(a) All facilities shall conduct analytical monitoring of NO_3+NO_2, TKN, NH_3, TSS and total Zn, and the data reported to the New Mexico State Program Manager at the address above (Part VI.B). A copy of the data shall be kept with the Pollution Prevention Plan. Monitoring for the additional parameters indicated shall be conducted at least quarterly (4 times per year) in the second and fourth year of the permit. The first period of monitoring to begin on the date one year following the date of issuance of this permit. Each year of monitoring (four quarters) shall be reported no later than the following March. The report to NMED shall be postmarked no later that the 31st day of the following March.

* * * * *

Y. Storm Water Discharges Associated With Industrial Activity From Rubber, Miscellaneous Plastic Products, and Miscellaneous Manufacturing Industries

* * * * *

5. Monitoring and Reporting Requirements

(a) * * * In addition to the parameters listed in Table Y–1 the following facilities shall conduct monitoring of the additional parameters indicated and the data reported to the New Mexico State Program Manager at the address above (Part VI.B). A copy of the data shall be kept with the Pollution Prevention Plan. Monitoring for the additional parameters indicated shall be conducted at least quarterly (4 times per year) in the second and fourth year of the permit. The first period of monitoring to begin on the date one year following the date of issuance of this permit. Each year of monitoring (four quarters) shall be reported no later than the following March. The report to NMED shall be postmarked no later that the 31st day of the following March.

(1) Rubber products manufacturing: shall monitor TSS, TKN, NO_3+NO_2, NH_3, and total Hg;
(2) Miscellaneous plastics products: shall monitor NO_3+NO_2, NH_3, TKN, TSS, and total Hg.

* * * * *

Z. Storm Water Discharges Associated With Industrial Activity From Leather Tanning and Finishing Facilities

* * * * *

5. Monitoring and Reporting Requirements

(a) * * * In addition to the visual monitoring, all facilities shall conduct analytical monitoring of COD, NO_3+NO_2, TKN, NH_3, and TSS, and the data reported to the New Mexico State Program Manager at the address above (Part VI.B). A copy of the data shall be kept with the Pollution Prevention Plan. Monitoring for the additional parameters indicated shall be conducted at least quarterly (4 times per year) in the second and fourth year of the permit. The first period of monitoring to begin on the date one year following the date of issuance of this permit. Each year of monitoring (four quarters) shall be reported no later than the following March. The report to NMED shall be postmarked no later that the 31st day of the following March.

* * * * *

AA. Storm Water Discharges Associated With Industrial Activity From Fabricated Metal Products Industry

* * * * *

5. Monitoring and Reporting Requirements

(a) * * * In addition to the parameters listed in Table AA–1,2 the following facilities shall conduct monitoring of the additional parameters indicated and the data reported to the New Mexico State Program Manager at the address above (Part VI.B). A copy of the data shall be kept with the Pollution Prevention Plan. Monitoring for the additional parameters indicated shall be conducted at least quarterly (4 times per year) in the second and fourth year of the permit. The first period of monitoring to begin on the date one year following the date of issuance of this permit. Each year of monitoring (four quarters) shall be reported no later than the following March. The report to NMED shall be postmarked no later that the 31st day of the following March.

(1) Metal products except coating: shall monitor TKN, NH3, and TSS;
(2) Metal coating & engraving: shall monitor TKN, and NH3.

* * * * *

AC. Storm Water Discharges Associated With Industrial Activity From Facilities That Manufacture Electronic and Electrical Equipment and Components, Photographic and Optical Goods

* * * * *

5. Monitoring and Reporting Requirements

(a) All facilities shall conduct analytical monitoring of total Aluminum (Al), total Zn and total Hg, and the data reported to the New Mexico State Program Manager at the address above (Part VI.B). A copy of the data shall be kept with the Pollution Prevention Plan. Monitoring for the additional parameters indicated shall be conducted at least quarterly (4 times per year) in the second and fourth year of the permit. The first period of monitoring to begin on the date one year following the date of issuance of this permit. Each year of monitoring (four quarters) shall be reported no later than the following March. The report to NMED shall be postmarked no later that the 31st day of the following March.

In addition to the above-referenced conditions, per 40 CFR 122.44(d)(6) to ensure consistency with work element 6 of the State-adopted Water Quality Management Plan (WQMP) approved by EPA under Section 208(b) of the CWA, NMED is requiring that all permittees covered under this general permit, who are required to do sampling, be additionally required to monitor and report pH.

* * * * *

E. Oklahoma (OKR05###)*

Oklahoma 401 certification special permit conditions revise the permit as follows:

Part I.B.3. Limitations on Coverage. Insert the following paragraph:

f. Discharges to Oklahoma Outstanding Resource Waters and Scenic Rivers. "New" point source discharges of storm water associated with industrial activity (those commencing after the June 25, 1992, effective date of the Oklahoma Water Quality Standards—Oklahoma Annotated Code Title 785, Chapter 45) to the following waters:

(1) waterbodies designated as "Outstanding Resource Waters" and/or "Scenic Rivers" in Appendix A of the Oklahoma Water Quality Standards;

(2) Oklahoma waterbodies located within the watersheds of waterbodies designated as "Scenic Rivers" in Appendix A of the Oklahoma Water Quality Standards; and

(3) waterbodies located within the boundaries of Oklahoma Water Quality Standards Appendix B areas which are specifically designated as "Outstanding Resource Waters" in Appendix A of the Oklahoma Water Quality Standards.

D. Texas (TXR05###)*

Texas 401 certification special permit conditions revise the permit as follows:

1. The following sections are added to Part V of the permit:

Part V. Numeric Effluent Limitations

* * * * *

C. All Discharges to Inland Waters

The maximum allowable concentrations of each of the hazardous metals, stated in terms of milligrams per liter (mg/l), for discharges to inland waters are as follows:

Total metal	Monthly average	Daily composite	Single grab
Arsenic	0.1	0.2	0.3
Barium	1.0	2.0	4.0
Cadmium	0.05	0.1	0.2
Chromium	0.5	1.0	5.0

Total metal	Monthly average	Daily composite	Single grab
Copper	0.5	1.0	2.0
Lead	0.5	1.0	1.5
Manganese	1.0	2.0	3.0
Mercury	0.005	0.005	0.01
Nickel	1.0	2.0	3.0
Selenium	0.05	0.1	0.2
Silver	0.05	0.1	0.2
Zinc	1.0	2.0	6.0

C. All Discharges to Tidal Waters

The maximum allowable concentrations of each of the hazardous metals, stated in terms of milligrams per liter (mg/l), for discharges to tidal waters are as follows:

Total metal	Monthly average	Daily composite	Single grab
Arsenic	0.1	0.2	0.3
Barium	1.0	2.0	4.0
Cadmium	0.1	0.2	0.3
Chromium	0.5	1.0	5.0
Copper	0.5	1.0	2.0
Lead	0.5	1.0	1.5
Manganese	1.0	2.0	3.0
Mercury	0.005	0.005	0.01
Nickel	1.0	2.0	3.0
Selenium	0.10	0.2	0.3
Silver	0.05	0.1	0.2
Zinc	1.0	2.0	6.0

2. The following section is added to Part VI. of the permit:

* * * * *

D. *Toxicity Testing.* All facilities that have demonstrated significant lethality, which has not been controlled, shall continue to perform WET testing in accordance with the requirements below. Permittees that are required to monitor for acute whole effluent toxicity shall initiate the series of tests described below within 180 days after the issuance of this permit or within 90 days after the commencement of a new discharge.

The permittee shall test the effluent for lethality in accordance with the provisions of this section. Such testing will determine if an effluent sample meets the Texas Surface Water Quality Standard listed at 31 TAC § 307.6(e)(2)(B) of greater than 50% survival of the appropriate test organisms in 100% effluent for a 24-hour period.

1. Test Procedures

a. The permittee shall conduct acute 24 hour static toxicity tests on both an appropriate invertebrate and an appropriate fish (vertebrate) test species (EPA/600/4–90–027 Rev. 9/91, Section 6.1.). Freshwater species must be used for discharges to freshwater water bodies. Due to the non-saline nature of rainwater, freshwater test species should also be used for discharges to estuarine, marine or other naturally saline waterbodies.

The following tests shall be used:

1. Acute static 24-hour definitive toxicity test using *Daphnia pulex*. A minimum of four (4) replicates with a minimum of five (5) organisms per replicate shall be used for this test.

2. Acute static 24-hour definitive toxicity test using fathead minnow (*Pimephales promelas*). A minimum of four (4) replicates with a minimum of ten (10) organisms per replicate shall be used for this test.

b. Five dilutions in addition to an appropriate control (0% effluent), shall be used in the toxicity tests. These effluent concentrations shall be 6%, 13%, 25%, 50% and 100%. The control and/or dilution water shall consist of a standard, synthetic, moderately hard, reconstituted water. If more than 10% of the test organisms in any control die, that test, including the control and all effluent dilution(s), shall be repeated, with all results from *both* tests reported.

c. All test organisms, procedures and quality assurance criteria used shall be in accordance with *Methods for Measuring the Acute Toxicity of Effluents and Receiving Waters to Freshwater and Marine Organisms*, EPA/600/4–90–027 (Rev. September 1991). EPA has proposed to establish regulations regarding these test methods (December 4, 1989, 53 *FR* 50216).

d. Tests shall be conducted semiannually (twice per year) on a grab sample of the discharge at 100% strength (no dilution), the dilutions specified in paragraph b. above, and a control consisting of either receiving water or synthetic dilution water. Results of all tests conducted with any species shall be reported according to EPA/600/4–90–027 (Rev. September 1991), Section 12, Report Preparation, and the report retained onsite. The test results shall be summarized in the format used on Table VI–A and submitted to EPA with the Discharge Monitoring Reports (DMR's). On the DMR, the permittee shall report test results in accordance with the instructions on Table VI–A.

3. The following definitions are added to Part X of the permit:

Part X. Definitions

"Inland Waters"—all surface waters in the State other than "tidal waters" as defined below.

"Tidal Waters"—those waters of the Gulf of Mexico within the jurisdiction of the State of Texas, bays and estuaries thereto, and those portions of the river systems which are subject to the ebb and flow of the tides, and to the intrusion of marine waters.

Region IX

Arizona (AZR05###) and Federal Facilities in Arizona (AZR05*##F)*

Arizona 401 certification special permit conditions revise the permit as follows:

1. Part I section B is amended by the addition of the following:

Part I. Coverage Under This Permit

* * * * *

B. Eligibility

* * * * *

8. Compliance with Water Quality Standards of the State of Arizona

Discharges authorized by this permit shall not cause or contribute to a violation of any applicable water quality standard of the State of Arizona (Arizona Administrative Code, Title 18, Chapter 11).

2. The following language is added to Part II section D:

Part II. Notification Requirements

* * * * *

D. Where to Submit

Notices of Intent shall also be submitted to the State of Arizona Department of Environmental Quality at the following address: Storm Water Coordinator, Arizona Department of Environmental Quality, 3033 N. Central Avenue, Phoenix, Arizona 85012.

NOIs submitted to the State of Arizona shall include the well registration number if storm water associated with industrial activity is discharged to a dry well or an injection well.

3. The following language is added to Part IV section E.2:

Part IV. Storm Water Pollution Prevention Plans

* * * * *

E. Special Pollution Prevention Plan Requirements

* * * * *

2. *Additional Requirements for Storm Water Discharges Associated With Industrial Activity From Facilities Subject to EPCRA Section 313 Requirements*

* * * * *

e. SARA Section 313 (Community Right to Know) Facilities shall have the following requirement:

Liquid storage areas for Section 313 water priority chemicals shall be operated to minimize discharges of Section 313 chemicals. Appropriate measures to minimize discharges of Section 313 chemicals shall include secondary containment provided for at least the entire contents of the largest tank plus sufficient freeboard to allow for the *25-year, 24-hour precipitation event,* a strong spill contingency and integrity testing plan, and/or other equivalent measures.

4. Part IV. Section E is amended by the addition of the following:

Part IV. Storm Water Pollution Prevention Plans

* * * * *

E. Special Pollution Prevention Plan Requirements

* * * * *

5. Delineation of Facility Areas Below Base Elevation

All facilities with any portion of the facility that is located at or below the Base Elevation shall delineate on the site map those portions of the facility that are located at or below the Base Elevation.

5. The following language is added to Part VI section B.2:

Part VI. Monitoring and Reporting Requirements

* * * * *

B. Reporting: Where to Submit

* * * * *

2. *Additional Notification.* Facilities subject to monitoring and reporting requirements shall also submit Discharge Monitoring Report Form(s) and other required monitoring information to the State of Arizona Department of Environmental Quality at the following address: Storm

Water Coordinator/DMR, Arizona Department of Environmental Quality, 3033 N. Central Avenue, Phoenix, Arizona 85012.

6. The following is added to Part IX section B:

Part IX. Termination of Coverage

* * * * *

B. Addresses

Notices of Termination shall also be submitted to the State of Arizona Department of Environmental Quality at the following address: Storm Water Coordinator, Arizona Department of Environmental Quality, 3033 N. Central Avenue, Phoenix, Arizona 85012.

7. The following definitions are added to Part X of the permit:

Part X. Definitions

"Significant Sources of Non-Storm Water"—includes, but is not limited to discharges which could cause or contribute to violations of water quality standards of the State of Arizona, and discharges which could include releases of oil or hazardous substances in excess of reportable quantities under Section 311 of the Clean Water Act (see 40 CFR 110.10 and CFR 117.21) or Section 102 of CERCLA (see CFR 302.4).

"Base Elevation"—elevation of a surface waterbody having a one percent chance of being equaled or exceeded during any given year.

NPDES FORM

EPA

United States Environmental Protection Agency
Washington, DC 20460

Notice of Intent (NOI) for Storm Water Discharges Associated with Industrial Activity Under a NPDES General Permit

Submission of this Notice of Intent constitutes notice that the party identified in Section II of this form intends to be authorized by a NPDES permit issued for storm water discharges associated with industrial activity in the State identified in Section III of this form. Becoming a permittee obligates such discharger to comply with the terms and conditions of the permit. ALL NECESSARY INFORMATION MUST BE PROVIDED ON THIS FORM.

I. Permit Selection: You must indicate the NPDES Storm Water general permit under which you are applying for coverage. Check one of these.

Baseline Industrial ☐ Baseline Construction ☐ Multi-Sector (Group Permit) ☐

II. Facility Operator Information

Name: ______ Phone: ______

Address: ______ Status of Owner/Operator: ☐

City: ______ State: ____ ZIP Code: ______

III. Facility/Site Location

Name: ______

Is the facility located on Indian Lands? (Y or N) ☐

Address: ______

City: ______ State: ____ ZIP Code: ______

Latitude: ______ Longitude: ______ Quarter: ____ Section: ____ Township: ______ Range: ______

IV. Site Activity Information

MS4 Operator Name: ______

Receiving Water Body: ______

If you are filing as a co-permittee, enter storm water general permit number: ______

SIC or Designated Activity Code: Primary: ______ 2nd: ______

Is the facility required to submit monitoring data? (1, 2, 3, or 4) ☐

If You Have Another Existing NPDES Permit, Enter Permit Number: ______

Multi-Sector Permit Applicants Only:

Based on the instructions provided in Addendum H of the Multi-Sector permit, are species identified in Addendum H in proximity to the storm water discharges to be covered under this permit, or the areas of BMP construction to control those storm water discharges? (Y or N) ☐

Will construction (land disturbing activities) be conducted for storm water controls? (Y or N) ☐

Is applicant subject to and in compliance with a written historic preservation agreement? (Y or N) ☐

V. Additional Information Required for Construction Activities Only

Project Start Date: ______ Completion Date: ______ Estimated Area to be Disturbed (in Acres): ______

Is the Storm Water Pollution Prevention Plan in compliance with State and/or Local sediment and erosion plans? (Y or N) ☐

VI. Certification: The certification statement in Box 1 applies to all applicants.
The certification statement in Box 2 applies only to facilities applying for the Multi-Sector storm water general permit.

BOX 1

ALL APPLICANTS:

I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

BOX 2

MULTI-SECTOR STORM WATER GENERAL PERMIT APPLICANTS ONLY:

I certify under penalty of law that I have read and understand the Part I.B. eligibility requirements for coverage under the Multi-Sector storm water general permit, including those requirements relating to the protection of species identified in Addendum H.

To the best of my knowledge, the discharges covered under this permit, and construction of BMPs to control storm water run-off, are not likely to and will not likely adversely affect any species identified in Addendum H of the Multi-Sector storm water general permit or are otherwise eligible for coverage due to previous authorization under the Endangered Species Act.

To the best of my knowledge, I further certify that such discharges, and construction of BMPs to control storm water run-off, do not have an effect on properties listed or eligible for listing on the National Register of Historic Places under the National Historic Preservation Act, or are otherwise eligible for coverage due to a previous agreement under the National Historic Preservation Act.

I understand that continued coverage under the Multi-Sector general permit is contingent upon maintaining eligibility as provided for in Part I.B.

Print Name: ______ Date: ______

Signature: ______

EPA Form 3510-6 (8-98)

R0016543

Instructions - EPA Form 3510-6
Notice Of Intent (NOI) For Storm Water Discharges Associated With Industrial Activity
To Be Covered Under a NPDES General Permit

Who Must File A Notice Of Intent (NOI) Form

Federal law at 40 CFR Part 122 prohibits point source discharges of storm water associated with industrial activity to a water body(ies) of the U.S. without a National Pollutant Discharge Elimination System (NPDES) permit. The operator of an industrial activity that has such a storm water discharge must submit a NOI to obtain coverage under a NPDES Storm Water General Permit. If you have questions about whether you need a permit under the NPDES Storm Water program, or if you need information as to whether a particular program is administered by EPA or a state agency, telephone or write to the Notice of Intent Processing Center at (703) 931-3230.

Where To File NOI Form

NOIs must be sent to the following address: Storm Water Notice of Intent (4203)
401 M Street, S.W.
Washington, DC 20460

Completing The Form

You must type or print, using upper-case letters, in the appropriate areas only. Please place each character between the marks. Abbreviate if necessary to stay within the number of characters allowed for each item. Use one space for breaks between words, but not for punctuation marks unless they are needed to clarify your response. If you have any questions on this form, call the Notice of Intent Processing Center at (703) 931-3230.

Section I Permit Selection

You must indicate the NPDES storm water general permit under which you are applying for coverage. Check one box only. The Baseline Industrial and Baseline Construction permits were issued in September 1992. The Multi-Sector Permit became effective October 1, 1995.

Section II Facility Operator Information

Provide the legal name of the person, firm, public organization, or any other entity that operates the facility or site described in this application. The name of the operator may or may not be the same as the name of the facility. The responsible party is the legal entity that controls the facility's operation, rather than the plant or site manager. Do not use a colloquial name. Enter the complete address and telephone number of the operator.

Enter the appropriate letter to indicate the legal status of the operator of the facility: F = Federal; S = State; M = Public (other than federal or state); P = Private.

Section III Facility/Site Location Information

Enter the facility's or site's official or legal name and complete street address, including city, state, and ZIP code. If the facility or site lacks a street address, indicate the state and either the latitude and longitude of the facility to the nearest 15 seconds or the quarter, section, township, and range (to the nearest quarter section) of the approximate center of the site. Do not provide a P.O. Box number as the street address.

Indicate whether the facility is located on Indian lands.

Section IV Site Activity Information

If the storm water discharges to a municipal separate storm sewer system (MS4), enter the name of the operator of the MS4 (e.g., municipality name, county name) and the receiving water of the discharge from the MS4. (A MS4 is defined as a conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains) that is owned or operated by a state, city, town, borough, county, parish, district, association, or other public body which is designed or used for collecting or conveying storm water.)

If the facility discharges storm water directly to receiving water(s), enter the name of the receiving water(s).

If you are filing as a co-permittee and a storm water general permit number has been issued, enter that number in the space provided.

Indicate the monitoring status of the facility. Refer to the permit for information on monitoring requirements. Indicate the monitoring status by entering one of the following:

1 = Not subject to monitoring requirements under the conditions of the permit.
2 = Subject to monitoring requirements and required to submit data.
3 = Subject to monitoring requirements but not required to submit data.
4 = Subject to monitoring requirements but submitting certification for monitoring exclusion.

List, in descending order of significance, up to two 4-digit standard industrial classification (SIC) codes that best describe the principal products or services provided at the facility or site identified in Section III of this application. If you are applying for coverage under the construction general permit, enter "CO" (which represents SIC codes 1500 - 1799).

For industrial activities defined in 40 CFR 122.26(b)(14)(i)-(xi) that do not have SIC codes that accurately describe the principal products produced or services provided, use the following 2-character codes.

HZ = Hazardous waste treatment, storage, or disposal facilities, including those that are operating under interim status or a permit under subtitle C of RCRA [40 CFR 122.26 (b)(14)(iv)];
LF = Landfills, land application sites, and open dumps that receive or have received any industrial wastes, including those that are subject to regulation under subtitle D of RCRA [40 CFR 122.26 (b)(14)(v)];
SE = Steam electric power generating facilities, including coal handling sites [40 CFR 122.26 (b)(14)(vii)];
TW = Treatment works treating domestic sewage or any other sewage sludge or wastewater treatment device or system, used in the storage, treatment, recycling, and reclamation of municipal or domestic sewage [40 CFR 122.26 (b)(14)(ix)]; or,
CO = Construction activities [40 CFR 122.26 (b)(14)(x)].

If there is another NPDES permit presently issued for the facility or site listed in Section III, enter the permit number. If an application for the facility has been submitted but no permit number has been assigned, enter the application number.

Facilities applying for coverage under the Multi-Sector storm water general permit must answer the last three questions in Section IV. Refer to Addendum H of the Multi-Sector general permit for a list of species that are either proposed or listed as threatened or endangered. "BMP" means "Best Management Practices" that are used to control storm water discharges.

Indicate whether any construction will be conducted to install or develop storm water runoff controls.

Section V Additional Information Required for Construction Activities Only

Construction activities must complete Section V in addition to Sections I through IV. Only construction activities need to complete Section V.

Enter the project start date and the estimated completion date for the entire development plan.

Provide an estimate of the total number of acres of the site on which soil will be disturbed (round to the nearest acre).

Indicate whether the storm water pollution prevention plan for the site is in compliance with approved state and/or local sediment and erosion plans, permits, or storm water management plans.

Section VI Certification

Federal statutes provide for severe penalties for submitting false information on this application form. Federal regulations require this application to be signed as follows:

For a corporation: by a responsible corporate officer, which means: (i) president, secretary, treasurer, or vice-president of the corporation in charge of a principal business function, or any other person who performs similar policy or decision making functions, or (ii) the manager of one or more manufacturing, production, or operating facilities employing more than 250 persons or having gross annual sales or expenditures exceeding $25 million (in second-quarter 1980 dollars), if authority to sign documents has been assigned or delegated to the manager in accordance with corporate procedures;

For a partnership or sole proprietorship: by a general partner or the proprietor; or

For a municipality, state, Federal, or other public facility: by either a principal executive officer or ranking elected official.

Paperwork Reduction Act Notice

Public reporting burden for this application is estimated to average 0.5 hours per application, including time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding the burden estimate, any other aspect of the collection of information, or suggestions for improving this form, including any suggestions which may increase or reduce this burden to: Chief, Information Policy Branch, 2136, U.S. Environmental Protection Agency, 401 M Street, SW, Washington, DC 20460, or Director, Office of Information and Regulatory Affairs, Office of Management and Budget, Washington, DC 20503.

NPDES FORM

EPA

United States Environmental Protection Agency
Washington, DC 20460

Notice of Termination (NOT) of Coverage Under a NPDES General Permit for Storm Water Discharges Associated with Industrial Activity

Submission of this Notice of Termination constitutes notice that the party identified in Section II of this form is no longer authorized to discharge storm water associated with industrial activity under the NPDES program. ALL NECESSARY INFORMATION MUST BE PROVIDED ON THIS FORM.

I. Permit Information

NPDES Storm Water General Permit Number: ____________

Check Here if You are No Longer the Operator of the Facility: ☐

Check Here if the Storm Water Discharge is Being Terminated: ☐

II. Facility Operator Information

Name: ____________ Phone: ____________

Address: ____________

City: ____________ State: ____ ZIP Code: ____________

III. Facility/Site Location Information

Name: ____________

Address: ____________

City: ____________ State: ____ ZIP Code: ____________

Latitude: ______ Longitude: ______ Quarter: ____ Section: ____ Township: ______ Range: ______

IV. Certification:

I certify under penalty of law that all storm water discharges associated with industrial activity from the identified facility that are authorized by a NPDES general permit have been eliminated or that I am no longer the operator of the facility or construction site. I understand that by submitting this Notice of Termination, I am no longer authorized to discharge storm water associated with industrial activity under this general permit, and that discharging pollutants in storm water associated with industrial activity to waters of the United States is unlawful under the Clean Water Act where the discharge is not authorized by a NPDES permit. I also understand that the submittal of this Notice of Termination does not release an operator from liability for any violations of this permit or the Clean Water Act.

Print Name: ____________ Date: ____________

Signature: ____________

Instructions for Completing Notice of Termination (NOT) Form

Who May File a Notice of Termination (NOT) Form

Permittees who are presently covered under an EPA-issued National Pollutant Discharge Elimination System (NPDES) General Permit (including the 1995 Multi-Sector Permit) for Storm Water Discharges Associated with Industrial Activity may submit a Notice of Termination (NOT) form when their facilities no longer have any storm water discharges associated with industrial activity as defined in the storm water regulations at 40 CFR 122.26(b)(14), or when they are no longer the operator of the facilities.

For construction activities, elimination of all storm water discharges associated with industrial activity occurs when disturbed soils at the construction site have been finally stabilized and temporary erosion and sediment control measures have been removed or will be removed at an appropriate time, or that all storm water discharges associated with industrial activity from the construction site that are authorized by a NPDES general permit have otherwise been eliminated. Final stabilization means that all soil-disturbing activities at the site have been completed, and that a uniform perennial vegetative cover with a density of 70% of the cover for unpaved areas and areas not covered by permanent structures has been established, or equivalent permanent stabilization measures (such as the use of riprap, gabions, or geotextiles) have been employed.

Where to File NOT Form

Send this form to the the following address:

Storm Water Notice of Termination (4203)
401 M Street, S.W.
Washington, DC 20460

Completing the Form

Type or print, using upper-case letters, in the appropriate areas only. Please place each character between the marks. Abbreviate if necessary to stay within the number of characters allowed for each item. Use only one space for breaks between words, but not for punctuation marks unless they are needed to clarify your response. If you have any questions about this form, telephone or write the Notice of Intent Processing Center at (703) 931-3230.

EPA Form 3510-7 (8-98)

Instructions - EPA Form 3510-7
Notice of Termination (NOT) of Coverage Under The NPDES General Permit for Storm Water Discharges Associated With Industrial Activity

Section I Permit Information

Enter the existing NPDES Storm Water General Permit number assigned to the facility or site identified in Section III. If you do not know the permit number, telephone or write your EPA Regional storm water contact person.

Indicate your reason for submitting this Notice of Termination by checking the appropriate box:

If there has been a change of operator and you are no longer the operator of the facility or site identified in Section III, check the corresponding box.

If all storm water discharges at the facility or site identified in Section III have been terminated, check the corresponding box.

Section II Facility Operator Information

Give the legal name of the person, firm, public organization, or any other entity that operates the facility or site described in this application. The name of the operator may or may not be the same name as the facility. The operator of the facility is the legal entity which controls the facility's operation, rather than the plant or site manager. Do not use a colloquial name. Enter the complete address and telephone number of the operator.

Section III Facility/Site Location Information

Enter the facility's or site's official or legal name and complete address, including city, state and ZIP code. If the facility lacks a street address, indicate the state, the latitude and longitude of the facility to the nearest 15 seconds, or the quarter, section, township, and range (to the nearest quarter section) of the approximate center of the site.

Section IV Certification

Federal statutes provide for severe penalties for submitting false information on this application form. Federal regulations require this application to be signed as follows:

For a corporation: by a responsible corporate officer, which means: (i) president, secretary, treasurer, or vice-president of the corporation in charge of a principal business function, or any other person who performs similar policy or decision making functions, or (ii) the manager of one or more manufacturing, production, or operating facilities employing more than 250 persons or having gross annual sales or expenditures exceeding $25 million (in second-quarter 1980 dollars), if authority to sign documents has been assigned or delegated to the manager in accordance with corporate procedures;

For a partnership or sole proprietorship: by a general partner or the proprietor; or

For a municipality, State, Federal, or other public facility: by either a principal executive officer or ranking elected official.

Paperwork Reduction Act Notice

Public reporting burden for this application is estimated to average 0.5 hours per application, including time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding the burden estimate, any other aspect of the collection of information, or suggestions for improving this form, including any suggestions which may increase or reduce this burden to: Chief, Information Policy Branch, 2136, U.S. Environmental Protection Agency, 401 M Street, SW, Washington, DC 20460, or Director, Office of Information and Regulatory Affairs, Office of Management and Budget, Washington, DC 20503.

	King County.*
	Pierce County.*
	Snohomish County.*
	Spokane County.†

[6] County was listed in regulation; however, population dropped below 100,000 in 1990 census.

[7] Unincorporated areas defined as: beginning at the mouth of the South Fork Deer River and extending west to SW corner Section 18, Township 6 South, Range 2 West, thence north to NW corner, Section 6, Township 2 South, Range 2 West, thence east to the Mobile County line, thence south along the county line to U.S. Highway 90 bridge.

[8] All unincorporated areas of Shelby County within the drainage basin of the Cahaba River upstream of the confluence of Shoal Creek and the Cahaba River.

[9] Unincorporated areas of St. Clair County within the drainage basin of the Cahaba River.

* Identified in November 1990 rule.

† 1990 Census unincorporated, urbanized population increased to more than 100,000.

Addendum E—Basic Format for Environmental Assessment

This is the basic format for the Environmental Assessment prepared by EPA from the review of the applicant's Environmental Information Document (EID) required for new source NPDES permits. Comprehensive information should be provided for those items or issues that are affected; the greater the impact, the more detailed information needed. The EID should contain a brief statement addressing each item listed below, even if the item is not applicable. The statement should at least explain why the item is not applicable.

A. General Information
1. Name of applicant
2. Type of facility
3. Location of facility
4. Product manufactured

B. Description Summaries
1. Describe the proposed facility and construction activity
2. Describe all ancillary construction not directly involved with the production processes
3. Describe briefly the manufacturing processes and procedures
4. Describe the plant site, its history, and the general area

C. Environmental Concerns
1. Historical and Archeological (include a statement from the State Historical Preservation Officer)
2. Wetlands Protection and 100-year Floodplain Management (the Army Corps of Engineers must be contacted if any wetland area of floodplain is affected)
3. Agricultural Lands (a prime farmland statement from the Soil Conservation Service must be included
4. Coastal Zone Management and Wild and Scenic Rivers
5. Endangered Species Protection and Fish and Wildlife Protection (a statement from the U.S. Fish and Wildlife Service must be included)
6. Air, Water, and Land Issues: quality, effects, usage levels, municipal services used, discharges and emissions, runoff and wastewater control, geology and soils involved, land-use compatibility, solid and hazardous waste disposal, natural and man-made hazards involved.
7. Biota concerns: floral, faunal, aquatic resources, inventories, and effects
8. Community Infrastructures available and resulting effects: social, economic, health, safety, educational, recreational, housing, transportation, and road resources

Basic Environmental Information Document Guidelines for New Source Category Industries

Addendum G—List of Applicable References

The following guidance manuals contain valuable information in assisting permittees in complying with the permit conditions of the multi-sector general permit and are available from The Office of Water Resources Center, USEPA—RC–4100, 401 M Street, SW., Washington, DC 20460, Telephone: (202) 260-7786.

Storm Water Management for Industrial Activities, Developing Pollution Prevention Plans and Best Management Practices (EPA–832–R–92–006, September 1992).

Summary: Storm Water Management for Industrial Activities, Developing Pollution Prevention Plans and Best Management Practices (October 1992).

NPDES Storm Water Sampling Guidance Document (EPA 833–B–92–001, July 1992).

Addendum H—Endangered Species Guidance

I. Instructions

Below is a list of species that EPA has determined may be affected by the activities covered by the multi-sector general permit (MSGP). These species are listed by county. In order to get MSGP coverage, applicants must:

- Indicate in box provided on the NOI whether any species listed in this Addendum are in proximity to the facility, and
- Certify pursuant to Section II.B.12 of the MSGP that their storm water discharges, and BMPs constructed to control storm water runoff, are not likely, and will not be likely to adversely affect species identified in Addendum H of this permit.

To do this, please follow steps 1 through 4 below.

Step 1: Review the County Species List to Determine if any Species are Located in the Discharging Facility County

If no species are listed in a facility's county or if a facility's county is not found on the list, an applicant is eligible for MSGP coverage and may indicate in the NOI that no species are found in proximity and provide the necessary certification. If species are located in the county, follow step 2 below. Where a facility is located in more than one county, the lists for all counties should be reviewed.

Step 2: Determine if any Species may be Found "In Proximity" to the Facility

A species is in proximity to a facility's storm water discharge when the species is:

- Located in the path or immediate area through which or over which contaminated point source storm water flows from industrial activities to the point of discharge into the receiving water.
- Located in the immediate vicinity of, or nearby, the point of discharge into receiving waters.
- Located in the area of a site where storm water BMPs are planned or are to be constructed.

The area in proximity to be searched/surveyed for listed species will vary with the size of the facility, the nature and quantity of the storm water discharges, and the type of receiving waters. Given the number of facilities potentially covered by the MSGP, no specific method to determine whether species are in proximity is required for permit coverage under the MSGP. Instead, applicants should use the method or methods which best allow them to determine to the best of their knowledge whether species are in proximity to their particular facility. These methods may include:

- *Conducting visual inspections:* This method may be particularly suitable for facilities that are smaller in size, facilities located in non-natural settings such as highly urbanized areas or industrial parks where there is little or no nature habitat; and facilities that discharge directly into municipal storm water collection systems. For other facilities, a visual survey of the facility site and storm water drainage areas may be insufficient to determine whether species are likely to be located in proximity to the discharge.
- *Contacting the nearest State Wildlife Agency or U.S. Fish and Wildlife Service (FWS) or National Marine Fisheries Service (NMFS) offices.* Many endangered and threatened species are found in well-defined areas or habitats. That information is frequently known to state or federal wildlife agencies. FWS has offices in every state. NMFS has regional offices in: Gloucester, Massachusetts; St. Petersburg, Florida; Long Beach, California; Portland, Oregon; and Juneau, Alaska.
- *Contacting local/regional conservation groups.* These groups inventory species and their locations and maintain lists of sightings and habitats.
- *Conducting a formal biological survey.* Larger facilities with extensive storm water discharges may choose to conduct biological surveys as the most effective way to assess whether species are located in proximity and whether there are likely adverse effects.

If no species are in proximity, an applicant is eligible for MSGP coverage and may indicate that in the NOI and provide the necessary certification. If listed species are found in proximity to a facility, applicants must follow step 3 below.

Step 3: Determine if Species Could be Adversely Affected by the Facility's Storm Water Discharges or by BMPS to Control Those Discharges

Scope of Adverse Effects: Potential adverse effects from storm water include:

- *Hydrological.* Storm water may cause siltation, sedimentation or induce other changes in the receiving waters such as temperature, salinity or pH. These effects will vary with the amount of storm water discharged and the volume and condition of the receiving water. Where a storm water discharge constitutes a minute portion of the total volume of the receiving water, adverse hydrological effects are less likely.
- *Habitat.* Storm water may drain or inundate listed species habitat.
- *Toxicity.* In some cases, pollutants in storm water may have toxic effects on listed species.

The scope of effects to consider will vary with each site. Applicants must also consider the likelihood of adverse effects on species from any BMPs to control storm water. Most adverse impact from BMPs are likely to occur from the construction activities.

Using earlier ESA authorizations for MSGP eligibility: In some cases, a facility may be eligible for MSGP coverage because actual or potential adverse affects were addressed or discounted through an earlier ESA authorization. Examples of such authorization include:

- An earlier ESA section 7 consultation for that facility.
- A section 10(a) permit issued for the facility.
- An area-wide Habitat Conservation Plan applicable to that facility.
- A clearance letter from the Services (which discounts the possibility of an adverse impact from the facility).

In order for applicants to use an earlier ESA authorization to meet eligibility requirements: (1) The authorization must adequately address impacts for storm water discharges and BMPs from the facility on endangered and threatened species, (2) it must be current because there have been no subsequent changes in facility operations or circumstances which might impact species in ways not considered in the earlier authorization, and (3) the applicant must comply with any requirements from those authorizations to avoid or mitigate adverse effects to species. Applicants who wish to pursue this approach should carefully review documentation for those authorizations ensure that the above conditions are met.

If adverse effects are not likely, an applicant is eligible for MSGP coverage and may indicate in the NOI that species are found in proximity and provide the necessary certification. If adverse effects are likely, follow step 4 below.

Step 4: Determine if Measures can be Implemented to Avoid any Adverse Effects

If an applicant determines that adverse effects are likely, it can receive coverage if appropriate measures are undertaken to avoid or eliminate any actual or potential adverse affects prior to applying for permit coverage. These measures may involve relatively simple changes to facility operations such as re-routing a storm water discharge to bypass an area where species are located.

At this stage, applicants may wish to contact the FWS and/or NMFS to see what appropriate measures might be suitable to avoid or eliminate adverse impacts to species.

If applicants adopt these measures, they must continue to abide by them during the course of permit coverage.

If appropriate measures are not available, the applicant is not eligible at that time for coverage under the MSGP. Applicants should contact the appropriate EPA regional office about either:

- Entering into Section 7 consultation in order to obtain MSGP coverage, or
- Obtaining an individual NPDES storm water permit.

II. County/Species List

[The following list identifies federally listed or proposed U.S. species by State and County. It has been updated through March 31, 1995.]

State/County	Group name	Inventory name	Scientific name	IR/FF*
ALASKA				
ALEUTIAN ISLANDS	BIRDS	GOOSE, ALEUTIAN CANADA	Branta canadensis leucopareia.	
ALEUTIANS EAST	BIRDS	EIDER, STELLER'S	POLYSTICTA STELLERI.

"NOTICE"

This guidance applies to the voluntary development of wellhead protection plans in

Oregon. It is intended solely as guidance for local jurisdictions and state officials implementing and certifying individual wellhead protection plans. Compliance with or use of these guidelines does not waive requirements from any other rules or statutes in Oregon.

Provided resources are available, the Oregon Department of Environmental Quality and Oregon Health Division will update this Guidance Manual in approximately two years (or earlier if necessary). We are always open to suggestions for changes or improvements to the document. Feel free to contact us:

Table 3-2: Potential Sources of Groundwater Contaminants (Return to: Chapter 3 - Step 1 ; Chapter 3 - Step 4) or Use Your Browser's Back Arrow to Return to Document

Source		Groundwater Contaminants[1,2,3]
Commercial/Industrial		
Automobile	Body Shops/Repair Shops	Waste oils; solvents; acids; paints; automotive wastes[4]; miscellaneous cutting oils.
	Car Washes	Soaps; detergents; waxes; miscellaneous chemicals; hydrocarbons.
	Gas Stations	Oils; solvents; miscellaneous wastes.
Boat Services/Repair/Refinishing		Diesel fuels; oil; septage from boat waste disposal area; wood preservative and treatment chemicals; paints; waxes; varnishes; automotive wastes[4].
Cement/Concrete Plants		Diesel fuels; solvents; oils; miscellaneous wastes.
Chemical/Petroleum Processing/Storage		Hazardous chemicals; solvents; hydrocarbons; heavy metals; asphalt.
Dry Cleaners		Solvents (perchloroethylene, petroleum solvents, Freon); spotting chemicals (trichloroethane, methylchloroform, ammonia, peroxides, hydrochloric acid, rust removers, amyl acetate).
Electrical/Electronic Manufacturing		Cyanides; metal sludges; caustic (chromic acid); solvents; oils; alkalis; acids; paints and paint sludges; calcium fluoride sludges; methylene chloride; perchloroethylene; trichloroethane; acetone; methanol; toluene; PCBs.
Fleet/Trucking/Bus Terminals		Waste oil; solvents; gasoline and diesel fuel from vehicles and storage tanks; fuel oil; other automotive wastes[4].
Food Processing		Nitrates; salts; phosphorus; miscellaneous food wastes; chlorine; ammonia; ethylene glycol.
Funeral Services/Graveyards		Formaldehyde; wetting agents; fumigants; solvents; leachate; lawn and garden maintenance chemicals[5].
Furniture Repair/Manufacturing		Paints; solvents; degreasing and solvent recovery sludges; lacquers; sealants.
Hardware/Lumber/Parts Stores		Hazardous chemical products in inventories; heating oil and fork lift fuel from storage tanks; wood-staining and treating products such as creosote; paints; thinners; lacquers; varnishes.
Home Manufacturing		Solvents; paints; glues and other adhesives; waste insulation; lacquers; tars; sealants; epoxy wastes; miscellaneous chemical wastes.
Junk/Scrap/Salvage Yards		Automotive wastes[4]; PCB contaminated wastes; any wastes from businesses[6] and households[7]; oils; lead.
Machine Shops		Solvents; metals; miscellaneous organics; sludges; oily metal shavings; lubricant and cutting oils; degreasers (tetrachloroethylene); metal marking fluids; mold-release agents.
Medical/Vet Offices		X-ray developers and fixers[8]; infectious wastes; radiological wastes; biological wastes; disinfectants; asbestos; beryllium; dental acids; miscellaneous chemicals.
Metal Plating/Finishing/Fabricating		Sodium and hydrogen cyanide; metallic salts; hydrochloric acid; sulfuric acid; chromic acid; boric acid; paint wastes; heavy metals; plating wastes; oils; solvents.
		Mine spills or tailings that often contain metals; acids; highly corrosive

Mines/Gravel Pits	mineralized waters; metal sulfides; metals; acids; minerals sulfides; other hazardous and nonhazardous chemicals[9].
Office Buildings/Complexes	Building wastes[6]; lawn and garden maintenance chemicals[5]; gasoline; motor oil.
Parking Lots/Malls (> 50 spaces) (H)	Hydrocarbons; heavy metals; building wastes[6].
Photo Processing/Printing	Biosludges; silver sludges; cyanides; miscellaneous sludges; solvents; inks; dyes; oils; photographic chemicals.
Plastics/Synthetics Producers	Solvents; oils; miscellaneous organic and inorganics (phenols, resins); paint wastes; cyanides; acids; alkalis; wastewater treatment sludges; cellulose esters; surfacant; glycols; phenols; formaldehyde; peroxides; etc.
Research Laboratories	X-ray developers and fixers[8]; infectious wastes; radiological wastes; biological wastes, disinfectants; asbestos; beryllium; solvents; infectious materials; drugs; disinfectants; (quaternary ammonia, hexachlorophene, peroxides, chlornexade, bleach); miscellaneous chemicals.
RV/Mini Storage	Automobile wastes[4]; gasoline and diesel fuel from vehicles and storage tanks
Wood Preserving/Treating	Wood preservatives: creosote, pentachlorophenol, arsenic; heavy metals.
Wood/Pulp/Paper Processing and Mills	Metals; acids; minerals; sulfides; other hazardous and nonhazardous chemicals[9]; organic sludges; sodium hydroxide; chlorine; hypochlorite; chlorine dioxide; hydrogen peroxide; treated wood residue (copper quinolate, mercury, sodium bazide); methanol; paint sludges; solvents; creosote; coating and gluing wastes.
Agricultural/Rural	
Auction Lots/Boarding Stables	Livestock sewage wastes; nitrates; phosphates; coliform and noncoliform bacteria; giardia, viruses; total dissolved solids.
Confined Animal Feeding Operations	Livestock sewage wastes; nitrates; phosphates; chloride; chemical sprays and dips for controlling insect, bacterial, viral and fungal pests on livestocks; coliform[10] and noncoliform bacteria; viruses; giardia; total dissolved solids.
Farm Machinery Repair	Automotive wastes[4]; welding wastes.
Crops - Irrigated and Nonirrigated	Pesticides[11]; fertilizers[12]; nitrates; phosphates; potassium (can be worsened by over-watering).
Lagoons/Liquid Wastes	Nitrates; Livestock sewage wastes; salts; pesticides[11]; fertilizers[17]; bacteria.
Pesticide/Fertilizer/Petroleum Storage & Transfer Areas	Pesticides[11]; fertilizers[12]; petroleum residues.
Rural Homesteads - Rural	Machine shops: Automotive wastes[4]; welding wastes; solvents; metals; subricants; sludges.
	Septic systems: Septage; coliform[10] and noncoliform bacteria; viruses; nitrates; heavy metals; synthetic detergents; cooking and motor oils; bleach; pesticides;[5,13] paints; paint thinner; photographic chemicals; swimming pool chemi-cals;[14] septic tank/cesspool cleaner chemicals;[15] elevated levels of chloride, sulfate, calcium, magnesium, potassium, and phosphate.
Residential/Municipal	

Airports (Maintenance/Fueling Areas)	Jet fuels; deicers; diesel fuel; chlorinated solvents; automotive wastes;[4] heating oil; building wastes[6].
Apartments and Condominiums	Swimming pool maintenance chemicals[14] ; pesticides for lawn and garden maintenance and cockroach, termite, ant, rodent, and other pest control[5,13], wastes from on-site sewage treatment plants; household hazardous wastes.
Camp Grounds/RV Parks	Septage; gasoline; diesel fuel from boats; pesticides for controlling mosquitoes, ants, ticks, gypsy moths, and other pests[11,13]; household hazardous wastes from recreational vehicles (RVs)[7].
Drinking Water Treatment Plants	Treatment chemicals; pesticides[11].
Fire Stations	General building wastes[6]; hydrocarbons from test burn areas.
Golf Courses	Fertilizers[12]; herbicides[11]; pesticides for controlling mosquitoes, ticks, ants, gypsy moths, and other pests[5].
Housing	Household hazardous wastes[7]: Household cleaners; oven cleaners; drain cleaners; toilet cleaners; disinfectants; metal polishes; jewelry cleaners; shoe polishes; synthetic detergents; bleach; laundry soil and stain removers; spot removers and dry cleaning fluid; solvents; lye or caustic soda; household pesticides;[13] photo chemical; paints; varnishes; stains; dyes; wood preservatives (creosote); paint and lacquer thinners; paint and varnish removers and deglossers; paint brush cleaners; floor and furniture strippers.
	Mechanical repair and other maintenance products: Automotive wastes;[4] waste oils; diesel fuel; kerosene; #2 heating oil; grease; degreasers for driveways and garages; metal degreasers; asphalt and roofing tar; tar removers; lubricants; rustproofers; car wash detergents; car waxes and polishes; rock salt; refrigerants.
	Lawn/garden care: Fertilizers;[11] herbicides and other pesticides used for lawn and garden maintenance[5] (can be worsened by over-watering).
	Swimming pools: Swimming pool maintenance chemicals[14].
	Urban runoff/storm water[3]: Gasoline; oil; other petroleum products; microbiological contaminants.
Landfills/Dumps	Leachate; organic and inorganic chemical contaminants; waste from households[7] and businesses[6]; nitrates; oils; metals; solvents; sludge.
Motor Pools	Automotive wastes[4]: solvents; waste oils; hydrocarbons from storage tanks.
Parks	Fertilizers[12]; herbicides[5]; insecticides[11,13].
Railroad Yards/Maintenance/Fueling Areas	Diesel fuel; herbicides for rights-of-way[11]; creosote from preserving wood ties; solvents; paints; waste oils.
Schools	Machinery/vehicle serving wastes; gasoline and heating oil from storage tanks; general building wastes[6]; pesticides[11,13].
Septic Systems	Septage; coliform[10] and noncoliform bacteria; viruses; nitrates; heavy metals; synthetic detergents; cooking and motor oils; bleach; pesticides[5,13]; paints; paint thinner; photographic chemicals; swimming pool chemicals[14]; septic tank/cesspool cleaner chemicals[15]; elevated levels of chloride, sulfate, calcium, magnesium, potassium, and phosphate; other household hazardous wastes[7].
	PCBs from transformers and capacitors; oils; solvents; sludges; acid

Utility Stations/Maintenance Areas	solution; metal plating solutions (chromium, nickel, cadmium); herbicides from utility rights-of-way.
Waste Transfer/Recycling Stations	Residential and commercial solid waste residues.
Wastewater	Municipal wastewater; sludge[16]; treatment chemicals[17]; nitrates; heavy metals; coliform[10] and noncoliform bacteria; nonhazardous wastes[16].
Miscellaneous	
Above Ground Storage Tanks	Heating oil; diesel fuel; gasoline; other chemicals.
Construction/Demolition Areas (Plumbing, Heating, and Air Conditioning, Painting, Paper Hanging, Decorating, Drywall and Plastering, Acoustical Insulation, Carpentry, Flooring, Roofing, and Sheet Metal etc.)	Solvents; asbestos; paints; glues and other adhesives; waste insulation; lacquers; tars; sealants; epoxy waste; miscellaneous chemical wastes; explosives.
Historic Gas Stations	Diesel fuel; gasoline; kerosene.
Historic Waste Dumps/Landfills	Leachate; organic and inorganic chemicals; waste from households[7]; and businesses[6]; nitrates; oils; heavy metals; solvents.
Injection Wells/Drywells/Sumps	Storm water runoff[3]; spilled liquids; used oils; antifreeze; gasoline; solvents; other petroleum products; pesticides[11]; and a wide variety of other substances.
Managed Forests	Pesticides; fertilizers; total suspended solids.
Military Installations	Wide variety of hazardous and nonhazardous wastes depending on the nature of the facility and operation[3,9]; diesel fuels; jet fuels; solvents; paints; waste oils; heavy metals; radioactive wastes; explosives.
Surface Water - Stream/Lakes/Rivers	Directly related to surface water quality in the stream, lake, or river which is recharging groundwater.
Transportation Corridors	Herbicides in highway right-of-way[11,5]; road salt (sodium and calcium chloride); road salt, anticaking additives (ferric ferrocyanide, sodium ferrocyanide); road salt anticorrosives (phosphate and chromate); automotive wastes[4]; fertilizers.
Underground Storage Tanks	Diesel fuel; gasoline; heating oil; other chemical and petroleum products.
Wells - Such as Water Supply Wells, Monitoring Wells, Unsealed or Abandoned Wells, and Test Holes	Storm water runoff[3]; solvents; nitrates; septic tanks; hydrocarbons; and a wide variety of other substances.

[1] In general, groundwater contamination stems from the misuse and improper disposal of liquid and solid wastes; the illegal dumping or abandonment of household, commercial, or industrial chemicals; the accidental spilling of chemicals from trucks, railways, aircraft, handling facilities, and storage tanks; or the improper siting, design, construction, operation, or maintenance of agricultural, residential, municipal, commercial, and industrial drinking water wells and liquid and solid waste disposal facilities. Contaminants also can stem from atmospheric pollutants, such as airborne sulfur and nitrogen compounds, which are created by smoke, flue dust, aerosols, and automobile emissions, fall as acid rain, and percolate through the soil. When the sources list in this table are used and managed properly, groundwater contamination is not likely to occur.

[2] Contaminants can reach groundwater from activities occurring on the land surface, such as industrial waste storage; from sources below the land surface but above the water table, such as septic systems; from structures beneath the water table, such as wells; or from contaminated recharge water.

[3] This table lists the most common wastes, but not all potential wastes. For example, it is not possible to list all potential contaminants contained in storm water runoff or from military installations.

[4] Automobile wastes can include gasoline; antifreeze; automatic transmission fluid; battery acid; engine and radiator flushes; engine and metal degreasers; hydraulic (brake) fluid; and motor oils.

[5] Common pesticides used for lawn and garden maintenance (i.e., weed killers, and mite, grub, and aphid controls) include such chemicals as 2,4-D; chlorpyrifos; diazinon; benomyl; captan; dicofol; and methoxychlor.

[6] Common wastes from public and commercial buildings include automotive wastes; and residues from cleaning products that may contain chemicals such a xylenols, glycol esters, isopropanol, 1,1,1,-trichloroethane, sulfonates, chlorinated phenols, and cresols.

[7] Household hazardous wastes are common household products which contain a wide variety of toxic or hazardous components (see also **Appendix F**: Household Waste Fact Sheet).

[8] X-ray developers and fixers may contain reclaimable silver, glutaldehyde, hydroquinone, potassium bromide, sodium sulfite, sodium carbonate, thiosulfates, and potassium alum.

[9] The *Resource Conservation and Recovery Act* (RCRA) defines a hazardous waste as a solid waste that may cause an increase in mortality or serious illness or pose a substantial threat to human health and the environment when improperly treated, stored, transported, disposed of, or otherwise managed. A waste is hazardous if it exhibits characteristics of ignitability, corrosivity, reactivity, and/or toxicity. Not covered by RCRA regulations are domestic sewage; irrigation waters or industrial discharges allowed by the *Clean Water Act*; certain nuclear and mining wastes; household wastes; agricultural wastes (excluding some pesticides); and small quantity hazardous wastes (i.e., less than 220 pounds per month) generated by businesses.

[10] Coliform bacteria can indicate the presence of pathogenic (disease-causing) microorganisms that may be transmitted in human feces. Diseases such as typhoid fever, hepatitis, diarrhea, and dysentery can result from sewage contamination of water supplies.

[11] Pesticides include herbicides, insecticides, rodenticides, fungicides and avicides. EPA has registered approximately 50,000 different pesticide products for use in the United States. Many are highly toxic and quite mobile in the subsurface. An EPA survey found that the most common pesticides found in drinking water wells were DCPA (dacthal) and atrazine, which EPA classifies as moderately toxic (class 3) and slightly toxic (class 4) materials, respectively.

[12] The EPA National Pesticides Survey found that the use of fertilizers correlates to nitrate contamination of groundwater supplies.

[13] Common household pesticides for controlling pests such as ants, termites, bees, wasps, flies, cockroaches, silverfish, mites, ticks, fleas, worms, rates, and mice can contain active ingredients include naphthalene, phosphorus, xylene, chloroform, heavy metals, chlorinated hydrocarbons, arsenic, strychnine, kerosene, nitrosamines, and dioxin.

[14] Swimming pool chemicals can contain free and combined chlorine; bromine; iodine; mercury-based, copper-based, and quaternary algaecides; cyanuric acid; calcium or sodium hypochlorite; muriatic acid; sodium carbonate.

[15] Septic tank/cesspool cleaners include synthetic organic chemicals such as 1,1,1,-trichloroethane, tetrachloroethylene, carbon tetrachlorine, and methylene chloride.

[16] Muncipal wastewater treatment sludge can contain organic matter, nitrates; inorganic salts, heavy metals; coliform and noncoliform bacteria; and viruses.

[17] Municipal wastewater treatment chemicals include calcium oxide; alum; activated alum, cabon, and silics; polymers; ion exhcange resins; sodium hydroxide; chlorine; ozone; and corrosion inhibitors.

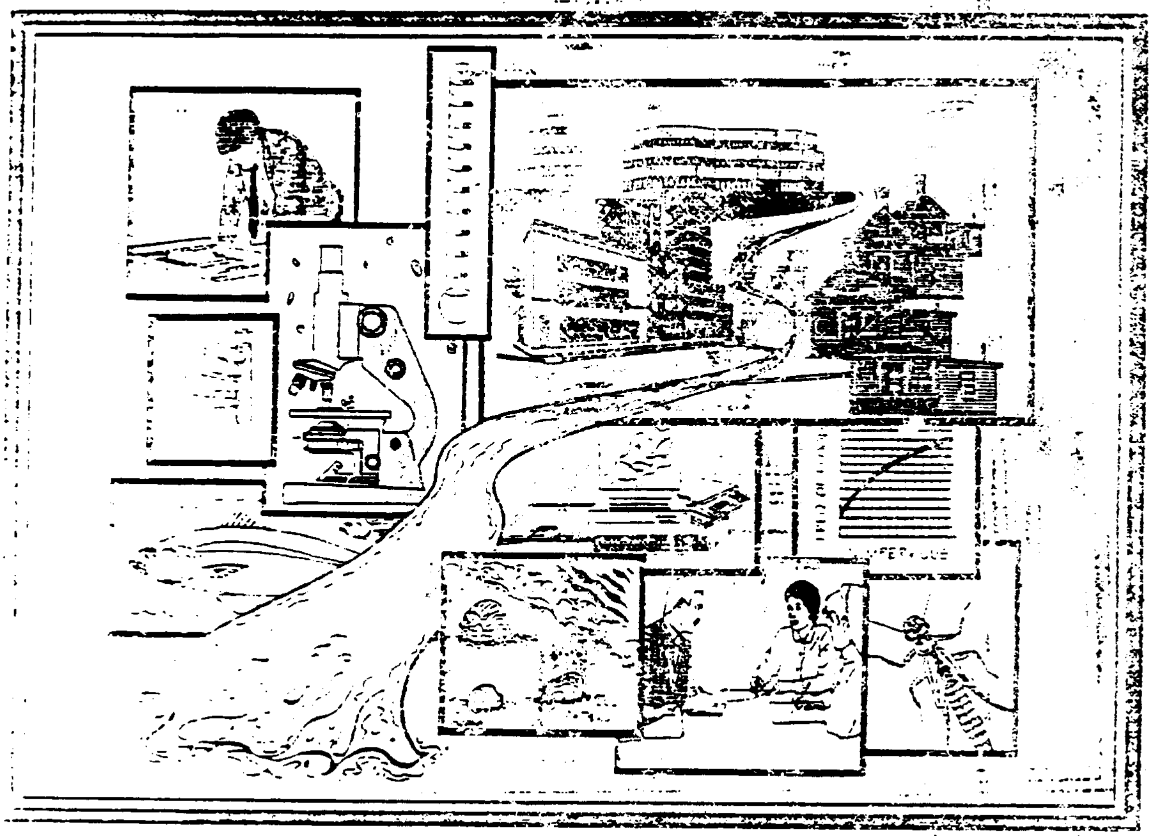
R0016611

ENVIRONMENTAL INDICATORS
to Assess
Stormwater Control Programs and Practices

FINAL REPORT



Center for Watershed Protection
Richard A. Claytor and Whitney E. Brown

July 1996

CENTER FOR WATERSHED PROTECTION

R0016612

Abstract

Title: Environmental Indicators to Assess Stormwater Control Programs and Practices

Date: July, 1996

Authors: Richard A. Claytor and Whitney E. Brown
Center for Watershed Protection

Publisher: Published under a cooperative agreement with the U. S. Environmental Protection Agency and the Center for Watershed Protection. The Center for Watershed Protection is a non-profit organization dedicated to the protection, restoration, and stewardship our nations water resources and watersheds through a watershed approach. The Center promotes the advancement of innovative and effective land and water management techniques, and serves as a forum for planners, engineers, landscape architects and municipal officials engaged in watershed protection.

Abstract: The document presents a series of alternate stormwater monitoring techniques which rely on indicators, or surrogates of chemical, biological, physical, social, and programmatic conditions to assess stormwater program and practice success. Twenty-six "environmental indicator" profile, or fact sheets are presented which describe the indicator, explain advantages and disadvantages for use, review indicator utility, present a case example, and cite references for further investigation. A framework for using indicators is presented, along with a potential methodology for crafting an indicator based monitoring program for municipal and industrial site managers. Three theoretical case examples are presented applying the principles of environmental indicator based stormwater monitoring programs.

ACKNOWLEDGMENTS

The preparation of this document was made possible through a Cooperative Agreement with the U.S. Environmental Protection Agency (Assistance ID No. C X 823668-01-0).

We would like to thank a number of individuals whose support and participation were key to the completion of this final environmental indicator document. In particular, we would like to extend our appreciation to Ms. Kimberly Ogden Hankins and Mr. William Swietlik of U.S. EPA for their direction and guidance through the preparation of this document. We would like to thank the numerous people who took time out of their busy schedule to respond to our telephone and mail requests, with specific appreciation to Mr. Roger Bannerman, Mr. Derek Booth, Mr. Gail Boyd, Mr. Charlie Gougeon, Ms. Marcia Guzetta, Dr. Melinda Lalor, Mr. Peter Mangarella, Mr. Keith Van Ness, Mr. Cameron Wiegand, Ms. Kia Whittlesey, and Mr. Chris Yoder.

In addition, we would like to extend our appreciation to Ms. Mary Marsters and Mr. John LaRocca of the Rensselaerville Institute for their facilitation of the stakeholder meetings. Their compilation of comments and remarks from the participants was invaluable in the preparation of this document. Furthermore, we would like to thank Mr. Chuck Noss and Ms. Raye Grant of the Water Environment Research Foundation for their participation and helpful suggestions during the preparation of this document.

Finally, we would like to extend our greatest appreciation to the following list of stormwater management experts who attended and participated in the several stakeholder meetings, held in four cities, and who provided invaluable input on the preparation of this document.

EXECUTIVE SUMMARY

In response to National Pollutant Discharge Elimination System (NPDES) stormwater regulations, many municipalities and industrial facilities have invested significant time, money, and manpower towards stormwater monitoring. Traditionally, the focus of these efforts have been end-of-pipe conditions and chemical and physical water quality criteria. However, many stormwater management professionals have begun to question the ability of traditional monitoring to accurately describe existing conditions in receiving waters, evaluate the overall integrity of aquatic communities, and assess the degree of improvement in stream systems. Environmental indicators have become popular as regulators, resource protection managers, and others look to alternative techniques to assess stormwater management efforts and environmental health.

Environmental indicators are select parameters and indices which can be used to characterize overall conditions in the receiving water and provide benchmarks for assessing the success of stormwater management efforts.

This report represents a component of a larger project call the Environmental Indicators/Measures of Success Project, funded by the U.S. Environmental Protection Agency (EPA) under the Clean Water Act, Section 104(B)(3). The first phase of this project, conducted by The Center for Watershed Protection, consisted of a review of approximately 500 research papers and studies. The results of the review were summarized in an annotated bibliography of environmental indicator resources. The second phase, performed by The Rensselaerville Institute, involved soliciting stakeholder input on the selection of appropriate indicators and on development of a flexible methodology for using indicators. The final phase of the project will focus on local and/or state demonstration projects testing the use of indicators. This effort will be performed by the Water Environment Research Federation. Case studies will be prepared on the outcome of the demonstration projects.

This report is intended for municipal stormwater managers, regulatory agencies, and industrial site managers. A framework for identifying appropriate indicators based on reference and baseline conditions, regional considerations, and available resources is provided (Chapter II). The applicability and usefulness of twenty-six environmental indicators for stormwater monitoring are summarized in a series of Profile Sheets (Chapter III). A suggested methodology for development of a comprehensive stormwater monitoring program, based on environmental indicators, is provided (Chapter IV). Lastly, three theoretical scenarios are presented to illustrate the potential application of stormwater indicators in real world situations (Chapter 5). A summary of the key findings in this report is presented below.

STORMWATER ENVIRONMENTAL INDICATORS

Environmental indicators are measurements of environmental conditions or trends in environmental quality which can be used by managers to evaluate resource protection programs and assess the general state of the environment. Environmental indicators can be viewed as analogous to economic indicators such as housing starts, new construction gains, and the Dow Jones index which, although based on diverse measurements, when examined in combination, give a general indication of improvements or downturns in the economy and the success of various economic strategies. Similarly, environmental indicators provide a general assessment of improvements (or downturns) in the environment and of the effectiveness (or success) of resource management strategies.

Environmental indicators are comprehensive and include a vast array of monitoring parameters applicable to a variety of management goals (i.e., water supply, point source) and environmental resources (i.e., forests, wetlands, groundwater). The term "stormwater indicator" applies to the select few environmental indicators which specifically focus on urban stormwater runoff impacts and can be evaluated to assess the success (or failure) of stormwater management efforts. These indicators are designed to be used by municipal stormwater managers, regulatory agencies, or industrial site managers to track general improvements or downturns in overall aquatic health due to implementation of various stormwater management practices and programs.

Twenty-six stormwater indicator categories were compiled through joint work sessions with EPA and Center for Watershed Protection staff and review of comments received from the stakeholders group (Table E.1). The indicators, organized into six categories, represent both traditional and less frequently used assessment methods. The stormwater indicators are described in indicator profile sheets which include descriptions of indicator applications, advantages and disadvantages, brief case studies and method references (Chapter III).

TABLE E.1

STORMWATER INDICATOR PROFILE CATEGORIES

	INDICATOR NAME	PROFILE NO.
Water Quality Indicators	Water quality pollutant constituent monitoring	1
	Toxicity testing	2
	Non-point source loadings	3
	Exceedance frequencies of water quality standards	4
	Sediment contamination	5
	Human health criteria	6
Physical and Hydrological Indicators	Stream widening/downcutting	7
	Physical habitat monitoring	8
	Impacted dry weather flows	9
	Increased flooding frequency	10
	Stream temperature monitoring	11
Biological Indicators	Fish assemblage	12
	Macro-invertebrate assemblage	13
	Single species indicator	14
	Composite indicators	15
	Other biological indicators	16
Social Indicators	Public attitude surveys	17
	Industrial/commercial pollution prevention	18
	Public involvement and monitoring	19
	User perception	20
Programmatic Indicators	No. of illicit connections identified/corrected	21
	No. of BMPs installed, inspected, and maintained	22
	Permitting and compliance	23
	Growth and development	24
Site Indicators	BMP performance monitoring	25
	Industrial site compliance monitoring	26

INDICATOR USEFULNESS AND ADVANTAGES

Potential indicator usefulness and advantages were qualitatively analyzed (Chapter III). To complete this analysis, two lists of questions were developed which provide some insight on the types of questions which should be considered when developing a successful stormwater management program.

The usefulness analysis focused on the ability of each indicator to adequately document stormwater impacts and/or the efficacy of management efforts in the following six areas:

- aquatic integrity of lakes, streams and estuaries;
- land use impacts;
- stormwater management programs;
- whole watershed quality;
- industrial sites; and
- municipal programs.

The analysis of indicator advantages concentrated on the applicability of the indicators with respect to the following nine areas:

- multiple geographic regions;
- establishment of baseline conditions;
- wide range of stormwater applications;
- identification of the health or quality of an aquatic system;
- cost effectiveness;
- varying environmental and geographical conditions over a long time period;
- site, subwatershed, watershed and river basin scales;
- acceptance and familiarity to professionals involved in urban runoff management; and
- inexpensive, rapid and relative easy personnel training.

Comparisons of the overall usefulness of each indicator category and of indicator advantages is presented in Tables E.2 and E.3. An overall effectiveness category is included in both tables. An indicator which receives the highest ranking for overall effectiveness in both the Usefulness and Advantages Matrices, is likely to be a very useful tool for stormwater program managers.

COST ANALYSIS

Cost estimates were developed for each indicator based on data collected through a telephone survey of stormwater practitioners, a literature review, the authors' experience, and general industry information (Chapter III). The cost basis for each indicator is identified in a concise format in a series of tables in Chapter III. Whenever possible, the cost data represents a unit basis of cost per station, per sample.

The indicator costs are planning level estimates and are not all-encompassing. There are many different methodologies that can be used to perform indicator monitoring, and implementation costs can vary significantly in different regions of the country. Program managers should use these estimate for comparison purposes only and verify all costs with other sources, before implementing program monitoring strategies.

FRAMEWORK FOR USING INDICATORS

Identification of appropriate stormwater indicators for monitoring programs should be conducted within a framework based upon regional and site-specific considerations. This framework, which acknowledges the impacts of urbanization on water resources, represents reference and baseline conditions, regional considerations, and available resources.

Reference conditions are used to establish a benchmark for assessing existing conditions or to measure trends in conditions. A reference site should be selected to represent a least or minimally impacted condition. Ecoregions, representing regions of homogeneity in land surface, form, soils, natural vegetation, and general land use, should be utilized in the establishment of reference sites. A variety of reference sites can be established in each ecoregion to represent a variety of gradients, substrates, and water body types.

Regional considerations provide a framework for the selection of appropriate indicators based on specific land use, climate and local geology and geography. Stormwater indicators require regional adaptation to be utilized in different regions of the country.

TOOLS FOR INDICATOR USE

Several "tools" can be used over a broad range of physical, chemical, and biological conditions to measure environmental indicators including:

- Watershed Simulation Modeling
- Geographic Information Systems (GIS)
- Paired Subwatershed Monitoring
- Comparison to Reference Conditions
- Photographic Records

Watershed simulation modeling has been used to assess various land uses and development scenarios to calculate pollutant load wash off Watershed simulation modeling can also be applied to predict changes in stormwater runoff quantity and stream dry weather flow impacts caused by changes in watershed imperviousness. Changes in peak stormwater flows can be related to the potential for stream channel erosion, channel widening and downcutting and related habitat damage.

Geographic Information Systems are used to assemble and compile watershed characteristics and other information into a graphical and/or tabular format for assessment of various conditions. GIS and watershed simulation modeling can be used in combination to calculate various land use/BMP combinations and their impacts on downstream water quality.

Paired subwatershed studies involve comparing the response of two physiographically similar watersheds when subjected to different management practices. A control watershed is established to account for climatic, seasonal, and other natural variations, while a treatment watershed measures the affects of implementation of management practices.

Photographic and video records can be used to document many different indicators, but are perhaps most suited to assessing changes in physical conditions. The use of digital cameras to document conditions can be integrated with GIS watershed mapping to convey this information to a wide range of potential viewers.

Crafting an Indicator Monitoring Program - A Methodology

Stormwater indicator monitoring programs can be tailored to address the specific information needs of individual municipalities and industrial sites. When selected correctly, stormwater indicators can assess the long-term effectiveness of stormwater management programs as well as provide required baseline data. A two-level methodology for development of stormwater monitoring programs was developed based on general considerations common to all monitoring efforts (Chapter IV). This methodology is presented as a flexible tool which can be adapted to a particular jurisdiction's or industrial site situation. The Level I methodology targets assessment of baseline conditions; the Level II methodology is for assessing program management efforts. The two-level methodology for crafting a stormwater indicator monitoring program is outlined in Figures E.1 and E.2.

FIGURE E.1
STORMWATER INDICATOR METHODOLOGY
LEVEL I, PROBLEM IDENTIFICATION

① ESTABLISH MANAGEMENT SPHERE

Who will be responsible for implementation? A government agency (municipality, county, or state) or a site-specific industry? What other programs are being implemented within the watershed? Can this program be developed and implemented on a watershed-wide or basin basis?

⇓

② GATHER/REVIEW HISTORICAL DATA

Identify what programs and studies have already been implemented in the watershed.
Determine what problems associated with stormwater have already been identified.
Assess the effectiveness of earlier efforts and programs.

⇓

③ IDENTIFY POTENTIAL RECEIVING WATER IMPACTS

Identify uses and characteristics which may be impacted by stormwater runoff.
Hydrology and Hydrodynamics (Flooding, Drainage)
Biological Integrity (Fish Diversity, Macro. Community)
Non-contact Recreation (Sports Fishing)
Supply (Potable Water)
Contact Recreation (Swimming)
Aqua-culture (Shellfish Harvesting, Food Fishing)

⇓

④ INVENTORY RESOURCES AND IDENTIFY CONSTRAINTS

Determine manpower and funding limitations.
Identify regulatory-mandated deadlines and programs.

Staffing
Scheduling Constraints
Funding
Regulatory Compliance

⇓

⑤ ASSESS BASELINE CONDITIONS

Use rapid (qualitative) assessment methods versus detailed quantitative techniques to assess baseline conditions.

Indicator Options by Receiving Water Use

Concern:	Hydrology & Hydrodynamics	Biological Integrity	Non-contact Recreation	Water Supply	Contact Recreation	Aqua-culture
Type of Indicator to be Considered:	*Physical* *Social* *Programmatic* *Site*	*Biological* *Water Quality* *Social* *Programmatic* *Site*	*Water Quality* *Physical* *Biological* *Social* *Programmatic* *Site*	*Water Quality* *Biological* *Social* *Programmatic* *Site*	*Biological* *Water Quality* *Physical* *Social* *Programmatic* *Site*	*Biological* *Water Quality* *Physical* *Social* *Programmatic* *Site*

FIGURE E.2
STORMWATER INDICATOR METHODOLOGY
LEVEL II. ASSESSMENT OF MANAGEMENT PROGRAM

① STATE GOALS FOR PROGRAM

Based on baseline conditions, resources, and constraints, articulate goals for stormwater management program in terms of measurable achievements.

Example: We want to increase the level and diversity of the fish population in the next 5 years.

To accomplish this, we must improve biological integrity, water quality, and physical conditions.

② INVENTORY PRIOR AND ONGOING EFFORTS

Identify prior stormwater management efforts and assess success of prior efforts.
Identify current stormwater management efforts both within the municipal boundaries and the larger watershed.
Assess success of ongoing efforts.
Incorporate complementary programs and goals.
Identify potential conflicts.

③ DEVELOP AND IMPLEMENT MANAGEMENT PROGRAM

Identify and implement specific program facets in order to achieve goal.

Example: In order to increase the fish population, we will retrofit BMPs, require stormwater BMPs all new development, remove fish barriers, and re-introduce some aquatic species.

④ DEVELOP AND IMPLEMENT MONITORING PROGRAM

Based on goals, program structure, resources and constraints, select indicators to be used to assess success of stormwater management program. Level II indicators will likely be more quantitative in comparison to Level I techniques. Quantitative analysis is required to identify pollutant sources and assess success of program.

Example: macro-invertebrate assemblage, fish assemblage, public opinion surveys, toxicity testing.

⑤ ASSESS INDICATOR RESULTS

Analyze indicator monitoring results.

What do the monitoring results indicate about the success of the stormwater management program?
Have the indicators accurately reflected the effectiveness of the management program?
What do the indicators suggest about the ability of the stormwater indicator monitoring program to measure of overall watershed health?

⑥ RE-EVALUATE MANAGEMENT PROGRAM

Re-evaluate resources and constraints.
Update (if necessary) assessment of baseline conditions.
Review and revise program goals.
Review and revise indicator monitoring program.
Implement revised management program.

SCENARIOS FOR INDICATOR USE

The potential application of stormwater indicators in real world situations is illustrated in three theoretical scenarios (Chapter V). The scenarios represent different regions of the country, while facing different resource management challenges. Scenario 1 focuses on a moderately sized, rapidly growing suburban municipality in the Southeast United States. The theoretical situation involves development of a watershed management program targeting non-point source control as well as water supply protection. Level I methodology (resource problem identification) and Level II methodology (management efforts assessment) is used to develop the comprehensive monitoring program. The scenario also demonstrates how costs associated with preparation and implementation of the watershed management plan and monitoring program must be weighed against available resources.

Scenario 2 illustrates efforts required to implement a resource restoration and protection management strategy for an older industrial municipality in the Great Lakes region of the county. This theoretical example identifies a five task management strategy, including: industrial runoff controls, residential runoff controls, combined sewer overflow (CSO) reductions, habitat and water quality assessments and public involvement initiatives. A monitoring program is identified and program costs are specified.

Scenario 3 illustrates management strategies for a smaller industrial park located on the Southwest United States. The theoretical situation involves an industrial park which has been identified as a significant source of non-point source pollutants being exported to a tidal estuary. Storm monitoring and toxicity testing have shown that dissolved metals are the principal pollutants leaving the site. A management strategy employing construction of structural BMPs and pollution prevention efforts is proposed. The costs of constructing the BMPs, implementing the pollution prevention efforts, and post-implementation monitoring are compared to the available budget.

All three scenarios demonstrate the impact of urbanization on aquatic quality and the necessity to utilize stormwater indicators within a watershed-wide context. Recent studies throughout North America and elsewhere have shown a consistent relationship between the impacts of urbanization and degraded water resource quality, even with the widespread use of BMPs. The increased frequency and magnitude of runoff and the increased pollutant load associated with urban stormwater, can dramatically degrade critical stream systems by destroying habitat, eroding channel bottoms and banks, and by producing an influx of toxic runoff and sediments. Stormwater managers must recognize this when using stormwater indicators to evaluate how effectively these mitigation measures are working.

It is also important to implement stormwater indicator monitoring strategies on a watershed-wide basis. At this scale, managers will be able to better differentiate between water resource impacts associated with land use changes, as opposed to poor performance of BMPs or poor stormwater management program implementation.

CHAPTER I INTRODUCTION

OVERVIEW

Stormwater runoff management has traditionally focused on end-of-pipe controls and compliance with chemical and physical criteria, usually set by Environmental Protection Agency (EPA) or state environmental protection agencies. In part, due to EPA stormwater permit requirements, many municipalities and industries have invested significant time, money, and manpower towards characterization of stormwater runoff and collection of chemical and physical data for receiving streams (or water bodies). Recently, however, many stormwater management professionals have questioned the applicability and usefulness of these data to accurately describe existing conditions in the receiving water, evaluate the overall integrity of the aquatic community, and assess the degree of improvement in the stream system (Swietlik et al 1994). EPA is now re-assessing stormwater monitoring parameters and goals with an eye towards development of comprehensive monitoring programs which characterize overall conditions in the receiving water and provide benchmarks for assessing the success of stormwater management efforts.

Many municipalities and industries are required to implement monitoring and management programs in compliance with National Pollutant Discharge Elimination System (NPDES) stormwater regulations. Stormwater indicators can be used by the municipalities and industries as alternatives to traditional end-of-pipe monitoring, to assess the effectiveness of their stormwater management programs and to focus these programs so that generally limited resources are used effectively.

BACKGROUND

EPA identified national environmental goals in the draft report "Proposed Environmental Goals for America with Benchmarks for the Year 2005: Summary (EPA 1995). These goals outline a commitment to continued restoration of the environment (including land, air, and water resources), enhancement of environmental resources, and full usage of the environment in ways that ensure sustainable development.

Following the overall agency lead, the EPA Office of Water (EPA/OW) outlined its commitment to protection and maintenance of healthy and clean waters and designated water uses. In order to measure their success in attainment of this goal, EPA/OW, in conjunction with other EPA, Federal, State, and tribal agencies, developed a list of environmental indicators. Environmental indicators are measurements and indices which can be used to assess existing environmental conditions, provide insight into general environmental trends over time, and measure the effectiveness of existing environmental monitoring and management programs. Environmental indicators are analogous to economic indicators such as housing starts, new construction gains, and the Dow Jones index which, although based on diverse measurements, when examined in combination, give a general indication of improvements or downturns in the economy and the success of various economic strategies. The environmental indicators will provide water resource managers with insight into the state of their aquatic environment and the effectiveness of current resource management strategies.

STORMWATER INDICATORS

The overall thrust of the EPA/OW effort is reduction or prevention of pollutant loadings and other stressors. One of the most significant sources of pollutant loads to receiving waters in this country is stormwater runoff. The significance of stormwater pollutants, especially from urban areas, was examined in the early 1980's as part of the National Urban Runoff Program (NURP). In recognition of the impacts associated with stormwater runoff, Congress required, in the 1987 amendments to the Clean Water Act, that EPA expand the NPDES program to include a stormwater component.

NPDES stormwater regulations focus on reduction of pollutants from large and medium-sized municipalities, as well as select industries. During Phase I of the NPDES stormwater program, participating municipalities and industries conducted "characterization" monitoring of stormwater runoff. The purpose of this monitoring was to characterize the stormwater runoff from separate land uses (industrial, commercial and residential), identify significant pollutant sources (i.e., illicit connections, outside material storage, etc.), and provide a basis for development of future monitoring and stormwater management programs as outlined in permit requirements.

A next step in assessing the effects of urban stormwater runoff on the environment is through the use of comprehensive monitoring practices. The comprehensive approach provides information on the health of receiving waters (as opposed to an end-of-pipe focus) and tracks improvements in overall aquatic integrity as various management programs are implemented. Comprehensive monitoring of all environmental parameters would be required to assess the total aquatic health of a particular waterway, given the vast array of environmental conditions and management practices. Since it is not practical nor cost effective to evaluate all biological, chemical, and physical parameters, a few select environmental indicators, focusing specifically on urban stormwater runoff impacts, can be evaluated to tell the story of the whole system.

"Stormwater indicators" will be used to track general improvements or downturns in the overall aquatic health of the receiving water and to assess the effectiveness of various management practices and programs. These indicators are designed to be used by municipal stormwater managers, regulatory agencies, or industrial site managers. EPA/OW has undertaken an effort to develop a list of stormwater indicators and to assess the usefulness of these indicators as predictors of effective stormwater management practices and programs.

Twenty-six stormwater indicator categories were compiled through joint work sessions with EPA and Center for Watershed Protection staff and review of comments received from the stakeholders group. (The stakeholders represent a cross-section of stormwater management professionals including administrators, scientists, and engineers.) The list of 26 indicator categories has been reduced from an original list of 33. These indicators have been evaluated with respect to the following considerations:

- Do the indicators provide an accurate representation of environmental conditions?
- Are they relatively easy to use and inexpensive?
- Do the indicators work (in a scientific sense) and how?
- What indicator or combination of indicators can be used to evaluate a stormwater management program?
- What aquatic uses do the indicators assess?

- How comparable are the indicators in different geographic locations (are they equally effective throughout the country and equally effective in different water bodies; i.e., lakes, streams, rivers, estuaries)?
- At what watershed scale are the indicators most effective (over the whole watershed, only in headwater streams, or only within the ultimate receiving water)?

Although the indicators are designed to focus on the success (or failure) of individual municipal, jurisdictional, or industrial site efforts, comprehensive monitoring results must also be examined in a watershed-wide context. Urban stormwater runoff represents only one potential impact to water systems. Other potential non-point source impacts include agricultural runoff and atmospheric deposition. Point sources are also of concern. Successful design and implementation of stormwater management programs for a particular catchment, drainage area, or subwatershed can depend upon more than implementation of effective BMPs, pollution prevention measures, aquatic restoration strategies, and public involvement. Land use management in the larger watershed, implementation of complementary stormwater management programs in upstream drainage areas, attention to other non-point sources of pollution, and a general watershed-wide commitment to minimize and alleviate stormwater impacts is required. Thus, a comprehensive monitoring program may reveal that although the selected stormwater management strategies are effective on a subwatershed scale, the overall aquatic environment may continue to degrade due to upstream influences not within the jurisdiction's control. Conversely, monitoring results may indicate that only limited additional measures are required because watershed-wide growth management controls have been implemented.

Report Outline

This report presents the results of the review of stormwater indicators, their applicability, and their usefulness for measuring the success of stormwater management programs. Developed for use by municipal stormwater managers, regulatory agencies, and industrial site managers, this report provides a framework for identifying appropriate indicators based on reference and baseline conditions, regional considerations, and available resources (Chapter II). Profile sheets which describe the various stormwater indicators; summarize application, advantages and disadvantages, and costs; and provide brief case studies and method references are presented in Chapter III. Draft versions of the profile sheets were previously published as <u>Environmental Indicators to Assess the Effectiveness of Municipal and Industrial Stormwater Control Programs</u> (Claytor, R. and R. Ohrel 1995a). The profile sheets have been revised to reflect stakeholder comments. Also presented in this report is a suggested methodology (decision matrix) for development of comprehensive monitoring programs based on stormwater indicators (Chapter IV). Lastly, three scenarios are presented to illustrate and further examine the potential benefits associated with use of stormwater indicators (Chapter V).

This study is part of a larger project called the Storm Water Program-Environmental Indicators/Measures of Success Project. The first phase of this effort, Step I: Research and Information Gathering, focussed on compilation and review of currently used indicators and development of a methodology for applying these indicators. An annotated bibliography of environmental indicators was developed and is presented in the <u>Annotated Bibliography of Environmental Indicators to Assess the Effectiveness of Municipal and Industrial Stormwater Control Programs</u> (Claytor, R. and R. Ohrel 1995b). This report presents the stormwater indicators and describes a methodology implementation.

During the second phase of the project, Step II: Stakeholder Input, stakeholders were convened to provide input on selection of appropriate indicators and development of a flexible methodology for use of the indicators. Step II was conducted by the Rennselaerville Institute and is summarized in Appendix A.

Appendix B presents an example of a recently issued NPDES municipal stormwater discharge permit. The permit is included as an example because it incorporates many of the environmental indicators presented in this document as part of a watershed based monitoring and management program.

During the final phase of the study, a series of grants will be awarded for development of comprehensive monitoring programs using stormwater indicators to assess stormwater management program effectiveness. The results of these demonstration projects will be reported under separate cover by the grantees.

URBANIZATION AND WATER RESOURCE QUALITY

Water resource quality is influenced by many different parameters, however, human induced alterations are probably the single biggest contributor to degraded conditions. The ability of streams, lakes, rivers, and estuaries to sustain healthy ecosystems is often a function of how much or how little humans have altered the natural conditions.

One primary way aquatic ecosystems are altered by human influences is through physical, chemical, and biological impacts associated with urban stormwater runoff. The increased frequency and magnitude of runoff and the increased pollutant load associated with urban stormwater, can dramatically degrade critical stream systems by destroying habitat, eroding channel bottoms and banks, and by producing an influx of toxic runoff and sediments. Stormwater management programs and practices are designed to mitigate these adverse impacts. Stormwater monitoring allows managers to evaluate how effectively these mitigation measures are working. Environmental indicators can provide managers with alternative monitoring tools to evaluate program success.

