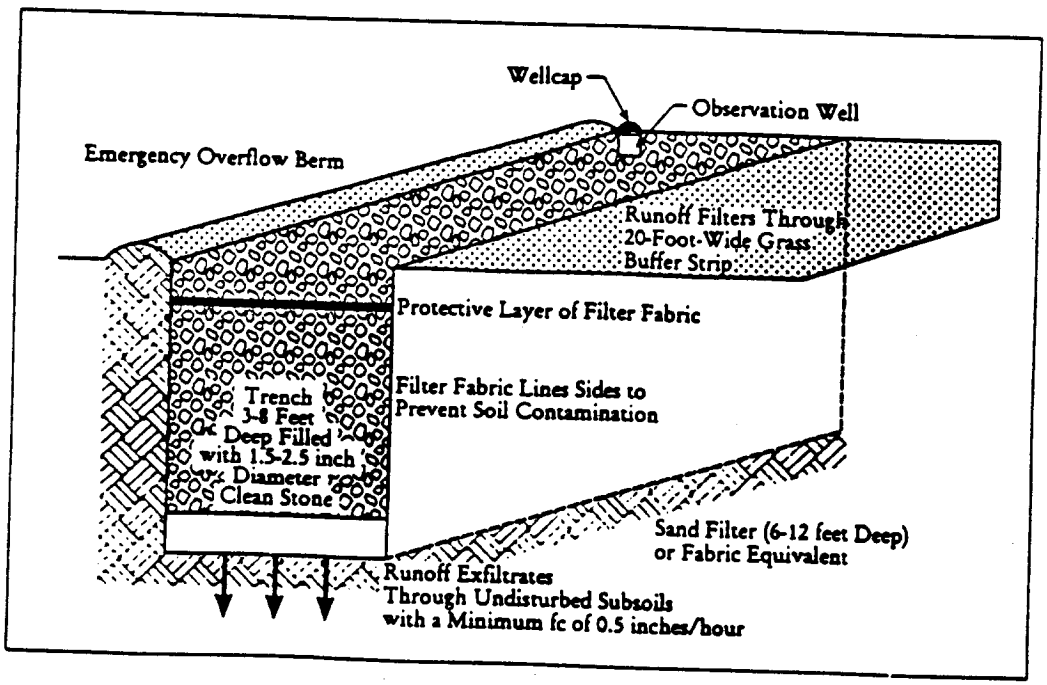

Figure 4 - Schematic of a Typical Infiltration Trench (MWCOG, 1987)

2.3.3.2 BMP Discussion

Where conditions are suitable, an infiltration trench is an adaptable BMP that effectively eliminates discharges containing soluble and particulate pollutants. However, as with other infiltration systems, trenches are not intended to trap coarse sediments and pretreatment is often necessary.

As with porous pavements, infiltration trenches are designed to allow rapid infiltration of storm water into subsurface soils. For this reason, there is a potential for fuel leaks or spills to contaminate subsurface soils and, in some cases, groundwater. RGOs that use infiltration trenches should be provided with a drainage sump equipped with a shut-off valve that can contain spills prior to discharge into the infiltration trench. In addition, depending on the types and concentrations of contaminants in the storm water discharge, metals and other contaminants may accumulate in the subsoils. There may also be waste discharge permitting requirements associated with use of infiltration trenches (Camp Dresser & McKee et. al., 1993).

VOL 12 2 5782

R0059075

VOL 12 2 5783

Several studies of existing infiltration trenches have revealed high failure rates. A study by Galli (1992) indicated that less than half of the nearly 50 infiltration trenches surveyed were working as designed. Another study indicated that less than one-third still functioned after five years (Schueler, 1994). Failure of infiltration trenches usually is the result of clogging, which can be caused by a variety of factors, including inadequate pretreatment devices and/or an unsatisfactory subsurface location (including poor soil infiltration rates and close proximities to bedrock and/or water table).

2.3.3.3 Range of Costs

The construction cost of infiltration trenches is dependent on the excavation, stone fill, filter cloth, and inlet and outlet pipe costs. Construction costs of trenches with storage volumes ranging from 100 to 10,000 cubic feet range from $1,000 to $10,000 (Wiegand et. al., 1986). Operation and maintenance costs for infiltration trenches range from 5 to 15 percent of the capital cost of the facility, with an average cost of 9 percent (NVPDC, 1992). Also, possible replacement or rehabilitation of infiltration trenches may be required every ten years, and the cost of this may be equal to the initial construction cost (MWCOG, 1992).

2.3.4 SEPARATORS

2.3.4.1 BMP Description

The terms oil/grit separator, oil/water separator, oil and grease trap, and water quality inlet are often used interchangeably to describe treatment devices commonly installed to remove separate-phase hydrocarbons and, in some cases, sediment from storm water runoff. These devices are adaptations of the American Petroleum Institute (API) separator. A schematic of a separator is presented as Figure 5. The separator usually is a long basin with multiple chambers or vaults, typically installed below grade. The devices can be fairly easily fitted into an existing drainage system. The separator is designed to slow water flow which promotes settling of particulates and stratifies the flow to enhance phase separation. In this manner, the heavier particulates settle out, and the oil and grease rise for removal and disposal.

Another type of separator, called the coalescing plate interceptor (CPI) separator has a more advanced design. The CPI separator contains closely spaced plates, which enhance

R0059076

VOL 12 2 5784

removal efficiencies. These are common for treating oil-bearing industrial wastewater, but, because they are typically designed to treat low flow rates with relatively high concentrations of oil, they are not typically used for treating storm water. A CPI separator generally achieves a greater removal efficiency than an API-type separator, but is more costly to purchase and operate.

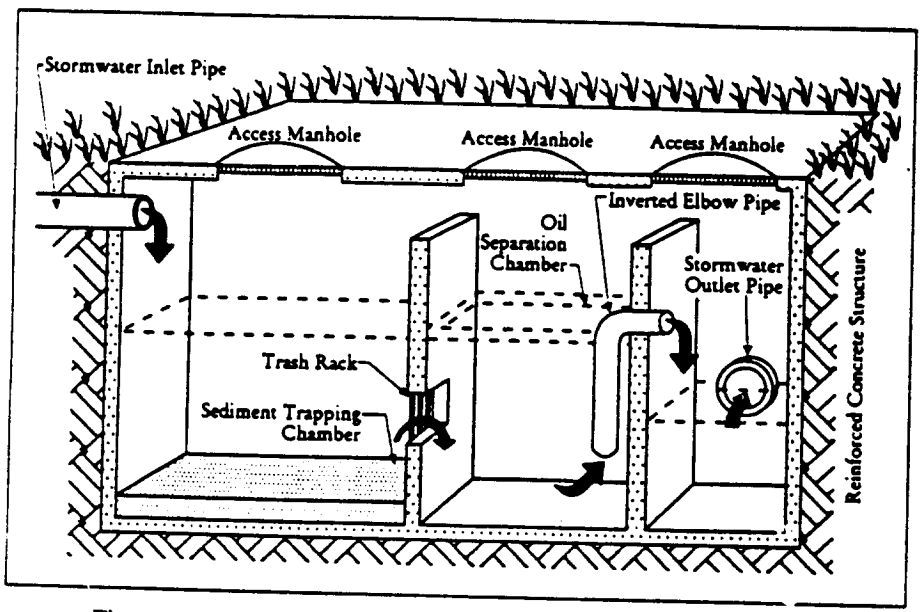

Figure 5 - Schematic of a Typical Oil/Grit Separator (NVPDC, 1992)

2.3.4.2 BMP Discussion

Although separators are commonly used, and are required in certain municipalities, recent research suggests that they are not appropriate as a storm water BMP. Separators are fairly costly to install and maintain, and most designs do not operate effectively with the low oil and grease concentrations typically found in properly operated and maintained RGOs. These devices are moderately effective for removing coarse-grained particulates along with hydrocarbons adsorbed onto particulates, but are typically not effective for removing fine-grained particulates or dissolved contaminants (NVPDC, 1992; MWCOG, 1987).

One significant problem with the use of separators as a storm water BMP is that the devices are typically designed as on-line systems with limited storage capabilities. This results in short detention times, which can cause significant re-suspension and discharge of pollutants. The

R0059077

VOL 12 2 5785

Northern Virginia BMP Handbook (1992) states that the average detention time of a conventional oil/grease separator system is barely more than one hour. Galli (1992) also demonstrated that the detention time within separators frequently is less than 30 minutes during storms. According to the California BMP Manual (Camp Dresser & McKee et. al., 1993), to provide the detention times necessary to effectively treat the majority of runoff resulting from a moderate storm event at a 1/2 acre paved site, a separator 57 feet long is required.

Alternative system designs treat the runoff only from the first approximate 0.06 to 0.12 inch of runoff and bypass the remainder for direct discharge. Although this methodology is somewhat effective in reducing the re-suspension of pollutants, it is ineffective for treating the volume of storm water customarily recommended or required. In Virginia, the Water Quality Volume (WQV), which is the minimum quantity of storm water that must be treated, is 0.5 inch. To store and effectively treat the volume of storm water that would result from this amount of rainfall, the separators would have to be significantly larger than those currently used at most sites.

In addition to alternative designs that bypass peak storm water discharges, several vendors currently offer innovative alternate designs that appear to significantly reduce the potential for re-suspension. However, these devices still rely on phase separation for removal of oil and grease, and have not been demonstrated effective for reducing the relatively low oil and grease concentrations typical of RGOs.

Maintenance is another factor that should be considered when evaluating separators. To function as designed, these devices require regular and frequent clean-out of trapped sediments to minimize re-suspension. The standing pool of water contained within the first chamber, along with the floating oil, must be periodically pumped out and replaced with clean water. Some commercial oil recyclers may accept this material for recycling; otherwise, it must be handled as hazardous waste. The maintenance requirements for separators have been termed the "Achilles heel" of existing separator technology. One study conducted in Maryland (Schueler, 1993) found not a single separator system out of more than 100 inspected that had ever been maintained. According to Schueler (1994), this poor track record is the result of several factors, including: a lack of outside companies that perform the required maintenance; a lack of enforcement by regulators; the expense associated with maintenance; and the actual or perceived

R0059078

VOL 12 2 5786

toxicity of the trapped sediments, resulting in limited options for safe and economical sediment disposal.

2.3.4.3 Range of Costs

The purchase and installation costs for a standard API-type system ranges from approximately $5,000 to $15,000 depending on the size and location of the facility (NVPDC, 1992). In general, separator systems are costly on a runoff volume treated basis, averaging three to four times the unit cost of other BMPs such as trenches or sand filters (MWCOG, 1992). Maintenance costs are estimated to range from $1,000 to $2,000 per site each year (Schueler, 1994).

2.3.5 SAND FILTERS

2.3.5.1 BMP Description

Sand filters are a type of structural BMP that relies on sedimentation and sand filtration to remove total suspended solids, hydrocarbons, and heavy metals. Sand filter technology is rapidly advancing, and a number of sand filter designs are currently available. A schematic of one design, the D.C. Sand Filter, is presented as Figure 6. The D.C. Sand Filter is a three-chamber gravity-flow system. The first chamber and a portion of the second chamber contain a permanent pool, which traps grit and floating material, including oil and grease. The remaining portion of the second chamber contains a 24-inch-thick sand filter underlain by a layer of filter fabric, gravel, and collector pipes. Storm water entering the structure causes the pool to rise and overflow onto the filter. The water percolates through the sand and into the underdrain system. The water then enters a clearwell and is discharged through a connector pipe. Depending on the depth of the sand filter installation and the elevation of the street, storm drain, or other conveyance, it may be necessary to use a sump pump to discharge the treated storm water.

The D.C. Sand Filter is designed as an off-line system that treats only the initial discharge or water quality volume (WQV) from a storm event. The WQV typically used is the volume of runoff from the first 0.5 inch of rainfall. For a 1/2-acre, entirely impervious RGO, the WQV is approximately 900 cubic feet of water. A flow splitter is normally used to divert the remainder of the discharge for direct discharge. The WQV must be stored until it can be processed through

R0059079

the sand filter. To store and treat this volume of storm water, the underground vault needs to be 10 feet deep, 10 feet wide, and 23.5 feet long (City of Alexandria).

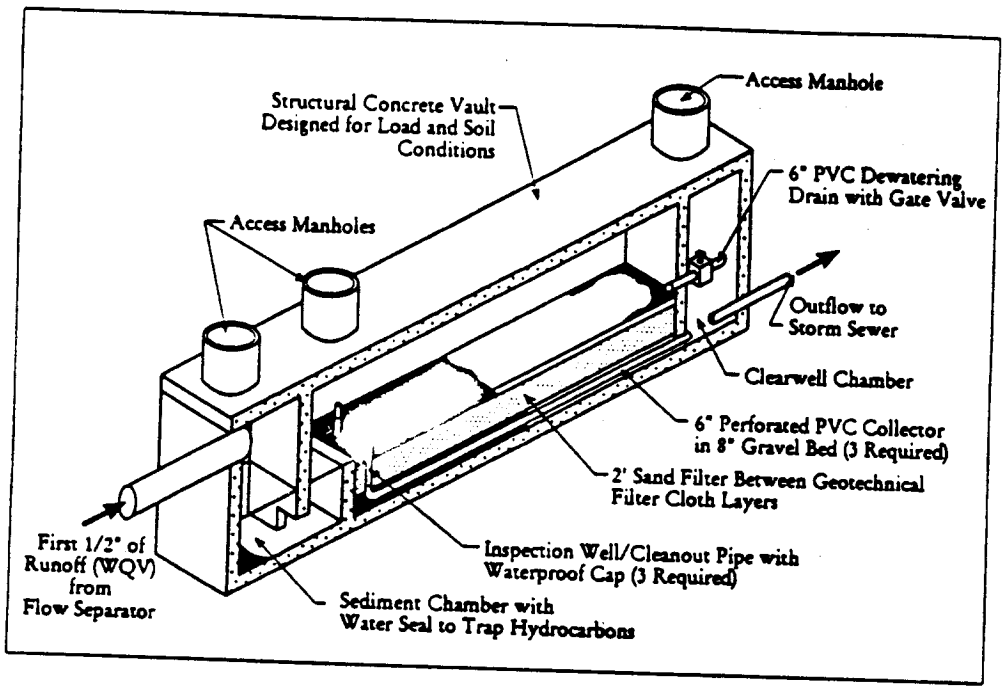

Figure 6 - Schematic of a D.C. Sand Filter (City of Alexandria, 1995)

A schematic of another type of sand filter, the Delaware Sand Filter, is presented as Figure 7. This filter consists of two parallel chambers connected by closely spaced notches in the top of the connecting wall. The filter is normally installed in-line. The first chamber is a sedimentation chamber with a permanent pool. Storm water flows into the first chamber through steel grates that cover the top of the chamber. As storm water enters the system, the permanent pool overflows through the weir notches into the second chamber, which contains an 18-inch-thick sand filter. The storm water percolates through the filter and is discharged through a filter fabric-covered grate located at the downhill end of the filter chamber. In some cases, a gravel bed and collector pipe are placed below the sand filter. The Delaware Sand Filter is designed to accept discharge until it has reached the capacity of the sedimentation chamber. The remaining storm water volume overflows and is discharged without treatment.