Environmental indicators have the utility and applicability to be extremely versatile tools for analyzing stormwater program and best management practice (BMP) effectiveness. However, before reviewing these tools in detail, a cautionary note is worth emphasizing. Too often local officials, planners, engineers, landscape architects, and others involved in urban stormwater management utilize best available technologies to attempt to solve complex ecological alterations of the natural environment. These professionals may mistakenly assume that the impacts of urbanization can be prevented through the use of BMPs. However, recent studies throughout North America and elsewhere have shown a consistent relationship between the impacts of urbanization and degraded water resource quality, even with the widespread use of BMPs (Schueler 1994).

Urbanization is often measured in terms of impervious area, population, or number of building permits issued. Water resource quality can be measured in terms of physical, chemical, and biological parameters, using many of the indicators examined in this document. One conclusion appears consistently throughout the several studies referenced above, which is, as the amount of urbanization surpasses certain thresholds, water resource quality and aquatic life diversity shows increasing signs of degradation. Even at relatively low levels of imperviousness, the most sensitive aquatic species tend to disappear from examined systems (Schueler 1995).

This presents a challenge for urban watershed managers attempting to evaluate the effectiveness of their stormwater management programs and practices. Officials must realize that even the most successful programs may have indicators which show partially degraded conditions. One benefit of utilizing a comprehensive monitoring program, relying on multiple indicators, is that managers are likely to be able to assess those components of a program which work, and those that may need further development. For these reasons, it is important to utilize environmental indicator monitoring strategies on a watershed-wide basis. At this scale, managers will be able to better differentiate between water resource impacts associated with land use changes, as opposed to poor performance of BMPs or poor stormwater management program implementation.

Another significant hurdle for program managers will be to identify, or more accurately, to eliminate confounding sources influencing water body health. This is necessary to be able to target control strategies for particular sources of pollutants. While some indicators will be useful for documenting that there are problems with water body health, a more significant value should be in the identification of pollutant sources and assessing whether or not management practices are working. It is important to recognize that indicators will be of limited value if there are multiple sources of pollutants influencing water body health. Non-point source pollution, by definition, is coming from locations and activities which are not easily identifiable.

In order to establish environmental indicators as effective tools to address this difficult problem, it is first useful to understand the typical pollution sources and pathways affecting water quality. Several non-point sources affecting water quality in urban areas are identified in Table 2.1, below:

TABLE 2.1

TYPICAL NON-POINT SOURCE PATHWAYS AND POLLUTANTS

ACTIVITY	POLLUTANT PATHWAY	PRINCIPLE POLLUTANTS
Agricultural runoff	Runoff and leachate	Nutrients Sediment Pesticides/herbicides
Atmospheric deposition	Fallout of pollutants in rainfall and dry deposition	Nutrients Metals
Combined sewage overflows and sanitary sewage overflows	Piped directly in drainage system	Pathogens (bacteria) Metals
Urban stormwater runoff	Drainage network	Whole host of "conventional pollutants"
Forestry	Overland runoff	Sediment
Septic discharges	Leachate through ground water	Bacteria
Boating activities	Direct discharge	Hydrocarbons Oil/grease Metals
Resuspension of previously settled solids	Thermal turn-over Bottom feeding fish activity Microbial activity	Phosphorus release Metals Other pollutants bound to sediments

To be effective, a monitoring program must be set up to isolate these confounding sources. For example, it is difficult to evaluate and analyze the confounding sources of larger rivers which flow through urban areas, if they first flow through large agricultural areas and/or other varied land uses. Similarly, it is difficult to assess the contribution of urban runoff for large drainage areas to larger lakes and estuaries which receive input from several sources. Therefore, a monitoring program should specify a drainage area which can be realistically identified and quantified. For example, stormwater runoff, draining a mostly residential and commercial subwatershed, is most likely to be the primary source of pollutants and hydrologic impacts to first or second order streams (commonly referred to as headwater streams).

Management strategies concentrating on reducing urban stormwater pollutants and hydrologic impacts can be evaluated by measuring changes within these smaller headwater streams. Once the drainage area gets significantly larger and industrial, agricultural, and other inputs are included in the non-point source load, it is more and more difficult to measure the effectiveness of stormwater management programs on water body health. Municipalities and industrial sites which concentrate on managing the smaller headwater streams, and which focus their urban stormwater monitoring efforts at this level, are more likely to be able to assess program and practice success and corresponding improvements in water resource quality.

IMPORTANCE OF REFERENCE CONDITIONS AND ESTABLISHMENT OF ECOREGIONS

Successful water resource management programs have traditionally focussed on efforts which reduce chemical or microbial pollutant loads or concentrations below a pre-determined numerical limit (Hughes and Larsen, 1988). These standards and criteria, developed under the auspices of the Federal Water Pollution Control Act, are intended to restore, protect, and maintain the biological, chemical, and physical quality of the Nation's aquatic environments. This management approach has resulted in significant reductions in point source discharges of conventional and toxic pollutants. However, the resultant benefits to the biological aquatic community have fallen below expectations. Chemical and physical criteria are often either under protective or inappropriate (e.g., the acceptable mercury standard is toxic to the resident fish population). In addition, quantitative biological criteria and standards have generally not been developed to the same degree as chemical and physical standards.

Comprehensive stormwater monitoring programs must focus on indicators which provide a realistic assessment of the total aquatic health of the system. Compliance with national standards will not necessarily ensure attainment of the best possible or most realistic level of aquatic protection which can be obtained in a specific watershed or water body. Traditional water quality and biological standards are generally not applicable across the broad range of diverse geological, ecological, and water quality conditions to which they are applied. These standards, therefore, have limited usefulness as benchmarks for success.

In order to realistically assess present conditions (including biological diversity and aquatic habitat), set achievable stormwater management goals, and accommodate diverse geology and ecology, reference conditions must be identified. Reference conditions are established through identification of watersheds (or water bodies) where human impacts are minimal. Existing conditions in the reference watershed are then determined through review of existing records or monitoring results. Stormwater management goals based on these reference conditions, (with consideration accorded for existing anthropogenetic influences) are then used as a benchmark for assessing the success of the stormwater management effort.

It is not always possible nor desirable to identify reference conditions which represent all possible geologic, habitat, and water quality conditions for each water body of concern. In order to minimize the number of reference watersheds required, a geographically based ecological region (ecoregion) approach may be used. Ecoregions are mapped regions of homogeneity in land surface form, soil, potential natural vegetation, and general land use (Hughes and Larsen 1988). They group water bodies together that would be naturally similar in the absence of human influences. Based on the work of Omernik, Hughes, and Griffith, and others, ecoregions are now considered a more appropriate framework for assessment of aquatic health. Seventy-six ecoregions in the United States were defined in 1987 by Omernik using regional patterns in climate, geology, and land use (Omernik 1987).

A variety of reference sites can be identified within each ecoregion to represent the variety of gradients, substrates, water quality, and body types in each ecoregion. The ecoregion approach allows stormwater managers to develop estimates of water quality conditions or organisms likely to be observed in a body of water. Stormwater mangers can then assess the success of their program in context of both the potential for restoration as represented by the reference watershed and the relative condition of the watershed as compared to other watersheds in the ecoregion.

REGIONAL CONSIDERATIONS

Ecoregions provide a framework for assessment of stormwater indicator results. Similarly, regional considerations provide a framework for selection of appropriate indicators based on specific land usage, climate, and local geology and geography. Selection of an indicator such as number of illicit connections detected would be more appropriate for an industrialized watershed versus an agricultural watershed. Similarly, selection of an indicator assessing changes in dry weather flows would be more appropriate for a perennial stream system in the semi-humid mid-Atlantic coastal plain than for an ephemeral stream system in the semi-arid high plains of Colorado.

Regional considerations also provide a framework for modification of stormwater indicators to more accurately represent local conditions. Biological and physical stormwater indicators can be used to assess stormwater management programs throughout the country. However, in order to establish realistic restoration goals, these indicators will need to be modified to more appropriately represent regional conditions. For example, Miller and others reported that the Index of Biotic Integrity (an indicator of biological diversity) has been modified in various states to reflect native species, thus providing an indicator of greater utility and applicability (Miller et al. 1988).

Upfront consideration of regional differences is required to ensure selection of appropriate stormwater indicators which accurately represent local conditions. Development of an appropriate framework for selection of stormwater indicators and establishment of restoration goals can only be achieved by taking into account regional considerations as well as reference conditions and ecoregional concerns.

TOOLS FOR INDICATOR USE

As has been discussed, one goal of this environmental indicator project is to recommend and analyze a group of indirect measurements of environmental conditions to assess water body health and stormwater management practice and program effectiveness. During the course of this project, the "indicators" used to measure environmental conditions have evolved. Several topics were originally categorized as Whole Watershed Indicators which were initially envisioned as measurements of "whole watershed" health. These included watershed simulation modeling, watershed geographic information systems (GIS), comparison to reference watersheds, paired watershed analysis, and watershed imperviousness studies. What became apparent through the Stakeholder meetings and through various comments received, was that these "indicators" were really "tools" used to measure other indicators. With the exception of watershed impervious studies, which has been renamed and incorporated into a the indicator topic called "Growth and Development," these other tools can all be applied over a broad range of physical, chemical, and biological indicators as identified in Chapter III.

Although the tools discussed here can be used to estimate specific water resource impacts, the emphasis for monitoring programs to be structured on a watershed-wide basis cannot be overstated. For it is at the watershed or subwatershed scale, that it is most obvious to differentiate between land use management strategies and other BMP implementation strategies.

The following discussion identifies some of the common "tools" watershed managers and stormwater practitioners can use to measure a range of environmental indicators, specifically:

- Watershed Simulation Modeling
- Geographic Information Systems
- Paired Subwatershed Monitoring
- Comparison to Reference Conditions
- Photographic Records

Not discussed are tools used to measure specific indicators, such as the Index of Biotic Integrity to measure fish assemblages (Karr et al. 1986). These specific tools are reviewed and discussed for each relevant indicator topic, in Chapter III - "Environmental Indicator Profile Sheets."

Watershed Simulation Modeling and Geographic Information Systems (GIS)

Watershed simulation modeling is a tool that can be used to characterize pollutant constituent load wash-off from various land surfaces, or to estimate the hydrologic and hydraulic affects upon receiving waters. Several computer models have been developed to assess the quality and quantity of stormwater runoff. These models must usually be calibrated to properly estimate watershed responses to various land use development patterns. Geographic information systems (GIS) are tools that can be used to compile watershed characteristics in a graphic and tabular format for use in examining the effects of various land use/land cover conditions.

Recent efforts to combine the capabilities of water quality/quantity simulation models with GIS have yielded powerful new tools for watershed analysis. The pollutant load estimation, transport, and flow rate computational capabilities of simulation models complement the database and spatial graphic capabilities of GIS. Combined, these tools provide a quick and efficient method to assess different watershed development scenarios and their impacts on receiving water quality. GIS is used to compile watershed parameters such as land use/land cover, soils, vegetative cover, drainage networks, topography, hydrologic data, watershed, and political boundaries. This data is linked spatially using the graphic capabilities of the software, and/or tabularly using database capabilities. In addition, GIS can compile data on pollutant sources such as on-site sewage disposal systems (OSDS), nutrient contributions for agricultural land uses, BMP effectiveness, and sediment loading.

The GIS/simulation model combination can be used to calculate pollutant loads and flow rates for various locations within the watershed. Different management strategies or land use scenarios can be evaluated for their impact on downstream water quality. Physical conditions can also be modeled. For example, streambank erosion and depositional areas can be estimated based on land use, channel geometry, and soil particle size characteristics. Flooding potential and frequency has traditionally been modeled using several computer models. These models are now being combined with GIS databases to quickly assess the physical flooding potential of alternative management efforts or land development patterns.

GIS to can also be used to assemble biological monitoring data into a spatial database. This information can then be used to compare biological integrity across various land use/land cover situations and locations to evaluate and assess conditions leading to biological degradation. Although little literature is available on this application, utilization of the GIS tool in this area is likely to be expanded in the future.

Kasi (1993) reported on the use of GIS to compute pollution potential indices. This approach compiles pollution load estimates for different land uses and then combines this data into a single quantifiable number. Watersheds, subwatersheds, or portions of watersheds can be prioritized for management based on the potential pollutant contributions of the respective areas. This program can then be used to target resources for protection and/or remediation.

GIS and simulation models are extremely versatile for evaluating different watershed development and restoration alternatives. By using these combined tools, stormwater runoff problems and alternative control measures can be rapidly evaluated. Analysis of watershed scenarios can be evaluated at a variety of scales including analysis of different structural BMPs at the micro-scale; evaluation of comprehensive planning and growth management options at the macro-scale; and assessment of alternative land use "location" (as opposed to just type and quantity).

Watershed simulation models and GIS are limited by the input data and require calibration to be truly effective. Calibration can be very costly and time consuming. Actual monitoring data is necessary to compare simulation modeling results against actual field measurements. Furthermore, the results of simulation modeling are dependent on the resolution of the database input. The source and precision of the data must be matched with the anticipated results. Databases must be continually updated to remain current with changing development activity and other watershed changes.

Perhaps the biggest complaint made by stormwater managers regarding GIS development is the cost and resources required to input the raw data into digital format. Much of this data may be less than desirable. For example, one watershed study, in Delaware, utilized zoning maps for inputting land use data, only to find that the agricultural zone had available more than half a dozen different land development options. In addition, the data storage requirements for topography alone required a completely new computer system to accommodate the millions of bytes of data (Shaver 1995). Data from digital sources is rapidly becoming the preferred data format for most GIS because input is quicker and usually cheaper (Griffin 1995). As national, state, and local databases become more common, the data input problem will likely become more manageable.

Paired Subwatershed Monitoring and Comparison to Reference Conditions

The use of paired watershed studies and comparison to reference conditions is becoming an increasingly important tool for watershed research and monitoring. The paired watershed study approach involves comparing the response of two watersheds when subjected to different management practices (Clausen and Spooner 1993). The approach requires two physiographically similar watersheds which are treated identically over a calibration period to establish a quantifiable relationship between the paired data. Then one watershed, the "treatment watershed," is actively subjected to management strategies. The other (control) watershed continues to be exposed to the same conditions as during the calibration period. The control watershed accounts for climatic, seasonal, and other natural variations, while the treatment watershed measures the affects of implementation of the management programs. The same process can also be used to measure impacts associated with the lack of management or to reflect the impacts of developing watersheds.

The comparison to reference conditions involves the same approach, except a reference watershed or water body, judged to be in a natural or a "least impacted" condition, serves as the control area. Responses to management strategies or impacts from land use changes are compared with the best attainable condition (as represented by the reference condition). The reference condition may be an isolated site or may encompass an entire subwatershed. This minimally impacted site should be selected to be as typical of the natural ecoregion condition as possible. Hughes (1989) recommends the following selection criteria for ecoregional reference sites:

- Minimal impacts from stressors, common elsewhere in the ecoregion
- Within close proximity to biological refuge areas

- Few natural or man made barriers to migration
- Water body, channel type, and basin size typical of ecoregion
- Contains data of historical conditions

The reference site may be hard to initially select, since the habitat and biological characteristics should be based on the aquatic life uses to be analyzed in the study watershed or site. This reference site may be representative of the best attainable conditions of a particular watershed or may be part of a regional reference station system to evaluate conditions on a larger scale (Plafkin et al. 1989).

Comparison between paired watersheds can be used as an assessment tool to estimate a wide range of biological, physical, and chemical environmental conditions. An example might include comparing flooding frequencies between two watersheds. As one watershed experiences development, growth in the control watershed remains reasonably constant. The frequency of flood events can be documented for each watershed over a period of time and then compared to assess the impact of urbanization. An important component to this analysis is establishing the control condition through a calibration process. A variation of this type of study was reported by Weiss, in a paper entitled "Effects of Urbanization on Peak Streamflows in Four Connecticut Communities, 1980-84" (Weiss 1990).

Photographic Records

Another tool which is not technical in nature, but may provide valuable information, is a simple photographic or video record. Photographs can be used to document many types of indicators, but perhaps most effectively, they can be used to record physical conditions. Examples include: flood damage, channel erosion and sediment deposition, trash and debris accumulation, visible water clarity impairment, and habitat loss (both instream and riparian cover).

Photographic or video records are easy to do, require little special training, are inexpensive, and are easily understood by a wide audience. Photographs are particularly useful in documenting changing conditions over time. Application of digital camera technology can be particularly effective in linking photographic evidence of aquatic conditions at specific sites directly to a GIS watershed map. Photographs can be combined with other tools, such as watershed models, to document the complete conditions of a waterbody.

Photographs can sometimes be misleading, usually implying an un-impacted status. For instance, a water body can appear very clean, have plentiful habitat cover and other appearances of physical quality, but contain a degraded biological community due to severe water chemistry contamination. It should be emphasized that this tool is most valuable as a supporting role, and not as a stand alone measurement of a particular indicator topic.

OVERVIEW

The twenty-six environmental indicators for stormwater monitoring are organized into six categories representing both traditional monitoring practices such as water quality monitoring, and less frequently used methods such as programmatic analyses. The indicator categories include:

- Water Quality Indicators;
- Physical and Hydrological Indicators;
- Biological Indicators;
- Social Indicators;
- Programmatic Indicators; and
- Site Indicators.

An Environmental Indicator Profile Sheet has been prepared for each indicator. The Profile Sheets provide a concise and analytical compilation of information gathered during a literature review (published separately as an Annotated Bibliography of Environmental Indicators). Each Profile Sheet contains a description of the indicator; a list of applications, advantages and disadvantages; a brief case study; and method references. The Profile Sheets are intended to function as a quick reference and provide stormwater program managers with a general introduction to various monitoring techniques. The Profile Sheets are designed to function as a guide for obtaining more information on specific indicator protocols and implementation. The Profile Sheets are only short guidance "fact sheets," therefore, they will likely best serve program managers when used to compare the applicability and utility of the various indicators.

A qualitative analysis of indicator usefulness and advantages, as well as a cost analysis, has been completed for each stormwater indicator. The analysis methodology and results are described below. The individual Profile Sheets are presented later in this chapter.

INDICATOR USEFULNESS AND ADVANTAGES

The results of a qualitative analysis of potential indicator usefulness and advantages are presented as a concise visual guide in the Profile Sheets. This guide can be used to ascertain the usefulness of an indicator for a particular application and to determine what advantages one indicator might have over another method. To complete this analysis, two lists of questions were developed which are intended to provide some insight on the types of questions which should be considered when developing a successful stormwater management program. The questions can be answered either yes, no, or partially. The key identified below corresponds with the characters used in the Profile Sheets.

Usefulness Matrix: Questions for Usefulness Assessors

1. Aquatic Integrity of Lakes, Streams and Estuaries: Can the indicator assist in adequately documenting changes in overall aquatic health for lakes, streams and/or estuaries?

2. Land Use Impacts: Can the indicator be useful for identifying impacts of different urban and suburban land uses on aquatic systems?

3. Stormwater Management Programs: Does the indicator measure the overall effectiveness of a stormwater management program or a component of a stormwater management program?

4. Whole Watershed Quality: Can the indicator assess the complete range of long term change/impacts in aquatic health or quality over an entire watershed?

5. Industrial Sites: Is the indicator applicable for assessing industrial site stormwater management practices and programs?

6. Municipal Programs: Is the indicator applicable for assessing municipal stormwater management practices and programs?

Key: Yes (Very Useful) ●
Partially (Moderately Useful) ◖
No (Not Useful) ○

Advantages Matrix Questions for Advantages Assessors

1. Geographic Range: Can the indicator be applied over multiple geographic regions, assuming moderate changes are made in measuring techniques?

2. Baseline Control: Can the indicator be applied to various conditions (including geographic locations) without requiring re-establishment of baseline conditions against which change is measured?

3. Reliable: Can the indicator be considered a dependable measure of aquatic system health over a wide range of stormwater applications?

4. Accuracy: Can the indicator identify the health or quality of an aquatic system with reasonable confidence?

5. Low Cost: Is the indicator cost effective in obtaining the useful and meaningful results?

6. Repeatable: Can different investigators use the same indicator and get consistently similar results under varying environmental and geographical conditions, and over a long time period?

7. All Watershed Scale: Does the indicator provide useful information across site, subwatershed, watershed and river basin scales?

8. Familiar to Practitioners: Is the indicator commonly accepted and familiar to professionals involved in urban runoff management?

9. Easy to Use and Low Training: Can personnel be trained to apply the indicator inexpensively, rapidly and with relative ease?

Key: Yes (Very Advantageous) ●
Partially (Moderately Advantageous) ◖
No (Not Advantageous) ○

The results of the indicator usefulness analysis are presented in Tables 3.1A through 3.1G (Usefulness Quick Reference Guide). The first six tables correspond to the six indicator categories. The seventh table presents a comparison of the overall usefulness of each indicator category. Similarly, the results of the analysis of indicator advantages (Tables 3.2A through 3.2G, Advantages Quick Reference Guide) are presented in six tables organized by category and one table for the overall comparison.

An overall effectiveness category has been included in both the Usefulness Guides and the Advantages Guides. Overall effectiveness was estimated based on the cumulative responses to the questions identified above. An indicator which receives a solid circle (●) for both the Usefulness and Advantages Matrices and is reasonably cost efficient, is likely to be a very useful tool for stormwater program managers.

COST ANALYSIS

Costs for each indicator are presented by category in Tables 3.3A through 3.3F. The costs are based on a review of available data collected through a telephone survey of stormwater practitioners, a literature review, the authors' experience, and general industry information. For example, the cost for Indicator No. 20, User Perception, is based on development and implementation of a telephone survey. According to the results of the data review, this is a common method for conducting user perception surveys.

The indicator costs should only be considered planning level estimates, and should not be relied upon as all encompassing. There are many different methodologies that can be used to perform the indicator monitoring and implementation costs can vary significantly in different regions of the country. (Examples which demonstrate how these costs comparisons may be used are presented in three case study scenarios in Chapter IV.) Program managers should verify all costs with other sources, before implementing program monitoring strategies.

TABLE 3.3A
WATER QUALITY INDICATORS
COST COMPARISON

INDICATOR/ BASIS FOR COST	IMPLEMENTATION COSTS	NOTES
(1) *Water Quality Constituent Pollutant Monitoring* • Per site, one person at each site • Sampling site accessible from land • Conventional pollutants* and physical parameters (pH, temperature, conductivity) only • Four hour sampling event • Single composited sample provided for laboratory analysis • Weir or flume used to establish stage-discharge relationship • Stage recorded during monitoring event to determine flow • Grabs sample collected manually • Composite aliquots collected using automated sampler • Compositing based on constant time-volume proportional to flow increment or rate relationship • Cost includes analysis to compile and arrange data	$700 - $850 per station, per storm event	Cost to set-up station (installation and calibration of weir or flume; development of stage discharge relationship; acquisition of automated samplers and DO, temperature, conductivity, and pH meters; aquisition of reagents, sampling buckets, etc.) not included in cost estimate. Set up costs (based on the above-listed assumptions) will be on the average of $7,000 - $9,000 dollars per station. Cost may be reduced by using same sampler at different stations during different storm events and/or by using alternative methods to determine flow (i.e., USGS data). *Conventional pollutants include those typically reported as pollutants of concern in "normal urban runoff"--(e.g., TKN, nitrate + nitrite, ammonia nitrogen, TP, ortho-phosphate, cadmium, copper, lead, zinc (both total and dissolved), TSS, BOD_5, COD)(Strecker 1995)
(2) *Toxicity Testing* • Per sampling event test, assumes 10 replicate samples collected and analyized • Short term, chronic 7 day toxicity test using *Ceriodaphnia dubia* or *Pimephales promelas*	$2,500 - $3,750 per sampling event	Cost estimate does not include sampling/collection costs. Cost is based on laboratory analysis only. In-situ and/or flow through testing involves sophisticated equipment and station set-up which can dramatically add to cost.

TABLE 3.3A
WATER QUALITY INDICATORS
COST COMPARISON

INDICATOR/ BASIS FOR COST	IMPLEMENTATION COSTS	NOTES
(3) *Nonpoint Source Loadings* Method #1: Sub-watershed assessment with computer modeling • Water quality data collection not included • Land use/imperviousness data collection not included Method #2: Simple method, EMC based on land use • Land use/imperviousness data collection not included	Method #1: $70,000 - $84,000 per sub-watershed Method #2: $500 - $1,000 per sub-watershed	Estimates for water quality data collection costs can be based on Water Quality Constituent Pollutant Monitoring costs. In Sub-watershed assumed to be approximately 5 square miles.
(4) *Exceedance Frequencies of Water Quality Standards*	N/A	Costs associated with implementation of this indicator are assumed to be minimal. The most significant portion of the cost would be associated with data collection. The data required to implement this indicator is most likely collected as part of an ongoing baseflow and/or wet weather water quality monitoring program.
(5) *Sediment Contamination* • Per site • Conventional pollutants only* • Single sample collected and laboratory analysis • Interpretation of results not included	$450 - $550 per sample	Cost estimate does not include sampling collection costs. *Conventional pollutants include those typically reported as pollutants of concern in "normal urban runoff"--(e.g., TKN, nitrate + nitrite, ammonia nitrogen, TP, ortho-phosphate, cadmium, copper, lead, zinc (both total and dissolved), TSS, BOD_5, COD)(Strecker 1995)
(6) *Human Health Criteria* • Annual cost • Based on shellfish bed or beach closures • Per growing area or beach, average 5 samples per year • Fifteen to twenty locations within each growing area • Two people monitoring, 8 hours per monitoring event	$5,250 - $6,500 per area (beach)	Cost based on analysis of f. coli or E. coli samples.

R0016651

TABLE 3.3B
PHYSICAL AND HYDROLOGICAL INDICATORS
COST COMPARISON

INDICATOR/ BASIS FOR COST	IMPLEMENTATION COST	NOTES
(7) ***Stream Widening/Downcutting*** • Per reach cost • Reach defined as approximately 2000', 10 measurements per reach • Two staff members required per site • Stream cross-sections measured with taped surveys, not traditional field survey equipment • Field cross-sections established and recorded with flagged steel reinforcing bar • Includes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent, printing, and equipment) • Includes data analysis and preparation of summary report	\$575 to \$700 per 2000 foot reach	Cost is based on surveying first and second order headwater streams, in semi-humid to humid climates. For start-up add: steel reinforcing bars, flagging, hip chain, 50' tape, wading rod, notebooks, clinometer, and computer(s).
(8) ***Physical Habitat Quality*** • Per reach cost • Reach defined as approximately 275' (75 meters), 10 observations per reach. • Quantitative assessments of natural habitat structures (such as fallen trees, large rocks, etc.), channel alterations, recently deposited sediments, riffle/pool sequences, and length of erosional areas. • Qualitative assessment of presence of trash and debris, and stream character (morphology, dominate substrate, etc.). • Substrate composition measured at 3 stations per reach using modified Wolman pebble count. Percent embeddedness, wetted width, bank height, gradient, and canopy coverage measured at all stations. • Two staff members required per site • Includes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent, printing, and equipment) • Includes data analysis and preparation of summary report	\$400 to \$490 per 275 foot reach	Cost is based on a series of discrete measurements using quantitative and semi-quantitative descriptive parameters. For start-up costs add: 50' tape (or walktax), clinometer, notebooks, and computer(s).

TABLE 3.3B
PHYSICAL AND HYDROLOGICAL INDICATORS
COST COMPARISON

INDICATOR/ BASIS FOR COST	IMPLEMENTATION COST	NOTES
(9) *Impacted Dry Weather Flows* • Per study cost • Study cost assumes long term (≥ 10 years) stream flow gaging data is available • Study involves comparing data from one or more gaging station(s) undergoing changed land use with gaging station data from an unchanged (control) area • Includes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent, printing, and equipment) • Includes data analysis and preparation of summary report	$4,500 to $5,500 per study area	Based on long term data (≥ 10 years) availability. For start-up costs add: Long term stream flow monitoring data and computer(s). Study area assumed to include data from five stations or less.
(10) *Increased Flooding Frequency* • Per study cost • Study cost assumes long term (≥ 10 years) stream flow gaging data is available • Study involves comparing data from one or more gaging station(s) undergoing changed land use with gaging station data from an unchanged (control) area • Includes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent, printing, and equipment) • Includes data analysis and preparation of summary report	$4,500 to $5,500 per study area	Based on long term data (≥ 10 years) availability. For start-up costs add: Long term stream flow monitoring data and computer(s). Study area assumed to include data from five stations or less.
(11) *Stream Temperature Monitoring* • Per monitoring station cost, per year • Cost includes automated samplers, recording temperature hourly, requiring downloading every six months • Automated samplers are downloaded in office (laboratory), not at site • Analysis of data includes computing daily mean, maximum and minimum temperature • Includes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent, printing, and equipment)	$400 to $500 per station per year	Based on yearly monitoring costs, temperature meters deployed once, data downloaded twice per year. Data is automatically downloaded into a desktop computer, additional data analysis required to compute daily mean, maximum and minimum temperatures.

TABLE 3.3C
BIOLOGICAL INDICATORS
COST COMPARISON

INDICATOR/ BASIS FOR COST	IMPLEMENTATION COST	NOTES
(12) *Fish Assemblage Analyses* • Per sample, per site cost • Three staff members per site (one intern) • Includes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent, computers, printing, and equipment) • Includes data analysis and preparation of summary report	$400 to $475 per sample, per site	Based on methodology of Karr's IBI (1986). Cost for first or second order stream (only one electofishing shocker required) For start-up costs add: electrofishing equipment, computer(s), and basic field gear (e.g., hip waders, fish holding buckets, etc.).
(13) *Macro-Invertebrate Assemblage* • Per sample, per site cost • Two staff members required per site • Includes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent, computers, printing, and equipment) • Includes sub-sample analysis, identification to genus level, and preparation of summary report	$500 to $600 per sample, per site	Based on RBP protocol III, and sampling to genus level. Cost for 200 individual sub-sample count For start-up costs add: Microscope, kick-screen sampler(s), glassware, preservative, and computer(s).
(14) *Single Species Indicator* • Per sample, per site cost • Two field staff members required per site • Includes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent, computers, printing, and equipment) • Includes data analysis and preparation of summary report	$375 to $425 per sample, per site	Based on fish electro-shocking surveys of trout or salmon. For start-up costs add: Electrofishing equipment, computer(s) and basic field gear.
(15) *Composite Indicators* • Per sample, per site cost • Two field staff members required per site • assumes at least two biological indicators investigated per site • Includes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent, computers, printing, and equipment) • Includes data analysis and preparation of summary report	$900 to $1,075 per sample, per site.	Based on combining fish and macro-invertebrate sampling at one site. For start-up costs add: Equipment referenced under fish and macro-invertebrates.

TABLE 3.3C
BIOLOGICAL INDICATORS
COST COMPARISON

INDICATOR/ BASIS FOR COST	IMPLEMENTATION COST	NOTES
(16) *Other Biological Indicators* • Per sample cost, lake site • Two staff members required per sample • Phytoplankton community sampling costs • Incudes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent, printing, and equipment) • Includes data analysis and preparation of summary report	$340 - $420 per sample, per lake	Based on single index sampling for phytoplnkton only. Multi-metric protocols, incorporating habitat assessments (requiring at least two trips per sample and two or more sample locations) cost between $1,800 to $2,200 per assessment (excluding start-up costs).

COST COMPARISON

INDICATOR/ BASIS FOR COST	IMPLEMENTATION COSTS	NOTES
(17) ***Public Attitude Surveys*** • Per survey cost per 1,000 households contacted (implementation costs) • Interviews conducted over telephone • Includes survey implementation, data analysis, and summary of findings	$14,500 - $17,750 per 1,000 households	Generally, 50% of those households contacted respond to survey.
(18) ***Industrial/Commercial Pollution Prevention*** • Per survey cost per 1,000 industrial facilities contacted (implementation costs) • Interviews conducted over telephone • Includes survey implementation, data analysis, and summary of findings	$14,500 - $17,750 per 1,000 facilities	Generally, 50% of those industrial facilities contacted respond to survey.
(19) ***Public Involvement and Monitoring*** • Per 100,000 people • Substantial in-kind support required from citizens' groups such as Save Our Streams, Trout Unlimited, Izaak Walton League • Major costs associated with development and printing of educational materials training of volunteer monitors	$8,000 - $10,000 per 100,000 persons	No additional comments
(20) ***User Perception*** • Per survey cost per 1,000 households contacted (implementation costs) • Interviews conducted over telephone • Includes survey implementation, data analysis, and summary of findings	$14,500 - $17,750 per 1,000 households	Generally, 50% of those households contacted respond to survey.

TABLE 3.3E
PROGRAMMATIC INDICATORS
COST COMPARISON

INDICATOR/BASIS FOR COST	IMPLEMENTATION COSTS	NOTES
(21) *No. of Illicit Connections Identified/Corrected* • Per illicit connection identification survey • Assumes survey will be conducted visually; smoke, dye, or other methods will not be used • Illicitness of dry-weather flows will be determined by tracing source upstream in system and through use of field test kits	\$1,250 - \$1,750 per mi^2	Cost does not include costs associated with correction of illicit connections. Nationally, approximately 15 to 20 percent of storm drain outfalls carry illicit discharges (Lalor, 1995).
(22) *No. of BMPs Installed, Inspected, and Maintained* • Per survey cost • Includes data reporting and summary report of findings • Assumes telephone survey and on-site visit to records office will be required • Assumes municipalities maintain records of BMP installation and inspection • No field inspections performed	\$15,000 - \$20,000 per survey	Cost does not include field inspecton of each facility. For file inspection program, add \$80 to \$100 per BMP inspected (assumes one trip per year)
(23) *Permitting and Compliance*	N/A	No cost data provided since methods and procedures to conduct surveys of permits and compliance will vary depending on the type of permit, whether or not a jurisdiction already has existing data, the means with which data is recorded, and the capability to retrieve data.
(24) *Growth and Development* • Annual cost • Based on use of GIS database for multiple sub-watersheds • Assumes growth will be tracked through imperviousness or other land use variable	\$26,000 - \$21,250 per sub-watershed	Initial capital expense not included in cost estimate. Costs for collection of data not included. Instead, cost is based on updating GIS system using already digitized land use or imperviousness data. Sub-watershed assumed to be approximately 5 square miles.

TABLE 3.3F
SITE INDICATORS
COST COMPARISON

INDICATOR/ BASIS FOR COST	IMPLEMENTATION COST	NOTES
(25) *BMP Performance Monitoring* • Per site, annual cost • Two automated samplers collecting composite aliquots, one inflow, and one outflow • Flow/stage relationship established using hydraulic capacity of inflow pipe • Conventional pollutants* and physical parameters only (PH, temperature, and conductivity) • 10 storms per station collected, and analyzed per year • Compositing based on constant time-volume proportional to flow increment or rate relationship • Includes overhead expenses • Includes bi-weekly equipment maintenance and inspections • Includes data analysis and preparation of summary report	$22,000 to $26,000 per site, per year	Cost to set-up stations not included in cost estimate. For set-up costs add: $14,000 to $18,000 per site (two stations) *Conventional pollutants include those typically reported as pollutants of concern in "normal urban runoff"--(e.g., TKN, nitrate + nitrite, ammonia nitrogen, TP, ortho-phosphate, cadmium, copper, lead, zinc (both total and dissolved), TSS, BOD_5, COD)
(26) *Industrial Site Compliance Monitoring* • Per Industrial site (based on 5 acre site) • Light industrial land use • Visual inspections of compliance with pollution prevention plans • One technical inspector per site • Includes overhead expenses (supplies, vehicles, travel, utilities, maintenance, rent printing, and equipment) • Includes preparation of summary report	$290 to $350 per 5 acre site	Based on visual inspections only, for pollutant constituent monitoring refer to Table 3.3A. For start-up costs add: Notepads, computer(s), camera.

R0016658

Water Quality Indicators

The costs comparison for the water quality indicators is presented in Table 3.3A. Costs for Water Quality Constituent Pollutant Monitoring, Toxicity Testing, Sediment Contamination, and Human Health Criteria are based on sampling considerations and/or laboratory analyses. The cost comparison for Nonpoint Source Loadings, however, does not include sampling or analytical costs. Instead, the cost comparison for Nonpoint Source Loadings focuses on costs associated with model development and data manipulation.

No cost comparison is provided for Exceedance Frequencies of Water Quality Standards. Labor and capital costs associated with this indicator are most likely already incorporated into existing monitoring efforts.

Physical and Hydrological Indicators

The cost comparison for physical indicators are computed on the basis of reach length for stream assessment techniques (e.g., physical habitat quality), study area for watershed-wide assessment techniques (e.g., increased flooding frequency), and station-year for time based monitoring techniques (e.g., stream temperature monitoring). The assumptions for the cost comparison are included in Table 3.3B. Since the costs are closely tied to the assessment methodologies, and since these methodologies can vary from study to study, the specific assessment methodology is depicted for each indicator. Other alternative methodologies may be used, but the cost assumptions will need to be verified.

Biological Indicators

The cost comparison for biological indicators are, in general, computed on a per sample, per site basis. The assumptions for the cost comparison are included in Table 3.3C. These include the number of staff required, overhead expenses, the methodology used to conduct the monitoring, and items needed to compute start-up costs. The cost data was obtained from a brief survey of stormwater practitioners, the authors' experience and general industry information.

The data is reported on unit cost to aid stormwater program managers in planning monitoring programs. For implementation of a state-wide or large municipality program, add administrative and management staff costs. The cost is reported as a range, which encompasses the average of costs obtained from the survey results. Programs which have a large number of monitoring stations will undoubtably receive the rewards of economy of scale, whereas programs with a small number of stations can expect to pay more per station.

Social Indicators

The costs comparison for the social indicators is presented in Table 3.3D. Costs for Public Attitude Surveys, Industrial/Commercial Pollution Prevention, and User Perception are based on the same assumptions regarding development costs, implementation costs (via telephone), and analysis costs. Although these indicators represent different methods for assessing the social aspect of stormwater management, the tools used to measure the indicators are similar. The costs for these indicators are presented on a per 1,000 households (or industrial facilities) contacted basis.

Costs for Public Involvement and Monitoring are based on a survey of various citizen groups and local watershed protection and nonpoint source government agencies. These costs are presented on a per 100,000 person basis.

Programmatic Indicators

Table 3.3E presents the costs comparison for the programmatic indicators. The major portion of the costs for Permitting and Compliance; Number of BMPs Installed, Inspected, and Maintained; and Number of Illicit Connections Identified/Corrected are labor costs. Implementation of these indicators will probably require a significant man-hour investment. However, little, if any, capital costs will be expended.

Growth and Development costs, on the other hand, include significant capital costs for computers and workstations, as well as labor costs associated with development, maintenance, and updating of a GIS database.

Site Indicators

The cost comparison for site indicators are computed on the basis of each BMP monitored for BMP performance monitoring and each site for industrial site compliance monitoring. The assumptions for the cost comparison are included in Table 3.3F. The specific assessment methodology is depicted for each indicator. Other alternative methodologies may be used, but the cost assumptions will need to be verified.

INDICATOR PROFILE SHEETS

The twenty-six Environmental Indicator Profile Sheet are listed by category in Table 3.4. Each Profile Sheet contains a brief description of the indicator; a discussion of indicator utility; a review of indicator advantages and disadvantages; a case study; and method references. In addition, the results of the analysis of indicator usefulness and advantages are presented in the sidebar on the right side of each Profile Sheet.

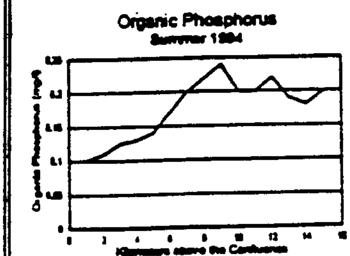
Environmental Indicator Profile Sheet



Indicator Profile No. 1

Water Quality Pollutant Constituent Monitoring

Category: **Water Quality**

Tools Used to Measure Indicator:

- Pollutant Concentrations
- Event Mean Concentrations
- Spatial and Temporal Trend Analysis

Description:
Water quality monitoring has traditionally focussed on examination of chemical parameters such as oxygen demand, nutrients, and metals, and physical parameters such as pH and temperature. Stormwater monitoring usually requires collection of water samples from stormwater detention and retention facilities, structural and non-structural conveyance channels, stormwater outfalls, and receiving waters during storm events. Evaluation of the parameters may be conducted in the laboratory (e.g. for chemical parameters) or in the field (e.g. pH).

Depending upon the geographic and temporal scope of the monitoring effort, monitoring results may be used to assess current water quality conditions at a specific location; evaluate changes in water quality throughout different seasons or over a period of years; or identify longitudinal or spatial trends in water quality along a river or within a lake. The monitoring results may also be used to identify significant sources of pollution or times of the year when water quality noticeably worsens.

Utility of Indicator to Assess Stormwater Impacts:

- Monitoring results from long-term efforts (five years or more) can be examined to identify trends in water quality conditions over time.
- Monitoring results from urban stormwater studies can be compared to pollutant concentrations in reference rural or "least impacted" watersheds to assess the relative degree of impairment.
- Trends may correlate with land use changes or watershed restoration efforts, helping watershed managers determine priorities for problem sources and pollutants.
- Monitoring results can be used to identify pollution problems and identify potential sources of degradation.
- Monitoring can be implemented on both a regional and local level.

Indicator Useful for Assessing:

Mod. Advantageous	◖
Not Advantageous	○

Cost

See Table 3.3A

Advantages of Method:

- Reasonably well standardized, generally accepted sampling methods and protocols are already established in many jurisdictions.
- Many jurisdictions have an extensive historical database which may be examined to determine whether water quality degradation has occurred over a specified period of time.
- Monitoring results are easily presented in graphic form.
- Violations of regulatory standards may be quantified and, therefore; are more likely to be legally defensible.
- Large existing databases on urban and highway stormwater runoff quality allows comparison between local and national concentrations.

Disadvantages of Method:

- Generally, samples must be collected during representative storm event (i.e., volume and duration of rain varies by less than 50 percent from average) to provide accurate characterization of event mean concentrations.
- Multiple sampling events over an extensive period of time are usually required to identify statistically defensible trends in water quality due to the tremendous variability seen in urban runoff data.
- This method is essentially a derivation of traditional, baseflow water quality monitoring using primarily chemical parameters. The applicability of this method to stormwater characterization has been questioned by many municipal stormwater managers.
- Requires accurate measurement of storm flow and automated sampling

Case Study: Wright, R.M.; Roy Chaudhury, R.; Makam, S. 1995
Experiences from the Blackstone River Wet Weather Initiative
In: Stormwater NPDES-Related Monitoring Needs. Conference Proceedings. American Society of Civil Engineers. Mt. Crested Butte, CO. Aug. 7-12, 1994

A program, initiated by the U.S. EPA, to study the Blackstone River under dry and wet weather conditions was conducted to pinpoint and rank major sources degrading water quality. The river was monitored at 13 locations along 48 miles, in addition to, six tributaries and five point sources. Three storms were monitored for 23 constituents with at least ten samples at each of the stations. Methods of interpreting the water quality data and isolating the sources into dry and wet weather sources are presented. The wet weather component is studied to establish loadings from point sources, new materials (runoff related) and old materials (bottom sediment re-suspension). A procedure to estimate annual loading rates is presented.

Total suspended soils and lead concentrations in the river generally increased during wet weather conditions. Copper concentrations also increased. This is attributed to re-suspension of copper from the sediments on the bottom. The original source of the copper is probably dry weather discharges from a wastewater treatment plant. Calcium and magnesium concentrations decreased during wet weather due to dilution. Overall, fluctuations in wet weather concentrations are attributable to pollutant loadings from runoff and re-suspension of pollutants in the sediment.

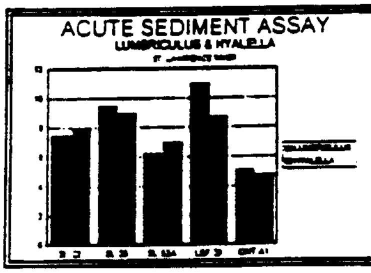
Environmental Indicator Profile Sheet



Indicator Profile No. 2

Toxicity Testing

Category: **Water Quality**

Tools Used to: Measure Indicator:

- Acute, Chronic, and In-Situ Toxicity Testing
- Microtox
- Toxicity Identification Evaluation (TIE)

Description:

Toxicity testing is used to assess the impact of stormwater pollutants on the overall quality of aquatic systems. Toxicity testing is usually conducted in a laboratory setting using sample water (e.g. stormwater runoff) and test organisms such as *Ceriodaphnia dubia* or *Pimephales promelas*. A single species or microcosm is exposed to collected stormwater runoff for a period of time. The organisms are analyzed for evidence indicating that exposure to pollutants in the stormwater produced lethal or sublethal effects such as mortality, limited reproduction, or stunted growth. Negative physiological and behavioral changes in response to stormwater exposure may also indicate the presence of pollutants in toxic concentrations.

Acute toxicity testing focuses on effects which become apparent over a relatively short interval (i.e., usually 24 to 96 hours). Chronic toxicity tests are used to identify effects which become apparent only after long periods of exposure, usually ten percent of the test organism's life span or longer. Chronic toxicity tests are commonly conducted over a seven-day period; longer periods of exposure are also used.

In-situ or flow through toxicity testing may also be conducted. Test organisms are transported to the site and placed in submerged exposure chambers designed to allow water flow in and out of the chamber. After the exposure period, the organisms are collected and analyzed in the laboratory for evidence of lethal or sublethal effects. Both acute (short-term) and chronic (long-term) toxicity testing can be conducted in-situ.

In order to identify the probable agent of the observed toxicity, toxic identification evaluation (TIEs) procedures may be performed. TIE is a step-wise procedure which first identifies the probable class of toxicant (e.g., metals, nonpolar organics) and then the specific toxicant (e.g., mercury, creosote). Once the probable toxicant has been identified, control measures may be developed and implemented.

Cost

See Table 3.3A

Utility of Indicator to Assess Stormwater Impacts:

- Various species with specific levels of sensitivity can be used to evaluate the severity and identify the potential causes of degradation (i.e., pollutants).
- Toxicity testing can be used to evaluate the effectiveness of stormwater BMPs and other stormwater pollution reduction measures.
- Species-specific toxicity testing can be used as a rallying point for aquatic system restoration, especially if a particularly sensitive, well-known, and economically significant species is used.
- Applicable on both local and regional levels.
- Results of toxicity testing can be used by watershed managers to identify areas of high concern and to establish restoration priorities.
- Phase I, II, and III TIE procedures can be used to help identify specifc pollutant sources.

Advantages of Method:

- A great deal of data is available describing acute and chronic toxicity limits for various species.
- Toxicity testing can easily be incorporated into tiered stormwater monitoring programs. First tier indicators such as fish and macroinvertebrates assemblages and water quality monitoring can be examined to determine if the system is degraded. Toxicity testing, a second tier indicator, can then be used to identify the probable cause and source of the degradation.
- Watershed managers can identify potential severity of water quality degradation by using species with differing levels of sensitivity to environmental parameters.
- Different species sensitivity assists watershed managers' ability to distinguish between potential causes of existing water quality problems.
- The obvious visual impacts on species (e.g., tumors, stunted growth, and discoloration) can generate public concern and motivate involvement with restoration efforts.

Disadvantages of Method:

- Several possible factors influence toxicity for a given species, including concentration of the contaminant, concentrations of other substances, temperature, the organism's environmental conditioning and acclimation, toxicant interactions, and duration of exposure.
- Toxicity testing has historically focused on short term and lethal effects. Sublethal effects, which may not become apparent for years and which can include impacts to reproductive behavior, migration patterns, and predator avoidance, have not been as thoroughly studied.
- The same species may exhibit varying tolerance levels for different pollutants or combination of pollutants.
- Toxicity testing often occurs in a laboratory setting where conditions may not simulate exactly those found in the natural environment.
- There is some disagreement among practitioners about what constitutes acceptable and unacceptable aquatic impacts.
- Organisms' actual exposure to pollutants in stormwater is generally limited. Many toxicants in runoff are usually in biologically less available forms. Standard toxicity limits (generally developed under simulated baseflow conditions) are therefore, not wholly representative of stormwater toxicity response.
- A large quantity of the test organisms must be available quickly and the health of these organisms must be established through reference or control conditions.
- Reliance on single species tests or using only one species may not provide an accurate assessment of ambient toxicity.

Case Study: Hall, K.J.; B.C. Anderson. 1988
The Toxicity and Chemical Composition of Urban Stormwater Runoff
Canadian Journal of Civil Engineering, Vol. 15, pp. 98-106 (1988)

The authors studied the effects of land use on the chemical composition of urban stormwater runoff and its subsequent acute toxicity to the aquatic invertebrate *Daphnia pulex* in a drainage basin in British Columbia. It was determined that both land use and interval between rainfall events influenced the chemical composition and toxicity of the stormwater. Six of the twelve sites studied produced stormwater that was toxic to some degree. Stormwater from all open and/or green space areas was nontoxic to *Daphnia* in static 96-h tests. The frequency of occurrence of toxicity in stormwater, in relation to land use, appeared to be commercial > industrial > residential > open space.

An examination of the pattern of toxicity in the watershed showed higher toxicity in the upper and lower reaches of the basin; those sites in the middle of the basin all had runoff that was nontoxic. In general, these middle reaches of the basin are at the lower, gently sloping elevations, close to the main water bodies and have been predominantly used for residential and open and/or green space land uses.

In laboratory bioassays with *Daphnia*, toxicity of iron was low and it reduced the toxicity of other metals. Lead increased the toxicity of copper and zinc. There was an increase in metal toxicity as pH decreased and suspended solids concentrations increased. The laboratory experiments begin to explain the variable nature of stormwater toxicity and provide an understanding of why field measurements of toxicity in stormwater can change rapidly, as a storm flushes particulate and soluble materials from the watershed.

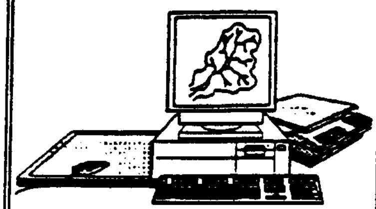
Environmental Indicator Profile Sheet



Indicator Profile No. 3

Nonpoint Source Loadings

Category: **Water Quality**

Tools Used to Measure Indicators:

- Computer Simulation Models (HSPF, SWMM, SLAMM, ILLUDAS, WASP)

Description:

Nonpoint source (NPS) pollutant loadings represent the amount of pollutant in stormwater runoff from various land uses. NPS loadings are not directly measured, but instead are estimated based on empirical monitoring data, land use imperviousness and cover, area, and rainfall volume. NPS loadings can be used to estimate baseline water quality or to determine the relative decrease or increase in NPS pollutant loads due to changes in land use or implementation of restoration efforts.

NPS loading estimates can be calculated using the simple method or simulation models. The simple method is appropriate for small-scale studies. Comprehensive NPS loading estimates may be obtained with simulation models such as HSPF, SLAMM, or SWMM. Changes in NPS pollutant loadings in response to changes in watershed land use (typically pre-developed, existing, and anticipated future conditions) can be estimated using simulation models. Estimates may be reported on an average annual or seasonal mass basis or for a single storm event.

Utility of Indicator to Assess Stormwater Impacts:

- Trends in NPS pollutant loadings can be compared with land use changes or implementation of BMPs to assess potential increases or reduction in NPS pollution.
- Can be used to help identify major land uses which are significant sources of NPS pollution.
- Can be used as a planning tool to evaluate loads associated with different development options.
- Can be used to help identify portions of a watershed where loadings may be concentrated and pollutant accumulation is likely.

Cost

See Table 3.3A

Advantages of Method:

- Calibrated NPS loading models can quickly and efficiently evaluate many different land use development options.
- Good method for evaluating pollutant load distribution throughout a watershed with respect to various land uses and restoration strategies.
- Allows for geographic analysis of watersheds and priority ranking of possible nonpoint sources.
- Identifies which NPS pollutants are most prevalent, allowing for programs targeted at reducing those specific pollutants.
- Calibrated NPS loading models partially alleviate the need for additional water quality monitoring.

Disadvantages of Method:

- Accuracy in estimating NPS pollutant load may vary from method to method and model to model.
- Development and calibration of watershed NPS loading models can be relatively expensive and time consuming. It may take several years to accurately evaluate trends in NPS loads.
- Accurate modeling requires fairly sophisticated data collection conducted over several years and a reasonably in-depth personnel training program.
- BMP pollutant removal efficiencies used in modeling may substantially differ from actual removal rates.
- Focus on urban stormwater loading and in-stream pollutant concentrations can be misleading in assessing land use impacts since these indicators do not address critical hydrological impacts and effects.

Case Study: Wulliman, J.T., 1994

Application of Nonpoint Source Loading Relationships to Lake Protection Studies in Denver, Colorado

Pawlukiewicz, J.; et. al. (eds.), 1994. Proceedings from Watershed '93: A National Conference on Watershed Management., Alexandria, VA., Mar 21-24, 1993., USEPA No. 840-R-94-002

The paper evaluates various approaches to estimate nonpoint source loads from watershed areas to help assist watershed managers in selecting alternative options. Ten loading estimation options, consisting of 4 basic methods are presented. They consist of various levels of analysis ranging from simple calculations to complex approaches which require hydrologic modeling and site-specific monitoring. The four methods are: the Unit Load Method, where loads are calculated based on a unit loading rate multiplied by the upstream drainage area; the EMC Method, where loads are expressed as the product of the constituent concentration and the runoff volume; the Regression Method, where watershed loads are estimated using regression relationships developed from local, regional, or national stormwater monitoring data; the Sediment Method, where loads are expressed as the product of the constituent concentration and the sediment volume. A number of these options have been used effectively in lake protection studies in the Denver area. In selecting which option to use, it is important to keep in mind the accuracy required and the budgetary limits. In general, there is a direct relationship between the accuracy and the level of complexity of the method. The Unit Load Method, for example is relatively quick and simple to calculate loads but does not incorporate physical hydrologic processes or site specific data and therefore may yield highly uncertain results. The other methods may be much more accurate but require a more sophisticated approach and are more difficult and costly to perform.

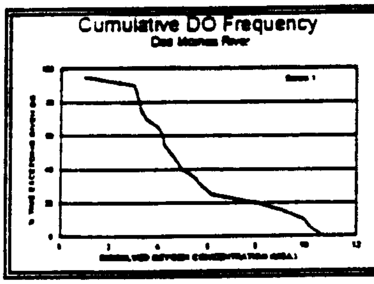
Environmental Indicator Profile Sheet



Indicator Profile No. 4

Exceedance Frequencies of Water Quality Standards

Category: **Water Quality**

Tools Used to Measure Indicator:

- Chemical Monitoring
- Trend Analysis

Description:

Water quality standards have been established by federal, state, and local governments for various pollutants and receiving water classifications. The frequency with which a particular standard is exceeded or the percentage of water bodies, river-miles, or lake-acres failing to meet designated uses may be indicative of the relative success or failure of stormwater management efforts.

While physical characteristics (e.g., downcutting, flooding) and biological parameters (e.g., assemblage or diversity) could be evaluated by this method, few jurisdictions have standards for such parameters. Consequently, current use of this indicator is based primarily on chemical standards.

The frequency analysis can incorporate data already collected by local and State agencies as part of the 305(b) reporting process. Section 305(b) of the Federal Water Pollution Control Act requires States to prepare a biennial report including analyses of the extent to which pollution reduction; maintenance of specified levels of water quality; and protection of aquatic habitat, wildlife, and recreational usage has been achieved.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to evaluate the performance of stormwater BMPs with respect to various storm frequencies.
- Can be used to identify long-term and seasonal trends in regional water quality.
- Can be used to characterize water quality impacts due to urban runoff with respect to various storm categories (frequent storms, flood events).
- Can be used to document periods of poor water quality (e.g., following large storm events, during low-flow summer months).

Cost

See Table 3.3A

Advantages of Method:

- Many jurisdictions already have long-term databases which may be examined to determine if standard exceedances are increasing in frequency (trend analysis).
- Required sampling and parameter determination for this indicator are already incorporated into regular monitoring programs and the 305(b) reporting process in many jurisdictions.
- Results are easy to interpret, making the method a good tool for initiating policy actions, securing funding sources, etc.
- Provides a reliable and legally defensible benchmark for enforcement actions.

Disadvantages of Method:

Exceedance frequencies are developed on a constituent by constituent basis. Comprehensive assessment of a particular water body or stormwater management effort requires identification and evaluation of several parameters and standards.

- Several sample locations are required within a relatively small area to determine the actual cause or source of the standard exceedance.
- Exceedance frequencies alone may not identify the causes and sources of observed degradation. Additional long-term and/or longitudinal monitoring may be required, especially if in-stream samples are used.
- Most criteria and standards are based on a few chemical water quality parameters that present indirect measure of the presence or absence of aquatic life.
- There are almost none that are based on physical or biological parameters that reflect the actual versus inferred presence or absence or aquatic species.
- Exceedance frequency may be an artifact of monitoring effort as much as water quality degradation. The more frequently monitoring is conducted, the more likely exceedances will be detected.
- Exceedance of a water quality standard or criteria may only occur briefly during storm events. Exceedance of the standard may not be reflected in the sample collected, and actual long-term impacts on the aquatic community are difficult to predict.

Case Study: Cooke, T.; Drury, D.; Katznelson, R.; Lee, C.; Mangarella, P.; Whitman, K. 1995
Storm Water NPDES Monitoring in Santa Clara Valley
Stormwater NPDES-Related Monitoring Needs. Conference Proceedings. 1995.

The authors compared metals monitoring data from four years of sampling with water quality objectives contained in the April 1991 California Inland Surface Waters Plan. Dissolved concentrations seldom exceeded objectives, whereas total metal concentrations exceeded the objectives with greater frequency. Most exceedances occurred at stations whose watersheds were smaller and more highly urbanized. Exceedances of objectives by dissolved metal concentrations were considered better indicators of potential toxicity problems than exceedances by total metals concentrations because dissolved metals are more bioavailable.

The duration of exceedance was also measured at one station. The duration of exceedance of acute water quality objectives for total copper, lead and zinc was always less than the duration of the storm runoff event. The frequency of exceedance varied depending on the metal, and was greatest for copper, followed by zinc and lead. For those cases where an exceedance was measured, the average duration of exceedances, expressed as a percent of the storm duration, was approximately 60% for copper, 40% for zinc, and about 20% for lead.

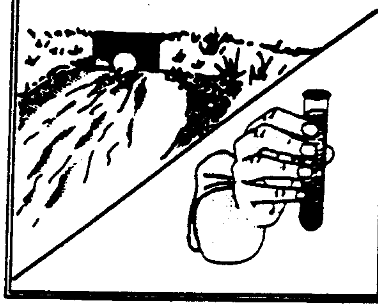
Environmental Indicator Profile Sheet



Indicator Profile No. 5

Sediment Contamination

(Constitutent/toxicity analysis)

Category: **Water Quality**

Tools Used to Measure Indicator:

- Constituent Concentrations
- Sediment Quality Assessment Guidelines
- Spectrophotometry
- Chromatography

Description:

Many pollutants found in stormwater runoff, such as metals, organic toxins, and aromatic compounds, become attached to sediments and settle to the bottom in slower receiving waters, wetlands, and stormwater retention and detention basins. The presence and mass concentration of pollutants can be determined through spectrometric and chromatographic analyses of sediment samples.

Sampling may be conducted in natural water bodies (e.g. streams, lakes, estuaries) or artificial basins (e.g. detention ponds). To determine whether sediments are contaminated by anthropogenic sources, samples are often compared to a reference water body where human impacts are minimal or nonexistent. The mass of contaminant is often cross-referenced with the distance from the suspected pollutant discharge location (e.g., stormwater outfall) or source (e.g., urban area).

Sediment may adversely impact the aquatic community. Benthic organisms feed and dwell in the bottom sediments. Nonbenthic organisms are potentially exposed to sediment contaminants through re-suspension, ingested benthic organisms, and exposure to the sediment as it settles to the bottom.

In order to identify potential ecological effects, contaminant concentrations may be compared to sediment quality assessment guidelines. Ecological impacts may also be assessed through analysis of the associated interstitial (pore) water and water immediately overlying the sediment. This water can be collected and analyzed for conventional pollutants. Acute and chronic toxicity testing of the water immediately overlying the sediment may be conducted either in the field or in the laboratory. Toxicity testing of the interstitial water and the sediment elutriates (recreated sediment suspensions) are performed in the laboratory.

See Table 3.3A

Utility of Indicator to Assess Stormwater Impacts:

- Analysis of the sediment within urban embayments can provide an indication of the level of contamination and, by proximity, the probable source of contamination in the drainage area.
- Analysis of samples taken within and/or immediately upstream and downstream of stormwater management facilities can be used to evaluate the performance of BMPs.
- Trends in sediment pollutant levels over time can reveal long-term changes in pollutant loadings.
- Can be used to evaluate local stormwater management efforts for the control of particular pollutant sources over the long term.

Advantages of Method:

- The relatively static nature of this indicator may increase public interest and involvement in stormwater issues.
- The likelihood that sediment pollutants come from nearby sources promotes local accountability thereby reducing the potential for jurisdictions to blame problems on others and instead encouraging them to assume responsibility for restoration.

Disadvantages of Method:

- There are few criteria or standards against which ambient sediment pollutant concentrations may be compared.
- Levels of concern and the long-term impact of sediment pollutant concentrations with respect to ecological impacts are still being studied and are not clearly defined.
- The method requires numerous samples (both spatially and at various depths) to determine whether pollutants come from anthropogenic sources.
- The method is useful only for pollutants that become adsorbed to dense particulates.
- Since sedimentation occurs primarily in low-energy embayments, the indicator is less appropriate for use in free-flowing channels.
- The usefulness of this indicator for "real-time" assessment of current pollutant reduction measures is limited due to resuspension of sediments, dredging, and other activities which inhibit the short-term settlement of pollutants.
- Several decades may be necessary to accumulate sufficient data for trend analysis.
- Industrial spills, wastewater discharges, illicit connections, atmospheric deposition and runoff from agricultural and industry sources can all deliver pollutants to sediments, making it very difficult to trace the actual source.
- While suspended in the water column, pollutants may undergo differential chemical behavior, microbial degradation, and photo-degradation. Correlation of the original pollutant source to pollutants identified in the sediment may, therefore, be difficult.

Case Study: Byrne, C.J.; DeLeon, I.R. 1987
Contributions of Heavy Metals from Municipal Runoff to the Sediments of Lake Pontchartrain, Louisiana
Chemosphere, Vol. 16, Nos. 10-12: 2579-2583, 1987.

The authors analyzed sediment samples from eight stations along the northern and southern shorelines of Lake Pontchartrain to determine the distribution and sources of heavy metal pollutants. Sampling sites were at stormwater runoff canals, the mouth of a highly industrialized canal, and the mouths of two lake tributaries. The authors used atomic absorption spectrometry to determine sediment concentrations of barium, copper, nickel, lead, and zinc. Metal concentrations tended to increase with increasing population densities, with the most highly impacted areas being adjacent to the metropolitan area of New Orleans. Lower metal concentrations were found in suburban/residential areas, with the lowest levels observed at the rural, low-density station.

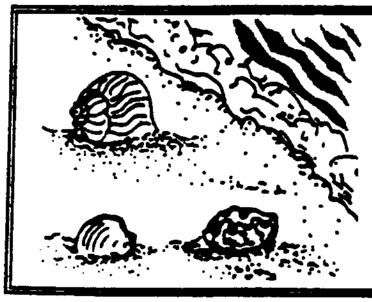
Environmental Indicator Profile Sheet



Indicator Profile No. 6

Human Health Criteria

Category: **Water Quality**

Tools Used to Measure Indicator:

- Bacteria concentrations
- Shellfish Bed Closures
- Fishing Restrictions
- Beach Closures

Description:

Bacteria (usually fecal coliform, *Escherichia coli*, or *enterococci)* are often used as indicators of human pathogens in the water column. Large bacterial concentrations are assumed to be indicative of harmful levels of pathogens. Pathogens are of special concern in shellfish harvesting and recreational contact waters. Water quality criteria for these uses are among the strictest of all water use classifications.

Contact recreation such as water-skiing and swimming potentially expose humans to harmful pathogens; when bacterial levels exceed established standards, beaches may be closed. Since shellfish are filter feeders, they tend to accumulate pathogens in their tissues. When bacteria concentrations exceed the acceptable standard, it is assumed that shellfish taken from the area are unfit for human consumption. Consequently, the shellfish beds are closed to recreational and commercial harvesting.

Because bacteria concentrations tend to sharply increase following storm events, it is strongly suspected that stormwater runoff contributes significantly to elevated bacteria levels. A change in the frequency of shellfish bed closures or beach restrictions, therefore, can provide an early indication of degradation and may be used to assess the effectiveness of stormwater management programs.

Increases in fishing restrictions may also indicate degradation due to urban runoff. Similar to shellfish, fish tend to accumulate pathogens in their tissue. It should be noted that not all fishing restrictions are due to elevated bacterial concentrations. Restrictions may also be implemented in response to high toxic metal, or other pollutant concentrations.

Utility of Indicator to Assess Stormwater Impacts:

- The tendency for many shellfish beds to be closed immediately following a storm event suggests that it can be used as an indicator of short term stormwater impacts.
- Consistent, long-term shellfish bed closures and beach restrictions can be used to detect early stages of water quality degradation.
- Can be used to assess the relative effectiveness of stormwater BMPs or watershed restoration efforts.
- Can be used as a motivational tool for initiating public support for stormwater management efforts.

Not Advantageous	○

Cost

See Table 3.3A

Advantages of Method:

- Provides an early indication of water quality degradation and allows managers to address the problem before it becomes substantial.
- Since no shellfish may be harvested near areas with wastewater treatment plants, bed closures located away from such areas are more likely to indicate problems resulting from stormwater runoff.
- Long-term data is usually available for trend determination.
- The public is generally knowledgeable about this issue; consequently, this indicator may generate public pressure on officials to initiate cleanup efforts.
- Beach closures and shellfish bed closures impact the local economy which increases the likelihood that government officials and the business community will support pollution reduction efforts.

Disadvantages of Method:

- Many of the bacterial species used in human health criteria are common in soil, in other warm-blooded animals, and on the surface of plants, making it difficult to ascertain whether water quality problems are human-induced.
- There is some debate about which bacteria best correlates with presence of human pathogens.
- There are several anthropogenic sources of indicator bacteria (e.g. industrial wastewater, septic systems, agricultural and stormwater runoff), making it somewhat difficult to determine which specific source or sources require management measures.
- Application is limited only to areas where bacteria is regularly monitored, usually shellfish harvesting areas and recreational waters.
- Coliform dies off rapidly when introduced to surface waters and high concentrations can return to normal levels in a matter of days. This makes it difficult to determine whether stormwater runoff causes a chronic water quality problem.
- Relatively little is known about the capability of stormwater BMP's to actually remove bacteria from urban runoff.

Case Study: Barber, R; Ohrel, R.; Fowler, P.; Gilbert, G.
Why We Are Convinced That Traditional Strategies for Wastewater Management Are Not Working
Symposium Proceedings: Integrated Coastal Wastewater Management in North Carolina. 1994.

In the North Carolina coastal region from Cedar Island to the South Carolina border, there have been increases and decreases in the acreage of shellfish beds closed to harvesting during the period 1980-1992. A large net annual decrease in prohibited area occurred once (1983/1984) in the Cape Fear River and the New River. This decrease in prohibited area resulted from both improvements in and elimination of point source discharges. When Cape Fear River and New River areas are excluded from the analysis, the remaining coastal region is shown to have increases in prohibited areas which have been steady and small, but numerous and widespread. The pattern of steady, widespread, and small annual increases in prohibited area does not match the pattern of agricultural or forestry activities; instead, the observed pattern suggests that expanding coastal development, with its associated increase in land disturbance, drainage, and urban runoff, is responsible for the observed pattern of degradation.

North Carolina's anti-degradation policy that protects existing uses of public trust waters. The evidence of shellfish bed closures indicates that State procedures for permitting development adjacent to shellfish waters do not protect the existing uses in those waters; that is, the permit process consistently violates North Carolina's anti-degradation policy.

Environmental Indicator Profile Sheet

Indicator Profile No. 7

Stream Widening/Downcutting

Category: **Physical and Hydrological**

Tools Used to Measure Indicator:

- Stream cross-sectional geometry measurements
- Prevalence of stream bank erosion
- Sediment embeddedness

Description:
The change in stream geometry is measured over time to determine the extent of channel widening/downcutting in response to changes in the magnitude and frequency of stormflows. Stream channel and bank erosion can be documented by measuring channel cross-sections at monumented locations, by measuring channel bankfull width and depth of representative reaches or by measuring the percent of channel-bank scour within specified channel reach lengths. Measurements should be conducted over a period of time in response to upstream land use changes.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to help document stream segments which are susceptible to channel erosion (by comparison to other stream systems with similar channel slopes and geologic materials).
- Can help provide documentation regarding the rate of stream channel erosion as a function of increased urbanization.
- Can be useful to estimate BMP quantity effectiveness, and in documenting locations where additional controls are needed to protect the stream.
- Can be useful in estimating habitat quality and therefore provide information regarding whether water quality or excessive flow discharges are limiting factors in a stream with respect to overall aquatic health.
- Can help a municipality develop better storm event management criteria to reduce streambank erosion.

Advantages of Method:

- Reasonably easy to measure. Requires little specialized equipment and only minor training.
- Can provide similar results regardless of the experience or preferences of the investigator, very repeatable.
- Inexpensive and conducive to rapid assessment techniques.
- Valuable in assessing impacts over time as a result of upstream land use changes.
- Can help relate post-development changes in stream hydrology to changes in stream habitat.

Indicator Useful for Assessing:

Cost

See Table 3.3B

Disadvantages of Method:

- Many stream networks may have already been substantially modified by channelization or storm drain enclosure.
- May not accurately assess aquatic habitat impacts in the absence of stream channel erosion.
- Is not by itself a predictive indicator. Once stream widening and downcutting are observed, degradation associated with upstream land uses is already occurring. The absence of erosive conditions may lead to false conclusions regarding future disturbances.
- May not adequately evaluate current land use impacts where past erosion and sedimentation has modified natural stream morphological processes (e.g., in urbanizing areas with past intensive agricultural land uses).
- May not be applicable for larger streams and rivers.

Case Study: Krug, W.R.; G.L. Goddard, 1986
Effect of Urbanization on Streamflow, Sediment Loads, and Channel Morphology in Pheasant Branch Basin Near Middleton, Wisconsin
USGS Water-Resources Investigations Report 85-4068

A five year monitoring and modeling study was conducted on Pheasant Branch basin near Middleton, WI. The study analyzed the effects of urbanization on streamflow characteristics, sediment loads and channel morphology and took steps to predict the future effects associated with urbanization. The results of the study showed significant increases in sedimentation downstream from highly urbanized areas. Stream beds were lowered an average of two feet and significant stream widening occurred over the five year period downstream from the fully urbanized portion of the basin. Storm runoff modeling of full urban buildout revealed that simulated mean annual flood peaks would increase by more than a factor of 2 and stream widening would increase another 40 to 50% over current conditions.

Environmental Indicator Profile Sheet

Indicator Profile No. 8

Physical Habitat Quality

Category: **Physical and Hydrological**

Tools Used to Measure Indicator:

- Rapid Bioassessment Protocols (Habitat Assess.)
- Rapid Stream Assess. Technique (RSAT)
- Lake Habitat Quality Index

Description:
Physical habitat evaluations are conducted to determine the potential of waterbodies to sustain aquatically healthy systems. Degradation is evaluated to assess whether or not habitat or water quality is the limiting factor to aquatic biodiversity. Specific measurements of streams include channel stability, channel cover, instream sediment embeddedness and substrate condition, riffle, run, pool structure, and riparian habitat. Lake and estuary measurements include: prevalence of submerged aquatic vegetation, percent littoral dominance, depth variation, substrate condition, shoreline development, and submerged structure.

Utility of Indicator to Assess Stormwater Impacts:
- Can help isolate and assess whether water quality or habitat is the limiting factor for aquatic biological health by evaluating what aquatic community might be expected to be present based on habitat alone.
- Can evaluate restoration potential based on the presence or absence of habitat characteristics.
- Can be used as the basis to enhance physical structure of a stream system to increase or maintain available habitat.
- Can help identify causes of degraded habitat (e.g., uncontrolled stormwater runoff).

Advantages of Method:
- Reasonably inexpensive and conducive to rapid assessment techniques.
- Reasonably easy to measure. Requires little specialized equipment and moderate training.
- Provides information on past, present, and potential future channel morphology when conducted over time.
- Useful in detecting the impacts of relatively low levels of development on stream habitat (e.g., trout streams).

Disadvantages of Method:
- May not accurately assess water quality impacts where habitat is in good condition but biological integrity is impaired.
- May be difficult to identify the sources of degraded habitat.
- Results may vary depending on the preferences and experience of the investigator.

Case Study: Maxted, J.R.; E.L. Dickey, G.M. Mitchell, 1994
Habitat Quality of Delaware Nontidal Streams
From Delaware Section 305(b) Report, 1994, Appendix D

Habitat assessments were conducted at 189 sites throughout the state of Delaware during the fall of 1991 and 1993. Sampling stations were selected randomly to provide results which could be statistically extrapolated to the entire state. 87% of all nontidal streams in Kent and New Castle Counties and 78% of all perennial streams throughout the state were found to have degraded physical habitat. The majority of the degraded sites were severely degraded compared to reference conditions. In the Northern Piedmont region, the habitat degradation was caused primarily by urbanization and stormwater. Peak stormwater flows with erosive velocities have caused stream bank failure and channel substrate sedimentation. Management implications are presented. They include the need for aggressive compliance with the state's Sediment and Stormwater Control Regulations.

Environmental Indicator Profile Sheet

Indicator Profile No. 9

Impacted Dry Weather Flows

Category: **Physical and Hydrological**

Tools Used to Measure Indicator:
- Monitoring stream low flow data over time as land use changes.
- Comparing urban stream low flows with nearby rural stream low flows.

Description:
Dry weather flows are measured over a period of time to assess the effects of urbanization on stream base flow. An alternative approach is to analyze streamflow data for various urban streams and compare this data with streamflow data from nearby rural areas (within the same physiographic ecoregion). This alternative approach may require further partitioning for valid comparisons (e.g., within the same physiographic/geologic regime).

In more humid climates, the indicator is reduced dry weather flows (as urbanization increases) as a result of decreased groundwater recharge. In more arid climates, the indicator is increased dry weather flows (as urbanization increases) as a result of increased irrigation/domestic water use.

Dry weather water chemistry, as a result of illicit connections or other discharges, may degrade with increasing urbanization (reviewed as part of pollutant constituent monitoring, Indicator Profile No. 1).

Utility of Indicator to Assess Stormwater Impacts:
- Can assess the low flow quantity effects of increased urbanization.
- Can help assess the causes of reduced low flows in streams by evaluating effects associated with sanitary sewer and storm drainage pipe installation and by evaluating effects of increased impervious surfaces (humid climates).
- Can be used to help watershed managers to institute practices which encourage groundwater recharge and minimize impervious areas.
- Can help assess the causes of increased low flows in streams by evaluating domestic water usage and behavior patterns (arid climates).
- Degraded water chemistry, during low flow conditions can help identify pollutant causes and sources.
- Extremely useful when done in conjunction with stream widening/downcutting studies.

Indicator Useful for Assessing:

* Aquatic Integrity of:	
Lakes	○
Streams	●
Estuaries	○
* Land Use Impacts	◖

* All Watershed Scale	●
* Familiar to Practitioners	◖
* Easy to use & Low training	●

Key
Very Advantageous ●
Mod. Advantageous ◖
Not Advantageous ○

Cost

See Table 3.3B

Advantages of Method:

- Provides a direct indicator of low flow quantity as related to watershed urbanization.
- Relatively easy to monitor flows and report results.
- Reduced stream low flow is easily understood by the general public who can apply pressure on decision makers to make appropriate land use decisions (humid climates).
- Most useful in assessing the impact of development on headwater streams.

Disadvantages of Method:

- May take several years to obtain statistically valid results showing trends in flow data with increasing urbanization.
- May not adequately address varying geologic or climatic conditions where other influences (such as irrigation, well drawdown, public water supply use, sea water intrusion, long term drought, etc.) can affect results, unless method is partitioned to account for this variability.
- Areas with excessively poor natural infiltration rates may show inconclusive trends with changing land use.
- The handful of studies conducted have not shown consistent trends.
- Trends are hard to detect in larger streams or where long term hydrology records are not available.
- In arid climates, where low flow tends to increase with increasing urbanization, resultant condition may be perceived by some as more beneficial than natural conditions.

Case Study: Ferguson, B.K.; P.W. Suckling, 1990
Changing Rainfall-Runoff Relationships in the Urbanizing Peachtree Creek Watershed, Atlanta, Georgia
Water Resources Bulletin, American Water Resources Association, Vol. 26, No. 2

Peachtree Creek is a gaged watershed located in a rapidly urbanizing area. The relationships of runoff to rainfall were studied for total annual flow, low flows and peak flows. Flows were compared between a later, more urbanized condition and an earlier, less urbanized condition. An increase in total runoff in wet years was observed as urbanization increased, but a decrease occurred during dry years. A decrease in low flow was also observed during dry years.

Increasing peak flows and declining low flows can be adequately explained by urban hydrologic theory. A decline in total runoff in dry years can be explained only by taking into account evapotranspiration. The concept of advectively assisted urban evapotranspiration is presented. Urban hydrologic theory must take into account vegetation and evapotranspiration, as well as impervious surfaces and their direct runoff, to explain the magnitude of total annual flows and low flows.

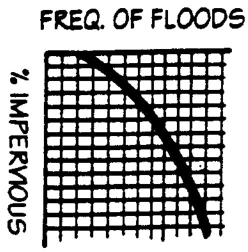
Environmental Indicator Profile Sheet



Indicator Profile No. 10

Increased Flooding Frequency

Category: **Physical and Hydrological**

Tools Used to Measure Indicator:

- Stream gaging data
- Computer modeling
- Stream channel obstruction assessments

Description:

Flooding frequency (or flowrate magnitude change) is measured over time to determine the response to changing levels of urbanization. The number and magnitude of flooding events (in response to rainfall or snowmelt) for a particular location or specific stream segment is documented and compared with the relative changes in land use. Another method is to compare peak flows for different frequency events in urban watersheds and in rural watersheds with similar physiographic characteristics.

The amount of debris and obstructions identified and documented for a given stream reach also provides an indirect measure of flooding potential. Obstructions are identified through stream channel reconnaissance assessments.

The frequency of bankful storm events (in streams) and the corresponding amount of rainfall are essential in understanding stormwater impacts and planning restoration efforts.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to assess the frequency, duration, and quantity of flooding with increasing urbanization.
- Can be used to evaluate the effectiveness of structural BMPs in reducing flooding and streambank erosion potential.
- Can be used to evaluate flooding potential associated with different land use development patterns.
- Can help identify specific flood prone areas.
- Can indirectly predict potential for streambank erosion and habitat degradation.
- Frequently identified debris and obstructions can be an indicator of increased flooding potential which can underline the need for corrective actions.

Indicator Useful for Assessing:

* Aquatic Integrity of:	
Lakes	○
Streams	●
Estuaries	○

* Easy to use & Low training	◐

Key	
Very Advantageous	●
Mod. Advantageous	◐
Not Advantageous	○

Cost

See Table 3.3B

Advantages of Method:

- Flooding is a well-known occurrence and is understood by the general public. Corrective measures are more readily addressed than less tangible water quality issues.
- Increased flooding is fairly easily documented and can be reasonably accurately modeled using several computer models.
- Can help focus public attention and support for urban stormwater programs. Can act as a catalyst in developing other watershed restoration initiatives.

Disadvantages of Method:

- May focus too much attention on structural solutions (such as levees, flood control channels, etc.) rather than more natural, biologically based alternatives.
- Increased flooding frequency may encourage jurisdictions to institute more stringent onsite stormwater regulations without evaluating the hydrologic/hydraulic implications within the watershed.
- Does not provide any data on changes in water quality.

Case Study: Weiss, L.A., 1990
Effects of Urbanization on Peak Streamflows in Four Connecticut Communities, 1980-84
USGS Water-Resources Investigations Report 89-4167

Peak stormwater flows for six urban streams in Connecticut were determined from rainfall and runoff data collected from 1981 to 1984 and from a computer rainfall-runoff model that simulated storm runoff for a period from 1951 to 1980. Recurrence intervals for these six streams and three other urban streams were estimated using the log-Pearson Type III method. These results were compared with peak flows for rural streams that were computed from regression equations.

Ratios of peak flows in urban basins to peak flows in rural basins are about 1.5 to 6.1 for the 2 year frequency event and 1.1 to 4.3 for the 100 year frequency event. The lower ratios, for each case, apply to areas where 30% of the basin is served by storm sewers. The higher ratios apply to areas where 90% of the basin is served by storm sewers.

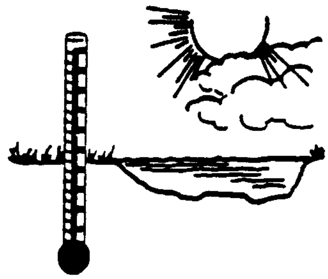
Environmental Indicator Profile Sheet



Indicator Profile No. 11

Stream Temperature Monitoring

Category: **Physical and Hydrological**

Tool Used to Measure Indicator:

- Stream Temperature Monitoring

Description:
Stream temperature is monitored over time to assess changes in response to increasing urbanization. Alternatively, stream temperatures in urban areas may be compared with stream temperatures in nearby rural areas. Monitoring includes both storm events and low flow conditions. For a comparative analysis, streams should be located in close proximity and in the same physiographic province (subject to similar weather events or weather related stressors).

Utility of Indicator to Assess Stormwater Impacts:
- Can be used to assess the effects of urbanization on stream temperature base flows and storm flows.
- Can be used to assess the effects of BMPs on stream temperatures and help in promoting practices which have less impacts.
- Can help identify stream reach lengths which may benefit from riparian buffer enhancement.
- Can be used as a watershed land use planning tool in protecting cool water stream systems.

Advantages of Method:
- Provides a direct indicator of temperature impacts as related to watershed urbanization.
- Since stream temperature changes will likely affect the most sensitive organisms, can provide an early warning indicator of environmental stress which may make remediation easier.
- Reasonably easy to monitor temperatures and report results.
- Stream thermal pollution is easily understood by the general public, public officials, and decision makers who can use the information to make appropriate land use decisions.

See Table 3.3B

Disadvantages of Method:

- May be of limited value in warm water systems.
- Results may be skewed due to natural conditions such as a prevalence of springs and seeps within a watershed or unusually hot summers.
- Changing climatic conditions could have more effect on stream temperatures than urbanization, over the long term.
- Provides only a single measure of the impact of urbanization on water quality.
- Once temperature increases are detected, few management measures are available to decrease them.

Case Study: Galli, J.; R. Dubose, 1990 -
Thermal Impacts Associated with Urbanization and Stormwater Management Best Management Practices
Produced by the Metropolitan Washington Council of Governments for The Maryland Department of the Environment.

The study consisted of a two part approach to evaluate thermal and dissolved oxygen impacts to aquatic life associated with urbanization and various stormwater management BMPs. Part one of the study involved water temperature monitoring and water quality grab sampling at six headwater streams and four stormwater management BMPs located in the Piedmont portion of the Anacostia River basin. The urban streams studied spanned the entire spectrum of watershed imperviousness from undeveloped to approximately 60% impervious cover.

The four representative BMPs monitored in the study included: an infiltration facility, an artificial wetland, an extended detention dry pond and a wet pond. The second part of the study consisted of a comprehensive literature review to evaluate potential temperature and dissolved oxygen impacts at major levels of the aquatic food chain.

The major findings of the study are as follows: (1) Air temperature and other local meteorological conditions had a greater influence on stream temperature than stormflow for 90-95% of the time. Rainfall amount and intensity was second in importance. (2) Watershed imperviousness together with local meteorological conditions had the largest influence on urban streams. (3) Riparian canopy coverage played a key role in insulating small streams from warming. (4) Stream temperature increased with increasing order in a downstream direction. (5) All four BMPs had a positive average effect in increasing stream temperatures. Temperature increases were the most severe in the wet pond and the extended detention dry pond. The artificial wetland was next and the infiltration facility had the least effects on both stormflow and baseflow.

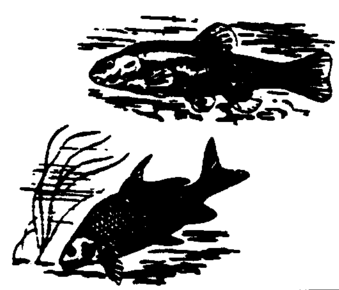
Environmental Indicator Profile Sheet



Indicator Profile No. 12

Fish Assemblage Analyses

Category: **Biological**

Tools Used to Measure Indicator:

- Index. of Biotic Integ., (IBI)
- Index. of Well Being, (I_{WB})
- Rapid Bio. Assess., (RBP)
- Species Extinct./Reduction.
- Presence of fish with disease, tumors, fin damage, etc.

Description:

Fish diversity, species richness, species pollutant tolerance, disease prevalence, and other metrics are used to evaluate the aquatic health of waterbodies as compared to a regional reference condition. This indicator, used by state and local governments, volunteer monitoring groups, and environmental organizations for measuring in-stream water resource quality, is widely regarded as one of the more reliable methods for assessing human-caused ecological impacts.

Fish are collected (usually by electrofishing or seining) and a biosurvey of the resident fish community is conducted. Stations for collection must be representative of the entire reach system in terms of habitat. Wherever possible, multiple habitats (i.e., riffle, run and pool) are sampled for each site.