VOL 12 2 5787

R0059080

GEOMATRIX

VOL 12 2 5788

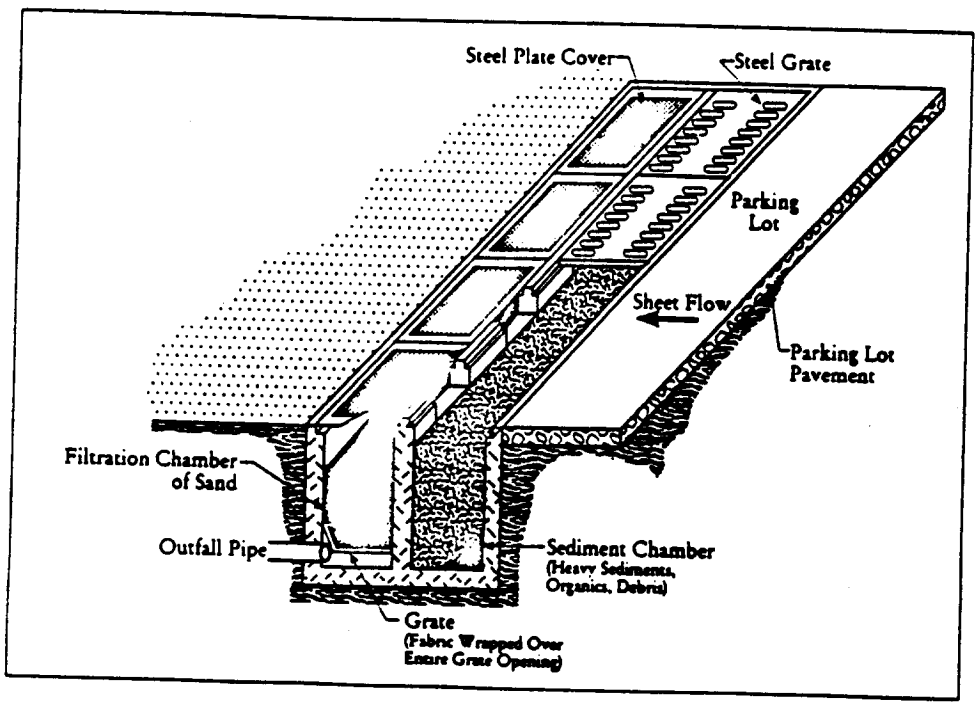

Figure 7 - Schematic of a Delaware Sand Filter (Bell & Nguyen, 1995)

2.3.5.2 BMP Discussion

Several studies have evaluated the performance of sand filters for treating storm water (City of Austin, 1991; Bell & Nguyen, 1995; Horner, 1994). The results of these studies indicate that sand filters are effective in removing particulate pollutants such as total suspended solids, lead, zinc, organic carbon, and organic nitrogen, with removal efficiencies generally exceeding 75 percent. These studies have not provided information regarding capabilities for removing dissolved metals. In some cases this could be significant, because dissolved metals are more mobile and toxic than particulate metals. The studies do indicate that sand filters can discharge nitrate and total dissolved solids, resulting in effluent concentrations of these constituents that are actually higher than influent concentrations. The net increase in nitrate concentrations suggests that nitrification may be occurring in the filter media. The net increase in total dissolved solids concentrations has been attributed to preferential leaching of cations from organic matter trapped on the surface of the sand (Schueler, 1994).

R0059081

Sand filters appear to be prone to clogging, particularly in areas where high concentrations of suspended solids are present in storm water. Clogging problems are greatly reduced in areas that are completely impervious. The sedimentation chambers are also prone to freezing when used in colder climates. One significant concern with vault filters, such as the D.C. Sand Filter, is the buildup of potentially explosive gases within the vault and the determination that the vault is considered a "confined space," requiring special health and safety procedures for entry.

Routine maintenance is a fundamental requirement for the proper functioning of sand filters. In general, maintenance operations for sand filters include periodic excavation and replacement of the top layer filter media, regular removal of trash and other larger-sized debris, and routine visual inspections of the overall filter unit, particularly after storm events. Specific recommended maintenance for D.C. Sand Filter units include semi-annual pumping and refilling of the first chamber permanent pool, and replacement of the top two to three inches of sand or overlaying layers of geotechnical cloth every three to five years (Bell & Nguyen, 1995). The disposal of used sand filter media can be an additional maintenance burden if it is classified as a hazardous waste material.

2.3.5.3 Range of Costs

Construction costs for sand filters range from approximately $10,000 to $20,000 per impervious acre treated (Schueler, 1994). Maintenance costs for sand filters have been estimated to be approximately 5 percent of the construction cost per year (MWCOG, 1992), with the required maintenance operations including raking, disposal of contaminated sand, and trash and debris removal.

2.3.6 COMPOST FILTERS

2.3.6.1 BMP Description

Compost filters are similar to sand filters, except they use compost instead of sand for the filter media. Filtration through compost provides filtration, ion exchange, molecular adsorption, and biodegradation for pollutant removal. Currently, leaf compost is the most widely used compost media in storm water compost filters. A suitable compost has maturity, low

VOL 12 2 5189

R0059082

contaminant levels, and high humic acid content and permeability (Schueler, 1994). Filtration through compost is a patented process. The patent holder, CSF Treatment Systems, has developed a drop-in compost storm water filter unit that is sized for small impervious sites such as RGOs. A schematic of a drop-in unit is presented in Figure 8. The drop-in unit is a three-chamber system. The first chamber collects and disperses the flow over the filter media. The second chamber contains an energy dissipator, a scum baffle, the compost filter media, and an overflow route. As storm water enters the second chamber, the design flow is filtered through the media, collected by a perforated underdrain system, and then discharged through a connector pipe. If the design storm is exceeded, overflow into the third chamber will occur and storm water will be discharged without treatment. Depending on the depth of the compost filter installation and the elevation of the street, storm drain or other conveyance, it may be necessary to use a sump pump to discharge the treated or bypassed storm water.

The drop-in unit is an in-line storm water treatment structure. It is typically installed below grade and its pre-cast concrete vaults range from a 6-foot by 12-foot to an 8-foot by 18-foot configuration. These vaults can be connected in series or parallel, depending on the design flow rate. Single drop-in units are rated to treat storm water discharges between 0.28 and 0.64 cubic feet per second. The drop-in filter is sized to handle a maximum of 2.5 gallons per minute per square foot of filter surface area (CSF, 1995).

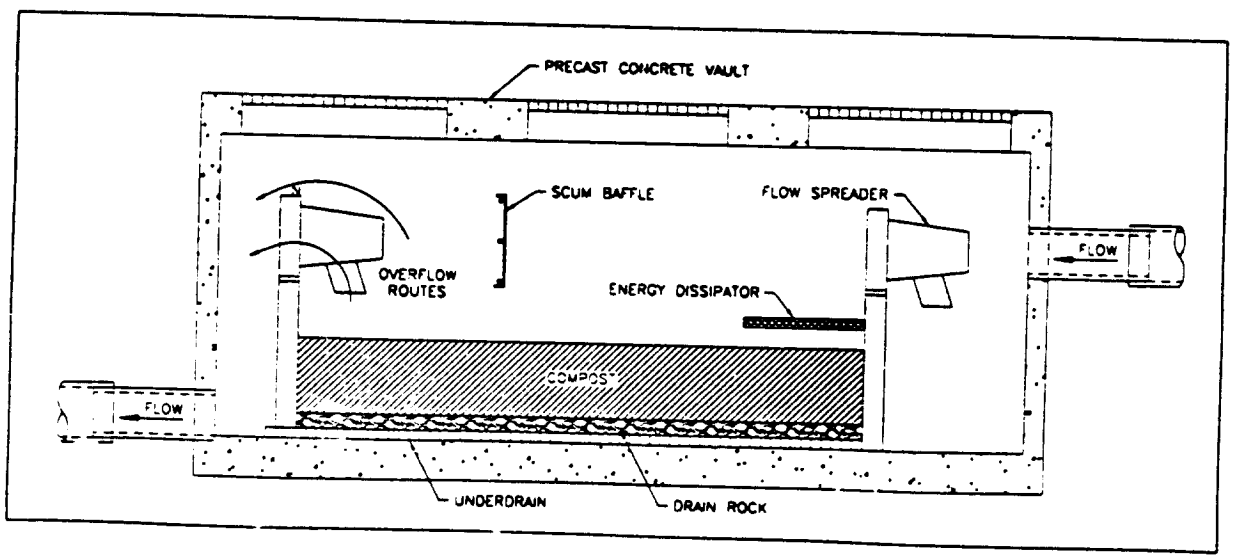

Figure 8 - Schematic of a Drop-In Compost Filter Unit (CSF, 1995)

VOL 12 2 5190

R0059083

VOL 12 2 5791

2.3.6.2 BMP Discussion

A limited number of compost filters have been installed to date, and there is limited independent data regarding the actual performance. Based on results provided by the manufacturer, the drop-in CSF unit averages approximately 90 percent removal for total suspended solids, and ranges from 85 to 95 percent metals removal. The drop-in unit has also shown high efficiencies in removal of hydrocarbons and oil and grease at the low concentrations (5 to 10 ppm) typical of RGO operations. Average removal rates for hydrocarbons and oil and grease at these concentrations are approximately 80 percent. The Snohomish County (Washington) Surface Water Management Agency, which considers the compost filter to be an experimental BMP, has recently installed two compost filters. The performance of these filters will be monitored over the next wet season.

Some deficiencies of the compost filter system include the potential for a net increase in the concentrations of certain pollutants, including orthophosphorous, organic nitrogen, and total dissolved solids, in the compost filter discharge. The increase in orthophosphorous concentrations may be due to the inability of compost to perform anion exchange of soluble phosphorous, and the increase in organic nitrogen may suggest the occurrence of nitrification within the filter media. The increase in total dissolved solids may be explained through possible cation leaching processes within the compost filter media.

2.3.6.3 Range of Costs

In the northwest, initial costs for drop-in units designed for small sites such as RGOs range between $17,000 and $25,000 (CFS, 1995). For drop-in units, the manufacturer recommends that the compost media be replaced annually. The cost of this maintenance procedure should range from $800 to $1,200 per year (CFS, 1995). According to information provided by the manufacturer, the used compost can be directly landfilled as a non-hazardous waste.

R0059084

VOL 12 2 5192

2.3.7 CATCH BASIN INSERTS

2.3.7.1 BMP Description

Catch basin inserts are filtering devices that can be inserted into existing catch basins. Catch basin insert types include felt bags, tray(s), or "lobster trap" filters. A tray configuration is presented as Figure 9. Catch basin inserts are designed to remove suspended solids, trace metals, and hydrocarbons through mechanical straining, particle settling, and physical adsorption processes.

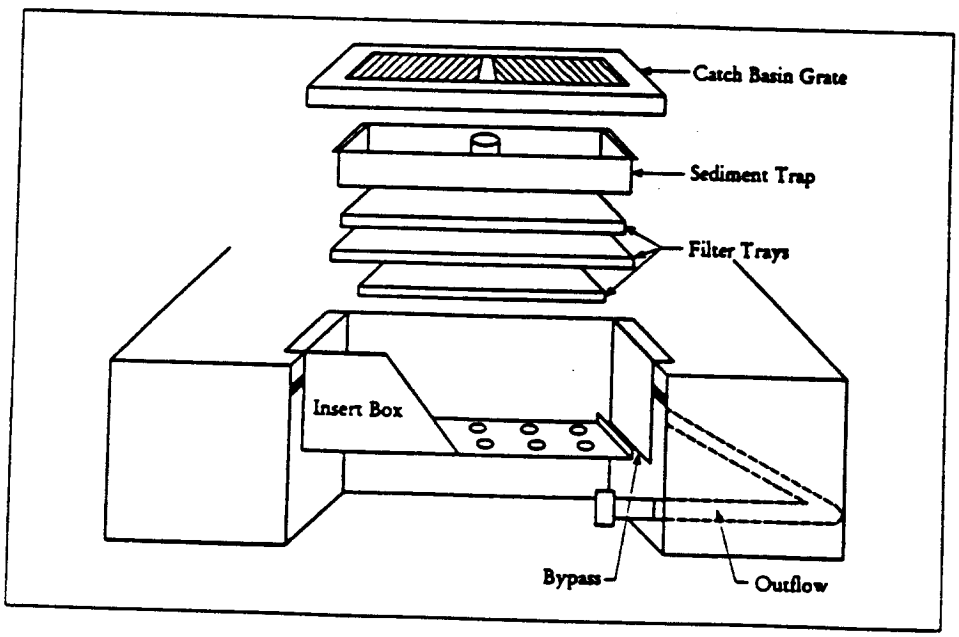

Figure 9 - Schematic of a Catch Basin Insert Tray (McPherson, 1992)

2.3.7.2 BMP Discussion

Results of one study on filter inserts indicates that filter inserts are nominally effective in removing fine sediment and associated pollutants and somewhat more effective in removing coarse material and debris (Interagency Catch Basin Insert Committee, 1995). There is little information regarding the effectiveness for hydrocarbons at the low inflow concentrations typical of properly operated and maintained RGOs. The available data does suggest, however, that removal efficiencies for hydrocarbons are low at low inflow concentrations and somewhat higher

R0059085

for high inflow concentrations. Clogging appears to be a potential problem with filter inserts, even on sites that are completely paved. In addition, preliminary indications are that the filters may require frequent replacement or cleaning.

2.3.7.3 Range of Costs

One vendor listed initial costs ranging from $1,600 to $3,200 for a three-tray filter with a flow rate capacity of 180 gpm. Annual maintenance costs for this three-tray system ranged from $6 to $520, depending on the frequency of maintenance and the respective filter media used. Disposal costs also need to be considered, and can vary considerably depending upon the classification of the used filter material waste.

R0059086

GEOMATRIX

VOL 12 2 5794

SECTION 3.0 -- CONCLUSIONS

Based on the results of several storm water studies, it appears that the contaminant levels in storm water runoff from properly operated and maintained RGOs are not appreciably different from those of many other similar sources, such as parking lots and streets. In most cases, the mean concentrations of oil and grease, total suspended solids, and chemical oxygen demand in storm water runoff from RGOs are below the NPDES storm water permit limitations set by several states for vehicle-related activities.

Properly operated and maintained RGOs may currently be implementing a variety of BMPs to reduce storm water contaminant concentrations. Two basic categories of BMPs are presented in this paper. The first category consists of practical pollution prevention measures. These are the basic, common operational practices and relatively simple facility modifications that are effective in preventing storm water pollution. The second category consists of storm water treatment BMPs. These include structural controls that involve installation of equipment to reduce contaminant concentrations in storm water runoff.

Practical pollution prevention measures are appropriate for RGOs because they are simple, cost effective, and protective of storm water quality. In contrast, the storm water treatment BMPs are less appropriate for RGOs because they are ineffective or unproven for treatment of low contaminant concentrations and are relatively expensive to install and maintain.

Table 5
Summary of Storm Water BMPs

BMP	Description	BMP Considerations	Approximate Range of Costs[1]	Suitability for RGOs[2]
Using Spill Containment & Overfill Prevention Equipment	Prevents spills caused by overfilling USTs.	Federally required by 1998, already required in some areas.	Initial costs - high O&M costs - moderate	Suitable for RGOs.
Posting Signs Warning Against "Topping Off"	Minimizes spill occurrences by reminding employees and customers not to top off tanks.	None	Initial costs - low O&M costs - low	Suitable for RGOs.
Installing dispenser "hold open" latches	Minimizes spill occurrences by automating fuel dispensing.	Prevents use of fixed objects such as gas caps, wallets, pieces of wood, etc. to keep dispenser latches open. Can increase potential for spills caused by customer drive-offs unless used in conjunction with break away hoses. May not be allowed by local fire departments.	Initial costs - low to moderate O&M costs - low	Suitable of RGOs.
Providing Canopies and Use of Concrete for Fueling Areas	Canopies over fueling areas can minimize contact of storm water with potential pollutants. Portland Cement Concrete pavements are less prone to soak up fuel than asphaltic concrete.	Canopies also shield customers from sun and rain.	Initial costs - high O&M costs - low to moderate	Suitable for RGOs.
Avoiding Storm Water Runon	Reduces contact of storm water with fueling and maintenance areas.	Should be considered in the initial design of an RGO. Difficult to retrofit in most cases.	Initial costs - low (Initial costs for retrofit can be high) O&M costs - low	Suitable for RGOs.
Maintaining Existing Oil & Grease Separators and other treatment BMPs	The pollutant removal capabilities of oil & grease separators and other treatment BMPs can be maximized by conducting regular sediment cleanout.	Disposal of sediments removed must be properly managed.	Initial costs - N/A O&M costs - low to moderate	Suitable for RGOs with existing structural BMPs.

R0059096

GEOMATRIX

Table 5 (Continued)
Summary of Storm Water BMPs

BMP	Description	BMP Considerations	Approximate Range of Costs[1]	Suitability for RGOs[2]
Avoiding RGO Wash Downs	Discharges from RGO wash downs may violate local municipal ordinances and may introduce pollutants to the storm drain system.	Discharges to the sanitary sewer from RGO wash downs may require permits.	Initial costs - low O&M costs - low	Suitable for RGOs.
Sweeping Exposed Areas	Removes particulates thereby reducing the concentrations in storm water runoff.	BMP also enhances RGO appearance.	Initial costs - low O&M costs - low to moderate	Suitable for RGOs.
Eliminating Non-Storm Water Discharges and Illicit Connections	Can eliminate potentially significant sources of storm water pollution.	Discharges from floor drains or other sources to the sanitary sewer may require permits.	Initial costs - low to moderate O&M costs - low	Suitable for RGOs.
Standardizing Spill Response Plans	Eliminates a potential source of storm water pollution by ensuring that spills are promptly detected, contained as necessary, and properly cleaned up.	Employees should be trained to properly implement the spill response plan.	Initial costs - low O&M costs - low	Suitable for RGOs.
Training Employees	Ensures that inspections and spill response procedures are properly conducted by employees.	Training program should emphasize routine inspections and standardized spill response procedures.	Initial costs - low O&M costs - low	Suitable for RGOs.
Providing Overhead Coverage of Vehicle Maintenance and Repair Areas	Prevents direct storm water contact with potential storm water pollution sources.	None	Initial costs - low to high O&M costs - low to moderate	Suitable for RGOs.
Preventing Discharges When Changing Fluids	Eliminates a potential source of storm water pollution.	Recycling fluids when possible can reduce disposal costs.	Initial costs - low O&M costs - low	Suitable for RGOs.

Table 5 (Continued)
Summary of Storm Water BMPs

BMP	Description	BMP Considerations	Approximate Range of Costs[1]	Suitability for RGOs[2]
Using Parts Cleaning Stations	Prevents parts cleaning wash-off from contacting storm water.	Recycling fluids when possible can reduce disposal costs.	Initial costs - low to moderate O&M costs - moderate	Suitable for RGOs.
Collection and Storage of Oil Filters, Waste Oil, and Other Fluids	Minimizes contact of storm water with potential pollutants.	Used oil filters and automotive fluids should be stored in covered drums. The exterior of drums stored in exposed areas should be wiped clean on a routine basis.	Initial costs - low O&M costs - low	Suitable for RGOs.
Catch Basin Inserts	Filters storm water using devices that are inserted into existing catch basins.	Filter inserts appear to be nominally effective in removing fine sediment and associated pollutants and somewhat more effective in removing coarse material and debris. There is little information regarding the effectiveness for hydrocarbons at the low inflow concentrations typical of properly operated and maintained RGOs. The available data does suggest, however, that removal efficiencies for hydrocarbons are low at low inflow concentrations and somewhat higher for high inflow concentrations. Clogging appears to be a potential problem and frequent replacement may be necessary.	Initial costs - low to high O&M costs - low to high	May prove to be suitable for RGOs, but additional study is necessary to confirm effectiveness with low hydrocarbon inflow concentrations. Use may not be warranted where practical pollution prevention measures effectively control pollutants.
Sand Filters	Relies on sedimentation and filtration through sand to remove total suspended solids, hydrocarbons, and heavy metals.	Effective for removing particulate pollutants. Limited data regarding effectiveness for removing dissolved pollutants. May cause an increase in concentrations of nitrates and total dissolved solids.	Initial costs - high O&M costs - moderate	May be suitable for RGOs but may not be warranted where practical pollution prevention measures effectively control pollutants.

R0059098

GEOMATRIX

Table 5 (Continued)
Summary of Storm Water BMPs

BMP	Description	BMP Considerations	Approximate Range of Costs[1]	Suitability for RGOs[2]
Compost Filters	Relies on sedimentation and filtration through compost to remove total suspended solids, hydrocarbons, and heavy metals.	Still considered to be an experimental BMP by many regulators and there is limited independent data regarding pollutant removal capabilities. Results provided by the manufacturer indicate a 90 percent removal for total suspended solids, 80 percent removal for hydrocarbons, and 85 to 95 percent removal for metals. The net export of orthophorous, organic nitrogen, and total dissolved solids may be problematic.	Initial costs - high O&M costs - moderate to high	May prove to be suitable for RGOs but additional independent study is necessary to confirm effectiveness. Use may not be warranted where practical pollution prevention measures effectively control pollutants.
Vegetative Buffer Areas	Removes particulate pollutants by filtration through grass and infiltration through soil.	Requires a fairly large surface area which may be problematic for highly urbanized areas and retrofits. Studies have indicated that vegetative buffer areas are somewhat effective for removing particulates and less effective in removing soluble nutrients. Because vegetative buffer areas rely on infiltration, there is a potential to contaminate subsurface soil and, in some cases, groundwater.	Initial costs - moderate to high O&M costs - low to moderate	Not suitable for most RGOs as detailed in BMP considerations.
Infiltration Trenches	Collects, stores, and slowly exfiltrates storm water runoff into subsoils.	For sites with permeable subsoils, an infiltration trench can effectively eliminate storm water discharges containing soluble and particulate pollutants. However, use at RGOs is problematic because of the significant potential for fuel leaks or spills to contaminate subsurface soils and, in some cases, groundwater. Studies have indicated high failure rates caused by clogging.	Initial costs - moderate to high O&M costs - moderate to high	Not suitable for most RGOs as detailed in BMP considerations.

R0059099

GEOMATRIX

Table 5 (Continued)
Summary of Storm Water BMPs

BMP	Description	BMP Considerations	Approximate Range of Costs[1]	Suitability for RGOs[2]
Porous Pavement	Specially designed pavements allow infiltration of approximately 60 to 90 percent of the storm water runoff.	Use is limited to sites with relatively pervious subgrade conditions. Use at RGOs is problematic because of the significant potential for fuel leaks or spills to contaminate subsurface soils and groundwater. Studies also indicate a significant problem with clogging.	Initial costs - high O&M costs - moderate to high	Not Suitable for RGOs.
Separators	Designed to slow water flow which promotes settling of particulates and stratifies flow to enhance phase separation.	Most designs do not operate effectively with the low oil and grease concentrations typical of properly operated and maintained RGOs. Limited ability to remove fine-grained particulates and trace metals. On-line systems with insufficient detention times may cause re-suspension of pollutants.	Initial costs - high O&M - moderate	Not suitable for RGOs.

[1] Basis for cost estimates: Initial costs, Low: < $999, Moderate: $1000 to $5,000, High: $5000+; Operation and maintenance costs; Low: < $499 per year, Moderate: $500 to $999 per year, High: $1000+ per year

[2] Suitability determination based ability of BMP to effectively reduce concentrations of contaminants in storm water discharges from properly operated and maintained RGOs.

Automotive-Related Industries

Best Management Practices for Storm Water and Industrial Sanitary Sewer Pollution Control

Storm drains and sanitary sewers are the two principal routes by which pollutants reach Santa Monica Bay. Storm drains carry runoff from streets, urban centers, industrial sites, and open spaces into local streams, creeks, marshes, and beaches. Sanitary sewers carry wastes to wastewater treatment plants, but small amounts of some pollutants reach the Bay in the treated water. This manual explains how you can operate your shop to reduce the amounts of antifreeze, heavy metals, oily wastes, and other substances you discharge into storm drains and sanitary sewers. Understanding and using this manual will help you keep your shop in tune, protect the Bay, and comply with local storm water pollution requirements and wastewater discharge restrictions.

R0059103

Keep Your Shop in Tune

If your shop is tuned up and running smoothly, you will generate fewer wastes. Following the practices described in this manual will help keep heavy metals, oils, grease, and other pollutants out of the Bay.

This manual describes specific Best Management Practices (BMPs), and is intended as guidance on pollutant control for automotive shops and other automotive-related industries. Many formerly non-regulated activities are now coming under increasing scrutiny and some once acceptable practices are no longer allowed. BMPs are recommended procedures that will assist you in complying with environmental requirements of your municipality, California state agencies, and federal agencies. Specific regulations may vary from one municipality to another, so you should use this manual in conjunction with the ordinances in your community.

This section summarizes the principles behind the BMPs and describes the general guidelines you can use to keep your shop in tune. Specific BMPs are described in the following section.

Run a dry shop.

You can comply more easily with storm water and sanitary sewer requirements by cutting down on the liquids you discharge. If you are successful, your discharge will be limited to wastewater from your lavatories and rain water from your roof and parking lot. Any drains that carry wastewater from your shop must be connected to the sanitary sewer, never the storm drain. Check with your sanitary wastewater authority before connecting any drains to the sanitary sewers; sanitary sewer connections require the approval of the wastewater authority. The floor drainage may also need to be treated before discharge.

Clean up leaks, drips, and other spills without water whenever possible. Use rags for small spills, a damp mop for general clean up, and dry absorbent material for larger spills. Clean up spills immediately. Avoid hosing or wet-mopping your work areas.

Train employees and keep customers informed.

Employee misunderstanding about how to handle waste might lead to a costly pollution incident. Make sure that *all* your employees understand and implement the practices in this manual. Educate your customers, as well, and prevent them from disposing improperly on your site.

Be a zero discharger.

If you succeed in making your shop a dry operation, you can seal off your floor drains and attain zero discharge of cleanup and process wastewater. (Before sealing off any floor drains, be sure to check with your local building and fire departments to ensure the drain is not required to meet their requirements.) Prevent leaks and spills to avoid wet cleanup. Where possible, use shop equipment that does not produce wastewater, such as enclosed parts cleaners. Reduce or eliminate the hazardous materials you use to reduce the quantity of hazardous or "hot" waste you need to dispose. If you are a zero discharger, you may not need to permit, monitor, and maintain a sewer connection and will not need to install costly pretreatment equipment. Contact your sanitary wastewater authority to determine whether you need a permit if you are a zero discharger.

"Close the loop"

A closed-loop system is an easy path to pollution prevention. If you reuse or recycle fluids and other products, they never become a waste to dispose. Close the loop by purchasing reusable or recyclable materials whenever you can. By sending used liquids to a recycler, you can take advantage of special hazardous waste exemptions and cut down on the expense and paper work of handling waste liquids. A solvent service can supply solvent and parts cleaning equipment, and collect the spent solvent. Use other closed-loop services for batteries, metal scrap, and shop rags. To help avoid disposal problems, check with vendors or suppliers that any samples they give you can be returned before accepting them.

R0059104

Specific Practices to Control Waste from Auto Shop Activities

This section contains BMPs keyed to specific shop activities, and describes recommended management practices to control waste from that activity.

As a rule, the BMPs are intended to describe "state of the practice," to be implemented every day for the indefinite future, except where the practice is not reasonable or economically feasible. Many of these practices are straightforward, common sense housekeeping activities, and many may already be in place in your shop.

These recommended practices are intended to help you comply with the storm water and sanitary sewer requirements. Local requirements may vary, and you should always check with your municipal agencies for their pollution control requirements. But in general, municipal and state agencies have reviewed these practices and agree that they will help you avoid causing pollution incidents and being subject to enforcement actions.

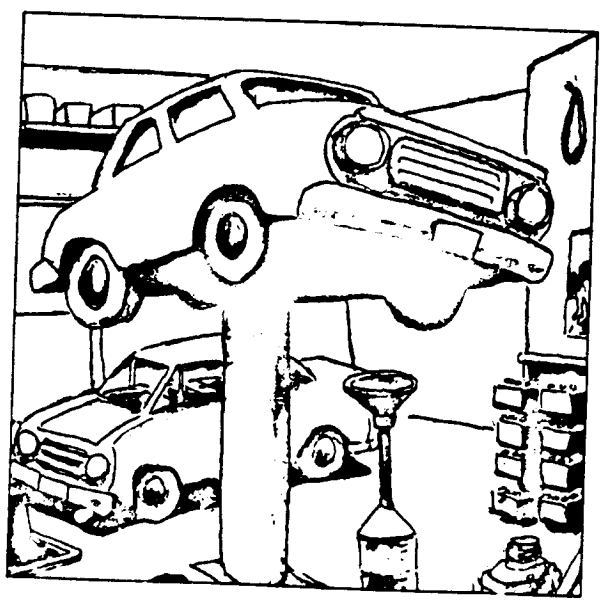
1. Changing Automotive Fluids

Drain and replace motor oil, coolant, and other fluids in a designated special area where there are no connections to the storm drain or the sanitary sewer. Minor spills can be cleaned up before the spill reaches the drains. Collect all spent fluids, store them separately, and take them to a recycler. Store waste liquids as hazardous materials. (Check with your fire department about storage requirements for hazardous materials.) If you do not recycle, the fluids must also be disposed as hazardous materials—with the associated high costs, legal liabilities, and heavy paperwork.

Brake fluid, transmission fluid, gear oil, and similar fluids pose a special problem. These may or may not be recyclable. Check with your recycler and the liquid's supplier. Some may be acceptable to mix with your recyclable motor oil. For the most part, liquids that don't contain chlorinated hydrocarbons are the least costly to recycle and the most widely accepted.

Radiator fluids usually can be accepted by an antifreeze recycler. Collect radiator **flushing fluid** rather than pouring it into your shop drain. Reuse the flushing fluid for as many radiators as possible to minimize waste discharges. If your recycler won't accept the spent flushing fluids, consider changing to another brand of fluid that can be recycled.

If your shop services **air conditioners,** you must use special equipment to collect the freon or other refrigerant. One option is a recycling machine sealed off from the atmosphere that collects the refrigerant as a liquid. Re-using the refrigerant on-site is much less costly than sending it to an off-site recycler (the only other allowable option). In many locations, it is not permissible to vent the refrigerant to the atmosphere. Check with the Air Board and your municipality to find the rules that apply to you.



VOL 12 2 5812

R0059105

2. Working on Engines, Transmissions, and Miscellaneous Repairs

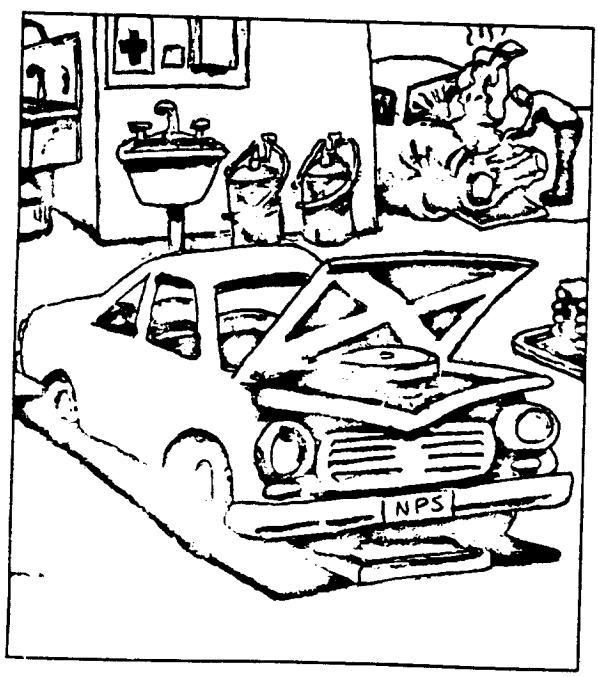
Use the "dry shop" principle whenever you work on a vehicle. When you spill or drip fluids onto the floor, clean them with a rag, instead of letting them evaporate. To reduce spills, use the following practices:

- Collect leaking or dripping fluids in drip pans or containers. If the fluids are kept separate, usually they may be recycled.

- Keep a drip pan under the car while you unclip hoses, unscrew filters, or remove other parts. Use a drip pan under any vehicle that *might* leak while you work on it to keep splatters or drips off the shop floor.

- Use larger, flat, low-brimmed pans under cars where mechanics are working, where ordinary drip pans are too cumbersome

- Promptly transfer used fluids to the proper waste or recycling drums. Don't leave drip pans or other open containers unattended.