Fish pathology, indicated by the presence of tumors, fin damage, parasite infestations, and discoloration, among other anomalies is also used in the designation of water body health.

Utility of Indicator to Assess Stormwater Impacts:

- Can characterize the existence and severity of degradation and help identify causes and sources of degradation.
- Can be used to evaluate the effectiveness of restoration programs and help prioritize sites for future evaluation.
- Can be used to help evaluate the effectiveness of BMP controls (both structural and non-structural).
- Can be used on both a regional and local level.
- Can help identify barriers to fish migration.
- Can be used to mobilize public support when popular species are impacted.

Indicator Useful for Assessing:

Mod. Advantageous	◐
Not Advantageous	○

Cost

See Table 3.3C

Advantages of Method:

- Because of a longer lifespan (3 to 4 years), fish exposed to years of impacts, provide a good assessment of long-term impacts.
- The fish assemblage represents a broad range of trophic levels and may be strongly influenced by lower trophic levels (i.e., algae, macroinvertebrates, etc.). Therefore, the fish assemblage provides an integrated view of the entire environmental system.
- Fish are relatively easy to collect and identify. The environmental requirements and life history of fish are fairly well documented.
- The general public is familiar with fishing for sport and food.
- Waterbody aquatic life uses are depicted in terms of fish.

Disadvantages of Method:

- Careful regional analysis is required to ensure that metrics and data are representative of ecoregion. This can require substantial calibration of metrics prior to application monitoring.
- Seasonal changes in fish populations and distribution are natural occurrences. Therefore, multiple sampling sessions are required to obtain representative results.
- Data collected after major flow events may not be representative of normal conditions.
- The relative health of a selected reference condition can skew the results of the system being evaluated.
- Monitoring must account for stream size and order as a factor in natural biological diversity and species density. Fish that spawn elsewhere may be impacted by degraded spawning grounds. Reduced richness in the study area may not be a true indicator of its water quality conditions.
- Lack of fish diversity can be due to confounding problems (poor habitat, low flow, channelization, fish barriers, fishing pressures, etc.), making impact source identification difficult.

Case Study: Schueler,T.R. 1994
The Importance of Imperviousness
Watershed Protection Techniques, Vol.1, No. 3 Fall 1994

Four streams in the Maryland Piedmont were monitored to identify the number of fish and number of sensitive fish present as related to watershed imperviousness. As the level of imperviousness increased the total number of fish species present decreased. For a watershed of less than 10% imperviousness, a total of 12 species were present (7 of which were sensitive). At a percent impervious between 10 and 12, two sensitive species (brown trout and sculpin) were no longer present. As the percent imperviousness rose to above 25, four more species were no longer identified. At 55% imperviousness only two, pollutant tolerant species existed.

This relatively simple study shows that as the intensity of development increases (as measured in terms of impervious area, the total number of fish species decreases. Those fish species which are the most sensitive are adversely affected in watersheds of relatively low impervious area.

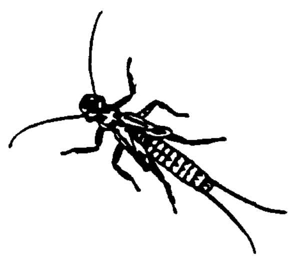
Environmental Indicator Profile Sheet



Indicator Profile No. 13

Macro-Invertebrate Assemblage

Category: **Biological**

Tools Used to Measure Indicator:

- Hilsenhoff Biotic Index
- Rapid. Bioassess. (RBP)
- EPT Index
- Invertebrate Community Index (ICI)

Description:

Benthic macro-invertebrates are used to evaluate the aquatic health of waterbodies. Several metrics (e.g. taxa richness, ratio of scrapers to filterers, ratio of sensitive to tolerant species, abundance, etc.) are used to assess the relative health of a given system. Aquatic systems are usually compared to a reference condition which is defined as the natural or "least impacted" habitat of a particular region. The maximum expectations for macro-invertebrate community structure and function are determined by monitoring the set of streams selected to establish reference conditions.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to depict the existence and severity of degradation.
- Can be used to help screen possible sources and causes of degradation.
- Can be used to help assess the performance of watershed restoration measures (particularly in-stream habitat restoration projects).
- Can be used to help evaluate the performance of stormwater BMPs (both structural and non-structural)
- Provides short term responses to changes in aquatic systems and therefore is a valuable tool to measure short term impacts (such as effects from construction projects).

Advantages of Method:

- Macro-invertebrates have limited mobility, and therefore are good assessors of site specific impacts (mobility, however, may be affected by storm flows and drift).
- Aquatic insects have relatively short lifespans and respond quickly to stress. Therefore, they provide good short term monitoring results.
- Macro-invertebrates are relatively easy to identify, sampling is reasonably easy and does not effect the resident biota. It is relatively easy to identify degraded systems through casual observations.
- Macro-invertebrates are usually abundant in most small streams where few fish are present.
- Citizen volunteers can quickly learn insects to family level, more comprehensive training is required for other metrics.

Indicator Useful for Assessing:

* Aquatic Integrity of:	
Lakes	●
Streams	●
Estuaries	◖

See Table 3.3C

Disadvantages of Method:

- Some regional modifications of metrics are required to ensure that data is representative of ecoregion.
- Seasonal changes in species composition and populations requires strict adherence to consistent sampling frequency.
- Data collected after major flow events is likely not to be representative of normal conditions due to habitat disruptions.
- The relative health of a selected reference condition can skew the results of the system being evaluated.
- Species identification may be time consuming and complex.
- Sensitive macro-invertebrate species seem to decline significantly at relatively low watershed imperviousness (≤ 15%) and therefore are less effective as predictive tools for more densely urbanized areas.
- Paired sampling sites must have comparable habitat to produce valid results. Macro-invertebrate prevalence may be as much a function of habitat type as quality.

Case Study: Jones, R.C.; Clark, C.C. 1987
Impact of Watershed Urbanization on Stream Insect Communities
Water Resources Bulletin, American Water Resources Association, Vol 23, No. 6

The effects of urbanization on aquatic insects were analyzed for 22 sites in five watersheds in northern Virginia. The amount of urbanization was measured in terms of human population. Population densities ranged from near 0 in one watershed to nearly 20 individuals per hectare at one sampling site. Sampling sites were located so as to only collect data for non point source discharges. Three samples were obtained for each stream reach, each for a separate riffle. Organisms were collected using a modified circular Hess sampler. During sample collection other physio-chemical parameters were also measured: temperature, dissolved oxygen, conductivity, pH, alkalinity and hardness, and canopy coverage. Organisms were identified to genus using the method of Merrit and Cummins (1984).

Results of the study showed that abundance of Diptera was strongly correlated with increasing urbanization. The relative abundance of other groups was negatively correlated with urbanization. Trichoptera and Ephemeroptera as a percent of total organisms, each decreased with increasing urbanization. Coleoptera, Megaloptera, Plecoptera and Odonata were found almost exclusively at low to moderately urbanized stations. The 22 sites were placed into two groups; 9 sites were in watersheds that had population densities less than 10 per hectare and 13 sites were in watersheds with human populations greater than 10 per hectare. The less urbanized watersheds had significantly less Diptera and significantly more Ephemeroptera, Coleoptera, Megaloptera, Plecoptera and Odonata. The total number of insects was not significantly affected by urbanization. Trichoptera was the only group which did not vary significantly with increasing urbanization. Genus richness and diversity was also significantly higher in the less urbanized group. The result of the study indicates that the relative urbanization has a significant effect on aquatic insect community.

Environmental Indicator Profile Sheet

Indicator Profile No. 14

Single Species Indicator

Category: **Biological**

Tools Used to Measure Indicator:

- Electrofishing Surveys
- Physical Habitat Assessments
- Bioassays

Description:
The biological status of a carefully chosen single species is used as an assessment tool for representing the environmental health of an aquatic system. The presence, absence and/or trend in population of a particular environmentally sensitive species (such as trout, salmon or freshwater mussels) in a waterbody provides a measure of aquatic health. Single species reproduction rates and mortality rates are compiled to evaluate trends in aquatic system integrity. Species pathology, indicated by the presence of tumors, fin damage, parasite infestations, and discoloration, among other anomalies is also used to assess water body health.

Utility of Indicator to Assess Stormwater Impacts:

- Useful in identifying degradation associated with land use for the single species and/or trophic level.
- Potential to act as a focal point for aquatic system protection and restoration. Can induce public education, support and activism.
- Can solicit political pressure and support regarding planning issues.

Advantages of Method:

- Usually on a higher trophic level and therefore potentially representative of broader range of environmental quality.
- Easy to identify, sample and has low training costs.
- Single species monitoring is conducted relatively quickly.
- The general public is usually very familiar with the species being monitored (such as trout and salmon).
- The use of sensitive species as an indicator species identifies degradation in its early stages which may make remediation easier.

Indicator Useful for Assessing:

* Aquatic Integrity of:	
Lakes	◖
Streams	◖
Estuaries	◖
* Land Use Impacts	◖
* Stormwater Mgmt Programs	◖
* Whole Watershed Quality	◖
* Industrial Sites	◖
* Municipal Programs	◖

Key:

Mod. Useful	◖
Not Useful	○

Indicator Advantages

* Geographic Range	●
* Baseline Control	◖
* Reliable	○
* Accuracy	◖
* Low cost	●
* Repeatable	◖
All Watershed Scale	◖
* Familiar to Practitioners	◖
* Easy to use & Low training	●

Key	
Very Advantageous	●
Mod. Advantageous	◖
Not Advantageous	○

Cost

See Table 3.3C

Disadvantages of Method:

- Management activities, such as fish stocking, can distort monitoring results.
- Habitat protection/restoration measures (based only on single species) may not adequately address other aquatic species needs.
- The natural variability and population fluctuations of the single species being measured may skew results. The advantage of multiple metrics to account for aberrations is not present.
- Species that migrate make it difficult to isolate whether the effect is occurring in the study area or somewhere else.
- If the species is not currently or historically present in the aquatic system, the method provides little useful data.

Case Study: Scott, J.B.; Steward, C.R.; Stober, Q.J.
Effects of Urban Development on Fish Population Dynamics in Kelsey Creek, Washington
Transactions of the American Fisheries Society 115:555-567, 1986

The authors presented a paper from a 30 month study comparing the relative fish dynamics for two small streams in Washington, one located within a predominately urban area and one located in a predominately rural area. Kelsey Creek is located in the City of Bellevue, Washington and has land uses consisting of mainly single-family and multi-family residential, but also has a significant commercial and industrial land use component. Nearby Bear Creek is in a predominantly rural area with only 15% of the land use occupied by single-family residential and the remaining land cover is in forest and pastureland.

According to historic studies Coho salmon *Oncorhynchus kisutch* and cutthroat trout *Salmo clarki* were the most abundant salmonids present in the early 1940's in both streams. Although there were no detailed lists of the other species inhabiting the study streams at that time, more recent investigations indicate that sculpins *Cottus* sp. were originally widely distributed in the area.

Study methods included conducting outmigrant netting and resident fish sampling. Netting of downstream migrants was conducted at the mouth of Kelsey Creek. Resident fish were sampled at five sites on Kelsey Creek and three sites on Bear Creek. Fish were sampled using a backpack electrofisher. Fork lengths of all salmonids were measured, scale samples were obtained and wet weights were determined. Nonsalmonid fish species were recorded as present or absent except for one sampling session when numbers and weights were recorded. Ages of the fish were determined, population of each species-age group at each study site was estimated by the removal method and the Seber-Jolly mark-recapture method. Population growth rates were calculated.

Impacts from urbanization appeared to have a greater affect on coho salmon and nonsalmonid fish species than on cutthroat trout. The total biomass of fish in each stream was determined to be about the same, but the composition of the fish assemblage differed substantially. The majority of fish in Kelsey Creek were cutthroat trout between age 0 and 1 year. Bear Creek had a much more diverse salmonid community of various ages and numerous non-salmonids were present.

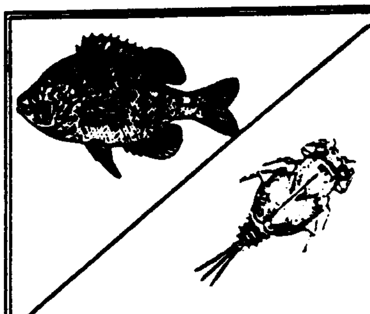
Environmental Indicator Profile Sheet



Indicator Profile 15

Composite Indicators

Biological Indicators

Tools Used to Measure Indicator:
Two or more of the following:

- Ind. of Bio. Integrity (IBI)
- Rapid Bioass. Pro. (RBP)
- Index of Well Being (I_{wb})
- Invertebrate Community
- Index (ICI)

Description:

Multiple groups of organisms and/or taxa (e.g., macroinvertebrates, fish, plankton, amphibians) are used to comprehensively portray the health of aquatic systems. A series of biological metrics, ranging from fish diversity indices, macro-invertebrate indices, algal communities, and/or other communities are evaluated to assess the effects of urban runoff on aquatic biota. Composite indicators require comparison to reference conditions as a measure of use attainability.

Utility of Indicator to Assess Stormwater Impacts:

- Provides the same utility to assess stormwater impacts as both fish and macro-invertebrate sampling but may provide a more thorough and comprehensive evaluation.
- Can be used to prioritize further and more detailed monitoring, such as chemical characterizations or toxicity testing.

Advantages of Method:

- Composite monitoring allows for both long-term trend analysis as well as short-term impact assessments.
- Composite monitoring provides more comprehensive information relative to pollutant source identification. Locations are more easily confirmed when multiple metrics are indicating degradation.
- Composite monitoring is useful for whole watershed assessments as well as site specific impact assessments.

Disadvantages of Method:

- Regional modifications of metrics will be necessary over a fairly wide range of taxa.
- Seasonal changes in species composition will require strict adherence to consistent sampling frequency.
- Major flow events will affect data validity.
- Reference condition health can skew results.
- Cannot alone characterize the precise causes of degradation, this will usually involve other tools.

Case Study: Pitt, R.E.
Effects of Urban Runoff on Aquatic Biota
Handbook of Ecotoxicology, Lewis Publishers, Inc. 1994; Chapter 30

This case study analyzes the effects of urban runoff on the receiving waters of Coyote Creek, near San Jose, California. The study describes the changes to the aquatic environment as the creek passes from an upstream non-urban area through an urbanized area.

The Coyote Creek is a reasonably large waterway which drains an area of approximately 200,000 acres. The urban portion of San Jose is within the downstream one-third of the approximately 45 mile long watershed. Sampling was conducted during the period of March 1977 to August 1980. Several parameters were sampled during the study period, including; basic hydrologic conditions, water quality, sediment properties, general habitat characteristics, fish, benthic organisms, attached algae, and rooted aquatic vegetation. The use of the above array of indicators provided a broad picture of the impacts of urbanization on Coyote Creek. The results of the study showed that there were distinct differences in species diversity, composition and abundance between the urban and non-urban portions of the study area. The non-urban areas supported a more diverse aquatic community, more native fishes and many more benthic macroinvertebrate taxa. The urban portions of the study area were composed of an aquatic community of mainly the most pollutant-tolerant species of fish and macroinvertebrates. There were changes in the physical habitat between the non-urban and urban portions of the creek, however it is believed that these differences could not account for the magnitude of change to the aquatic community through the urban reach.

Due to a wide variety of possible factors affecting the biological community, it is impossible to directly identify all of effects as being attributed to urban runoff alone. In a system as large as the Coyote Creek other factors such as extreme flows, drought, stream gradient, effects of impoundments, etc. may contribute to biological degradation. The evidence presented in this case study indicates that urban runoff is responsible for a large portion of the impacts to biological organisms.

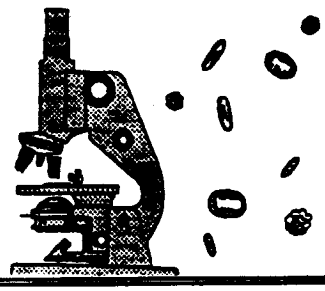
Environmental Indicator Profile Sheet



Indicator Profile No. 16

Other Biological Indicators

Biological Indicators

Tools Used to Measure Indicator:

- Phytoplankton Indices
- Zooplankton Indices
- Diatoms community measurments
- Periphyton Indices

Description:

There are several additional biological monitoring methods that have been used to assess water quality. Examples of some of these include surveys of: plankton (phytoplankton, zoophankton, periphyton, diatoms) Bryozoans, algal microfossils, amphibians and bacteria. Some of these are more commonly used than others and some have been used for direct assessment of urban stormwater runoff while others are for different water quality evaluations (such as wastewater effluent monitoring, water treatment plant monitoring, CSOs, etc.). This profile is targeted primarily at the utility of plankton surveys as a biological indicator. Bryozoans are technically considered macro-invertebrates, algal microfossils are part of sediments and bacteria are addressed separately under the Human Health Criteria indicator profile.

Utility of Indicator to Assess Stormwater Impacts:

- Plankton can be used to assess water quality through changes in community structure, patterns of distribution and relative proportions of sensitive and insensitive species.
- Plankton can be used to evaluate thermal pollution, presence of toxic pollutants, nutrients and excessive sedimentation.

Advantages of Method:

- Valuable as a continuous monitoring tool because the nature of the cell structure allows for continuous integration of stresses that effect growth and reproduction. Good for assessing short term impacts.
- Phytoplankton (free floating algae) have distinct species which flourish in eutrophic conditions and distinct species which are indicitive of clean water. This is particularily useful in estuaries and freshwater lakes.
- Periphyton (attached forms of algae) are traditionally used in lotic systems as an indicator of water quality.
- Diatoms and other single-celled microscopic plants provide a quantifiable measure of water quality degradation over a wide geographic area.

Indicator Useful for Assessing:

* Aquatic Integrity of:	
Lakes	●

Very Advantageous	●
Mod. Advantageous	◐
Not Advantageous	○

Cost

See Table 3.3C

Disadvantages of Method:

- May have limitations due to transient nature and variable distribution of species, and the influence of large storm events (washout).
- Requires fairly sophisicated sampling and laboratory work to quantify analysis and report results. Some methods and indices may over-simplify the ecological conditions by evaluating only species composition rather than community structure and dynamics.
- Short lifespans of organisms are not particularly suited for long term monitoring studies.
- Indicator populations are often highly seasonal in nature.
- Few stormwater managers have training or experience in interpreting sample data.

Case Study: Morgan, M.D., 1987
Impact of Nutrient Enrichment and Alkalinization on Periphyton Communities in the New Jersey Pine Barrens.
Hydrobiologia, Vol. 144, No. 3, p 233-241

Periphyton was used to evaluate impacts associated with urban residential and agricultural land uses in the New Jersey Pine Barrens. Communities of periphyton in three developed streams were compared with those of three undeveloped streams. 53 periphyton species were encountered in a sampling period of one year. Species richness was significantly greater in the disturbed streams. Species composition also varied between the two conditions. Elevated pH and nitrates in the disturbed conditions contributed to the effects of species composition.

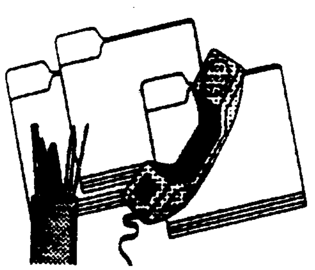
Environmental Indicator Profile Sheet



Indicator Profile No. 17

Public Attitude Surveys

Category: **Social**

Tools Used to Measure Indicator:

- Direct mail to public
- Public workshops with citizens/citizen assoc.
- Interviews with targeted audience

Description:

Public attitude surveys are directed at targeted groups to assess general awareness of key water quality problems and willingness to finance (via government spending) restoration efforts. A targeted group is solicited with a direct mailout, an interview or other mechanism of communication to gather information regarding an existing or potential program. The results of a survey are usually gathered into a summary report which may, for example, indicate that the public believes urban runoff to be the most significant source of pollution in the watershed or that funding for restoration efforts should be increased. This information is then used by decision makers in helping to formulate watershed management policy, develop restoration budgets and workplans, or implement stream restoration programs, for example.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to assess the public's perception of existing or proposed water quality programs (e.g., citizen volunteer monitoring, proposed waterbody restoration program, maintenance program implementation for BMP's, etc).
- Can be used as a foundation for political action to stress the relative value the public places on a particular water quality issue.
- Can be used as a mechanism for soliciting public or private funding for a particular water resource issue.
- Can be a major component of a public educational program which incorporates results of surveys into future programs.
- Helps managers develop more effective pollution prevention programs based on reported behaviors and targets scarce resources toward specific watersheds, population groups, or watershed interest groups.

Advantages of Method:

- Effective way to obtain information regarding citizen attitudes/concerns for a particular issue or set of issues.
- Gives decision makers information on how proposed programs are likely to be received by the targeted audience.
- Generally is relatively easy to interpret results and therefore can be an effective tool for non technical applications.

Cost

See Table 3.3D

Disadvantages of Method:

- Results of survey are dependent on the number of people who respond and the degree of importance people place on water quality issues.
- Results can be dependent on the socioeconomic status of the community being surveyed and the relative importance water quality plays in people's lives.
- Results of survey can be skewed by the relative knowledge of the target audience. Survey practitioners must consider target audience's understanding of topic in formulating questionnaires and be prepared to follow up with future surveys.
- Language barriers and lack of phone or address information may result in missing key population groups.
- Does not directly measure changes occurring in the receiving water.

Case Study: Blair, J., G. Slater, A. McLaughlin, 1994
The Chesapeake Bay Attitudes Survey
Chesapeake Bay Program, Communications Subcommittee, Final Report, April 28, 1994.

The Survey Research Center at the University of Maryland at College Park conducted a survey of residents in the Chesapeake Bay watershed. The goal of this study was to provide baseline data on the attitudes, behaviors, and opinions of residents about pollution, water quality, funding, and clean-up efforts in the Bay watershed. The survey was conducted from October 6, 1993 through January 27, 1994. A total of 2004 people were interviewed.

The study results indicated that 85% of all respondents were either very concerned or somewhat concerned about pollution in the Bay. This level of concern varied by distance from the Bay. Concern was greatest for people living closest to the Bay. Approximately one-third of the respondents thought that business and industry was the main cause of pollution in the Bay. About half of the respondents thought the Bay was more polluted today compared to ten years ago.

Seventy-eight percent of the respondents who reported being familiar with the Bay said that pollution had not interfered with any of the things they do for recreation on the Bay. Sixty-eight of these respondents thought that the water quality was unsafe for aquatic life; sixty percent thought water quality was unsafe for swimming, and fifty-three percent thought the water quality made seafood unsafe.

The major sources of pollution identified by respondents were business and industry, commercial shipping spills, recreational boating, landfills, construction, and farming. Sixty-one percent said efforts to clean-up the Bay were too little.

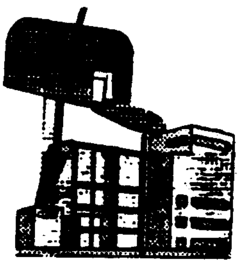
Environmental Indicator Profile Sheet



Indicator Profile No. 18

Industrial/Commercial Pollution Prevention

Category: **Social**

Tools Used to Measure Indicator:

- Direct mail out to industry
- Workshops with industry representative groups
- Interviews with individual industry personnel

Description:

Surveys of pollution prevention efforts for industrial sites are conducted to assemble data regarding the costs and benefits associated with NPDES stormwater permit compliance. Site managers are surveyed to obtain information regarding permit implementation costs (e.g., BMP construction costs, spill prevention training costs), technical issues regarding implementation of structural and nonstructural BMPs, and potential benefits gained.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to assess industry's perception of effectiveness of stormwater BMPs and methods for improvement.
- Can be used to assemble cost information and compare implementation costs between different industries and different geographic locations.
- Can be a component of an industry stormwater educational program which incorporates results into future pollution prevention programs.
- Can foster partnerships with industry and help managers identify site conditions that they may be unaware of (e.g., illicit connections from floor drains).

Advantages of Method:

- Effective way to obtain information regarding industry attitudes and perception of the importance of stormwater programs.
- Results of survey are based on industry input and therefore will likely be more directed at specific concerns/problems which affect industry operations which may lead to more cost effective ways of doing things.
- Generally is relatively easy to interpret results and therefore can be a useful tool for non-technical policy decisions.

Disadvantages of Method:

- Results of survey are dependent on the information provided by industry personnel and may be skewed to industry's advantage
- Surveys are not usually based on highly technical information and may not adequately address complex water quality issues.
- Industry may be suspicious that participation in the surveys may lead to costly regulation.

Case Study: Beck, P.C.
Stormwater Permit Program An Industrial Experience
Stormwater NPDES- Related Monitoring Needs. Conference Proceedings, American Society of Civil Engineers. MT. Crested Butte, CO August 7-12, 1994

The Coors Brewing Company, located in the foothills of the Rocky Mountains west of Denver, is the third largest brewer in America and subject to the NPDES stormwater discharge permit. Coors' will be operating under four general stormwater permits. Coors has completed stormwater outfall sampling at more than twenty stormwater discharge locations. The results of the sampling showed that average concentrations fell within requirements for bottled water and RCRA Health Based Standards. Maximum values were in some cases substantially above the average values. Additional work is probably necessary to fully assess the normal distribution of data at any given outfall. Nutrients and suspended solids showed a wide range of variation among different samples and different results.

Coors has taken some corrective actions for areas with unusually high pollutant concentration values. For example, an outfall with a 3190 mg/l BOD_5 concentration was near a yeast drying facility and spilled yeast was responsible for the high value. Corrective actions were taken to reroute storm drains from the existing outfall to the process treatment plant. Other problems were also addressed: Roof drains on fermenting buildings were rerouted from a discharge into the adjacent creek to the process treatment plant. Storm drains in high traffic areas were modified to collect the five year storm and divert it to the sanitary system. Lean-to roof structures were installed over waste material collection bins and over above ground fuel storage facilities.

Environmental Indicator Profile Sheet

Indicator Profile No. 19

Public Involvement and Monitoring

Category: **Social**

Tools Used to Measure Indicator:

- Number and type of public involvement groups
- Quantity of volunteer monitoring performed
- Number of hotline reports
- Advisory council

Description:
Public participation in stormwater programs is one measure of overall program effectiveness. Successful implementation of stormwater programs depends, in large part, upon the active support and participation of the public. Citizen monitoring programs, stream segments adopted, watershed stewardship groups, public education (including school curricula), participation in watershed education events are all components of public involvement programs. Other measures of public participation include participation in household hazardous waste recycling efforts, number of calls made to report illegal dumping into the storm sewer system or streams, and membership in citizen advisory groups.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to help modify citizen behaviors related to source controls.
- Can help reduce monitoring expenses and expand a jurisdiction's monitoring database.
- Can help identify pollutant sources through citizen watchdog actions.
- Can help prepare students to be knowledgeable about water pollution issues and respectful of existing water resources.
- Can generate political support for additional stormwater and watershed funding.
- Can foster acceptance of projects through close relationships with communities, and can provide input for adjacent residents on siting and aesthetic concerns

Advantages of Method:

- Jurisdictions with active public involvement programs are more likely to have a population which is informed about water quality issues and therefore is more receptive to program initiatives, funding issues, and pollution prevention efforts.
- Programs can be initiated by local governments with relatively little expense.
- Provides decision makers with information on public perceptions which is useful in watershed management programs.

Indicator Useful for Assessing:

* Aquatic Integrity of:	
Lakes	◖
Streams	◖
Estuaries	◖
* Land Use Impacts	◖
* Stormwater Mgmt Programs	◖
* Whole Watershed Quality	◖
* Industrial Sites	○
* Municipal Programs	◖

* Easy to use & Low training	●

Key	
Very Advantageous	●
Mod. Advantageous	◖
Not Advantageous	○

Cost

See Table 3.3D

Disadvantages of Method:

- Monitoring may not always meet strict quality control protocols and, therefore, may not be scientifically useful for expanding databases.
- Citizen activists may not understand technical issues and may be less receptive to political and financial tradeoffs associated with particular projects.
- Educational efforts may take several years to affect citizen behavior.
- The lack of citizen involvement group participation may be a function of socioeconomic environment rather than actual program effectiveness.
- Does not measure or change the behavior/attitudes of residents that do not participate in the programs.

Case Study: Texas Natural Resource Conservation Commission
Texas Watch: Volunteer Environmental Monitoring
Texas Natural Resource Conservation Commission, P.O. Box 13087, Austin, TX 78711

This information packet describes Texas Watch, the statewide volunteer environmental monitoring program of the Texas Natural Conservation Commission. The program is one component of the agency's strategy to combat nonpoint source pollution. Texas Watch addresses nonpoint source pollution in two ways: it assists professional data gathering efforts by enlisting volunteers to monitor water quality in their communities and it provides an excellent tool with which to educate the public about nonpoint source pollution through teacher involvement and the media.

Method References:

- Number and type of public involvement groups: Fullmer, J., 1994. Environmental Indicator Profile Sheet

Indicator Profile No. 20

User Perception

Category: **Social**

Tools Used to Measure Indicator:

- Direct mail to public
- On-site interviews
- User survey and counts

Description:
Successful stormwater management efforts depend, in large part, on public support. Public support, in turn, depends upon its valuation of water resources. The public's valuation of a particular water body is usually based on more than water chemistry. Appearance, surroundings, ease of access, and apparent water quality are all considered by the average user. Trash, floatables, and turbidity will detract from the appearance of the water body. Surroundings are perceived as less than ideal when there is limited tree cover or other bank-side vegetation. Extremely dense vegetation, limited physical access, or remoteness may also detract from perceived value. Finally, oily waters, unusual colors and odors will also count against the water body.

It is possible that water bodies with generally good water quality may be perceived as being in poor condition by the public if access is limited or the water is turbid. On the other hand, biologically impaired waters may be perceived by the public as "clean" solely based on the lack of obvious pollution such as tires or bottles.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to assess the public's perception of existing conditions in the watershed.
- Can be used as a foundation for educating the public about the "hidden" impact of water quality pollution.
- Can be used as a platform for generating stewardship programs and public support for water restoration efforts.
- Can be a major component of a public educational program which incorporates results of surveys into future programs.

Advantages of Method:

- Effective way to obtain information regarding citizen attitudes/concerns for a particular issue or set of issues.
- Gives decision makers information on what aspects of watershed restoration are most important to the public.
- Survey results are generally easy to interpret and therefore can be an effective tool for non-technical applications.
- Targets the portion of the public most likely to be knowledgeable about water quality issues and be supportive of watershed restoration efforts.

Indicator Useful for Assessing:

Cost

See Table 3.3D

Disadvantages of Method:

- Results of survey are dependent on the number of people who respond and the degree of importance people place on water quality issues.
- Results can be dependent on the socioeconomic status of the community being surveyed, the proximity of the water body, and the designated recreational usage.
- Results of survey are site-specific. The survey results assess concerns about a specific water body, not the entire watershed.
- Language barriers and lack of phone or address information may result in missing key population groups.
- Does not directly measure changes occurring in water quality.
- Can be very costly to obtain a representative survey sample.

Case Study: Desvousges, W.H.; V.K. Smith, M.P. McGivney, 1983.
Interviews with Target Audiences: Comparison of Alternative Approaches for Estimating Recreation and Related Benefits of Water Quality Improvements
Environmental Protection Agency, Misc. Rep Ser. U.S. EPA. No. EPA/230/05-83/001

Pollution control policy can reduce the amount of effluents going into a particular river. In turn, this changes the water quality and ecological habitat. The public then may be able to use the river more for in-stream activities such as swimming, boating, and fishing and for withdrawal purposes such as drinking water, irrigation, and cooling. However, measuring change in use understates the total benefits of the pollution control if there are positive "intrinsic" benefits for preserving the potential for future use and vicarious consumption. This study compares three methods for measuring overall recreation and related benefits of improved water quality. These methods are travel cost, contingent calculation, and contingent ranking. The comparison is based on detailed interview data for 305 user and nonuser households in the Pennsylvania portion of the Monogahela River watershed. The benefits measurement approaches show consistent results for comparable changes in water quality. The results of this project strongly support the feasibility of measuring the recreation and related benefits of water quality improvement.

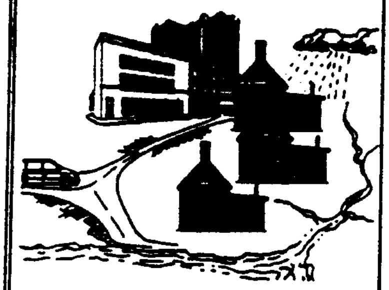
Environmental Indicator Profile Sheet



Indicator Profile No. 21

No. of Illicit Connections Identified/Corrected

Category: **Programmatic**

Tools Used to Measure Indicator:

- Investigative monitoring using wet and dry weather sampling, visual observations, GIS, dye testing, smoke testing, etc.

Description:

This indicator involves the identification and correction of illegal and/or improper waste discharges into storm drainage systems and receiving waters. Dry weather flows potentially contribute substantial loadings to receiving waters. Jurisdictions have programs to identify, prioritize pollutants, and implement corrective actions to eliminate or minimize these non-stormwater entries.

Utility of Indicator to Assess Stormwater Impacts:

- Since illicit connections can contribute substantially to pollutant loadings, the number identified and corrected can have a direct and immediate effect on water quality.
- Can be used as a measure to assess the effectiveness of a municipality's overall stormwater program.
- Sampling can help define the frequency and severity of illegal discharges to the storm sewer system (i.e., non sanitary system).

Advantages of Method:

- Results are easily interpreted by politicians and administrative officials which help make programs sustainable and justify funding.
- Can be part of a citizen volunteer monitoring program.
- Helps many communities identify the locations and size of all storm and sanitary outfalls. Often many are "lost" over time due to poor record keeping.

Disadvantages of Method:

- The number of illicit connections identified is not necessarily representative of the total number of illicit connections in existence.
- Programs to identify, prioritize, and correct illicit connections can be very costly to operate and personnel training can be expensive.
- Does not measure the hydrological impact of storm flows in the pipe system.
- Site-specific monitoring may be required to characterize volume of flow and pollutant constituents of illicit connection.

Case Study: Minor, J.D., 1995
Finding Illicit Connections and Discharges with P²IL
Torno, J.C. (ed.) 1995. Stormwater NPDES-related monitoring needs. Conference proceedings. American Society of Civil Engineers. Mt Crested Butte, CO. August 7-12, 1994

Finding illicit connections for the City of Scarborough, Ontario, Canada, located on the north shore of Lake Ontario, requires dedicated *Programs* and *Procedures*, executed with *Intuition* and *Luck* (P^2IL). The City of Scarborough with a population of approximately 550,000, is about 85% developed. Sixteen per cent of the total area is within industrial districts. There are approximately 400 industrial/commercial/institutional (ICI) sites with stormwater discharges. The City has more than 800 storm drainage outfalls draining to three watercourses. Pollution prevention efforts occupy approximately 6000 manhours per year, equipment and lab costs are approximately $50,000 (CDN) and start up costs were approx. $200,000 CDN. The drainage system with outfalls has been mapped using GIS, waterways are monitored during wet and dry weather, and problem outfalls are identified with chemical, biological and visual techniques. Outfalls are further evaluated using flow meters, non-intrusive sensors, video cameras, dye testing, smoke testing, and pressure testing for the presence of illicit connections.

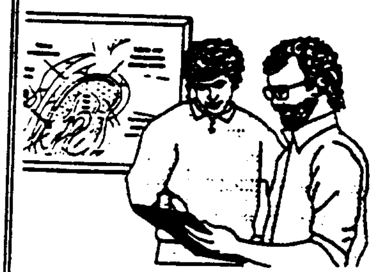
Environmental Indicator Profile Sheet



Indicator Profile No. 22

No. of BMPs Installed, Inspected, and Maintained

Category: **Programmatic**

Tools Used to Measure Indicator:

- Development Site Plans
- Property Owner/Developer Interviews
- No. of Construction Permits Issued
- Local Inspection Programs

Description:

By tracking the number of BMPs that are installed, inspected, and maintained in a given area, stormwater practitioners may be able to measure the progress and effectiveness of municipal programs. As more BMPs are installed, one may assume with reasonable confidence that progress in the stormwater arena is being made. Regular inspection and maintenance of BMPs will ensure that existing stormwater management resources are fully utilized, will help identify facilities which require retrofits, and will identify areas requiring additional management resources.

Program implementation can also be tracked through review of the maintenance backlog. Large BMP maintenance backlogs may indicate that additional monetary and manpower resources are required to ensure effective operation of existing BMPs.

Utility of Indicator to Assess Stormwater Impacts:

- Inspections can expose weaknesses in BMP design, reveal maintenance needs, and determine needs for enforcement actions.
- Can be used to determine whether existing BMPs are sufficient in scope and size to adequately address a community's stormwater management needs.
- Helps a municipality improve the design criteria for future BMPs by determining which practices have more problems.
- Provides useful data when conducting stormwater retrofit inventories.

Advantages of Method:

- Since BMPs are specifically designed to provide a particular level of performance, it is relatively easy to determine whether their functions are being achieved.
- Educational programs can be developed to involve private organizations in data collection. Such programs may also serve to educate the public about BMP usage, performance, and maintenance needs.
- Increased performance monitoring and reporting increases the likelihood that BMPs will be properly maintained.
- Can be combined with GIS and watershed simulation models to determine the cumulative watershed benefits of implementation of stormwater BMPs.

Indicator Useful for Assessing:

* Aquatic Integrity of:	
Lakes	○
Streams	○
Estuaries	○
* Land Use Impacts	◖
* Stormwater Mgmt Programs	◖
* Whole Watershed Quality	◖

* Repeatable	●
* All Watershed Scale	◖
* Familiar to Practitioners	◖
* Easy to use & Low training	○

Key

Very Advantageous	●
Mod. Advantageous	◖
Not Advantageous	○

Cost

See Table 3.3E

Disadvantages of Method:

- There is little standardization in place for reporting BMP performance, possibly resulting in conflicting inspection reports.
- Many watershed managers choose BMPs based on cost, with design performance a secondary consideration. As a result, even if a BMP performs according to design, it still may not adequately protect receiving water quality.
- BMP inspections and maintenance are costly and require extensive staff time.

Case Study: Lindsey, G.; L. Roberts, and W. Page. 1992
Maintenance of Stormwater BMPs in Four Maryland Counties: A Status Report
Journal of Soil and Water Conservation. 47(5): 417-422, Sept./Oct. 1992.

Field inspections were made of more than 250 stormwater facilities in four Maryland counties. The types of facilities inspected included dry basins, wet and extended detention basins, infiltration basins and trenches, dry wells, underground storage facilities, and vegetated swales. Trained inspectors evaluated performance (inappropriate ponding of water, slow infiltration, incorrect flow patterns, clogging of facility, excessive sediment or debris, water bypassing facility, design shortcomings, structural failures, erosion at intake or outfall) and maintenance criteria (facility functioning as designed, quantity controlled as designed, quality benefits produced by ability, enforcement action needed, maintenance action needed) for each facility. While most (64%) of the facilities were found to be functioning as designed, many needed maintenance, especially to correct excessive sediment and debris problems. Inspectors believed that enforcement action was warranted at many sites. The condition of different types of facilities varied significantly. Several models were used to explain results, including a series of chi-square tests to determine the independence of facility status and objective and subjective variables. Overall, the investigations documented the need for improved inspection and maintenance by stormwater management regulatory authorities.

Environmental Indicator Profile Sheet

Indicator Profile No. 23

Permitting and Compliance

Category: **Programmatic**

Tools Used to Measure Indicators:

- NPDES Industrial Permits
- Construction Permits
- Local Inspection Programs

Description:
NPDES stormwater regulations require many municipal and industrial stormwater dischargers as well as construction site developers to obtain discharge permits. Permit requirements generally focus on identification and control of significant sources of nonpoint source pollution. Most permits also require implementation of pollutant reduction measures. These measures encompass structural BMPs such as sediment control basins and non-structural measures such as good housekeeping and personnel training.

Tracking the number and type of NPDES stormwater permits issued, the number of stormwater discharges in compliance with their permits, and the number and type of BMPs implemented in conjunction with the permits allows municipalities to gauge the relative impact of various pollutant sources (i.e., urban versus industrial versus construction), determine if regulatory baselines are being met, and identify the need for additional enforcement activities.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to identify potentially significant contributors of pollutants.
- Can be used to assess the level of industrial support for stormwater management efforts.
- Can be used by NPDES program managers to assess compliance with regulations and designate areas for improvement.
- Allows identification of uncontrolled sources of pollution to stormwater.

Advantages of Method:

- Permitting is already required by many states.
- Comprehensive permitting structures have already been established.
- The majority of the cost and time burden associated with implementation and identification of pollutant control measures is borne by private sources.
- Fosters communications between developers, industry, and regulatory agencies responsible for developing and implementing stormwater management strategies.

Indicator Useful for Assessing:

See Table 3.3E

Disadvantages of Method:

- Some industrial sites are reluctant to identify the most effective measures, instead opting for less expensive measures with meet the minimal requirements.
- Processing permits and inspections to ensure compliance require significant staff time.
- Many permitting programs are conducted under the auspices of State or regional EPA programs. Local and municipal jurisdictions and watershed advisory bodies may have difficulty in obtaining permit

Case Study: Newport, R.G. and T.E. Davenport. 1988
Stormwater Nonpoint Source Pollution Control
American Water Resources Association Technical Publication Series. TPS 88-4, p 183-193, 1988

The Rouge Basin in Southeast Michigan is a significant example of a situation where stormwater is contributing to use impairment. To address urban stormwater problems, EPA and State pollution control agencies will issue discharge permits to the owner/operators of stormwater collection and conveyance systems and related outfalls. These permits will require data collection and reporting, and the development and implementation of pollution reduction programs. In some cases, these programs will require capital improvements, but in many instances, the cost-effective approach for solving the problems will be BMPs. These BMPs will reduce the introduction of pollutants to the storm sewer through management of nonpoint source (NPS) pollution. Requiring nonpoint source control components as part of stormwater permits will ensure (1) that the permits address all pollutants originating from nonpoint sources; (2) that the BMPs required under the permits will economically control the identified pollutants; and , (3) that the NPS control activities identified will be fully implemented.

Method References:

Environmental Indicator Profile Sheet

Indicator Profile No. 24

Growth and Development

Category: **Programmatic**

Tools Used to Measure Indicator:

- GIS Systems, land use mapping
- Other physical, biological or chemical monitoring techniques.

Description:

As development in a watershed grows, imperviousness increases and the aquatic system is generally subjected to greater stress. This stress may include higher NPS pollutant loadings and increased stormwater runoff flows. Erosion within the stream system increases as the stream downcuts and widens to adjust to the new flow regime.

The relative health of a given system as measured through ecological impacts to the aquatic community (i.e., water quality, physical habitat, and biological diversity and health) can be correlated with the impervious percentage of the watershed. Zoning patterns in a watershed can be used to estimate existing and potential watershed imperviousness based on land use-imperviousness relationships.

The potential for continuing urbanization (and thus increased watershed imperviousness) can be tracked through review of building permits, environmental impact statements, and changes in population. Increases in the numbers of building permits issued and environmental impact statements completed and increased population are indicative of continuing urbanization.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to evaluate existing and potential impacts to aquatic systems. Imperviousness can predict aquatic health degradation thresholds.
- Can be used to evaluate the effectiveness of BMPs in extending development thresholds (e.g., increasing impervious area limits without increasing aquatic health degradation).
- Can be used as a planning tool in making zoning and master planning decisions.

Cost

See Table 3.3E

Advantages of Method:

- Easily measured using land use mapping or GIS technology.
- Easily understood by policy decision makers and politicians.
- Inexpensive to measure and report (however, development of a detailed GIS can be very expensive).
- Can provide a uniform method for measurement and assessment.
- Provides a comprehensive measure of the cumulative impact of land development on subwatersheds.
- Many of the indicator parameters are already tracked by local jurisdictions.

Disadvantages of Method:

- Measurement and use of growth indicators is not yet standardized.
- Assessment of stream quality has not been statistically correlated with impervious area.
- Does not precisely measure imperviousness, but rather estimates relative increases in imperviousness.
- Zoning changes, environmental impact statements, and building permits represent probable (not definite) changes in imperviousness.
- Does not take into account that development can increase without increasing aquatic health degradation.

Case Study: Booth, D.B.; L.E. Reinelt, 1994

Consequences of Urbanization on Aquatic Systems - Measured Effects, Degradation Thresholds, and Corrective Strategies

Pawlukiewicz, J.; et. al., (eds.). 1994. Watershed '93: A National Conference on Watershed Management, USEPA 840-R-94-002

Several watersheds in King County, Washington were evaluated to assess the effect of urbanization on stream and wetland system health. Watershed imperviousness was used as the unit of measure of urbanization. Stream structure (bankfull width, depth and fluctuations in water level) and biological function (species and population counts and rapid field assessments of habitat quality) were evaluated. Results indicated that aquatic system function (as measured by fish populations) was indirectly proportional to watershed impervious area. While there was no distinct threshold where population densities dropped, there was a measurable effect at reasonably low levels of imperviousness (10 - 15%). Habitat degradation was measured in terms of "degraded, good or excellent". There was marked degradation at imperviousness between 8 and 10%. Change in physical structure with increasing imperviousness was also measured. For example, stable channels, with little or no erosion, and unstable channels, where long continuous reaches of bare and eroding banks occur, were evaluated as impervious area increases. At impervious area percentages above 10%, stream channel instability is dominant.

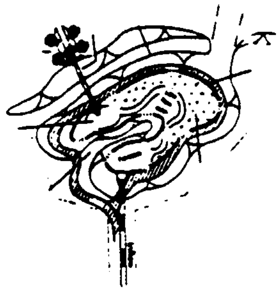
Environmental Indicator Profile Sheet



Indicator Profile No. 25

BMP Performance Monitoring

Category: **Site Indicators**

Tools Used to Measure Indicator:

- Biological Monitoring
- Chemical Monitoring
- Physical Monitoring

Description:

Stormwater BMPs are specifically designed to reduce pollutant loadings into natural water bodies. The evaluation of BMP performance can provide stormwater program managers with a more accurate assessment of pollutant removal capability.

BMP effectiveness is evaluated based on stormwater sampling of the mass and concentration of pollutants into and out of the facility. Alternatively, biological and/or physical indicators can be evaluated upstream and downstream of a facility to aid in assessing effectiveness of a specific practice or series of practices.

Controls are measured relative to design, cost, and other similar factors. Secondary characteristics which may be evaluated include habitat provisions, safety, aesthetics, groundwater recharge, and recreational opportunities.

Utility of Indicator to Assess Stormwater Impacts:

- By comparing BMP performance data, stormwater managers may be able to select BMPs that provide the best pollutant removal effectiveness in the most cost-effective manner.
- Comparison of temporal data can be used to determine the need for BMP maintenance.
- Can be used in conjuction with biological and physical/hydrological indicators, to get a more accurate representation of the total aquatic community condition.
- Can be used to identify those BMPs which are not meeting pollutant removal expectations.
- Can be used as a basis to create, update, and enforce minimum design standards to meet target pollutant removal expectations.

Cost

See Table 3.3F

Advantages of Method:

- Since BMPs are specifically designed to provide a particular level of performance, it is relatively easy to determine whether their functions are being achieved.
- Educational programs can be developed to involve private organizations in data collection. Such programs may serve to educate the public about BMP usage, performance, and maintenance needs.
- Increased performance monitoring increases the likelihood that BMPs will be properly maintained.

Disadvantages of Method:

- There is little standardization in place for reporting BMP performance, resulting in a wide range of effectiveness being reported.
- Many watershed managers choose BMPs based on cost, with design performance a secondary consideration. As a result, even if a BMP performs according to design, it still may not adequately protect receiving water quality.
- Extensive monitoring is required to gain sufficient understanding of BMP effectiveness.
- A large number of paired samples must be collected to establish performance.
- Method requires extensive data interpretation and management.
- The performance of a monitored BMP may reflect site specific or watershed specific conditions, and may not always be generalized.

Case Study: Martin, E.H. 1988

Effectiveness of an Urban Runoff Detention Pond-Wetlands System

Journal of Environmental Engineering, 114(4): 810-827. August 1988.

An urban detention system, composed of a detention pond and wetlands in series (approximately 800 and 3000m^2, respectively), was analyzed to determine its effectiveness in reducing stormwater runoff constituent loads. The pond inlet, pond outlet/wetlands inlet, and wetlands outlet were monitored during eleven storm events. Samples were analyzed for concentrations of major ions, selected chemical and physical characteristics, metals, and nutrients. The system's efficiency was determined using three quantifying methods: event mean concentration, summation of loads, and regression of loads. For most pollutants, the three methods yielded similar results.

The detention pond was generally effective in removing 42-66% of suspended solids and suspended metals. Nutrient removal efficiencies were more variable due to changes in species and phase during transport through the pond.

The wetlands were effective in reducing both suspended and dissolved loads of solids and metals. Removal efficiencies for total nitrogen and phosphorus were 21 and 17%, respectively.

The full system, combining the pond and wetlands treatment, achieved appreciable reductions of most pollutants. The system was particularly effective in reducing solids, lead, and zinc, with efficiencies ranging between 55 and 83%. Total nitrogen and phosphorus efficiencies were somewhat lower: 36 and 43%, respectively.

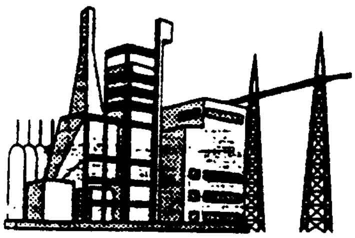
Environmental Indicator Profile Sheet



Indicator Profile No. 26

Industrial Site Compliance Monitoring

Category: **Site Indicators**

Tools Used to Measure Indicator:

- Visual inspections

Description:
NPDES permitting now requires most industrial sites to develop and implement pollution prevention plans and implementation of on-site best management practices. Compliance monitoring is conducted by either industry representatives, regulatory officials or certified inspectors. Monitoring may include pollutant constituent monitoring, as part of a permit condition, or visual inspections to check compliance with the approved and adopted pollution prevention plan.

While pollutant constituent data and compliance with pollution prevention plans documenting the success or failure of a program can be extremely useful, water quality managers may consider other information in assessing management efforts. Examples include: number of staff hours devoted to monitoring, public outreach efforts, pollution prevention training for employees, and documentation of pollution prevention teams.

Utility of Indicator to Assess Stormwater Impacts:

- Can be used to help evaluate the performance of structural and non-structural stormwater BMPs.
- Can help assess the contribution of industry to overall water quality degradation or improvement.
- Can induce public education, support and activism.
- Can solicit political pressure and support regarding planning issues.
- Can be used to determine industrial stormwater management needs, evaluate water quality trends, and target restoration efforts.
- Can help identify areas where technical support or research are needed to help address problems.

Cost

See Table 3.3F

R0016727

Advantages of Method:

- Because the land areas involved are often small, few sampling stations are necessary.
- Several sites may combine efforts in the same area, resulting in the efficient use of monitoring resources.
- Several like industries may combine efforts, across a broad geographic area, to maximize efficiency of resources.
- Pollution reductions may show a correlation with various industrial efforts, enhancing the chances that runoff problems can be solved with relative ease.
- Can contribute significant understanding to pollutant source area problems.

Disadvantages of Method:

- Overall watershed health may be difficult to assess by this method.
- Industrial sites may be reluctant to employ the method for reasons such as cost, time, and concern about regulatory consequences resulting from data revelations.
- NPDES sampling requirements, to date, have not been stringently enforced by permitting agencies and quality assurance/quality control concerns may pose a problem for future compliance monitoring.
- The results and impacts of many techniques may be difficult to assess (e.g., BMPs, pollution prevention, public outreach), and may be a disincentive for industrial site managers to implement them.
- Very few industrial sites have streams, lakes or estuaries on-site.

Case Study: Settine, R.L.; K Burchfield. 1983
Sampling and Analysis of Industrial Benthic Polynuclear Aromatic Hydrocarbons in Industrialized Urban Watersheds. Completion Rept. 1 Oct 82 - 31 Mar 83.

A method is reported for the sampling and analysis that accurately describes the contour and distribution of benthic polynuclear aromatic hydrocarbons of Opossum Creek. The analytical methodology consisted of using fused silica capillary chromatography coupled with selected ion mass spectrometry to identify and quantify areas of high concentration of specific benthic compounds. It is apparent from the 'grid technique' herein reported that this model can be applied for future stream system analysis and would be an extremely reliable aid for engineering decisions with regard to cleanup.

CHAPTER IV CRAFTING AN INDICATOR MONITORING PROGRAM - A METHODOLOGY

Historically, stormwater monitoring programs were often "cookbook" efforts, regulatory-driven, and focused almost exclusively on end-of-pipe water chemistry. Although the data collected through such efforts could be used to determine baseline conditions, the monitoring results were generally unsuited for assessment of long-term stormwater management success. On the other hand, monitoring programs which incorporate stormwater indicators can be specifically tailored to address the information needs of individual municipalities and industrial sites. When selected correctly, stormwater indicators can assess the long-term effectiveness of stormwater management programs as well as provide the baseline data.

Stormwater indicator monitoring programs are based on specific data requirements, management goals, and resource constraints as determined by individual stormwater management authorities. Therefore, monitoring parameters and indicators will vary from municipality to municipality and from industrial site to industrial site. However, a common methodology can be used to develop stormwater indicator monitoring programs. This methodology is based on the general considerations which are common to all monitoring efforts.

- What is the overall purpose of the monitoring program? Is the purpose to assess baseline conditions, assess the effectiveness of the stormwater management program, or both?
- What resources are available? Is there historical data; complementary or conflicting efforts; sufficient staff, funding, and political support?
- Does the stormwater monitoring program have the ability to adequately assess the success of the stormwater management effort?

A comprehensive two-phase methodology (or protocol) for crafting a stormwater indicator monitoring program is outlined in Figures 4.1 and 4.2. The two phases correspond to the two over-riding purposes for stormwater monitoring: Level 1, Problem Identification and Level 2, Assessment of Management Program. Municipalities and industrial sites with limited or no data available for characterization of baseline conditions will most likely begin at Level 1. When baseline conditions are known, a Level 2 monitoring program should be implemented.

This methodology is presented as a flexible, dynamic tool for development of an effective stormwater indicator monitoring program. Stormwater management officials do not have to begin with Step 1 of Level 1. Instead, stormwater managers are encouraged to review the methodology and determine which level most accurately represents their monitoring needs. Furthermore, because this assessment is an ongoing task, stormwater managers should frequently review their monitoring program. An effective stormwater indicator monitoring program will address current data requirements and provide an adequate basis for a long-term assessment of the management program.

FIGURE 4.1
STORMWATER INDICATOR METHODOLOGY
LEVEL I, PROBLEM IDENTIFICATION

① ESTABLISH MANAGEMENT SPHERE

Who will be responsible for implementation? A government agency (municipality, county, or state) or a site-specific industry? What other programs are being implemented within the watershed? Can this program be developed and implemented on a watershed-wide or basin basis?

⇓

② GATHER/REVIEW HISTORICAL DATA

Identify what programs and studies have already been implemented in the watershed.
Determine what problems associated with stormwater have already been identified.
Assess the effectiveness of earlier efforts and programs.

⇓

③ IDENTIFY POTENTIAL RECEIVING WATER IMPACTS

Identify uses and characteristics which may be impacted by stormwater runoff.

Hydrology and Hydrodynamics (Flooding, Drainage)
Biological Integrity (Fish Diversity, Macro. Community)
Non-contact Recreation (Sports Fishing)
Supply (Potable Water)
Contact Recreation (Swimming)
Aqua-culture (Shellfish Harvesting, Food Fishing)

⇓

④ INVENTORY RESOURCES AND IDENTIFY CONSTRAINTS

Determine manpower and funding limitations.
Identify regulatory-mandated deadlines and programs.

Staffing
Scheduling Constraints
Funding
Regulatory Compliance

⇓

⑤ ASSESS BASELINE CONDITIONS

Use rapid (qualitative) assessment methods versus detailed quantitative techniques to assess baseline conditions.

Indicator Options by Receiving Water Use

Concern:	Hydrology & Hydrodynamics	Biological Integrity	Non-contact Recreation	Water Supply	Contact Recreation	Aqua-culture
Type of Indicator to be Considered:	*Physical Social Programmatic Site*	*Biological Water Quality Social Programmatic Site*	*Water Quality Physical Biological Social Programmatic Site*	*Water Quality Biological Social Programmatic Site*	*Biological Water Quality Physical Social Programmatic Site*	*Biological Water Quality Physical Social Programmatic Site*

FIGURE 4.2
STORMWATER INDICATOR METHODOLOGY
LEVEL II, ASSESSMENT OF MANAGEMENT PROGRAM

① STATE GOALS FOR PROGRAM

Based on baseline conditions, resources, and constraints, articulate goals for stormwater management program in terms of measurable achievements.

Example: We want to increase level and diversity of the fish population in the next 5 years.
To accomplish this, we must improve biological integrity, water quality, and physical conditions.

⇓

② INVENTORY PRIOR AND ONGOING EFFORTS

Identify prior stormwater management efforts and assess success of prior efforts.
Identify current stormwater management efforts both within the municipal boundaries and the larger watershed.
Assess success of ongoing efforts.
Incorporate complementary programs and goals.
Identify potential conflicts.

⇓

③ DEVELOP AND IMPLEMENT MANAGEMENT PROGRAM

Identify and implement specific program facets in order to achieve goal.

Example: In order to increase the fish population, we will retrofit BMPs, require stormwater BMPs all new development, remove fish barriers, and re-introduce some aquatic species.

⇓

④ DEVELOP AND IMPLEMENT MONITORING PROGRAM

Based on goals, program structure, resources and constraints, select indicators to be used to assess success of stormwater management program. Level II indicators will likely be more quantitative in comparison to Level I techniques. Quantitative analysis is required to identify pollutant sources and assess success of program.

Example: macro-invertebrate assemblage, fish assemblage, public opinion surveys, toxicity testing.

⇓

⑤ ASSESS INDICATOR RESULTS

Analyze indicator monitoring results.

What do the monitoring results indicate about the success of the stormwater management program?
Have the indicators accurately reflected the effectiveness of the management program?
What do the indicators suggest about the ability of the stormwater indicator monitoring program to measure of overall watershed health?

⇓

⑥ RE-EVALUATE MANAGEMENT PROGRAM

Re-evaluate resources and constraints.
Update (if necessary) assessment of baseline conditions.
Review and revise program goals.
Review and revise indicator monitoring program.
Implement revised management program.

CHAPTER V THREE SCENARIOS FOR INDICATOR USE

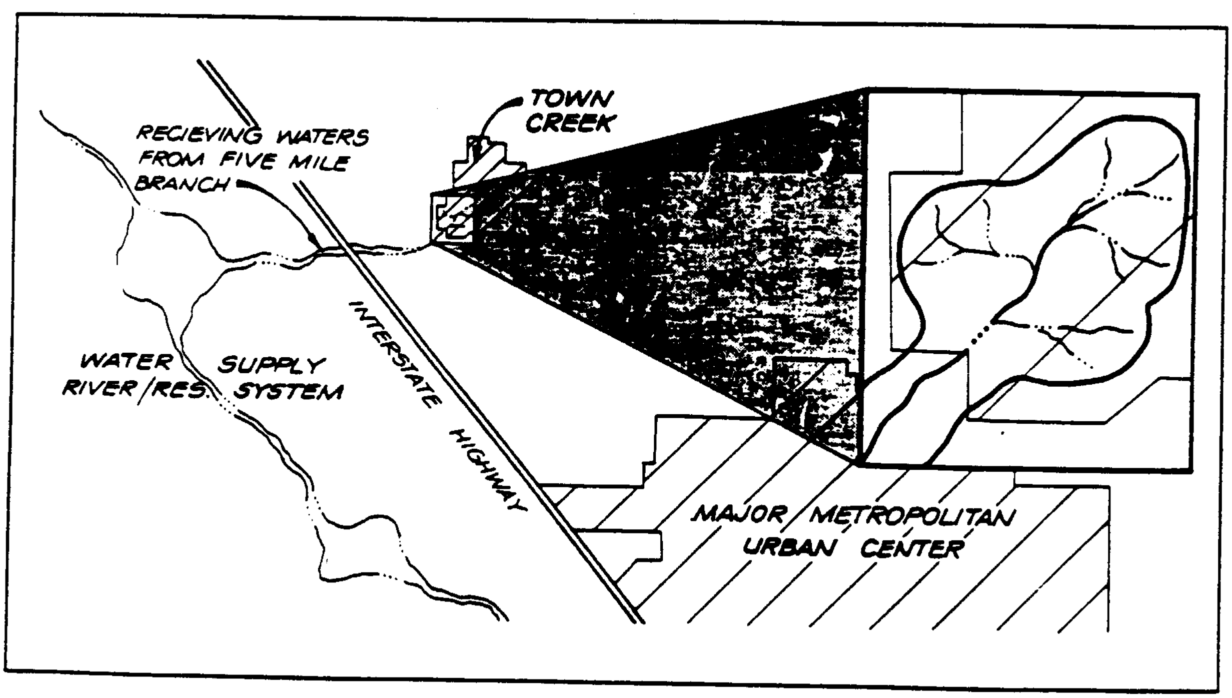
Three theoretical scenarios are described to illustrate the potential application of stormwater indicators in real world situations. The three scenarios are imaginary case studies, but are based on actual locations and conditions. Some of the baseline facts have been modified to more fully illustrate the utility of stormwater indicators as assessment tools for stormwater management program evaluation. The locations and scenarios were selected to represent different regions of the country and to test application of the indicators to different resource management situations.

The first scenario is an example of using both the Level I and Level II methodologies discussed in Chapter IV; the second scenario primarily focuses on Level II methodology; and the third scenario is intended to present a simplified Level I and Level II methodology for a small industrial park site.

SCENARIO I - MODERATELY SIZED MUNICIPALITY - EXPERIENCING RAPID GROWTH

Five Mile Branch is a third order stream located in the Southern Piedmont region of the United States. The entire five-square mile Five Mile Branch Watershed lies within the medium-sized municipality of Town Creek. Town Creek is a rapidly growing, moderately sized town with a population of approximately 40,000 and is located 15 miles from an adjacent major urban center (Figure 5.1). A majority of the town citizenry seeks to protect the natural integrity of Five Mile Branch and its tributaries, while encouraging an atmosphere of sustainable development. The Five Mile Branch Watershed lies exclusively within the town boundaries and drains to a drinking water-supply river/reservoir system which serves the adjacent large metropolitan area. As part of

FIGURE 5.1 LOCATION AND CONTEXT OF TOWN CREEK AND FIVE MILE BRANCH



a state-initiated effort to protect source areas for drinking water-supply, the Town is being encouraged to prepare a watershed management plan to help reduce stormwater-borne pollutant loads to the receiving waters. A two year period is being allocated to develop and begin implementation of the watershed stormwater management plan. Every five to seven years the watershed stormwater management plan is reviewed and modified as necessary to reflect current and anticipated future conditions.

Responsible Party Identification

One of the first recommended elements of preparing a watershed management plan is to identify the parties with authority to conduct and implement the plan. Since the Five Mile Branch Watershed falls completely within the boundaries of Town Creek, the Town will have complete authority to develop and implement the plan. The Town is the recipient of a $200,000 grant from the State, covering a two year period, to study the implementation of source controls within the watershed. The Town Creek Council has allocated an additional budget of $150,000 ($75,000 per year) to prepare and begin implementation of the Five Mile Branch Watershed management plan.

Portions of the Town drain to receiving waters outside its limits (outside of the Five Mile Branch Watershed). Even though these areas are not part of the Five Mile Branch Watershed management plan, they are under the town's overall management authority. A cooperative agreement, in the form of a Regional Water Quality Authority, between the region's municipalities and the State has been set up to coordinate watershed management efforts. The Town is a member of the Regional Water Quality Authority and contributes an annual fee to belong to the organization. In return, the organization provides technical staff and expertise for watershed and land use planning, enforces regionally adopted land use plans, and provides inter-local coordination for watershed management issues. The Five Mile Branch Watershed Management Plan is being prepared in compliance with the land use guidelines and recommendations of the Regional Water Quality Authority.

Previously Collected Data

A comprehensive flood plain and flood management study was completed for the watershed within the last 10 years. This effort produced the original data-set of land use and topography, which is used to establish baseline conditions for the current work effort. The flood management report documented flood prone areas, identified potential flood control structures, and established a 100 year floodplain limit. Water quality analyses or impact assessments to the aquatic environment were not addressed in this report.

Although very little water quality data has been previously collected within the watershed, two separate studies have yielded some baseline information. First, as part of the State's 305(b) reporting and drinking water-supply source protection strategy, several chemical and some physical parameters were monitored at three locations in the watershed over a five year period. Grab samples were collected three times a year during both wet weather and dry weather periods. The monitoring data appears to indicate that in general, dry weather water quality is exceptionally good at the locations tested. Furthermore, only moderately high levels of TSS were present in three of five storm events sampled.

R0016733

An additional set of data was recently collected by a citizen's stream stewardship organization, consisting of two years of data, collected at two separate locations, two times per year. This information consisted of biological monitoring data, using macro-invertebrates (identified to family level only) as an indicator species. The results indicate that at least one location, located downstream from an older large-lot residential area, appears to have a reasonably healthy biotic community. The biological community at the second location, located downstream from a regional shopping mall, shows indications of a moderately degraded system.

Receiving Water Uses and Targeted Protection Areas

Five Mile Branch drains to a larger river/reservoir system which serves as a drinking water-supply to the adjacent large municipality. The control of nutrients, particularly phosphorous, is of primary concern to water-supply managers. In addition, a rare darter species has been found in the drainage basin, downstream of the Five Mile Branch basin. This rare darter species is considered a warm water fish and requires clean water and a sandy/gravely substrate for reproduction. The darter has been known to use the lower Five Mile Branch as refuge during the hot summer months of July and August. Over 10 miles of headwater streams (first and second order) flow through the Five Mile Branch Basin. The protection of these small streams from the impacts of urbanization, particularly with respect to controlling erosion and other physical disturbances, are of primary concern to many citizens of Town Creek.

Town Creek Staff and Fiscal Resources

Town Creek has several full-time employees within the Department of Public Works (DPW), Division of Water Resources (DWR). Only one staff member has been assigned to the project with the understanding that the work effort will require approximately 50% of her time.

As discussed above, Town Creek has a annual budget of $175,000 for two years to prepare the watershed management plan, begin partial implementation of the plan, and provide one year of monitoring. The Town has retained an outside consultant to conduct baseline monitoring, assist in identification of program goals, develop implementation management strategies, prepare a long-term monitoring plan, and conduct monitoring to assess management efforts after the first year of implementation. The Town staff person is responsible for managing the consultant's contract. including contract management; helping the consultant with presentations to the Town Council; and providing input and reviews for issues related to Town goals, prioritizing Town citizen concerns, or providing direction in allocating future Town resources.

Assessment of Baseline Conditions in Five Mile Branch Watershed

Since the primary objectives of the watershed management plan are to identity and control non-point source pollutants and protect the streams within Five Mile Branch Watershed, the following indicators are used to identify problems areas:

- Growth and development (Profile No. 24) is evaluated for all existing development and projected for all future development within the whole watershed.
- Biological monitoring (Profile No. 12 & No. 13) is conducted for the Five Mile Branch mainstem and tributaries for a total of 10 stations (Fish assemblage and macro-invertebrate assemblage).

- Physical assessments (Profile No. 7 & No. 8) are conducted for the mainstem and tributaries for a total stream length of approximately 3.5 miles (stream widening/downcutting, and habitat monitoring).
- Water quality monitoring (Profile No. 1) is conducted at one station at the confluence with the receiving water body (pollutant constituent monitoring of phosphorus, dissolved oxygen, TSS, and fecal coliform).
- Public attitudes (Profile No. 17) are surveyed once within a portion of the watershed.

The timetable to collect and assemble the baseline information is limited to one year. Growth and development is assessed over a two month period. Biological and physical assessments are conducted two times per year (in the spring and fall) and compared against a reference condition from a nearby watershed. Water quality monitoring is conducted for three storm events, using manually collected grab samples and a flume to establish the stage-discharge relationship. The public attitude survey is conducted within a portion of the watershed containing a mix of commercial, light industrial, and residential land uses, for a population of approximately 3,500 people.

Using the Town's already established geographic information system (GIS), existing development is measured in terms of impervious area. Based on current zoning, the ultimate impervious area is estimated and mapped. This effort yields valuable information on areas of the watershed which are at risk of degradation due to proposed levels of imperviousness.

Biological monitoring of the streams yielded the following results:

- The undeveloped areas are almost pristine, with a high abundance of species and high diversity.
- The residential land uses show moderate stream channel erosion, fair to poor aquatic habitat, and a moderately impacted aquatic community.
- The commercial/light industrial land uses show moderate to severe channel alterations, and a degraded aquatic biological community.
- The newly developed areas (constructed with BMPs) show light to moderate channel alterations and a moderately impacted aquatic community

The water quality pollutant constituent monitoring results indicate moderate nutrient levels, low fecal coliform levels and very low TSS levels for two of the three storm events. Data for one winter storm showed elevated TSS following several days of above average rainfall.

The public attitude survey results indicate that a majority of citizens are concerned with growth- related impacts to streams; consider water quality and biological integrity to be important; are willing to support moderate management efforts with money from the town's General Fund, realizing that other services may be slightly compromised; and are unwilling to increase taxes or pay user fees to provide for substantial protection of water resources.

The cost to conduct the baseline monitoring efforts discussed above, compile the results, and prepare a summary report is approximately $116,000. This figure includes the consultant fee plus the proportionate salary and overhead costs of the town staff person. Therefore approximately $234,000 is available to complete the management plan report, institute some implementation measures, and conduct one year of post-implementation monitoring.

Watershed Management Plan - Implementation Program

Identification of Watershed Management Goals for Five Mile Branch

Based on the results of the baseline monitoring, the consultant, town staff and Town Creek Council have developed the following realistic goals as strategic elements of the watershed management plan.

- Protect, to the maximum extent possible, pristine streams in undeveloped areas by limiting development in those areas where the highest quality streams systems exist, instituting extensive and redundant BMP controls in areas already slated for development, and instituting land development techniques which minimize impervious area and maximize stream protection.
- Improve stream habitat and biological diversity for already degraded streams.
- Reduce nutrient and sediment loadings in receiving waters.
- Maintain or increase the habitat and population of the sensitive darter species within the lower reaches of Five Mile Branch.

Prioritize Goals for Implementation Strategy

The consultant, town staff and Town Council in conjunction with the general public (through a series of pubic meetings) have developed the follow priority for implementation of management strategies. This hierarchy will form the basis for allocating limited resources for implementation of management measures over the next several years.

1. Protection of most pristine resources
2. Increased protection for other undeveloped lands
3. Nutrient and sediment reduction to receiving water body
4. Protection of rare darter species
5. Enhancement of degraded streams

Implementation of Management Strategies

The implementation plan being developed by the consultant reflects the priority of achievable goals. The list of specific management measures include:

- Revisions to land use plans and zoning modifications to limit growth within the most pristine areas (may require innovative strategies, such as overlay zoning, transfer of development rights, conservation easements, etc.).
- Revisions to subdivision codes and stormwater management ordinance to require/encourage additional site planning techniques to reduce impervious areas and require more stringent BMPs for stream protection in developing areas.
- Public education and outreach program for nutrient reduction; investigate retrofit opportunities for existing residential areas.
- Revisions to erosion/sediment control regulations for areas draining directly to darter habitat to require additional redundant practices; additional inspections of construction sites for these areas; provide increased buffer requirements through the subdivision process for lower reaches of Five Mile Branch; provide instream habitat improvement projects for lower Five Mile Branch.

- Investigate retrofit opportunities upstream of degraded stream reach lengths; provide instream habitat enhancement and channel stabilization projects; replace or augment riparian cover along stream banks and buffers.

These measures will certainly not be implemented overnight; they require time and a change in public opinion to be fully implemented. Whether the management measures work or not is tested through post- implementation monitoring and assessment of results. A re-evaluation of these management strategies is likely as time passes.

As part of the consultant's scope of services, a management plan report is prepared which includes: a summary of baseline conditions, the goals and implementation strategy priority, a cost estimate, and a timetable for implementation of the management measures. The cost estimate is assessed on an annual basis with capitalization costs identified up front. The Town Creek Council reviews the cost analysis and determines whether sufficient funding is available within the General Fund to pursue implementation. Based on the current financial projections, only the last element (restoration of degraded streams) is likely to be beyond the budgetary means of the town. However, since this element has been prioritized as the last component of implementation, it is retained in the plan as a longer term goal when adequate funding is available.

It is projected that the town will expend approximately $135,000 to implement the first four elements of the management strategy in the first year of the plan. Therefore, approximately $99,000 will remain to conduct assessment monitoring and compile a summary report of results.

Monitoring Program Development Strategy and Assessment of Results

An indicator monitoring program will be used to assess the success of the management strategies. The consultant develops the monitoring program to directly measure the effects of management measures on the targeted resources with respect to protection and/or restoration. The following list of indicators is presented to the town staff and Council for review and approval:

- Biological and physical/hydrological indicators are proposed in areas experiencing growth to evaluate the effects of more stringent stormwater management controls and site planning techniques. These indicators are structured as a paired subwatershed analysis with one area being developed without modified stormwater and site planning controls and the other area being developed with the more stringent stormwater regulation and enhanced site planning techniques (Profile Nos 7, 8, 12, and 13).
- Water quality assessment at one station at the confluence with the receiving water body (pollutant constituent monitoring of phosphorus, dissolved oxygen, TSS, and fecal coliform - Profile No. 1)
- Public attitude survey of citizens within the watershed to evaluate the public's perception of how well management practices are working and to determine whether additional funding would be supported by the general populace (Profile No. 17).

The results of the first year of monitoring are compared directly with the management strategies to assess the effectiveness of the program. However, because nearly all of the management strategies will take several years to fully implement, several years of monitoring data will be required to completely assess the effectiveness of the program. A 5-year duration is recommended for re-assessment of the watershed management plan. As monitoring data is compiled over this 5-year period, sufficient data will emerge to enable assessment. At this end of the 5-year period, a re-evaluation of resource protection goals, management strategies, and implementation priority should be conducted.

SCENARIO 2 OLDER INDUSTRIAL MUNICIPALITY - RESOURCE RESTORATION

The Town of Kelsey, an older industrial city, is developing a stormwater management program in compliance with NPDES regulations for medium-sized municipalities (current population is approximately 150,000). The Town lies on the shore of Hannah Bay, a shallow embayment to one of the Great Lakes (Figure 5.2). Most of the 25 square mile Bay watershed lies within city boundaries. The Town of Kelsey's stormwater management program will focus on the portion of the watershed within Town boundaries, including seven miles of stream which drain to Hannah Bay.

Within the Town, there is significant older residential development and some light industrial and commercial areas. Industrial and commercial development is also concentrated along the Bay waterfront. The area surrounding the Town of Kelsey is mostly agricultural, although there is some low density residential development.

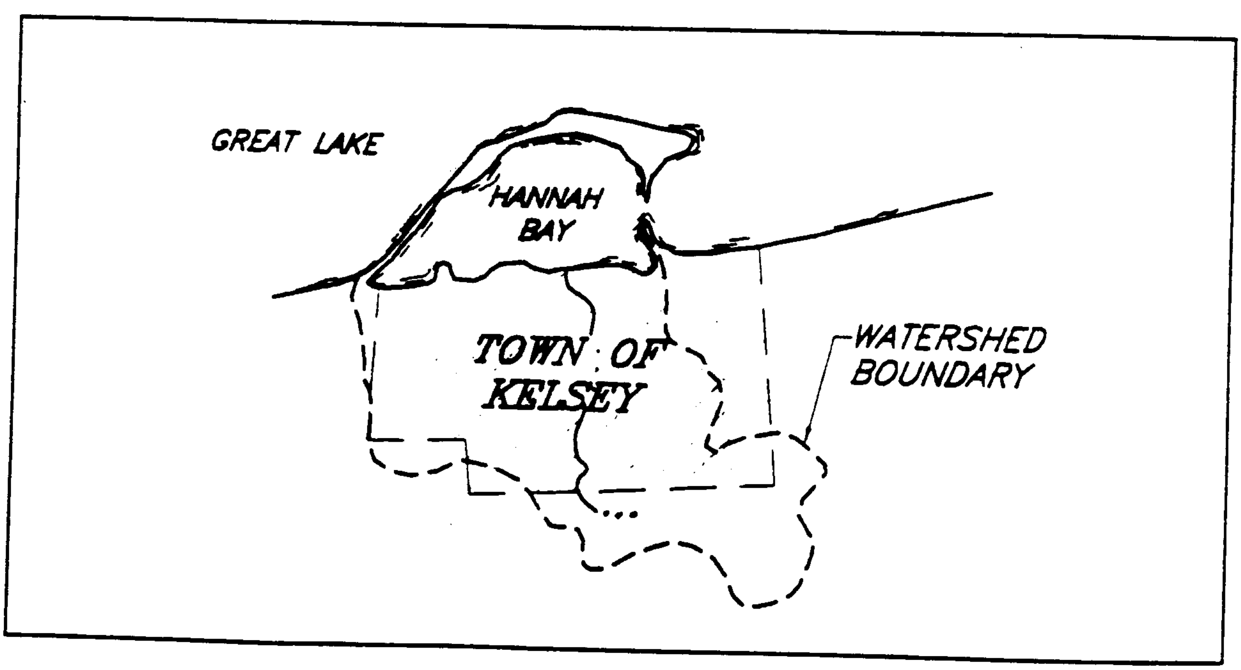
Almost all of Hannah Bay watershed is sewered and serviced by a wastewater treatment plant which discharges outside the Bay. The storm sewerage system contains both separate and combined sewers. Hannah Bay has designated water uses including warm water fisheries, potable water supply, and contact recreation (i.e., boating, fishing, and swimming).

The Town of Kelsey has completed NPDES Phase I stormwater monitoring. (NPDES regulations are enforced and regulated by the State.) The State has implemented a vigorous point source control program, but has not established stormwater quality standards.

Program Objectives and Prior Efforts

The Town of Kelsey's stormwater management program will complement the Hannah Bay Remedial Action Plan (RAP). The RAP outlines strategies to restore and protect aquatic resources in the Hannah Bay watershed. The RAP was developed by the State in conjunction with EPA, the

FIGURE 5.2 THE TOWN OF KELSEY



R0016738

International Joint Commission, and the Town of Kelsey and is based on guidance provided by the Great Lakes Water Quality Board.

Included in the RAP is a review of historical and current water quality data. Degraded water quality conditions have been reported since the 1970's. Problems include algal blooms, dissolved oxygen depletion, fish kills, malodorous conditions, reduced clarity, excessive growths of aquatic macrophytes, and high fecal coliform. Warm water fisheries have been impaired by polycyclic aromatic hydrocarbons (PAHs) and algal blooms. Contact recreation has been impacted by high fecal coliform concentrations. In addition, sediment dredging is restricted due to high heavy metals, nutrient, oil and grease, volatiles, and PAH concentrations. The most significant sources of these pollution problems are nonpoint source pollution from urban runoff and combined sewer overflows (CSOs).

The Town of Kelsey has two objectives for its stormwater management program: (1) protection of Hannah Bay fisheries and (2) minimization of impacts affecting recreational use of Hannah Bay.

Responsible Parties and Resources

The Town of Kelsey does not have the staff nor monetary resources needed to implement a full-scale stormwater management program. Growth in the Town is stagnant, and many factories have closed. Furthermore, there is little citizen support for allocating funds towards this effort. The Town has allocated $50,000 for stormwater management during this year. The stormwater management program will be implemented by the Town's Public Works Department which has assigned (part-time) one engineer and one technician to the stormwater effort.

The Town has entered into a partnership with the State and a nearby land grant university. The State has supplied a twelve-month, $150,000 grant and will provide technical support. Additional staff resources and technical support (including computers and research documents) will be provided by the university. Finally, because CSOs have been identified as a significant pollution source, the wastewater treatment plant authority has also been identified as a potential source of support.

Management Program

In a series of meetings with the State, the WWTP authority, and the university, the Town of Kelsey outlined a five task stormwater management program which includes:

- Task 1, Industrial Runoff Control;
- Task 2, Residential Runoff Control;
- Task 3, CSO Reduction;
- Task 4, Habitat and Water Quality Assessment; and
- Task 5, Public Involvement.

Task 1, Industrial Runoff Control

The focus of this effort is reduction of the toxicity and volume of runoff from industrial facilities. The Town, with assistance from the State, will ensure that all industrial facilities within the Town of Kelsey and subject to NPDES stormwater regulations have applied for, or are operating under, a valid NPDES stormwater permit. The Town will also work with the State to develop stormwater runoff guidelines; identify pollution prevention techniques (e.g., no exposure, good housekeeping); and identify feasible pre-treatment and structural BMP options for industrial facilities. In conjunction with the WWTP authority, the Town will investigate possible diversions of runoff from industrial facilities to the treatment plant. Because there are a significant number of boating support and marina operations along the Hannah Bay waterfront, the Town will focus much of its NPDES compliance efforts on these facilities.

Task 2, Residential Runoff Control

The purpose of this task is to reduce the toxicity of runoff from residential areas. The Town will establish a household hazardous waste collection/recycling center, possibly in conjunction with local industries. The Town and the university will develop and conduct lawn care seminars to train homeowners in proper lawn care procedures including mowing regimes, types and amounts of products, and application procedures. Finally, a storm drain stenciling program will be started, possibly with the assistance of local Girl and Boy Scout Troops.

Task 3, CSO Reduction

This is a planning-level effort. This task will focus on identification of options for increasing sewer capacity, re-routing overflows, and/or providing treatment for the overflows (in cooperation with the WWTP authority). The relative cost of the various options will be determined. Potential funding options, including user fees, stormwater utility, and increased taxes, will also investigated. The Town will enlist the expertise of the WWTP authority. The university and State will be responsible for identifying reduction options and funding opportunities.

Task 4, Habitat and Water Quality Assessment

Shale sediment from eroding stream channels has been identified as a significant factor with respect to water quality problems in Hannah Bay. It has been speculated that the fine shale sediment encourages precipitation of pollutants in the water column. Prior to consideration and construction of streambank protection measures, the Town will assess current physical habitat and water quality conditions in the stream system. The focus of this effort is 3.5-mile Tate Creek, the largest tributary to Hannah Bay, which flows through a highly developed subwatershed. The assessment will be conducted in conjunction with the university and citizen monitoring groups.

Task 5, Public Involvement

Public involvement efforts are included in Task 2 (storm drain stenciling) and Task 4 (citizen monitoring). In addition, the Town and the university will develop and implement a series of seminars designed to educate the public regarding stormwater runoff, its environmental impacts, and management options. One of the primary purposes of this effort is to garner public support for current and future funding of the stormwater management effort.

Monitoring Program

The success (or failure) of the Town of Kelsey's stormwater management program will be assessed within a long-term (i.e., 5 years or more) framework. Most of the management program is in the planning phase. Full implementation of structural BMPs, pollution prevention measures, and storm sewer modifications may not be achieved for many years. Some measures may be eliminated from consideration based on the results of the CSO reduction and habitat and water quality assessment efforts.

The Town of Kelsey monitoring program will focus on anticipated long-term benefits and is designed to assess the five management program tasks. Indicators included in the monitoring program include water quality pollutant constituent monitoring (Indicator No. 1), human health criteria (No. 6), physical habitat monitoring (No. 8), fish assemblage (No. 12), public attitude surveys (No. 17), and permitting and compliance (No. 23). These indicators will be used to assess the program as follows:

Task 1, Industrial Runoff Control:

Permitting and compliance (No. 23): The State will provide the Town with a list of industries (within Town boundaries) subject to NPDES stormwater regulations; the number of permits issued; and copies of the permits. The Town will request copies of the Storm Water Pollution Prevention Plans from each permitted facility. An increase in the percentage of facilities subject to NPDES controls which have obtained permits is a potential indicator of success.

Water quality pollutant constituent monitoring (No. 1): The Town will select three locations in Hannah Bay and three locations in the stream system to monitor total phosphorus, total Kjedhal nitrogen, nitrate, dissolved oxygen, PAH, hydrocarbons, copper, lead, pesticides, and chemical oxygen demand. At least one site will be located upstream and at least one site downstream of major industrial development.

A total of 12 events will be monitored; 6 monthly baseflow events(April through September) and 6 storm events. The university will be responsible for collection and most analyses. A private laboratory will be contracted for the pesticides and PAH analyses. Long-term, general improvements in the monitored constituents is a potential indicator of success.

Fish assemblage (No. 12): The State (via the Department of the Environment) currently conducts fish pathology studies in Hannah Bay and its tributaries. The studies are used to track fishery health and focus on disease and poor health as evidenced by liver tumors, fin rot, and lesions. The State will continue these studies and will provide the Town of Kelsey with the monitoring results. The RAP linked fish tumors to elevated PAH levels in Hannah Bay. A reduction in the number of liver tumors is considered a potential indicator of success.

Task 2, Residential Runoff Control

Water quality pollutant constituent monitoring (No. 1): The water quality monitoring effort outlined in Task 1 will be used to assess the success of this effort. Monitoring sites will be located upstream and downstream of major residential development. Long-term, general reductions in pesticide concentrations have been identified as a potential indicator of success.

Task 3, CSO Reductions

Human health criteria (No. 6): The County (via the Health Department) conducts monthly fecal coliform surveys in Hannah Bay and immediately following storm events. During the swimming season, the maximum fecal coliform level is a geometric mean of 200 per 100 milliliters based on five samples. When fecal coliform levels exceed this level, the County closes beaches along Hannah Bay. Consumptive fishing is restricted whenever fecal coliform levels exceed 14 per 100 milliliters. The County has agreed to provide the Town of Kelsey with its survey results. The Town will use this information as baseline data.

Task 4, Habitat and Water Quality Assessment

Physical habitat monitoring (No. 8): Rapid Bioassessment Protocols will be used to evaluate physical habitat conditions in Tate Creek. University staff and students, citizen monitoring groups, and individual volunteers will be trained to conduct these surveys. The survey results will be used to describe baseline conditions. It is anticipated that these surveys will be conducted on an annul basis. General improvements in the habitat scores is considered a potential indicator of success.

Water quality pollutant constituent monitoring (No. 1): The water quality monitoring effort outlined in Task 1 will also be used to assess water quality in the stream system. Two monitoring sites will be located in Tate Creek. Long-term reductions in pollutant concentrations (or increases in dissolved oxygen) have been identified as potential indicators of success.

Task 5, Public Involvement

Public attitude surveys (No. 17): The Town, in partnership with the university, will develop and conduct a public attitude survey. This survey will focus on the public's knowledge about problems associated with stormwater, CSOs, the cost of various solutions, habitat and water quality conditions in Hannah Bay, sources of pollution in the watershed, and willingness to fund stormwater management efforts. Approximately 2,000 households will be included in the survey.

The Town tentatively plans to conduct a similar survey in five years. Heightened awareness of stormwater issues and increased willingness to fund stormwater management have been identified as potential measures of success.

Program Costs

The costs incurred by the Town of Kelsey for each phase of its stormwater management effort is outlined below.

Task 1, Industrial Runoff Control		
Stormwater runoff guidelines	$	2,000.00
Identification of industrial site options	$	5,000.00
Review of potential runoff diversions to WWTP	$	5,000.00
Permitting and compliance assessment	$	2,000.00
Water quality pollutant constituent monitoring	$	70,000.00 [1]
Fish assemblage (fish pathology) studies	$	0.00 [2]
subtotal	**$**	**84,000.00**
Task 2, Residential Runoff Control		
Household hazardous waste collection/recycling center	$	10,000.00
Lawn care seminars	$	5,000.00
Storm drain stenciling program	$	2,000.00
Water quality pollutant constituent monitoring	$	0.00 [3]
subtotal	**$**	**17,000.00**

[1] Cost for successive years will be approximately $45,000. This year's cost included $35,000 start-up costs.
[2] Conducted by State Department of the Environment.
[3] Costs included in Task 1.

Task 3, CSO Reductions		
Review of options		$ 5,000.00
Human health criteria (fecal coliform) surveys		$ 0.00 [4]
	subtotal	**$ 5,000.00**
Task 4, Habitat and Water Quality Assessment		
Physical habitat monitoring (Rapid Bioassessment Protocol)		$ 30,000.00
Water quality pollutant constituent monitoring		$ 0.00 [3]
	subtotal	**$ 30,000.00**
Task 5, Public Involvement		
Public seminars		$ 10,000.00
Public attitude surveys		$ 30,000.00
	subtotal	**$ 40,000.00**
	TOTAL	**$ 176,000.00**

[4] Conducted by County Health Department.

SCENARIO 3 - SMALLER INDUSTRIAL PARK - SOURCE CONTROL FOCUS

Century Industrial Park is a 30-acre industrial park, located in a highly urbanized, southern west-coast municipality. Century consists of 16 properties of individually owned facilities. The major industrial uses are trucking related services, an auto salvage yard, and metal plating operations, in addition to several smaller, less intensive uses.

The site is located in a semi-arid region, which receives approximately 14 inches of rainfall per year, most of this during the fall and winter months. All stormwater runoff is collected by an on-site drainage system and piped to the property line. A small, off-site intermittent channel conveys stormwater runoff from the industrial park directly to a tidal estuary surrounded by a highly urban area (Figure 5.3).

Five years have elapsed since Century Industrial Park was originally issued a National Pollution Discharge Elimination System (NPDES) permit. During this period, a pollution prevention plan has been in effect which includes an intensive outreach program to assist site owners with methods for implementing source controls (good housekeeping measures). In addition, several structural best management practices (BMPs) were proposed for the most intensive activities. For one reason or another, only one on-site oil/water separator structure had been installed at the metal plating facility.

Responsible Party Identification

The individual property owners were identified as regulated industries under the state's implementation of the Phase I NPDES permit process. The site owners pulled together their resources and filed a single joint application for an individual NPDES permit, instead of 16 separate ones. The state recognizes Century Industrial Park as the legal entity responsible for implementation and compliance with the NPDES permit conditions.

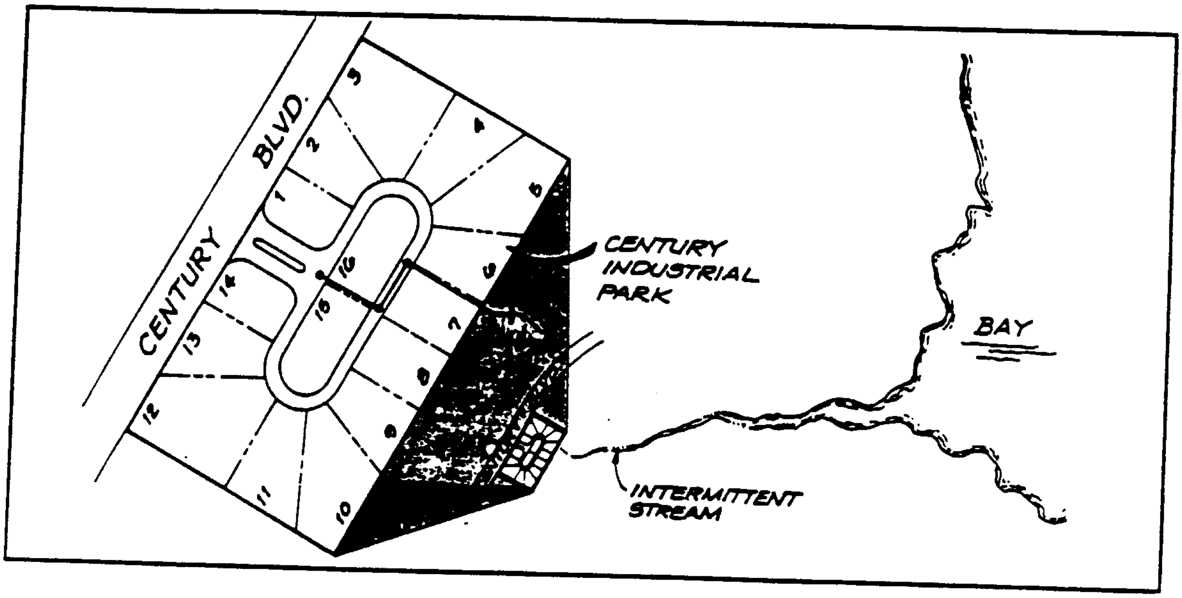


FIGURE 5.3 CENTURY INDUSTRIAL PARK

Previously Collected Data and Assessment of Baseline Conditions

Data collected for the NPDES permit application and subsequent monitoring conducted as a condition of the permit contained end-of-pipe pollutant constituent data from five storm events. Rainfall from these events ranged in size from 0.12" to 1.96". The data confirmed that high levels of dissolved and total zinc, copper, and lead were being exported from the site during storm events. These levels were compared with the Water Quality Exceedance Frequencies (WQEFs) for total metals. All five storm samples exceeded the target water quality objectives.

Toxicity tests consisting of a two tiered approach were also conducted. Short-term, 7-day chronic toxicity tests were carried out on wet weather samples on *Ceriodaphnia Dubia* to establish the condition of consistent toxicity at the site. Next, a Toxicity Identification Evaluation (TIE) was performed to measure and identify chemical constituents responsible for the observed toxicity. This procedure involves both physical and chemical alterations of water samples to eliminate particular compounds or classes of compounds. The results of the TIE indicated that a large majority of toxicity was due to dissolved metal ions. Another conclusion appears to be that the WQEFs which are based on total metals, may be overly conservative. In many cases, particulate-bound metals are less toxic (based on the results of the TIE) and only the dissolved component is consistently causing toxicity.

Receiving Water Uses and Target Protection Areas

As stated above the site drains to an urban estuary. This waterbody has been impacted by human influences for many years. It is believed that metals are the principal pollutant affecting aquatic health, particularly those particulate-bound metals within the bottom sediments. Other parameters, such as poly-aromatic hydrocarbons (PAHs), and nutrients are often cited as contributors to the degraded aquatic community.

The intermittent stream which drains the site has been armored over the years to stabilize the channel banks and bottom to reduce erosion. Since the channel is intermittent and reasonably well stabilized, the primary management strategy for this site is targeted towards reducing pollutant loadings being delivered to the bay.

Resources

The property owners pay an annual fee to fund the compliance measures of the NPDES permit. Each property owner pays a percentage of the total budget based on the amount of impervious surface and type of industry. The annual budget for the total 30 acre site is $20,000. Century Industrial Park has been identified as a significant contributor of non-point source pollutants to the receiving waters. A $100,000 grant has been appropriated by the State Water Conservation Board for this site to go towards addressing non-point source pollution control. A consultant has been hired to update the on-site pollution prevention plan, prepare a structural BMP implementation plan, and conduct monitoring for the term of the renewal permit.

Management Plan Goals and Priority of Implementation

The consultant in conjunction with the property owners and the State Water Conservation Board have developed the following goals and implementation priority for the term of the permit.

- Reduce total metal export from the site by 40% over existing levels by constructing structural BMPs to serve those properties with the greatest metal loading potential (i.e., auto salvage yard and metal plating facility).
- Reduce total pollutant loadings from the site to increase the percentage of *Ceriodaphnia* survival for a majority of storm events.
- Review and update pollution prevention plans for all on-site properties.
- Ensure compliance with pollution prevention plans.
- Increase the general public's awareness of the management efforts being implemented at Century Industrial Park for use as a platform for increased support for bay-wide stormwater non-point source controls.

Implementation of Management Strategies

The implementation of management efforts will involve the following basic steps to achieve the goals identified above. The approach must be carefully orchestrated since there is limited funding available and potential disruption of business operations must be avoided.

- Structural BMP locations are first identified and a feasibility analysis is conducted. Since the site is an industrial land use, little space is available for larger detention/retention facilities. Additionally, since downstream quantity controls are not warranted, the BMPs should be designed as quality-control facilities. A filtering BMP (such as a sand, compost or peat/sand filter) will probably be the most suitable given the site constraints. These facilities can be located along the edge of existing paved areas or even underground. Given the implementation budget constraints, and potential construction cost of approximately $3,500 per impervious acre (City of Austin, 1990), only about 15 acres can be realistically controlled by these facilities. The structural BMPs should be designed so as to control those portions of the site contributing the greatest pollutant loads (e.g., auto salvage yard, trucking services, and metal plating). Approximately $5,000 should be budgeted annually for the maintenance of these facilities. An additional $1,000 per year should be budgeted for the cleanout and maintenance of the existing oil/water separator structure.

- The pollution prevention plan for each property is reviewed and evaluated to ensure that the good housekeeping and source control measures are incorporated into the plans. Some of these measures include: spill prevention and clean-up procedures; covered storage of materials; covered loading docks and/or cleanup procedures; covered vehicle maintenance and refueling areas; and floor drains connected to sanitary sewers. The cost to conduct this portion of the management plan is approximately $7,500. Construction costs for providing covered facilities will cost more. Each business may need to phase in these expenditures over a few years. Cleanup activities can be paid for, in part, out of the annual NPDES implementation expenses.
- Compliance monitoring is conducted to verify that all properties are following the measures outlined in the pollution prevention plans. Compliance monitoring is in the form of visual inspections only. Compliance monitoring will cost approximately $1,800 per inspection for the entire 30 acre site. This should be conducted at least once per year, but preferably twice.
- The public awareness element consists of distributing informational flyers; news releases; presentations at political forums, technical workshops and conferences; among other media. These elements are spaced over the term of the permit and should be incorporated into the annual budget. $5,000 should be budgeted to set up the program in the first year with $2,500 per year provided, thereafter.

The total cost to implement the above measures is approximately $75,000, not including engineering design costs. Given the $100,000 implementation grant, there should be sufficient funds available to cover the cost of design and construction inspection.

Monitoring Program and Assessment of Results

The monitoring program is developed to select indicators which will assess success of the management efforts in meeting the goals stated above. The following indicators are utilized:

- Pollutant constituent monitoring (Profile No. 1) at inflow and effluent of one structural BMP (for a minimum of three storm events per year).
- Pollutant constituent monitoring (Profile No. 1) at the outfall of the site to assess metal reduction success (for a minimum of three storm events per year).
- 7 day, chronic toxicity testing and TIEs (Profile No 2) at the outfall of the site to assess reduction in toxicity, conducted once per year during the term of the project.
- Industrial site compliance monitoring (Profile No 26), two times per year
- Public attitude survey (Profile No. 17) conducted in the vicinity of the site in year three of the program implementation, to assess the effectiveness of the public awareness efforts.

It is projected that the monitoring will cost $ 23,000 per year for the five year term of the permit. This number is slightly larger than the $20,000 budgeted for NPDES compliance, so some elements may need to be conducted on a bi-annual basis or the annual budget may need to be increased. As monitoring data is compiled over the duration of the permit term, data will emerge to be able to assess the success of the management strategies. After the five year term, a re-evaluation of the management efforts should be conducted and appropriate changes made.

APPENDIX A: REPORT ON STORMWATER INDICATORS MEETINGS

Conducted April - June 1995
By The Rensselaerville Institute
as part of a cooperative agreement with
the U.S. Environmental Protection Agency

INTRODUCTION

As part of a three-stage cooperative agreement with the U.S. EPA, and in conjunction with the Center for Watershed Protection (CWP) and the Water Environment Research Foundation (WERF), The Rensselaerville Institute convened and facilitated six stakeholder meetings which gathered storm water experts from throughout the U.S. The stakeholder groups represented at the meetings included: state and local regulators, EPA regional offices, industry, consultant engineers, and regulated municipalities.

The purpose of these meetings was to gain feedback on the Storm Water Indicator Profiles Document as prepared by the Center for Watershed Protection, and also examine the potential for identifying a core set of storm water indicators that could be used nationwide to track program effectiveness. Participants at these meetings were individuals who are recognized for their expertise in the area of storm water pollution prevention and control. Suggestions for participants were received from professional organizations including ASIWPCA, NAFSMA, APWA, and ACEC, as well as recommendations from EPA headquarters and regional offices, WERF and CWP. The list of participants at each meeting is appendixed to this report.

This report provides a short section describing the methods and approaches used for designing and implementing these six expert stakeholder meetings, and summarizes the key responses and recommendations made by the experts that seemed to become common "threads" throughout most or all of the meetings.

METHODS

Six expert meetings were designed and organized by The Institute: the first three were designed to include mixed stakeholders representing a specific geographic area of the country. These three meetings were held in Denver, CO; Sacramento, CA; and Philadelphia, PA. The second three meetings were designed to gain feedback from single-constituent stakeholders representing various geographic regions of the country and, in one case, Canada. The stakeholder groups represented in these latter three meetings were: regulated municipalities, state regulators, and academia. All three of these latter meetings were conducted in Washington, DC.

The meeting format was designed to stimulate high interaction among participants. The basic guidelines set at each meeting were: experts were to speak their own opinions based on their personal expertise, not represent a corporate or agency "line" when responding to questions; participants were encouraged to ask questions to effectively probe areas of discussion rather than make assertions that tend to cut off interaction between participants; and issues beyond the scope of the defined area of discussion, i.e. selection and application of storm water indicators, and comments pertaining to the Profiles document, were off-limits, e.g. discussions on pending permit applications between permittees and regulators were inappropriate for these meetings.

All participants received the draft Indicator Profiles Document at least one week prior to their assigned meeting to familiarize themselves with the contents of the document and the format designed for meeting discussions. The key questions posed at each meeting were:

- Is there a core set of indicators that could be used nationwide to identify storm water problems?
- Is there similarly a core set of indicators that could be used consistently nationwide to assess storm water program effectiveness?
- What are the strengths and weaknesses of the Profiles document in its present draft form, and what information could be added or modified to improve its usefulness as a guidance tool for communities addressing storm water issues?
- Given certain conditions (as provided to the group in a simulated situation), how would participants approach the development of a storm water monitoring program for a given waterbody?

In each of the sessions, both small-group and whole-group discussions were used to engage participants. In each case of small group deliberations, highlights of those deliberations were presented to the plenary for further consideration and discussion. Consensus and divergent views were equally welcome from participants. The desired outcomes from these expert meetings were to determine:

- Which, if any, indicators that could be used nationwide to assess stormwater programs. If yes, what are the indicators, and what are the parameters of their use as national indicators.
- Those changes that could be made in the Profiles document draft to make it more user-friendly and useful to a wide range of community representatives in making rational and reasonable decisions for determining baseline conditions and selecting appropriate indicators to monitor change after implementation of BMPs.
- What approaches, steps, criteria or protocols would prove useful to communities starting or improving a storm water monitoring program, and the rationale behind using these approaches.
- What small pilots or tests could be tried by WERF or others to test the ability of these approaches to improve present storm water program monitoring efforts.

This report presents some of the key common responses and opinions expressed by participating experts on what they believed to be the most reasonable and cost-effective approaches to storm water monitoring, and what needed to be done to improve both understanding of storm water as a pollutant source and program performance.

Key Responses and Recommendations for Improving Storm Water Program Monitoring and Performance

Some of the key responses and recommendations made by the expert participants which seemed to "thread through" these six meetings were:

1. There are no specific storm water indicators that could be used nationwide comparably as a measure of program effectiveness. Most particularly, no indicator could be comparable in terms of its numerical (quantitative) standard. What experts did believe to be comparable nationwide were strategies and tactics that could be applied to select appropriate indicators

R0016748

for any given watershed or sub-watershed. These would include strategies and tactics both for problem identification and determination of program effectiveness.

2. The availability of comparable baseline data is non-existent. Lack of standards and protocols for collection of data in the early promulgation of the regulations resulted in data which are not comparable from program to program and state to state. Further, the large expenditures for initial data collection that have no comparability strongly suggests that better guidance be provided to program developers and implementors on how to decide which data to collect that would be informative, useful and applicable to program improvement.

3. The Profiles document has excellent potential for providing such guidance both to communities starting a storm water monitoring program as well as those wishing to improve their present program. (Note: In each of the six expert meetings, staff from the Center for Watershed Protection received and carefully noted specific references to areas that could be improved for better document use and reference.) The overall conclusion was that the document did an excellent job in presenting key information in an understandable format; experts noted that the document needs to include approaches and protocols that could help bring consistency and common sense to the practice of program implementation and monitoring. Too often indicator selection is a result of what is known or comfortable, not what has been identified as needed to determine or deal with the problem. Basic decision-trees or decision strategies would be highly useful to laypeople referring to the document, as would guiding principles and questions that would help community members better identify and respond to problems.

4. Experts were clear: indicators have distinct roles in program assessment, and not all indicators can be used to serve the same role. Some indicators are used for problem identification; others are used to determine program effectiveness. Still others can only be used to look at program effectiveness over the long-term, while others can only effectively detect short-term gains in the program. Experts believe that problem identification is one of the biggest difficulties with the storm water program; municipalities in particular don't understand how to identify their storm water problems, and therefore often select the wrong indicators for the wrong reasons, thus generating useless data that provide no assessment of whether or not the problem is being solved.

5. One realistic approach to designing a monitoring program is to look first at those indicators that are easiest and least costly to use in order to determine the storm water problems being dealt with, e.g. indicators that are observational in nature are an excellent way to begin (example: walking a stream to assess physical and macro-biological indicators). Cost and time-intensity are two realistic constraints that must be considered in the development of any monitoring program. A third is time-appropriateness of using any given indicator: some indicators are appropriate for problem "screening" (earliest use) while others may need to be used later for finer identification of problems. Overall, experts feel that the indicators represent a toolbox from which the most appropriate tools for the job are selected at the time that they are needed. Not all indicators are used in all programs at all times...nor should they ever be required to be so used by a regulating agency.

6. Beneficial uses must be the target toward which any monitoring program is directed. There has to be a realistic understanding among all parties of what is trying to be achieved through the program. While it is clear that the program's purpose is to close the gap between present water quality conditions and what the desired beneficial uses are, it also has to be made clear

that different waterbodies have different designated uses; "pristine condition" cannot and should not be the goal for every waterbody. The storm water program, designed by a community, has to be based on what is realistically achievable for that given waterbody. All community representatives need to be part of the goal-setting process for the program to succeed; they need to be part of the decision-making on the trade-offs they are willing to make to achieve the goals they set.

7. Education is key to gain buy-in and active support from stakeholders. If a storm water program is to be effective, it must play to all the audiences of a given location. Helping people understand and commit to the program requires attending to their values and beliefs. These different audiences must not only be informed, but they must be persuaded to change their behavior.

SUMMARY

At all six meetings, participant experts offered numerous suggestions for ways to make the Storm Water Indicator Profiles document more widely applicable and more user friendly. Staff at the Center For Watershed Protection made careful note and consideration of each of these suggestions, and many of the suggested changes are reflected in this final version. As more becomes known about storm water and effective approaches for dealing with pollutant sources, The Rensselaerville Institute is confident that this "living document" can grow and develop so that it continually meets community needs with accurate, helpful, up-to-date information and guidance.

The Rensselaerville Institute report ends with what we believe is probably the most important message received from the many experts involved: storm water programs will only be effective when a paradigm shift occurs in regard to our approaches to dealing with it as a pollutant source. Perception has to move from traditional, end-of-pipe, water chemistry, broad-spectrum pollutant monitoring, treatment and command-and-control enforcement, to a mindset focusing on receiving water body quality and the beneficial uses that the community desires for that waterbody. There needs to be strong emphasis on problem identification before a program is designed, and then there needs to be very judicial choice of appropriate indicators so that real progress toward return of the waterbody to beneficial uses can truly be measured. This new mindset must incorporate regulatory flexibility and emphasis on education and voluntary effort as key parts of the implementation plan. Government needs to move from the role of enforcer to be an enabler and technical advisor to communities that are putting forth best-faith efforts to deal with their storm water problems.

APPENDIX B: SAMPLE NPDES PERMIT - MONTGOMERY COUNTY, MD

The enclosed NPDES permit for Montgomery County, Maryland, a large municipal separate storm sewer system jurisdiction, incorporates many of the indicators identified in this document. Several of the following elements are analogous to the Level 1 methodology described in Chapter IV:

- Watershed inventories (e.g., land use and impervious cover) are conducted and GIS mapping is utilized to help identify potential pollution source areas. This provides a quick assemblage of necessary databases, and supports watershed modeling efforts, among other applications.
- Pollutant constituent chemical monitoring is conducted to help characterize stormwater discharges as part of a pilot "pipe detectives" program (Profile No. 1).
- Physical and biological monitoring, on a watershed basis, is applied as a screening tool to identify water quality and habitat impairment (Profile No. 7, 8, 12, and 13).

A watershed-based management program is proposed that further supports the use of indicators in developing and assessing the county's stormwater program. Some elements of the Montgomery County stormwater management program include:

- Maintenance inspections of BMPs are being conducted (Profile No. 22).
- Stormwater waivers issued are incorporated into a tracking system (Profile No. 23).
- Commercial/industrial and residential pollution prevention and public outreach programs are established (Profile No. 18, 19, and 20).
- Illicit connections detection, correction, and enforcement programs are established (Profile No. 21).
- Watershed restoration action plans are being developed to define watershed protection goals, determine monitoring needs, incorporate public education and involvement elements, identify stormwater retrofit and stream restoration opportunities, and implement other projects needed to achieve these goals (Profile No's 1, 7, 8, 12, 13, 19, and 24).

In addition, Montgomery County's permit calls for assessing the effectiveness of controls in reducing pollutant loads. The non-point source loading indicator (Profile No. 3) and various watershed simulation model tools can be used to achieve this objective.

These are just a few of the indicator applications that are incorporated in the attached NPDES permit. A careful review of Montgomery County's permit can provide insights for other jurisdictions in either renewing a permit, carrying out permit conditions, or structuring a new permit.

We would like to acknowledge Mr. Cameron Wiegand of Montgomery County, Department of Environmental Protection, Division of Water Resources Management for his efforts in providing background information on Montgomery County's permit and for his invaluable insights on the application of environmental indicators in the NPDES permit arena.

MARYLAND DEPARTMENT OF THE ENVIRONMENT

NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM

MUNICIPAL SEPARATE STORM SEWER SYSTEM DISCHARGE PERMIT

PART I. IDENTIFICATION

A. Permit Number: MS-MO-95-006

B. Permit Area

This permit covers stormwater discharges from the municipal separate storm sewer system in Montgomery County, Maryland.

C. Effective Date: March 15, 1996

D. Expiration Date: March 15, 2001

PART II. STANDARD PERMIT CONDITIONS

A. Legal Authority

1. Montgomery County shall maintain adequate legal authority, in accordance with National Pollutant Discharge Elimination System (NPDES) regulations 40 CFR 122.26(d)(2)(i), throughout the term of this permit. In the event that any provision of its legal authority is found to be invalid, the County shall make the necessary changes to maintain adequate legal authority.

B. Source Identification

1. Montgomery County shall continue the development of its Geographic Information System (GIS) and submit appropriate topographic maps with a scale between 1:10,000 and 1:24,000 and their associated data layers to the Maryland Department of the Environment (MDE). GIS mapping shall include the location of the County's storm sewer system; each currently operating or closed municipal landfill or other treatment, storage or disposal facility for municipal waste; any known NPDES stormwater discharger; and major structural controls for stormwater discharges. Additionally, Montgomery County shall submit land use activities; an estimate of the average runoff coefficient for each land use type; estimates of population densities and projected growth for a ten year period; and the location of publicly owned parks, recreational areas, and other open lands.

2. Montgomery County shall complete GIS development according to the following schedule:

a) By 3/17/97, Little Falls watershed and Anacostia River drainage including the Sligo Creek, Northwest Branch, Paint Branch, and Little Paint Branch watersheds.

b) By 3/16/98, Potomac River drainage including the Cabin John Creek, Lower Rock Creek, and Upper Rock Creek watersheds.

c) By 3/15/99, Great Seneca Creek watershed and Potomac River drainage including the Watts Branch and Muddy Branch watersheds.

d) By 3/15/2000, Little Seneca Creek, Patuxent River drainage including the Lower Patuxent, Hawlings River, Haight's Branch, Scott's Branch, and Upper Patuxent watersheds, and Potomac River drainage east of Great Seneca Creek including the Potomac River Direct, Minnehaha Branch, and Rock Run watersheds.

e) By 3/15/2001, Dry Seneca Creek watershed, Potomac River drainage west of Great Seneca Creek including the Potomac River direct, Horsepen, and Broad Run watersheds, and Monocacy River drainage including the Monocacy River Direct, Furnace Branch, Little Monocacy River, Little Bennett Creek, Bennett Creek, and Farney Branch watersheds.

3. Montgomery County shall compile and submit any new source identification information including the identification and mapping of storm sewer system outfalls, land use activities, population estimates, runoff coefficients, major structural controls, landfills and controls, publicly owned lands, NPDES dischargers, and industries organized by watershed and Standard Industrial Classification (SIC) codes in the annual reports submitted to MDE pursuant to PART IV "ANNUAL PROGRESS REPORTS" of this permit.

C. Discharge Characterization

1. By 6/17/96, Montgomery County shall submit storm event monitoring data and analysis to MDE for the remaining storm events at each of its five Part 2 representative outfalls.

2. Within 6 months of MDE's approval of Montgomery County's proposed long-term monitoring program, the County shall commence chemical sampling at one outfall and its appropriate in-stream monitoring station.

3. Chemical sampling at these and any additional outfalls or in-stream stations shall comply with procedures developed as a direct result of the County's involvement in NPDES monitoring committee meetings established according to PART III "SPECIAL PROGRAMMATIC CONDITIONS" of this permit.

4. Montgomery County shall complete the following minimum requirements for chemical monitoring:

a) A total of 12 storm events shall be monitored per year at each monitoring location with at least three occurring per quarter. Quarters shall be based on calendar year. If extended dry weather periods occur, baseflow samples shall be taken at least once per month. If no flow is observed at the outfall during periods of dry weather, samples shall be taken at the in-stream monitoring stations only.

b) Three discrete samples shall be taken for stormwater flow at both outfall and in-stream monitoring stations. Samples submitted for analysis shall be representative of the approximate flow at the following three intervals along the hydrograph: the midpoint of the rising limb, the peak, and the midpoint of the falling limb.

c) Flow rates and temperature shall be recorded at points when discrete samples are taken.

d) Collected samples shall be submitted to a laboratory for analysis according to methods listed under 40 CFR Part 136 for the following parameters:

BOD_5	Fecal Coliform
TKN	Nitrate plus Nitrite
Total Phosphorus	Cadmium
Copper	Lead
Zinc	Oil and Grease
pH	TSS

e) For each storm event, a description of any equipment problems and weather conditions such as duration and intensity shall be recorded.

5. Montgomery County shall incorporate physical and biological monitoring with the chemical monitoring described in PART II., C., 2. above. Physical and biological monitoring shall commence with the chemical monitoring and procedures and protocols shall be determined through the County's involvement in NPDES monitoring committee meetings established according to PART III "SPECIAL PROGRAMMATIC CONDITIONS" of this permit.

6. Beginning in 1996, Montgomery County shall conduct habitat, physical, and biological monitoring on a watershed basis as a County-wide screening tool to identify water quality impairment and establish reference stream criteria. Where the source of impairment is determined not to be a result of physical limitations, chemical specific testing shall be conducted to identify the source of impairment. The source of impairment shall be eliminated in accordance with the County's illicit connection inspection program as identified in PART II., D., 8. and 9. of this permit.

a) Sampling procedures shall be in accordance with Montgomery County's Water Quality Monitoring Program: Stream Monitoring Protocols document which has been incorporated into this permit as Appendix 6. or any subsequent revisions as a result of the NPDES monitoring committee meetings established according to PART III "SPECIAL PROGRAMMATIC CONDITIONS" of this permit.

b) By 3/15/2001, baseline watershed and reference stream biological monitoring shall be completed for all County watersheds

7. Reporting Frequency and Requirements

a) Chemical laboratory results shall be recorded on MDE's long-term monitoring database (Appendix 3) and submitted with annual reports.

b) Field results and analysis for physical and biological monitoring shall be submitted with annual reports. The analysis shall integrate the results from chemical, physical, and biological monitoring.

c) Annual and seasonal pollutant load estimates, using data collected as a result of the long-term monitoring efforts, shall be submitted with annual reports.

d) Pollutant loads shall be estimated for all identified municipal storm sewer outfalls and submitted to MDE according to the schedule established for GIS development in PART II., B., 2. of this permit.

e) By 3/16/98, Montgomery County shall assess its monitoring program and, if warranted, outline potential alternative sampling sites and procedures.

D. Management Programs

1. Montgomery County shall maintain an acceptable stormwater management program in accordance with the Environment Article, Title 4, Subtitle 2, Annotated Code of Maryland.

2. Montgomery County shall conduct preventative maintenance inspections of all stormwater management facilities at least on a triennial basis. Inspections, necessary corrective action, and enforcement actions shall be documented and summarized in annual reports.

3. Montgomery County shall submit information regarding its stormwater management program on the latest version of MDE's stormwater management spreadsheet (Appendix 4) in annual reports.

4. By 3/17/97, Montgomery County shall establish a database for tracking and evaluating the impacts of stormwater waiver issuance in each watershed. Emphasis shall also be placed upon strengthening the criteria for evaluating stormwater management waiver requests and providing enhanced public input.

5. Montgomery County shall conduct watershed studies and submit action plans for protecting surface and ground water resources. These plans shall include restoration/mitigation measures and include an implementation schedule to reduce or eliminate sources of water quality impairment. Montgomery County shall submit summaries of the watershed assessments and action plans according to the following schedule:

   a) By 3/17/97, the Little Falls and Sligo Creek watersheds.

   b) By 3/15/99, the Paint Branch, Little Paint Branch, Upper Rock Creek, and Lower Rock Creek watersheds.

   c) By 3/15/2001, the Watts Branch, Cabin John Creek, and Northwest Branch watersheds.

6. By 3/17/97, Montgomery County shall perform an assessment regarding the effects of road maintenance activities including street sweeping, litter control, deicing procedures, and the application of herbicides for vegetation control on stormwater discharges. This assessment shall include an analysis of alternative practices for reducing pollutants associated with road maintenance activities. By 3/16/98, Montgomery County shall incorporate effective alternative practices in its road maintenance procedures for reducing pollutants.

7. By 6/17/96, Montgomery County shall implement its proposed industrial, residential, and commercial pollution prevention and public outreach programs. These programs are to include educational information regarding the proper use of herbicides, pesticides, and fertilizers. Hazardous waste and general water quality information shall also be provided to the public. Education efforts shall be documented and summarized in annual reports.

8. By 6/17/96, Montgomery County shall implement its illicit connection detection and enforcement program. During the first year, program implementation shall occur in the Little Falls and Paint Branch watersheds. Each year thereafter, program implementation shall be expanded into at least five additional watersheds until all of the County's 29 designated watersheds have been assessed. At a minimum, the program shall include the following:

   a) The number of outfalls to be screened in targeted areas. Targeted areas shall include industrial and commercial land uses and those outfalls where pollutants were detected during Part 1 dry weather flow screening.

   b) Visual inspection of targeted areas. Follow-up inspections using chemical testing shall be performed immediately after discovering an illicit discharge in which the source is not apparent.

   c) Provisions for field screening data to be recorded on MDE's Part 1 field screening database.

   d) Fines for continued noncompliance by illicit dischargers.

   e) Procedures for public identification and reporting of illicit discharges.

   f) Progress reports that include an updated list of targeted outfalls and an inspection schedule.

9. Beginning 6/17/96, Montgomery County shall eliminate any illegal storm drain system discharge discovered through its illicit connection inspection program. Additionally, the County shall work cooperatively with MDE to ensure that industrial dischargers secure NPDES permits and that agricultural sources are minimized.

10. Montgomery County shall maintain an acceptable erosion and sediment control program in accordance with the Environment Article, Title 4, Subtitle 1, Annotated Code of Maryland.

11. By 6/17/96, Montgomery County shall implement "responsible personnel" certification classes to educate construction site operators regarding erosion and sediment control requirements. Education efforts are to be documented and summarized in annual reports.

12. Beginning in 1997, Montgomery County shall evaluate all management programs and identify any necessary changes. This information shall be submitted in annual reports.

E. Program Funding

1. Montgomery County shall maintain adequate program funding to comply with all conditions of this permit.

F. Assessment of Controls

1. Annually, Montgomery County shall submit estimates of expected pollutant load reductions as a result of its implementation of management programs. Additionally, the effectiveness of resource protection and stream habitat improvements shall be used to assess the effectiveness of the County's management programs and pollutant control strategies.

PART III. SPECIAL PROGRAMMATIC CONDITIONS

Since the signing of the Chesapeake Bay Agreement in 1983, the State of Maryland has been working toward meeting the goal of reducing by 40% the discharge of nutrients to the Chesapeake Bay by the year 2000. To achieve this nutrient goal, the State has developed strategies to improve the water quality in the tributaries that drain to the Bay. In Maryland, the Bay watershed has been subdivided into ten major tributaries which have each been assigned a 40% nutrient reduction goal. Characterizations of specific tributaries have been made in terms of land use, nutrient loads, and water quality. Additionally, strategy options have been developed based on identified problems in order to guide the restoration effort in each individual tributary.

Montgomery County lies within three of the Chesapeake Bay's ten major tributaries. These include the Upper Potomac, Middle Potomac, and Patuxent River basins. This NPDES permit requires Montgomery County to assist with the implementation of the strategy designed to meet the nutrient reduction goals of the above basins. The specific permit conditions presented below will promote a watershed based approach to controlling the contribution of pollutants from stormwater runoff. Coordination between and among other jurisdictions is a major requirement and the identification of those appropriate jurisdictions will occur jointly with MDE. Additionally, deadlines, priorities, and scheduling to satisfy specific conditions will be determined in conjunction with MDE. In any case, progress toward meeting these conditions shall be reported to MDE.

A. Programmatic Coordination

1. Montgomery County shall coordinate water quality restoration and protection efforts in watersheds shared with other jurisdictions. These efforts shall include:

a) the exchange of information on restoration/protection program effectiveness;

b) the definition of watershed management measures to support restoration/protection efforts;

c) the identification of appropriate watershed boundaries for planning and program development efforts; and

d) the coordination of planning and zoning activities to support the goals of watershed management.

B. Data Management

1. Montgomery County shall develop standards for record keeping and databases to meet the standard permit conditions in Part II of this permit. These standards shall be developed in concert with other appropriate jurisdictions and include:

a) management practice databases and GIS compatibility among jurisdictions for base maps, pollutant source area locations, stormwater management facility location and description, and land use and zoning designations;

b) comparable population estimates and growth projections; and

c) consistent land use and runoff coefficients.

C. Discharge Characterization

1. Montgomery County shall develop standards for discharge characterization. These standards shall be developed in concert with other appropriate jurisdictions and include:

a) coordination of long-term monitoring site selection among other appropriate jurisdictions;

b) standards for field and laboratory methods;

c) standards for monitoring databases; and

d) standards for annual and seasonal pollutant load estimates.

D. Management Programs

1. Montgomery County shall develop management program standards. These standards shall be developed in concert with other appropriate jurisdictions and include:

a) preventative maintenance procedures;

b) watershed management plans and retrofit assessments;

c) development and implementation of public information and educational programs; and

d) watershed inventories, illicit discharge inspection programs, and water quality enforcement.

E. Assessment of Controls and Annual Progress Reporting

1. Montgomery County shall develop standards for loading reduction estimates, annual progress reports, and stormwater management program effectiveness.

2. Along with other jurisdictions, Montgomery County shall evaluate the cumulative impact of its stormwater management waiver policy with regard to receiving water quality.

PART IV. ANNUAL PROGRESS REPORTS

Annual progress reports required under 40 CFR 122.42(c) will facilitate the long-term assessment of Montgomery County's NPDES stormwater program. According to EPA guidance, these reports shall be based on assessment techniques proposed by jurisdictions in Part 2 NPDES applications. These reports shall include:

§122.42(c) "(1) The status of implementing the components of the storm water management program that are established as permit conditions;"

§122.42(c) "(2) Proposed changes to the storm water management programs that are established as permit conditions...;"

§122.42(c) "(3) Revisions, if necessary, to the assessment of controls and the fiscal analysis reported in the permit application...;"

§122.42(c) "(4) A summary of data, including monitoring data, that is accumulated throughout the reporting year;"

§122.42(c) "(5) Annual expenditures and budget for year following each annual report;"

§122.42(c) "(6) A summary describing the number and nature of enforcement actions, inspections, and public education programs;"

§122.42(c) "(7) Identification of water quality improvements or degradation;"

MDE has developed a spreadsheet (Appendix 4) for the reporting and tracking of NPDES data. This spreadsheet lists components of Montgomery County's NPDES stormwater program along with appropriate reporting parameters. Annual progress reports, including MDE's spreadsheet, shall be submitted to MDE by the anniversary date of permit issuance for each year of the permit term.

PART V. ENFORCEMENT AND PENALTIES

A. Program Review and Evaluation

In order to assess the effectiveness of the permittee's NPDES program for eliminating non-stormwater discharges and reducing the discharge of pollutants to the maximum extent practicable, MDE will review and evaluate program implementation, annual reports, and periodic data submittal on an annual basis. Procedures for the review of local erosion and sediment control and stormwater management programs exist in Maryland's Sediment Control and Stormwater Management Laws. Additional periodic reviews and evaluations will be conducted to determine compliance with permit conditions. Continuation or reissuance of this permit beyond March 15, 2001 will be subject to MDE's review and evaluation of Montgomery County's compliance and implementation of the conditions of this permit.

B. Discharge Prohibitions and Receiving Water Limitations

The permittee shall effectively prohibit non-stormwater discharges through its municipal separate storm sewer system. NPDES permitted non-stormwater discharges are exempt from this prohibition. Discharges from the following will not be considered a source of pollutants when properly managed: water line flushing; landscape irrigation; diverted stream flows; rising ground waters; uncontaminated ground water infiltration to separate storm sewers; uncontaminated pumped ground water; discharges from potable water sources; foundation drains; air conditioning condensation; irrigation waters; springs; footing drains; lawn watering; individual residential car washing; flows from riparian habitats and wetlands; dechlorinated swimming pool discharges; street wash water; and fire fighting activities. The discharge of stormwater containing pollutants which have not been reduced to the maximum extent practicable is prohibited.

The permittee shall not cause the contamination or other alteration of the physical, chemical, or biological properties of any waters of the State, including a change in temperature, taste, color, turbidity, or odor of the waters or the discharge or deposit of any organic matter, harmful organism, or liquid, gaseous, solid, radioactive, or other substance into any waters of the State, that will render the waters harmful to:

(1) Public health, safety, or welfare;

(2) Domestic, commercial, industrial, agricultural, recreational, or other legitimate beneficial use;

(3) Livestock, wild animals, or birds; or

(4) Fish or other aquatic life.

C. Duty to Mitigate

The permittee shall take all reasonable steps to minimize or prevent any discharge in violation of this permit which has a reasonable likelihood of adversely affecting human health or the environment.

D. Duty to Comply

The permittee must comply with all conditions of this permit. Any permit noncompliance constitutes a violation of the Clean Water Act (CWA) and is grounds for enforcement action; permit termination, revocation, or modification: or denial of a permit renewal application. The permittee shall comply at all times with the provisions of the Environment Article, Title 4, Subtitles 1, 2, and 4; Title 7, Subtitle 2; and Title 9, Subtitle 3 of the Annotated Code of Maryland.

The permittee shall at all times properly operate and maintain all facilities and systems of treatment and control (and related appurtenances) which are installed or used by the permittee to achieve compliance with the conditions of this permit. Proper operation and maintenance also includes adequate laboratory controls and appropriate quality assurance procedures. This provision requires the operation of back-up or auxiliary facilities or similar systems which are installed by the permittee only when the operation is necessary to achieve compliance with the conditions of the permit.

E. Sanctions

1. Penalties Under the CWA - Civil and Criminal

The CWA provides that any person who violates any permit condition is subject to a civil penalty not to exceed $25,000 per day for each violation. Any person who negligently violates any permit condition is subject to criminal penalties of $2,500 to $25,000 per day of violation, or imprisonment of not more than 1 year, or both. Any person who knowingly violates any permit condition is subject to criminal penalties of $5,000 to $50,000 per day of violation, or imprisonment for not more than 3 years, or both.

2. Penalties Under the State's Environment Article - Civil and Criminal

Nothing in this permit shall be construed to preclude the institution of any legal action nor relieve the permittee from civil or criminal responsibilities and/or penalties for noncompliance with Title 4, Title 7, and Title 9 of the Environment Article, Annotated Code of Maryland, or any federal, local, or other State law or regulation.

The Environment Article, §9-342, Annotated Code of Maryland, provides that any person who violates a permit condition is subject to a civil penalty up to $1,000 for each violation, but not exceeding $50,000 total. The Environment Article, §9-343, Annotated Code of Maryland, provides that any person who willfully or negligently violates a permit condition is subject to a criminal penalty not exceeding $25,000 or imprisonment not exceeding 1 year, or both.

The Environment Article, §9-343, Annotated Code of Maryland, provides that any person who falsifies, tampers with, or knowingly renders inaccurate any monitoring device or method required to be maintained under this permit shall, upon conviction, be punished by a fine of not more than $10,000 per violation, or by imprisonment for not more than six months per violation, or both.

The Environment Article, §9-343, Annotated Code of Maryland, provides that any person who knowingly makes any false statement, representation, or certification in any records or other document submitted or required to be maintained under this permit, including monitoring reports or reports of compliance or noncompliance shall, upon conviction, be punished by a fine of not more than $10,000 per violation, or by imprisonment for not more than six months per violation, or both.

F. Permit Revocation and Modification

1. Permit Actions

This permit may be modified, revoked and reissued, or terminated for cause. The filing of a request by the permittee for a permit modification, or a notification of planned changes or anticipated noncompliance does not stay any permit condition. A permit may be modified by the Department upon written request by the permittee and after notice and opportunity for a public hearing in accordance with and for the reasons set forth in the Code of Maryland Regulations (COMAR) 26.08.04.10 C.

After notice and opportunity for a hearing and in accordance with COMAR 26.08.04.10., the Department may modify, suspend, or revoke and reissue this permit in whole or in part during its term for causes including, but not limited to the following:

a) Violation of any terms or conditions of this permit;

b) Obtaining this permit by misrepresentation or failure to disclose fully all relevant facts;

c) A change in any condition that requires either a temporary reduction or elimination of the authorized discharge; or

d) A determination that the permitted discharge poses a threat to human health or welfare or to the environment and can only be regulated to acceptable levels by permit modification or termination.

2. Duty to Provide Information

The permittee shall furnish to the Department, within a reasonable time, any information which the Department may request to determine whether cause exists for modifying, revoking and reissuing, or terminating this permit; or to determine compliance with this permit. The permittee shall also furnish to the Department, upon request, copies of records required to be kept by this permit.

G. Property Rights

The issuance of this permit does not convey any property rights in either real or personal property, or any exclusive privileges nor does it authorize any injury to private property or any invasion of personal rights, nor any infringement of federal, State, or local law or regulations.

H. **Severability**

The provisions of this permit are severable. If any provision of this permit shall be held invalid for any reason, the remaining provisions shall remain in full force and effect. If the application of any provision of this permit to any circumstance is held invalid, its application to other circumstances shall not be affected.

I. **Signature of Authorized Administrator and Jurisdiction**

All applications, reports, or information submitted to the Department shall be signed as required by COMAR 26.08.04.01 D. As in the case of municipal or other public facilities, signatories shall be either a principal executive officer, ranking elected official, or other duly authorized employee.

EFFECTIVENESS OF INDUSTRIAL STORM WATER GENERAL PERMITTING PROGRAM

Prepared for the United States Environmental Protection Agency
Under a Cooperative Agreement with the
Water Environment Federation

EPA COOPERATIVE AGREEMENT
No. CX 823667 - 01
General Permit Review Program No. 4315

Final Report
October 1996

Acknowledgments

This document was developed by the Water Environment Federation (WEF) under a cooperative agreement with the United States Environmental Protection Agency (EPA) in partial fulfillment of EPA cooperative agreement No. CX 823667 - 01. William Swietlik served as EPA project manager. Linda Blankenship and Susan Merther served as project coordinators for WEF and Dr. William Hancuff served as principal author. The services of K.C. Associates of Wilmington, DE were used to distribute and collect the questionnaires, enter the data for computer analysis and perform the required correlations.

Members of the Working Group who helped develop the questionnaire and formulate the study included:

Dan Viscardi (CDM)	Airports Council International - North America
Tony MacDonald	American Association of Port Authorities
Rich Weaver	American Public Transit Association
Robert Fronczak	Association of American Railroads
Robbi Savage/Linda Eichmiller	Association of State and Interstate WPCAs
Tony Wagner/Eric Free	Chemical Manufacturers Association
Jeff Longsworth	Collier, Shannon, Rill and Scott
Frank Sobata	Conrail
Ken Wood	DuPont Nemours (for SOCMA)
Robin Wiener	Institute of Scrap Recycling Industries
John Groenewold	Kraft General Foods
Rick Jarman	National Food Processors Association
Thomas Purcell	Printing Industries of America
Christine Reiter	Synthetic Organic Chemical Manufacturers Association
Joan LeLacheur	Washington Metropolitan Area Transit Authority
John Melby	Wisconsin DNR (for ASIWPCA)

EFFECTIVENESS OF INDUSTRIAL STORM WATER GENERAL PERMITTING PROGRAM

I. EXECUTIVE SUMMARY

Introduction

In 1987 the Clean Water Act was amended by Congress to require the regulation of point source discharges of storm water from industry and from municipal separate storm sewer systems serving over 100,000 people. In 1990 the Environmental Protection Agency (EPA) promulgated implementing regulations requiring, in part, National Pollution Discharge Elimination System (NPDES) permits for all storm water discharges associated with industrial activity. Since then, close to 150,000 industrial facilities have been permitted by EPA and the States. A key requirement of an industrial storm water general permit is the preparation and implementation of a pollution prevention plan by each regulated industrial facility. The purpose of the overall study was to evaluate the effectiveness of this storm water control approach in a way that would aid in improving storm water regulations as well as reducing the burden on business and industry.

This executive summary is subdivided into five parts: introduction, background, methodology, key findings and conclusions. The background provides a general description of the objectives, the methodology provides a summary of the study approach, the key findings highlight the most important results in bullet format, and the conclusions provide observations and recommendations based on the key findings.

Background

The Water Environment Federation (WEF) entered into a cooperative agreement with the EPA in 1994 to study the effectiveness of the NPDES Industrial Storm Water Permit Program. EPA's objective was to increase stakeholder involvement in setting priorities for this program by working with WEF and industry in obtaining input on the effectiveness of the industrial portion of the program. The objective was accomplished through WEF actively involving an industry group in the development of a survey to determine industry's perception of the effectiveness of the general permit requirements.

Methodology

The methods used to conduct this assessment employed the preparation of a questionnaire and its distribution to a broad cross section of industries which are affected by the program. The questionnaire was developed by a work group primarily comprised of representatives from industrial associations but also with input from state water pollution control authorities and EPA.

R0016766

A mailing list was constructed from a large number of independent data bases. EPA, which was the NPDES authority in 11 states at the time of the study, maintains a centralized data base of all those who have filed a Notice of Intent (NOI). And all but two States that have permitting authority also maintain similar data bases. These data bases contain various amounts of information about industries which have filed an NOI with EPA, or its equivalent with their appropriate State water pollution control authorities.

Of the 7,500 questionnaires distributed, 376 were undeliverable and 584 were completed and returned, giving an effective return rate of 8.2%. Responses were received from all geographic and climatic regions of the US, representing 237 different four digit SIC code classifications.

Key Findings

The following are the most relevant findings of the survey and are presented in bullet format for brevity.

- The USEPA and the States have been highly effective in providing technical assistance to industry on pollution prevention plan preparation through written guidance: 71.3% used government provided direction exclusively.

- There is some overlap of the requirements of the NPDES Industrial Storm Water Permit Program with other mandated requirements, such as the Spill Prevention Control and Countermeasures (SPCC) and Best Management Practices (BMP's) of the Clean Water Act.

- For those companies which expended resources for compliance with the storm water regulations typical costs were roughly :
  - $ 7,500 for pollution prevention plan preparation,
  - $ 2,500 for annual operating cost (35% incur no annual costs), and
  - $ 25,000 for capital improvements (61% incurred no capital costs)

- Of those respondents who had conducted water quality monitoring, a significant number (36.9%) felt that presently water quality data is not useful in determining whether pollution prevention plan components are successful; i.e. the data is either insufficient (15.7%) or inconclusive (21.2%).

- A subjective evaluation of whether water quality improvement or reduction in storm water runoff is possible resulted in a 50/50 split - half saying "yes" and half "no".

- There was almost an even distribution of respondents when asked if water quality improvements were worth the expenditures with 30.5% saying "yes", 31.2% saying "no" and 31.6% saying "maybe"; there were 6.8% said they didn't know.

- The pollution prevention plan components found to be the most highly effective in preventing pollution from storm water runoff were:
  - good housekeeping,
  - spill prevention and response,
  - preventative maintenance,
  - visual inspections, and
  - employee training.

- When the cost factor was included in the prior analysis by requesting the respondent to identify the most cost effective activities implemented two additional items were provided in the top rankings:
  - ponds and other containment structures, and
  - covered structures and improved storage.

- The pollution prevention plan components found to be the least effective in preventing pollution from storm water runoff were:
  - record keeping and reporting,
  - site mapping,
  - annual site compliance evaluations, and
  - raw material or product substitution.

- When the cost factor was included in the prior analysis by requesting the respondent to identify the least cost effective activities implemented by the companies, sampling and analysis topped the list.

- If the mandated storm water program were discontinued the vast majority (95.1%) would voluntarily continue at least part of the pollution prevention plan: 42.8% all of it; and 52.3% some of it.

- The most frequently identified significant obstacles which prevent the general permits program from being effective include:
  - costs to implement,
  - no follow through (lack of field inspections and enforcement),
  - regulations are complex, confusing and burdensome,
  - arid regions are not uniquely addressed, and
  - lack of company concern.

- Other "comments" received included:
  - hassle for small businesses,
  - other sources cause more pollution,
  - remote and small sites should not be controlled, and
  - program has high costs with low water quality improvements.

Conclusions

The following conclusions and recommendations are based on interpretation of the results of the survey, the key findings and analysis of the questionnaire data.

- There was a high level of response to the questionnaire, and an excellent representation of industrial sectors. The diversity of responses covered all identified variables such as: geographical distribution, gross income, physical plant size, number of employees, and hydrological conditions.
- The USEPA and the States which have primacy in the NPDES permit program have been very thorough in defining the major components of a storm water pollution prevention plan.
- Of those companies regulated by the Storm Water Permit Program 12.5% appear to be out of compliance with the requirement to have a pollution prevention plan.
- Companies which lease their facilities are less likely to comply with the requirement of having a pollution prevention plan than those companies which own their property.
- The cost of a storm water pollution prevention plan and its implementation seem reasonable for most companies although there is concern among small firms.
- Small businesses spend less money on compliance and are more likely to be out of compliance because they lack environmental staff and a clear understanding of the requirements.
- The subjective evaluation of water quality improvement or reduction in storm water pollution as a result of the program is debatable depending on how the data is viewed - 68% felt there is at least some improvement while 66% felt there is little or no improvement. Interpretation of "minor" improvement accounts for the difference.
- Based on the observation that only a very low percentage of the most cost effective storm water pollution prevention controls were in place prior to initiation of the program, the NPDES storm water program has been highly effective in encouraging controls to be implemented.
- The majority of respondents have implemented the plans on time. However, there appears to be about 12% per year increase in plan implementation. This may be attributable to new industries as well as existing companies which become aware of the requirements through enforcement or public awareness programs.

- There are several areas where EPA and the States may improve effectiveness. One of the primary areas is to increase emphasis on those components of the storm water pollution prevention plan that have demonstrated to be effective, such as: good housekeeping, employee training, preventative maintenance, visual inspections, employee training and annual site compliance evaluations.

- It may also be worthwhile to look at improving the efficiency of monitoring since a large quantity of expensive sampling and analysis data is being generated and perceived by industry as being the least cost effective element of the program.

- Consideration should also be given to improving the overall image of the storm water permits program through simplifying the regulations and following up with outreach, education and/or enforcement activities.

II. BACKGROUND

In the eleven states where EPA has NPDES permit program authority it is estimated that approximately 39,000 industrial and municipal dischargers in Phase I are covered by general permits to discharge storm water. It has further been estimated that over an additional 100,000 dischargers are in Phase I covered by states that have primacy.

A majority of these dischargers were required to implement pollution prevention plans by October 1, 1993, one year after the Notice of Intent deadline of October 1, 1992. Many industries have opted to be covered by EPA's multisector storm water general permit proposed November 19, 1993 and finalized on September 25,1996.

EPA is interested in increasing stakeholder involvement and consulting with its "customers" in setting priorities and regulations; and is beginning to look more to industry and its associations for input. Based on this new direction, EPA requested the Water Environment Federation to expand its outreach program under its cooperative agreement to study the general permit program, with a goal of increasing the participation of industrial and state government stakeholders.

The objective of the original project work plan developed in the FY 95 WEF grant project was to provide the Phase I industries (located in the states where EPA has permit authority) an opportunity to report to EPA on the effectiveness of pollution prevention plans used in the NPDES industrial storm water general permitting program and to provide EPA feedback on the success of the program. The approach of the original work was to establish a working group by inviting members of industrial associations, state water program administrators, and other individuals with special qualifications or interests in the regulations, to assist with the development of an industrial survey to be used to assess the effectiveness of the pollution prevention plans. During the early stages of that project, a survey form was completed and a small test survey was conducted.

In FY 96, WEF's grant was expanded. The objectives of this expansion were twofold: 1) to conduct a more broadly based study on the effectiveness of pollution prevention plans covering a wider selection of industries in <u>all</u> States; and 2) to assess whether or not it would be beneficial for industry to be allowed a "no exposure" exemption from the storm water permit program and, if so, examine possible mechanisms for implementation.

Since a portion of the FY 95 grant project had been completed, the original work plan was folded into and became a part of the revised work plan. The work completed under the FY 95 grant included formation of a small work group, development of an industrial survey form, distribution and collection of a limited number of test surveys, and preparation of a preliminary data base management system to analyze results. The expansion of the grant at this stage of the project, i.e. prior to full distribution of the survey, was fortuitous since the majority of the work involving data collection and analysis had not yet been initiated. The expanded requirements were able to take advantage of the survey developed and allow for improved efficiency of data collection and analysis using a professional survey firm.

III. QUESTIONNAIRE DEVELOPMENT

In order to develop a questionnaire that would most accurately reflect the concerns of industry and also result in a high response rate by industry, a working group comprised primarily of industrial representatives was established. The first meeting of the work group was held on January 31, 1995 at the Water Environment Federation Headquarters building in Alexandria Virginia. As a result of this working meeting, WEF was able to formulate a basis for the survey. The questions were put into questionnaire format and distributed to the working group for further refinement. Written comments were received on the form and after a second draft was developed, a conference call was held on March 20, 1995 to discuss the final details.

On completion of the final draft of the survey, it was recommended by the working group that a test survey should be sent out to a select group of recipients. The purpose of this test survey was to obtain the recipients' reactions to the effectiveness of the format, to determine the length of time required to complete the survey and to determine whether a good response could be expected. The test surveys were mailed to 15 firms and returned on April 28, 1995. The form was determined to require about 15 to 20 minutes to complete and the recipients made minor suggestions for refinements.

Shortly after this was completed, it was determined that the cooperative agreement would be expanded to include not only the eleven states over which EPA had jurisdiction, but all 50 states. In addition, it was determined to expand the scope to include an assessment of the "no exposure" exclusion. The expansion of the agreement caused some delays in progress while awaiting final approval. The next meeting of the working group was held on November 13,1995 to take one final look at the survey and finalize the cover letter. The final copy of the cover letter and survey questionnaire are presented in the Appendix. The questionnaire was mailed after the holidays in January, 1996 with a response date request of February 16, 1996.

Method of Approach Used for Questionnaire Distribution.

In order to obtain a good geographical distribution as well as diverse industrial activity representation, the following method of approach was used to distribute questionnaires.

First, it was necessary to obtain a mailing list of all industries in the United States that had submitted a Notice of Intent (NOI) or its equivalent to the controlling governing agency. These industries are the ones that must comply with the storm water permit requirements associated with preparation of storm water management plans.

EPA maintains a database containing all of the names and addresses of those firms which have submitted an NOI in the eleven states over which it maintains jurisdiction. For the remaining states (not including territories such as Puerto Rico and Guam), contact was made with each to obtain a similar database. While the majority of the states maintained some form of database, there was little consistency in the information, format or software used. Only two states did not maintain any data base; Vermont and West Virginia. And two others elected not to participate; Minnesota and Kansas. This level of participation gave the excellent geographical distribution that was desired.

The compilation of all of the data from 46 of the 50 states, after removing duplicates and incomplete records, resulted in a total of 76,286 separate industrial activities. It was determined that a mailing to 10% of the industries would result in a high level of confidence (over 90%) for this study, even with only a 5% response rate. Therefore, it was decided to mail 7,500 questionnaires.

In reviewing the databases obtained from EPA and the states, it was observed that the vast majority of records had identified industries by using SIC codes, so these were used to determine the distribution of questionnaires. Only the states of Hawaii, Iowa, Montana, Washington and one section of Pennsylvania did not have their databases formatted with SIC code designations.

While EPA has specifically defined by SIC code each of the industrial categories which must have an NPDES storm water permit, a few states require all industries regardless of SIC code to file an NOI and develop a storm water pollution prevention or management plan. Additionally, no state has been identified that will not accept an industry's application for an NPDES storm water permit because it does not fall into one of those SIC categories identified in the regulations. Some industrial activities submit a NOI and comply with the regulations even though they may not currently be required to do so. It is speculated that some do it out of lack of familiarity with the regulations and some do it as a precautionary measure to minimize the possibility of litigation.

It is recognized that some states have different requirements from those of the baseline EPA storm water permit program, however it was determined that the majority of those firms which submitted NOI's were required to meet the minimum standards established by EPA relating to development of storm water management plans. It was therefore concluded that since the thrust of this effort was to obtain as broad a representation as possible of all industries which may be affected by the EPA storm water permits program, all SIC codes (with NOI's or equivalent submitted) were included in the database for questionnaire distribution.

The selection of which firms to receive the questionnaire was performed in two steps. The first step was to obtain the distribution of the total number of industrial activities (NOI's) nationwide by state. For example, California had 10.84% of the total, New Jersey had 2.42%, Wyoming had 0.66%, etc. This data was then ranked by state, highest to lowest.

The second step involved using the percent of NOI's by SIC codes within each state and determining the number of questionnaires to be distributed to each based on the SIC code percent distribution within the state. For example, the State of California, which had 10.84% of the total, received 813 of the 7,500 questionnaires distributed.

The next step in the example was to distribute these 813 questionnaires within the State of California in proportion to the SIC Codes. The percent distribution of all SIC codes found in the state of California was made and the number to be mailed to each was determined. For example, if SIC code 0000 represents 4% of California's total, then 4% of 813 or 33 questionnaires should be sent to SIC code 0000 within California.

Using this approach, the number to be distributed to each state was determined and then the number to be distributed to each SIC code within that state was calculated. A quick check was made after distributing among the SIC codes within each state to assure that the total number for the state was correct.

Additionally, as a final check the distribution to SIC codes nationwide was also made. First, the total of all questionnaires to be sent to each SIC code for all of the states, as determined using the above approach for distribution, was made. The results were then ranked numerically in descending order. The same type of calculated distribution was made for each SIC code using the entire original data base. Once the percentage distribution was made, the 7,500 mailing list was used to make a quick check on the numbers obtained using the state distribution approach verses the national distribution approach.

On attempting to implement this approach, it was found that a further refinement of the method was necessary when using the four digit SIC codes for distribution of the questionnaires. In reviewing the actual data for a state with a small number of NOI's, it was determined that distributing questionnaires based on the four digit SIC codes would be a difficult task because of the small numbers falling within each SIC category.

One method considered was to distribute the questionnaires based on percentages of two digit SIC codes. This uses the rationale that two digit groups of SIC codes are similar enough to justify this method. While this is a good generalization for some major groups like SIC 16 - Heavy Construction; it unfortunately doesn't apply for many of the other majors like SIC 20 - Food and Kindred Products; i.e. there are few similarities among the operations of a slaughterhouse and grain milling; or vegetable canning, beverages, dairies and bakeries. Therefore, the refinement in the approach which was employed is as follows.

The four digit SIC codes were used for determining the distribution of questionnaires employing the same rounding approach which is used in math and sciences, i.e. if the decimal part of the whole number is .500 or greater the value is rounded to the next higher whole number and if the decimal fraction is less than .500 it is rounded to the next lower whole number. For example, 13.500 was rounded up to 14 and 13.495 was rounded down to 13. There was little problem with this process for States that had over 1000 in the data base, however a problem presented itself in states like Idaho that only had 235. Therefore, the following refinement was used.

In states with low numbers, the exact same approach was used for selecting the four digit SIC code distribution, however as was mentioned above, there were a large number of codes receiving between 0.5 and 1.5. Nevertheless, after rounding these values to whole numbers the total number to be distributed to the State in question was summed. If the total resulted in too many questionnaires being distributed because of the rounding error; the excess number over that desired was taken from the lowest values in a descending order list of SIC codes. For example, in the case of Idaho, using this selection method resulted in 28 surveys to be mailed. However the initial calculations reveal that only 23 were to be mailed to Idaho, resulting in 5 that must be deleted from the list. By ranking the original SIC code data in descending order from the largest number at the top to the smallest number at the bottom, the lowest five from the bottom of the list were removed and the balance was used for determining the mailing.

Similarly, if the final tabulation had resulted in only 20 on the list then an additional three would have to be added using basically the same approach, only adding the next three on the list. This method eliminated the problems associated with rounding small numbers and simultaneously had the least impact on the overall project objectives.

For the four states and the section of Pennsylvania which did not have SIC code designations in their databases, a completely random sample was taken for distribution of the appropriate number within each state/section.

IV. DISCUSSION OF RESULTS

The survey questionnaire was distributed to 7,500 industrial facilities throughout the United States among a diversity of industries which had filed a Notice of Intent or its equivalent under the NPDES Storm Water Permit Program. Of the 7,500 questionnaires, 376 were returned as non-deliverable. This results in 7,124 being delivered which is used as the base for calculating the "valid" response rate. Since 584 questionnaires were completed and returned this results in a "valid" response rate of 8.2%. The concept of "valid" response is used throughout the report and represents the percentage of those respondents that actually answered the question being analyzed not the total number returning the questionnaire. The response to this survey resulted in a 95 % +/- 4.04 % confidence level.

Responses were received from all geographic and climatic regions of the U.S. representing 237 different four digit SIC code classifications.

Industrial Classification

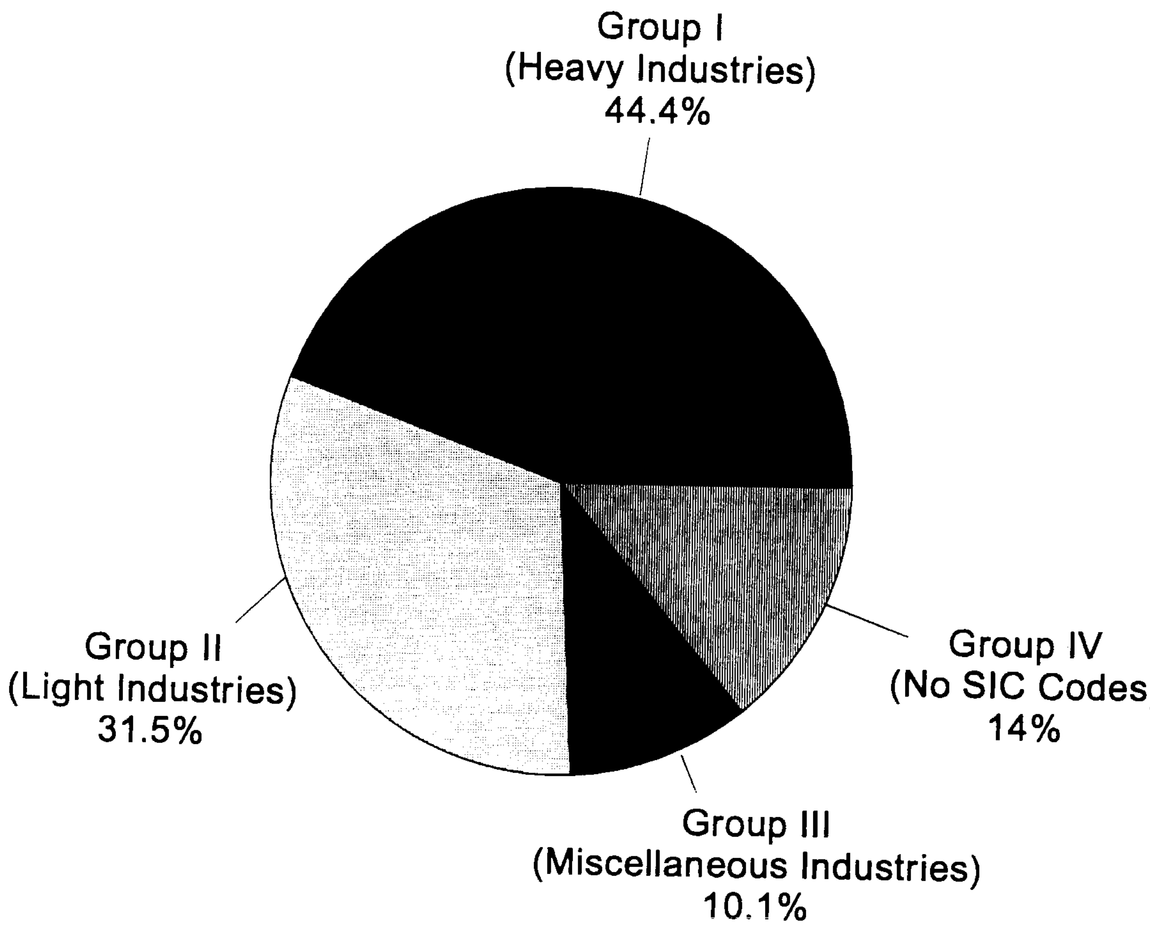
The questionnaire was distributed to industrial activities which had submitted a Notice of Intent or its equivalent to either the State or EPA. The assumption was made that any industry that submitted an NOI to these authorities was aware of its obligation and no attempt was made to validate whether the industry was in fact legally required to do so.

Question 1 asked "What is the primary and secondary standard industrial classification (SIC) code for your facility?" The industries were asked to identify themselves by a primary SIC code and a secondary SIC code. Of the 584 respondents, 82 did not provide an SIC classification. This resulted in 86% identifying a primary SIC code. Only 21% of those providing a primary SIC code also gave a secondary SIC category.

Those industries providing a primary SIC code in the multisector group of industries specifically identified in the Clean Water Act Section 122.26(b)(14)(i) through (x) made up 44.4 % of the respondents and were grouped into a category called Group I for convenience and to facilitate construction of diagrams. Those industries falling under the definition of Section 122.26(b)(14)(xi), i.e. the so called light industries which were allowed the "no exposure" exclusion (before it was remanded to EPA) if it applied to their facility represented 31.5% of the responses and were identified as Group II. In Group III, Miscellaneous, 10.1 % of the responses were received from industrial activities which were in SIC categories not specifically identified in Section 122.26(b)(14). And Group IV included those respondents which did not provide an SIC code. They represented 14.0 % of the responses.

Of the thirteen companies which provided a primary SIC code that fell within Group III, the Miscellaneous group, and also listed a secondary SIC; only three fell into Group I, one fell into Group II and ten, once again, fell into Group III. A pie chart entitled "Standard Industrial Classification Codes" presents the distribution of respondents by Group.

Standard Industrial Classification Codes



Question 1

Three possible explanations were identified for why a company fell into the Group III category: (1) it was located in a state which required all industries to submit an NOI regardless of SIC; (2) the company management felt more comfortable by having a permit whether it was required or not; (3) the industry misinterpreted the requirements. Regardless, it was assumed that all respondents had complied with at least a portion of the regulatory requirements and had valuable input into the survey. Therefore, none were eliminated because they fell into the miscellaneous group. Additionally, those which did not provide an SIC code were also included in the analyses for the same reasons.

Description of Facilities, Staff and Storm Water

Question 2 asked "Concerning industrial storm water run-off, how many facilities are under your responsibility?" The purpose of this question was to determine typically how many industrial facilities an environmental manager may have to control under the storm water program. It was also asked to establish the basis for answering the balance of the questions on the survey as called for in the note preceding Question 3, which states "If you are responsible for more than one facility, answer the following questions based on only one (your primary) facility."

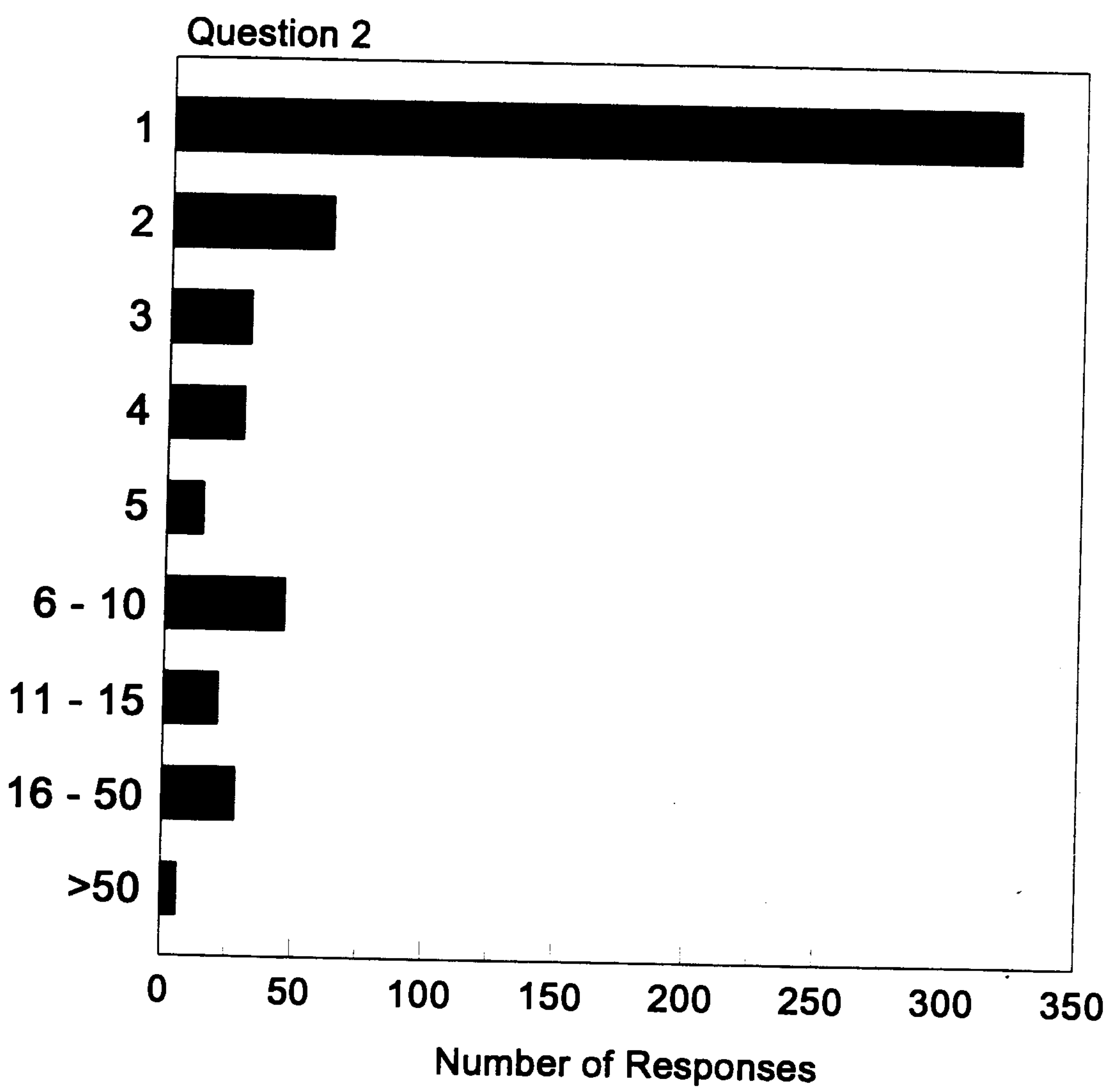
The analysis of the responses to Question 2 are as follows. Slightly over 76% reported that they had environmental staff, even if it was only a part time position. From this response it can be concluded that the majority of individuals who completed the survey questions were knowledgeable about environmental programs.

Over half (57.8%) of the respondents stated that they had responsibility for only one facility. Further, 80.0% had responsibility for four or fewer facilities. This indicates that for the majority of facilities the individual filling out the questionnaire was in all probability sufficiently familiar with the details of his or her primary facility to answer the questions accurately. Only 22 respondents did not answer this question. The chart entitled "Number of Facilities under Respondents Responsibility" presents the distribution of the number of facilities managed by the respondents.

Question 3 requested specific information on the size of the facility; namely the number of full time staff, an estimate of the acreage of the facility, and the number of environmental staff. Although the questionnaire form inadvertently included a blank after the generic question title "What is the size of this facility?", most people ignored the blank and correctly answered the question using the descriptors given in the subsequent parts of the question.

The first part of Question 3 requested the estimated number of full time employees at the facilities. There were 516 respondents that provided an estimate of the number of employees which means that 68 did not respond to this part of the question. The range of full time employees which represented the largest percentage of the distribution was between 1 and 25 with 36.6% falling with those margins. Slightly over half (50.4%) of the

Number of Facilities Under Respondents' Responsibility



R0016779

facilities had between 1 and 50 employees, while 9 facilities (1.7 %) reported no employees. The latter cases were probably unstaffed operations such as storage facilities, or natural gas or oil pumping facilities. There were 175 facilities or 33.9% which reported over 100 employees. This demonstrates, using another parameter, that there was considerable diversity in business sizes responding to the questionnaire. The diagram entitled " Number of Full Time Employees" presents a histogram showing the distribution of number of employees.

The responses to the second part of Question 3 on the size of the facility as measured by the acreage varied greatly. There were 497 responses to this part of the question which means that 87 did not provide the land size. The range of facility size which represented the largest percentage of the distribution was between 1 and 5 acres, with 32.2% of the respondents falling within these areas. Only a small percentage (3.8%) had less than one acre. Another 15.7% fell between 5 and 10 acres and 18.7% fell between 10 and 25 acres. As a percentage of the total, the majority of the facilities (70.4%) were located on less than 25 acres. It should not be overlooked that there were 105 facilities which responded that had over 50 acre facilities. Review of the diagram entitled "Estimated Acreage of Facility" gives a good indication that a very wide distribution of facility sizes were represented in the survey.

The portion of Question 3 which showed the most interesting results was that related to the number of environmental staff responsible for the facilities. While 81 did not respond to this part of the question, a significant 120 respondents or 23.9% stated that they had no environmental staff. And not including this 23.9%, about half (50.9%) said they had one or less than one (part time) environmental staff. The majority (53.4%) of those with no environmental staff were small businesses, which represents about 30% of all small businesses. The histogram entitled "Number of Environmental Staff" presents the results.

Question 4 addressed ownership of the property on which the facility was located by asking if the property was either owned or leased. The objective of this question was to determine if those who lease property are more or less likely to prepare a storm water pollution prevention plan. The hypothesis was that if a facility did not own its property it may perceive that it does not have to comply with requirements that are primarily associated with land they don't own.

Only 50 respondents did not answer Question 4. As shown on the pie chart entitled "Facility Property Status", the response showed that the vast majority (80.3%) of companies owned as opposed to leased the facility or the property. The analysis testing the hypothesis showed that for those who lease property, 27.6% said (in response to Question 9) that they either didn't have a plan (21.9%) or they didn't know if they had one (5.7%). For all practical purposes, all of these facilities can be concluded to have not prepared a storm water management plan.

This percentage is substantially greater than the 18.7% of the facilities which owned their property and indicated that they either did not have a plan (15.2%) or didn't know if they

Question 4

had one (3.5%). It appears that industrial activities which lease their facilities have a more relaxed approach to complying with the storm water management plan requirements than those who own their facilities. In other words the data appears to validate the hypothesis.

It is speculated that many of those who lease industrial facilities have misinterpreted their responsibilities to comply with environmental regulations. This could stem from the fact that many leasees are restricted from making modifications to the grounds, without written consent from the owner. This gives the impression to the leasee that contamination originating from surface runoff is not their responsibility. Although preparation of a pollution prevention plan does not necessarily require alteration of the property, the foregoing misperception may carry over into the plan preparation requirement.

Question 5 was developed to determine which companies were small businesses so that additional analyses could be performed with this group. The question specifically asked "Is your company categorized as a small business?" The choices of answers were yes, no and don't know. If the respondent answered yes, it was requested that they provide the basis for that determination.

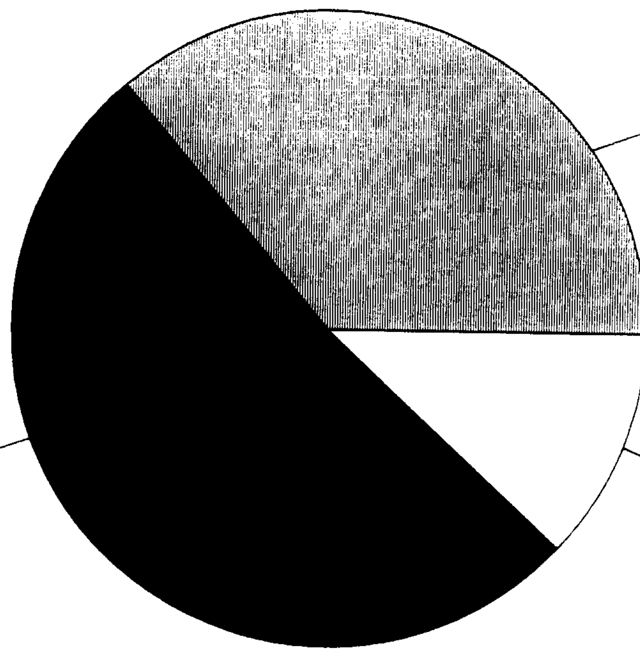
Of the 579 respondents to this question, the majority, 51.8%, stated they were not a small business enterprise; another 36.3% said they were and 11.9% said they didn't know. Only five respondents did not answer this question. A pie chart entitled "Is the Company a Small Business?" displays these results.

During the development of the questionnaire, it was suggested that the Small Business Administration (SBA) definition of "small business" be utilized. It was pointed out that the definition varies based on SIC code and is inconsistent. It was also noted that most small businesses wouldn't know the definition of small business for their SIC code unless they were familiar with a federal government program. It was concluded that anyone who knew the SBA definition for their industry would use it in answering the question but many others who were legitimately small businesses would simply not answer the question because they had never used any of the SBA programs.

Even though the question on why the industry considers itself small was simplified, less than half (40.9%) of those who claimed to be small businesses stated why. One of the respondent's answer to this question, "because it is", probably summarizes the answer for most of those who did not state a reason.

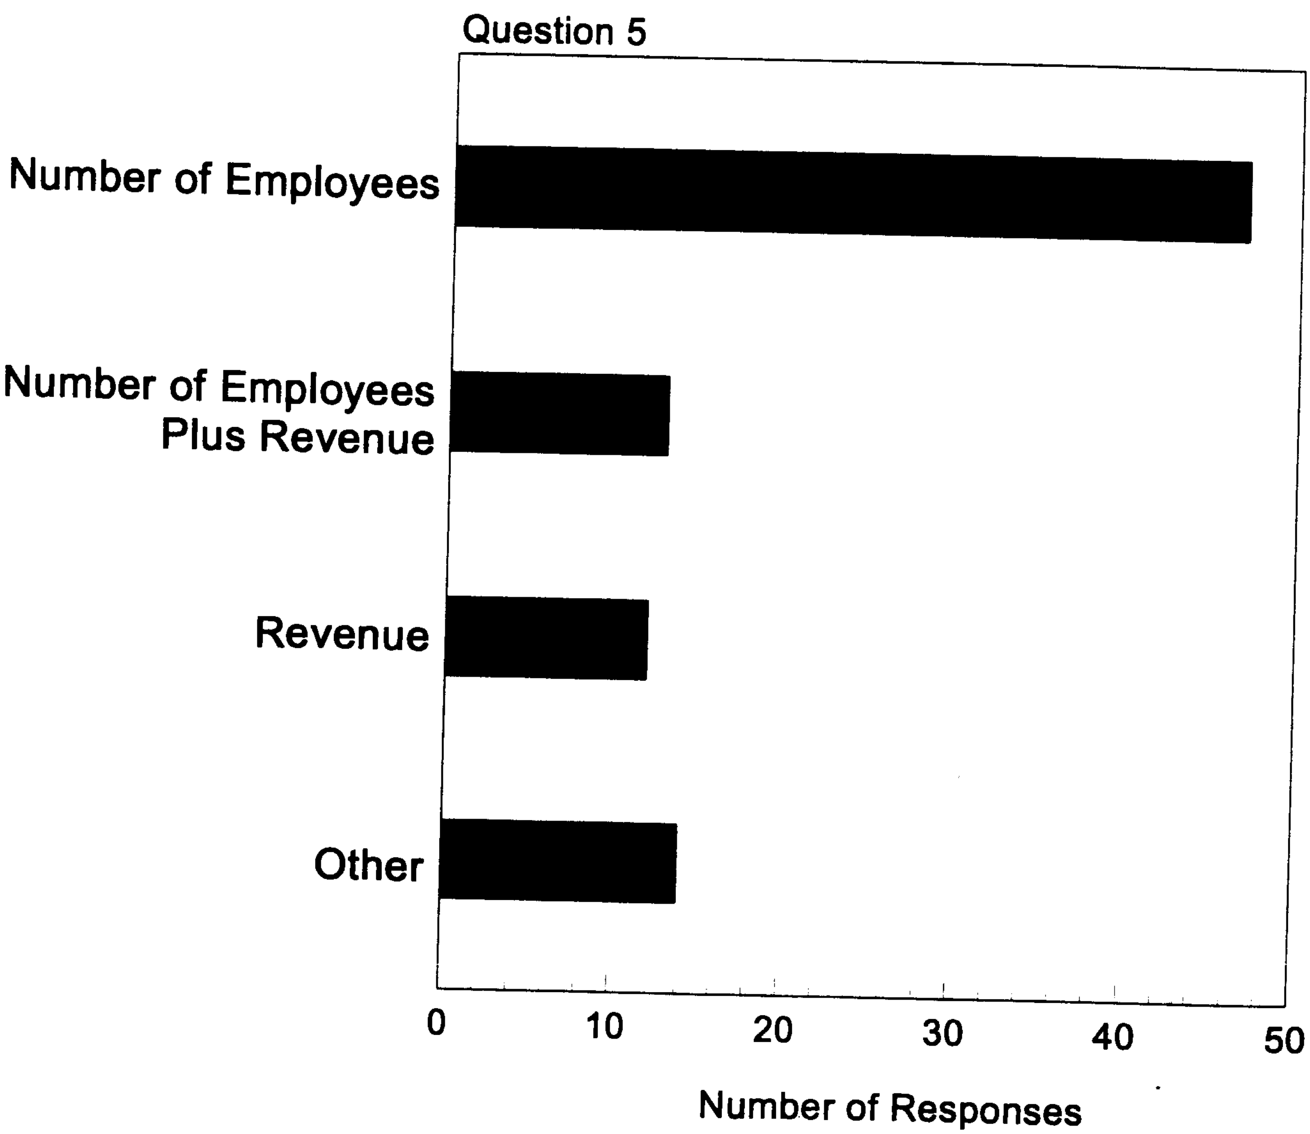
Of the 210 respondents which indicated they were a small business enterprise, only 86 or 40.9 % provided a reason why they were classified as small. The normal basis for determining whether a company is small or not is number of employees and/or annual revenues. Those providing a basis for being classified small were distributed as follows: 54.6% were based on number of employees only, 13.9% were based on revenues only, 15.1% were based on number of employees and revenues and 16.3% provided other reasons. A histogram entitled "Definition of a Small Business As Based On:" presents a distribution of the rationale provided by the companies for why they are a small business.