3. Preventing Leaks and Spills

Minimize wastes and discharges by practicing careful housekeeping to prevent leaks from vehicles and from equipment on to the shop floor. Put drip pans under leaking autos while you await permission to repair them, then make the repairs as soon as possible. Empty and wipe the drip pans when you move them to another vehicle, or when they are about half-full, to avoid spills.

Maintain your shop floor equipment to identify and repair small leaks. Check all equipment at the end of the working day to find and wipe up leaks and spills.

Be especially careful with ***wrecked vehicles*** as well as cars you keep for parts and vehicles kept on site for scrap or salvage, whether you keep them indoors or out.

- Place drip pans under vehicles as they arrive even if you believe that all fluids have leaked out before the car reaches your shop. Wrecked vehicles can continue to drip for days.

- If you need it, keep a portable inflatable berm on hand for immediate response. An inflatable berm can be quickly deployed to cover an auto-sized area conveniently. Empty the mixed fluids that leak into the berm to a "hot" waste drum.

- Drain all fluids, including air conditioner coolant, from wrecked vehicles and "parts" of cars upon arrival. Some locales require that wrecked cars be drained within 24 hours of arrival. Also drain engines, transmissions, and other used parts you keep for rebuilding.

- If you wish to park wrecked vehicles outdoors, you may need to construct a roofed and drained area for them. Visually monitoring storm water runoff from an area used to store wrecked vehicles may help you determine if roofing and draining is necessary to prevent pollutants from entering the storm drain system. Check with your local fire department before adding or making structural changes to your building.

R0059106

VOL 12 2 5813

4. Cleaning Up Spills

To clean up after a job or at the end of the week, use dry cleanup practices whenever possible. Use a damp mop for routine cleanup, and wet-mop the floor only in the areas that need it. As a regular practice, avoid cleaning up spills and splatters by wet-mopping the whole floor. This could make your mop water a hazardous waste.

Train your employees in how to respond to a spill.

Small spills can be cleaned up with rags. Avoid paper towels. You can "close the loop" on this waste stream by sending used rags to a laundry service. Do not saturate rags with gasoline, solvents, or other hazardous liquids. Inform your laundry of what the shop rags have been used for; when rags are washed, the solvents, oils and metals are transferred to the wastewater discharged from the laundry. Some laundries will not accept heavily soiled rags.

For ***medium-sized spills***, use dry absorbent material (known as "kitty litter") to soak up the liquids. Use absorbent "snakes" as temporary booms to contain a liquid while you clean it up. (These are sold by waste control equipment manufacturers.) Sweep up the used absorbent and snakes and dispose of them with the "hot" wastes. If you keep several vacuums on hand, you can designate one for each waste (motor oil, antifreeze, etc.) and recycle the fluid. *Do not* use vacuums for gasoline, solvents or other volatile fluids because of the explosive hazards. A squeegee can also be used to help contain spills.

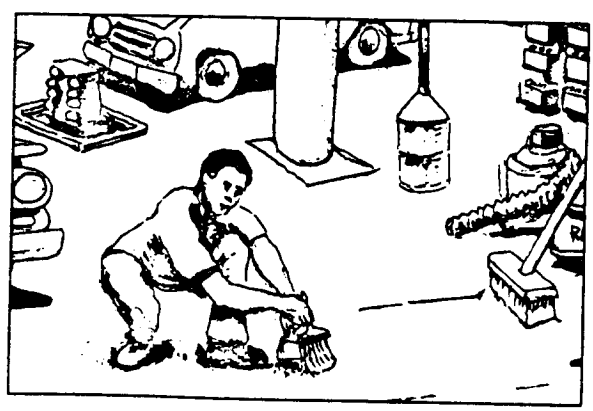
Larger spills in the shop or outdoors must be contained, then cleaned up. Your hazardous materials response plan, filed with your fire department or other hazardous materials "HazMat" authority, describes how to prepare for and respond to larger spills. If you have a floor drain, it must have an emergency shutoff. Temporary plugs can be used to prevent the spill from entering the storm drain and/or sanitary sewer. (Be sure to check with your local building and fire departments before permanently sealing off floor drains.) In the case of a spill, notify the authorities as required in your emergency response plan.

5. Identifying and Controlling Wastewater Discharges

Inspect your shop to be sure you have no unauthorized connections to the sanitary sewer or storm drain system. Sanitary sewer connections require the approval of your wastewater authority, who increasingly contends that any discharge requires costly pretreatment. Storm drain connections from indoor drains or sinks are prohibited.

Make sure employees do not pour waste liquids into floor drains, sinks, outdoor storm drain inlets, or other connections. Spent or leftover cleaning solutions, solvents, and automotive fluids are often toxic and are not acceptable for the sanitary sewer. Post signs at sinks to remind employees, and paint stencils at outdoor drains to inform customers and others. Some sanitary wastewater authorities do not allow the discharge of any material other than sanitary sewage and vehicle wash water to the sanitary sewer.

If your dry cleanup practices are successful, you can seal off your floor drains and become a zero discharger. Permanently seal the drain when you can, or use a temporary inflatable plug for an immediate response. (Check with your local fire and building departments before sealing off any floor drains to ensure the drain is not required to meet their requirements.) You may wish to use the plugged drain as a sump to collect cleanup water or spilled liquids. Pump the liquid into a drum when you need to empty the sump. Check with your HazMat authority or fire department for requirements they may have for this use of a sump.



VOL 12
2
5814
R0059107

6. Fueling Vehicles

In general, your fueling area should be designed and operated to minimize spilled fuel and leaked fluids coming into contact with rainwater. Steps you can take include:

- Clean up spills with the "dry shop" principle. Spread absorbent material and sweep it up with a broom; dispose of it with your "hot" wastes.

- When you clean the area, use a damp cloth on the pumps and a damp mop on the pavement rather than using a hose. If you spray water from a hose here, the water becomes an illegal discharge to the storm drain.

- Install fuel pump shut-offs as directed by your fire department or HazMat authority. Usually this means an automatic shut-off at each pump, and a manual shut-off inside the building.

Fuel tanks, including temporary tanks, need to be permitted by your local fire department and HazMat authority. They will specify design features, such as size of containments. Storm drain and sewer inlets that drain the fueling area must be equipped with a shut-off valve to keep fuel out of the drains in the event of a spill from the pumps.

The *parking and approach areas* outside the immediate fueling area are also of concern. This area will receive rain, so you can't avoid discharging storm water. The storm water will carry off pollutants from spills and leaks from parked or waiting vehicles.

- Don't allow customers to wash their vehicles, change oil, or work on cars in these areas.

- Clean up spills or leaks right away, using the dry shop approach, so they don't contaminate rain water.

7. Removing and Storing Batteries

Return used batteries to your battery supplier, who will recycle them with a battery reclaimer. Batteries sent for reclamation are controlled as a modified category of hazardous wastes. You do not need to file a manifest or pay disposal taxes, but you do need to keep a shipping receipt.

Be careful with cracked or leaking batteries. Store batteries, new and used, either on an open rack (so that you can tell immediately if any are cracked and leaking) or in a double containment (as required by some locales). If you handle a large volume of batteries, or if you work on wrecked vehicles so that you commonly handle cracked batteries, take the following precautions.

- Store cracked batteries in a watertight secondary containment, such as a concrete bin with sealer on the floor and walls. Do this with all cracked batteries, even if you think all the acid has drained out, because they may not be completely dry.

- If you drop a battery, treat it as if it's cracked. Put it into the containment until you're sure it's sound.

- Cracked batteries may be shipped for recycling under the special hazardous waste category if they are carried in proper containers.

- Handle spilled acid from broken batteries with care. If you use baking soda to neutralize spilled acid during cleanup, remember that the residue is still dangerous to handle, and must be disposed of as hazardous waste because it may contain lead and other contaminants.

VOL 12
2 5815
R0059108

8. Cleaning Parts

Clean parts without liquid cleaners whenever possible. Scrape parts with a wire brush, or use a bake oven if one is available.

Prevent spills and drips of solvents and cleansers onto the shop floor. Perform all liquid parts cleaning at a centralized station so the solvents and residues stay in one area. If you immerse parts in liquid, remove them slowly to avoid spillage. Install drip pans, drain boards, and drying racks in a way that directs drips back into the sink or the fluid holding tank. The preferred methods for liquid parts cleaning use zero-discharge equipment, such as:

- Self-contained solvent sinks cycle the liquid directly back into a storage drum. A number of good "closed-loop" services will pick up spent solvent and supply fresh solvent. You must file hazardous waste manifests for transporting the recycled solvents.

- Enclosed parts washers that use filters to remove contaminants can re-use the washing fluid almost indefinitely. Many of these use only hot water and detergents, no hazardous fluids. You need to remove a small amount of oily residue from the machine periodically, which might be a hazardous waste. Check with your oil recycler to see if this residue can be taken with the used oil. Do not put the residue in the sanitary sewer.

- Solvent recycling equipment can purify solvents for re-use on-site.

If you prefer to dispose your own solvent:

- Spent solvent must be disposed of as hazardous waste.

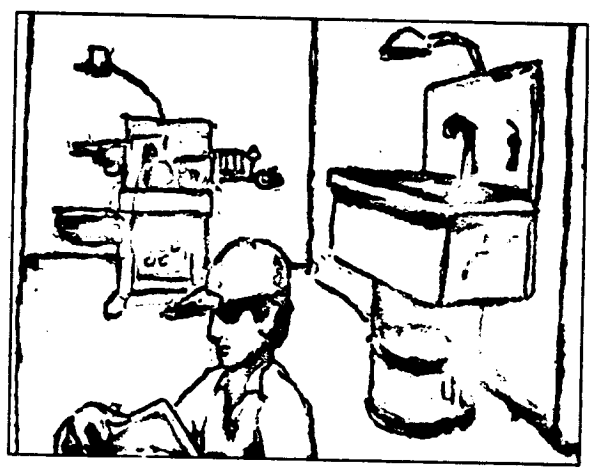
- Don't pour spent solvents, even biodegradable solvents, into your sewer drain.

- Don't dispose of the solvents by storing them in open buckets for evaporation. This leads to air emissions that are not allowed, and produces a residue that is a hazardous waste.

9. Metal Grinding and Finishing

Capture metal filings produced by grinding or machining metal parts. Enclose the unit as much as possible, and keep a bin under the lathe or grinder to hold the filings. Vacuum loose chips and metal filings to keep them out of the storm drains and sanitary sewers. Avoid wet mopping the machine shop floor. Consider spreading a tarpaulin or plastic liner on the floor to collect metal filings, and then carefully empty the tarp into a storage bin.

Capture filings from asbestos brake shoes in a separate container. Asbestos dust must be handled as hazardous waste, stored in an enclosed container and disposed to a hazardous waste hauler. If you contaminate other metal filings with asbestos, none of the mixture may be sent to ordinary scrap dealers.



VOL 12
2
5816
R0059109

10. Storing and Disposing of Waste

The table on the opposite page summarizes the preferred storage and disposal practices for some common solid, liquid, and gaseous wastes. The overriding principle is to keep different kinds of wastes *separate*. If you recycle used oil, antifreeze, or solvents, you know how important it is to keep them separate so the recycler will accept them. Keep your non-recyclables separate, too.

Store and handle *hazardous wastes* in special hazardous waste containers, or closed drums within a secondary containment that is approved by your fire department and HazMat authority. Select a hazardous waste hauler with care; ask for customer recommendations, and review the firm's permits and authorizations. Empty containers,such as oil containers, paint buckets, aerosol cans, antifreeze bottles, and carburetor cleaner solvent cans, are hazardous wastes if they once held hazardous materials. You cannot discard these with the regular trash. Containers should be returned to the vendor or sent to a reclaimer/ refinisher whenever possible.

You might save money if you use more than one drum to hold different "hot" wastes. Keeping brake fluids, transmission fluids, and solvents containing chlorinated hydrocarbons separate from other hazardous wastes may reduce the cost of shipping and disposing of them. To be sure you aren't violating hazardous waste requirements, don't contaminate sewer discharges and clean trash with small amounts of "hot" wastes. Also, be sure to check with your local fire department about storage quantity requirements before separating hazardous materials.

In Manhattan Beach the municipal fire department is the HazMat authority that controls hazardous materials storage, handling, and response. For information about hazardous waste regulations, call the City's Fire Department, or Cal-EPA's Toxic Division.

Waste oil, antifreeze, spent solvents, and other liquids that you hold for *recycling* are special categories of hazardous waste. They must be stored on your site in accordance with hazardous waste requirements, but can be transported under somewhat less stringent requirements. Many recycling services have special variances or permits that reduce your paperwork requirements and allow shipping at reduced cost.

If you store materials *outdoors*, keep them under a roof, cover, or tarpaulin. (Be sure to check with your local fire department before adding or making structural changes to your building.) Keep solid wastes in a covered dumpster to be picked up by municipal trash services. Do not let rain water contact old parts, tires, or dumpsters. Keep scrap parts or other metals in a shed or under a roof, out of the rain. Oily contaminants can wash off long after you think all the oil has drained from parts.

If you keep *liquid containers* outdoors, keep them on a paved impermeable surface and within a berm or other secondary containment to prevent spills from running off into the yard. This is a good idea even if the liquids are not a hazardous waste (and mandatory if they are). Put a lid or cover on buckets or barrels, because any rain that enters becomes an oily waste. Consider keeping all your waste oil and other hazardous liquids indoors or in a locked area, to keep nighttime trespassers away.

Collect *waste metal*, such as used parts, for delivery to a scrap metal dealer. Deliver metal lathe filings to a scrap dealer also.

Used *oil filters* need not be handled as hazardous waste if you meet special handling requirements. Oil filters should be drained into your waste oil bin, stored in leak-proof containers, and delivered to a recycling facility. Some waste oil and fluid recyclers in Los Angeles County will pick up oil filters and help you meet the state regulatory requirements.

VOL 12 2 5811 7

Preferred Storage and Disposal Practices

		Recommended storage	Preferred disposal	Hazardous waste?
Liquids	Waste oil	Drum (segregate)	Oil recycler	Special*
	Transmission fluid	Drum (segregate)	Oil recycler	Special*
	Gear oil	Drum (segregate)	Oil recycler	Special*
	Solvents (solvent sink)	Solvent sink	Solvent Recycler	Special*
	Solvents, thinners, and miscellaneous fluids	Tank ("hot waste") (segregate)	Fluid recycler (where possible or waste hauler)	Possibly
	Brake fluid	Bottle or tank ("hot" waste)	Hazardous waste hauler	Yes
	Antifreeze	Tank (segregate)	Recycler	Special*
	Paints	Original container, with lid	Hazardous waste hauler	Yes
Solids	Used parts: clean metal scrap	Bin (covered or indoors)	Scrap collector	No
	Used oily parts, fuel filters, etc.	Drum	Hazardous waste hauler	Yes
	Metal shavings	Bin (covered or indoors)	Scrap collector	No
	Asbestos filings	Sealed bin	Hazardous waste hauler	Yes
	Tires	Covered or indoors	Tire hauler	No
	Batteries	Open rack	Battery supplier	Special*
	Oil filters	Drum (drain first)	Oil recycler	Special*
	Used rags	Rag bin with lid	Rag laundry	Possibly
	Empty cans, bottles, aerosol cans, etc.	Drum	Municipal trash or hazardous waste hauler	Possibly
	Soiled cleanup absorbent	Drum	Hazardous waste hauler	Yes
Gases	Air conditioner refrigerant	Recycling machine	Reuse in-house	No

**Recyclable under special hazardous waste restrictions.*

11. Selecting and Controlling Inventory

Careful selection and management of the materials you use can make a big difference in your waste handling and disposal and can save you money.

Choose materials that can be recycled. For example, avoid transmission and brake fluids that contain chlorinated hydrocarbons if another type is satisfactory.