Is the Company a Small Business?



Question 5

Definition of a Small Business As Based On:



As stated before, one of the main reasons for selectively identifying small businesses was to be able to separate analyses of responses and determine if they were significantly different from the rest. The individual analyses for small businesses are addressed in each question for which it was determined such an analysis might provide valuable information.

Question 6 asks "Does storm water run off this property?" and provides five choices for how it may run off: ditches, trenches, pipes, other point sources (with a request to identify the source) and <u>only</u> surface flow, i.e. no point sources. The respondents were permitted to answer as many of the choices as were applicable to their facility. In retrospect, this question would have been more clearly stated as; "how is storm water conveyed off your property." Also, some clarification should have been made on the definition of a point source for those not familiar with water pollution control terminology. The results are presented in the histogram entitled "Storm Water Runoff Conveyance Structures."

It's clear from the responses to Question 6 that many of the respondents did not understand the question or possibly the choices of answers, because 210 answered the question stating that they had <u>only surface flow</u> and therefore no point sources. If this were the only choice selected (as it should have been to be technically correct) it would mean that all of those 210 industrial activities were not subject to the NPDES storm water regulations. In addition, of those 210 that stated they had only surface flow, 59 or 28.1% stated that they had one or more of the other choices of point source discharges. This is a contradiction in the definition of choices given.

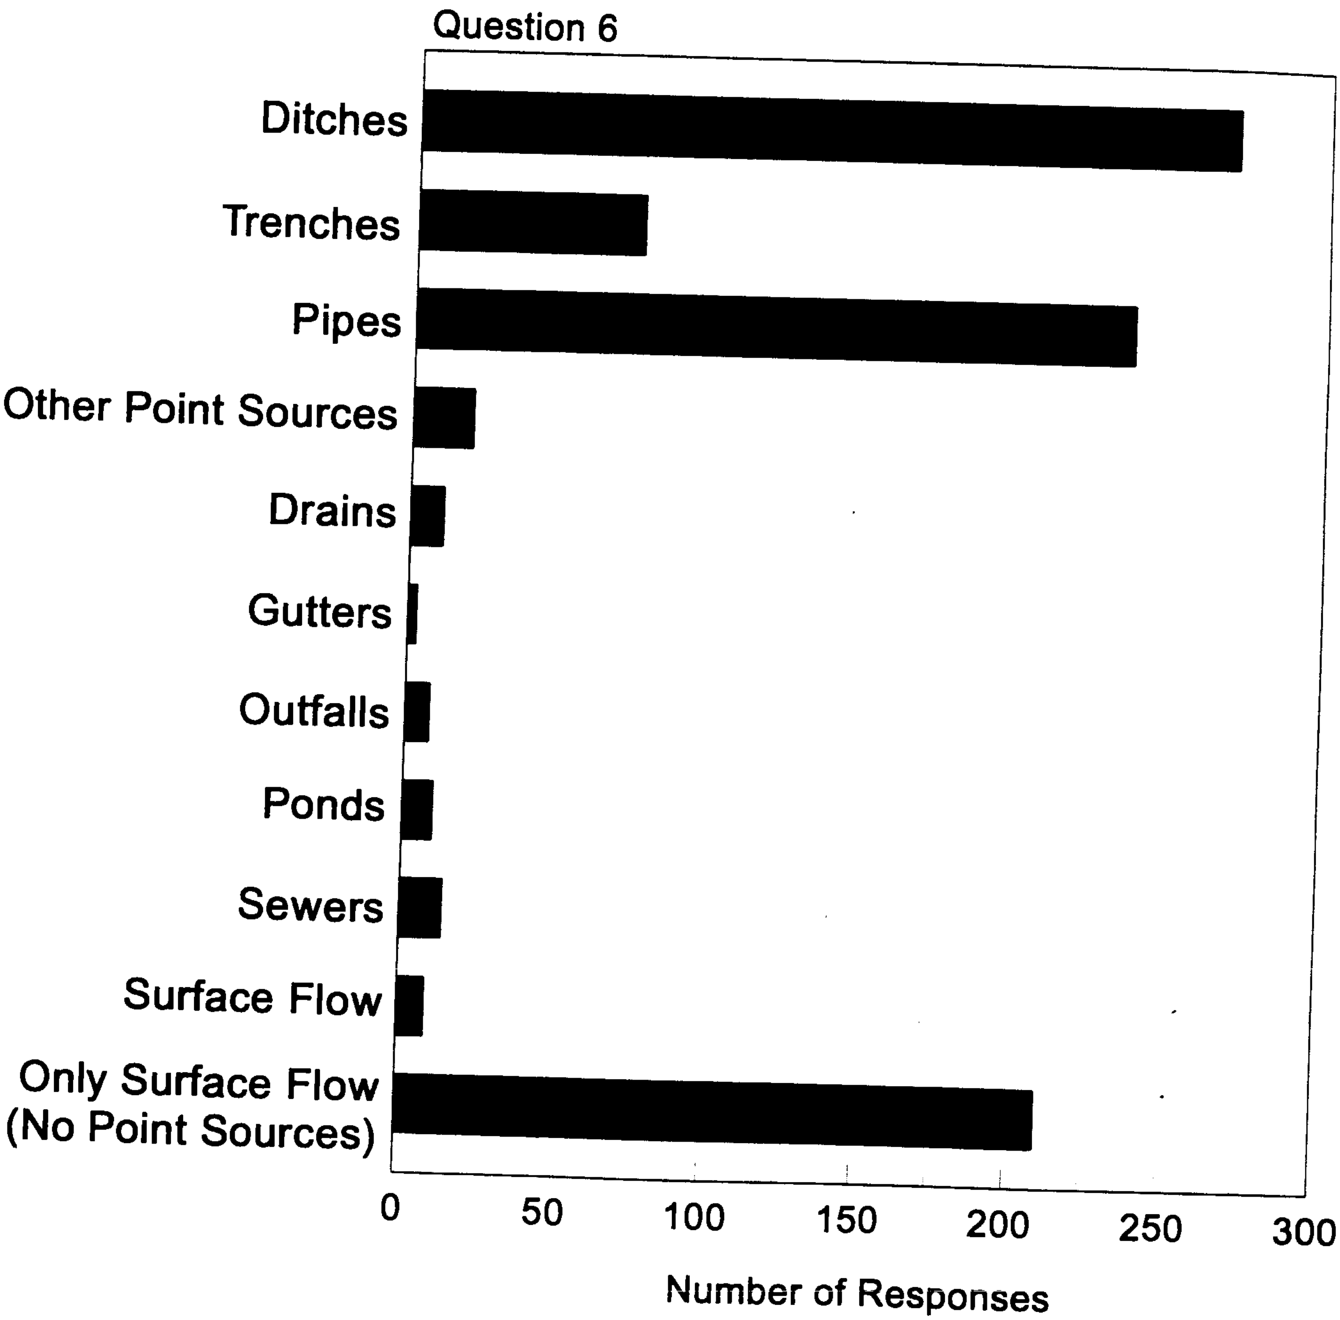
Of the 151 that chose the selection indicating that they had surface flow only and did not also indicate they had other point sources of storm water runoff, 30 (20.0%) stated that they did not have a storm water related pollution prevention plan for this facility and 9 (6.0%) stated they didn't know if they had one.

Question 7 was designed to gather information regarding climatological data to assure there was a representative sample of all weather conditions. It specifically asked "What is the average annual rainfall at your location?" Choices given were presented in 10" increments, i.e. 0 - 10", 11"- 20", 21" - 30", 31" - 40", 41" - 50" and over 50". As can be seen in the histogram entitled "Average Annual Rainfall", the responses represent the full spectrum of hydrological conditions experienced throughout the United States. Analysis of the data resulted in a skewed normal distribution with a median rainfall of 25.75 inches per year and a mode of 18 inches per year. Only 49 facilities did not respond.

Specific Regulatory Requirements

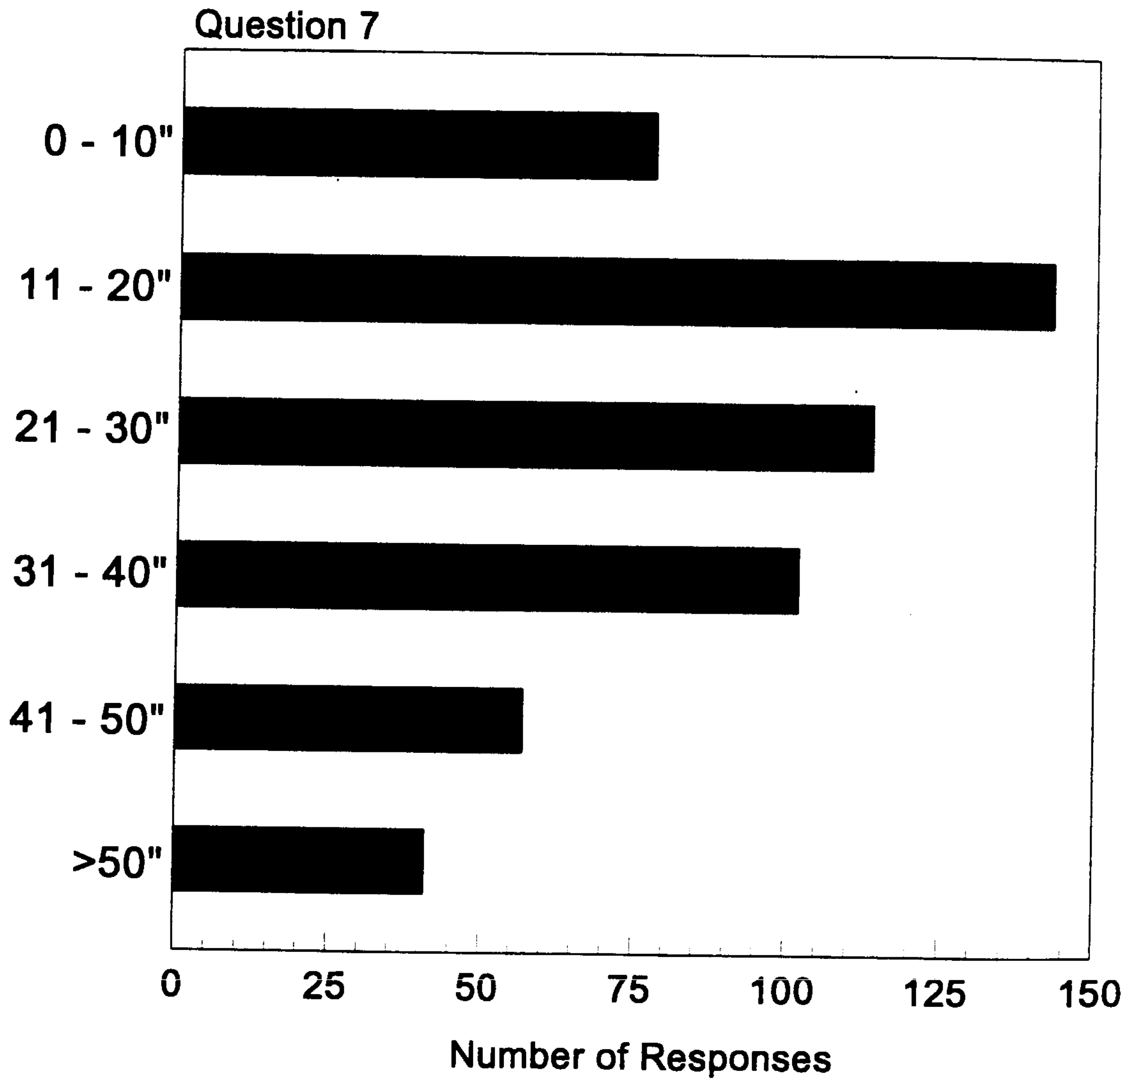
Question 8 was developed to determine how many or what percentage of those being regulated under the storm water permits program were already having to meet perhaps more restrictive hazardous waste requirements under EPCRA. This question specifically asked "Is this facility required to meet the reporting requirements of EPCRA Section 313 regarding 'water priority chemicals'?"

Storm Water Runoff
Conveyance Structures



R0016789

Average Annual Rainfall



R0016790

The answers provided some interesting but not surprising results. Only 6 respondents didn't answer the question. Of those that answered it, more said they didn't know if they were required (24.6%) than said yes (20.6%). It appears from this response that a large percentage of industrial facilities (75.4%) which have requirements under the storm water permits program do not have requirements under EPCRA. The pie chart entitled "Facility Required to Meet EPCRA Section 313" presents the distribution of answers.

The NPDES storm water permit program requires that each facility develop a storm water pollution prevention plan. The major goal of this project is evaluating the effectiveness of the program and relies on gathering information on the plan itself. It is recognized that many companies which have submitted an NOI or its equivalent may not have met the requirement of plan preparation yet.

Question 9 was used to separate those facilities which had a storm water management plan from those who did not. Separating those who had a plan allowed the survey to assess more accurately the effectiveness of the program by developing questions that related specifically to those industrial activities which had complied with the requirements. Additionally, it allowed a separate set of questions to be asked of those who had not prepared a plan; to perhaps determine why they had not. Question 9 specifically stated "Do you have a storm water related pollution prevention plan for this facility?" The choices of answers were; yes, no and don't know. Only two facilities did not respond to this question. A pie chart on the following page presents the distribution of responses to this question.

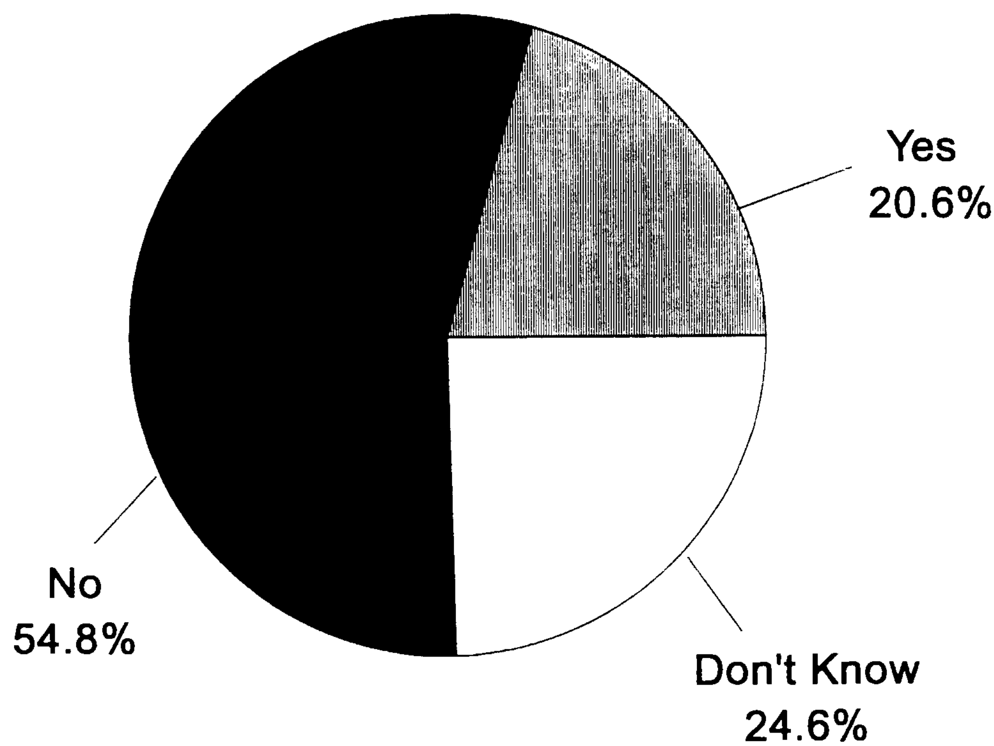
There were 124 respondents or 20.3% who stated that they either did not have a storm water related pollution prevention plan for their facility (101 or 17.4%) or didn't know if they had one (23 or 3.9%). In reviewing the information provided by small businesses in response to this question, it was observed that a higher percentage of facilities replied they did not have a plan (23.0%) or didn't know if they had a plan (7.2%). In fact, of the total of 23 facilities which indicated that they didn't know if they had a plan, 15 were small businesses. This result shows that small businesses tend to not understand the regulatory requirements as well as larger businesses.

Further analysis of those without a plan was made utilizing Questions 10 through 15 which were contained in Section A of the questionnaire. Those who responded that they had a plan were requested to answer Questions 16 through 36 contained in Section B of the questionnaire.

Facilities with No Storm Water Management Plans (Section A)

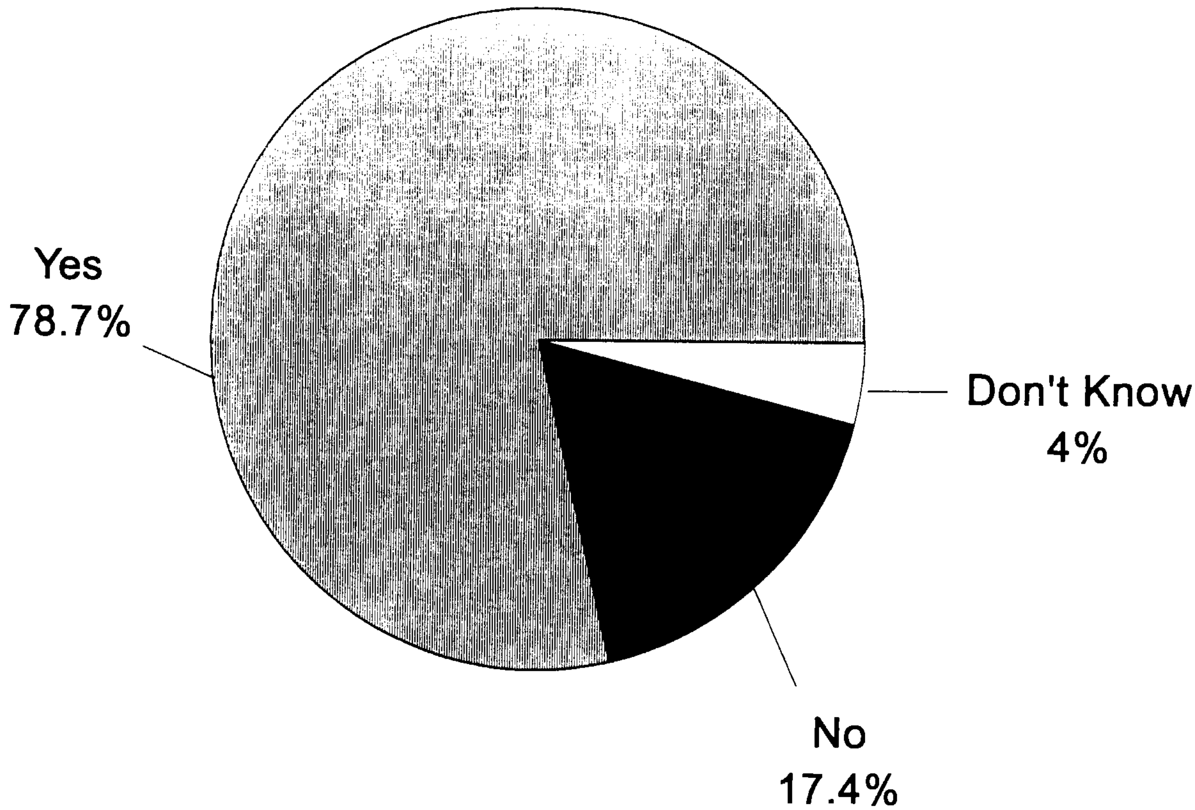
Probably the most important requirement of the storm water permit program is that a facility prepare a storm water management plan. The obvious first question to ask a company which does not have such a plan is whether the facility is regulated. Question 10 asked "Is your facility regulated by the storm water permit program?" The choices of answers were yes, no, and don't know.

Facility Required to Meet EPCRA Section 313



Question 8

Do You Have A Storm Water Related Pollution Prevention Plan?



Question 9

Only three did not respond to this question. And of those that did respond 73 (60.3%) said they were regulated, 27 (22.3%) said they were not and 21 (17.4%) said they didn't know. This data indicates that 58 or roughly 10% of all of the facilities that are in the NOI data bases are either not regulated or don't realize they are regulated by the storm water permit program. A pie chart entitled "Is Facility Regulated by the Phase I Storm Water Permit Program" presents the results of this question.

The next obvious question is whether the industrial activity modified its facility in order to eliminate the need for compliance. Question 11 asked "Did you or will you modify your facilities in order to eliminate the need for compliance with regulations?" There were 109 responses to this question with 24 firms (22.0%) responding yes. Of those 24, fifteen replied yes to Question 10 indicating that if they had modified their facilities to remove themselves from the program, they were either still regulated or will be modifying their facilities sometime in the future to remove themselves from the program. Five of those who said they didn't know if they were being regulated nevertheless said they had modified or will modify their facilities to eliminate the need for compliance.

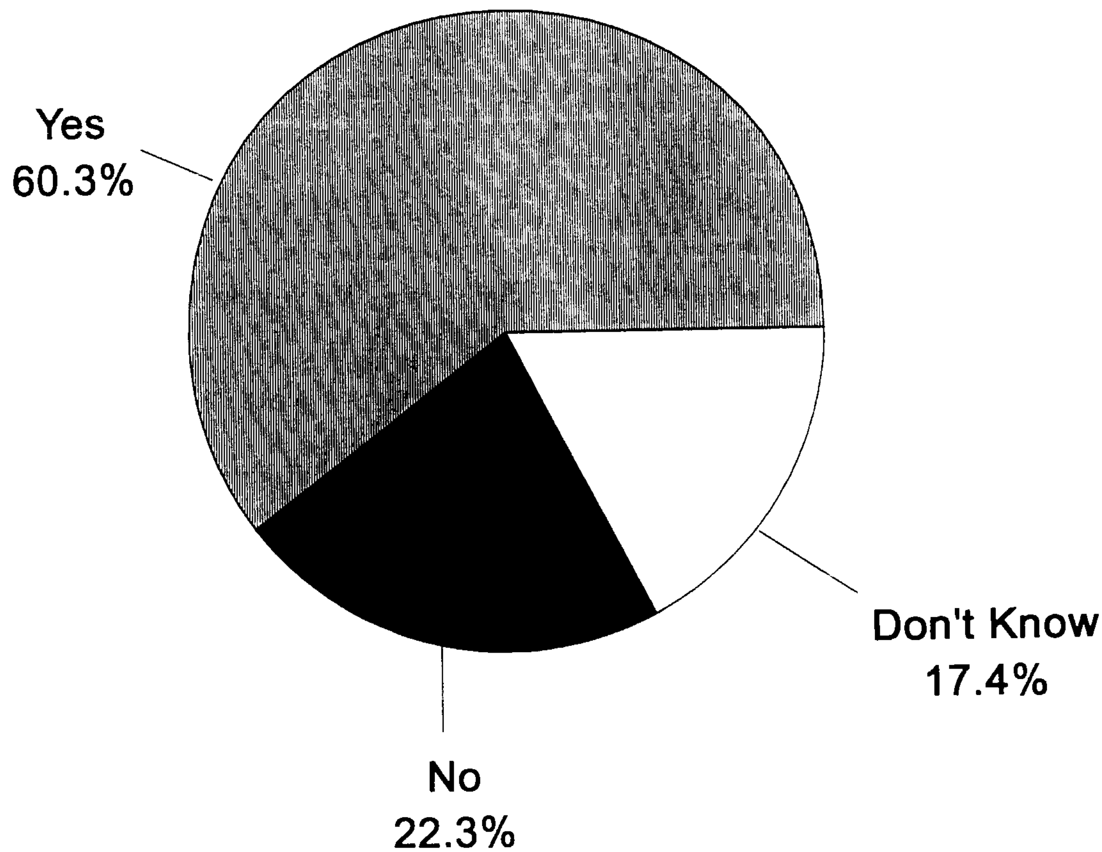
An important follow-up question to be asked of those who modified or plan to modify their facilities in order to avoid the need for compliance relates to how much companies are spending to opt out of the program through the "no exposure" exemption. Question 12 asked "If the answer to Question 11 is yes, how much did it or will it cost? In what year?"

Of the 24 that indicated they had modified their facilities, only 11 provided the cost of modifications. The range was from $1000 to $20,000,000. The latter is planned to be expended in 1997. The only other figure that was given to be expended in the future was $60,000 in 1998; the remainder represented expenditures which had already taken place, most of them occurring in the past three years. Dropping the extremes, i.e. the two highest and two lowest values gives a range of $5,000 to $60,000.

Some of the more expensive projects are probably the total investment in storm water pollution control, as opposed to construction exclusively to eliminate contact with storm water to take advantage of the "no exposure" exclusion. This is clearly a possibility since none of those who invested in facilities to eliminate the need for compliance actually reported that they were not regulated by the storm water permit program and only one reported it didn't know if it was being regulated.

Question 13 asked, "If your facility is regulated by a storm water permit program, who is the lead permitting authority?" The choices of answers were: Environmental Protection Agency - Region _____; State of _____; Local Government Authority (specify) ______; and Other (Specify) _______. This question was included in order to obtain knowledge of the geographical distribution of the respondents and to determine if there were any patterns to facilities that did not have a storm water management plan.

Is Facility Regulated by the Phase I Storm Water Permit Program?



Question 10

In response to this question, of the 124 respondents who said they did not have a storm water management plan, only 66 or 53.2% indicated who was the lead permitting agency responsible for their industrial facility. This left 58 facilities which did not respond. One of the reasons for this is that 48 facilities responding to Question 10 indicated they were not regulated or didn't know if they were regulated by the storm water permit program and therefore were not requested to answer Question 13. The reason for the balance of 10 not responding was either because the facility did not want to reveal the information or, more likely, because they didn't know or weren't sure of the lead agency.

The results of Question 13 revealed that 15.2% of the facilities fell under EPA authority, 81.8% fell under State authority and the remaining 3% were equally split between local government and other authorities.

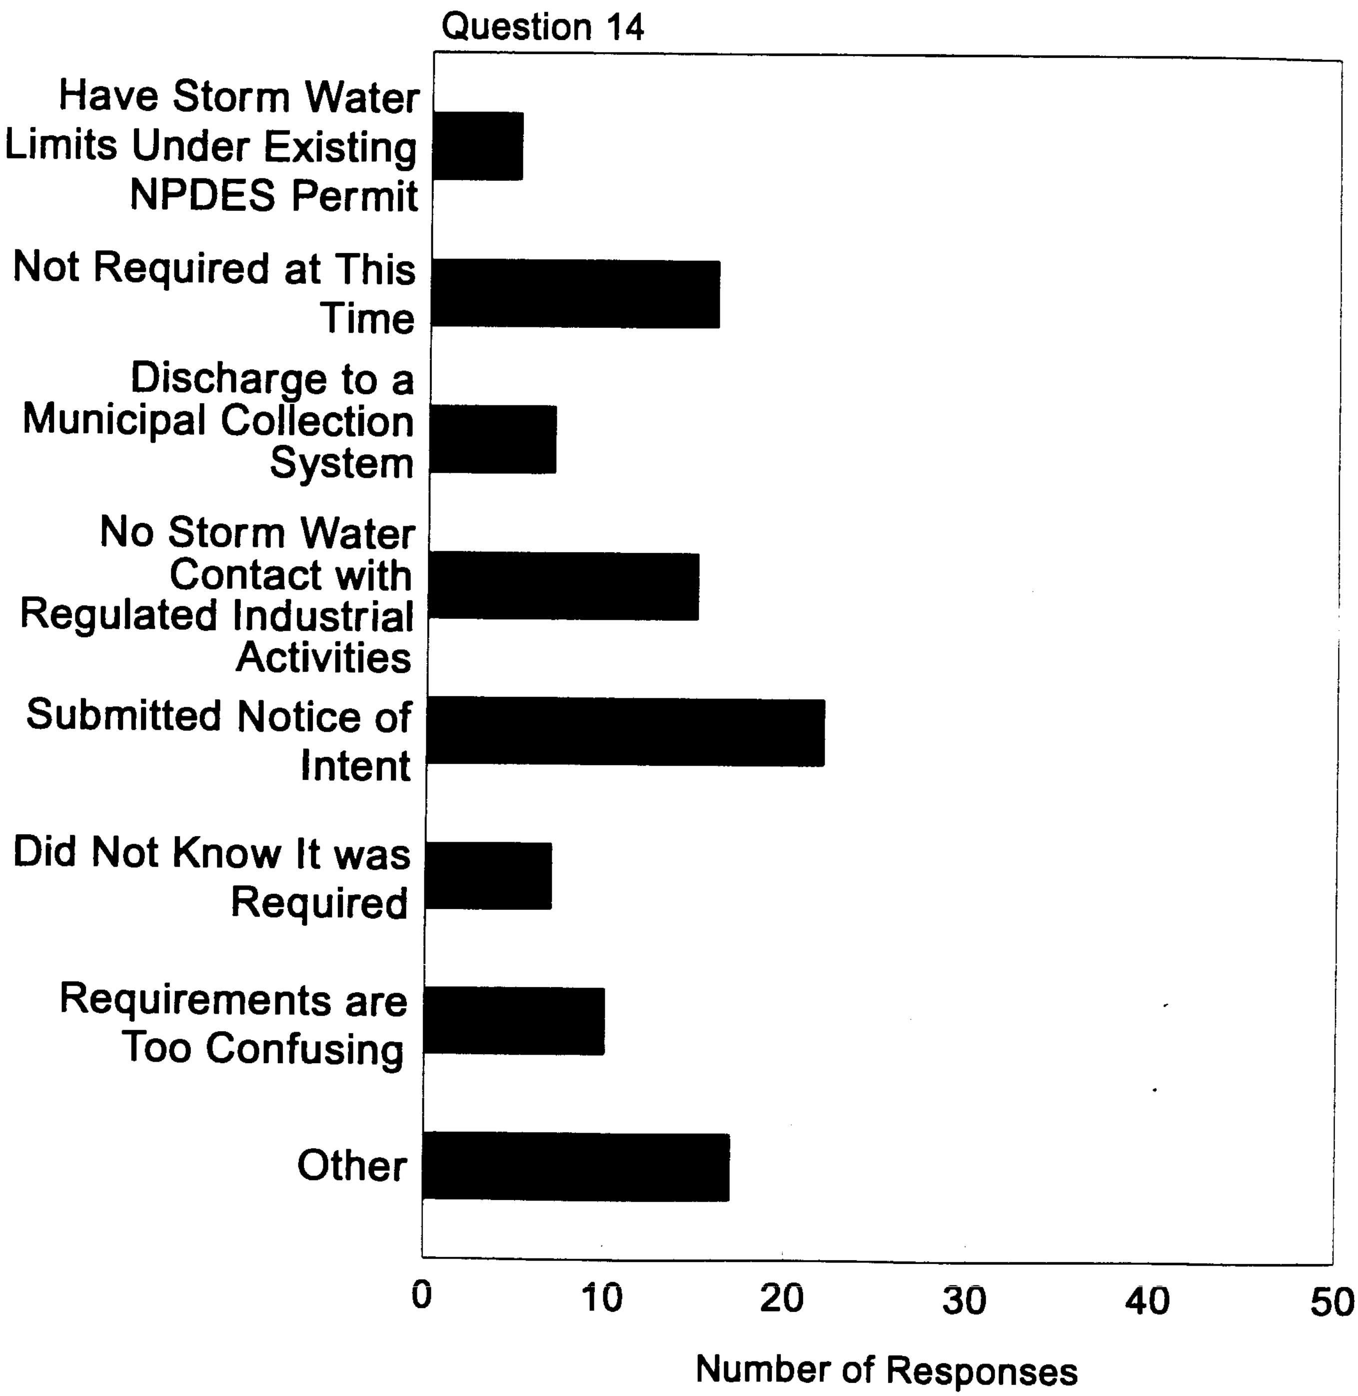
It appears based on the response to the questions in Section A and Question 10 in particular that 73 or 12.5% of regulated respondents may be out of compliance with the regulations requiring a storm water management plan. In order to determine why various industrial activities have not prepared a storm water pollution prevention plan, Question 14 was developed asking specifically, "Why have you not prepared a storm water pollution prevention plan?" The choices given were: have storm water limits under existing NPDES permit; not required at this time; discharge to a municipal collection system; no storm water contact with regulated industrial activities; submitted Notice of Intent; did not know it was required; requirements are too confusing; and other (specify).

It appears from the responses to this question that most firms are confused by the requirements. Of the 73 industrial activities that are probably required to have a plan but don't have one or don't know if they have one, 65 provided one or more reasons as to why. The most frequently chosen reason for not having a plan was that the facility had filed a Notice of Intent (22.2%). However, filing an NOI does not alleviate the firm of its responsibility to prepare a storm water management plan. While this choice perhaps technically should not have been listed, it illustrates a lack of understanding of the program requirements.

The second most frequently selected choice was "other" with 17.2%. By far the most frequently identified reason for not having a plan was that one was being prepared or reviewed or in some other intermediate stage of completion. Following this was the selection of "not required at this time" with 16.2%. Apparently, some states have established a system of priorities that give certain industrial activities more time to comply with the storm water management plan implementation. Next was "no storm water contact with regulated industrial activities" with 15.2%. These, plus the balance of reasons for not having a plan, are presented in the pie chart entitled "Reason(s) for Not Preparing a Storm Water Pollution Prevention Plan."

An analysis to determine why small businesses did not prepare a storm water pollution prevention plan revealed the following reasons as being the most frequently selected:

Reason(s) for Not Preparing a Storm Water Pollution Prevention Plan



R0016797

requirements are too confusing, one is not required at this time and there is no storm water contact with regulated industrial activities.

The final question in Section A, Question 15, asked, "Any comments?" from those industrial activities which did not have a pollution prevention plan. There were 19 comments received. The majority of these indicated that either the plant did not need a plan or one was being prepared. A few other comments questioned the value and effectiveness of the storm water permits program indicating it was a waste of time or that resources could be better spent elsewhere.

Facilities with Storm Water Management Plans

There were 458 respondents to Section B of the questionnaire relating to those industrial facilities which had storm water management plans.

Question 16 asked, "Who is the permitting authority for this facility's storm water permit?" The choices of answers were: Environmental Protection Agency - Region ______; State of _______; Local Government Authority (specify)______; and Other (Specify) _______. This question was included in order to obtain knowledge of the geographical distribution of the respondents and to have the ability to obtain correlations with responses to other questions. The distribution of permitting authority was EPA 19.0%; States 73.3%, Local governments 5.2% and other authorities 2.5%.

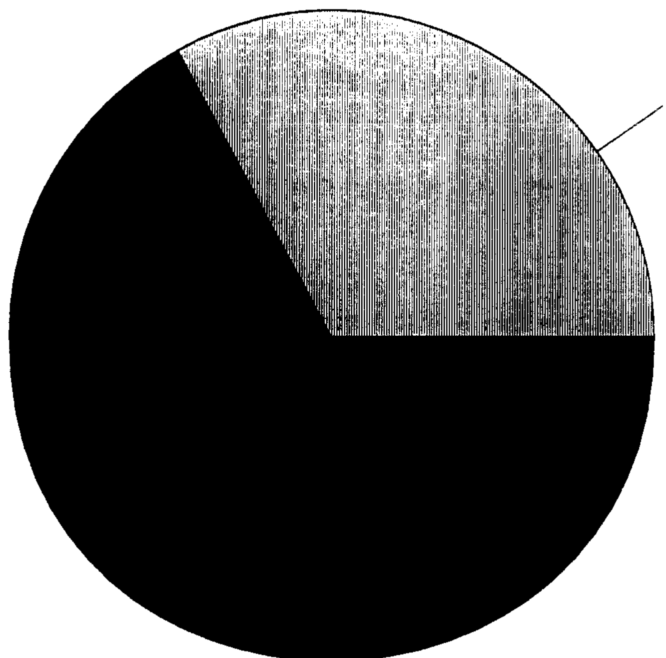
The next question was asked to determine if facilities would have had any pollution concerns with storm water had the program not existed. Question 17 asked, "prior to the Storm Water Permit Program, did this facility have any experience with either voluntary or regulation required pollution prevention plans that directly affected storm water?" The choices given were yes or no.

Only 9 respondents did not answer this question and of the 449 that did, the vast majority, 301 or 67.0% said no. When looking only at small businesses, the "no" response increased to 73.0%. This is a clear indication that the program alerted the industrial community to the fact that there is serious concern over storm water pollution. On the other hand, with148 or 33.0% responding yes to this question, there is evidence that other pollution control programs have definitely had an impact on storm water. A pie chart entitled "Prior Experience with Voluntary or Regulated Storm Water Plans" presents the distribution of the answers to this question.

The logical next question was to determine if there are apparent regulatory overlaps, and if so, specifically which mandated requirements overlap the storm water program. Question 18 asked, "Does this facility's storm water pollution prevention plan overlap with other mandated requirements?" The choices given were yes, no and don't know.

The second part of Question 18 asked, "If yes, which requirements?" The choices given were: best management practices plan (Clean Water Act - Nonpoint Source), waste

Prior Experience with Voluntary or Regulated Storm Water Plans



Question 17

minimization plan (CERCLA/SARA), Spill Prevention Control and Countermeasures (SPCC), and other (specify). Since the choices are not mutually exclusive, multiple choices were optional.

The responses to this question were observed to be somewhat inconsistent with those of Question 17. There were only 148 who said yes to Question 17 - stating there was either a voluntary or regulatory requirement for pollution prevention plans that directly affected storm water. Yet, when asked basically the same question in Question 18, nearly 100 more respondents: 257 or 56.4% answered that there was overlap. Of the remaining, 132 or 28.9% said there was not, and 67 or 14.7% said they didn't know. Only 2 respondents didn't answer this question.

A possible explanation for this inconsistency is that Question 18 gave a list of regulatory requirements that could conceivably overlap with storm water requirements; thus providing suggestions to the respondent which may not have previously been considered.

Even though the respondents may have been prompted to answer yes by making them aware of the programs which might overlap; still almost half (43.6%) said there was none or they didn't know of any. This would still indicate that many industries were not previously aware of the fact that storm water pollution was an environmental concern. A pie chart presenting these results is entitled "Does This Facility's Plan Overlap with Other Mandated Requirements". The reader's attention is drawn to the contrast between the responses to Question 17 and Question 18.

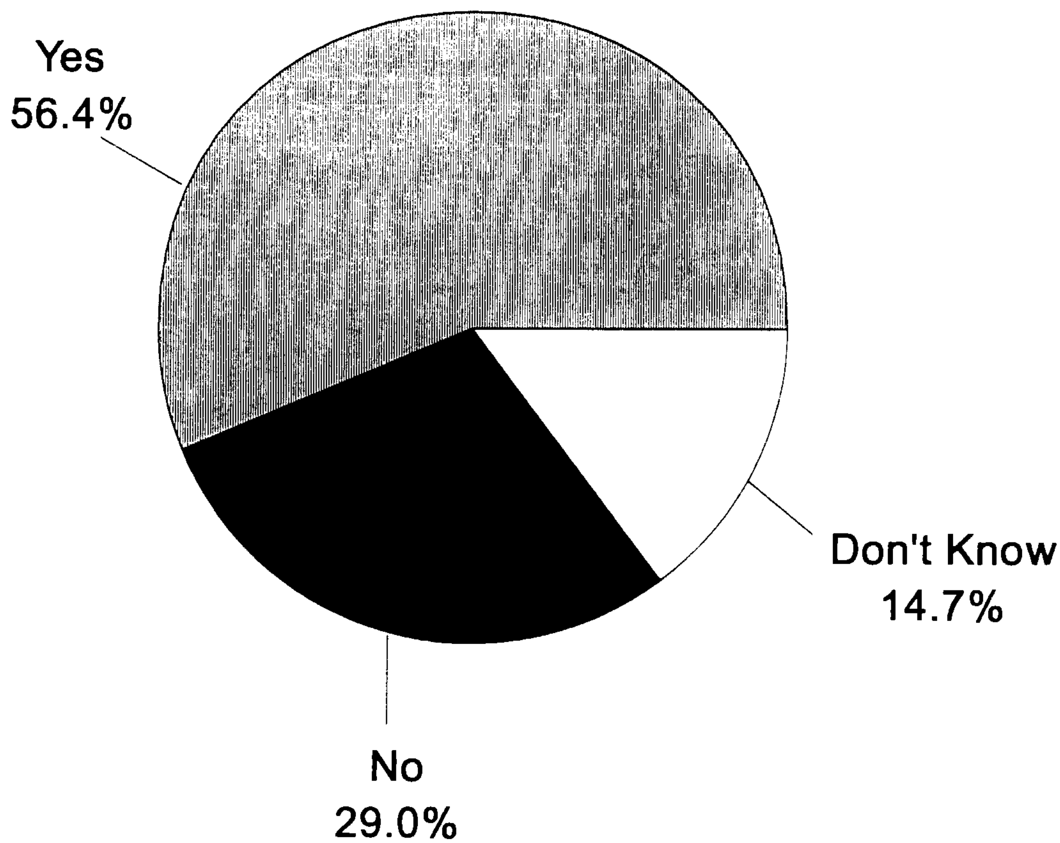
As previously described, the second part of Question 18 attempted to specifically identify possible overlapping regulatory requirements. In the presentation of the analysis of this question's results, the percentages of each selection do not total 100% because the respondents could choose more than one answer.

Of the 254 respondents who selected at least one overlapping regulation, by far the most frequently selected requirement was the Spill Prevention Control and Countermeasures (SPCC) Plan of the Clean Water Act and RCRA with 63.8%. In descending order, the others were Best Management Practices (BMP's) required under the Clean Water Act for nonpoint sources with 37.8%; followed by Waste Minimization Plans required under CERCLA/SARA with 26.8%. This was followed by "others" with 19.7%. A histogram presenting the results of this question is entitled " Requirements That Overlap."

Of the fifty respondents who specified what the "other" requirements were, about half identified them as state and local regulations. The majority of the other half can be grouped into groundwater protection plans, RCRA requirements, solid waste management plans, hazardous waste management plans, and emergency response plans.

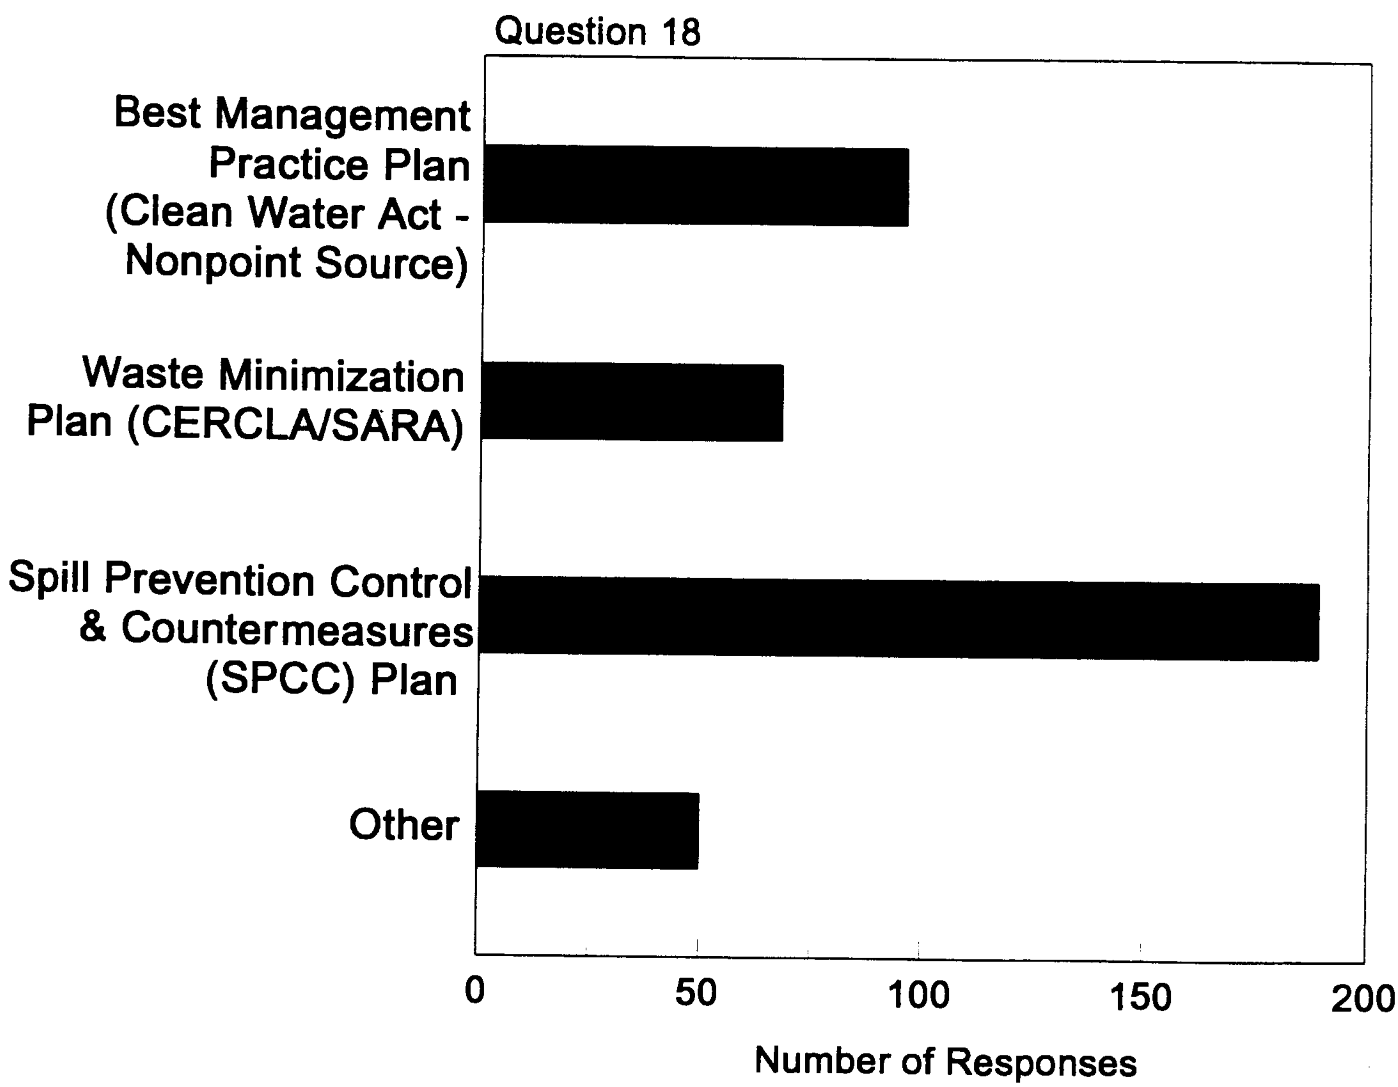
Two other parts of determining the effectiveness of the storm water permit program were assessing the ability of the industrial activities to prepare a storm water pollution prevention plan, and evaluating the usefulness of EPA and State guidance.

Does This Facility's Plan Overlap With Other Mandated Requirements?



Question 18

Requirements That Overlap



R0016802

Question 19 asked, "How was the facility's storm water pollution prevention plan developed?" The choices of answers were grouped into three areas and the respondent was requested to select all that apply. The first area was directed at who prepared the plan and the selections were: facility staff, corporate staff and/or external consultant. The second area was directed at identifying outside sources of guidance for preparation of the plan, and the selections were: used trade association guidance, used EPA guidance, and used State Agency guidance. The third area was directed at identifying internal sources of guidance for preparation of the plan, and the selections were: adapted model plan supplied by company or corporate office, adapted standard operating procedures from company, adapted plan from another pre-existing plan, and other (specify).

There were 418 responses that provided information on who prepared the plan. There were 262 responses that identified outside sources of guidance for preparation of the plan. And there were 104 responses that identified internal sources of guidance for preparation of the plan.

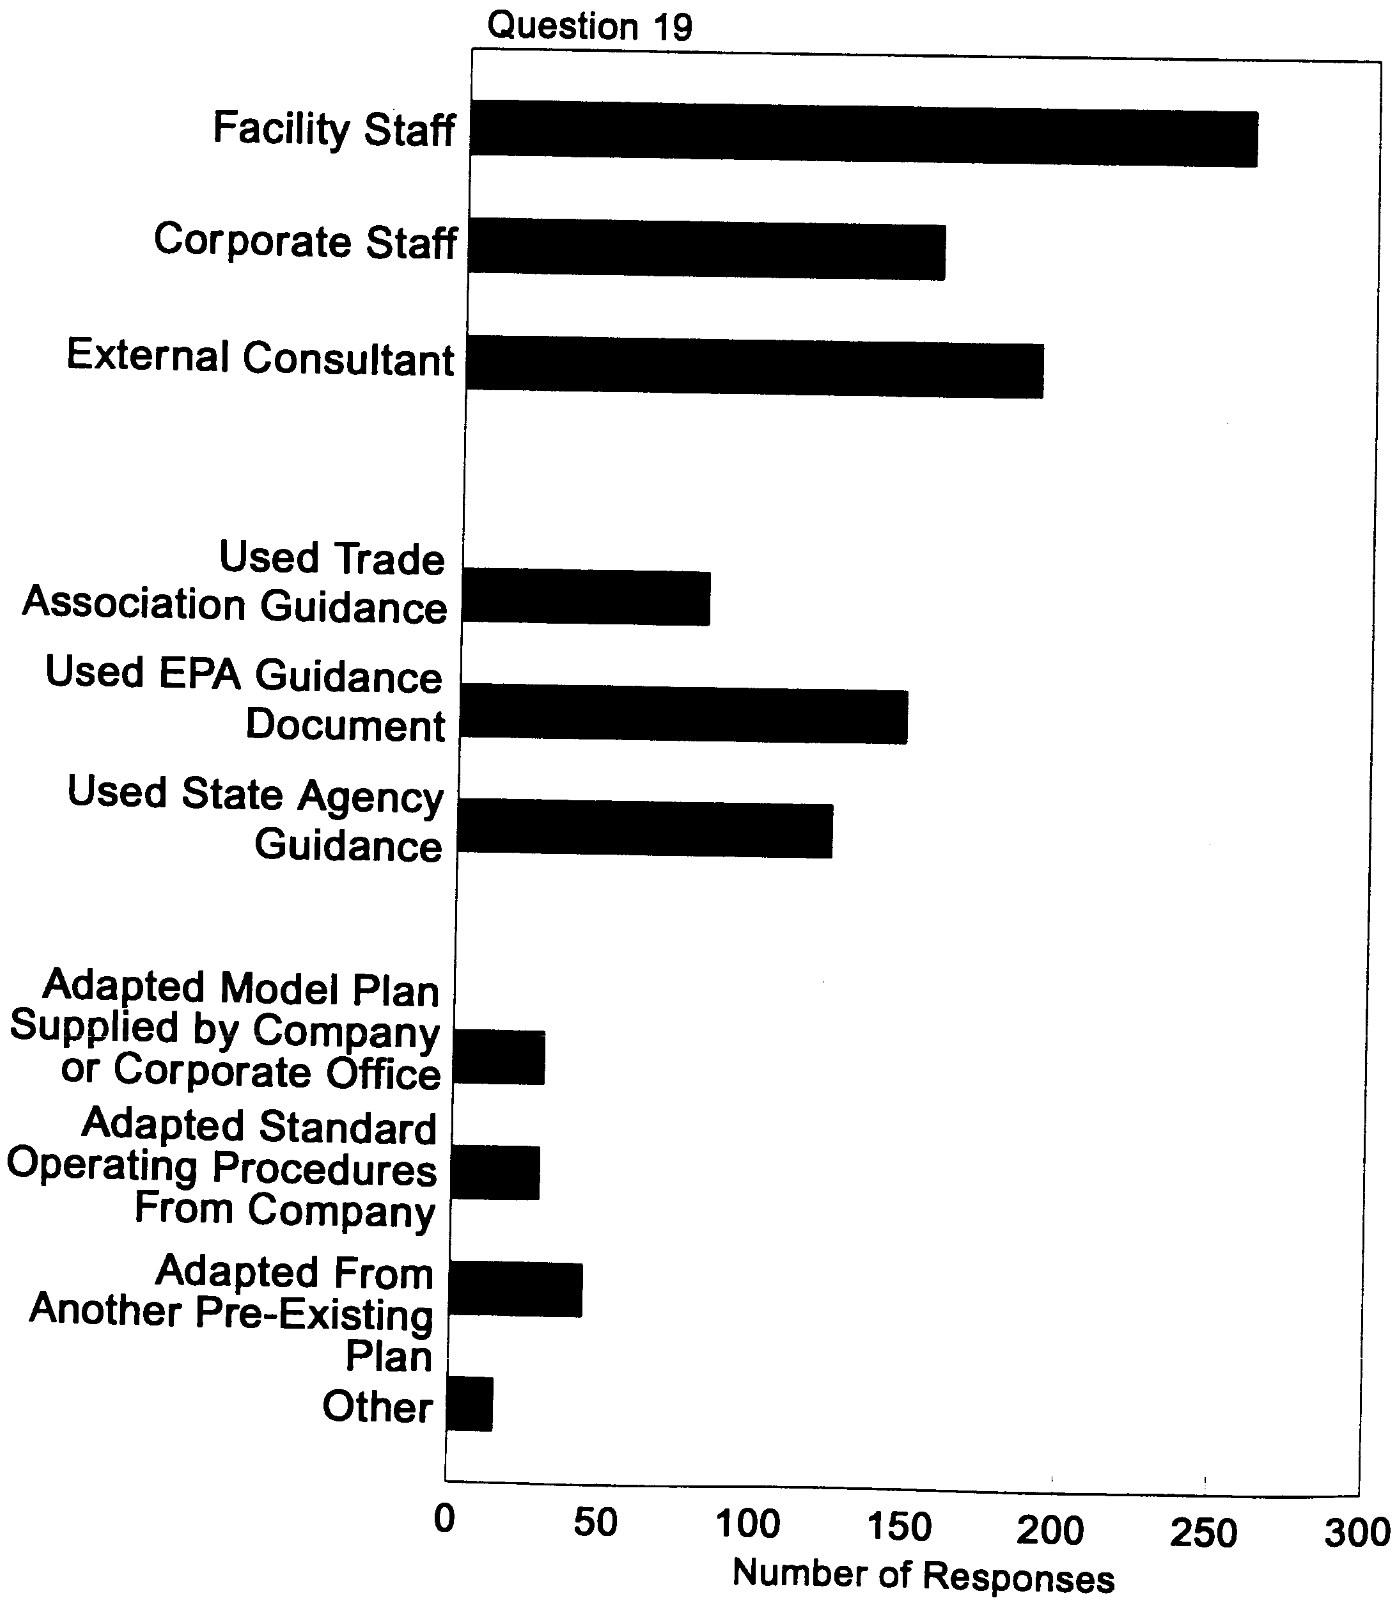
Of those respondents which indicated who they used to prepare the storm water pollution plan, 120 or 28.7% were able to prepare the plan by themselves. And of those who prepared the plan by themselves, 31.0 % used only EPA guidance and 22.8 % used only state guidance, while another 17.5% used both EPA and State guidance combined. From this response, it can be seen that 71.3% used governmental guidance exclusively and it appears that both EPA and the States have done an excellent job in providing the necessary assistance to prepare a storm water management plan. In fact, only 11.1% used neither EPA nor State guidance, relying on Trade Association guidance solely. Not determinable by the survey was the extent to which Trade Associations relied on EPA and State guidance.

If an individual facility required additional assistance in preparation of its pollution prevention plan, it relied on external consultants 63.6% of the time and then on corporate staff 21.4% of the time; while 15.0 % used both corporate assistance and consultants. If the plan was prepared by the corporate staff, it relied on external consultants much less than the individual facilities, only 23% of the time.

The data also show that 24.9 % of the industrial facilities employed internal sources of guidance for preparation of the storm water management plan. Of those which used internal sources, 42.3% adapted components from another pre-existing plan, 26.9% used company standard operating procedures and 29.8% employed a model plan provided by the company or corporate office. In addition, 14.4% used other internal sources. A histogram entitled "How Was the Pollution Prevention Plan Developed" presents the number of respondents using various resources for plan preparation.

Related questions which arise at this point are: how much did the preparation of these plans cost and how do the costs compare based on who prepared them and what source

How Was the Pollution Prevention Plan Developed?



R0016804

they used in preparation. To conduct and discuss this analysis, a jump to Question 26, which addresses costs, is necessary.

Using the results from the first component of Question 26 which provides the cost of plan preparation (excluding the three companies that reported that they had spent over $100,000 for their plan), the average cost was $7,606 per plan. Those facilities that prepared the pollution prevention plans themselves incurred an average cost of $6,950; those that used corporate staff exclusively had an average cost of $5,513 and those that used consultants exclusively had an average cost of $8,215. Those facilities that used all three sources: local staff, corporate staff and consultant assistance had the highest average cost at $12,667 per plan. An additional analysis showed that small businesses spent an average of $4,341 per plan.

Those firms that used only Trade Association guidance had an average cost of $ 8,617 for plan preparation. Those that used EPA guidance exclusively had an average cost of $7,625 while those that used State provided guidance exclusively had an average cost of $5,958 per plan.

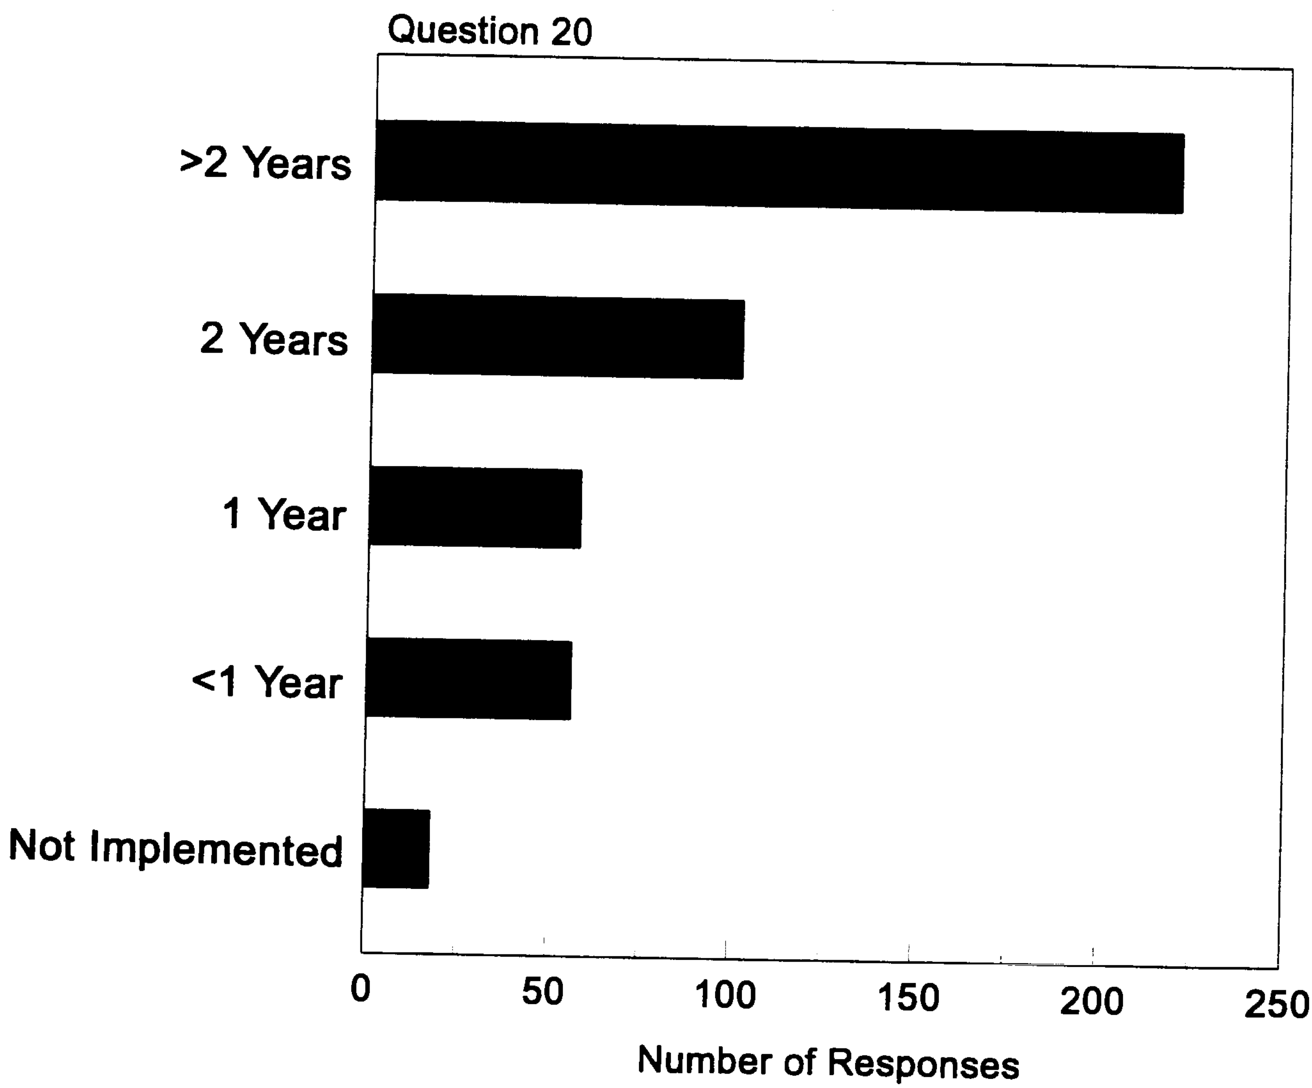
As an interesting side analysis, the three companies that spent over $100,000 each on their storm water management plans indicated that they had used completely different preparers and external sources. One used only facility staff, one used only external consultants and one used all three; facility staff, corporate staff and an external consultant. One used only trade association guidance, one used only EPA guidance and one used only State guidance. None adopted a model plan, a pre-existing plan or standard operating procedures.

The next question regarding the length of time that the storm water management plan had been implemented was requested in order to determine timing progress of this aspect of the program. Question 20 asked, "How long has the storm water pollution prevention plan been implemented?" The choices of answers provided were: not implemented, less than one year, one year, two years, and greater than two years. A histogram entitled "Length of Implementation Time for Storm Water Pollution Plan" gives the distribution of the answers to this question.

This question was answered by 455 respondents (all but three). The results indicate that after the initial surge of plan implementations (221) over two years ago, the number dropped to 102 two years ago and then to 58 last year, and 56 this year. Only 18 respondents had not yet implemented their plans. It appears that the number of new pollution prevention plans being implemented is approaching a constant 12%. This is probably due to new facilities going on line plus additional facilities that have been joining the program as enforcement activities increase.

Question 21 asked "Has water quality monitoring and analysis been performed on the storm water runoff from this facility?", in order to establish the basis for the answer to Question 22 which stated "If yes, in your opinion, did results indicate whether Best

Length of Implementation Time for Storm Water Pollution Plan



Management Practices (BMP's) are successful?" All but three respondents answered Questions 21. And of the 258 that responded in the affirmative to Question 21 only 3 did not respond to Question 22. The answers to Question 21 are presented in a pie chart. Similarly another pie chart entitled "Evaluation of Best Management Practices (BMP's)" follows and presents the respondents perception of whether BMP's are successful.

Those facilities which had performed water quality analysis represented 56.7% of the respondents. Of that 56.7%; 56.9% indicated that they felt there was water quality improvement as a result of BMP's. A sizable percentage, 36.9%, gave the opinion that either there was insufficient data (15.7%) or inconclusive data (21.2%).

The latter percentages can be interpreted in two ways; either there is more data collection required or the natural variation in water quality of the receiving waters is such that a determination of water quality improvement is not possible. However, it should be noted that if there are natural variations in the water quality of the receiving waters which make the determination impossible; there is a high probability that there are immeasurable changes in water quality in the receiving waters due to storm water controls, resulting in insignificant water quality improvement.

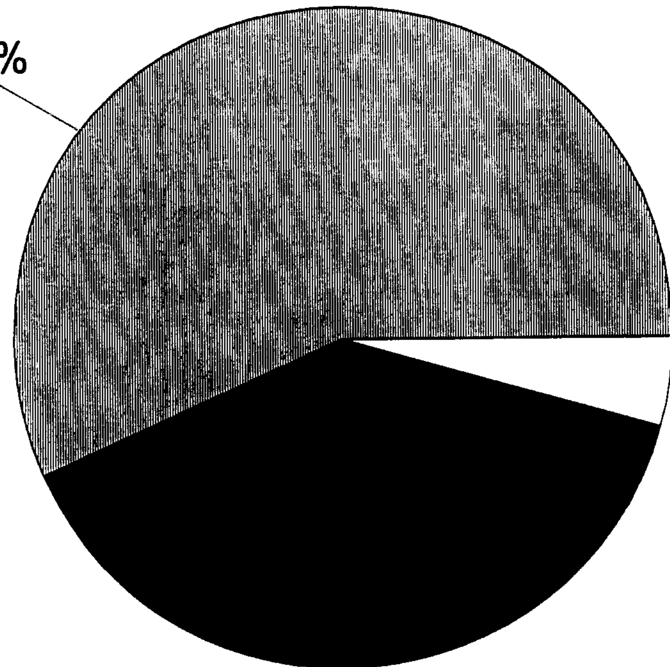
One of the most significant questions of the survey was Question 23 which asked "Whether you have conducted water monitoring or not, in your opinion, how much improvement in water quality or reduction in storm water pollution has there been or is there likely to be as a result of your storm water (or other) plan?" Only one respondent didn't answer this question. A pie chart entitled "How Much Water Quality Improvement or Reduction in Storm Water Pollution Resulted From Your Plan?" presents the results.

The results show that 9.2% believe that there is significant improvement, 20.1% moderate improvement, 38.7% minor improvement and 27.1% no improvement. The remainder, 4.8%, said they didn't know. The results of this question can be interpreted in different ways. One view is that the program is perceived as effective because a sizable majority, 68.0%, believe there is at least some improvement in water quality. Another view is that the program is perceived as ineffective because a sizable majority, 65.8%, believe there is little or no improvement in water quality.

An interesting side analysis showed those individuals who had conducted water quality monitoring and analysis on the storm water runoff from their facility, had close to the same results as the previous analysis with 12.1% determining there is significant improvement, 20.8 % moderate improvement, 40.8% minor improvement, and 23.1% no improvement. There is a slight increase in favor of those who would choose to believe the program is effective, 73.7%; verses a slight decrease for those who would choose the opposite, 63.9%.

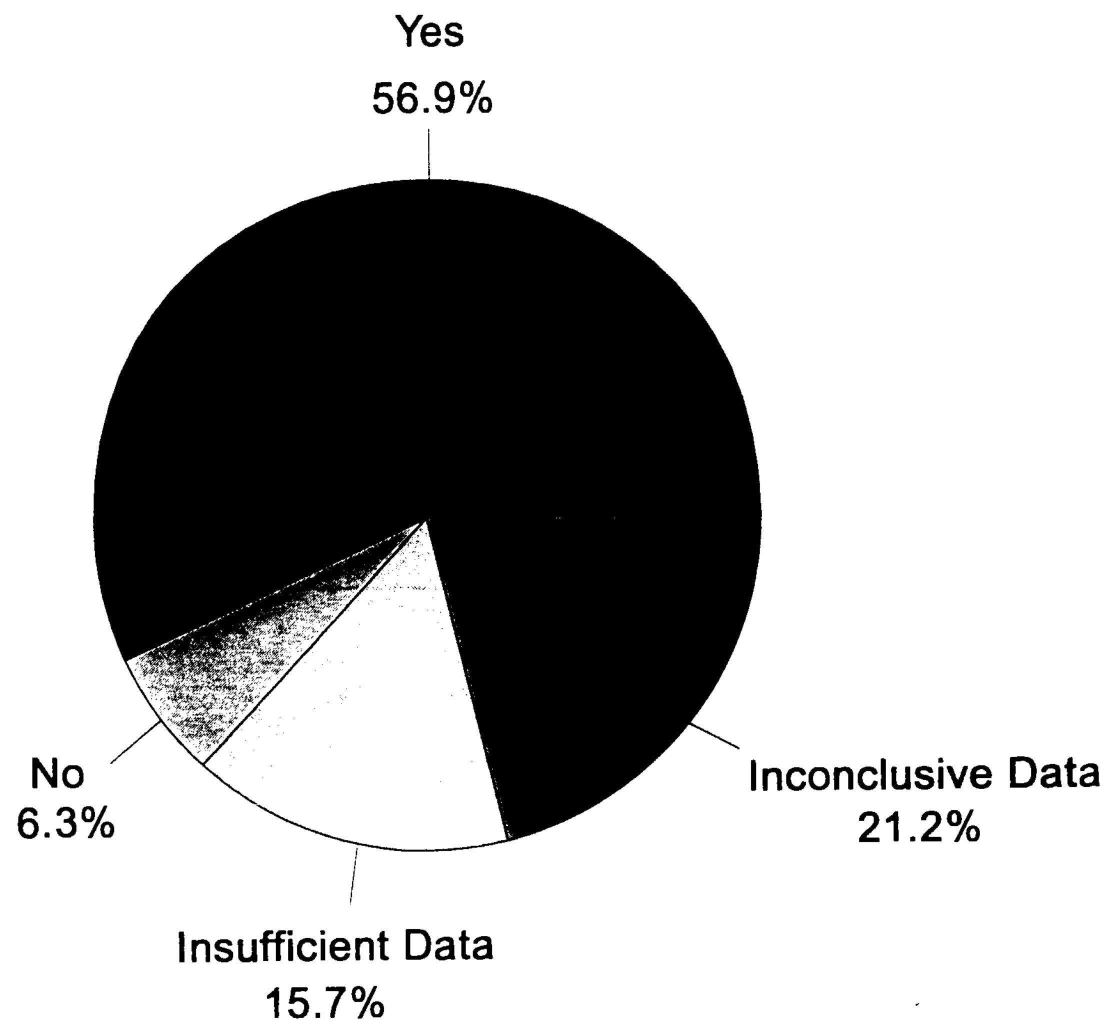
An additional analysis was made by looking only at those industrial facilities which stated BMP's were successful (i.e. those who answered yes to Question 22) and also had the water quality data to evaluate the level of improvement. Although these respondents said

Has Water Quality Monitoring and Analysis Been Performed?



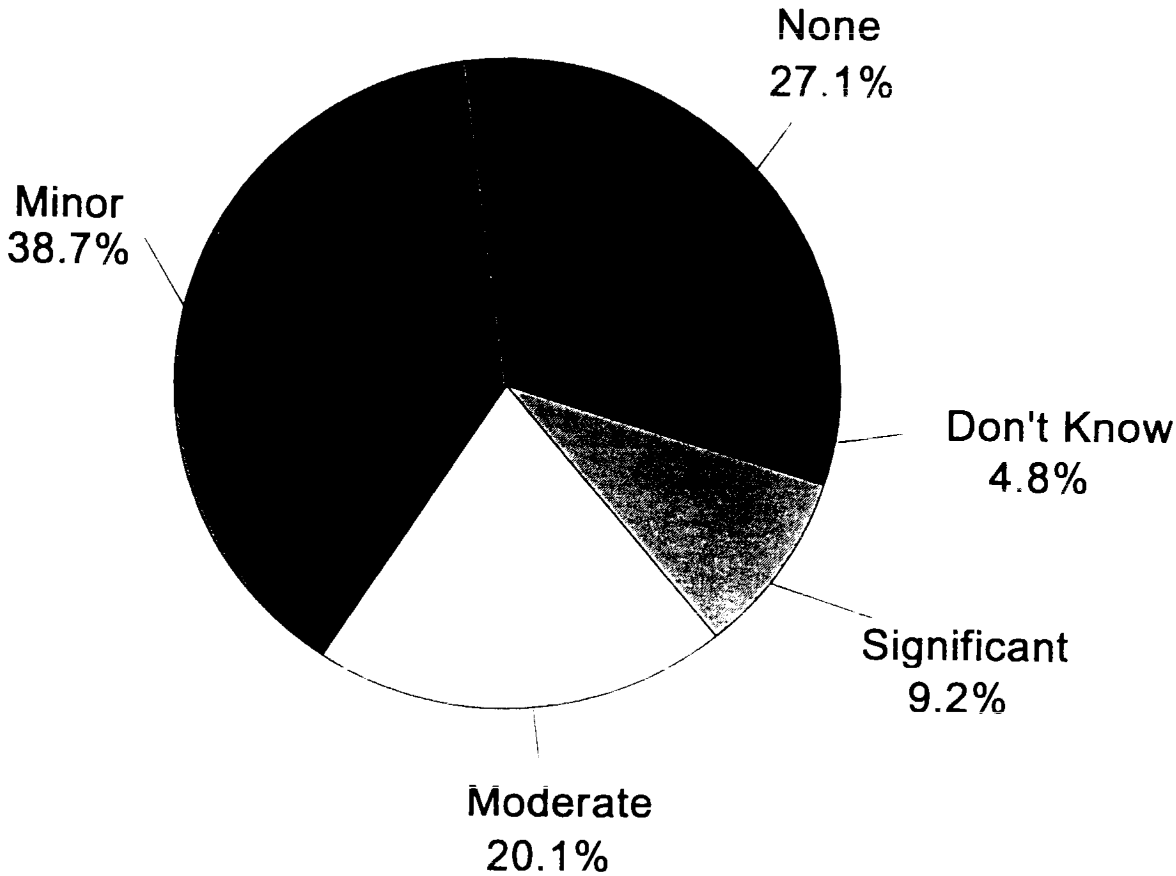
Question 21

Evaluation of Best Management Practices (BMPs)



Question 22

How Much Water Quality Improvement or Reduction in Storm Water Pollution Resulted From Your Plan?



Question 23

that BMP's were successful; 22.1% said in their opinion, there was no water quality improvement. Of the same group 31.7% said there was minor improvement, 25.5% said there was moderate improvement, 17.2% said there was significant improvement and 3.4% didn't know. Therefore, 74.4%of those with successful BMP's and water quality data have the opinion that there is at least some improvement in water quality or reduction in storm water pollution; while from the alternative viewpoint 57.2% feel there is little or no improvement.

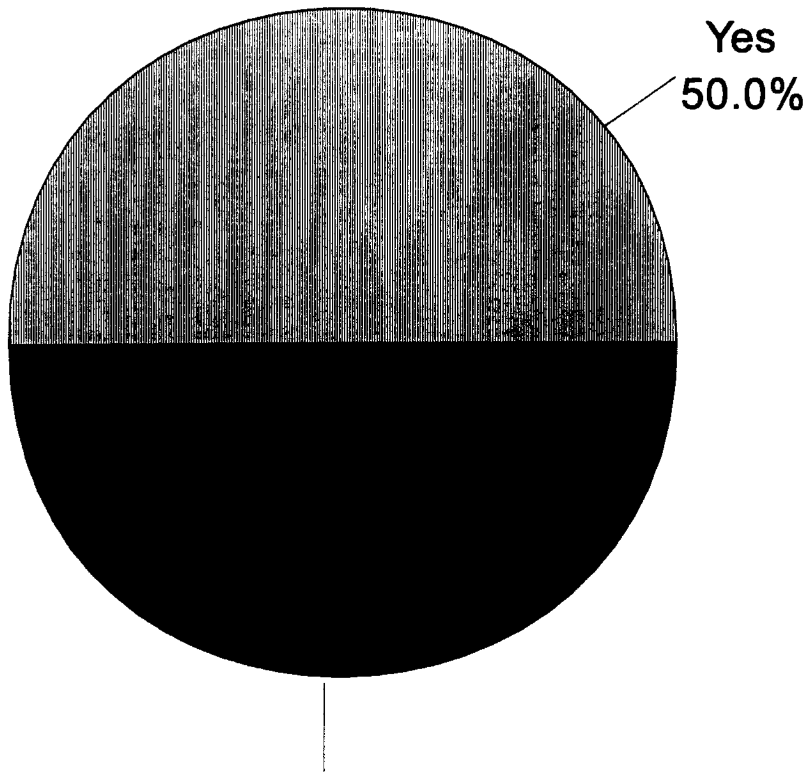
Another important question was Question 24, which simply asked, "Was any improvement to the water quality or reduction in storm water runoff possible?" The purpose of this question was to determine whether or not industry felt the existence of any type of storm water control program could result in water improvements. As shown in the pie chart with the same title as the question, the responses were split down the middle with 50.0% saying yes and 50.0% saying no. Only 9 firms did not answer this question.

The answers given to Question 24 were then compared with the answers given by the same individuals to Question 23 regarding the level of improvement likely to result from the storm water (or other) plan. Of those who said there was no improvement possible, 47.3% said that there was no improvement likely to result from the storm water plan and 37.5 % said that only minor improvement was likely. A number of individuals said no improvement to water quality was possible; yet stated moderate (7.6 %) or significant (2.7%) improvement resulted from their storm water (or other) plan. These individuals may have found Question 24 imprecise because it asked if any improvement to the water quality or reduction in storm water run-off was possible. The latter half of the option could be interpreted as flow related not pollutant related, and could have been more clearly stated as "reduction in storm water pollution" rather than reduction in run-off.

Of those who said that improvement to water quality or reduction in storm water run-off was possible 7.6% said that no improvement was likely to result from the storm water (or other) plan; while 40.0% said that minor improvements are likely. Those who said that moderate improvements are likely represented 32.9% and those who suggested significant improvements were possible were 15.6%. Those who simply didn't know represented 3.9% of the respondents.

Question 25 was developed in order to assess various impressions of the level of effectiveness of the different possible components of pollution prevention plans. The question states, "Considering actual and potential benefits and based on your impression, rate the following elements of the facility's pollution prevention plan as to their effectiveness in preventing pollution from storm water runoff." The choices of ratings were: highly effective, moderately effective, not effective or not applicable. The components presented for evaluation included: good housekeeping, preventative maintenance, elimination of industrial source discharges, sediment and erosion control, visual inspections, spill prevention and response, site mapping (operations, drainage, and runoff collection mapping), employee training, record keeping and reporting, raw material

Was Any Improvement to Water Quality or Reduction in Storm Water Runoff Possible?



Question 24

or product substitution, annual site compliance evaluation, physical facility modification (requiring construction) and other (specify).

Each item was evaluated separately and between 436 and 447 respondents addressed each component depending on the item rated. A histogram entitled "Plans Effectiveness in Preventing Runoff" presents the ratings of each component. Following that are individual histograms which present those components determined to be highly effective, moderately effective, not effective and not applicable.

Good housekeeping was assessed as the most highly effective component of a storm water management plan, with 61.5 % evaluating it as highly effective and 34.0 % determining it moderately effective. Less than 5% determined it not effective or not applicable.

The second most highly rated component of the plan was spill prevention and response. It was the only other item besides good housekeeping that had a higher rating as "highly effective" 44.2 % than it had as "moderately effective" 41.7 %. Only 6.1% rated it as not effective, while 8.0% indicated it was not applicable.

This was followed by preventative maintenance which was rated by 36.0 % as highly effective and 47.0 % as moderately effective. And it in turn was followed by visual inspections, which 33.1 % rated as highly effective and 56.2 % rated as moderately effective. And finally, of those components found to be effective, employee training was next with 30.2 % finding it highly effective and 58.6 % finding it moderately effective.

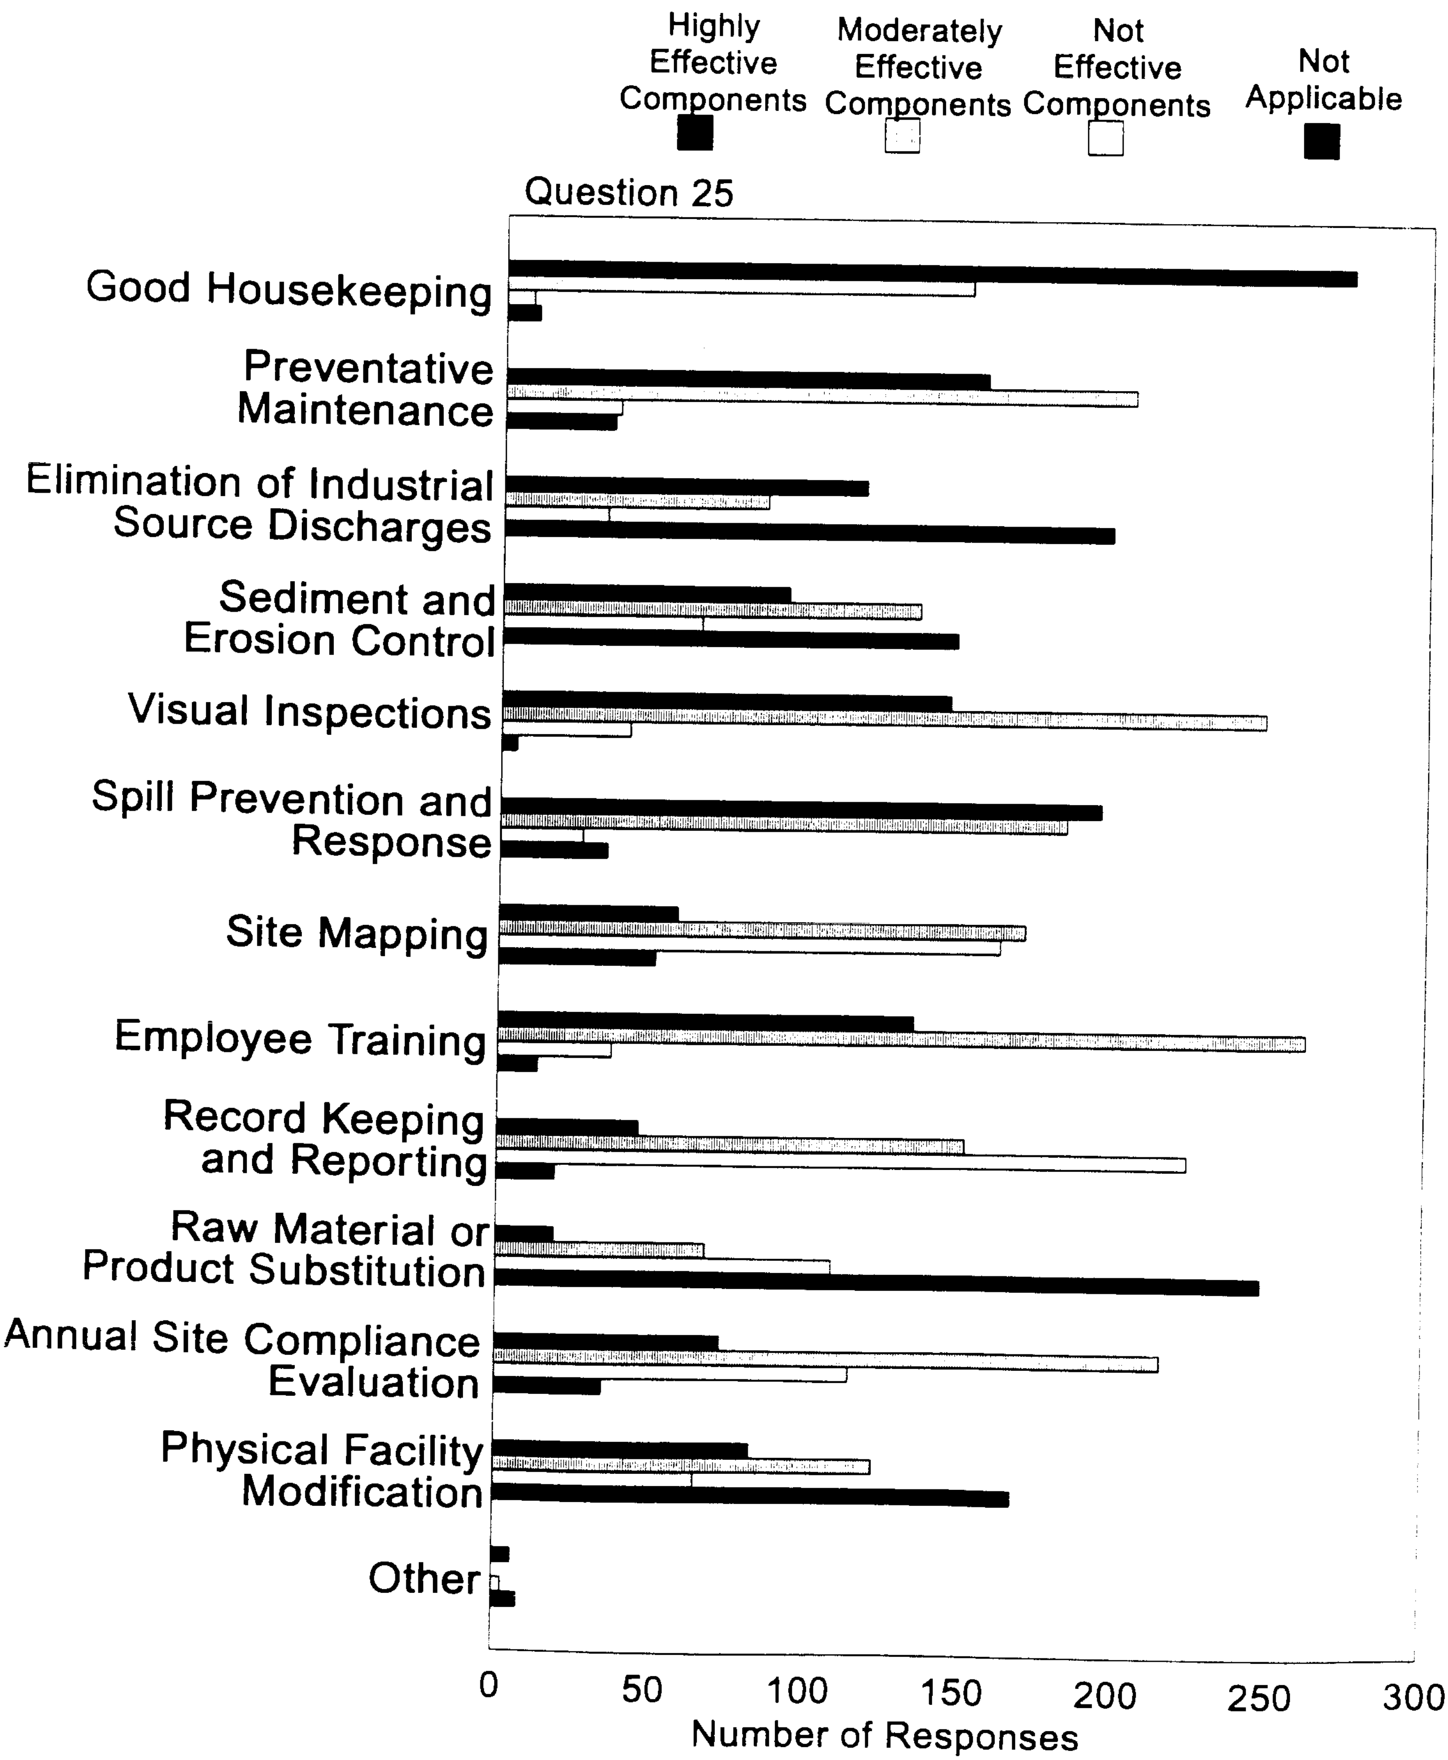
An interesting observation regarding the results of this part of the survey is associated with the relatively high number of respondents who reported that certain components were not applicable to their plan or facility. In descending order of frequency those components selected as non applicable were: raw material and product substitution, elimination of industrial discharges, annual site compliance evaluation, and sediment and erosion control.