Whenever possible, choose parts, cleaning solutions and other materials that are non-toxic. Water-based cleansers can provide acceptable cleaning; experiment with concentrations to find one that works. Avoid halogenated compounds, petroleum-based cleansers, and cleansers with phenol. These are highly toxic, cause difficult problems if spilled to a sewer connection, and are often costly to recycle or dispose. Control your inventory to reduce the wastes you generate. For example:

- Purchase supplies in bulk and keep them in bulk dispensers. This eliminates empty waste containers that, depending on the original contents, may need to be disposed of as hazardous waste.

- Keep on hand only the quantities of materials that you need and use them on a "first-in, first out" scheme, to avoid the need to discard unopened cans when the materials' shelf lives expire.

- Consider reducing the number of different brands or grades of materials that you need to reduce the number of containers.

- Where possible, select suppliers who provide fresh materials and accept the used materials for recycling in order to "close the loop."

R0059111

VOL 12 2 5818

12. Outdoor Parking and Auto Maintenance

If you park vehicles outdoors while they await repair, watch them closely for leaks.

Surround the parking area with a berm to prevent storm water from flowing into dirt lots, grassy areas, or storm drains. If possible, park the cars indoors or under cover of a roof or shed so storm water does not contact the area.

As a rule, avoid using ***outdoor working areas***. If you do use any areas in this way, roof them if possible, and treat them as an extension of your service bays. Keep them clean and use dry cleanup practices. The areas need specific design features, such as:

- Pave the surface with concrete, not asphalt. The automotive fluids may dissolve asphalt, or may be absorbed into the blacktop and released later.
- Drain the surface to a single drain connected to a sanitary sewer. The drain may require an oil/water separator or oil/grease trap. The drain must be approved by your wastewater treatment authority.
- Grade the working area to be higher than the parking lot, or surround it with a berm, to prevent storm water ***run-on***.
- Constructing a roofed space will require a building permit, so consider in advance whether you need to work outdoors. Do not plan to build a new temporary roof when a wrecked vehicle arrives.

Be sure to check with your local fire department before bringing an operation indoors.

If you park wrecked cars outdoors, or store vehicles outdoors, for salvage or for parts, you may need to create a special area to accommodate them. The area should be roofed, paved, mounded or bermed, and kept clean in the same fashion as an outdoor working area.

13. Vehicle Washing, Engine Cleaning, and Automotive Steam Cleaning

If you ***occasionally wash vehicle exteriors*** with water only (no soap), you need to take only simple precautions with the discharge. Check with your wastewater authority because city requirements differ. Generally you may discharge wash water to the storm drain *directly*. Wash cars next to the drain, and don't allow wash water to flow across a parking lot or working area. Or, if you have a landscaped area, wash cars there to avoid any discharge, but be sure *all* wash water soaks into the soil.

You need to make special efforts if ***car washing is a main activity***, such as commercial car wash, or if you regularly clean trucks or dirty, greasy field equipment.

- Wash the vehicles in a covered, contained bay where the water can be collected and recycled as part of a water conservation program.
- Do not discharge vehicle wash water to a storm drain; *this is prohibited.*
- You may need a discharge permit from the sanitary wastewater authority. The discharge usually requires treatment, such as oil and grease removal, and perhaps metals removal. The treatment unit may also need a hazardous waste permit.
- Check into a closed-loop water reuse/recycling system for vehicle washing. This may be more cost effective than burdensome permit fees and analytical costs associated with a discharge permit fee from the sanitary wastewater authority.

Engine cleaning and *steam cleaning* should be done on your site *only* if you are equipped to capture all the water and other wastes. You will need to remove oils and grease in an oil/water separator or a small treatment unit before discharge. This discharge is prohibited from storm drains, requires a permit from your wastewater authority, and may require you to determine whether it is hazardous waste. If you steam clean, use an enclosed bay where the condensed steam can be collected in a sump and treated for discharge.

VOL 12 2 5819

R0059112

14. Training and Educating Employees and Customers

Train your employees to use the practices in this manual. When you first implement them, review your current practices to see how they compare and change practices where it is appropriate. Thereafter, assign experienced workers to train new employees. Review procedures as a group at least once a year.

Check employees' work practices to be sure the BMPs are implemented properly. Post signs as reminders, such as notices not to pour liquid wastes into sinks and floor drains. Develop a routine to inspect shop equipment and procedures regularly. A once-a-week walk-through can help identify potential difficulties before they become major problems.

To keep abreast of new developments, participate in workshops, trade association meetings, and seminars. Trade association publications can be valuable sources of information. Modify your practices whenever you find a new idea that serves your shop better.

Encourage your customers to be waste-conscious. Post "don't top off" signs at gas pumps, and stencil "No dumping! Drains to Ocean" signs at storm drains.

Be aware of customer activities on your site. If they dispose of materials improperly, *you* will be responsible for the violation. Ask your customers not to discard liquids into your trash cans or storm drains. If you have persistent problems, you may need to monitor your customers more carefully at the fuel pumps, storm drains, and other potential disposal areas on your property.

You can help encourage customers to dispose properly if you can accept their waste motor oil and other fluids, either for recycling or for your "hot waste" barrels. Let your customers know how you are minimizing wastes and recycling fluids to show that you are a "good neighbor," and encourage your customers to be the same.

15. Re-Grade or Re-Pave Outdoor Areas

Strategic grading of parking lots and outdoor spaces can be used to prevent *run-on* storm water from contacting potentially contaminated areas. Run-on is water that flows from elsewhere across the problem area, and can then carry contaminants to the storm drains. Examine your site to identify areas of concern that might contribute pollutants to storm water such as the area around fuel pumps; areas where wrecked vehicles have been parked; areas that were once used for outdoor service; and others.

Grade a parking lot or an approach to fuel pumps to "mound" the fueling area and prevent run-on. Long-term parking areas and places where wrecked vehicles are parked can also be mounded, or can be surrounded by a berm or speed-bump-sized barriers. The diagram below shows a possible grading scheme.

Use concrete paving instead of asphalt in areas where autos may leak fluids such as fueling islands, former or current outdoor work spaces, and heavily-used parking areas. Asphalt absorbs organic contaminants and can be slowly dissolved by some fluids. Over time, these two effects can cause the asphalt to become a source of storm water contaminants. You may need to remove asphalt paving that has been in place for a long time in heavily-used areas. Replace it with concrete if you intend to continue using it as a working space. To determine whether you need to remove the asphalt, you can sample the runoff and have it chemically tested.

16. Recycle Spent Fluids On-Site

On-site equipment to purify and recycle spent automotive fluids can fully "close the loop" and avoid generating a hazardous waste. The residue from the process generally is a hazardous waste, but the equipment itself does not need a hazardous waste treatment permit *if* you reuse any of the materials that come out of the process.

Solvent recycling distillation equipment can distill solvents to almost as high a level of purity as that produced by large hazardous waste treatment facilities. Stills can extend a solvent's lifetime almost indefinitely.

Antifreeze reclamation equipment is made in a wide range of designs, with varying equipment costs and varying quality of results. Simple units merely filter out impurities, and can extend the life of the antifreeze only a short time. More costly equipment can distill antifreeze to nearly-new quality so you can reuse it in another vehicle.

EXECUTIVE SUMMARY

This report presents the results of a two-part study of constituents present in simulated storm water runoff from six retail gasoline outlets (RGOs) and four commercial parking lots. The objective of the study is to characterize storm water runoff from RGOs and to compare the results with runoff from commercial parking lots and published urban "background" values. The study was funded by the Western States Petroleum Association (WSPA) and the American Petroleum Institute (API).

The study demonstrates that for the constituents analyzed, median event mean concentrations (EMCs) in storm water runoff from normally operated and maintained RGOs are no higher than those in runoff from commercial parking lots. Additionally, median EMCs of total suspended solids, copper, lead, and zinc in runoff from RGOs and parking lots are no higher than background levels present in urban runoff as established by the National Urban Runoff Program. Furthermore, there are no significant differences in median EMCs in runoff from RGO pump islands and driveways for the constituents analyzed. These results indicate that fueling activities at normally operated and maintained RGOs do not contribute additional significant concentrations of measured constituents in storm water runoff.

In 1987, Section 402(p) was added to the Clean Water Act to establish a framework for addressing storm water discharges under the National Pollutant Discharge Elimination System (NPDES) program. Storm water discharges from commercial facilities, such as RGOs and parking lots, are not included under the initial regulations. However, regulations are now being promulgated that are expected to increase the number and types of dischargers required to obtain NPDES permit coverage for storm water discharges. EPA, in a report to Congress (EPA, 1993), identified several business categories that are not currently regulated by NPDES permits. Automotive service facilities, including RGOs, are included on EPA's list of potential Phase II permittees.

VOL 12 2 5826

GEOMATRIX

This study used a simulated rainfall method to induce runoff from representative RGO and parking lot test sites. The RGO and commercial parking lots used as test sites provide a variety of site and operational conditions. Simulated runoff was collected at two areas within each test site. These areas include pump islands and driveways at RGOs and high-use and moderate-use areas within commercial parking lots. Both discrete and composite runoff samples were collected during the 45-minute test. The collected samples were analyzed in accordance with appropriate EPA methods for a variety of constituents including California Code of Regulations Title 26 Metals, total suspended solids, oil and grease, total petroleum hydrocarbons as gasoline (TPHg), and benzene, toluene, ethyl benzene, and total xylenes (BTEX).

GEOMATRIX

RESULTS OF A RETAIL GASOLINE OUTLET AND COMMERCIAL PARKING LOT STORM WATER RUNOFF STUDY

1.0 INTRODUCTION

This report presents the results of a two-part study of simulated storm water runoff from six retail gasoline outlets (RGOs) and four commercial parking lots. Part I was conducted by Hart Crowser and characterized simulated storm water runoff from five RGOs. Part II was conducted by Geomatrix Consultants, Inc. (Geomatrix) and characterized simulated storm water runoff from four commercial parking lots and one RGO. The study was funded by the Western States Petroleum Association (WSPA) and the American Petroleum Institute (API).

1.1 Objective

The objective of this study is to characterize storm water runoff from RGOs and to compare the results with runoff from commercial parking lots and published urban "background" values.

1.2 Background

In 1972, the Federal Water Pollution Control Act (also known as the Clean Water Act or CWA) was amended to provide that any discharge of pollutants from a point source to Waters of the United States is effectively prohibited unless it is in compliance with a National Pollutant Discharge Elimination System (NPDES) permit. Although this technically prohibits the discharge of pollutants in storm water, the focus at that time was on the bigger problems of industrial waste and sewage treatment.

As more significant sources of water pollution were brought under control, the impact of pollutants in storm water became more noticeable. Water quality studies conducted in the 1970s and 1980s identified urban runoff as a diffuse, or nonpoint source of pollution. In response to these studies, the

R0059120

VOL 12 2 5828

1987 amendments to the Water Quality Act added Section 402(p). This section established a comprehensive two-phased approach for the U.S. Environmental Protection Agency (EPA) to follow in addressing storm water discharges. Five types of storm water discharges are covered under the Phase I program. Dischargers within these five categories, listed below, were required to obtain permit coverage before October 1, 1992:

A) A discharge for which a permit has been issued prior to February 4, 1987;

B) A discharge associated with industrial activities;

C) A discharge from a municipal separate storm sewer system serving a population of 250,000 or more;

D) A discharge from a municipal separate storm sewer system serving a population of 100,000 or more, but less than 250,000; or

E) A storm water discharge determined by the EPA Administrator or the State to contribute to a violation of a water quality standard or to be a significant contributor of pollutants to the waters of the United States.

Discharges from commercial facilities, such as RGOs and parking lots, are not included under the Phase I regulations. However, Phase II regulations now being promulgated are expected to increase the numbers and types of dischargers that are required to obtain NPDES permit coverage for storm water discharges. EPA, in a draft Phase II report to Congress (EPA, 1993), identified several business categories that are not currently regulated by NPDES permits. Automotive service facilities, including RGOs, are included on EPA's list of potential Phase II permittees. It should be noted that, according to the EPA draft Phase II report, the list of potential permittees was created using limited reliable data on storm water problems associated with Phase II sources nationwide. In order to provide data regarding storm water runoff from potential Phase II facilities, WSPA and API commissioned this study.

1.3 Other Studies

This study utilized the results from a recently published RGO runoff study titled *Action Plan Demonstration Project, Demonstration of Gasoline Fueling Station Best Management Practices, Phase I Report* (September, 1993), prepared by Uribe & Associates and Larry Walker Associates for the County of Sacramento, Water Resources Division. Another storm water runoff study used for the WSPA/API study described herein is the *Final Report of the Nationwide Urban Runoff Program* (December 30, 1983) prepared by the Water Planning Division of EPA. These storm water studies are described in the following sections.

1.3.1 Sacramento County's Action Plan Demonstration Project

Sacramento County's Action Plan Demonstration Project characterized storm water runoff from RGOs and identified potential best management practices (BMPs) to reduce storm water runoff pollution. EPA provided funding of the study by a grant through the San Francisco Estuary Project and the Sacramento County Water Resources Division. The report presents the analytical results of samples collected from storm water runoff from three RGOs in Sacramento County.

The Sacramento County project selected high-volume (over 200,000 gallons per month), self-service RGOs with convenience markets and without automobile repair service bays for the study. The selected RGOs are located less than 2 miles apart.

Within each RGO, a single representative sampling point was selected where station runoff leaves the property and includes drainage from the fueling and auxiliary services areas. Uribe collected samples during six storm events during the 1992/93 wet season. For five of the storms, the sample collection procedure consisted of placing a 1 liter sampling bottle into a below-grade concrete sump. A portion of the storm water discharge flowed over the lip of the sump directly into a sampling bottle. Samples were collected in this manner for each 0.05 inch increment of measured rainfall. The samples were composited immediately into a 5-liter borosilicate bottle until the 5-liter bottle was filled. The one exception to this sample collection method occurred during the first storm event, when only grab samples were collected.

R0059122

VOL 12 2 5830

The initial analytical program for the collected samples included analyses for oil and grease, total suspended solids, metals (13 EPA priority pollutant metals plus aluminum and iron), polycyclic aromatic hydrocarbons (PAHs), and petroleum hydrocarbons. However, some of the metals, petroleum hydrocarbons, and PAHs were consistently not detected in samples collected from the first three storm events. On the basis of these results, the following parameters were selected for the final three sampling events:

- oil and grease
- total suspended solids
- heavy metals (cadmium, chromium, copper, lead, and zinc)

Pertinent results of Sacramento County's Action Plan Demonstration Project are discussed in Sections 3 and 4 of this report.

1.3.2 National Urban Runoff Program

The National Urban Runoff Program (NURP) was conducted from 1978 through 1983 with funding and guidance provided by EPA. NURP characterized the chemicals present in discharges from separate storm sewers that drain residential, commercial, and light industrial areas. NURP included 28 projects across the nation, conducted separately at the local level, but centrally reviewed, coordinated, and guided. The overall objective of the program was to collect information from a national perspective that could be used to characterize urban runoff, assess the impact of non-point source urban runoff on the quality of the receiving waters, and assist decision makers in developing control measures to limit its impact. The results of NURP provide insight on what can be considered background levels for urban runoff.

The resultant NURP data represent a cross section of regional climates, land use types, and ground surface conditions. The sites sampled during NURP included 81 sites that were unaffected by hydraulic devices, such as detention basins, that would modify runoff. A total of more than 2300 separate storm events were sampled from these sites during the project. Samples collected from these sites were tested for the following standard pollutants:

VOL 12 2 5831

- total suspended solids
- biochemical oxygen demand
- chemical oxygen demand
- total phosphorus
- soluble phosphorus
- total Kjeldahl nitrogen
- nitrite and nitrate as N
- heavy metals (copper, lead, and zinc)

Pertinent results of NURP are discussed in Sections 3 and 4 of this report.

2.0 WSPA/API PART I AND PART II STORM WATER RUNOFF STUDIES

This section describes both parts of the WSPA/API runoff study. Part I, conducted by Hart Crowser, characterized simulated storm water runoff from five RGOs. Part II, conducted by Geomatrix, characterized simulated storm water runoff from four commercial parking lots and one RGO.

2.1 Literature Search

As part of this WSPA/API study, Hart Crowser conducted a literature search to assess whether analytical results from prior RGO runoff studies were available for this study. The search was conducted using the Dialog Information Database and included a search of the following databases:

NTIS (National Technical Information Service)
COMPENDEX (Engineering Information Inc.)
APILIT (American Petroleum Institute)
Pollution Abstracts/Cambridge Scientific Abstracts
Water Resources Abstracts
WATERNET (American Water Works Association)
CA SEARCH (Chemical Abstracts)

The database search did not disclose prior RGO storm water runoff studies.

R0059124

VOL 12 2 5832

GEOMATRIX

2.2 Selection of RGOs and Test Sites

In selecting the RGOs to be used for the study, the following characteristics were evaluated for a number of potential RGO sites:

- monthly throughput
- site location
- anticipated level of use by commercial vehicles
- age and general appearance
- types of ancillary services provided including on-site vehicle service, car washes, or convenience stores
- on-site drainage patterns and adjacent property usage.

On the basis of this evaluation, six RGOs, all located in Southern California, were selected for the study. The six RGOs provide a representative cross section of typical RGOs in Southern California. Site characteristics for each RGO are summarized in Table 1. Each of the selected RGOs was considered "normally operated and maintained". For the purposes of this study, "normally operated and maintained" signifies that the RGOs utilize Best Management Practices (BMPs) to minimize the buildup of potential storm water contaminants on exposed areas. These BMPs include regular sweeping of exposed areas, regular site inspections, and standardized spill response procedures.

Hart Crowser and Geomatrix conducted the simulated rainfall application and sample collection at a pump island and driveway approach area within each RGO. These areas were selected to provide results that are representative of discharge from the entire RGO. A summary of pavement types and conditions of each test site location is presented in Table 2.

A simulated gasoline spill was performed at RGO 5 to provide data regarding the effectiveness of standardized spill response procedures. One quart of regular unleaded gasoline from a pump nozzle was discharged onto the pump island pavement. Absorbent material was applied to the spill after one

R0059125

VOL 12 2 5833

minute. The absorbent material was then swept up after it appeared to have absorbed the spilled liquid, and the simulated runoff test was conducted.

2.3 Selection of Parking Lots and Test Sites

Commercial parking lots for the second part of the study were evaluated using the following criteria:

- site use
- relative parking duration
- traffic and parking volume
- pavement type, condition, and visual appearance
- cleaning methods and frequency
- on-site drainage patterns.

On the basis of this evaluation, Geomatrix and WSPA selected four commercial parking lots, all located in Southern California, for the study. The selected parking lots were associated with a grocery store, bank, office complex, and restaurant.

Simulated rainfall was applied and samples were collected at two locations at each of the four parking lots for a total of eight test sites. The test locations included one high-use and one moderate-use parking area. The high-use area was generally closer to the commercial facility entrance, and was occupied more frequently than the moderate-use area. Each of the parking lots used scheduled sweeping as a good housekeeping BMP. Parking lot test locations, conditions, and BMPs are summarized in Table 3.

2.4 Testing Methodology

To minimize test variability caused by differing rainfall intensities and durations, both parts of the WSPA/API runoff study used a simulated rainfall method to induce runoff from the study sites. The water-dispensing system and sampling procedures were identical for both the RGO and commercial

R0059126

VOL 12 2 5834

parking lot sites. The water-dispensing system was designed to apply water uniformly over the test area and create sheet flow.

During the test, potable water was distributed uniformly over an approximate 400-square-foot area using a network of perforated 1-inch-diameter, schedule 80 polyvinyl chloride (PVC) pipes elevated approximately 4 feet above the pavement surface. A schematic of the simulated rainfall system is shown on Figure 1.

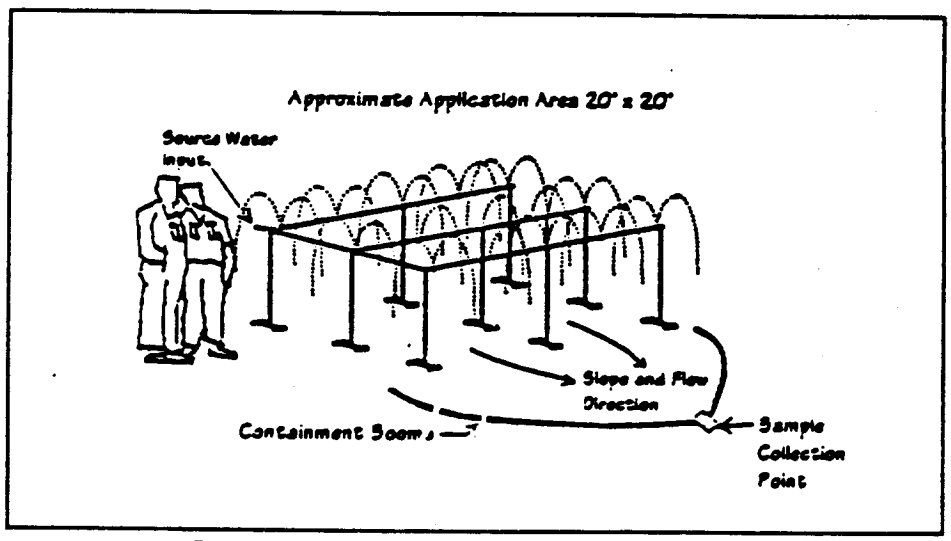

Figure 2. Schematic of Simulated Rainfall System

The water was applied at a rate of approximately 2.0 gallons per minute (gpm) for the duration of the 45-minute test. This rate represents a rainfall rate of approximately 0.008 inch per minute or 0.12 inch every 15 minutes over the test application area.

The runoff from the simulated rainfall application was channeled by gravity and sand-filled polyethylene tubing containment berms to a collection point. The runoff was diverted into a stainless steel collection trough and was pumped into a poly-lined 55-gallon steel drum.

R0059127

VOL 12 2 5835

GEOMATRIX

2.5 Sampling Procedures

Sampling procedures for both Part I and II studies follow the sampling protocol established by SW-846, "Test Methods for Evaluating Solid Waste" (including surface and groundwater).

The following samples were collected at each test site.

- A discrete grab sample from the collection trough every 15 minutes during the 45 minute test
- One composite sample from the runoff pumped into the 55-gallon drum.

In addition to these samples, a background sample of the on-site water supply was collected at the point of discharge from the simulated rainfall application apparatus, and a duplicate oil and grease sample was collected at each test site. Samples were obtained using cleaned sampling equipment and were placed into laboratory-supplied and certified "clean" sampling containers. Collected samples were labeled, placed on ice in a cooler, and maintained under proper chain-of-custody procedures. A trip blank sample was included in each of the sample coolers used for this study.

2.6 Analytical Testing

GTEL Environmental Laboratories, a state-certified analytical laboratory located in Torrance, California analyzed samples from RGOs 1 through 5. Del Mar Analytical, a state-certified laboratory located in Irvine, California analyzed samples from RGO 6 and all four parking lots.

Laboratory analyses were conducted in accordance with appropriate EPA methods. The constituents, analytical test methods, and detection limits used for the WSPA/API study are listed in Table 4.

2.7 Quality Assurance and Quality Control

Both parts of the WSPA/API study described herein developed and implemented field and laboratory quality assurance/quality control (QA/QC) procedures. Field QA/QC includes following strict sampling protocols as specified in the project work plans and standard operating procedures. These

R0059128

VOL 12

procedures include an evaluation of cross-contamination through the analysis of trip blanks. Laboratory QA/QC addressed the following:

- Accuracy (analysis of matrix spike recoveries on each batch of samples and regular analysis of certified samples)
- Precision (analysis of matrix spike duplicates)
- Contamination (analysis of method and filter blanks)
- Holding Time (specified holding times associated with each chemical method)
- Certified Methods of Analysis (EPA or State certified methods of analysis).

3.0 RESULTS AND DISCUSSION

The following sections present the results of the WSPA/API simulated runoff study and provide summaries of analytical data from Sacramento County's Action Plan Demonstration Project and NURP. Also presented are data plots that provide comparisons between the pump islands and driveway RGO results and between RGOs, parking lots, and NURP.

3.1 Analytical Results

The analytical results of simulated runoff samples collected from RGOs as part of this study are summarized in Tables 5a and 5b. These tables present the results of both the Part I study conducted by Hart Crowser (RGOs 1 through 5) and the Part II study conducted by Geomatrix (RGO 6). Tables 6a and 6b summarize the results of laboratory analyses of simulated runoff samples from commercial parking lots. Tables 7 and 8, respectively, summarize the results from Sacramento County's Action Plan Demonstration Project and median concentrations reported in NURP.

2 5836

R0059129

VOL 12 2 5837

3.2 Data Comparisons

This report compares analytical data from the WSPA/API RGOs and parking lots, the Action Plan Demonstration Project, and NURP using a series of box plots, Figures 3 through 24. Box plots are a simple and useful method of data comparison because they effectively describe the characteristics of single groups of data and reveal differences between groups. The components of a typical box plot are presented on Figure 2. Shown on this figure are the 25th and 75th percentiles of the data, which form the top and bottom of the box. Therefore, by definition, 25 percent of the data have a value equal to or less than the bottom line of the box, and 75 percent have a value equal to or less than the top of the box. The middle horizontal line within the box is the median, or 50th percentile (one-half of the data values are equal to or less than the median, and one-half are equal to or greater). Lines (called whiskers) extend vertically from the top and bottom of each box to the maximum and minimum data values.

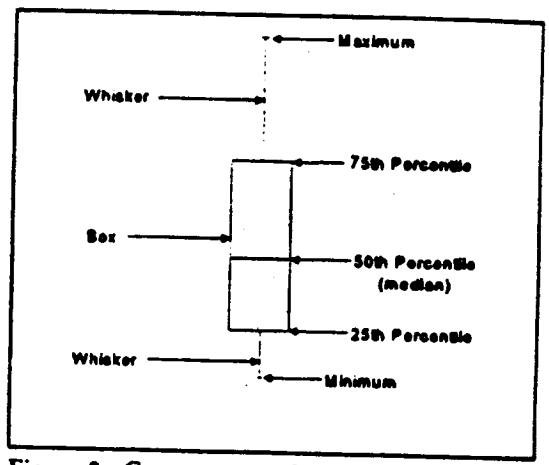

Figure 2. Components of a Typical Box Plot

In many cases, the boxes shown on Figures 3 through 24 are collapsed into a single horizontal line without a whisker extending to the minimum value. The principal reason for the shape of these plots is the presence of a large number of non-detect values in the data set. When this occurs, a single horizontal line is drawn at the detection limit, and the whisker and box segments below the reporting limit are masked.

Although Hart Crowser and Geomatrix collected and analyzed both discrete and composite samples for this study, only the composite results are used for comparison purposes in this report. Composite results are normally considered more meaningful than individual discrete results when evaluating pollutant loading in storm water discharges. It should be noted that the composite sampling

R0059130

VOL 12 2 5838

methodology used for the WSPA/API study is equivalent to the event mean concentration (EMC) reported in NURP (EPA, 1983), which is defined as the total constituent mass discharged divided by the total runoff volume. In addition, the flow weighted sampling method used for the Action Plan Demonstration Project (Uribe, 1993) provides an estimate of EMC. To provide consistency in comparisons between these studies, the EMC will be used when describing composite discharge concentrations for the remainder of this report.

The following sections discuss comparisons between the pump island and driveway results from the WSPA/API RGOs, and between the RGOs, parking lots, and NURP.

3.2.1 Comparison of Results from RGO Pump Islands and Driveways

Figures 3 through 9 present box plots that compare EMC results between the pump islands and driveways from the WSPA/API RGOs for total suspended solids, oil and grease, total petroleum hydrocarbons as gasoline (TPHg) and benzene, toluene, ethyl benzene, and total xylenes (BTEX). On the basis of these box plots, there is no significant difference in median EMCs in runoff from pump islands and driveways for these constituents. In each case, the median EMCs from pump islands and driveways are either at or very near the detection limit. Toluene, ethyl benzene, and total xylenes were detected more frequently in samples from pump islands, primarily the result of the simulated spill on the RGO 5 pump island. However, the EMCs of these chemicals were significantly below the Maximum Contaminant Levels (MCLs) for drinking water established by EPA and California Department of Health Services (Marshack, 1993).

3.2.2 Comparison of Results from RGOs, Parking Lots, and NURP

Figures 10 through 24 present box plots that compare the EMC results for RGOs and parking lots. The median EMC results from NURP are also presented on the data plots for total suspended solids, copper, lead, and zinc (Figures 10, 20, 22, and 24, respectively). On the basis of these box plots, there is no significant difference in median EMCs between RGOs and parking lots for these constituents. In addition, the box plots for total suspended solids, copper, and zinc indicate that for these constituents, there is no significant difference in median EMCs between RGOs, parking lots,

and background runoff levels established by NURP. The box plots for lead, Figure 22 indicate that the median and range of EMCs from RGOs and parking lots are significantly less than the background values reported in NURP.

4.0 CONCLUSIONS

The results of this study demonstrate that for the constituents analyzed in this report, median EMCs in storm water runoff from normally operated and maintained RGOs are no higher than those in runoff from commercial parking lots. Additionally, median EMCs of total suspended solids, copper, lead, and zinc in runoff from RGOs and parking lots are no higher than background levels present in urban runoff as established by NURP. Furthermore, there are no significant differences in median EMCs in runoff from RGO pump islands and driveways for the constituents analyzed. In all cases, the fueling related constituents (TPHg and BTEX) from pump islands were either not detected or below applicable Maximum Contaminant Levels (MCLs). These results indicate that fueling activities at normally operated and maintained RGOs do not contribute additional significant concentrations of measured constituents in storm water runoff.

VOL 12 2 5874

January 4, 1993

Dear Industrial Compliance Manual Owner:

Subject: Santa Clara Valley NPDES Industrial General Permit and Compliance Binder Update

The Santa Clara Valley Nonpoint Source Pollution Control Program (Program) is sending you the enclosed Best Management Practices (BMP) Manual, a copy of the amended portion of the Santa Clara Valley NPDES Industrial General Permit, updates of Sections 4 and 5 of the Handbook portion of the binder, a new outline for the Storm Water Pollution Prevention Plan (SWPPP), and a list of information materials available from the Program. We also describe below how, in the future, industries may be exempted from the sampling and analysis requirements of the Permit. We are sending you this information because you have purchased a Santa Clara Valley NPDES Industrial General Permit Compliance Binder from us.

If you are an industry which has filed an NOI, we are also enclosing a letter and questionnaire regarding exemptions from storm water sampling and analysis, which we request that you complete and return.

Please note that there are three NPDES Industrial General Permits. One was published by the EPA in the Federal Register on September 25, 1992. The EPA Industrial General Permit does not apply in California because it is an NPDES authorized state and the State Water Resources Control Board (State Board) has adopted a NPDES Industrial General Permit. The San Francisco Bay Regional Water Quality Control Board (Regional Board) adopted a NPDES Industrial General Permit specifically for Santa Clara Valley. If your industrial activity is located in Santa Clara Valley, only the Regional Board Industrial General Permit applies to you.

On September 16, 1992 the Regional Board amended the Santa Clara Valley Industrial General Permit to incorporate changes in the monitoring requirements under EPA's April 2, 1992 Final Rule. The State Board similarly amended the state-wide Industrial General Permit on September 17, 1992. Both permits became effective October 1, 1992, and NOI forms are still being accepted at this time without penalty. The attached permit amendment should be inserted into the Compliance Binder in the section with the Santa Clara Valley permit. The draft BMP Manual in your binder should be removed and replaced with the enclosed final manual.