Even though these were found to be not applicable to many facilities it does not mean that they are ineffective controls. For example, a substantial number (45.4%) rated "elimination of industrial source discharges" as not applicable; however, the vast majority for whom it was applicable, found it to be highly effective (49.6 %) or moderately effective (36.1%).

It appears that if a company has a problem with an industrial source being inadvertently discharged to a storm sewer, the elimination of this discharge was logically concluded to be highly effective in preventing pollution.

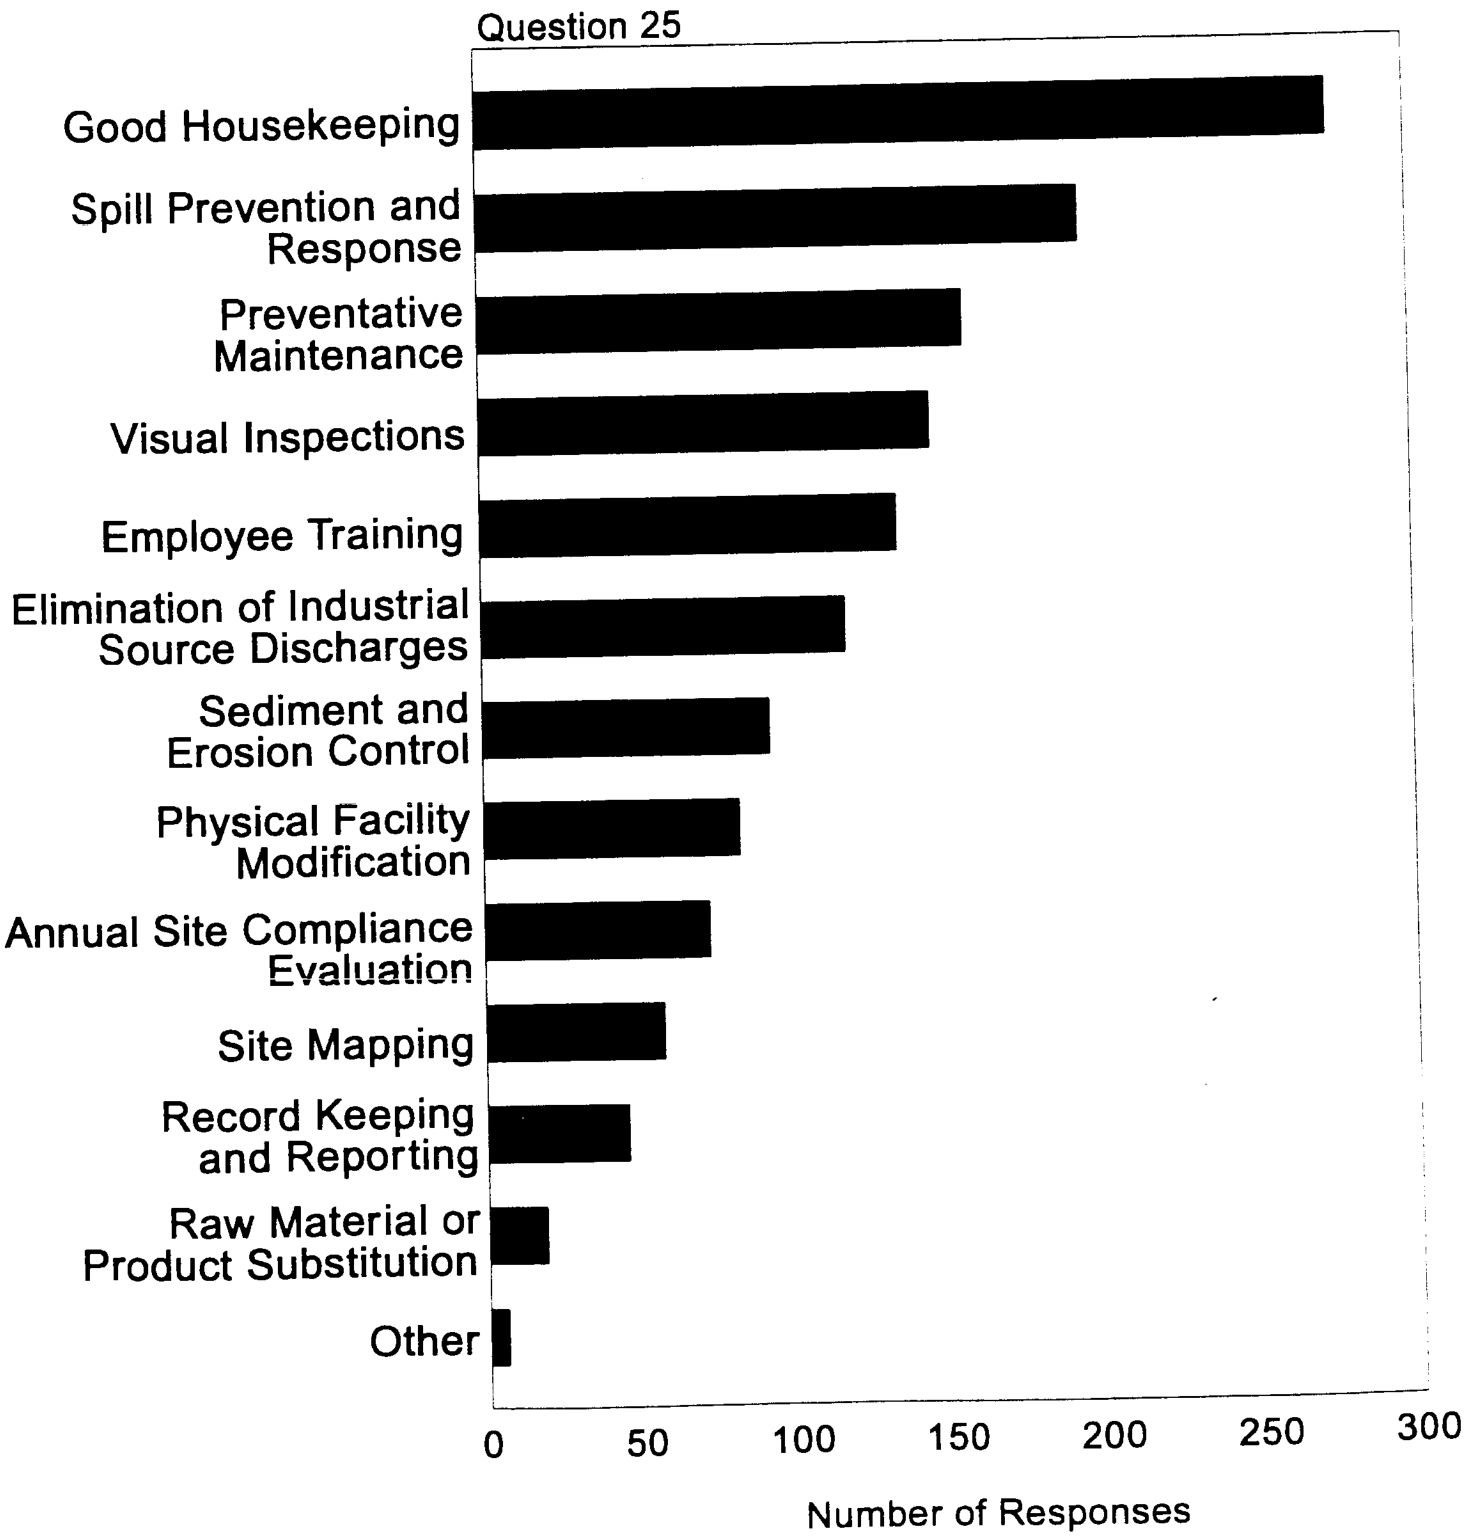
Another interesting observation is associated with that component receiving the lowest rating. A relatively large percentage of individuals determined that raw material or product substitution was not applicable to their operations (55.8%). In addition, of those 196 respondents that found it was applicable, 55.6% determined it to be not effective. It was concluded that this component is generally thought to be the least effective of the pollution prevention plan elements for storm water management.

Plan's Effectiveness in Preventing Runoff



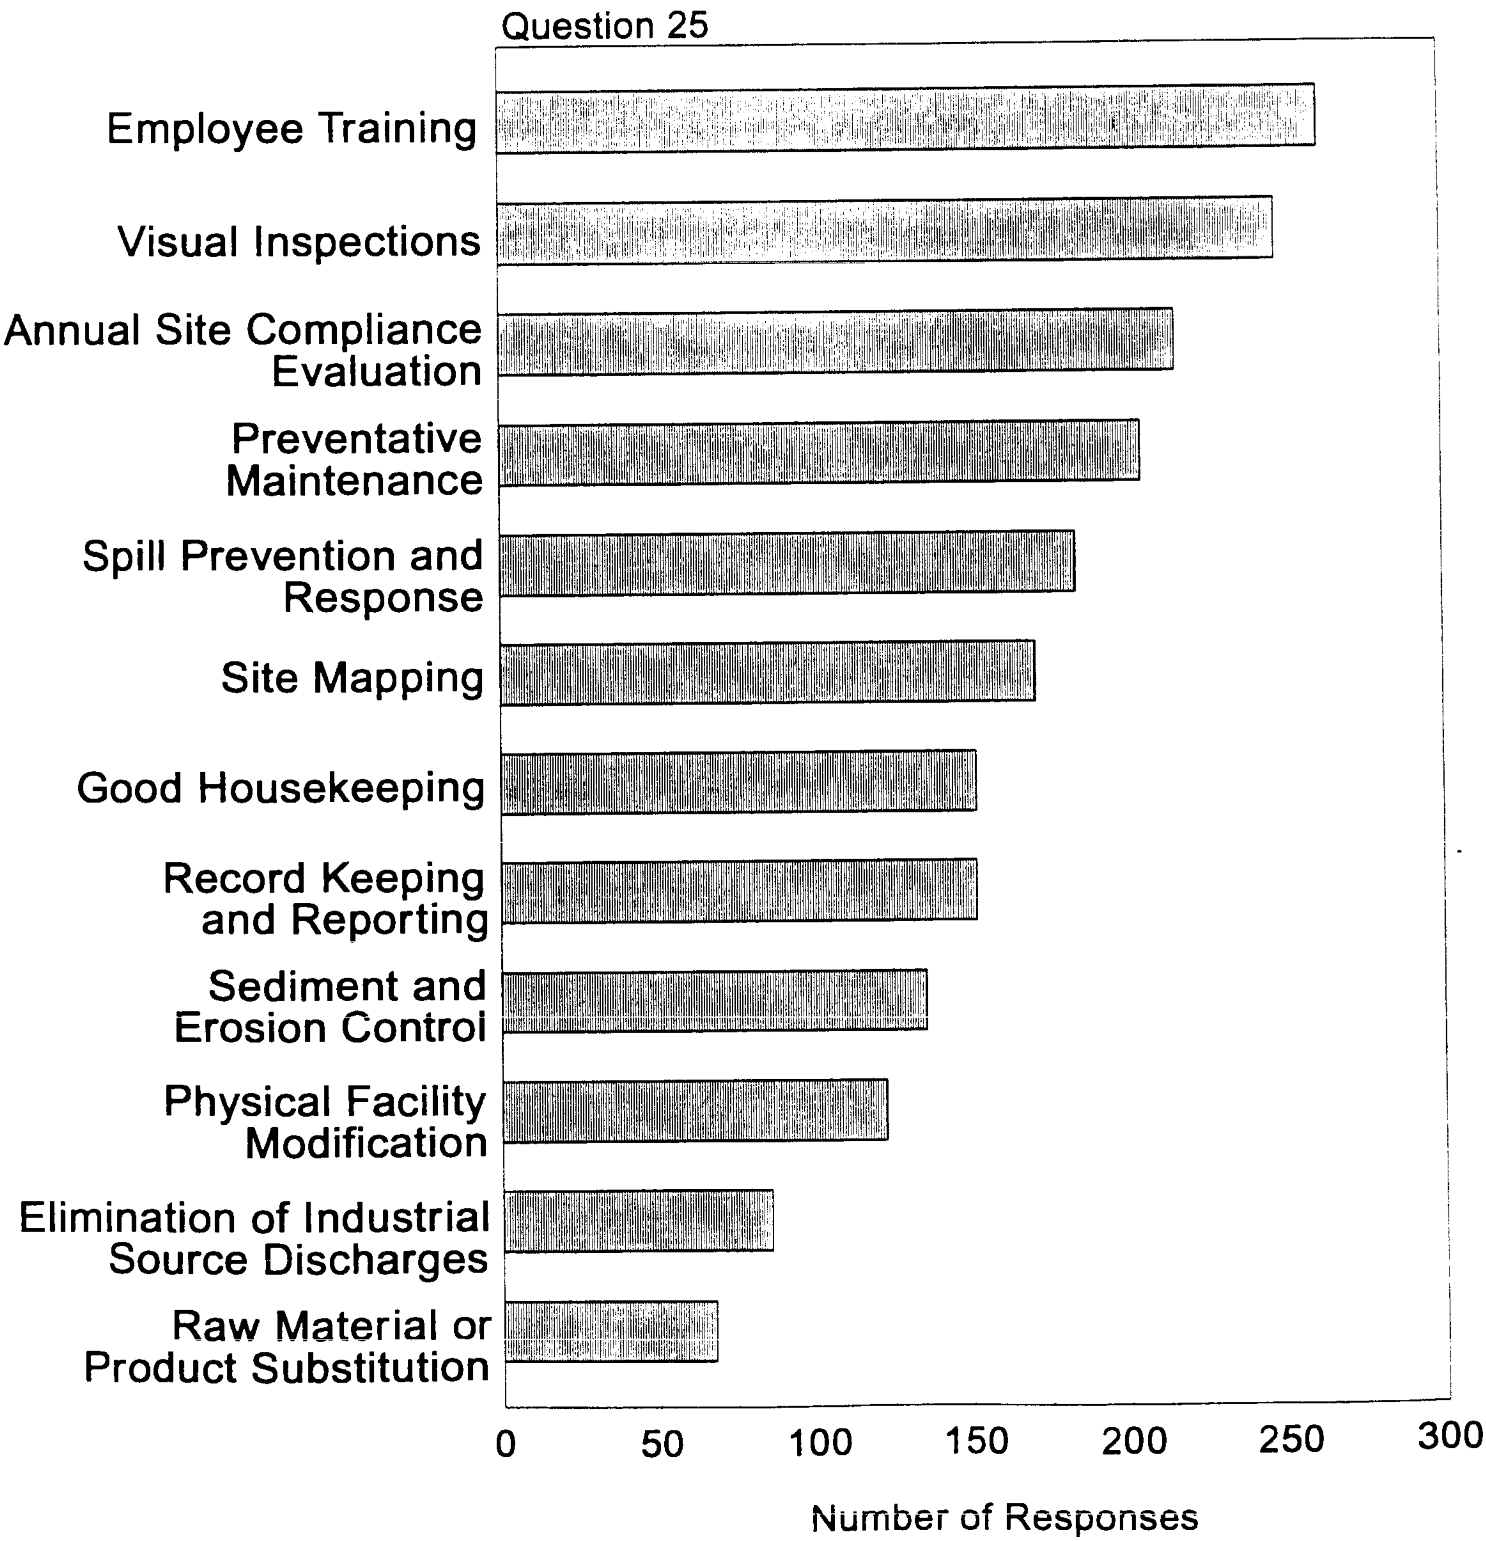
R0016814

Highly Effective Plan Components in Preventing Runoff



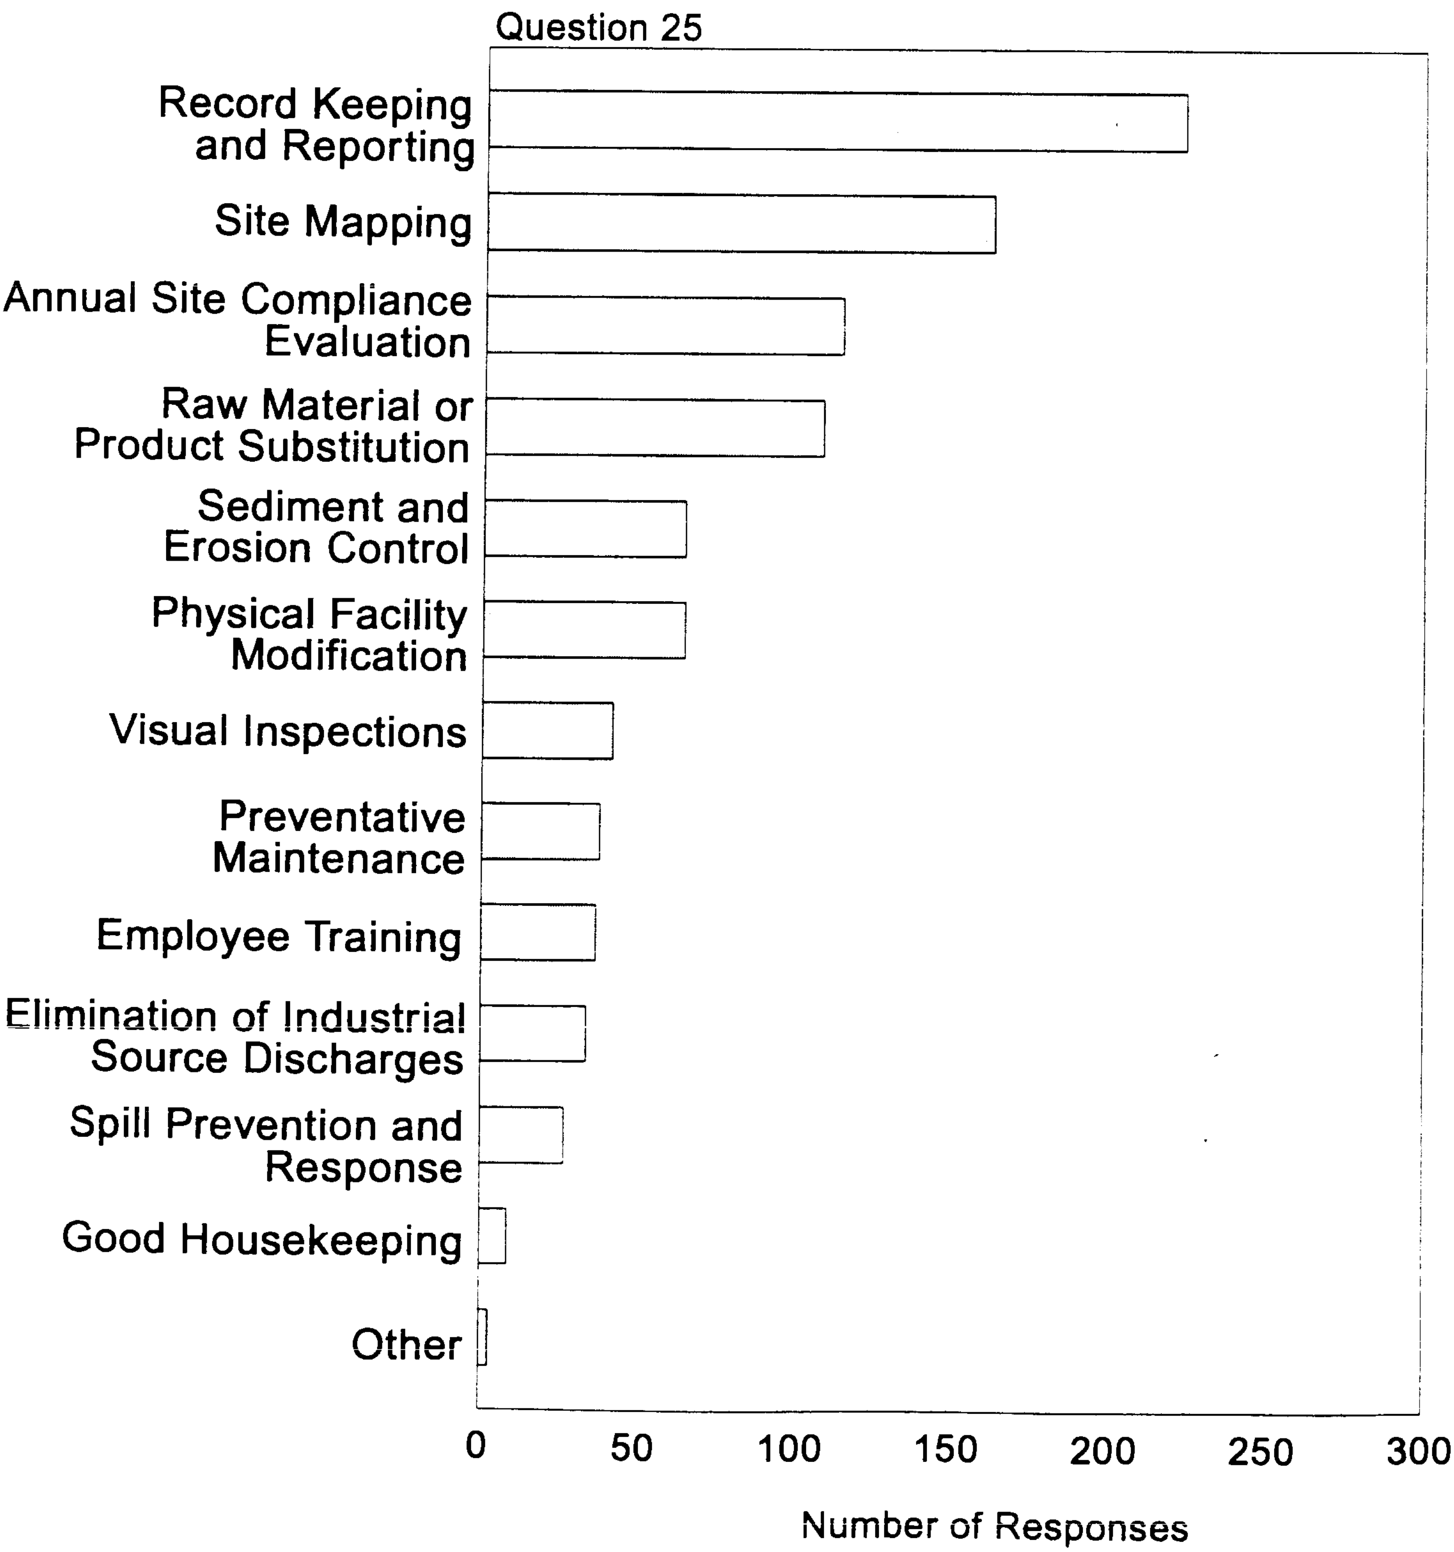
R0016815

Moderately Effective Plan Components in Preventing Runoff



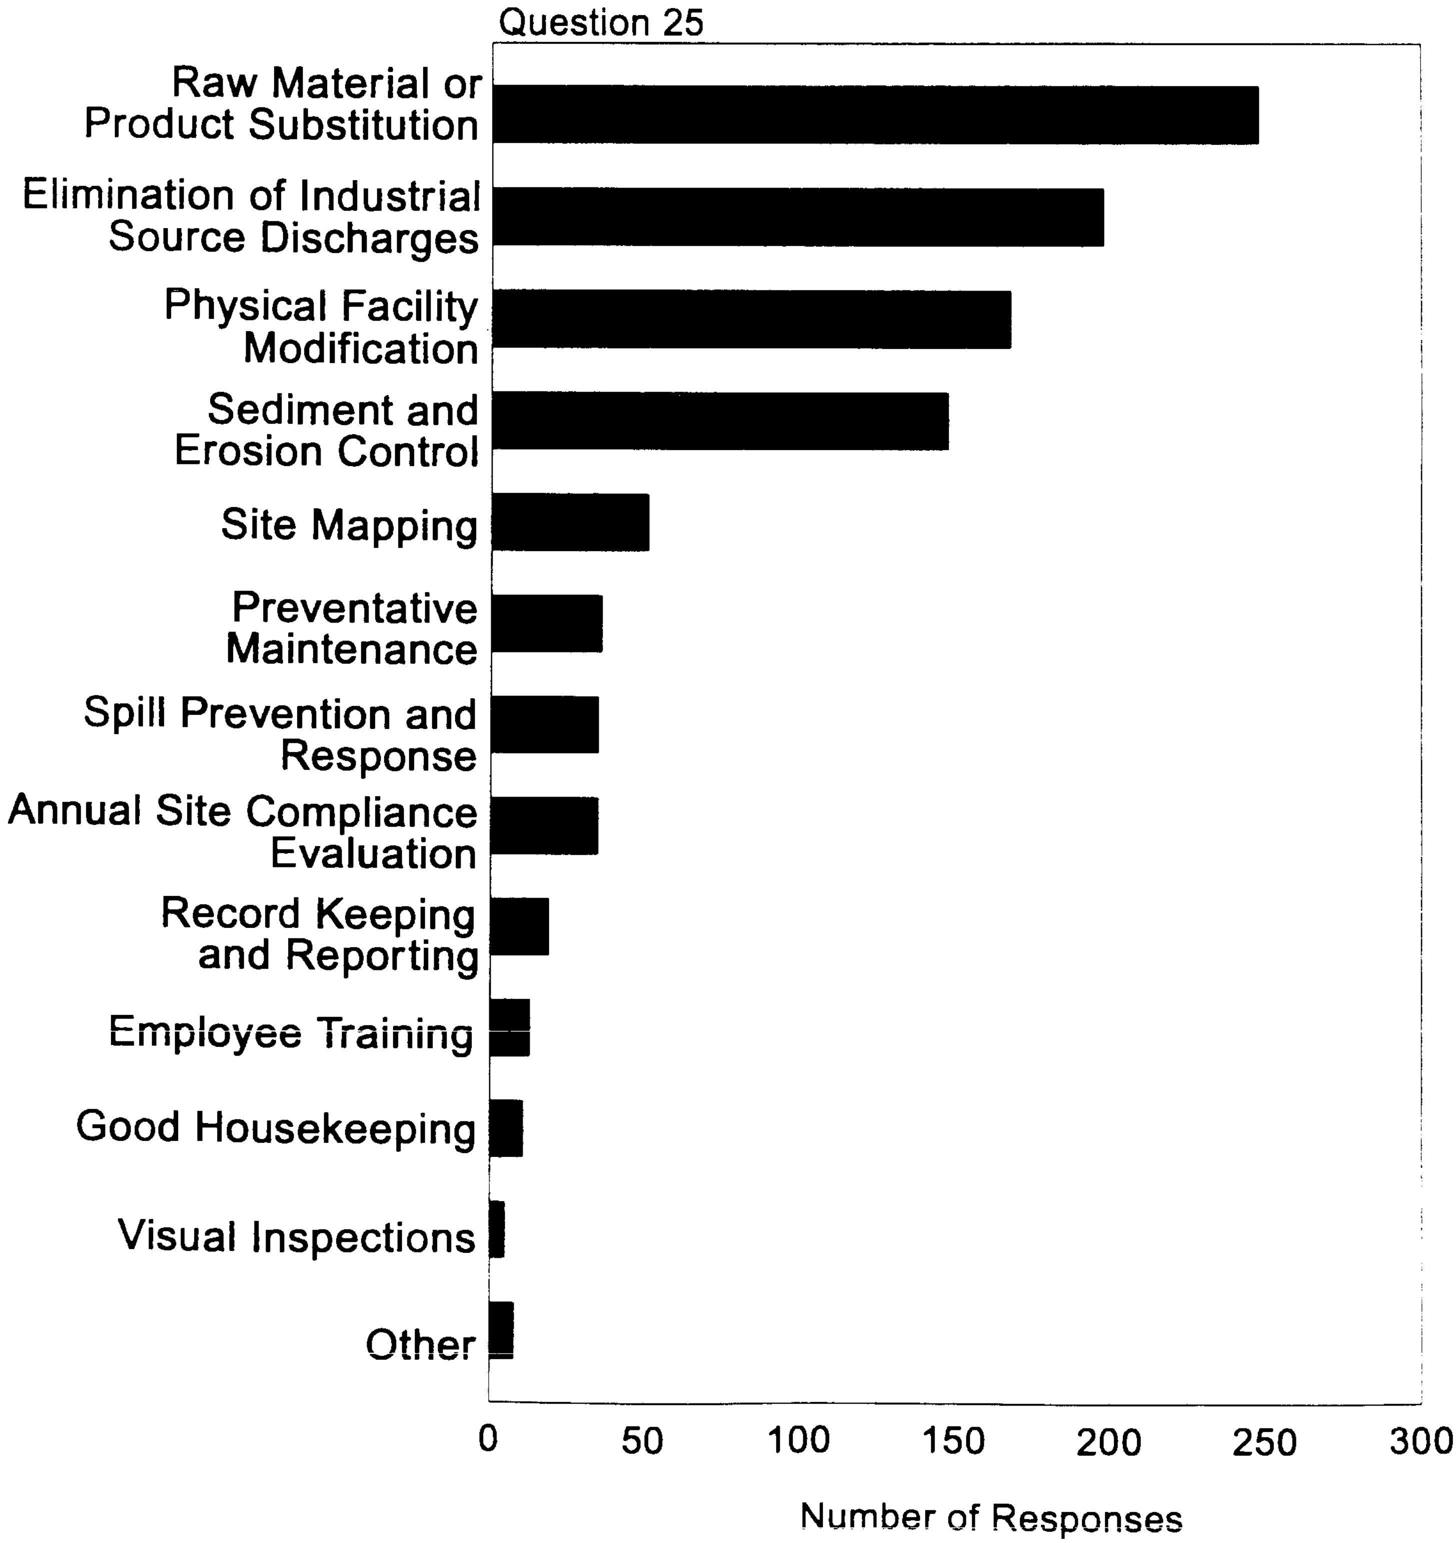
R0016816

Not Effective Plan Components in Preventing Runoff



R0016817

Not Applicable Plan Components in Preventing Runoff



R0016818

Of those components determined to be applicable, clearly the one perceived to be the least effective was record keeping and reporting. Of the 422 respondents that did not eliminate it as not applicable, 224 or 53.1% found this element to be not effective.

Question 26 states "How much did the development and implementation of this facility's storm water pollution prevention plan cost?" Blanks were provided to fill in the cost of plan development, the plan's implementation annual operating cost, and the capital cost of physical improvements. As part of the question, additional details were requested on the year expended or planned to be expended and the type(s) of physical improvements. Blanks were also provided for these answers.

The percentage of industrial activities providing costs dropped from 73.3% for those giving the cost of plan development, to 64.4% for those giving the cost of the plan's implementation annual operating cost, to 38.9% for those giving the capital cost of physical improvements. Many of those who did not provide costs for the plan development made the comments that the plan was prepared in house and therefore did not have an available cost.

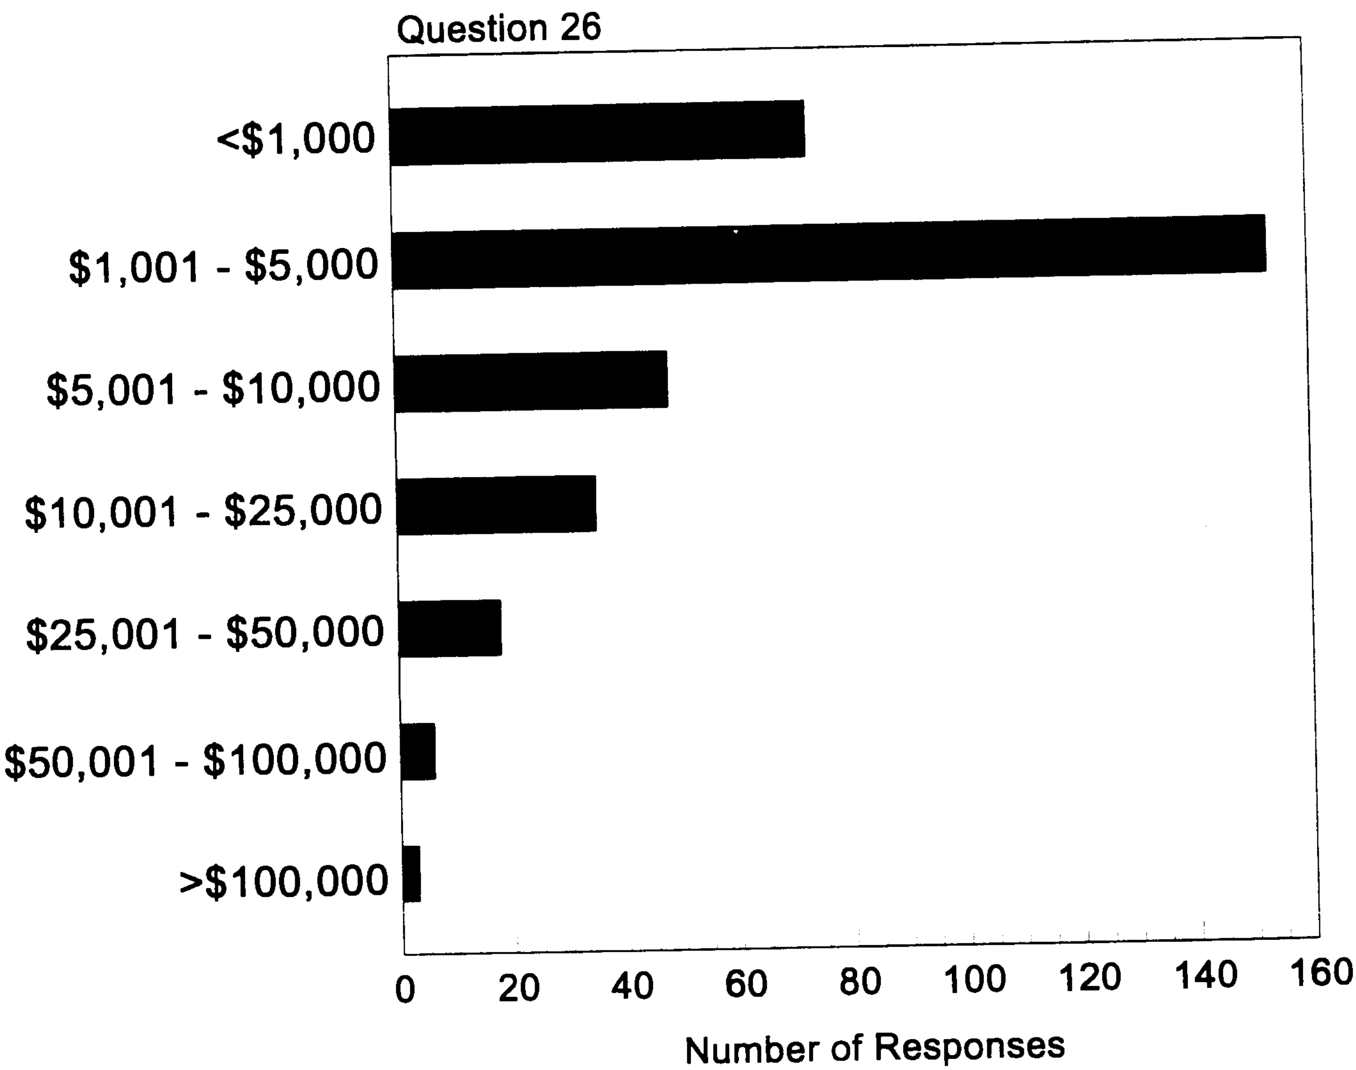
It appears from the above responses that some facilities (35.6%) which have a plan do not incur any significant annual operating costs. Additionally, it can be concluded that, of the facilities that currently have a pollution prevention plan, roughly 39% have had to expend resources for capital improvements to meet the requirements of the regulations.

The answers to the cost questions were grouped in order to be able to conveniently analyze the results. First the costs for the pollution prevention plan development were placed in the ranges of less than $1000, $1001 to $5,000; $5,001 to $10,000; $10,001 to $25,000; $25,001 to $50,000; $50,001 to $100,000 and over $100,000. Additionally, the capital costs of physical improvement were grouped in the same ranges. Because of the lower costs associated with annual operating costs, different ranges were used for this component, namely: less than $100; $101 to $500; $501 to $1,000; $1,001 to $2,500; $2,501 to $5,000; $5,001 to $10,000 and greater than $10,000. Results of these distributions are presented in histograms on the three following pages.

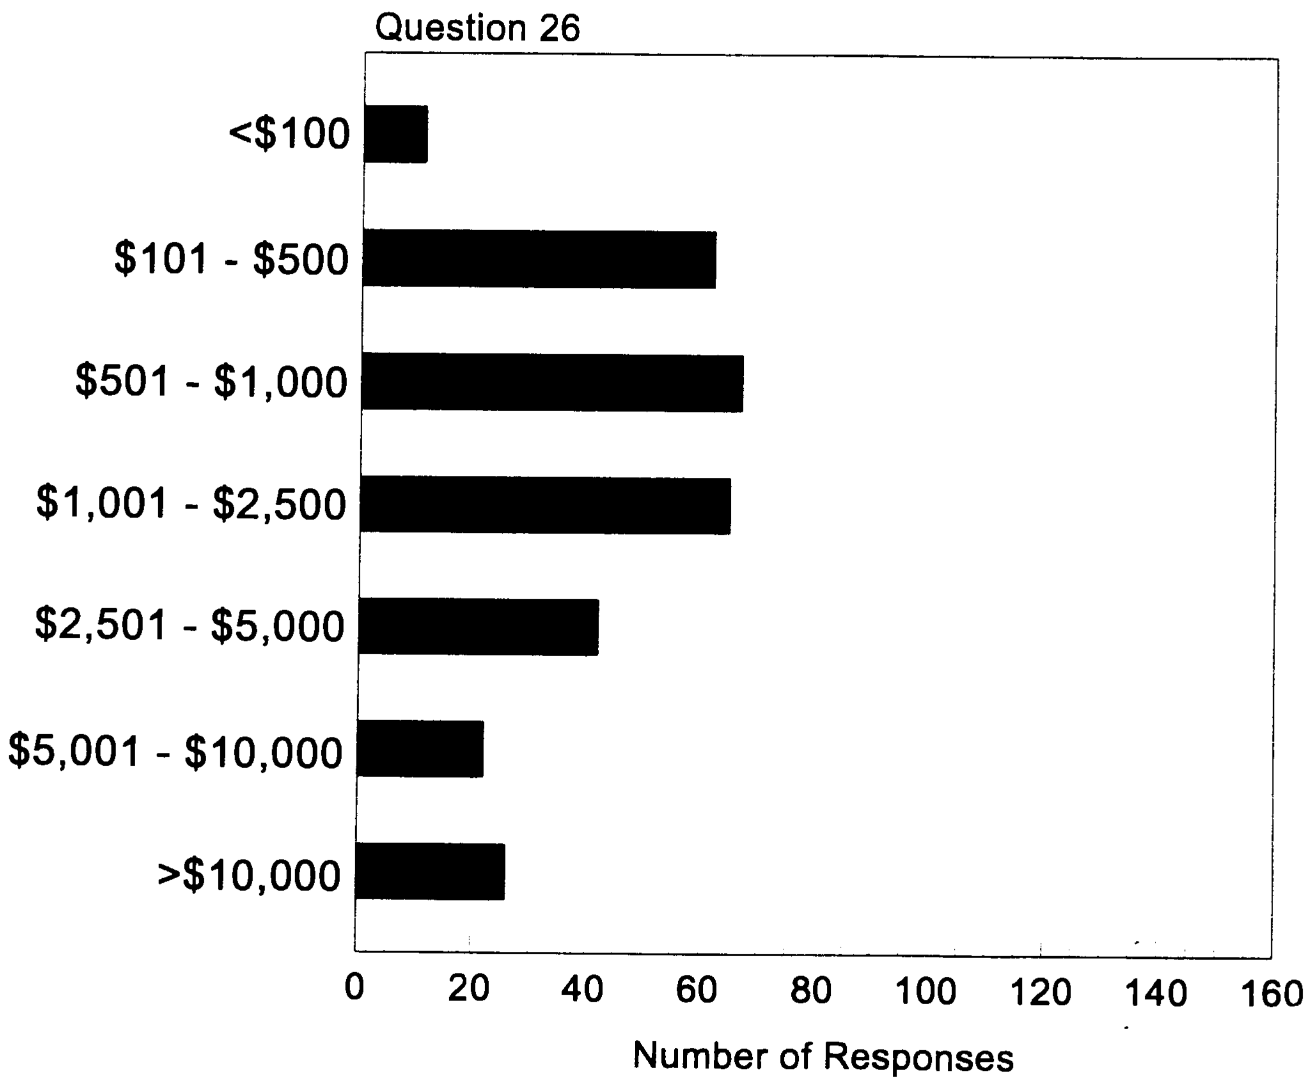
The range of costs for plan development having the highest frequency of selection, (the mode of the distribution) was between $1,000 and $5,000. This cost range represented 45.5% of the respondents. It is interesting to note that 67.2% of the survey spent less than $5,000 on plan preparation and 81.5% spent less than $10,000.

In reviewing the annual operating costs, it was determined that the vast majority of facilities (69.5%) incur annual operating costs of less that $2,500 per year. However, when adding the small number of facilities which have a very high annual operating cost, the average becomes $4,105.

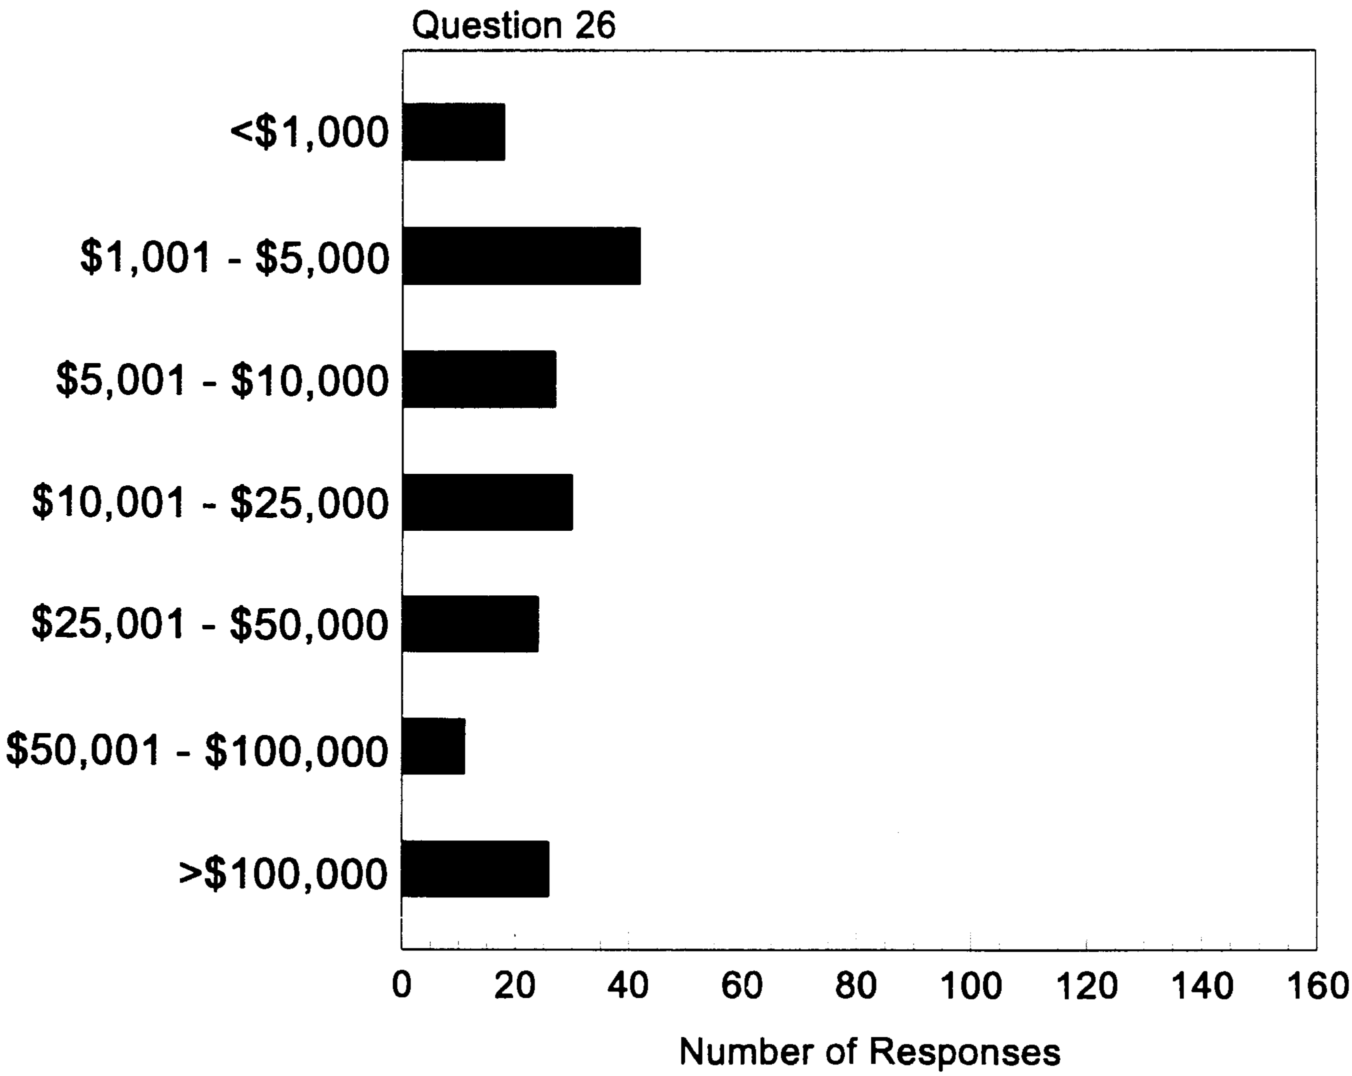
Cost of Plan Development



Plan's Implementation Annual Operating Cost



Capital Cost of Physical Improvements



It appears that roughly 39% of the facilities that have a plan had to expend resources for capital improvements to meet the regulation requirements. The capital costs of physical improvements have a trimodal statistical distribution. There were 33.7% of the facilities which reported spending less than $5000, another 45.4% spent between $5,000 and $50,000 while 20.7% spent over 50,000. Although it can be seen that almost 80% of the facilities spent less than $50,000; the average cost was $89,030, which was heavily influenced by the 22 facilities that spent over $100,000 on capital improvements. The latter group averaged $602,727.

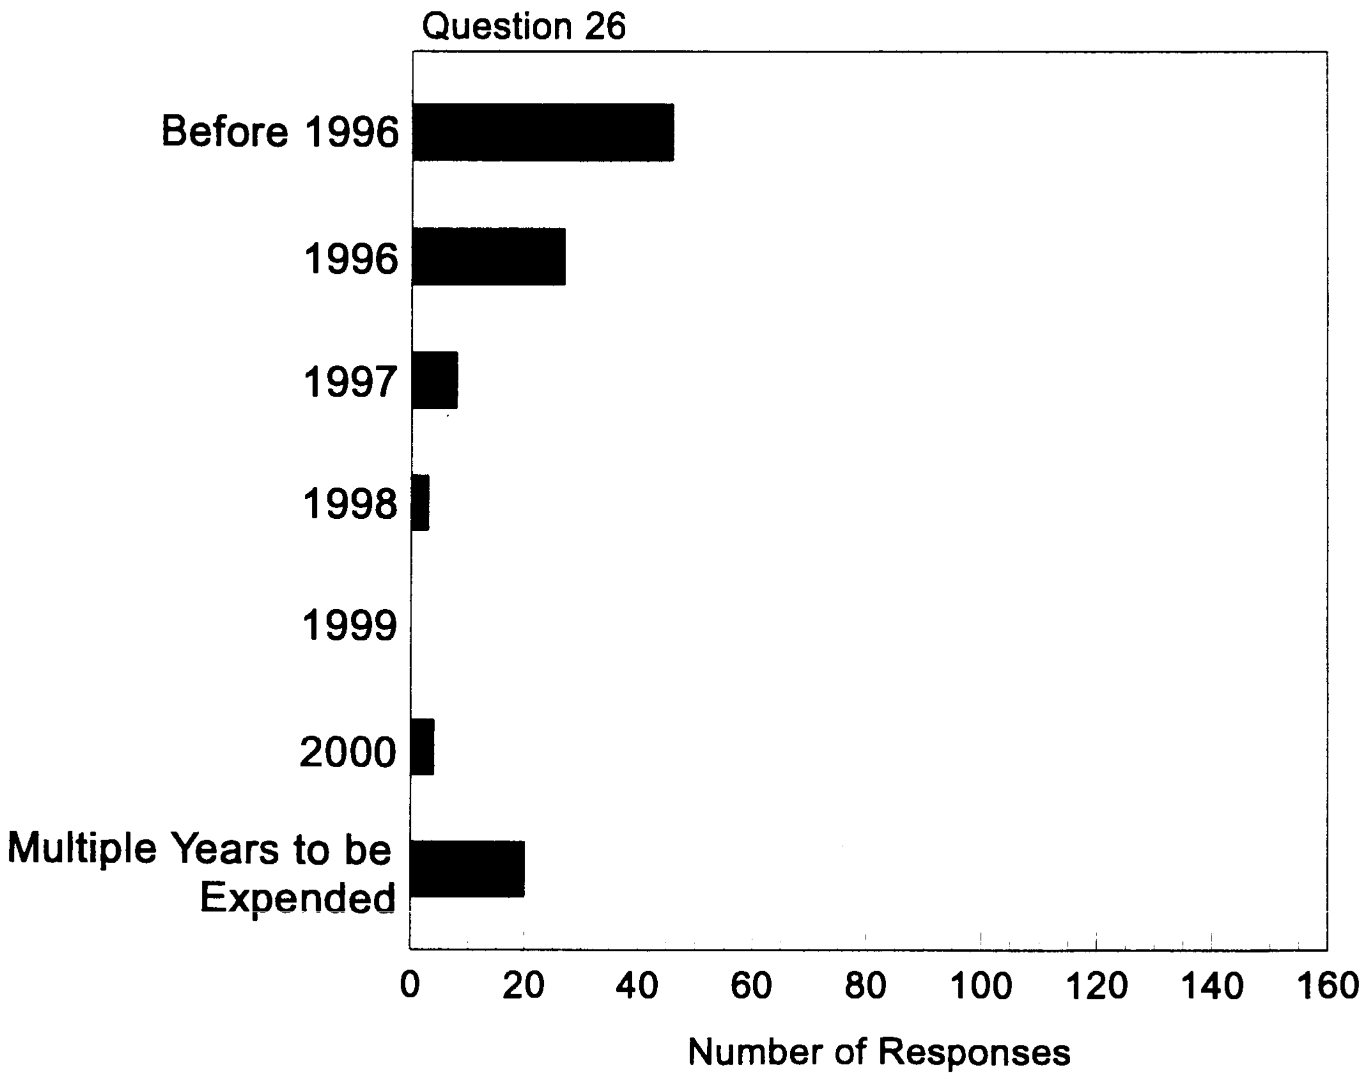
The year(s) in which the resources were either expended or planned to be expended were grouped as "before 1996" and each year from 1996 through the year 2000. However, an additional group was included to address expenditures taking place over multiple years. The numbers falling into each year are presented in the graph entitled "Year (Planned To Be) Expended". Most of the expenditures given by the respondents were in 1996 (25.0%) and before (42.6%). Only 10.5% gave cost expected to be incurred in the future and most of those were planned for 1997. Approximately 18.5% had multiple year investments.

The types of physical improvements were widely distributed primarily because the respondents were given the freedom to describe the improvements using their own terminology. But, for analysis purposes, they were grouped into the following categories: ponds and other containment structures; improved drainage, grading and erosion control, covered structures and improved storage; berms, dikes, and diversion of runoff; improved maintenance; pumping and treatment; and other physical improvements. The frequency distribution of "types of physical improvements" is presented in the histogram with the same title.

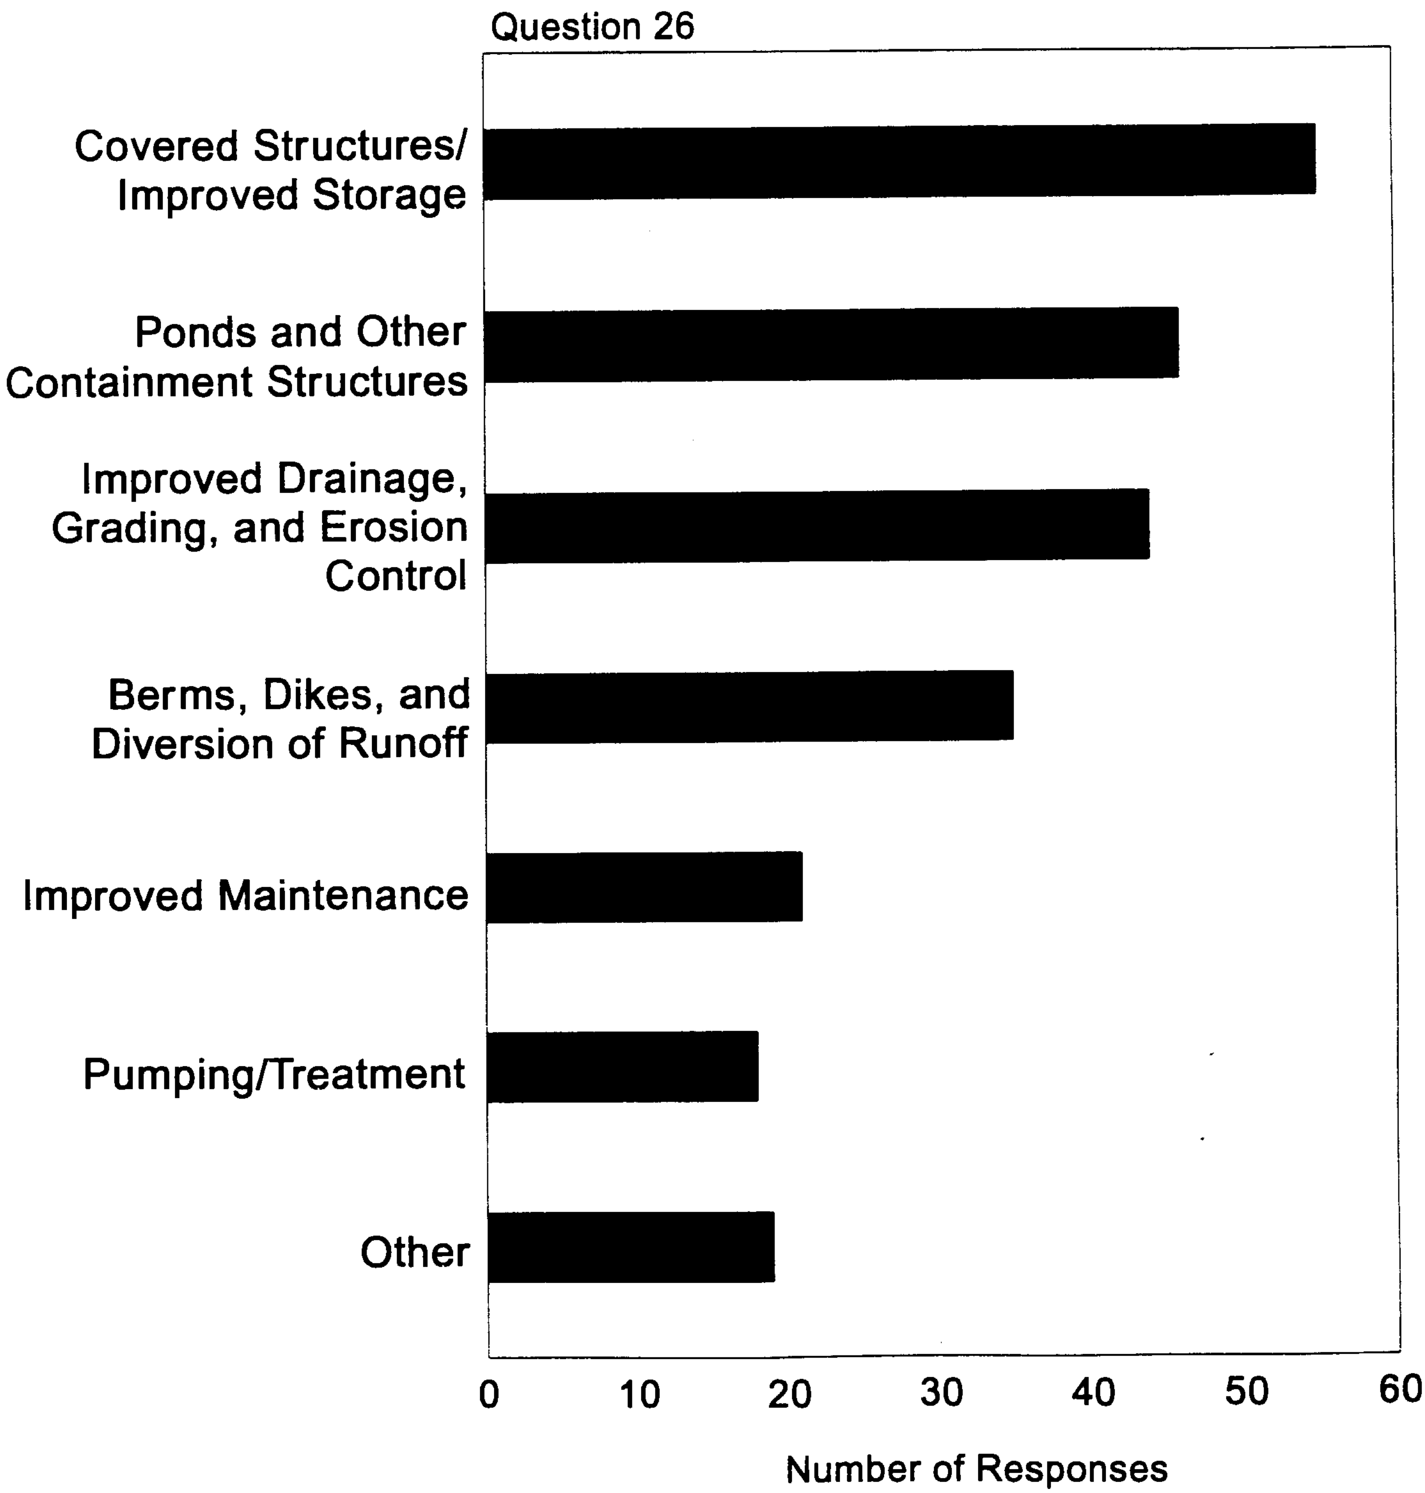
The most frequently selected type of storm water control construction project involved building covered structures and improving storage of materials and products (23.1%). The next most frequently used physical improvements were ponds and other containment structures (19.3%), followed closely by improved drainage, grading and erosion control (18.5%). The final most frequently used controls were berms, dikes and diversion structures (14.7%). Treatment was the least frequently used type of improvement and only 7.6% of the respondents employed this method of control.

Question 27 asked "Do you believe that the improvement or potential improvement in water quality is worth the corresponding expenditures?" The choices of answers were; yes, no and maybe. The purpose of this question was to obtain a subjective evaluation of whether or not those being regulated feel the storm water pollution control efforts are a worthwhile expenditure of pollution control funds. The responses to this question were about evenly split. Of the 443 respondents to this question, 30.5% said yes the improvements were worth the expenditures, 31.1% said no, they were not, and another 31.6% said maybe. The remaining 6.8% said they didn't know. The results are presented in a pie diagram with basically the same title as the question.

Year (Planned to Be) Expended

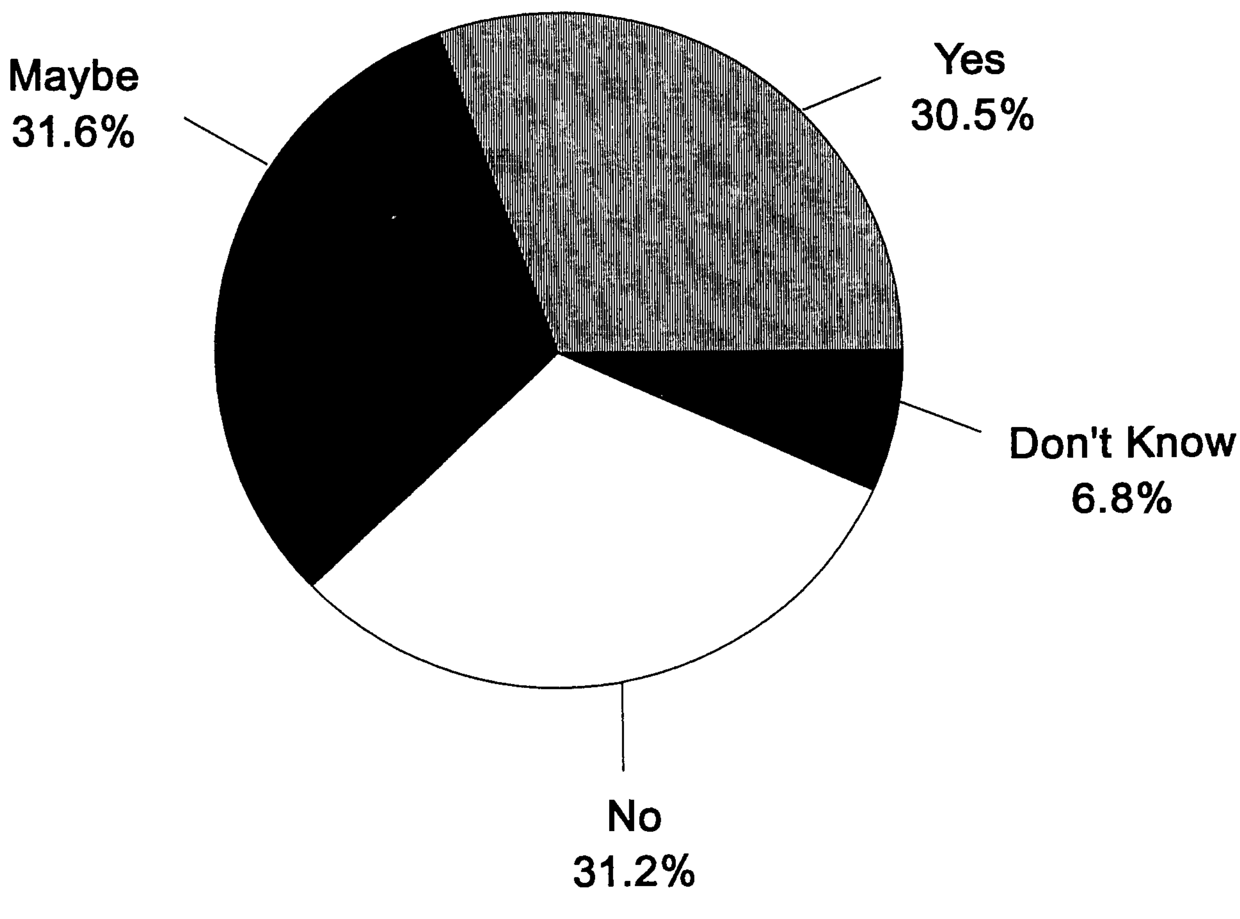


Types of Physical Improvements



R0016825

Is the Improvement or Potential Improvement in Water Quality Worth the Corresponding Expenditures?



Question 27

R0016826

In order to get a better understanding of how much expense was involved for those firms which felt water quality improvements were worth the expenditures versus those which did not, an analysis of the amount spent by firms on plans, annual operations, and construction was made. This was done by correlating those answering yes to Question 27 with the costs gathered in Question 26, and then correlating those answering no to Question 27 with the costs in Question 26.

Those in the group that felt it was a worthwhile expenditure spent an average of $6,466 on the preparation of their pollution prevention plan, had an average of $3,324 per year annual operating cost, and had expended an adjusted average of $ 47,186 in capital improvements. The latter figure was adjusted by excluding three facilities which reported to have spent $1,000,000; $1,400,000 and $4,000,000 in capital improvements. These figures are so overwhelmingly large when compared to those which fell in the normal distribution range that including them would increase the average spent by 340% to $160,436. The latter figure is clearly not representative for this analysis.

Those in the group which said it was not worth the expense spent an average of $7,537 to prepare a pollution prevention plan, had an average of $ 4,813 per year annual operating cost, and had expended an average of $ 46,873 in capital improvements. The latter figure excluded one facility as an anomaly significantly outside of the normal range which reported to have spent $800,000 in capital improvements. If it were included, it would bring the average spent to $61,589.

As can be seen, there is little difference in opinion regarding the worthwhile benefits based on the amount the respondents had to pay to improve water quality. Those who felt it was not worthwhile spent an average of $1,071 or about 16.5% more on the preparation of their pollution prevention plans than those who didn't feel it was worthwhile.

An interesting side analysis revealed 85.5% of the 138 respondents who felt it was not worth the expense provided costs, while only 70.4% of the 135 respondents who felt it was worth it didn't provide any costs. The latter analysis seems to indicate that if there were no costs or the costs were so low as to be insignificant or not memorable, the improvement in water quality was worth the expense.

In addition, the annual operating costs for those who felt it was not worthwhile was $1,489 per year or 45% more than those who felt it was worth it. In this case, 73.9% of the respondents who stated that the costs were not worth the expenditures provided costs, while only 61.5% of those who said it was worth the expense provided costs. Again, this seems to indicate that those without annual operating expenses found the improvement in water quality was worth the cost.

In the last category, that of capital improvements, the average capital cost of improvements of those who felt the improvement in water quality was a worthwhile expenditure was for all practical purposes the same as the cost for those who did not feel it was worthwhile. There was less than 1% difference in the average amount spent. In addition almost an equal number who said it wasn't, 51 (37.0 %), provided cost data as did the ones who said it was, 56 (41.5%). The facilities with the three highest expenditures, each over $1,000,000; all felt that the improvement in water quality was worth the corresponding expenditure.

One possible conclusion of this analysis is that costs in the range of $6,466, $3,324, and $47,186 for plan development, annual operating and maintenance, and capital improvements, respectively, are generally felt to be worthwhile expenditures to reduce pollution from storm water runoff and costs in the range of $7,537 for a storm water pollution prevention plan and $ 4,813 per year annual operating costs are not. In actuality, the opinion on whether it is worthwhile or not may be based more on the improvement or lack of improvement in water quality rather than the expense.

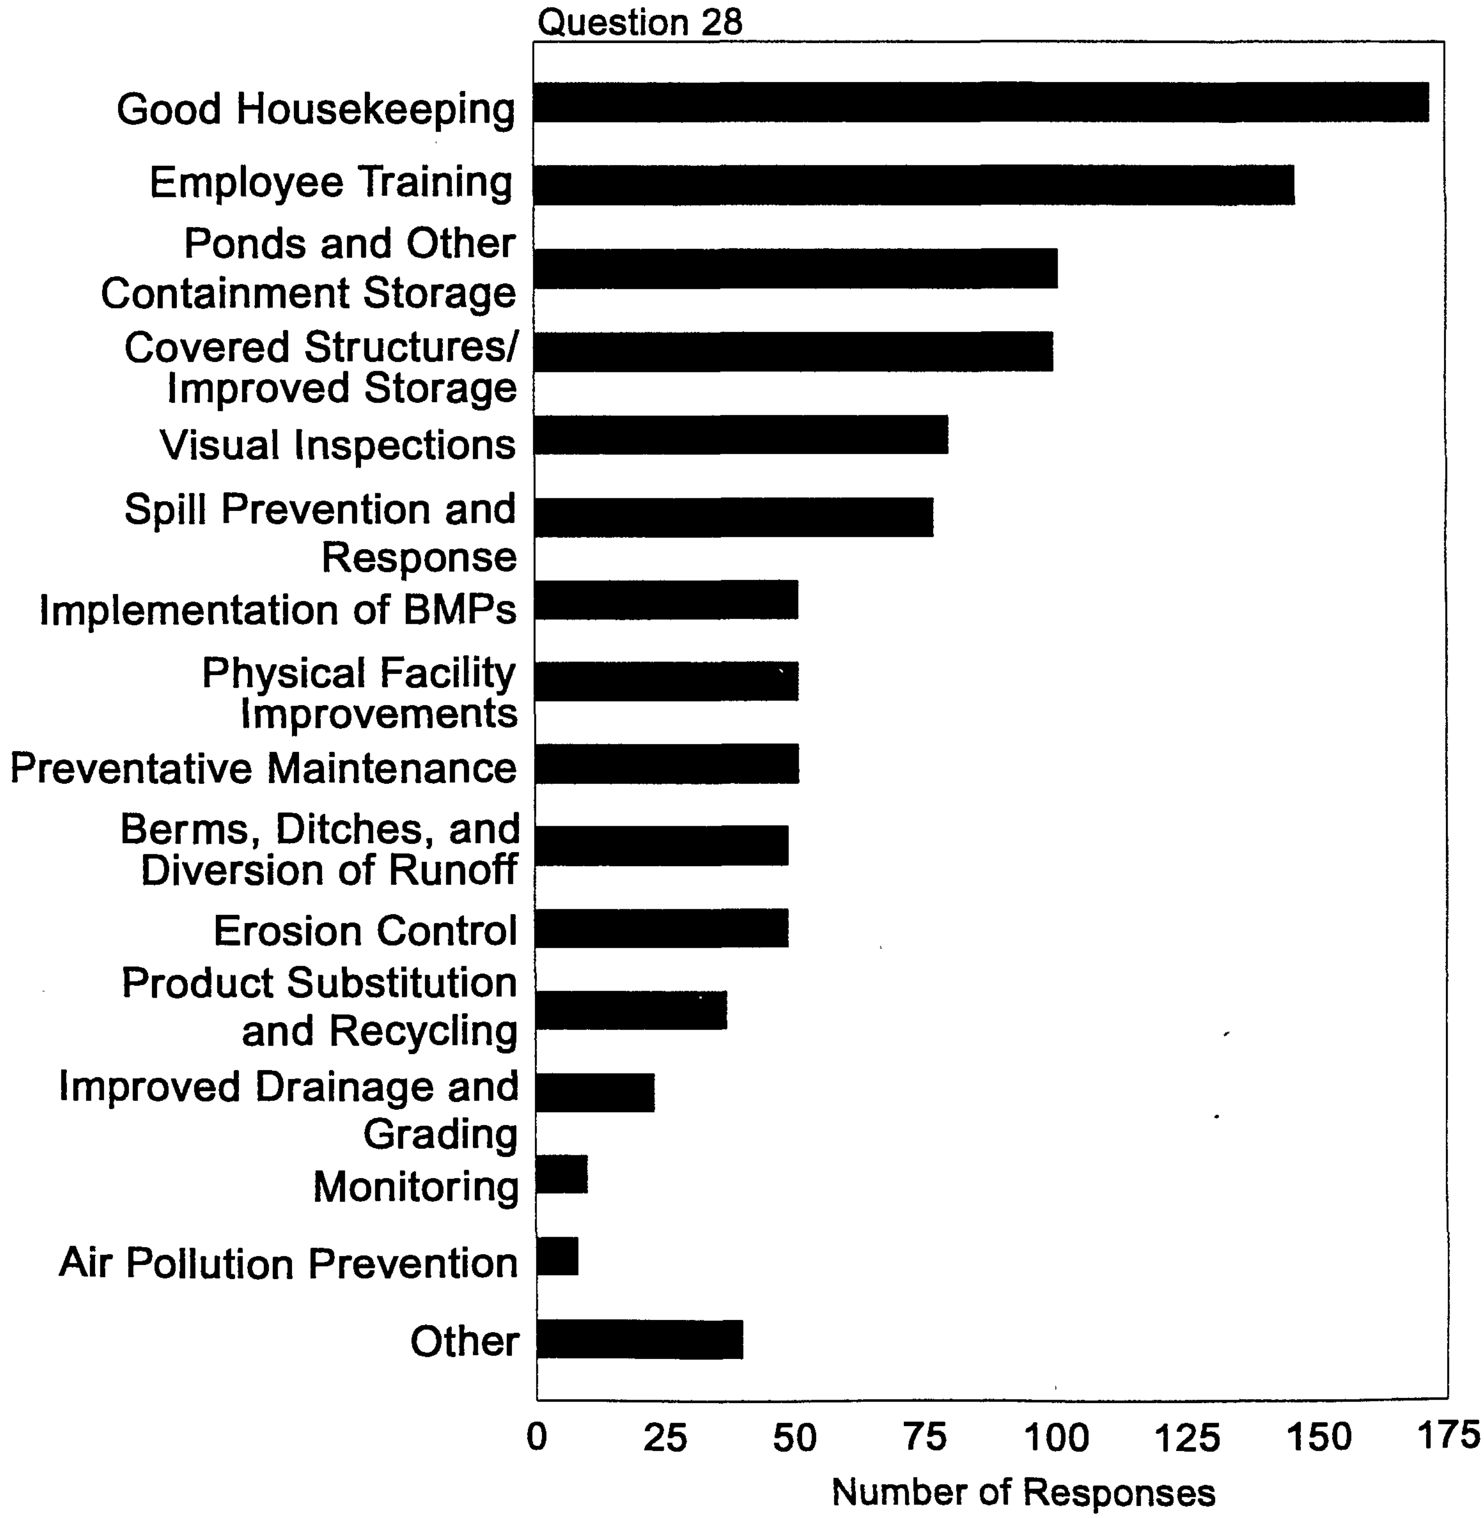
The effectiveness question was then broadened to include all actions taken to improve storm water quality and the cost factor was also brought into the analysis. Question 28 asked "What do you consider to be the three most cost effective activities that the facility has implemented or plans to implement to control storm water pollution?" The answers to this question were left wide open, i.e. the respondent was asked to simply fill in those three items which they felt to be most cost effective using whatever terms best suited the individual. The latitude permitted in terminology used to respond to this question made analysis of the results somewhat difficult. Nevertheless, groups of actions were formulated and these were analyzed. A total of 391 responded to this question.

Two major categories of activities logically evolved from the data. The first group parallels the elements of the facilities pollution prevention plan, namely: good housekeeping, preventative maintenance (of the facilities and equipment), erosion control, visual inspections, product substitution, and physical facility improvements. The second group includes specific physical facility improvements plus other miscellaneous activities. These include: ponds and other containment structures; improved drainage, grading and erosion control, covered structures and improved storage; berms, dikes, and diversion of runoff; monitoring; air pollution prevention; implementation of best management practices; and other. The frequency of selection is presented in the histogram on the following page.

The two most frequently occurring responses which industries identified as the most cost effective activities implemented to control storm water pollution were good housekeeping and employee training. These two activities, which are both critical components of a storm water pollution plan, were observed to be selected over 50% more frequently than the next two responses. The next two most frequently chosen responses both fell into the structural improvements group. These facility improvements included construction of ponds and other containment structures and improvement of storage including installation of covered storage facilities.

The next most cost effective activities, which were about 20% less frequently selected than the structural improvements described above, were two more components found in

Most Cost Effective Activities to Control Storm Water Pollution



R0016829

the typical storm water management plan. These were visual inspections and spill prevention and response activities.

While it is important to know what industry management feel are the most cost effective activities that have been implemented to control storm water pollution, it is equally important in evaluating the effectiveness of the storm water permit program to determine how many of these controls were in place prior to being required by the program.

Question 29 asked "Which of the above items were in place prior to or independent of the requirements of the storm water program?" The choices of answers were based on the responses to Question 28, that is the respondent was asked to identify each of the items in place prior to the requirements by placing a mark beside the item listed. The selections were item #1, item #2, item #3 and none. There were 397 respondents to this question. The selections are presented in the histogram entitled " Items in Place Prior to or Independent of the Requirements."

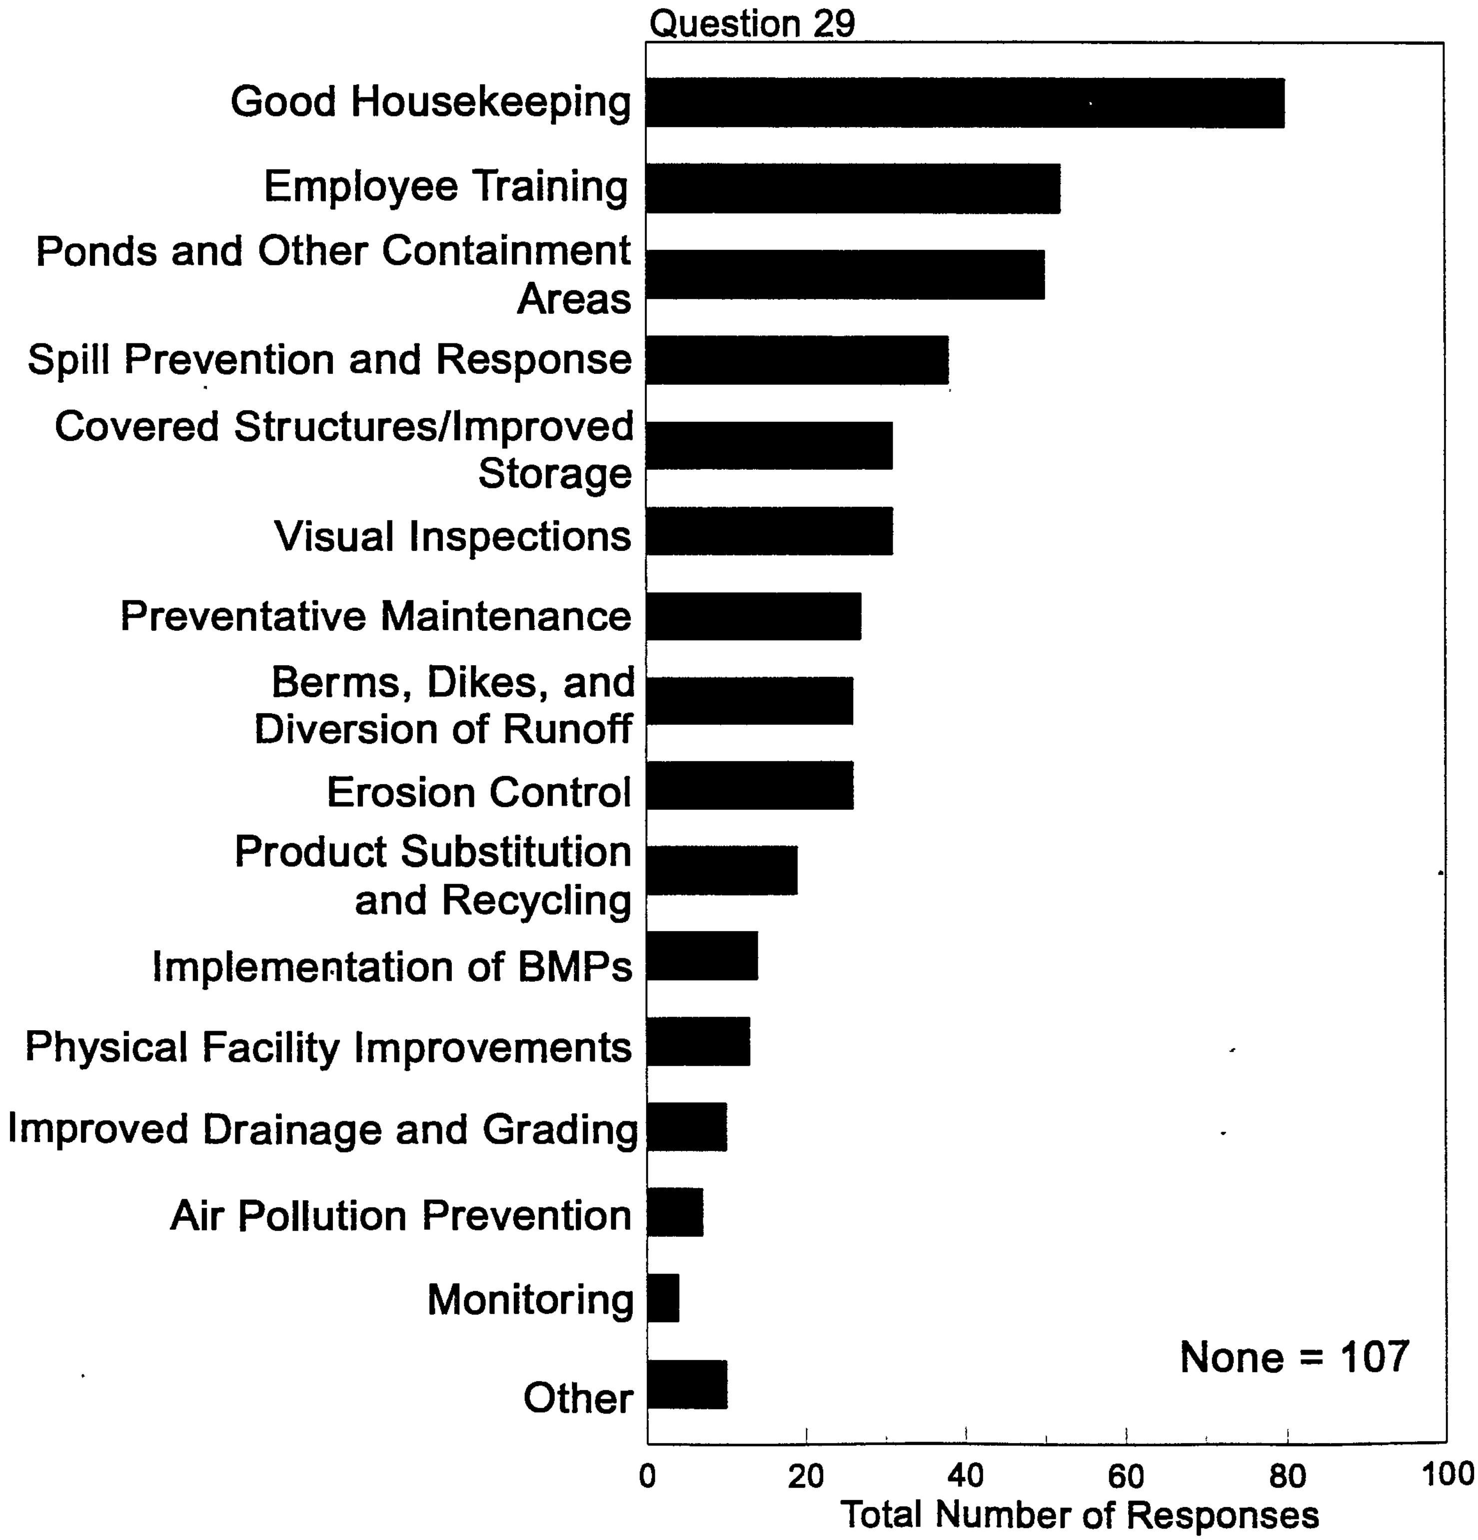
The data indicate the majority of industrial facilities (63.0%) already had instituted some level of storm water management activities even before they were required to do so by the permit program. However, in analyzing the data further, it can be concluded that a very low percentage of the most cost effective activities were in place prior to the storm water program. Specifically, 27.0% of the respondents indicated that <u>none</u> of the improvements were in place prior to the storm water permit program requirements; 18.3 % of the facilities had implemented good housekeeping practices; 11.9 % had implemented employee training, 11.4 % had implemented structural controls such as ponds and containment structures, 7.1 % had already constructed improved storage facilities, 7.1 % had instituted visual inspections and 8.7 % had spill prevention and response procedures.

There are two, not totally contradictory, ways of looking at the analysis of these data. It can be concluded that the majority of the industrial activities already had instituted some level of storm water management before they were required to do so by the NPDES permit program. It can also be concluded that a significant percentage of industries had no previous motivation to implement storm water pollution prevention techniques prior to the program.

Additionally, it can be seen from the data that about an equal number (53.4 %) of industrial activities had implemented nonstructural solutions to storm water problems as had constructed facilities to control storm water pollution (46.6%). This seems to indicate that as many operations had to construct facilities to comply with other regulations as had to implement the best management practices recommended in the storm water pollution prevention plans.

The next logical item to determine was which techniques are perceived to be the least cost effective. Question 30 asks "what do you consider to be the three least cost effective activities that the facility has implemented or plans to implement to control storm water pollution." As with Question 28, the respondent was asked to simply fill in those three

Items in Place Prior to or Independent of the Requirements



R0016831

items which they felt to be least cost effective using whatever terms best suited the individual. A total of 248 responded to this question and the results are presented in the histogram entitled "Least Cost Effective Activities to Control Storm Water Pollution."

By far the single largest response to this question and therefore the perceived least cost effective activity of the program is monitoring, or sampling and analysis. It appears that either the costs associated with monitoring are too high or the information derived from sampling and analysis is perceived as being of little value to effectively reducing storm water pollution. This is a consistent observation since no one listed monitoring or sampling and analysis among the top three most cost effective activities.

The second most frequently listed least cost effective activity of the storm water permit program was record keeping and reporting. This is consistent with the responses to Question 25 which showed that reporting and record keeping was the most frequently selected "ineffective" component of storm water pollution prevention plans by the majority of respondents.

Other activities considered to have low cost effectiveness include planning and mapping, visual inspections, and permits, fees and costs. A few respondents felt that some activities, which most people felt were highly cost effective, were the least cost effective for their facilities - namely good housekeeping and training.

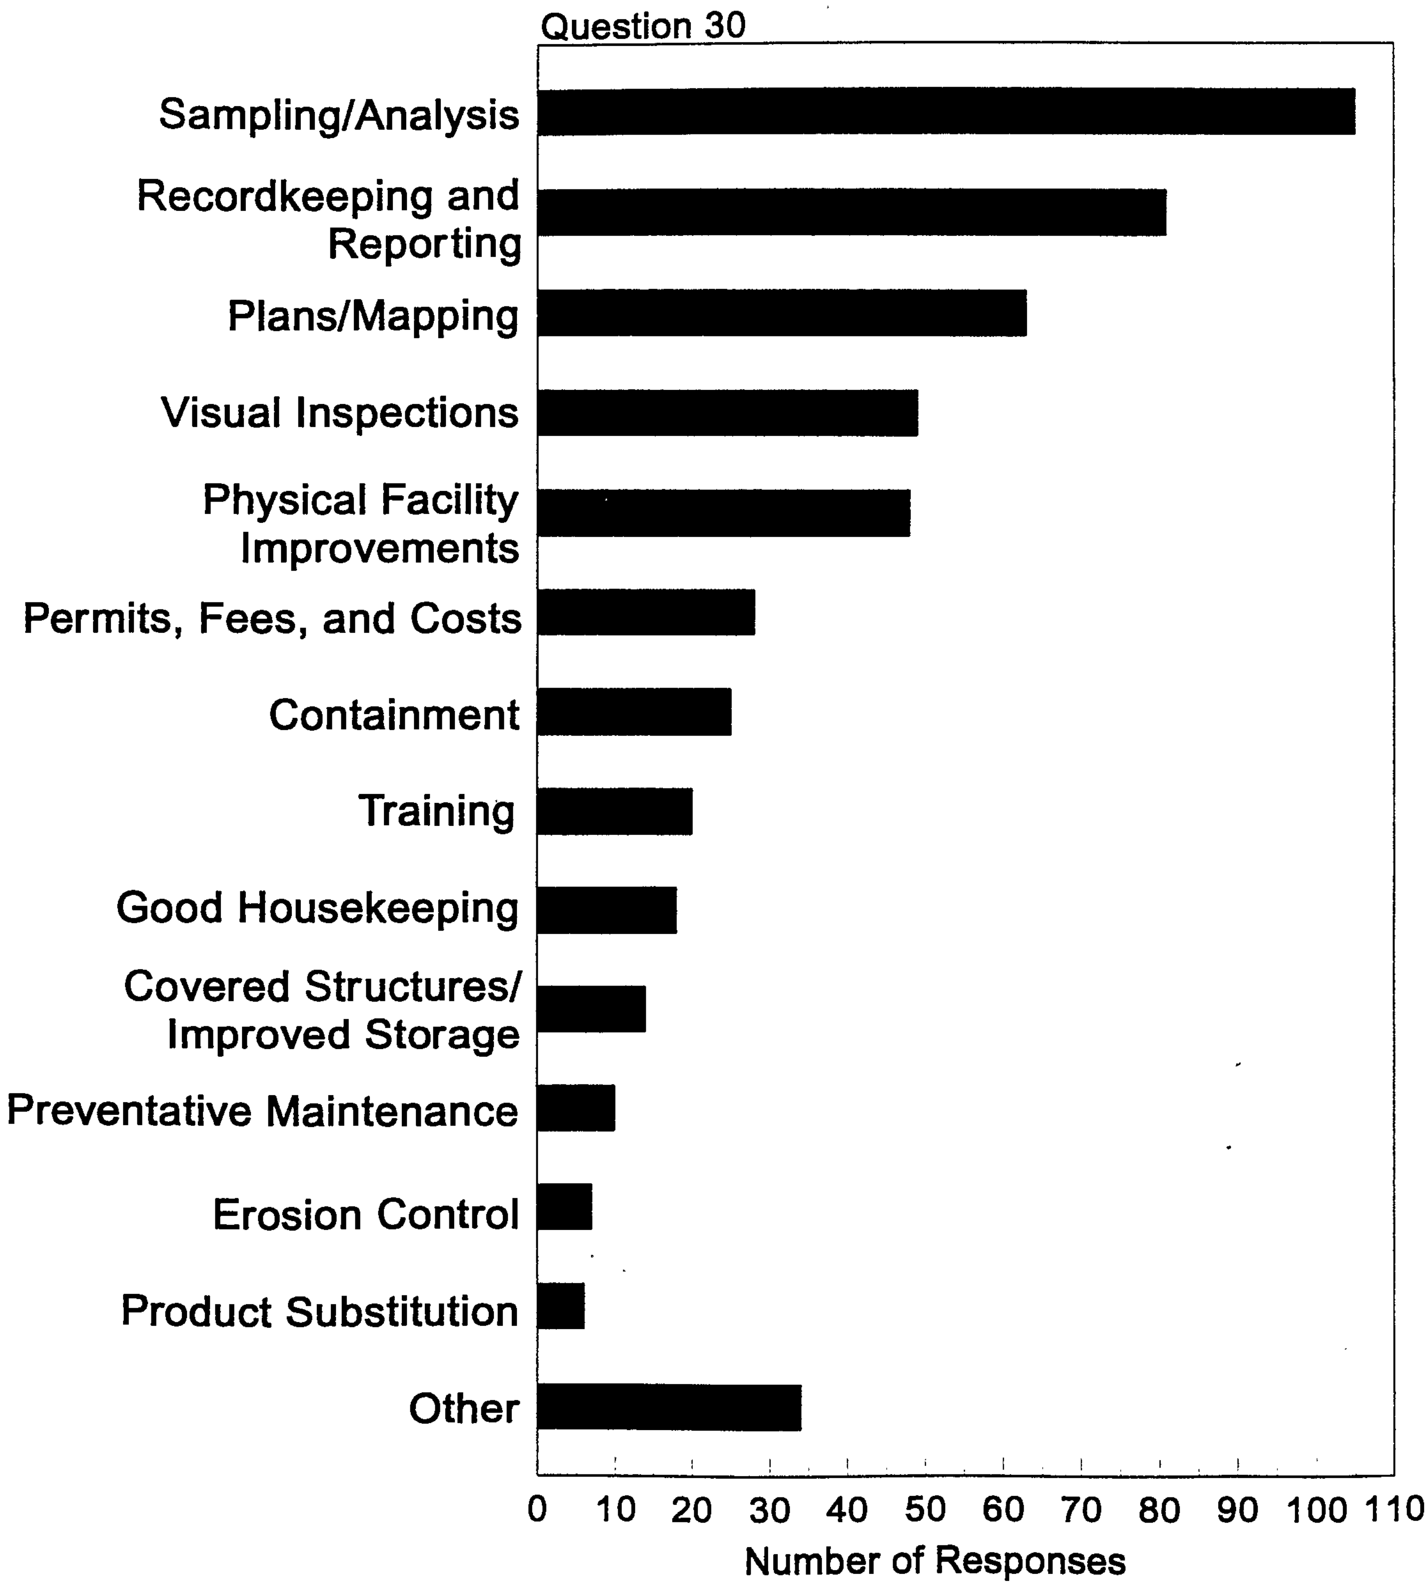
As one of the concluding questions, Question 31 asked "if you were no longer required to maintain BMP's under the storm water permit program, how much of the plan would you continue to implement?" The choices given were; all of it, some of it and none of it. A pie chart identified with the question as the title displays the results.

Of the 432 respondents to this question 42.8% said that they would retain the plan in its entirety, while 52.3% said they would retain some of it. It is interesting to note that only 4.9% or 26 respondents stated that they would retain none of it.

The follow-up question to this, Question 32, asked "if some, which would you retain?" Three blank lines were provided for the respondent to write the answer(s). The responses to this question followed very closely those of Question 25 and to some extent Question 28, relating to the most cost effective components of the pollution prevention plan and the most cost effective activities, respectively. A histogram entitled "If Voluntary, Which Practices Would Be Continued ?" presents the results. Again good housekeeping, inspections, employee training, spill prevention and response, and preventative maintenance were the leading answers.

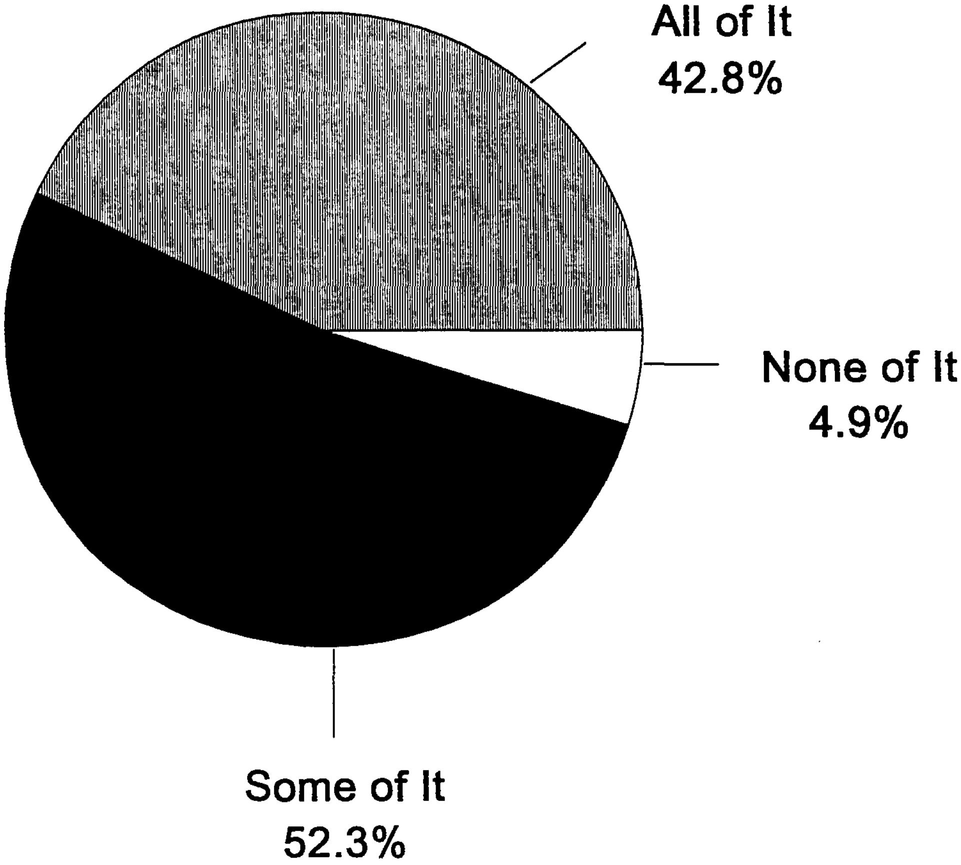
Question 33 then asks "If all or some of the plan would continue to be implemented, what are the main reasons?" The list of choices given were: required by other regulations, economic/production benefit, environmental benefit, corporate policy/procedures, and other (specify). A total of 410 industrial activities responded to this question by selecting

Least Cost Effective Activities to Control Storm Water Pollution



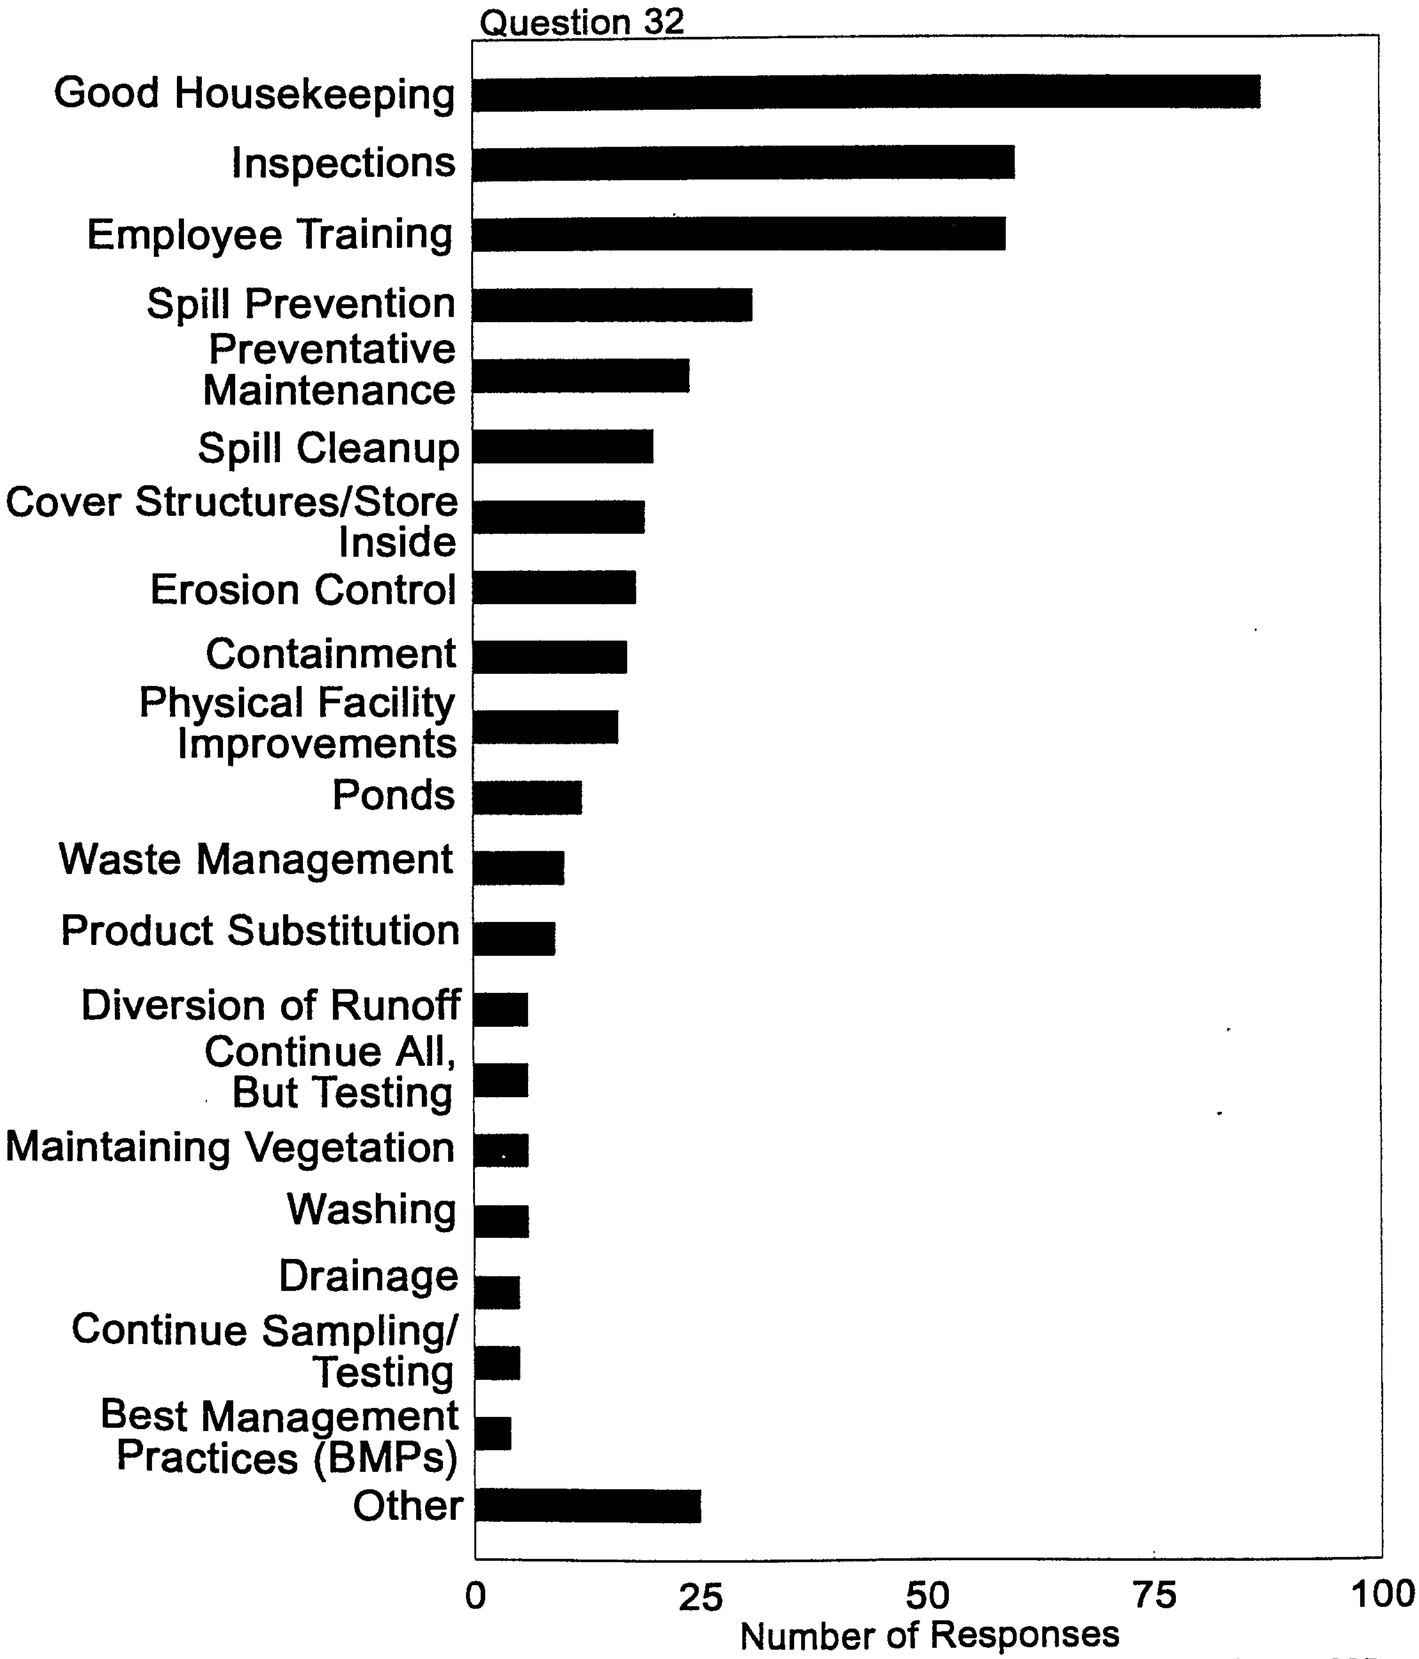
R0016833

How Much of the Plan Would be Voluntarily Implemented if BMPs Were No Longer Required?



Question 31

If Voluntary, Which Practices Would Be Continued?



R0016835

one or more from the list of choices. A histogram entitled "Reasons for Implementation of All or Some of the Plan" presents the results.

The most frequently selected choice was "environmental benefits" chosen by 80.0 % of the respondents. This was followed by "corporate policy/procedures" chosen by 59.0% and "required by other regulations" chosen by 46.3%. Substantially below this range of selected reasons were "economic benefits" selected by 23.7%. And at the lowest level were "public relations" with 2.2 % and "other" with 5.6%. It should be noted that "public relations" was not one of the given choices so it had to be filled in by the respondent.

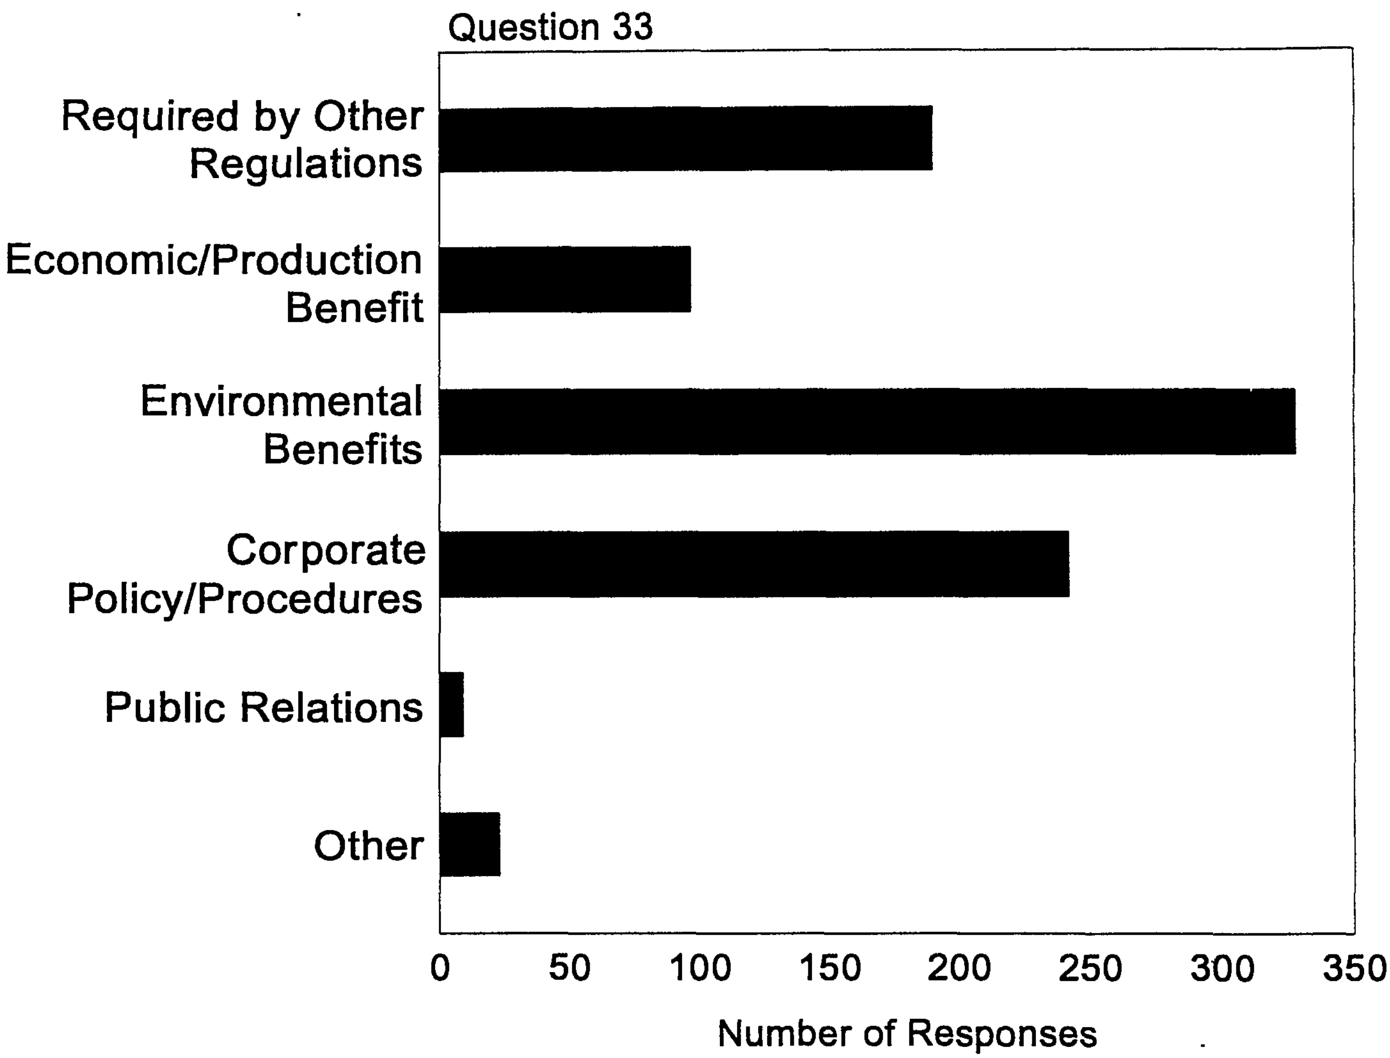
The final two questions requested the questionnaire recipients to comment. Question 34 asked "do you know of any significant obstacles which have prevented the general permits approach from being an effective component of the storm water program?" and Question 35 asked "any comments?" There were a few hundred responses to these questions, some of the most relevant of which are summarized below. An attempt was made not to repeat information which may have already been gathered in response to other questions contained in the survey.

Significant obstacles which prevent the general permits program from being effective include: costs to implement; no follow-up (i.e. lack of field inspections and enforcement); regulations are complex, confusing and burdensome; infrequent rainfall, and lack of company management concern.

A summary of other comments received includes: hassle for small businesses, redundant with other requirements, other companies and sources cause more pollution, remote and small sites should not be controlled, high costs and low water quality improvements.

The final conclusions and recommendations of the study are presented in the Executive Summary.

Reasons for Implementation of All or Some of the Plan



Appendix

January 26, 1996

Dear,

The Water Environment Federation (WEF) is a nonprofit scientific and technical organization devoted to the preservation and enhancement of water quality worldwide. WEF has cooperative agreement with the United States Environmental Protection Agency to study the effectiveness of the National Pollutant Discharge Elimination System (NPDES) Industrial Storm Water Permit Program. Under the Program, affected industries are required to develop Storm Water Pollution Prevention Plan to control the impact of storm water at their facilities. In this study, WEF is determining how well the pollution prevention plan approach is working. The overall objective of the study is to improve storm water regulations and reduce the burden on business and industry; it is **not** to use the information for compliance or enforcement purposes.

WEF, in conjunction with a number of affected industries and trade associations, had developed the enclosed questionnaire to gather information critical to the study. Due to the size and complexity of the storm water program, we are sending this questionnaire to a very limited percentage of those included in the permit program. Because our mailing is limited, we need **everyone's** help. We understand that your time is valuable, but we hope you will take fifteen minutes to complete this survey to help improve Storm Water Program, ultimately for your own benefit. If you are the best person to respond, please complete the survey as thoroughly as possible. If you know nothing about the storm water program, please forward the questionnaire to someone at your facility who does. We ask that you return the survey in the enclosed return envelope by **Friday, February 16, 1996.**

In trial survey, several companies expressed concern over anonymity. We assure you that your responses will be kept confidential by WEF, and your anonymity will be preserved. An outside firm had been contracted to handle the data and compile the final report. However, if you wish to receive a copy of an executive summary of the results, be sure to identify your firm on the separate request form provided in this mailing. You will receive a summary only if you complete the survey and identify your firm's name and mailing address.

Thank you in advance for your cooperation in this important effort. If you have any questions about the project, please feel free to include them in your response.

Very truly yours,

William R. Hancuff

Effectiveness of Industrial Storm Water Program Industry Questionnaire

MARKING INSTRUCTIONS
- Use a No. 2 pencil only, do NOT use pen.
- Completely erase any mark you change.
- Marks should completely fill in the squares.
- Make no stray marks.

CORRECT MARK ■

This survey is completely confidential. Please complete and return the enclosed survey in the prepaid envelope by **February 16, 1996**. Thank you for your help.

1. What is the primary and secondary standard industrial classification (SIC) code for your facility? Enter the SIC code in the box and fill in the corresponding squares in each column.

Primary ☐☐☐☐ Secondary ☐☐☐☐

Primary					Secondary				
0	☐	☐	☐	☐	0	☐	☐	☐	☐
1	☐	☐	☐	☐	1	☐	☐	☐	☐
2	☐	☐	☐	☐	2	☐	☐	☐	☐
3	☐	☐	☐	☐	3	☐	☐	☐	☐
4	☐	☐	☐	☐	4	☐	☐	☐	☐
5	☐	☐	☐	☐	5	☐	☐	☐	☐
6	☐	☐	☐	☐	6	☐	☐	☐	☐
7	☐	☐	☐	☐	7	☐	☐	☐	☐
8	☐	☐	☐	☐	8	☐	☐	☐	☐
9	☐	☐	☐	☐	9	☐	☐	☐	☐

2. Concerning industrial storm water run-off, how many facilities are under your responsibility? Enter the number of facilities in the box and fill in the corresponding squares in each column.

☐☐☐☐

0	☐	☐	☐	☐
1	☐	☐	☐	☐
2	☐	☐	☐	☐
3	☐	☐	☐	☐
4	☐	☐	☐	☐
5	☐	☐	☐	☐
6	☐	☐	☐	☐
7	☐	☐	☐	☐
8	☐	☐	☐	☐
9	☐	☐	☐	☐

NOTE: If you are responsible for more than one facility, answer the following questions based on only one (your primary) facility.

3. What is the size of this facility? ____________

Estimated number of full-time employees? ________

Estimated acreage of this facility? ____________

Number of environmental staff? ____________

4. Is the facility property -

☐ Owned
☐ Leased

5. Is your company categorized as a small business?

☐ Yes
☐ No
☐ Don't know

If yes, why? ____________

____

6. Does storm water run off this property? **Mark all that apply.**

☐ **Ditches**
☐ Trenches
☐ **Pipes**
☐ Other Point Sources (specify) ____________
☐ **Only Surface Flow (no point sources)**

7. What is the average annual rainfall at your location? **Mark only one.**

☐ 0-10"
☐ 11-20"
☐ 21-30"
☐ 31-40"
☐ 41-50"
☐ >50"

8. Is this facility required to meet the reporting requirements of EPCRA Section 313 regarding "water priority chemicals"?

☐ Yes
☐ No
☐ Don't Know

9. Do you have a storm water related pollution prevention plan for this facility?

☐ Yes
☐ No
☐ Don't Know

If the answer to Question 9 is **no or don't know**, please continue by completing **Section A.**
If the answer to Question 9 is **yes**, please complete **Section B** (go directly to Question 16).

R0016841

Section A

To be completed if the facility **does NOT** have a Pollution Prevention Plan

10. Is your facility regulated by the storm water permit program?

- ☐ Yes
- ☐ No
- ☐ Don't Know

11. Did you or will you modify your facilities in order to eliminate the need for compliance with regulations?

- ☐ Yes
- ☐ No

12. If the answer to Question 11 is **yes**, how much did it or will it cost? In what year?

Cost ____________

Year ____________

If the answer to Question 10 was **no or don't know,** please return the survey in the enclosed envelope. Thank you!

13. If your facility is regulated by a storm water permit program, who is the lead permitting authority?

- ☐ Environmental Protection Agency - Region # ______
- ☐ State of ____________
- ☐ Local government authority (specify) ____________
- ☐ Other (specify) ____________

14. Why have you not prepared a storm water pollution prevention plan? **Mark all that apply.**

- ☐ Meets storm water limits under existing NPDES permit
- ☐ Not required at this time
- ☐ Discharges to a municipal collection system
- ☐ No storm water contact with regulated industrial activities
- ☐ Submitted Notice of Intent
- ☐ Did not know it was required
- ☐ Requirements are too confusing
- ☐ Other (specify) ____________

15. Any comments? ____________

____

____

Thank you! Please return the survey in the enclosed envelope.

Section B

To be completed if the facility **has** a Pollution Prevention Plan.

16. Who is the permitting authority for this facility's storm water permit?

- ☐ Environmental Protection Agency - Region # ______
- ☐ State of ____________
- ☐ Local government authority (specify) ____________
- ☐ Other (specify) ____________

17. Prior to the Storm Water Permit Program, did this facility have any experience with either voluntary or regulation required pollution prevention plans that directly affected storm water?

- ☐ Yes
- ☐ No

18. Does this facility's storm water pollution prevention plan overlap with other mandated requirements?

- ☐ Yes
- ☐ No
- ☐ Don't Know

If yes, which requirements?

- ☐ **Best Management Practice Plan (Clean Water Act-Nonpoint Source)**
- ☐ Waste Minimization Plan (CERCLA/SARA)
- ☐ **Spill Prevention Control & Countermeasures (SPCC) Plan (Clean Water Act & RCRA)**
- ☐ Other (specify) ____________

19. How was this facility's storm water pollution prevention plan developed? **Mark all that apply.**

- ☐ **Facility staff**
- ☐ Corporate staff
- ☐ **External consultant**

- ☐ **Used trade association guidance**
- ☐ Used EPA guidance document
- ☐ **Used State Agency guidance**

- ☐ **Adapted model plan supplied by company or corporate office**
- ☐ Adapted standard operating procedures from company
- ☐ **Adapted from another pre-existing plan**
- ☐ Other (specify) ____________

R0016842

20. How long has the storm water pollution prevention plan been implemented?

☐ Not implemented
☐ < 1 year
☐ 1 year
☐ 2 years
☐ > 2 years

21. Has water quality monitoring and analysis been performed on the storm water runoff from this facility?

☐ Yes
☐ No
☐ Don't Know

22. If yes, in your opinion, did results indicate whether Best Management Practices (BMPs) are successful?

☐ Yes
☐ No
☐ Insufficient data
☐ Inconclusive data

23. Whether you have conducted water monitoring or not, in your opinion, how much improvement in water quality or reduction in storm water pollution has there been or is there likely to be as a result of your storm water (or other) plan?

☐ None
☐ Minor
☐ Moderate
☐ Significant
☐ Don't Know

24. Was or is any improvement to the water quality or reduction in storm water run-off possible?

☐ Yes
☐ No

25. Considering actual and potential benefits and based on your impression, rate the following elements of the facility's pollution prevention plan as to their effectiveness in preventing pollution from storm water runoff.

	Highly Effective	Moderately Effective	Not Effective	Not Applicable
Good housekeeping	☐	☐	☐	☐
Preventative maintenance	☐	☐	☐	☐
Elimination of industrial source discharges	☐	☐	☐	☐
Sediment and erosion control	☐	☐	☐	☐
Visual inspections	☐	☐	☐	☐
Spill prevention and response	☐	☐	☐	☐
Site mapping (operations, drainage, and runoff collection mapping)	☐	☐	☐	☐
Employee training	☐	☐	☐	☐
Record keeping and reporting	☐	☐	☐	☐
Raw material or product substitution	☐	☐	☐	☐
Annual site compliance evaluation	☐	☐	☐	☐
Physical facility modification (requiring construction)	☐	☐	☐	☐
Other (specify) ________	☐	☐	☐	☐

26. How much did the development and implementation of this facility's storm water pollution prevention plan cost.

Cost of plan development $________________

Plan's implementation annual operating cost $________

Capital cost of physical improvements $____________

Year (planned to be) expended ____________

Types of physical improvements ____________

____

27. Do you believe that the improvement or potential improvement in water quality is worth the corresponding expenditures?

☐ Yes
☐ Maybe
☐ No
☐ Don't Know

28. What do you consider to be the three **most** cost effective activities that the facility has implemented or plans to implement to control storm water pollution?

1. ______________________________
____

2. ______________________________
____

3. ______________________________
____

29. Which of the above items were in place prior to or independent of the requirements of the storm water program? **Mark all that apply.**

☐ None
☐ 1 above
☐ 2 above
☐ 3 above

30. What do you consider to be the three **least** cost effective activities that the facility has implemented or plans to implement to control storm water pollution?

1. ______________________________
____

2. ______________________________
____

3. ______________________________
____

31. If you were no longer required to maintain BMP's under the storm water permit program, how much of the plan would you continue to implement?

☐ All of it
☐ Some of it
☐ None of it

32. If some, which practices would you continue?

____
____
____

33. If all or some of the plan would continue to be implemented, what are the main reasons? **Mark all that apply.**

☐ Required by other regulations
☐ Economic/production benefit
☐ Environmental benefits
☐ Corporate policy/procedures
☐ Other (specify) ______________

34. Do you know of any significant obstacles which have prevented the general permits approach from being an effective component of the storm water program?

____
____
____

35. Any comments? ______________________________
____
____
____
____

Thank you for taking the time to complete this survey. Please return the questionnaire and the optional executive summary request and identification form in the enclosed envelope by February 16, 1996. If the envelope has been misplaced, send it to:

Final Report

of the

SBREFA Small Business Advocacy Review Panel

on EPA's Planned Proposed Rule for the

National Pollutant Discharge Elimination System

Storm Water Phase II

August 7, 1997

R0016846

Report of the Small Business Advocacy Review Panel

on EPA's Planned Proposed Rule for the

National Pollutant Discharge Elimination System

Storm Water Phase II

INTRODUCTION

This report describes the review by the Small Business Advocacy Review Panel convened for the proposed rulemaking by the Environmental Protection Agency (EPA) that would revise National Pollutant Discharge Elimination System (NPDES) regulations to address currently unregulated discharges of storm water. On June 19, 1997, EPA's Small Business Advocacy Chairperson convened this Panel under section 609(b) of the Regulatory Flexibility Act (RFA) as amended by the Small Business Regulatory Enforcement Fairness Act of 1996 (SBREFA). Section 609(b)(1) requires convening of a review panel prior to publication of an initial regulatory flexibility analysis that an agency is required to prepare under the RFA. In addition to its chairperson, the Panel consists of representatives of EPA's Office of Water (the EPA program office responsible for developing the rule), the Office of Information and Regulatory Affairs within the Office of Management and Budget, and the Chief Counsel for Advocacy of the Small Business Administration.

This report provides background information on the proposed rule being developed and the types of small entities that would be subject to the proposed rule, describes efforts to obtain the advice and recommendations of representatives of those small entities, and summarizes the comments, advice and recommendations that have been received to date from those representatives. The complete written comments of the representatives are attached to this report.

Section 609(b) of the RFA directs the review panel to report on the comments of small entity representatives and make findings as to issues related to identified elements of an initial regulatory flexibility analysis (IRFA) under section 603 of the RFA. Those elements of an IRFA are:

- The number of small entities to which the proposed rule will apply.
- Projected reporting, record keeping, and other compliance requirements of the proposed rule, including the classes of small entities which will be subject to the requirements and the type of professional skills necessary for preparation of the report or record.
- Other relevant Federal rules which may duplicate, overlap, or conflict with the proposed rule.

- Any significant alternatives to the proposed rule which accomplish the stated objectives of applicable statutes and which minimize any significant economic impact of the proposed rule on small entities.

Once completed, the Panel report is provided to the agency issuing the proposed rule and included in the rulemaking record. In light of the Panel report, the agency is to make changes to the proposed rule or the IRFA for the proposed rule, where appropriate.

It is important to note that the Panel's findings and discussion are based on the information available at the time this report was drafted. EPA is continuing to conduct analyses relevant to the proposed rule, and additional information may be developed or obtained during the remainder of the rule development process. The Panel makes its report at an early stage of the process of development of a proposed rule and its report should be considered in that light. At the same time, the report provides the Panel and the Agency with a timely opportunity to identify and explore potential ways of shaping the proposed rule to minimize the burden of the rule on small entities while achieving the rule's statutory purposes. Any options the Panel identifies for reducing the rule's regulatory impact on small entities may require further analysis and/or data collection to ensure that the options are practicable, enforceable, environmentally sound and consistent with the statute authorizing the proposed rule.

BACKGROUND

In 1987, Congress amended the Clean Water Act to require EPA to develop a phased regulatory program focusing on controlling contaminated discharges associated with storm water runoff.[1] In the 1987 Water Quality amendments, Congress established a tiered approach to address certain industrial, municipal, and other storm water discharges. In the first phase of the program, Congress directed the EPA and authorized States to control discharges of industrial storm water and storm water from municipal separate storm sewer systems (MS4) serving populations over 100,000, with the intent of identifying an appropriate second tier of sources following two Congressionally mandated studies.

To implement these requirements, EPA published the initial permit application requirements (Phase I) for the priority categories of storm water discharges identified by Congress.[2] Generally, Phase I sources include storm water associated with certain industrial activities, medium and large municipalities, and large construction sites. Staggered deadlines were established for permit applications for these sources, with the last of the applications scheduled for submission by May, 1993.

---

[1] CWA, § 402(p).

[2] 55 FR 47990 (November 16, 1990).

To control industrial sources, Phase I regulations cover "storm water discharges associated with industrial activity" which means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing, or raw material storage areas at an industrial plant. EPA estimates that this definition applies to approximately 100,000 facilities nationwide (U.S. EPA, 1990a). To facilitate permitting, EPA established various permit application options for industrial activity including individual permit applications and group applications. EPA and authorized States have issued (or modified) individual permits and general permits based on these respective forms of application. Large construction sites (disturbing 5 acres or greater) are regulated in Phase I as an industrial activity, but with permit requirements that differ from those applicable to other industrial discharges.

To control municipal discharges, the Phase I rule requires NPDES permits for discharges into municipal separate storm sewer systems serving populations greater than 100,000. This universe of regulated municipalities includes 173 cities and 47 counties having large unincorporated, urbanized areas. EPA regulations require that NPDES permits for municipal storm water programs regulated in Phase I include requirements to effectively prohibit non-storm water discharges into the storm sewers and controls to reduce the discharge of pollutants to the maximum extent practicable (including management practices, control techniques, and system design and engineering methods, and other provisions appropriate for the control of such pollutants).

In March 1995, EPA completed and submitted to Congress a study entitled, *Storm Water Discharges Potentially Addressed by Phase II of the National Pollutant Discharge Elimination System Storm Water Program: Report to Congress*. As required under CWA §402(p)(5), this report identified the remaining unregulated storm water discharges, which by this time were known as Phase II. The report also characterized the nature and extent of pollutants in such discharges. The Phase II storm water report identified two major classes of potential Phase II storm water discharges: discharges from municipal separate storm sewers systems not subject to Phase I regulations and discharges from individual facilities not subject to Phase I. In a document entitled, "President Clinton's Clean Water Initiative" (February 1994), EPA summarized procedures and methods to control Phase II storm water discharges sufficient to mitigate impacts on water quality. This document responded to the requirement for an additional report under CWA §402(p)(5). This document recommended that the second phase of the storm water program focus on urbanized areas because EPA concluded that the urbanized areas that were not regulated under the Phase I requirements contributed 60 percent of the pollutant loads in storm water discharged from urban areas.[3]

---

[3] Phase I of the NPDES storm water program addresses 81.7 million people in portions of 136 urbanized areas. EPA estimated that 28 percent of pollutant loads in storm water discharged from urbanized areas come from those portions of these 136 urbanized areas not subject to Phase I regulations. In addition, EPA estimated that 32 percent of the pollutant loads in storm water discharged from urbanized areas come from the 269 urbanized areas not regulated under Phase I. Storm Water Phase II Report to Congress, ES-7.

In August 1995, EPA published a final rule that established a sequential application process in two tiers for the remaining unpermitted discharges of storm water (Phase II).[4] This rule allows the NPDES permitting authority to require permits for Phase II dischargers contributing to water quality impairment, and requires all other Phase II storm water dischargers to apply for NPDES permits by August 7, 2001. The August, 1995 Phase II rule was published, in part, to protect Phase II dischargers from CWA citizen suit liability in the absence of Agency action to establish more focused regulations. The preamble to the August 7, 1995 rule explained that the Phase II regulatory program would undergo further development. The Phase II rule would replace the August 7, 1995 rule.

EPA is currently subject to a court order to propose supplemental rules under §402(p)(6) of the CWA by November 25, 1997, and finalize these rules by March 1, 1999. See Natural Resources Defense Council, Inc. v. Browner, Civ. No. 95-634 PLF (D.D.C., April 6, 1995).

OVERVIEW OF PROPOSED PHASE II RULE

EPA's current draft of the proposed Phase II storm water regulation would address storm water discharges associated with two categories of sources: small municipal separate storm sewer systems (small MS4s) and construction activities at small construction sites. Under the draft proposed rule, many of these Phase II sources would be required to obtain NPDES permit coverage under an individual or general NPDES permit to address their storm water discharges.

The small MS4s that would be covered include those located within incorporated places, counties, or other places under the jurisdiction of a governmental entity (including Tribal or Territorial governments) that are located in an urbanized area but not included in Phase I.[5, 6] Also covered would be MS4s that are connected to and contribute substantially to pollutant loadings in another covered MS4. Finally, the rule would cover small MS4s in any incorporated place, county, or other place under the jurisdiction of a governmental entity that is designated by the NPDES permitting authority as requiring a permit based on the system's potential for impacting water quality. The permitting authority would be required to evaluate places outside urbanized areas that have a population density of greater than 1,000 per square mile and a population of greater than 10,000 people against specified water

---

[4] 60 FR 40229 (August 7, 1995).

[5] The existing storm water regulations ("Phase I") addresses large and medium MS4s. Generally, a large MS4 includes incorporated places with populations of 250,000 or more, while a medium MS4 includes incorporated places with populations of 100,000 or more, but less than 250,000.

[6] Excluding Federal Indian Reservations located within urbanized areas and having a population of less than 1,000 persons.

quality-related criteria[7] and determine whether these require permits. In addition, the permitting authority may designate other communities as subject to permit requirements based on their contribution to water quality impairment.[8]

Under the draft proposed rule, small MS4s would develop and implement a storm water management program designed to reduce pollutants to the maximum extent practicable and protect water quality. Such programs would include, at a minimum, measures to address requirements concerning public education and outreach, public involvement, illicit discharge detection and elimination, construction site storm water runoff control, post-construction storm water management in new development and redevelopment, and pollution prevention and good housekeeping of municipal operations.

The draft proposed Phase II storm water regulation would also address storm water discharges associated with construction activity (e.g., clearing, grading, and excavating activities) resulting in the land disturbance of greater or equal to one acre and less than five acres. In addition, sites disturbing less than one acre would be subject to regulation if they are part of a larger common plan of development or sale. Similar to MS4s, the NPDES permitting authority could designate construction activities as subject to regulation based on the potential for the activity to adversely impact water quality or be a significant source of pollutants. The NPDES permitting authority may also waive storm water discharges from construction activities that disturb less than five acres where specified conditions are satisfied.

The draft proposed rule would maintain the NPDES permitting authority's residual designation authority to require any discharge that contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States to seek coverage under an NPDES permit.

The draft proposed rule also contains a "no exposure" provision that would make all classes of industrial facilities eligible for waivers from the identification as "associated with industrial activity" under the existing regulations. The draft proposal represents a significant expansion in the scope of the no exposure provision originally promulgated in the 1990 rule [55 FR 47990 (November 16, 1990)] for discharges only from facilities classified as "light industry." The intent of this provision is to provide a simplified method of complying with §402(p) for industrial facilities which are entirely indoors, such as

---

[7] Under the proposed Phase II regulation, the NPDES permitting authority must develop and apply criteria to evaluate whether a storm water discharge results or has the potential to result in significant water quality impacts (including habitat and biological impacts).

[8] The Phase II rule would also provide that persons can petition the NPDES permitting authority to add an MS4 for coverage under the storm water program. And the permitting authority may waive an MS4 from coverage where specified conditions are satisfied.

within a larger office building, or at which the only items permanently exposed to precipitation are roofs, parking lots, vegetated areas, and other non-industrial areas or activities.

In order to be covered under the no exposure provision, EPA would propose that an owner or operator of an otherwise regulated facility would need to submit to the NPDES permitting authority a certification that the facility meets the no exposure requirements. The facility would need to allow the NPDES permitting authority (or operator of a municipal separate storm sewer system if the discharge occurs through a municipal system) to inspect the facility and to make such inspection reports publicly available, upon request. Finally, EPA would propose that the certification require only minimal amounts of information from the facility claiming the no exposure exemption. The NPDES permitting authority would maintain a simple registration list which should impose minimal administrative burden, but which would allow for a way of tracking which industrial facilities are exercising the exemption. EPA developed these two aspects of the proposed no exposure provision (applicability to all forms of industrial storm water discharge and certification/tracking) in order to respond to a judicial remand that found the original no exposure provision to be "arbitrary and capricious" for its distinction between types of industrial discharge and for failure of the rule to either require self-reporting of actual exposure or to require EPA to inspect and monitor such facilities.

APPLICABLE "SMALL ENTITY" DEFINITIONS

The draft proposed rule to revise existing requirements in the National Pollutant Discharge Elimination System (NPDES) storm water program may impose a regulatory burden on two types of small entities. The first type of small entities that may be affected is a "small governmental jurisdiction".[9] A governmental jurisdiction is usually, though not always, the owner or operator of a small municipal separate storm sewer system (MS4). The second type of small entity is a "small business". One class of small business is the operator responsible for the discharge from a construction activity that results in the land disturbance of between one acre and five acres. The operator of a construction activity is usually a construction contractor. The second class of small business that may be affected by this proposed rule are "light industries" in Category xi that would need to certify to the no exposure provision. The current version of the proposed rule includes a "no-exposure" provision that would provide regulatory relief to Phase I industrial/commercial facilities. This report includes tables showing the estimated numbers of small entities that may be affected by the proposed rule.

<u>MUNICIPAL SEPARATE STORM SEWER SYSTEMS (MS4s)</u>

[9] EPA uses the Regulatory Flexibility Act's definition of "small governmental jurisdiction" as the government of a city, county, town, school district or special district with a population of less than 50,000.

Regarding municipal separate storm sewer systems, the proposed rule uses the term "small municipal separate storm sewer system" to refer to all municipal separate storm sewers that are located in an incorporated place with a population of less than 100,000 as determined by the latest Decennial Census by the Bureau of Census. The owner or operator of a covered small MS4 may or may not be a "small governmental jurisdiction" as defined by the Small Business Administration (SBA). The proposed rule would affect three categories of small MS4s that are also small governmental jurisdictions that own or operate a MS4. (See Table 1)

CONSTRUCTION ACTIVITIES

Regarding construction activities, the proposed rule would not directly target individual "small businesses" but the construction activity itself. However, EPA expects most, if not all, construction activities that would be covered by this proposed rule would be performed by construction contractors in Standard Industrial Classification (SIC) Group 15 and 16. The SBA defines small business by the category of business using SIC codes and uses different cut-offs for different SIC codes. (See Tables 2 & 3)

"NO-EXPOSURE" PROVISION

The proposed rule would provide regulatory relief to many small businesses that would not have storm water discharges "associated with industrial activity" if they certify to the "no-exposure" provision. Facilities under the following SIC codes are potentially subject to regulation under Phase I of the NPDES storm water program: 10-14, 20-39, 4011, 4013, 41-42, 4221, 4222, 4225, 4226, 4311, 44, 45, 491, 5015, 5093, and 5171. Therefore, those facilities that would potentially benefit from the no exposure provision are also under these SIC code groups. (See Table 4).

Table 1:
Small Governmental Jurisdictions That May be Affected by Proposed Rule

	<u>Automatic</u> Coverage	**<u>Required</u> Watershed-based Evaluation for Potential Designation/Coverage by NPDES permitting authority**	**<u>Optional</u> Watershed-based Evaluation for Potential Designation/Coverage by NPDES permitting authority**
Coverage	MS4s < 50,000 & Located in an Urbanized Area *Approx. # = 3,031	MS4s from 10,000-50,000 & and population density > 1000/sq mi Located outside an Urbanized Area *Approx. # = 583	MS4s < 10,000 & Located outside an Urbanized Area *Approx. # = 17,540
		MS4 contributing substantially to the pollutant loadings of a regulated MS4. *Number is unknown.	
Waiver from Coverage	1. MS4s < 1,000 & Located in an Urbanized Area with 1) no water quality impacts and 2) no direct or indirect connection to a regulated MS4. *Number is unknown. 2. Indian Tribes < 1,000 are automatically waived from coverage. *Approx. # is = 8		

Table 2:
Estimated Range of Small Businesses in SIC Group 15 That May be Affected by Proposed Rule When They Undertake Construction Activities That Disturb from 1 to 5 Acres of Land

MAJOR GROUP 15**BUILDING CONSTRUCTION**GENERAL CONTRACTORS AND OPERATIVE BUILDERS				
SIC Code	**Description**	**Size Standard by Millions of Dollars**[10]	**Establish-ments with <10 million annual revenue**[11]	**Establish-ments with ≥10 million annual revenue**
1521	General Contractors -- Single-Family Houses	$17.0	107,289	206
1522	General Contractors -- Residential Buildings, Other Than Single-Family	$17.0	6,367	123
1531	Operative Builders	$17.0	16,200	789
1541	General Contractors -- Industrial buildings and Warehouses	$17.0	7,330	353
1542	General Contractors -- Nonresidential Buildings, Other Than Industrial Buildings and Warehouses	$17.0	27,871	1,868

[10] The Small Business Administration defines a small business within each of these SIC codes as a firm having annual revenue of not greater than $17 million.

[11] Data is from the U.S. Bureau of the Census's Economic Census 1992. The Bureau of the Census uses an "establishment" as the unit of data. A firm may have more than one establishment. As a result, the number of firms is less than the number of establishments listed. The Economic Census 1992 did not have data corresponding to SBA's $17 million size cut-off. The highest cut-off is $10 million in annual revenue. Therefore, the actual number of establishments that are below the $17 million cut-off is greater than the number listed in this column.

Table 3:
Estimated Range of Small Businesses in SIC Group 16 That May be Affected by Proposed Rule When They Undertake Construction Activities That Disturb from 1 to 5 Acres of Land

MAJOR 16**HEAVY CONSTRUCTION OTHER THAN BUILDING CONSTRUCTION**CONTRACTORS				
SIC Code	**Description**	**Size Standard by Millions of Dollars[12]**	**Establish-ments with <10 million annual revenue[13]**	**Establish-ments with ≥10 million annual revenue**
1611	Highway and Street Construction, Except Elevated Highways	$17.0	9,205	885
1622	Bridge, Tunnel, and Elevated Highway Construction	$17.0	878	163
1623	Water, Sewer, Pipeline, and Communications and Power Line Construction	$17.0	9,882	351
1629	Heavy Construction, N.E.C. EXCEPT, Dredging and Surface Cleanup Activities (where size standard cut-off is $13.51)	$17.0	15,311	505

[12] The Small Business Administration defines a small business within each of these SIC codes as a firm having annual revenue of not greater than $17 million.

[13] Data is from the U.S. Bureau of the Census's Economic Census 1992. The Bureau of the Census uses an "establishment" as the unit of data. A firm may have more than one establishment. As a result, the number of firms is less than the number of establishments listed. The Economic Census 1992 did not have data corresponding to SBA's $17 million size cut-off. The highest cut-off is $10 million in annual revenue. Therefore, the actual number of establishments that are below the $17 million cut-off is greater than the number listed in this column.

Table 4:
Estimated Number of Facilities[14] That Could Potentially Benefit from the "No-Exposure" Provision

Part 1	**Total Facilities Nationwide**	
	Number of Facilities	Source
Total Number of Facilities Nationwide (including Category xi facilities) Potentially Subject to Regulation under Phase I[15]	636,454	Census Bureau; Dunn & Bradstreet
Percentage Range of Facilities That Could Potentially Benefit from the "No-Exposure" Provision	30% - 60%	EPA estimate
Estimated Range of All Facilities (including Category xi facilities) That Could Potentially Benefit from the "No-Exposure" Provision	**210,030 - 388,237**	
Mean	**299,133**	
Part 2	**Category xi Facilities Nationwide**	
Total Number of Category xi Facilities Nationwide Potentially Subject to Regulation under Phase I[15]	394,983	Census Bureau; Dunn & Bradstreet
Percentage of Category xi Facilities That Could Potentially Benefit from the "No-Exposure" Provision	40% - 75%	EPA estimate
Estimated Number of Category xi Facilities That Could Potentially Benefit from the "No-Exposure" Provision	**161,943 - 300,187**	
Mean	**229,090**	

[14]Given the complexity, there has been no attempt to calculate the number of facilities that are both 1) a "small business" as defined by the Small Business Administration and 2) could potentially benefit from the "no-exposure" provision.

[15]Facilities under the following SIC codes are potentially subject to regulation under Phase I: 10-14, 20-39, 4011, 4013, 41-42, 4221, 4222, 4225, 4226, 4311, 44, 45, 491, 5015, 5093, and 5171. The number of facilities was obtained from individual State County Business Patterns 1993, Bureau of the Census, U.S. Dept. of Commerce. Data for SIC codes 4011 and 4013 was obtained from Dun & Bradstreet's database (data run on 7/18/96).

SUMMARY OF SMALL ENTITY OUTREACH

Tribes, States, local governments, industries, and environmental groups have provided extensive input throughout the development of the NPDES Storm Water Phase II proposed rule's draft language. Since 1992, EPA has made a consistent effort to reach out to all stakeholders regarding this proposed rule.

First, EPA provided Tribes, States, local governments, industries, and environmental groups with the opportunity to comment on alternative approaches for the Phase II regulations through publishing a notice requesting information and public comment on the approach for the Phase II regulations required under §402(p)(6) of the Clean Water Act (See 57 *FR* 41344; 9/9/92). The September 9, 1992, notice presented a range of alternatives on a variety of issues in an attempt to illustrate, and obtain input on, the full range of potential approaches for the regulation of unregulated sources to protect water quality. EPA received more than 130 comments on the September 9, 1992, notice. Approximately 43 percent of the comments came from municipalities, 29 percent from trade groups or industries, 24 percent from State or Federal agencies, and approximately 4 percent from other miscellaneous sources. These comments are summarized in Appendix J of *Storm Water Discharges Potentially Addressed by Phase II of the National Pollutant Discharge Elimination System Storm Water Program: Report to Congress* (March, 1995). EPA considered these comments in developing many of the provisions in today's proposed rule, including reliance on the NPDES program framework (including general permits), providing State and local governments with flexibility in selecting Phase II sources, focusing on high priority polluters and providing certain waivers for facilities that do not pollute, focusing on pollution prevention and BMPs, and incorporating watershed-based concerns in targeting.

Second, in early 1993, EPA and the Rensselaerville Institute held public and expert meetings to assist in developing and analyzing options for identifying unregulated storm water sources and possible controls. These meetings again allowed participants an opportunity to provide input into the Phase II program development process. The proposed rule reflects several of the key concerns identified by these groups, including provisions that provide flexibility to the States and other permitting authorities to select sources to be controlled in a manner consistent with criteria developed by EPA.

Third, EPA convened the Urban Wet Weather Flows Advisory Committee (the "FACA Committee"), including the Storm Water Phase II Subcommittee, to assist EPA in the development of cost-effective solutions for controlling the environmental and human health impacts of wet weather flows with a minimum of regulatory burden. The Phase II proposed rule was discussed in the overall UWWF FACA committee. The UWWF FACA committee has been developing the framework and language of the no exposure provision for two years. Consistent with the Federal Advisory Committee Act, the membership of the Phase II Subcommittee was balanced among the EPA's various outside stakeholder interests, including representatives from municipalities, industrial and commercial sectors, agriculture, environmental and public interest groups, States, Indian Tribes, and EPA. As of February 1997, the Storm Water Phase II Subcommittee has met 11 times for two-day periods, approximately every other month between September 1995 and February 1997. In addition to the FACA Subcommittee meetings, other meetings, conference calls, and correspondence, Subcommittee members were provided three opportunities to comment in writing on the preliminary draft approaches to the Phase II proposed rule. EPA distributed to Subcommittee members three preliminary drafts approaches of the Phase II proposed rule on September 30, 1996, November 15/22, 1996, and February 14, 1997. This resulted in three rounds of written comments from Subcommittee members. These comments were taken into consideration as EPA revised the preliminary draft language to respond to the Subcommittee's concerns. The 32 FACA Subcommittee members have utilized these numerous opportunities for input to shape the development of the Storm Water Phase II proposed rule. The Agency intends to continue to meet with the Phase II Subcommittee in the development of this rule.

Recently, EPA conducted additional outreach to representatives of small entities that would be affected by the proposed rule as required by the Regulatory Flexibility Act, as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA). EPA, in consultation with the Small Business Administration, invited 29 small entity representatives and streamlining representatives to participate in this outreach. Many of these small entity representatives have been working closely with EPA in developing this proposed rule through the FACA process.[16] Small entity representatives included the following Phase II Subcommittee and Urban Wet Weather Committee members: Dr. Roy Cameron, Mr. Tom Delaney, Ms. Beth Gotthelf, Mr. Roger James, Mr. Stephen Jenkins, the Honorable David Kubiske, the Honorable Jean Michaels (alternate: Ms. Diane Shea), Mr. Don Moe, the Honorable Jim Naugle (alternate: Ms. Carol Kocheisen), the Honorable Jeffrey Wenneberg, and the Honorable Annabeth Surbaugh. Although Ms. Shea and Ms. Kocheisen are alternate small entity representatives, they are full fledged FACA members.

EPA's Office of Wastewater Management distributed a briefing package to each representative and prepared additional documents in response to requests from the representatives. EPA conducted two telephone conference calls on May 14 and May 15, 1997 to brief representatives on the draft proposed rule. In addition, an all-day meeting was held at EPA Headquarters on May 22, 1997, with representatives. OMB and SBA officials participated in the conference calls and all-day meeting. In addition, EPA's Small Business Advocacy Chairperson participated in the all-day meeting. As of June 13, 1997, EPA received 12 sets of written comments from representatives. These comments as well as all documents distributed to representatives were presented to the Panel for its review. On June 23, 1997, EPA's Small Business Advocacy Chairperson sent a letter to each small entity and streamlining representative requesting any additional or remaining comments that they would like to communicate directly to the Panel. In his letter, the Chairperson included a summation of the comments that representatives had submitted to EPA's Office of Wastewater Management for their review and comment.

The Chairperson received one comment. This comment was a re-submission of a comment that had been previously received by EPA's Office of Wastewater Management during its outreach. A summary of all comments is attached to this report.

---

[16] EPA has concluded that the RFA does not require an agency to conduct an initial regulatory flexibility analysis for a rule that significantly reduces the regulatory impact on a substantial number of small entities. RFA sections 603 and 604 both require an agency in conducting regulatory flexibility analyses to identify and consider regulatory alternatives that would "minimize" any significant economic impact on a substantial number of small entities. Since it would make no sense to minimize the beneficial impacts of deregulation, EPA interprets the RFA as requiring analyses of only new or additional regulatory requirements. However, EPA has agreed in the case of this rule to include in the Panel's outreach efforts representatives of small entities that might benefit from the rule's deregulatory aspects. In this document, EPA refers to the representatives of these small entities as "streamlining representatives."

SMALL-ENTITY REPRESENTATIVES

EPA, in consultation with the Small Business Administration, invited the following 12 small entity representatives to participate in its outreach efforts on the Storm Water Phase II proposed rule. Many of these representatives also submitted written comments.

Indian Tribes

Dr. Roy Cameron
Tribal Advisor
Representing–Certain New England Indian Tribes

INPUT FROM REPRESENTATIVES

The Panel received 12 sets of written comments from representatives. In addition, oral comments were submitted during the two telephone conference calls on May 14 and 15, 1997 and during the all-day meeting on May 22, 1997, at EPA Headquarters. A summary of the written comments and those oral comments that raise issues not raised in the written comments is attached as Appendix A. The complete written comments of representatives are attached at the end of this document as Attachment A. A summary of the telephone conference calls and a record of the all-day meeting are found on pages 91-105 of Attachment B.

PANEL FINDINGS AND DISCUSSION

The Panel's findings and discussion are arranged below according to the elements of the IRFA and the category of activity that would be regulated by the proposed rule, where appropriate.

The Types and Number of Small Entities to Which the Proposed Rule Would Apply

As indicated earlier in the report, the types of small entities to which the Storm Water Phase II proposed rule would apply include small governmental entities that own or operate a municipal separate storm sewer systems and small businesses. Small businesses include small construction firms and small industrial facilities. The Panel considers the ranges that EPA has provided (listed in this report as Tables 1, 2, 3, and 4) as reasonable indicators, given the available data, of the number of small entities that would be affected by the proposed rule.

The Panel notes that small entities raised comments concerning the existing permit requirements applicable to storm water discharges from Category xi facilities in general. In addition, the Panel also received small entity comments on the issue of whether the proposed rule increases burden on Category xi facilities with no exposure. EPA has stated that it believes all Category xi facilities are currently subject to NPDES coverage. Category xi facilities with exposure to storm water were required to obtain a permit by October 1994 [57 FR 60446]. Category xi facilities where there is no exposure to storm water are required to obtain permit coverage effective August 2001 [60 FR 17953]. The Panel finds that the proposed rule would not affect Category xi facilities with exposure. However, the Panel also finds that, as a practical matter, the proposed rule would represent additional burden for Category xi facilities with no exposure. [see Classes of Small Entities below]

Projected Reporting, Record Keeping, and Other Compliance Requirements of the Proposed Rule, Including the Classes of Small Entities Which Will Be Subject to the Requirements and the Type of Professional Skills Necessary for Preparation of the Report or Record

The above section entitled, "Overview of Proposed Phase II Rule" describes the basic elements of the proposed rule. The record keeping, reporting, and other compliance requirements associated with the construction component of the proposed rule would be similar to those required by currently regulated Phase I construction activities. However, EPA anticipates that the best management practices (BMPs) that typically would be implemented on construction sites below 5 acres to achieve compliance would be less sophisticated and less expensive than those BMPs implemented on a Phase I site. The proposed rule would provide the NPDES permitting authority with the discretion not to require notices of intent (NOIs) in general permits for storm water discharges from Phase II construction activities. NOIs are required of Phase I construction activities. The record keeping and reporting requirements for the municipal component of the proposed rule would be substantially less than those required for municipalities under the Phase I program. Currently regulated Phase I facilities that claim no exposure would need to file a self-certification form to document their exemption from otherwise applicable permit requirements.

Projected Reporting, Record Keeping, and Other Compliance Requirements

The Panel received many comments stating that the proposed rule would impose administrative and compliance burdens on small entities. The Panel supports EPA's efforts to explore ways to reduce these burdens on small entities while protecting water quality.

<u>No Exposure:</u>

Municipal representatives questioned the need for facilities with no exposure to so certify if they are not required, as a matter of law, to obtain an NPDES permit anyway. Industrial representatives stated that a five year certification and a one-time notice of termination (NOT) would be an acceptable burden for the small businesses they represent. However, industrial representatives and other commenters had significant concerns regarding the language in the "no exposure" self-certification form itself. They believe that to determine if there is an "interference" with water quality standards would require significant financial costs, for example, the need to hire a qualified engineer to make a determination. Additionally, both municipal and industrial representatives stated that there should be no requirement to assess flow impacts in the certification form. [see Type of Professional Skills below]

The Panel notes that, since the discussion in the first Panel meeting, EPA has responded to some commenters' concerns by deleting the requirement for "self-certifiers" to determine "no interference" with water quality standards in the no exposure self-certification form, thus, also removing any requirement to assess flow impacts. EPA has substituted a new question to ask whether actions to qualify for no exposure result in increased impervious surface area. Answering "yes" to this question would not disqualify a facility from the no exposure exemption. The answer to this question and other information, however, would enable the NPDES permitting authority to determine if the discharge would be likely to interfere with attainment of water quality standards, in which case, the permitting authority could exercise its existing authority under the Clean Water Act to disallow the no exposure exemption and require coverage under either a general or an individual permit, as appropriate.. The Panel supports this revision to the earlier draft of the self-certification form and expects that it would reduce the administrative and financial burden on small industrial facilities wishing to make use of the no exposure self-certification provision. [see Type of Professional Skills below]

Classes of Small Entities

As noted above, the Panel received comments stating that Category xi facilities are not currently subject to NPDES coverage and that therefore this proposed rule would expand coverage to a new class of small entities. EPA disagrees with these comments and maintains that Category xi facilities are currently covered under the NPDES program and that in fact many Category xi facilities with actual exposure have sought coverage under NPDES permits. Under EPA's interpretation of the current regulations, Category xi facilities with no exposure are required to obtain NPDES permits by August 2001.

The Panel notes that the proposed rule does not include any regulatory requirements applicable to Category xi facilities except the no exposure self-certification provision and therefore imposes no regulatory burden on Category xi facilities other than those wishing to make use of this provision. However, as a practical matter the Panel also finds that the proposed rule would represent additional burden for Category xi facilities claiming no exposure and considers this group to be a newly regulated class of small entities. At the same time, the Panel notes that EPA has attempted, both through consultation with its Stormwater Phase II Subcommittee and in response to comments from small entity representatives, to structure the no exposure self-certification provision in a way that minimizes the burden on facilities making use of it. In addition, by expanding the availability of the no exposure provision to all Phase I facilities that meet its requirements, EPA would provide significant regulatory relief to a large number of currently regulated entities, both large and small.

Type of Professional Skills

Municipal Program:

Municipal representatives stated, and the Panel agrees, that implementation of some program elements would not necessarily require staff with education beyond a high school diploma. However, municipal representatives also stated that some of the minimum control measures would definitely require a person with advanced education or significant work experience beyond high school. Specifically, these municipal representatives referred to the minimum control measures for: (1) post-construction storm water management, (2) pollution prevention, and (3) evaluation and effectiveness.

EPA has stated its commitment to develop guidance materials and training to ensure that the level of professional skills required to implement the municipal program would be kept to a minimum. The Panel supports EPA's efforts in providing guidance materials and training to assist in the implementation of the proposed program.

No Exposure:

The Industrial Representatives expressed concern that, as previously drafted, the no exposure provision would require someone with an advanced degree in engineering, chemistry, and/or water hydrology to properly determine whether actions taken to satisfy the no exposure requirements would result in "interference" with water quality standards. As indicated above, the Panel notes that EPA has made revisions to the no exposure self-certification provision that address this concern.

Other Relevant Federal Rules Which May Duplicate, Overlap, or Conflict with the Proposed Rule

The Panel received comments that the proposed rule may conflict with the requirements of the Clean Air Act, the Endangered Species Act, the Great Lakes Initiative, and Section 404 of the Clean Water Act as administered jointly by the EPA and the Corps of Engineers. Municipal representatives indicated that street sweeping activities designed to reduce pollutants in urban run-off may create "dust" or "soot" that could cause a violation of the National Ambient Air Quality Standards for particulate matter.

The Panel recommends that the Agency further evaluate in its regulatory flexibility analysis whether the proposed rule would conflict with those federal rules identified by commenters and revise the rule to address such conflicts as appropriate.

Any Significant Alternatives to the Proposed Rule which Accomplish the Stated Objectives of Applicable Statutes and Which Minimize Any Significant Economic Impact of the Proposed Rule on Small Entities

Before addressing specific alternatives suggested by commenters during the SBREFA outreach process to minimize the impacts of the rule on small entities, the Panel wishes to note and commend EPA's efforts over the past two years to work with stakeholders, including small entities, through the Stormwater Phase II Subcommittee of its Urban Wet Weather Flows Advisory Committee, as described above. Because of the extensive outreach already conducted and the Agency's responsiveness in addressing stakeholder concerns, commenters during the SBREFA process raised fewer significant concerns than might otherwise have been the case. However, the Panel did receive comments on the following issues.

Municipal Coverage

Municipal representatives expressed concern that the waiver provision for municipalities in urbanized areas with populations under 1,000 would be difficult to use in practice because these are exactly the municipalities that would be unlikely to have the resources to demonstrate that their activities have no water quality impacts. Furthermore, they raised concerns that tying the waiver provision to TMDL or watershed assessments will make it even more difficult to use. The Panel notes that where EPA or a State has conducted such the watershed assessments and developed any necessary TMDLs (as the Agency fully anticipates will occur), the municipal concern should prove unwarranted. In such cases, a municipality would not need to make any such demonstration but merely certify that a TMDL (or watershed plan) applies and does not assign any responsibilities to reduce pollutant loads. In cases where such assessment work is not completed by EPA or a State, however, the Panel shares the concern and recommends that the preamble invite comment on the concern.

The municipal representatives also questioned the rationale for treating Tribes under 1,000 differently from municipalities under 1,000. OMB and SBA recommend that the preamble invite public comment on whether both municipalities and Tribes under 1,000 located within an urbanized area should be treated like MS4s under 10,000 located outside an urbanized area, which is the approach EPA is proposing for Tribes under 1,000. That is, the preamble should invite comment on whether both municipal separate storm sewer systems serving a population of less than 1000 and urban Tribes with a population of less than 1000 should be exempt unless either (1) they contributed significantly to the pollutant loadings of a covered MS4 or (2) the permitting authority determines that they have a significant impact on water quality. This alternative would place the burden of proof for coverage on the permitting authority, which would have better resources for making the appropriate water quality impact determinations than the very small municipality or small urban Tribe. EPA believes that the rationale for inclusion of very small municipal separate storm sewer systems differs from the rationale for exclusion of small urban tribes. EPA believes that small urban tribes should be treated differently because it believes the population density should be much lower than the very small municipal separate storm sewer systems and because small urban tribes cannot rely on a State in the same way as a very small municipal separate storm sewer system (a political subdivision of a State).

Construction:

The Panel received many comments questioning the need to regulate construction activities that result in land disturbance of 1 to 5 acres. Several of the small entity representatives noted that there are many local control programs already in place. They stated that regulation below 5 acres would have significant economic impact on small businesses and that the proposed rule would greatly increase the number of affected small businesses. Several commenters also questioned whether regulation of such activities would provide significant water quality benefits.

Some of the commenters provided advice and recommendations. One commenter suggested an exemption for "routine maintenance" activities such as repairing potholes, clearing out drainage ditches, and maintaining fire breaks because these activities often involve rights-of-way extending across multiple regulatory jurisdictions. The commenter suggested that, at most, these activities be required to adhere to generic best management practices. A number of commenters encouraged EPA to adopt a voluntary program, including guidance and perhaps incentives, for construction sites below 5 acres. One commenter stated that many small operators may lack the resources to put together a good site plan.

Municipal commenters stated that regulation of construction sites below 5 acres will create a major burden to local governments and should be at the discretion of the permitting authority. Another commenter suggested that construction sites, regardless of size, that are located within a Phase I regulated MS4 be required only to comply with the requirements of the municipality. Several commenters suggested that if EPA does regulate construction sites under 5 acres, NOIs should not be required for these sites.

While the Panel has not thoroughly evaluated the merits of each of the small entity concerns, the Panel recommends that the preamble to the proposed rule invite comments on alternatives to the proposed requirements for regulation of construction sites that result in the disturbance of 1 to 5 acres.[17] The request for comments should include a discussion of concerns expressed by small entity representatives and suggestions they have made for addressing them. The request should ask for comment on the extent to which a nonregulatory voluntary program, or one that relies on the discretion of the permitting authority or covered MS4, would provide adequate protection against water quality impairment due to run-off from small construction sites, and on any specific experience commenters may have had in the past with voluntary regulation of discharges from such sites based on best management practices. The Panel also encourages EPA to consider revisions to the proposal itself that address some of the technical concerns raised by small entity commenters, such as the difficulty of obtaining permits for routine right-of-way maintenance involving multiple jurisdictions.

The Panel also received comments from municipal and industrial representatives suggesting that construction activities undertaken by municipalities or industrial facilities could be covered under these entities' existing stormwater permits, provided that such existing permits detail soil and erosion controls. Municipal representatives also recommended that any industrial facility operated by the municipality be covered by its MS4 permit and that the municipality be allowed to determine if there is exposure for these facilities as part of its MS4 plan without filing a separate no exposure self-certification. The Panel recommends that the preamble to the proposed rule explore and request comment on the ideas discussed in this paragraph. The Panel believes that the option for construction sites may be appropriate for municipalities or industrial facilities with individual NPDES permits but may be administratively difficult to implement under NPDES general permits. The Panel also supports and encourages efforts to minimize paperwork burden on municipalities, which are ultimately responsible for the success of their stormwater plans.

No Exposure:

The Panel received comments suggesting that the no exposure self-certification provision as written would not allow facilities that undergo a "temporary operational change" or transportation facilities that provide "non-pollutant generating outdoor maintenance of vehicles" to make use of the provision. One commenter suggested that concern over temporary operational changes could be addressed through the requirement of a management practice designed to prevent exposure as a result of a tempory change in operations. Commenters were also concerned about the requirement that there

[17] In order to avoid unnecessary regulatory duplication, the Small Business Administration recommends that EPA consider a regulatory option that would allow permit authorities to rely solely on the local program where the local program exceeds reasonable minimum criteria for program effectiveness. Many localities and states have sediment and erosion control programs that target the primary pollutants of construction sites. These local programs are often specifically designed to address the watershed specific issues and resources of those local areas. SBA also suggests that EPA relax the stringency of some of the draft minimum criteria of the proposed regulatory option, or SBA's suggested option, where applicable. In SBA's view, the minimum criteria would not necessarily require regulation for sites smaller than five acres in size. An NPDES permit would not be required to be issued for each site. Regular inspections of these small sites would not be required as part of the minimum criteria.

be no exposed containers that "might leak," since any container "might leak," and suggested that the provision should only prohibit exposed containers that are actually leaking.

The Panel is aware that EPA has been developing the no exposure language with extensive stakeholder involvement through the Urban Wet Weather Flows Federal Advisory Committee for the past two years. The Panel suggests that EPA examine these comments and discuss them with the Advisory Committee. The Panel hopes that the no exposure language can be revised to allow, to the extent possible, all facilities with no actual discharge of pollutants to make use of the no exposure self-certification provision.

ACKNOWLEDGMENTS

This project was made possible with the assistance and support of many organizations and individuals. Our gratitude goes out to our clients Mark Gold, D.Env.,and Alix Gerosa of Heal the Bay for their review, support and suggestions, and Lisa Dobbins for making this project a reality. Special thanks to Patsy Heasly of the California State Coastal Conservancy for her guidance, review, and suggestions about the project, and Julia McIver for recognizing the need to involve citizens in the protection of the Malibu Creek Watershed. We wish to thank Gwen Starrett of the State Water Resources Control Board and Dominic Gregorio from Southern California Marine Institute for providing technical review and suggestions about the monitoring procedures. We would like to thank Rex Hanson of ESRI for providing computer assistance and Bradley Owens of Cal Poly Pomona for his work on the runoff analysis. We would also like to acknowledge the National Park Service, the California Department of Parks and Recreation, Los Angeles County Department of Public Works, Ventura County Public Works Agency, Las Virgenes Municipal Water District, Metropolitan Water District, and the Resource Conservation District of the Santa Monica Mountains.

We would like to acknowledge the 606 Studio faculty, Joan, Jeff, Joan, and Kris for their advice and guidance. We also thank our classmates for their support, encouragement and humor during the past few years.

We especially thank our families and friends for their unfailing support and understanding despite the fact that they have been unappreciated and virtually ignored during the life of this project.

Finally, we dedicate this project to the memory of Professor John Tillman Lyle who nurtured the 606 Studio since its inception. The success of the 606 Studio over the years is due in large part to his dedication and commitment.

Introduction

Vision for the Watershed

It's late November 2018. The rains have begun and so has the annual steelhead migration from the ocean upstream into the Malibu Creek Watershed. The fish are in search of the perfect gravelly area to spawn. People are sitting on blankets in the dappled sunlight beneath the giant sycamores and alder trees, watching their kids. Children walk along the stream waiting to catch a glimpse of the shiny silver green bodies of steelhead trout as they leap out of the water and announce their presence. The peaceful sound of a rushing stream is periodically interrupted by the excited shouts of children as they follow the steelhead trout upstream.

The streams in the watershed have returned to their natural state, the water is clean and cool, the vegetation is flourishing and the wildlife is abundant. People have also returned to the stream. Swimming holes, on perennial streams, are crowded with kids during the hot dry summers. Bird watchers flock to the lagoon to catch a glimpse of the incredible diversity of migratory birds. Surfers enjoy the excellent surf break and clean water at Surfrider Beach, and people can be seen hiking, picnicking, and enjoying the beauty that is the Malibu Creek Watershed. This is quite a contrast to twenty years earlier when the watershed was a very different place.

In 1998, the health of the watershed, especially water quality, began to improve. Most visible were the teams of volunteers who began to monitor the streams within the Malibu Creek watershed. They walked many miles, surveyed stream reaches, tested water quality and sampled macroinvertebrates. The information was collected and distributed to various local and state agencies, which in turn, led efforts to make changes in policy.

Through the efforts of these volunteers, agencies and local governments have responded to the environmental concerns of citizens in the Malibu Creek Watershed. Zoning and building regulations are far different from what they were twenty years ago. Now, parking lots are smaller, greener, and the paving is porous, allowing storm water to infiltrate into the soil below. Vibrant, tree lined pedestrian-friendly shopping streets have replaced strip malls. The water that drains from parking lots flows into bioswales that filter out pollutants before they can enter the streams. Today, if you look at the Malibu Creek Watershed, there is a sense of community that celebrates the beautiful natural surroundings that attracted residents to this area in the first place.

Purpose

This project is a step towards achieving the above vision for the Malibu Creek Watershed. The purpose of this project is to design a citizen volunteer monitoring program, that over the long term can evaluate the water quality of the entire Malibu Creek Watershed and target areas for future studies, protection, restoration, and enhancement. The ultimate hope for this project is that citizens and agencies will work together to protect the Malibu Creek Watershed, identify problems, and implement measures to correct these problems.

The information collected by citizen volunteer monitors can be used to better understand the unique physical, biological, and recreational resources of the area. This information can hopefully be used to balance the need for human development while maintaining the ecological integrity and unique natural character of the Malibu Creek Watershed. It is the hope of the project team that private sector developers and local planning agencies work together for increased cooperation in implementing the recommendations that improve ecological functioning within the watershed.

This project document is intended for active use by citizens, local, state, and federal agencies and non-profit organizations concerned about the Malibu Creek Watershed. This project document begins with goals and objectives to explain the background of the project. The second section gives an overview of the natural processes and the history of settlement in the Malibu Creek Watershed. Key issues affecting ecological functions within the watershed are then discussed in Section 3. Section 4 details the monitoring element of the project, including the structure, organization and the flow of data. The fifth section describes the in-depth analysis and modeling that was used to select monitoring sites. It also presents a framework for other agencies that wish to monitor in the watershed. The final section, Section 6, considers design recommendations and alternatives that directly address the key issues identified in Section 3.

Background

Heal the Bay, a non-profit organization, and the California State Coastal Conservancy have contracted the 606 Studio, a team of landscape architecture graduate students and faculty members from the Department of Landscape Architecture at California State Polytechnic University, Pomona, to design a volunteer monitoring program. This program is to be used to evaluate the water quality and overall ecological health of the Malibu Creek Watershed. The monitoring program was designed to adjust to changes in volunteer participation and capabilities and be flexible to address new issues as they arise in the future.

To meet this contract, the 606 Studio has prepared two documents: *The Malibu Creek Watershed, Stream Team Field Guide* (a field guide to be used to train volunteer water quality monitors), and this document, *The Malibu Creek Watershed: A Framework for Monitoring, Enhancement and Action.*

The California State Coastal Conservancy and Heal the Bay are actively involved in issues of water quality. The California State Coastal Conservancy is a unique state resource agency that uses innovative techniques to purchase, protect, restore, and enhance coastal resources and to provide access to the shore. They work in partnership with local governments, other public agencies, nonprofit organizations, and private landowners. In funding and support of this project, the California State Coastal Conservancy has formed a partnership with Heal the Bay, a non-profit environmental group dedicated to making the Santa Monica Bay and the Los Angeles County coastal waters safe and healthy for people and marine life. Both organizations have a long history of successful projects throughout the State.