PROGRAM PARTICIPANTS:
Campbell, Cupertino, Los Altos, Los Altos Hills, Los Gatos, Milpitas, Monte Sereno, Mountain View, Palo Alto, San Jose, Santa Clara, Saratoga, Sunnyvale, County of Santa Clara, and the Santa Clara Valley Water District

recycled paper

R0059167

The amendments to the Santa Clara Valley Industrial General Permit require a monitoring program be implemented by January 1, 1993, annual inspection and certification, and annual reporting. The minimum monitoring program requirements include monthly visual observations of storm water discharge during the wet season, observation or testing for non-storm water discharge two times during the dry season, sampling of one storm event in the 1992-93 wet season and two storm events in subsequent wet seasons. Samples must be analyzed for pH, specific conductivity, Total Suspended Solids (TSS), Total Organic Carbon (TOC) (Oil and Grease (O&G) may be substituted for TOC), and for other pollutants believed present. Industries wishing to monitor in groups were required to submit a Group Monitoring Plan to the Regional Board for approval by December 1, 1992. The amendments to the Santa Clara Valley Industrial General Permit also provided three mechanisms for exemption from the storm water sampling and analysis requirements.

Exemptions from Sampling and Analysis of Storm Water:

A discharger is not required to collect and analyze storm water samples if the discharger can certify one of the following and submits the certification to the Regional Board by December 1, 1992 for the 1992-93 wet season, and by August 1 for subsequent years:

1. A discharger certifies, in accordance with the permit provisions, that there is no exposure, or possibility of exposure, of industrial processes or materials to stormwater. The following conditions must be met:

   a. All illicit connections have been eliminated.

   b. All materials must be completely contained at all times so, if spilled, they will not directly or indirectly contact storm water.

   c. All emissions from stacks or air exhaust systems, unhoused manufacturing and heavy industrial equipment, and emissions of dust or particulate matter must not be exposed to storm water.

Or,

2. The Program has certified in writing that the discharger has an acceptable Storm Water Pollution Prevention Plan and should not be required to collect and analyze storm water samples for pollutants.

Or,

3. The discharger requests in writing that the Regional Board waive the sampling and analysis requirements (for a very good reason) and the Regional Board grants the waiver.

VOL 12 2 5875

R0059168

Revisions to Monitoring Requirements:

The revisions to the monitoring requirements included the following four changes:

1. Eliminating the requirement to monitor the first storm event of the wet season.

2. Requiring sampling and analysis of only one storm event during the 1992-93 season.

3. Requiring either grab sampling or a combination of grab and composite sampling for analysis.

4. Allowing analysis for Oil and Grease as a substitution for Total Organic Carbon.

Certification of Elimination of Illicit Connections:

All illicit (un-permitted) connections to the storm drain system are prohibited as of October 1, 1992, and industries were required to submit certification of elimination of all illicit connections to the Regional Board by that date. Industries may have until July 1, 1993 to remove all illicit connections if a written request to the Regional Board is made which justifies the need for extension and provides a schedule for completing the work.

We hope this information has been of assistance to your compliance with the Santa Clara Valley NPDES Industrial General Permit. If you have any questions or comments or would like to obtain additional BMP manuals, please call Marcia Guzzetta at our Nonpoint Source Hotline at (800) 794-2482.

Sincerely,

Keith Whitman

The attached pages are updates to the March 1992 binder entitled "Industrial Storm Water Pollution Control Compliance: A Comprehensive Source Book." Three items are enclosed:

1. A new Section 4 of the Industrial Storm Water Handbook (the fourth division in the binder). Please discard the entire March 1992 draft Section 4 and replace it with this one.

2. A new Section 5 of the Industrial Storm Water Handbook. Please discard the entire March 1992 draft Section 5 and replace it with this one.

3. A new outline of the Sample SWPP Plan, contained in the fifth division of the binder. Please discard the Outline pages of the March 1992 draft and replace them with these pages.

VOL 12

5877

4. SWPP PLAN PART 1: SOURCE IDENTIFICATION

The first part of the SWPP Plan is a detailed description of potential sources of contaminants that may be exposed to storm water at your facility. The intent of identifying these sources for your site can be seen as two-fold.

The primary purpose is to encourage you to identify the important potential storm water pollution sources at your facility. This will assist you in more directly addressing your SWPP Plan and monitoring program regarding pollutants from these sources at your facility. Effective source identification is important to your compliance process. This will help you to eliminate potential sources or, if this is not possible, to design effective Best Management Practices (BMPs) to prevent storm water pollution.

The second purpose of the SWPP Plan is to direct future inspectors toward locations on your site that they should be aware of, in order to determine whether your BMPs are satisfactory in preventing storm water pollution.

If your facility is designed and operated to effectively prevent storm water pollution, you may be able to complete this section with a minimal description. You may have *no* areas where contaminants could be exposed to storm water. However, this may be an unattainable ideal for the typical industrial facility, since many manufacturing processes are "dirty" by nature. The intent of the permit is not to cause you to cease operations, just to conduct them in a way that is effective at preventing storm water pollution. Still, a clear (if unstated) purpose of this section of the SWPP Plan is to encourage you to look at the areas on your site that may lead to storm water contamination, and to alter or eliminate them, even *before* your SWPP Plan goes into effect. If you eliminate the potential of a particular activity or location to contribute polluants to storm water, then you do not need to list the activity or certify that you will take continuing actions to minimize pollutants that enter storm water.

ORGANIZATION OF THIS SECTION

This section of the Guidance Handbook describes how to conduct a source identification for your facility and how to complete Part 1 of the SWPP Plan. Section 4 consists of the following parts:

- Identifying Potential Sources: Guidance on how to evaluate your facility to locate potential sources of storm water pollutants associated with industrial activities.
- Line-by-Line Guidance: One possible approach to completing Part 1 of the SWPP Plan for your facility. These steps are not part of the General Permit, but are suggested by the Santa Clara Valley NPS Program.
- Table 4-1: A suggested format for a source identification, with a list of potential sources that are common to typical industrial facilities.
- Figure 4-2: Guidance regarding the kinds of industrial activities that are likely to be potential sources; the materials which most commonly are potential pollutants from these activities; and some suggestions about the kinds of evidence commonly found at an industrial facility if a potential source is present.

VOL 12 2 5878

R0059171

IDENTIFYING POTENTIAL SOURCES OF STORM WATER POLLUTION AT AN INDUSTRIAL FACILITY

The Source Identification part of the SWPP Plan is the record of a process that you conduct at your facility. You, the facility operator, carry the burden of identifying sources and potential sources of storm water pollution at your facility. The General Permit does not specify a list of areas that you must check, allowing you to acknowledge that once you have looked at them you've completed the job. The General Permit language instead requires you to identify *all* potential sources *specific to your facility*, and then to address these in the other parts of your SWPP Plan.

Your source identification must be a list specialized for your own facility. The Regional Board's definition of "storm water associated with industrial activities" *includes but is not limited to* some activities and materials listed in the EPA's 1990 regulations. The activities that are definitely included appear in the box on this page. The intent is to lead you to identify activities that are potential sources of storm water pollution, whether or not they are specifically listed. Activities that are not considered industrial activities are *not* included in the SWPP Plan.

The General Permit instructions state that you may *leave off the list* activities and locations that are clearly and demonstrably *not* related to industrial activities, even though they are on an industrial site and may be sources of contaminants. A prime example is employee parking lots, where motor oil leaks. Another is office buildings or commercial facilities on the industrial site, where loading docks or air conditioning equipment could drip contaminants. If these turn out to be significant sources of storm water pollutants, you may need to work with your local municipality to identify means to control the pollutants. However, they are not covered by the General Permit and need not be included in your SWPP Plan.

Storm Water Associated with Industrial Activity includes but is not limited to items on this list, developed as part of U.S. EPA regulations.

Storm water is associated with industrial activity if any of these are exposed to storm water:

- **Material handling equipment or activities**
- **Raw materials**
- **Intermediate products**
- **Final products**
- **By-products**
- **Waste products**
- **Industrial machinery**

which are located in one of these areas of your facility:

- Industrial plant yards
- Material handling sites
- Refuse sites
- Sites used for the application and disposal of process waste waters
- Sites used for residual treatment, storage or disposal
- Shipping and receiving areas
- Manufacturing buildings
- Storage areas (including tank farms) for raw materials, intermediate and final products
- Areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water

Some activities are definitely included, and some are definitely excluded. Many other activities fall into a grey area between the two. You will need to evaluate how and where they are conducted at your facility to determine whether they are potential sources. You should include in your

VOL 12 2 5819

R0059172

source identification any locations on your site where you conduct industrial activities that may be exposed to storm water, whether or not they appear on the General Permit's list.

Because the source identification is a process, and every site is different, this guidance document does not provide a complete checklist for your facility. This section provides general guidance about the kinds of operations that could be sources of storm water pollution on your site.

The regulations are intended to address "industrial activities exposed to storm water." Exposure to storm water is not always obvious. The Regional Board's General Permit and the U.S. EPA's storm water regulations both make clear that they are *not* restricted to outdoor activities. Direct rainfall onto an outdoor activity is one obvious exposure to storm water. Another is storm water that flows across the site and contacts the activity or residues left by the activity.

Equipment used in an indoor manufacturing operation and then moved to a location where storm water contacts it is an industrial activity exposed to storm water. A less obvious circumstance is storm water that contacts particles, dust, liquid spills, or other residues that are created by an activity *inside a building*. Contaminants may be carried outdoors, for example on the tires of a forklift or through a roof vent, and build up on outdoor surfaces. These contaminants are the results of industrial activities which are exposed to storm water, and may need to be identified as potential sources.

LINE-BY-LINE GUIDANCE ON COMPLETING THE SWPP PLAN PART 1

This section contains guidance on preparing Part 1 of the SWPP Plan to conform to the "letter of the law" as put forth in the General Permit. The headings of this section correspond to specific items in the provisions of the General Permit. They also correspond to sections of the sample SWPP Plan prepared by the NPS Program for a fictitious industrial facility. The sample SWPP plan is included as an appendix to this handbook. (If you received this handbook as part of a binder distributed at the NPS Program Workshops, the sample SWPP Plan is included in Section V of the binder.)

1.0 INTRODUCTION AND BACKGROUND

Provide a brief description of your facility. Describe in a few sentences where the facility is and what work happens on the site.

2.0 SITE LOCATION AND REGIONAL INFORMATION

This section addresses permit section 5.a. which requires inclusion of a topographic or other map. The map should extend 1/4 mile beyond the facility boundary, and should show the facility, surface water bodies (including springs and wells), and the point(s) where the facility discharges storm water to a municipal storm drain system or other body of water. The requirements here may be included on the site map for Section 3.0.

2.1 Location

Briefly describe the facility location. Include descriptions of roads or railroads that serve as site boundaries. Describe the uses of the land bordering each side of the facility (e.g. other industrial uses, undeveloped, residential, agricultural).

2.2 Topography, Surface Water Bodies, and Wells

Reference your attached topographic map. If you are using the site map in section 3.0 as your topographic map, state this fact.

Describe any surface water bodies within 1/4 mile of your facility, including springs and wetlands. This should include *former* surface water bodies as well. Include creeks or intermittent streams that

VOL 12 2 5880

R0059173

are dry due to drought, and/or creeks that are dry during summer months but are flowing during the rainy season. Also, identify any drinking water wells, water supply wells, and injection wells within 1/4 mile of your facility.

2.3 Regional Rainfall

Estimate the mean annual precipitation, in inches, for your site. This information is available from the National Weather Service, or from a local weather station with a rain gauge--for example, a central station in San Jose. For convenience, you may wish to estimate the mean annual precipitation at your site using the map in Figure 4-1. The map shows lines of equal rainfall (isohyetal lines) for the Santa Clara Valley. You can locate the approximate area of your facility and read the mean annual precipitation from the nearest isohyetal line. A rough approximation is generally adequate.

3.0 SOURCE IDENTIFICATION: SITE DESCRIPTION

Your introductory text will meet requirements in permit section 5.b. Briefly describe the facility, including the overall size in acres or square feet, the number of buildings on the site, and major activities at the site. Provide a site map that identifies the following:

- Storm water conveyance, drainage, and discharge structures
- An outline of the storm water drainage areas for each storm water discharge point
- Paved areas and buildings
- Areas of pollutant contact with storm water or release to storm water. Include potential areas as well as known areas. Examples of areas include outdoor storage or process areas; loading and unloading areas; and waste treatment, storage or disposal areas
- Location of existing storm water structural control measures (e.g., berms, etc.)
- Surface water locations, including springs and wetlands
- Vehicle service areas
- Location of each well where fluids from the facility are injected underground
- Location of each dry well or infiltration device, where fluids from the facility are allowed to drain underground. (Note that regulations now prohibit many forms of this kind of device.)

It may be more convenient to provide the required information on several maps or map layers rather than on a single map. The provided map(s) may be hand sketched, but the detail and scale must be sufficiently accurate to provide a clear illustration of storm water movement, control, and potential points of pollutant contact.

3.1 Buildings

Provide a brief description of the buildings located on your site. This section should include a description of the activities performed in the buildings, the materials utilized in the buildings, and (briefly) the management structures and procedures used in the buildings to minimize potential for contact of raw materials and wastes with storm water (e.g., berms or other secondary containment structures, oil/water separators, spill response procedures, etc.). You should reference any documents that you already have that contain this information. Examples include best management practice (BMP) manuals or spill prevention and control documents. It may be possible for you to satisfy this requirement entirely using information from existing documents.

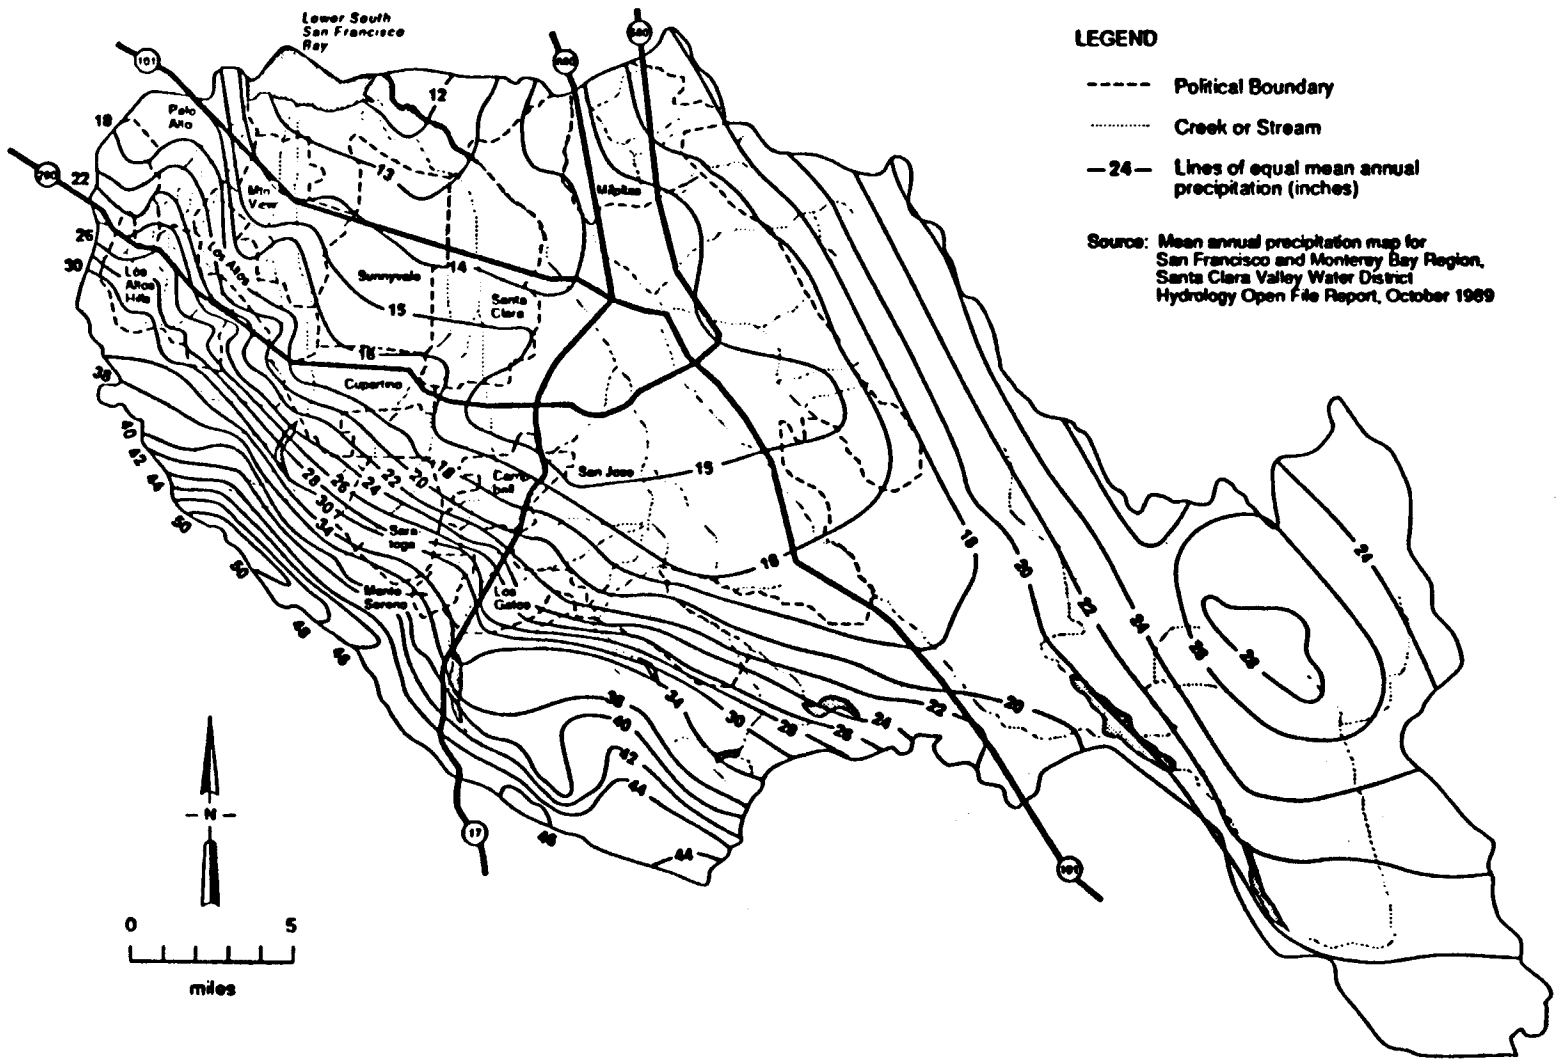
3.2 Outdoor Storage, Manufacturing, and/or Processing Areas

Describe areas of outdoor activities at your site. Include all storage, maintenance equipment parking, and manufacturing/processing areas. Describe the activities for each area, the materials handled, and management structures and procedures used to minimize potential for contact of raw materials and wastes with storm water. Identify any processes or activities that generate significant quantities of dust or particulate matter.

VOL 12 2 5881

R0059174

Figure 4-1. MEAN ANNUAL PRECIPITATION IN THE SANTA CLARA VALLEY



R0059175

Again, you may use references to applicable existing documents to satisfy this requirement.

3.3 Loading/Unloading Areas

Describe all loading/unloading areas. Describe the materials that are handled in each area and any management structures or procedures used to minimize potential for spills. Again, you may use references to applicable existing documents to satisfy this requirement.

3.4 Site Paving

Using best available estimates, describe the site paving and drainage. Estimate the percent of the facility that has impervious covering, that is, the percent that is paved or covered by buildings. Describe all paving (e.g., concrete or asphalt). Identify those areas that are not impervious.

Describe the drainage structures for the site, including trenches, storm drain lines, and holding ponds or tanks. Include a discussion of drainage areas that describes what areas drain to each drainage structure. Note that a small site may consist of a single drainage area.

3.5 Storm Drain System

Describe the storm drain system to which runoff from the site will drain. Identify the owner/operator of the system (typically, the city or municipality in which your facility is located) and the nearest receiving water (body of water into which runoff is discharged from the storm sewer). (See Section 3 of this handbook, describing the NOI, for advice on locating your receiving water.)

Identify all connections to the storm drain, and certify that no non-storm water discharges to the system are permitted. The certification should include a description of any tests for the presence of non-storm water discharges, the test methods used, dates of testing, and any on-site drainage points identified during testing. (Section 6 of this handbook describes the process in more detail.)

If this certification is not immediately possible because (a) this requirement necessitates significant structural changes or (b) you have applied for but not yet received an NPDES permit for non-storm water discharges, you must notify the Regional Board, the Program, and local agencies that a non-storm water discharge cannot be eliminated. The notification must include justification for a time extension, and a schedule (subject to modification by the Regional Board) indicating when non-storm water discharges will be eliminated. Note that the elimination of all non-storm water discharges must be completed prior to July 1, 1993.

3.6 Process Wastewater Sanitary Sewer System

Describe the sanitary sewer system for the facility. You must certify that there are no connections between the sanitary sewer and the storm water sewer. This certification may be incorporated into the above certification for the storm drain system.

3.7 Underground and Above Ground Storage Tanks

Describe all underground and above ground storage tanks at your site. Describe the materials that are handled in each tank and any management structures or procedures used to minimize potential for spills or leaks. This is another place where your SWPP Plan should make references to any applicable existing documents to satisfy this requirement partially or completely.

4.0 SOURCE IDENTIFICATION: DESCRIPTION OF POTENTIAL SOURCES OF POLLUTANTS IN STORM WATER DISCHARGES

4.1 Potential Pollutants

This section should discuss any materials or wastes that may be potential pollutants to storm water. These will include raw materials used in your process or maintenance activities and prod-

VOL 12 2 5803

R0059176

ucts and wastes generated by your process or maintenance activities.

4.1.1 List of potential pollutants to storm water

Identify potential pollutants that have a reasonable potential to be present in storm water. Developing this list is a large part of your SWPP Plan. One means to complete this task is to complete Table 4-1 in the following section, using the method suggested there.

4.1.2 Estimate of annual quantities of potential pollutants in storm water runoff

Identify those potential pollutants that may be present in storm water in significant quantities. Include any materials or wastes that are stored outside or in uncovered areas for any length of time. Include materials that are delivered or picked up on a regular basis and/or that have been leaked or spilled in the past (for example, bags of powdered raw materials that have been dropped and/or ripped, fuels, oils, or liquid raw materials or product that have been spilled or dripped).

Estimate the annual quantities of each of these identified potential pollutants that may be present in runoff. Utilize any existing sampling data describing pollutants in storm water discharge. If you have no sampling data, you may have to give rough initial guesses that will be verified by later sampling and analysis activities.

You may feel that your pollutant containment structures, coupled with your management practices (e.g., spill prevention and response, erosion control, employee training, storm water treatment procedures, etc.) are effective and that the annual quantities of the identified potential pollutants in storm water are likely not significant. If this is the case, you may state this in this section. Be sure to document your containment and management practices thoroughly in Part 2 of the SWPP Plan, the part where you describe storm water management controls for your facility.

If you have identified potential pollutants that may be present in significant quantities in runoff, but you have also developed management or containment practices that are to be initiated soon to eliminate or minimize the pollutants, summarize the practices here. Upon implementation, you may establish that the pollutants are no longer likely to be present in significant quantities in runoff. This will probably require some sampling and analysis activity, but it may then also minimize your storm water monitoring requirements.

4.1.3 Existing sampling data describing pollutants in storm water discharge

Provide any existing storm water analytical data. Data summaries may be provided in tabular or text form. Graphs or other pictorial data representations may also be included.

4.2 Isolation of Storm Drain from Sanitary Sewer

Summarize inspection, testing and other information that documents that your sanitary sewer lines do not discharge to the storm drain at any point. This information may be brief if provided in more

TABLE 4-1: IDENTIFYING POTENTIAL SOURCES FOR YOUR FACILITY

Table 4-1, following page 4-8, can be used to help you through the process of identifying potential sources of storm water pollutants at your facility. The table, "Identification of Potential Storm Water Pollutants," and the accompanying description in this section are only one means of completing this process, and are not specified by the Regional Board as a compliance process. However, the Santa Clara Valley NPS Program suggests that it is likely that you can comply effectively with the General Permit's SWPP Plan requirements if you use this process to locate and fully consider the possible sources of storm water pollutants on your site.

VOL 12 2 5804

R0059177

SOME COMMON POTENTIAL SOURCES AT A TYPICAL FACILITY

Manufacturing:
- Painting operations
- Washing operations
- Woodworking operations (sawdust)
- Primary metals operations (metal dust, coal dust)

Vehicles and Equipment:
- Outdoor or exposed maintenance areas
- Fueling areas
- Heavy equipment yards

Materials Handling Areas:
- Loading docks
- Bulk storage piles, dry materials
- Liquid storage tanks
- Liquid transfer stations
- Hazardous materials handling areas (refer to HazMat plans, SARA Title III requirements, and other requirements)
- Access roads
- Rail spurs
- Waste storage and handling areas

Rooftop and Outdoor Equipment:
- Cooling towers
- Air pollution control devices
- Roof vents from heavy manufacturing buildings
- Compressors
- Pumps
- Generators
- Transformers

SOME EVIDENCE OF PRESENCE OF POTENTIAL STORM WATER POLLUTANTS

- Stains on soil or pavement near outdoor equipment
- Small pools of standing liquid in periods long after a rain
- Equipment in poor repair or corroded
- Storage tanks corroded, stained, leaky, or in poor repair
- Particulates, soot, or oily film near roof or wall exhaust vents
- Open ports or hoses on equipment
- Metal dust, sawdust, other particles near doors to manufacturing buildings
- Uncovered storage of dry materials—large or small piles

You may wish to photocopy the blank pages of Table 4-1 and fill them in with information from your facility. You may then use the table itself to form the largest part of your "List of potential pollutants to storm water," described in paragraph 4.1.1 above, and the General Permit's Section A, provision 5.d. Or, you may prefer to use the table columns and the following steps as guidance in preparing your own tables and text to describe sources of potential storm water pollutants among your facility's industrial activities. To use the table, follow these steps.

Step 1. Identify industrial activities and materials handling areas. When you complete the table for your facility, include processes and areas at your site that are exposed to storm water. Any materials that are handled or stored outdoors (even for short time periods such as during delivery) should be listed in column 1. Potential sources may include handling of raw materials, products, or wastes, as well as process or maintenance activities.

Identifying industrial activities or materials handling areas that are sources of potential pollutants requires a thorough review by operating personnel who are familiar with the specific site and experienced in its industrial operations.

Note that in a few cases, you may need to include storm water from non-industrial activities in your source identification. Table 4-2 provides a list of potential sources to consider in a partially com-

VOL 12 2 5885

R0059178

pleted Column 1, and a revised Column A that will help determine whether you must list them as a potential source.

Step 2. Identify materials and wastes associated with each of the activities. The General Permit requires that you identify specific *substances* that are associated with each of the potential sources of storm water pollutants. The second step is to list the materials that you use in each of your process lines, industrial activities, and materials handling areas to be sure that you can identify the source of any substances that *might* later be detected in your storm water by your required monitoring program.

Your list should include potential pollutants directly related to your processes, as well as those not so directly related (for example, materials associated with vehicle maintenance). Dust or other particulate matter generated by your site activities should be included. If your facility includes unpaved areas that are bare (no vegetation), eroded soil should be included as a potential pollutant.

Step 3. Evaluate whether each substance may be present in storm water. The six columns under the heading of Column 3 may be used to determine, for each substance noted as being present in each industrial activity or materials handling operation, whether storm water may contact the industrial activity and, thus, whether the substance may be present in storm water discharge. Table 4-1 guides you in this effort using Columns A through F. Each of these columns asks a question about some typical ways in which storm water may contact an industrial activity or materials handling operation.

These categories may not be all-inclusive, but for the most part encompass those means by which storm water typically becomes associated with an industrial activity, as described by the General Permit. Consider carefully whether there are any other possible routes by which storm water may contact industrial equipment, its effluents and wastes, or materials that are to be used in its production processes. Refer again to the section beginning on page 4-2 for more suggestions on how to determine whether an industrial activity or material handling operation might produce substances that have a potential to contact storm water.

Step 4. Identify whether each activity is a source of potential storm water pollutants. In Column 4, simply mark "yes" for any substances for which you marked "yes" in *any* of the columns A through F in Step 3. This column becomes your list of potential storm water pollutants, or "pollutants that have a reasonable potential to be present in storm water discharge in significant quantities," as required in the General Permit (page 5, section A, provision 5.d).

Step 5. Select storm water management controls. Finally, in Column 5, for each of the substances identified as a potential pollutant in Column 4, describe the storm water management controls (or best management practices, BMPs) that you will implement at the facility to control the pollutants. This is merely a list of controls you will implement, as selected and described in Part 2 or your SWPP Plan.

Column 5 on Table 4-1 may be a short reference or the name and location of the BMP, since the column has very little space for a description. You will need to describe the controls in more detail in Part 2 of your SWPP Plan. Column 5 should include a reference to the page number or section number of the full description in the SWPP Plan.

The controls should include practices or structural BMPs that you currently have in place, those that are to be implemented as soon as the SWPP Plan takes effect, and those you intend to implement in the future. For example, if one of the industrial activities listed in Column 1 is loading and unloading of solvents at a railroad spur, the solvents are probably potential storm water pollutants (because spills can be prevented as best

TABLE 4-1. IDENTIFICATION OF POTENTIAL POLLUTANTS: NON-INDUSTRIAL ACTIVITIES

1. Industrial Activity or Material Handling Area	2. Materials used and wastes generated	3. Evaluation of Potential for Pollutants to be Present in Storm Water: Enter Y or N						4. Is this a Potential Pollutant? (Enter Y if you entered Y on A, B, C, D, E, or F)	5. Storm Water Management Controls (BMPs) Enter a brief description including reference to full description and site map in SWPP Plan.
		A. Does runoff commingle with storm water from industrial activities?	B. Transfer, handling, production, or other activities that might carry materials outdoors?	C. Evidence of spills or releases of products, materials, or wastes?	D. Secondary containment insufficient capacity, cracked, or with any openings?	E. Storm drains or storm drain connections in areas contacting material or waste?	F. Other possible points where storm water contacts equipment, materials, or waste?		
Non-Industrial Areas									
Open spaces within facility boundary	Soil (erosion)								
	Others								
Landscaped areas	Pesticides Herbicides Clippings Soil (erosion)								
	Others								
Employee parking lots	Oils, grease from leaking motors								
	Others								

R0059181

00005 2 27 NOV

as humanly possible but might never be reduced to zero probability). In this case, the facility probably has in place a hazardous materials management plan or spill control and response plan which is fully described in some other document in order to comply with other environmental regulations. The facility should reference that BMP in Column 5, and Part 2 of your SWPP Plan should refer to the exact title of the other document and the page on which the description of the practice may be found.

If the BMP is a structure that is not yet in place or a practice that has not been initiated, the description in the SWPP Plan should include a schedule for implementation and a sufficiently detailed description. The SWPP Plan should include enough text so that a regulator may evaluate whether it will sufficiently control the potential pollutant from the specific industrial activity that is its source.

Also in Column 5, for each of the substances identified as potential pollutants in Column 4, you should include the identifying number that you use on the SWPP Plan's site map that shows the location of the industrial activity or material handling area that is the source of the potential pollutant. Since the SWPP Plan is expected to be reviewed by a regulator who is visiting your site, the SWPP Plan should include enough information that the inspector may locate the storm water management controls at your facility.

The completed Table 4-1 can work in combination with the completed site map to summarize all the information required in the General Permit's provision requiring identification of potential pollutants, and the two can provide a reliable "road map" to any further text or documentation that plant employees need to continue implementing the correct practices.

FIGURE 4-2: SOME GUIDANCE ON POTENTIAL SOURCES OF POLLUTANTS

Figure 4-2 includes, in the left-hand column (Column 1), a number of suggested potential sources of pollutants that are common to industrial facilities of many kinds. Identify which of the listed activities or areas apply to your facility, and add them to your Table 4-1, along with others that are specific to your plant. This generic table can provide some guidance, but you can be sure that others exist on your site that do not fit these simple descriptions.

VOL 12 2 5889

R0059182

FIGURE 4-2.