Objectives

Monitoring Program Structure and Process

Research

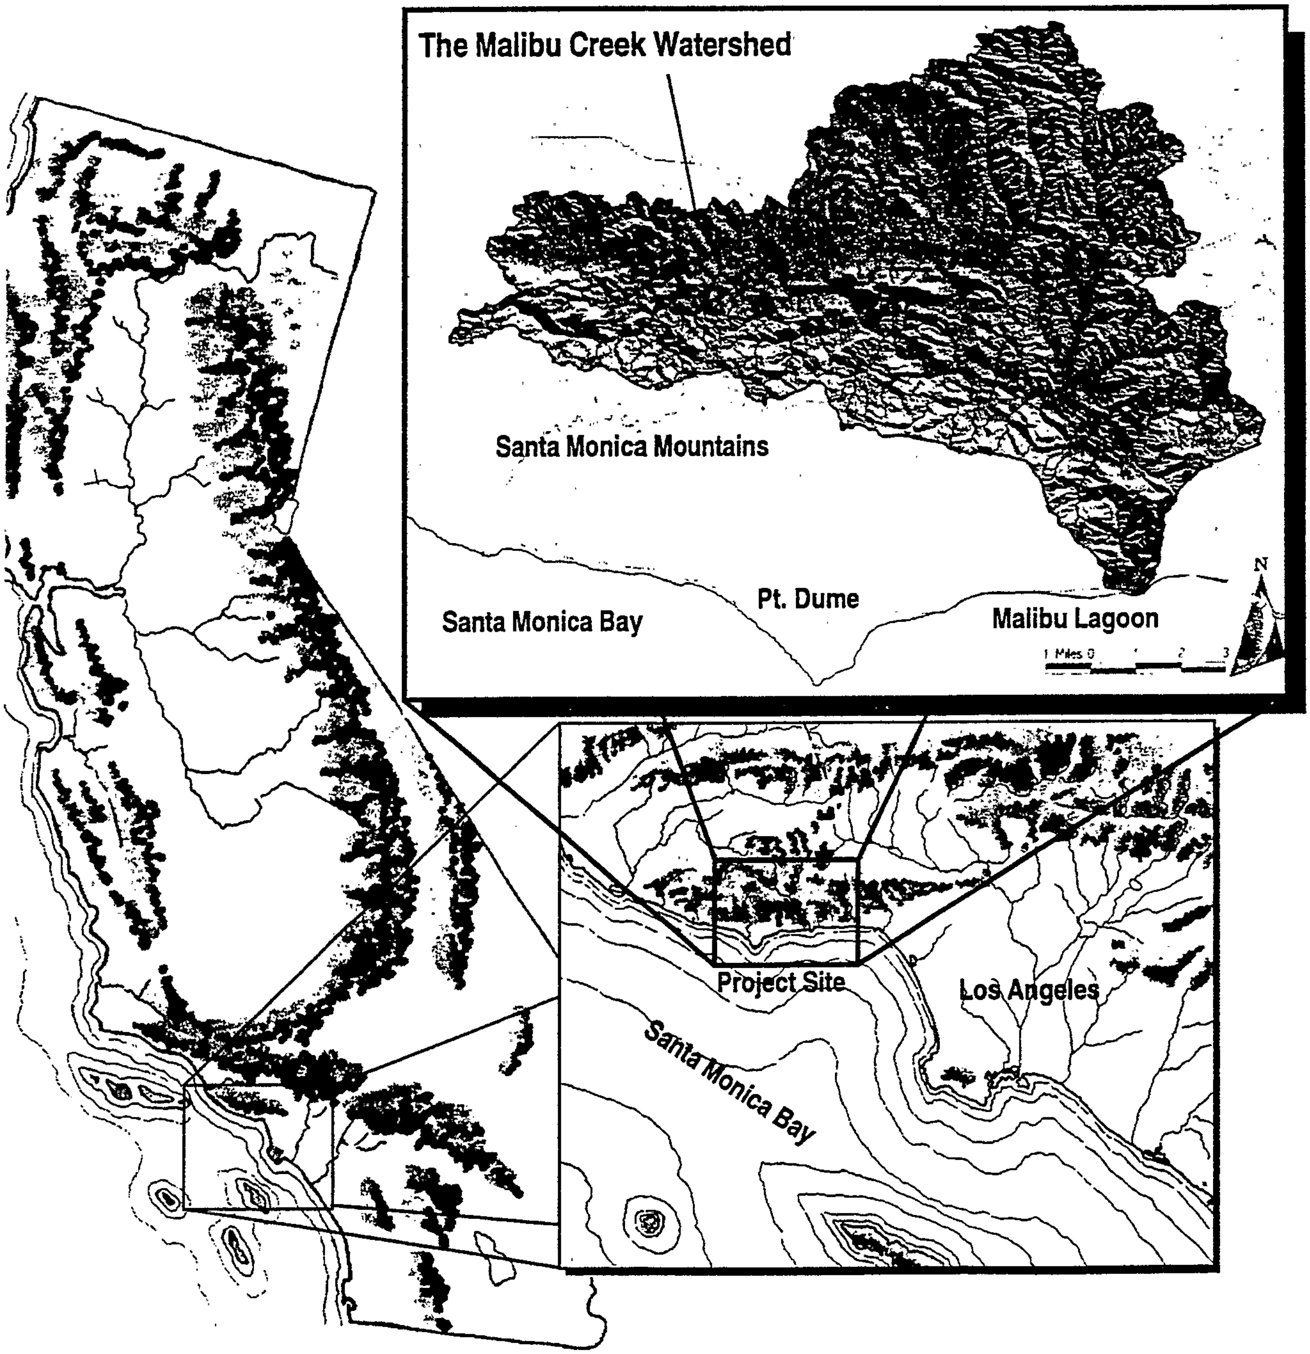
- Conduct a watershed inventory of the Malibu Creek Watershed. This involves collecting and analyzing past studies of the watershed and identifying the major ecological issues of concern.
- Study existing monitoring programs and the strategies used to collect and distribute information.

Design

- Design a volunteer monitoring program that addresses the specific issues and needs of the Malibu Creek Watershed. This program will provide information needed by private and public agencies to identify opportunities to improve the overall ecological health of the Malibu Creek Watershed.
- Create a field guide volunteers can use in conjunction with hands on training to collect and record pertinent information about the Malibu Creek Watershed.

Planning & Management Framework

- Develop an overall strategy that can be used to coordinate current and future individual monitoring efforts within the watershed, to maximize the quality of information collected and utilize the limited resources of these programs.
- Design a monitoring program framework that can be used by Heal the Bay to organize and train volunteers to collect information about the Malibu Creek Watershed. This framework will be designed so that the monitoring program can adapt to changes in levels of volunteer participation.
- Create a framework that Heal the Bay can use to organize, store, and distribute the information collected by volunteers to the numerous local, state, and federal agencies that are charged with protecting the Malibu Creek Watershed.
- Provide a tool box of design recommendations and references for improving the Malibu Creek Watershed ecosystem. As volunteers identify areas that are degraded or in trouble, decision-makers will be armed with strategies to enhance these areas.



te Context, the Malibu Creek Watershed

Section 2
Natural Processes and the History of Settlement

Context

The Malibu Creek Watershed, at 109.9 sq. miles, is the second largest watershed draining into the Santa Monica Bay (Figure 2-1). Rain falling within its boundaries eventually reaches the Pacific Ocean via the system of surface streams and groundwater. The watershed is located approximately 35 miles to the west of the City of Los Angeles in the Santa Monica Mountains and Simi Hills. Approximately 65% of the watershed is located in Los Angeles County with the remaining 35% in Ventura County. Within its boundaries are the cities of Agoura Hills, Westlake Village, and portions of Malibu, Calabasas, Thousand Oaks, Hidden Hills, and Simi Valley.

The topography varies throughout the watershed. In the uppermost region, the Simi Hills roll gently. In contrast, the steep, rugged Santa Monica Mountains cover the remaining majority of the watershed. The Malibu Creek Watershed can be divided into seven smaller subwatersheds. These are Hidden Valley, Westlake, Agoura, Las Virgenes, Malibou Lake, Malibu Creek, and Cold Creek. A major tributary drains each subwatershed, eventually joining Malibu Creek. The creek flow south into the Malibu Lagoon, one of the few remaining coastal wetlands in southern California. Here the freshwater mixes with the Pacific Ocean at Malibu Surfrider Beach.

Natural Processes

Climate

The climate of the Malibu Creek Watershed is generally characterized as a Mediterranean type with mild wet winters, hot dry summers, and coastal fog occurring in spring and mid summer between the months of May and July. The area is frost-free 275 to 325 days on average. Spring temperatures range from 65 to 85 degrees Fahrenheit during the day and can drop as low as 45 to 65 degrees at night.

The phenomenon known as the "Pacific High" diverts storms away from southern California, causing the warm dry summers. Inland summer daytime temperatures generally remain around 85 degrees and will occasionally exceed 100 degrees with low temperatures dipping into the mid-fifties. Coastal temperatures are generally 15 degrees cooler than those of inland valleys (Jorgen 1995, p. 6).

Fall temperatures range from 65 to 90 degrees inland during the day and can dip down between 20 to 60 degrees at night. Fall is usually associated with the warm, dry Santa Ana winds that blow in from the deserts. Due to these dry summer and fall conditions, fire has become an integral part of the local ecosystem.

Winter is characterized by periodic rainfall, which accounts for nearly all the precipitation in the area. The majority of rainfall occurs between November and April averaging 25 inches over the mountainous regions to the north and along the coast, to rainfall averages of about 13 inches in the inland valleys. Measurable precipitation occurs on average 35 days per year with December and January usually the wettest months (Jorgen 1995, p. 7). Average winter temperatures reach highs in the mid-60s with average lows in the mid-40s. Freezing temperatures sometimes occurs at the higher elevations of the Santa Monica Mountains. Snow falls very rarely but has occurred within the watershed.

Geology

The Santa Monica Mountains and Simi Hills are part of the Transverse Ranges. They were formed through a process of deposition, erosion, volcanic activity, and tectonic forces. 135 million years ago, the ocean covered the area where the Santa Monica Mountains are located. Over millions of years, sediments settled on the ocean bottom, and eventually, through pressure and chemical processes, were transformed into sedimentary rocks–shale and sandstone–that compose most of the area (Jorgen 1995, pp. 7-8).

The greatest volume of rock mass in the Malibu Creek Watershed is composed of young sandstone, shale, and volcanic flows that occurred between 10 to 20 million years ago during the Miocene Epoch (Warshall, et al. 1992, p. 18). The distinctive black-gray and reddish volcanic rocks in the central and upper western portions of the watershed are known as the Conejo Volcanics. It was not until four million years ago that northward pushing tectonic forces caused the Santa Monica Mountains to thrust their way out of the ocean (Warshall, et al. 1992, p. 18). Erosion of the volcanic and sedimentary rocks created sediments which were deposited by flowing water, filling valleys and streambeds with alluvial soil (Figure 2-2). This alluvial layer is 30 feet deep in streambeds and canyon bottoms and tapers off rapidly to less than four feet thick up canyon slopes (USDA NRCS MCWNRP 1995, p. 8).

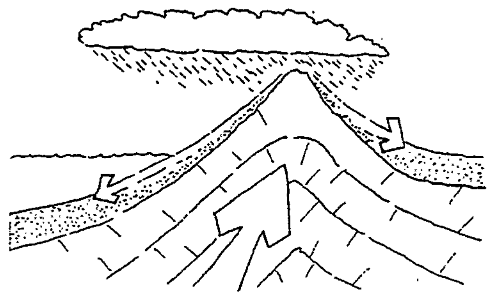


Figure 2-2: Uplift and erosion

Soils

The soils of Malibu Creek Watershed are susceptible to high erosion rates. This is due to a combination of climate, topography, vegetation and soil structure. Mediterranean climates provide the highest sediment yields in the world (Levy, Korkosz 1997, p. II-9).Soils in the area are derived from sandstone, shale, volcanic and igneous rock, and from alluvium composed of a mixture of rock sources that compose the Santa Monica Mountains. Soil types determine the amount of water storage and the ability to absorb and filter runoff within the watershed. The Malibu Creek Watershed contains 40 soil mapping units in the Los Angeles County portion, and 38 soil mapping units in the Ventura County portion of the watershed (USDA NRCS MCWNRP 1995, p.13).

Vegetation

The Malibu Creek Watershed is covered with plants that have evolved to fit the unique soils and climate of the region. Chaparral and Coastal Sage Scrub are two plant communities that dominate the Santa Monica Mountains. These plant communities are adapted to wet winters and dry summers. For example, many of these plants have small, waxy leaves to retain moisture, as well as the ability to drop their leaves in times of drought.

Vegetation plays a critical role in the watershed. It helps control erosion by holding the soil together with its roots and by breaking the force of rainfall with its canopy of leaves and branches (Figure 2-3). This slows the flow of water and allows more water to percolate into the soil. Runoff is minimized and less water flows all at once into streams. It also provides food and shelter for a wide variety of animals.

Vegetation within the Malibu Creek Watershed can be categorized into plant communities based upon similar characteristics. Figure 2-4 shows some of the various dominant plant communities found within the watershed and their approximate locations.

Riparian Zone

The Riparian Zone is the vegetative corridor on either side of a body of water (Figure 2-5) (US EPA 841-B-97-003 1997, p. 203). This area is unique because it is where the land-based (or terrestrial) and aquatic ecosystems interface (Murdoch, Cheo, and O'Laughlin 1996, p. 60). Riparian zones contain an important plant community that helps to maintain

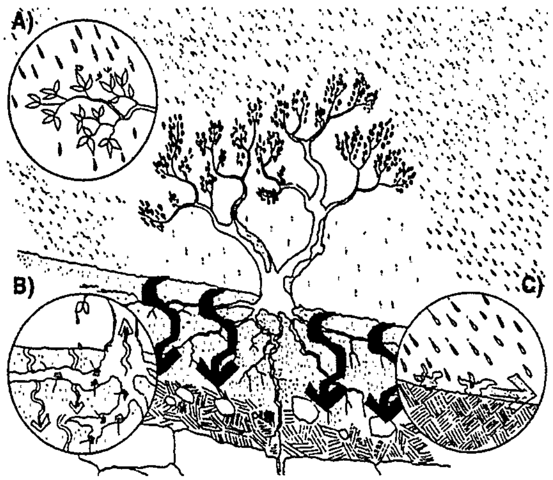

Figure 2-3: Vegetation aids infiltration and prevents erosion by A) intercepting the rain and slowing down water flow, B) roots creating pore spaces for water to infiltrate and C) rain impacting exposed soils, picking up sediments, carrying them into waterways.

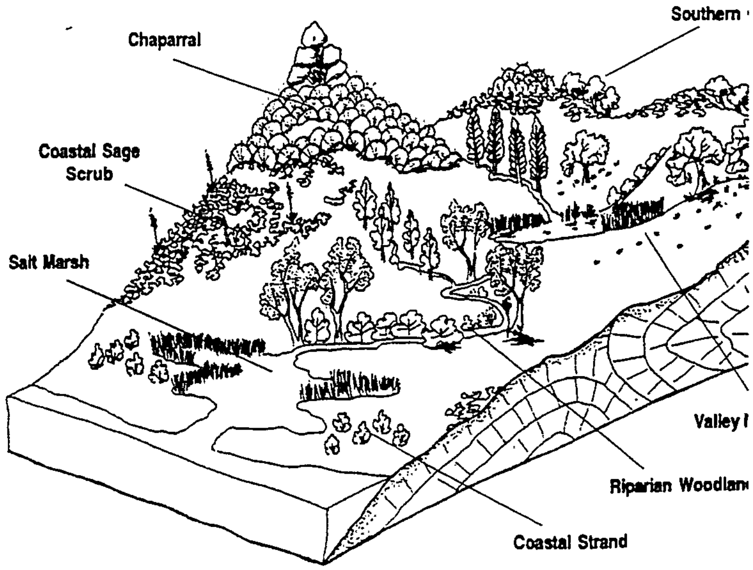

Figure 2-4: Plant communities and their approximate locations within the watershed

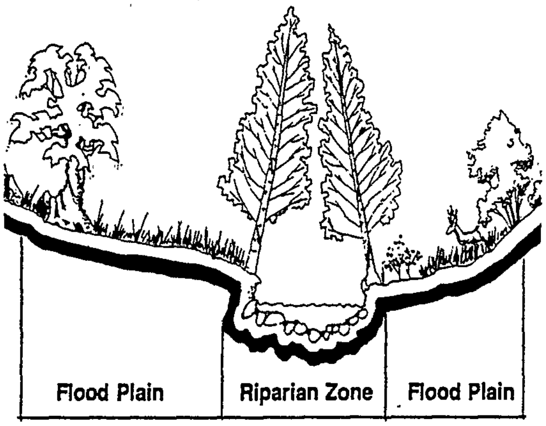

Figure 2-5: The riparian zone

water quality and stream health. Riparian vegetation generally has a higher need for water, thus occurs in drainages or areas with a high water table. The plants of a healthy riparian corridor are diverse and can include trees such as oaks, sycamores or willows, and various shrubs and groundcovers.

A healthy riparian zone supports birds, aquatic life, and additional diverse wildlife. According to the Washington State Department of Wildlife, more than 85% of wildlife inhabit riparian areas at some time during their life cycle to find water, shelter, and food. Trees provide shade for the stream, maintaining cooler water temperatures that are important for certain fish species like the steelhead trout. Shade also minimizes evaporation, providing water for the long, hot summer season. Trees and other vegetation drop leaves, twigs, and branches that provide food for aquatic organisms located at the bottom of the food chain. This debris also accumulates in the streams, providing habitat for fish and other aquatic organisms.

Nutrients

Natural sources of nitrates include soil, animal wastes, and decomposing plants that are washed off the surface of the landscape and eventually into the streams (Figure 2-6). Phosphorous is an essential nutrient for plant growth and for the metabolic reactions in plants and animals (Behar, Dates, and Byrne 1996, p. 130). Phosphates are considered a limiting factor, because they are the least available of all nutrients for plant growth. If phosphate is added to a freshwater system, even in small quantities, the plant growth will usually increase substantially (Behar, Dates, and Byrne 1996, p. 130). Natural sources of phosphates include soil, decomposing plants, rocks that contain phosphate, and animal wastes.

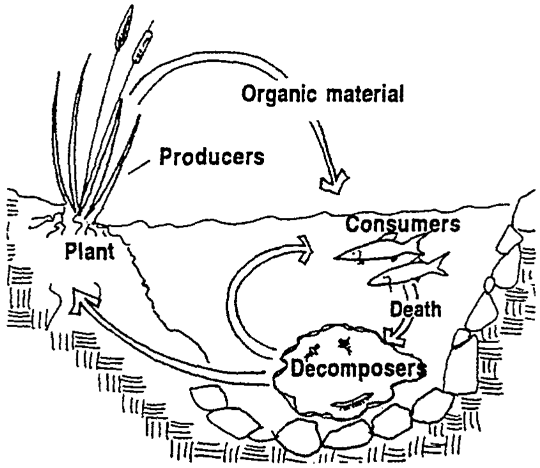

Figure 2-6: Basic aquatic nutrient cycle

Fire

Fire is an essential part of the natural processes in the Malibu Creek Watershed. Chaparral plants such as Toyon and Chamise, and Coastal Sage Scrub plants such as Black Sage and California Sagebrush

R0016883

are fire-adapted and depend on regular burning to remove old growth and rejuvenate the plants. Fires mineralize organic matter into potash, which provides nutrients to the soil and stimulates new plant growth

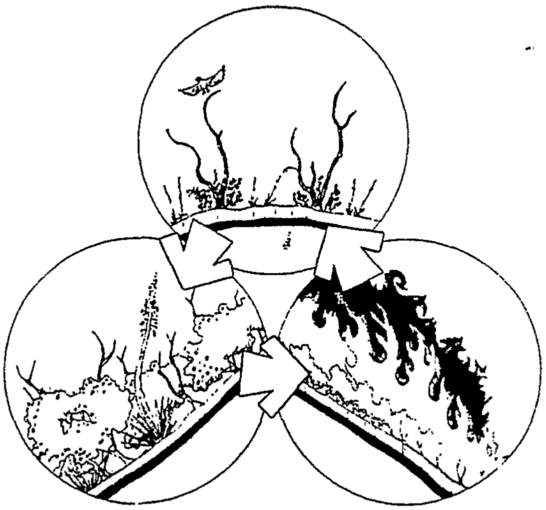

Figure 2-7: Chaparral fire cycle

(Jorgen 1995, p.16). Many of these plants have seeds that need fire to stimulate them to germinate, or have the ability to crown sprout from their roots after a fire (Figure 2-7). Animal populations decrease following a fire because of limited shelter and available food, but these populations soon return when the fire- dependent seeds germinate providing tender young shoots for browsing animals to eat. Fires were believed to have started from lightning strikes in the San Fernando Valley and the San Gabriel Mountains prior to recent human settlement. Santa Ana winds fanned these flames over the hills and into the Santa Monica Mountains (Jorgen 1995, p. 16). The watershed is most susceptible to fires beginning in early May and lasting through October, when annual grasslands dry out and temperatures are higher. Fire within the Santa Monica Mountains occurs at natural intervals between 10 to 50 plus years (Levy, Korkosz 1997, p. II-9).

Wildlife

The Malibu Creek Watershed is home to a diverse range of wildlife. This includes about 50 species of mammals, over 380 bird species, 25 species of reptiles, 11 species of amphibians, 5 species of fish, and a large number of invertebrates (USDI 1993). There are also several listed endangered species within the watershed.

Hydrologic Cycle

The hydrologic cycle is a closed loop system driven by the energy of the sun, which continually transports water between the atmosphere and the earth's surface (Figure 2-8). The three main processes of the hydrologic cycle are precipitation, evaporation, and transpiration. Once precipitation falls onto the land, approximately two-thirds is evaporated back into the atmosphere. The remainder is either absorbed into the ground and soils, or flows over the land as surface water. Transpiration occurs when energy from the sun draws water from the leaves of plants back into the atmosphere in the form of water vapor. The total amount of water on the earth's surface is finite, and in essence, it is the same water cycling over and over again.

The hydrologic cycle process can be explained beginning with surface water. Surface water stored in lakes, streams, lagoons, and oceans, is heated by the sun's energy and turned into vapor through the process of evaporation. Transpiration begins

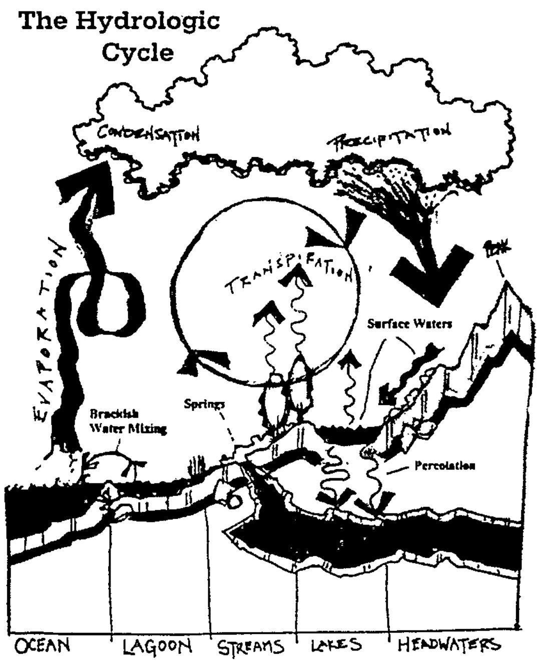

Figure 2-8: The Hydrologic Cycle

when plant roots absorb water stored in the soil. The water migrates up the stem or trunk until it eventually comes out of thousands of tiny holes on the bottom of leaves. A large oak tree transpires approximately 39,578 gallons per year (Leopold 1997, p. 5). The warmer the air temperature, the more water vapor the air can carry. When this air is cooled, the water vapor exceeds the carrying capacity of the air. This vapor turns back into its heavier liquid form, and falls to earth as precipitation. The rain is trapped by the leaves of plants, stored in the soil, or flows over the land and into the streams and eventually into wetlands, lakes, and the ocean.

Infiltration

One important aspect of the hydrologic cycle in terms of watersheds, is the process of infiltration, the rate at which water is absorbed into the ground. Infiltration is influenced by two main factors: the characteristics of the soil material, and the type and density of the vegetation growing or lying on the ground (Leopold 1997, p. 10). Soil is composed of millions of tiny particles that have air spaces, or pores, separating each particle. Precipitation that falls onto the land is absorbed, or infiltrated, through these pores. Soils with bigger pores, like sand, allow precipitation to infiltrate more quickly. Conversely, soils with smaller pores, like clay, infiltrate water more slowly. When rain falls faster than the pores can absorb, or when soil becomes saturated, the excess rain flows onto the surface of the land. This surface runoff flows over the ground and eventually into streams.

Vegetation plays an important role in the infiltration of rain by reducing the velocity of water flow over the landscape, and minimizing rapid sheet flows of water into streams and creeks. The roots of plants and burrowing insects that live near plants loosen compacted soils and create additional pore spaces that help to infiltrate water. Studies conducted on plots of land with varying amounts of vegetation reveal the benefits of vegetation on the infiltration process. On one plot, 37% of the land was covered with grass or other vegetation, and the other plot was bare ground. The land with 37% vegetative cover infiltrated water at six times the rate as bare ground (Leopold 1997, p. 12).

Groundwater

Another important element of the hydrologic cycle is groundwater (Figure 2-9). Once water has infiltrated into the soil, three results can occur: the water can be absorbed by plant roots and transpired back into the atmosphere, move laterally into streams as subsurface storm runoff, or move downward into the groundwater zone (Murdoch, Cheo, and O'Laughlin 1996, p. 5). Water is able to seep lower into the earth through

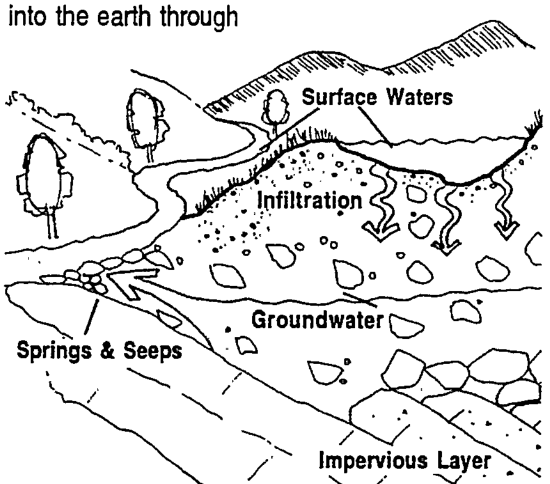

Figure 2-9: Infiltration of water into the groundwater

fractures, cracks, and pore spaces in rocks and soil material that are numerous towards the surface and become less abundant at greater depths (Leopold 1997, p. 18). Natural pore spaces may exist among the rocks. Sandstone and other sedimentary rocks that compose the geology in the Malibu Creek Watershed are excellent examples of porous rock.

Water will eventually find a level where it can sink no farther, and will begin to fill the same voids and pores that allowed it to penetrate into the earth. Eventually, the height of the groundwater zone will reach a level where it re-emerges as surface water through a seep or spring. This area where groundwater resurfaces is called a "discharge area" (Murdoch, Cheo, and O'Laughlin 1996, p. 5). Discharge areas are found in topographically low spots, usually the deepest cut in a stream channel (Leopold 1997, p. 20). The contribution of groundwater to surface water systems is called "baseflow" (Murdoch, Cheo, and O'Laughlin 1996, p. 5). This is one reason that streams continue to flow long after the last rain.

Surface Water

Streams are dynamic forces, both reflecting and changing the character of the surrounding landscape. There are three types of streams in the Malibu Creek Watershed (figure 2-10). The first type of stream is ephemeral, flowing only during

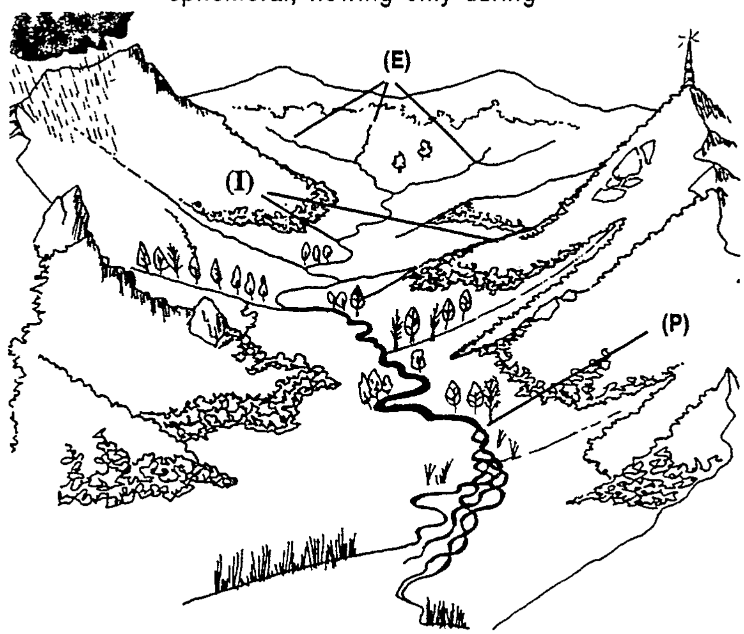

Figure 2-10: The Three types of streams within the watershed: (E) ephemeral, (I) intermittent, (P) perennial.

storms. Many of the streams in the upper watershed are ephemeral. The second is intermittent, a type of stream that has surface flows during the wet season, but still may be flowing subsurface during drier periods. Intermittent streams are the most dominant stream type in the Malibu Creek Watershed. Lower in the watershed, streams converge and the water table remains high enough to maintain the year round flows of the third type of streams, perennial streams. Historically, much of the flow that occurs during the summer season originates from springs, seepage areas, and areas of stored groundwater (Trim 1994, p. 1).

The Stream Continuum

A watershed drainage network continuously attempts to establish a balance between the shape of its stream channels and the amount and force of water running off the hillsides (Murdoch, Cheo, and O'Laughlin 1996, p. 63). Healthy streams have reached a state of equilibrium when the amount of sediments and water that enter the stream are the same amount that leave the stream. This process of equilibrium occurs as sand and gravel is scoured from the outside bend of a curve, and are then deposited on the inside of the curve (Figure 2-12). The meandering pattern of streams forces water to travel over a longer distance and dissipates the erosive power of the water. Unusual natural events or permanent alterations in the stream continuum caused by development can upset the balance of erosion and deposition of stream sediments.

Lining each stream are materials such as sand, cobbles, or boulders, making up the substrate of the stream. The type of substrate is a direct result of many factors including elevation, soils, geology, and slope. Substrate material, in general, is larger in size in the upper reaches of a stream. Headwater streams are narrow with stable substrates consisting of large cobble, boulders, or bedrock. In middle stream sections, the substrate will generally be composed of medium-sized cobbles and gravel. Heading downstream, the bottom material becomes finer, and is composed of sand and silt. The insoluble soil particles are carried in the water as suspended solids. Suspended solids remain in the water as long as the flow is significant enough to hold these particles in the water (Figure 2-11). At the base of the watershed,

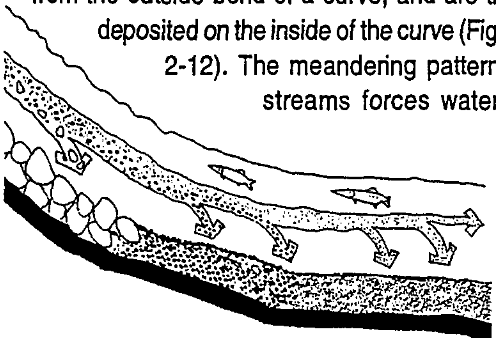

Figure 2-11: Sediment transport, as the stream gradient and velocity decrease, smaller particles are deposited.

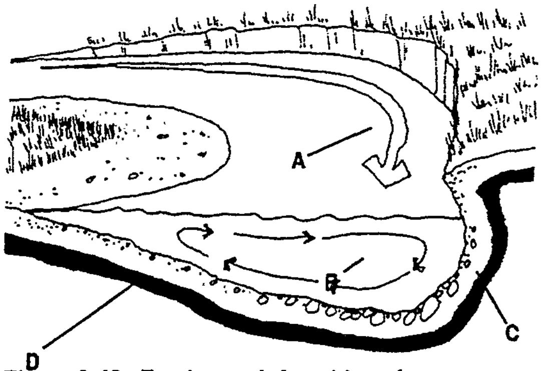

Figure 2-12: Erosion and deposition along stream curves: A) path of current around curve, B) circulatory current in water flowing around curve, C) area of erosion, and D) area of deposition (from figure 28, Leopold. Water, Rivers and Creeks 1997).

the amount of water continues to increase while the gradient flattens out, resulting in slower flowing, wider stream channels. The slower flowing water loses the ability to transport suspended solids, and may deposit them as sediments. These deposits create large sandbars that give the stream a braided appearance. In the natural process, much of the sediment washed into the waterways are deposited during intense storm events. This is why the streams and ocean look muddy after a large storm.

The Lagoon

At the bottom of every watershed is an outlet, either into another watershed, or into a large body of water. The outlet for the Malibu Creek Watershed is the Malibu Lagoon within the Santa Monica Bay. Lagoons act as large natural water filters, with plants and animals absorbing and breaking down nutrients, purifying the water. The maze of channels, the wetland plants, the tidal action, and the aquatic life contribute to the filtering and cleansing of water. The Malibu Lagoon is where freshwater and seawater interface. The Santa Monica Bay Watershed, which contains Malibu Lagoon, is recognized as one of four estuaries in California currently included in the U.S. EPA's National Estuary Program, which is aimed at improving or maintaining coastal water quality (USDA NRCS MCWNRP 1995, p. 7).

Sandbars are a key feature of the lagoon ecosystem. During the summer months, the closed sandbar separates the lagoon from the ocean. This is because less freshwater reaches the lagoon, due to the decreased flow of ephemeral or intermittent streams. As the freshwater flows diminish, sediments build up and close off the lagoon from the ocean.

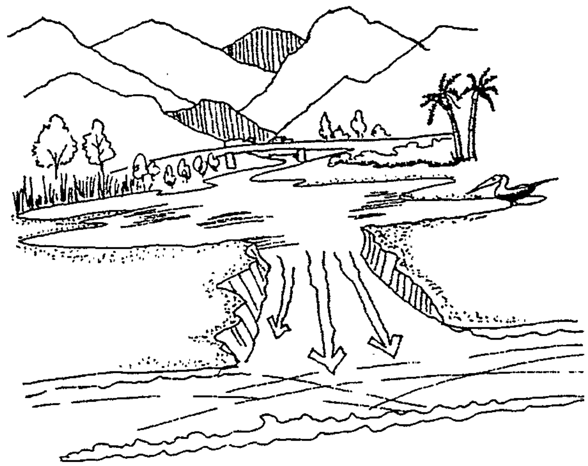

Figure 2-13: Increased flows of water during the winter months cause the lagoon's sandbar to breech.

This creates an important brackish or partially saline wetland condition that supports a large diversity of terrestrial and aquatic life. In the wet winter months, the high quantity of water flowing into the lagoon breaches or breaks open the sandbar (Figure 2-13).

The lagoon is a critical estuarine habitat. Currently it houses a population of the endangered Tidewater Goby that was reintroduced into the lagoon from the Ventura River Estuary (Figure 2-14). Migrating birds use the Malibu Lagoon as a rest stop on their long journey. The lagoon also supplies a critical rearing habitat for the endangered Southern Steelhead Trout. Steelhead use the lagoon to make the transition from salt water to fresh water before they begin their spawning runs up the Malibu Creek. Young steelhead use the brackish waters of the lagoon to adjust to saline conditions as they leave freshwater streams and migrate into the ocean.

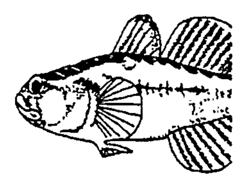

Figure 2-14: Tidewate

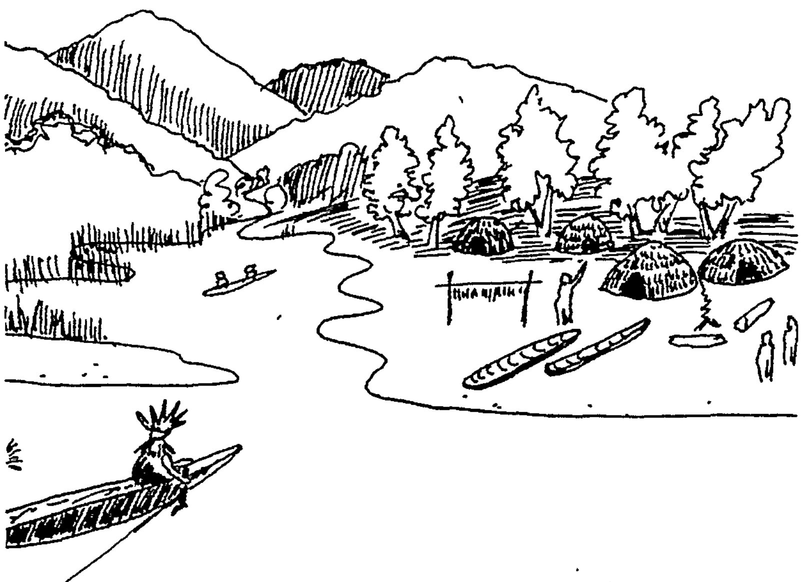
History of Settlement

The earliest evidence of human habitation in the Malibu Creek Watershed dates back over 7,500 years ago. These inhabitants were the predecessors of what would eventually develop into the Chumash culture. Malibu Canyon is located along the interface between the Chumash and the Gabrielino (Tongva) peoples. The Chumash inhabited the area from Malibu Canyon west and then north into San Luis Obispo County. Many Chumash archaeological sites have been found in the Santa Monica Mountains. These mountains were a plentiful source of game and plants were used for making shelter and for providing food. An extensive foot trail system was established throughout the mountains to facilitate traveling, trading, and hunting and gathering of food.



· *Malibu Lagoon was thought to be the location of a trading village of the*

Within the Malibu Creek watershed, Malibu Creek and its tributaries served as a major north-south travel route through the mountains. A major Chumash village was located along the ocean at the base of Malibu Canyon (Figure 2-15). The Chumash are believed to have used the Malibu Lagoon as a launching area for their canoes (Ambrose, Suffet, and Hee 1995, p. 9). Fish and shellfish were some of the abundant resources available to the Chumash at this site. The watershed supported a viable and rich Native American culture.

Spanish explorers traveled through this area starting in the 1500s, but it wasn't until the late 1700s that Spanish settlers and missionaries started coming to the Santa Monica Mountains. This had a profound impact upon the lives of the Chumash people. The community of villages fell apart under the influence of the mission system, the introduction of European diseases, and the assimilation of the Chumash culture into the Spanish, and later on into the Mexican and American, cultures.

During the 1800s, settlement and ranching activities started to take hold throughout southern California, including the Santa Monica Mountains. Under Mexican authority, land grants were made for private ownership of land and large ranchos were established. These privately held ranchos continued after California became part of the United States in 1850. Over time, these have been sold and subdivided until today we see a patchwork of privately and publicly held land with a mixture of land uses and development within the Santa Monica Mountains.

In the early 1800s, cattle grazing started in and around the Malibu Creek Watershed. The Rindge Ranch, a cattle and grain raising operation, occupied much of the area in the latter half of that century (Doyle et al. 1985, p. 39). In 1908, a railroad was built which spanned 15 miles of coast including the Malibu Lagoon. This Rindge line began near Las Flores Canyon and went all the way to Yerba Buena Road in what is now Ventura County. In 1928, the Rindge Dam was constructed in Malibu Creek to store water for irrigation to be used on the ranch (Doyle et al. 1985, p. 39). Construction of the Roosevelt Highway was completed and opened to the public in June of 1929. It was later renamed the "Pacific Coast Highway", and, as with the railroad, crosses over Malibu Lagoon.

Development in and around the watershed continued, and in the late 1950s and early 1960s growth was fueled by the rapid expansion around the Los Angeles area. In 1965, the Tapia Wastewater Treatment Plant (Tapia) was built to accept wastewater from the growing community within the watershed.

Recreational Opportunities

The Malibu Creek Watershed has some of the best recreational opportunities within the Santa Monica Mountains, and perhaps some of the best within southern California. Close to and easily reached from the Los Angeles metropolitan area of over 13 million people, the Santa Monica Mountains is a popular destination for those wanting to find high quality recreational activities.

Creation of parklands within the Santa Monica Mountains began in the 1940s by the State of California. At the national level, the need to preserve and protect the unique resources of the Santa Monica Mountains was recognized by Congress in 1978 when it established the Santa Monica Mountains National Recreation Area under the National Park System. Various governmental agencies and private groups have joined in the effort to preserve land within the Santa Monica Mountains. The result is an evolving system of parklands that not only protect the natural resources of the mountains, but also offer many opportunities to recreational users.

There is a wide range of sites where the public can visit and learn about the unique natural and cultural resources within the Malibu Creek Watershed. These include Tapia Park, Malibu Creek State Park, Rocky Oaks Park, Peter Strauss Ranch, Cheseboro Canyon, and Malibu Lagoon State Park. Adjacent to the lagoon is Malibu Surfrider Beach, one of the most heavily used beaches in southern California. It is world-renowned for its excellent surf break and is used year-round. Throughout the watershed is an extensive trail system. Most trails are limited to hikers, but others are designated for use by mountain bikers and equestrians. Additional activities enjoyed by visitors include, biking, horseback riding, birdwatching, swimming, picnicking, scuba diving, fishing, whale watching, and beach going.

Section 3

Issues and Analysis

Settlement in the area has altered the natural hydrologic regime and ecological functioning within the watershed. This section details issues of concern in the Malibu Creek Watershed due to settlement. Of primary concern are the influences of imported water, the increased acreage of impervious surfaces, accelerated erosion and sedimentation, and increased levels of nutrients flowing into the receiving waters. Further, settlement has altered the natural fire regime, the distribution of vegetation, loss of wildlife habitat, and the size and function of the lagoon within the Malibu Creek Watershed.

Imported Water

In response to the demand of a growing domestic, commercial, and industrial community, water has been imported into the watershed since the 1960s. Approximately 20,000 acre-feet, or 6.6 billion gallons a year, is imported into the watershed primarily from the California State Water Project, which collects and transports water from northern California. Imported water and any pollutants it may carry enter the stream system in three ways: by discharges into Malibu Creek from Tapia, by surface runoff via the storm drain network, and through groundwater. Increased water quantity and decreased water quality have altered chemical, biological, and physical characteristics of the streams and lagoon.

Tapia receives wastewater from households and businesses within and beyond the watershed, and services an estimated population of 90,000 people. By the year 2020, the population serviced by Tapia is predicted to rise to 160,000 (Bauer Environmental Services March 1996, p. 54). Tapia is located along Malibu Creek approximately five miles north of the Malibu Lagoon. Tapia filters and treats the wastewater, reclaiming it to a condition that allows it to be reused safely for irrigation (Figure 3-1). Tapia also composts the solid waste into fertilizer for fodder crops at their Rancho Las Virgenes Compost Facility (Las Virgenes Municipal Water District 1994, p. 36).

Tapia has increased its capacity since it opened in 1965, and now has the capacity to handle 16 million gallons per day (mgd). Current inflows average 7.75 mgd, or 8,680 acre-feet per year. Tapia sells

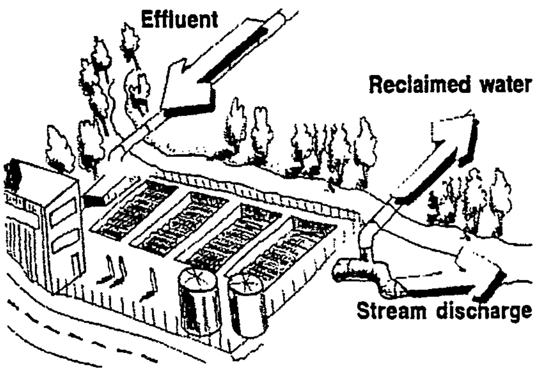


Figure 3-1: The Tapia Wastewater Treatment Facility

approximately 4,000 acre-feet of reclaimed water each year for use in irrigating open space and landscaping. The additional 4,680 or so acre-feet is treated and discharged to Malibu Creek (USDA NRCS MCWNRP 1995, p. 35). Reclaimed water has higher than normal levels of nutrients that can enhance the growth of algae. When these algal blooms die, the decomposition process may rob the water of the oxygen that fish and other aquatic life need to survive. Tapia is the only such facility in the watershed.

2: Overview of runoff associated with development.

The use of imported water for a variety of purposes outdoors, including landscape and agricultural irrigation, has altered the quantity, quality, and seasonal flow of water within the watershed. Runoff from overwatering or improperly designed and installed irrigation systems can flow onto streets and into the storm water drainage network. In addition, water can enter stormdrains from the hosing down of driveways, sidewalks, and streets as well as from washing cars in areas where water can not be absorbed into the soil. Unlike water that enters the sewage system, this water is conveyed directly into a nearby receiving water body without any form of treatment.

Runoff associated with landscape and agricultural irrigation may carry herbicides and pesticides, and nutrients from fertilizers. Water that is used to wash cars and hose down driveways and streets may wash metals, nutrients, oil, and grease into receiving waters (Figure 3-2).

Imported water can also reach the streams through groundwater. Water that is not absorbed by plants may move laterally into streams as subsurface storm runoff, or move downward into the groundwater zone (Murdoch, Cheo and O'Laughlin 1996, p. 5). Water from landscape irrigation or from septic systems is infiltrated through the soils. This water can carry nutrients from the over fertilization of lawns and agriculture, and improperly functioning septic systems. The watershed has an estimated 2,300 septic tanks (USDA NRCS MCWNRP 1995, p.16).

Impervious Surfaces

Impervious surfaces are constructed surfaces that do not allow water from rainfall or other sources to be effectively absorbed or infiltrated directly into the soil. Examples include rooftops, roads, parking lots, driveways, and sidewalks, usually made out of asphalt, concrete, brick or other types of paving materials, but they may also be areas with compacted soils, such as dirt roads. Such surfaces replace vegetation and soils, thereby affecting the area's ability to clean and infiltrate surface runoff. Storm water rushes off of the impervious surfaces, into the storm drain network, and eventually into a channel or creek (Figure 3-3).

Impervious surfaces collect and accumulate pollutants from a variety of sources, including those from the atmosphere, oil from cars, tossed debris, and fecal matter from animals. These accumulate over time until they are eventually washed away into the watershed's drainage network via the storm drain system. This runoff concentrates in creeks and streams, and eventually flows through the watershed and out into the Santa Monica Bay at Surfrider Beach. Storm water runoff is normally at its highest level of contamination during the "first flush" which is the first significant storm event of the rainy season after pollution has had a chance to accumulate during the long, dry summer period. A health effect study conducted by the University of Southern California, reported that people swimming within 100 yards of a flowing storm drain reported increased incidents of becoming sick. The amount of pollution washed into the riparian system can be directly related to the amount of impervious surfaces in the watershed (Schueler 1995, p. 24).

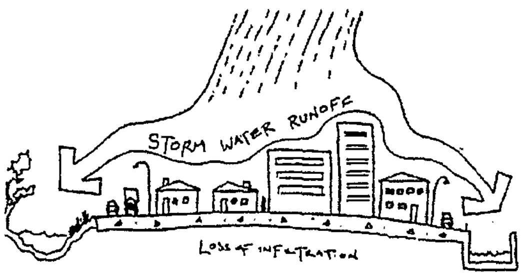

Figure 3-3: Impervious surfaces prevent infiltration, dramatically increasing stormwater volume and peak intensity.

The runoff of pollutants into streams and the accelerated rate of soil erosion that impervious surfaces cause can drastically alter the vegetation along streams. Decreased amounts of vegetation that shades the stream can increase water temperature and decrease the available dissolved oxygen needed by aquatic organisms. This, along with a variety of pollutants, can cause a decrease in the health of aquatic animals, including amphibians and fish.

Besides accumulating pollutants, impervious surfaces increase storm water runoff and cause accelerated erosion of soil. Accelerated erosion is due to the greater rate and volume of runoff during storm events. Studies have shown that runoff from a one acre parking lot can be about 16 times the amount of runoff from a one acre undeveloped meadow. The increased volume of storm water runoff into the riparian system also increases the frequency of bankfull conditions in creeks and streams, resulting in streambank erosion and greater degradation of riparian habitats. The threshold for maintaining good quality urban stream habitats is about 10% to 15% impervious surfaces. An increase in the percentage of impervious surfaces above this level results in the decline of predevelopment water quality and stream habitat (Schueler 1995, p. 24).

Dealing with the effects of impervious surfaces is costly. An extensive storm water drainage system is built with pipes, concrete culverts and channels. Construction activity is needed to handle the erosion of slopes and streambanks. It is cheaper and more cost effective to limit the amount of impervious surfaces in the watershed rather than to try later to fix the problems impervious surfaces can cause.

The construction of impervious surfaces and the importation of water have resulted in increased runoff and stream flows in the watershed. The Natural Resource Conservation Service (NRCS) collected data at the stream gauge located below Tapia in Malibu Creek for the years 1931-1994. From this data, they constructed a water budget. Their analysis

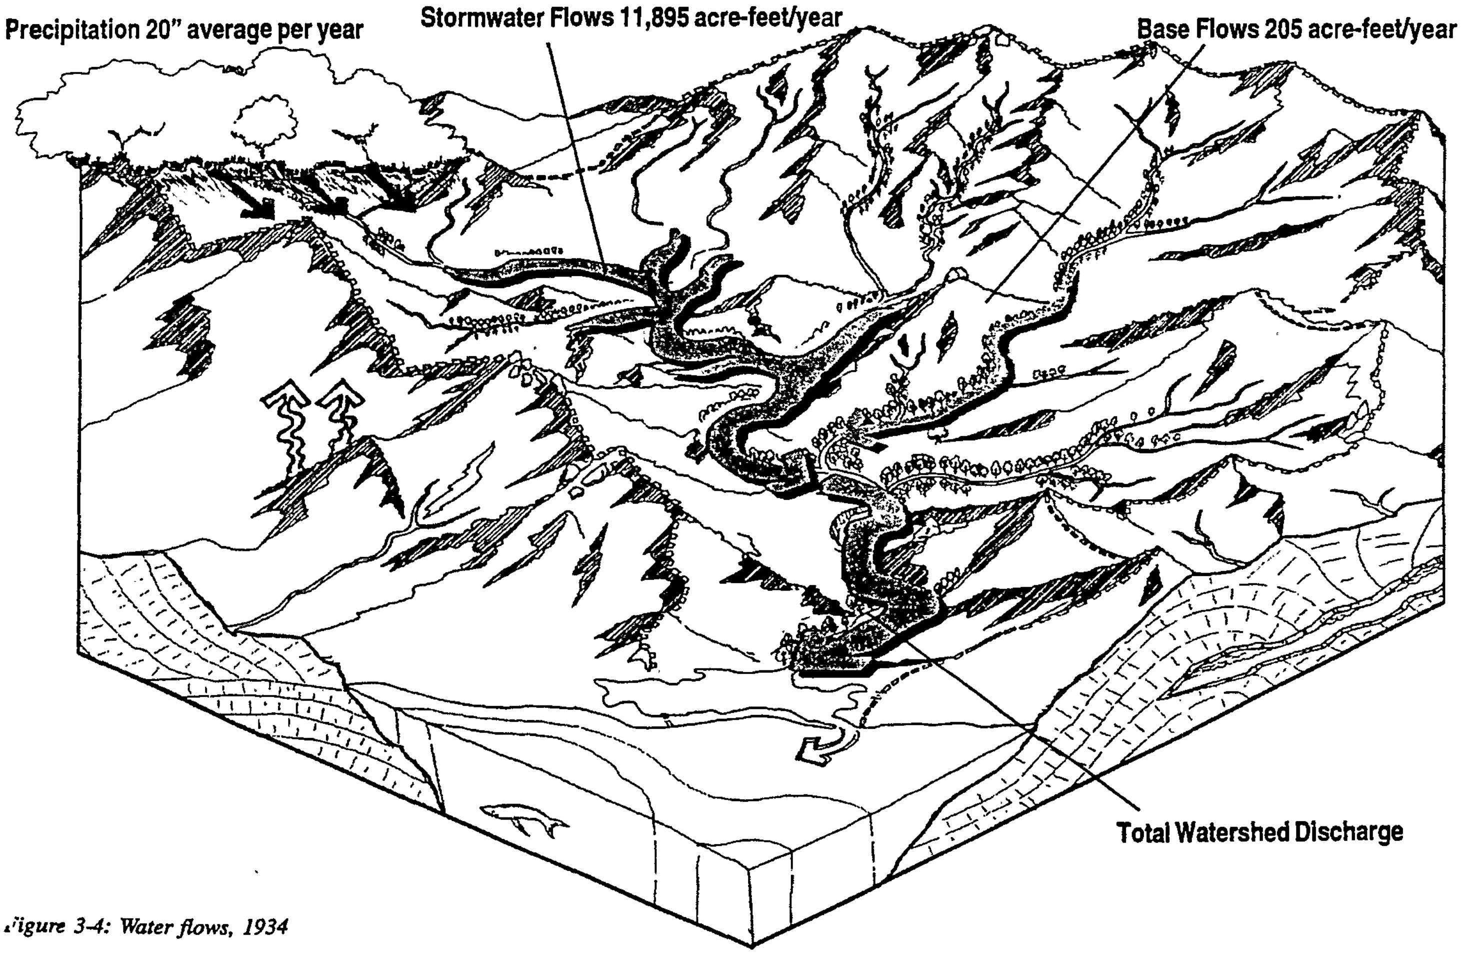

Figure 3-4: Water flows, 1934

[redacted]

demonstrates how stream flows have been altered due to changing land uses within the watershed, the importation of water, and the replacement of vegetation with impervious surfaces. Their analysis also reveals a change in base flows within Malibu Creek from 205 acre-feet in 1934 (Figure 3-4) to 2,050 acre-feet in 1994 (Figure 3-5). Base flow is the water volume measured in the creek and excludes releases of reclaimed water from Tapia. In addition to increases in base flows, stream flow during storm events also increased dramatically, from an annual average of 11,895 acre-feet in 1934 to over 21,000 acre-feet in 1994.

From 1931 to 1965, prior to significant upstream development, imported water, and discharges by Tapia into Malibu Creek, the average annual stream flows recorded at the stream gauge were about 12,000 acre-feet. The average annual flow of water since 1966, after significant upstream development, has averaged 27,000 acre-feet per year (USDA NRCS MCWNRP 1995, p. 36).

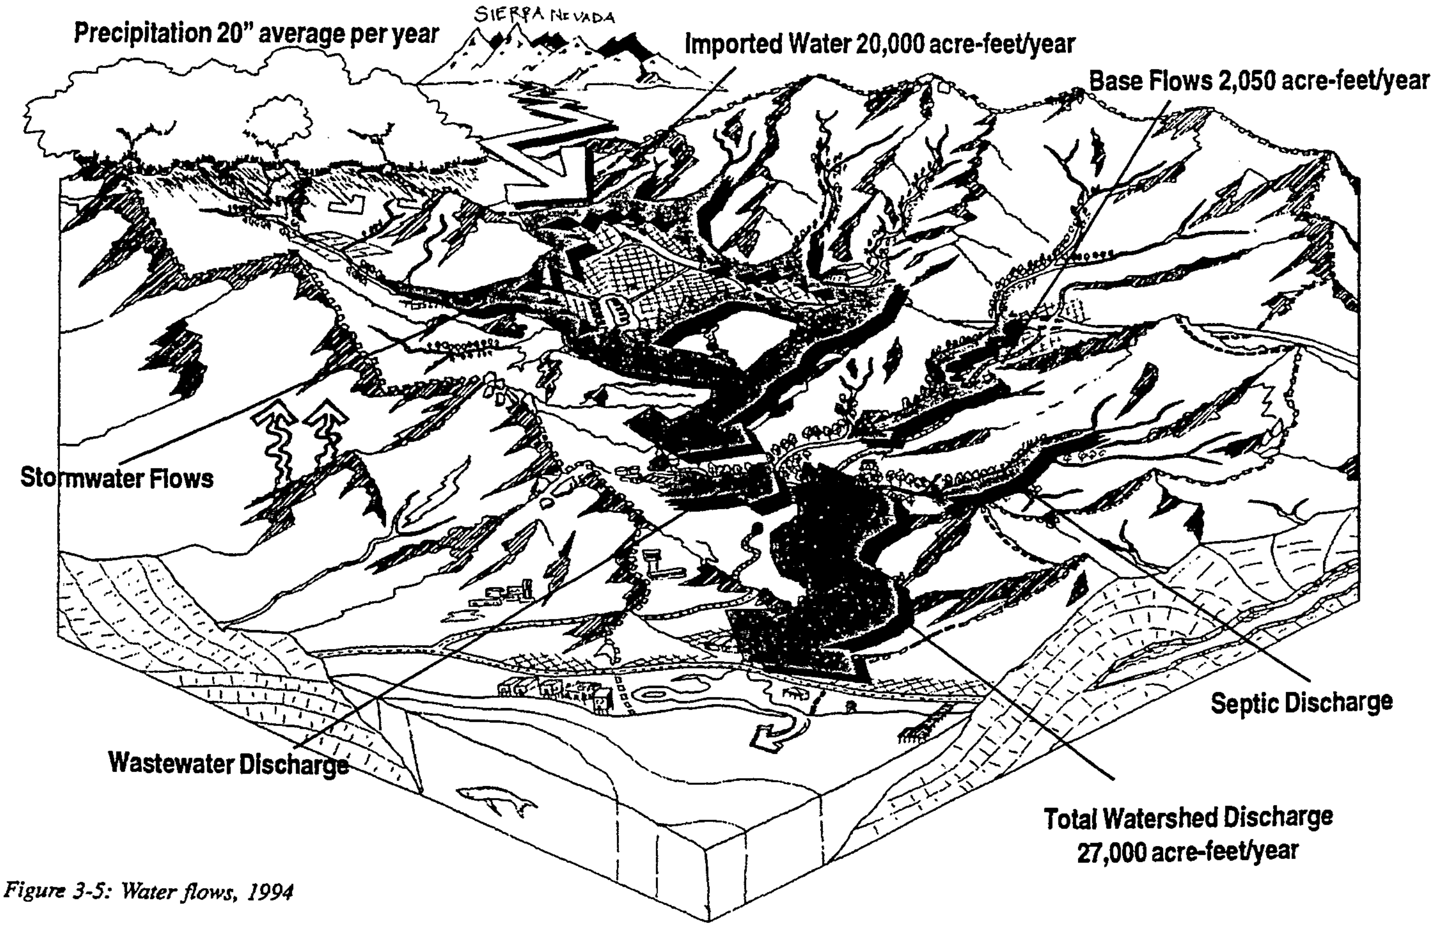

Figure 3-5: Water flows, 1994

R0016895

The NRCS Malibu Creek Watershed Natural Resources Plan (MCWNRP 1995), estimates the break down of these increased flows as follows:

Discharge from Tapia	4,000 acre-feet
Runoff from home use and landscape irrigation	2,500 - 3,500 acre-feet
Septic tanks seepage	500 acre-feet
Storm runoff	19,000 - 20,000 acre-feet

A model was created to determine the effects of increasing development and impervious surfaces on peak discharges for each of the seven major tributaries. The model compares the natural conditions prior to human influence with the current conditions in the watershed. The model calculates runoff and peak discharges for 2, 5, 10, 25, 50, and 100-year storm events. The results demonstrate the overall increase in peak flows and the volume of runoff that is particularly evident in the more densely developed subwatersheds of Westlake and Agoura. This model does not consider inputs from Tapia. The overall flows entering the lagoon have also more than doubled. The details and the model can be seen in Appendix A.

To avoid flooding caused by the increased volume and intensity of runoff created by impervious surfaces, many streams and creeks are channelized (Figure 3-6). Potrero Creek from Lake Sherwood to Westlake Lake is almost completely channelized. Significant channelization has also occurred throughout the City of Agoura Hills. Channelization affects a watershed's hydrologic functioning. Designed to move water quickly out of the area, channelized streams are artificially lined with concrete for flood control purposes. The result is a waterway that has few, if any plants, and little wildlife habitat value. The channelization of an area diminishes other benefits of riparian corridors, such as water purification, and slowing water flows. Because there are no cobbles, boulders, plants, or streambank irregularities that could slow down rushing water, downstream riparian areas are often overwhelmed by the increase in water velocity.

Erosion and Sedimentation

Erosion and sedimentation are also important issues of concern within the Malibu Creek Watershed. Erosion is the process of surface water cutting into

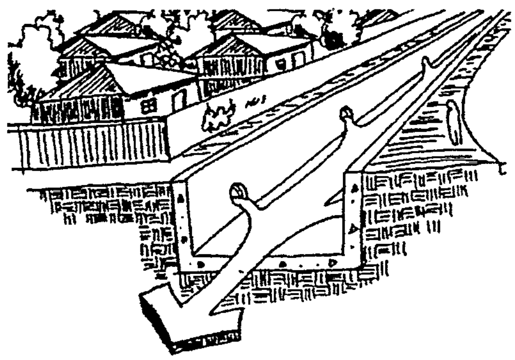

Figure 3-6: Channelization eliminates any benefits provided by riparian corridors.

and carrying soils, organics and rock material into waterways. When they settle, these insoluble particles are called "sediments". The Santa Monica Mountains contains many soil types that are considered highly erodible. An area's erodibility is dependent on the type of soils, slope, vegetative cover, and its exposure to water and rain. Consequently, erosion is a natural process that

happens frequently within the watershed, and erosion adds sediments and nutrients to the streams. Erosion is also part of the natural cycle of wildfires; however, in developed areas, fire suppression measures have resulted in older, unburned plants. This in turn increases fuel loads, and therefore the intensity of a potential fire. The resulting erosion from such intense fire events increases sediment loading into streams.

Increased sedimentation of waterways can have a significant effect on instream habitat quality. Several factors have caused an increase in the sedimentation of streams, altering their natural process. Construction sites have exposed soils that erode, increasing sedimentation (Figure 3-7). Typically, 35 to 45 tons of soil per year per acre is washed from construction sites (Center for Watershed Protection n.d., p. 23). As well, agriculture, animal husbandry, and areas of disturbed or non-vegetated land significantly contribute to sediment loading. These sediments can cover stream bottoms, altering the habitat for aquatic life. The local steelhead trout is particularly sensitive, since they need gravelly stream bottoms for reproduction (Figure 3-8).

Dams used to create reservoirs or recreational lakes also play a role in the sedimentation process. They slow water flow to the point that suspended solids are dropped. The dam then becomes a sediment trap that quickly fills in (Figure 3-9). This has happened at Rindge Dam, located two and one-half miles north of the Malibu Lagoon. It creates barriers, preventing the migration of steelhead trout to their historic spawning grounds in the upper parts of Malibu Creek. The dam also traps sediments that may have been carried to the ocean and used for beach replenishment (Ambrose, Suffet, and Hee 1995, p. 10). Many of the reservoirs and constructed lakes within the Malibu Creek Watershed require regular dredging. Dredging is expensive, particularly if these sediments are placed in a landfill. These reservoirs and dams interrupt the natural migration of sediments.

Figure 3-7: Construction sites can be a significant source of sediments.

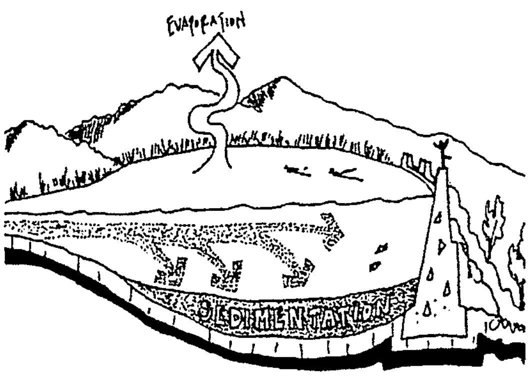

Figure 3-9: Reservoirs slow sediment transport to the point of becoming sediment sinks.

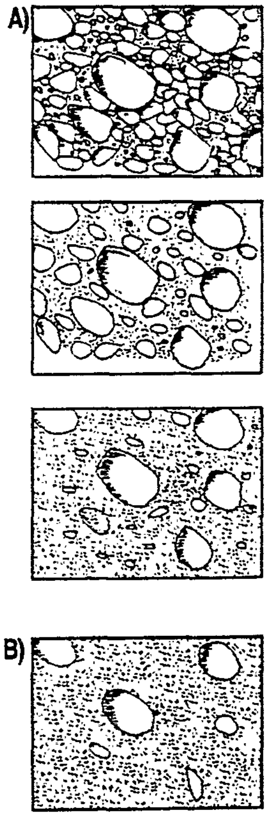

Figure 3-8: How a stream can become embedded in sediments, changing the substrate from gravelly (A) to silty (B), degrading Steelhead Trout breeding areas.

R0016897

Nutrient Loading

Nutrients are necessary for the growth of plants and animals in natural water systems, and are primarily composed of nitrates and phosphates (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 47). Nutrient loading takes place when there is an overabundance of nutrients. High nitrate levels may cause increased algae production, cloudy water, decreased oxygen levels, and objectionable odors (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 47). Areas of standing water like the various constructed lakes and the Malibu Lagoon may be subject to increased effects of excessive algal growth and low dissolved oxygen levels causing fish kills and odor problems (Figure 3-10). Persistent eutrophication problems can change the composition of plant and animal species and decrease the biological diversity of a particular water body (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 48). To minimize the growth of algae, many of the constructed lakes

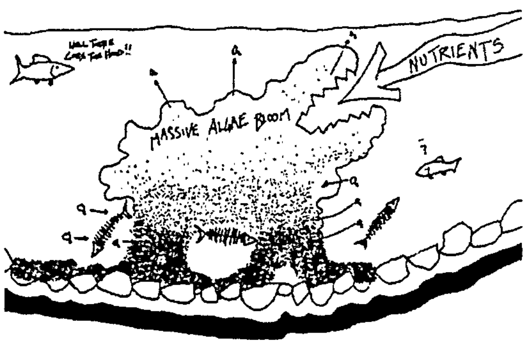

Figure 3-10: Algae blooms sparked by excessive nutrient can result in depleted oxygen level with detrimental effects to aquatic life.

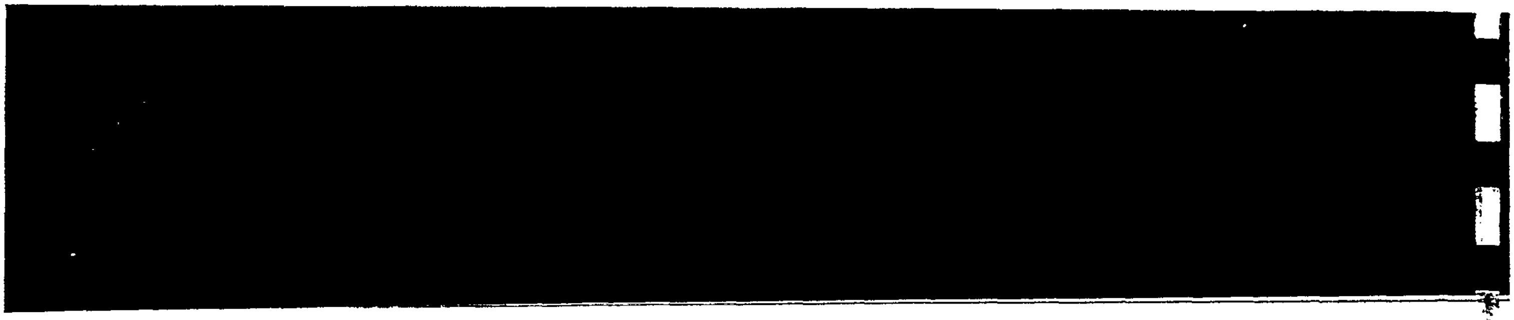
are treated with copper sulfate, a powerful chemical; this may further contribute to degraded water quality and be a threat to the ecological functioning of the watershed. Prior sampling in the watershed has revealed that nutrient loading is a problem throughout the watershed.

High phosphates levels can also disrupt water quality. Sources include runoff from manure storage areas, feedlots, barnyards, leaking or improperly maintained septic systems, wastewater treatment plants, detergents and commercial cleaning preparations, soil erosion, and phosphate rich fertilizers (Behar, Dates, and Byrne 1996, p. 130). The fire retardant used to fight fires is a significant source of phosphorous and ammonia. A 1989 study found that during the first 24 hours following an aerial application of fire retardant, significant amounts of phosphorous, ammonia, and nitrogen were present in nearby streams (Ambrose, Suffet, and Hee 1995, p. 15).

Fire

Fire suppression near developed areas has allowed the plants to age, increasing woody fuel loads, and decreasing wildlife habitat value. Fire within older chaparral and coastal sage scrub stands has resulted in more intense fires and increased erosion. Fires cause increased runoff and stream flow, increasing sediment transport and nutrient loading to the lagoon (Ambrose, Suffet, and Hee 1995, p.7). The natural fire regime affects both water quality and water quantity within the watershed. Chaparral vegetation exudes oils, fats and other organic residues during combustion, which fall to the ground and create water-repellant soils. Water quantity is increased due



to the removal of vegetative cover and the decreased porosity of soils. Increased runoff and less vegetative cover cause soil to be transported into the streams. The increased sediment load raises the turbidity, temperature, and dissolved organic nutrients content in the stream (Levy, Korkosz 1997, p.II-51). Plants that are burned from fire are washed into the streams during rain events causing elevated nutrient levels.

Effects of Settlement on Vegetation & Wildlife

Settlement has altered the native vegetation in the Malibu Creek Watershed. Much of the native vegetation has been eliminated by the addition of housing, roads, and surfaces that do not allow water to be absorbed into the ground, increasing the volume and intensity of storm water run off. Native vegetation is important in the riparian zone because they provide shade, which cools the water temperature, and provide food, habitat and shelter for aquatic animals and fish. Non-native plants brought in by early cattle ranchers and settlers, as well as plants used for landscaping, have been introduced into the watershed, and some of these plants are extremely invasive, displacing large areas of native vegetation. Landscaping practices affect water quality with the use of fertilizers, herbicides, pesticides.

Wildlife is dependent upon vegetation for shelter and food. Though the Santa Monica Mountains provide a large amount of healthy habitat, increased development is taking its toll through loss of habitat and habitat fragmentation.

The Lagoon

Development throughout the watershed has also had a significant effect on the lagoon's ecosystem. Pollutants from urban runoff, sediments, nutrients, and debris collect in the lagoon, creating a sink, or point of deposition. Although lagoons are excellent water purifiers, the additional quantity and lower quality of water reduces the lagoon's capacity to effectively filter the water. Prior to modern development, the lagoon was substantially larger than it's present 13 acres, and had greater species richness and abundance than today's 13 fish species (Ambrose, Suffet, and Hee 1995, p. i). The earliest maps seem to confirm a much larger lagoon that extended eastward around the point and to the west up to the base of the hill where Pepperdine University is now located (Ambrose, Suffet, and Hee 1995, p. 4). In essence, this smaller lagoon is asked to treat more water of lower quality. Excess flows of wastewater discharged into Malibu Creek cause the sandbar to breech during the dry season. This has the potential to suddenly change the lagoon's salinity, disrupting natural processes and affecting wildlife.

Section 4

The Monitoring Program

Many monitoring programs throughout the country utilize a variety of techniques to assess the overall ecological health within a watershed. A comprehensive approach to monitoring, one that takes into account the chemical, biological, and physical aspects of the stream ecosystem, yields the most usable data. This information allows decision-makers to attack the sources of problems from many different angles, not just one. Monitoring techniques include water quality or chemical testing, macroinvertebrate sampling, and stream reach surveying. The methods vary for each monitoring program, and grow out of the program goals and objectives.

The Cal Poly Team has designed a monitoring program that utilizes citizen volunteers to evaluate the overall ecological health of the Malibu Creek Watershed. The monitoring program is designed to address the issues related to imported water, impervious surfaces, erosion and sedimentation, nutrient loading, and pollutants associated with urban runoff. It is hoped that the monitoring program will determine the degree of degraded riparian habitats within each of the subwatersheds and target areas for future enhancement and restoration. Details about the specific monitoring procedures can be found in *The Malibu Creek Watershed, Stream Team Field Guide*, prepared by the Cal Poly Team.

The monitoring program is designed to represent an overall view of the entire watershed. This is a pilot project; therefore, it may not be practical to implement every element in the initial start-up phase. A phased approach allows the program flexibility, and is intended to provide Heal the Bay with options and the flexibility to adjust the program as necessary.

Involvement by citizen volunteers in the monitoring program should allow Heal the Bay and the California State Coastal Conservancy to meet the following long-term objectives:

- To establish baseline information that will ascertain the current overall health of the watershed.
- To determine the potential impacts of impervious surfaces and water quality due to urbanization within the watershed.
- To locate areas of degradation along stream corridors and to identify potential future restoration efforts.
- To assess the effectiveness of planning recommendations or Best Management Practices (BMPs) that are implemented to protect the watershed or mitigate potentially negative impacts.

Design Process

The design of the volunteer monitoring program began with a watershed inventory that involved the collection of studies conducted on the Malibu Creek Watershed. These studies were researched to gain a clear understanding of the natural processes at work in the watershed. A summary of this information can be found in section 2 of this document, Natural Processes. The second step was to analyze the collected information, and consult with concerned groups and local, state, and federal agencies that are active in the watershed. This helped identify key issues and questions that needed answers from the monitoring program. Section 3, Issues and Analysis, summarizes these elements. In addition, monitoring programs and protocols being used around the country were researched. Telephone surveys and questionnaires were distributed to the leaders of these monitoring programs to identify and avoid potential pitfalls. A workshop with a pool of potential volunteers was conducted, wherein volunteers were asked to identify potential monitoring sites and problem areas, to create a name for the program, to evaluate the proposed program for ease of use, and to establish a level of commitment Heal the Bay could expect from volunteers. Monitoring protocols and early drafts of the field guide were tested at two training events. Volunteers were asked to critique the protocols and the field guide. The monitoring program was revised based upon the input and suggestions of volunteers to the current design detailed in this section.

Successful Programs

The following elements were identified as being critical to ensure a successful volunteer monitoring program, as identified in the San Francisco Estuary Institute's *Riparian Station How-To Manual,* and from phone interviews with other monitoring programs around the country.

Motivating Volunteers

- Meet the needs of volunteers. This may be a simple as giving praise for a job well done or providing snacks and water at monitoring events.
- Listen and consider volunteer recommendations and suggestions.
- Acknowledge and reward the efforts of volunteers.
- Explain how the information collected by volunteers is being used to enhance the watershed.
- Involve volunteers in restoration activities and solutions, as well as in identifying problems.

Quality Control

- Provide the necessary equipment to collect good quality information.
- Assure the quality of the data by having frequent quality control checks and ongoing training.
- Ensure the quality of data collected through regularly scheduled training events, and appropriate protocols.

[redacted]

Program Organization and Expansion

- Organize a well structured program.
- Develop additional funding to support and expand the monitoring program as interest grows.

Using the Information

- Ensure the information collected by volunteers is analyzed and made available to interested agencies and groups that work in the watershed, for planning and resource protection.
- Integrate other locally collected data for analysis and dissemination.
- Use the Stream Team Program to educate the public about watershed issues.

Monitoring Program Overview

The Stream Team Volunteer Monitoring Program has been designed by the Cal Poly team for use in two phases. The purpose of Phase 1 is to provide useful monitoring information while at the same time providing volunteers with an opportunity for hands-on participation. Phase 1 will involve two types of monitoring activities–Stream Walking, and Water Chemistry Testing. This is a fact-finding phase that will help Heal the Bay to ascertain the existing condition of the watershed. In addition, trouble spots will be identified and located for further investigation and restoration. Phase 1 is the pilot phase of the project. Phase 2 expands on Phase 1 by adding the additional activities of Stream Reach Surveying and Macroinvertebrate Sampling.

All the information collected by the volunteers will be entered into a Geographic Information System (GIS) database (a computer mapping and database program) that will be maintained at Heal the Bay. This GIS program will allow the information to be analyzed by Heal the Bay and distributed to agencies throughout the area. The following is a brief description of the activities that will occur during each phase of the project.

Phase 1

Stream Walking

Stream Walking is the systematic visual observation of physical conditions along streams within the Malibu Creek Watershed. The focus includes locating all types of discharges flowing directly into streams, and areas of disturbance such as erosion and invasive plant species, barriers to fish passage, illegal dumpsites, and human alterations to the streambank (Figure 4-2). This is a method for quickly collecting

Figure 4-2: Stream walker with GPS device noting location of discharge point.

information on elements that are impacting the water quality and ecological functions of the stream. This gathered information should alert Heal the Bay to the locations of suspected impacts within the Malibu Creek Watershed so that these impacts can be targeted for immediate removal or restoration. Stream Walking provides valuable information that should help prioritize the more specific testing that will occur during Phase 2.

Water Chemistry Testing

The Water Chemistry Testing team will use chemical testing to examine the water quality of a number of fixed stream sites throughout the watershed (Figure 4-3). Tests include pH, temperature, dissolved oxygen, turbidity, conductivity, nitrates, ammonia, and phosphates. Once the data is compiled and analyzed, a picture of the existing conditions of the watershed should be revealed. This procedure is designed to determine how much each subwatershed is contributing to downstream flows

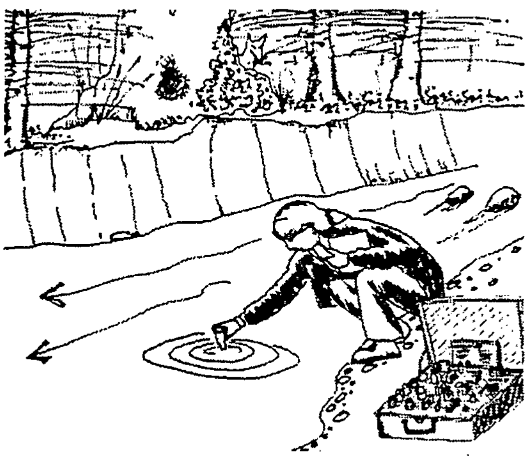


Figure 4-3: Water Chemistry tester taking pH reading.

and water quality. This information will be used to guide the expansion of the Water Chemistry Tes g in Phase 2, and will be shared with the Regic al Water Quality Control Board so that the sources of pollution can be identified and eliminated.

Phase 2

Macroinvertebrate Sampling

Biological monitoring is an important tool for tes g water quality and assessing the health of the watershed. Aquatic macroinvertebrates live mos r all of their lives in the water. They react to polluta , water temperature, and habitat conditions like sedimentation of substrate, and are theref e continuous indicators of water quality. Monitors ll collect macroinvertebrates, identify them, and sort them into taxonomic categories. If a monitor g sample shows a great number of pollution-toler t

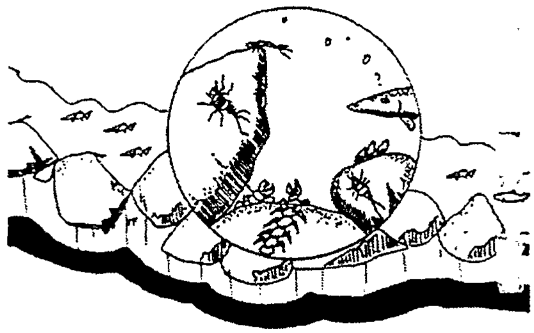

Figure 4-4: View of the macroinvertebrate environm t

macroinvertebrates, and very few, if any, of t pollution-sensitive macroinvertebrates, it can indicate that water quality is poor. A healthy stream sho l demonstrate excellent species diversity for t various types of aquatic macroinvertebrates in the watershed (Figure 4-4).

Stream Reach Survey

Stream Reach Surveying is the detailed measurement and assessment of physical characteristics of randomly selected 100-foot stream segments along the entire length of a stream (Figure 4-5). Further, the Stream Reach Survey involves walking the same tributaries as the Stream Walk procedure, and will be used to monitor the progress made during Phase 1. By examining existing stream characteristics and comparing them against future observations, it may be determined if habitat is being lost or degraded due to upstream development.

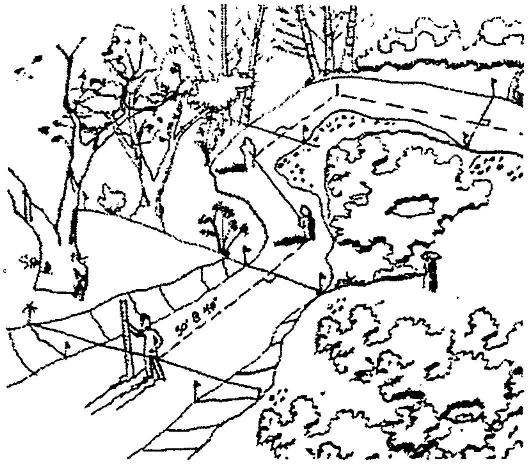

Figure 4-5: Overview of stream reach surveying.

Monitoring relatively undisturbed stream reaches can yield baseline information that can be compared to areas impacted by land use activities, in order to determine if those activities are affecting the conditions of the stream. These same locations can be monitored over time to determine the long term effects of upstream development.

How The Program Works

Volunteers have a choice of taking part in one or more components of the Phase 1 monitoring program. These include Stream Walking or Water Chemistry Testing. Both Stream Walking and Water Chemistry Testing are conducted on a monthly basis, requiring a four-hour commitment on one weekend day per month. Volunteers should be placed on one or more of these teams, based upon their interests, skills, time, and the needs of the volunteer monitoring program.

Each volunteer should attend an initial orientation session, which will provide an overview of the monitoring program and introduce the different components of the program. Following the orientation session, volunteers will be asked to attend two training events. During these events, they will be given the opportunity to learn the basic skills necessary to perform the monitoring tasks. Once they have acquired the necessary skills for monitoring, they can join the Stream Team (Figure 4-6).

Establishing a Core of Volunteers

Volunteers are essential to the Stream Team Program and are an important link between Heal the Bay and the community (Rigney, Fischer, and Sawyer 1996, p. 19). Extensive research on implementing volunteers was conducted through interviewing the program coordinators of other monitoring programs across the country, who were eager to share their experiences and to help others avoid problems they faced. The following suggestions were made:

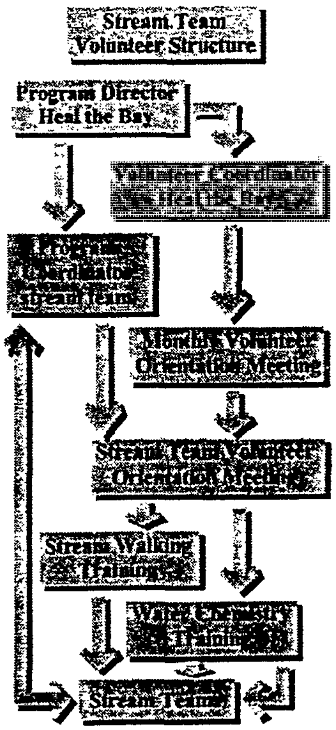

Figure 4-6: Volunteer flow

R0016904

- Develop a core of volunteers that are very dedicated to the project. This core will assist the program coordinator in many activities involved with the program.
- Create an open channel of two-way communication. Encourage input from volunteers and good suggestions should be incorporated into the program. Volunteers will get discouraged with any program that is not well organized and does not acknowledge their efforts and emphasize what the program is accomplishing.
- Feedback is critical. Any program should be flexible and have the ability to adapt to change. If the manual or procedures are hard to understand, volunteers can provide excellent feedback that can greatly improve the comprehension of the monitoring procedures. A workshop at Heal the Bay revealed that social interaction and meeting people with like interests was an important factor to becoming involved in the Stream Team Program.

Recruiting Volunteers

Heal the Bay is very experienced in recruiting volunteers and can develop and maintain a significant volunteer pool utilizing their existing channels. Several modifications to existing procedures that incorporate the Stream Team Program will ease the workload and save time within the organization. Currently Heal the Bay attends many events where they provide information and literature about the organization as well as opportunities to get involved on a voluntary basis. This literature should include the Stream Team Program and the volunteer opportunities associated with it. It is important that this literature provide some detail about the physical nature of the project as well as the time commitment necessary to participate.

Heal the Bay should include a section about Stream Team activities on their website. A section of their newsletters should be dedicated to activities and accomplishments of the Stream Team and to volunteer opportunities. Newsletters are an excellent way to recruit new volunteers to the Stream Team program and to share accomplishments of the Stream Team program.

Additional potential sources of volunteers:

- Local residents that live in or near the watershed
- Local high schools, colleges, and universities
- Local environmental groups like the California Native Plant Society, Audubon Society, Surfrider Foundation, Cal Trout, Ducks Unlimited, and the Sierra Club
- Local scuba diving clubs, fishing clubs, and equestrian groups

Training Volunteers

The key to collecting high quality data is good training (Rigney, Fischer, and Sawyer 1996, p. 19).
The volunteers need to feel confident in their abilities and the training they receive. A minimum of two hands-on training events is recommended. Volunteers should be accompanied in the field for at least the first two monitoring events by a Stream Team Captain, the Program Coordinator, or the field biologist.

Tips given by existing programs:

- Training events should have clear goals that are attainable. Do not overwhelm the volunteers with too much information during the first event (Rigney, Fischer, and Sawyer 1996, p. 20).
- Volunteers should receive one-on-one attention for all testing procedures. It is not enough to demonstrate the procedures to a large group. Let each volunteer use the equipment and master the procedures.
- Training should occur in the field.
- Volunteers should set their own limits and tell the Stream Team Captain or other person leading the training event if they feel personally uncomfortable or unsafe.
- Tell volunteers how their efforts are important, who is going to use the information they collect, and what they will gain from the Stream Team Program.

A field guide has been developed for the Stream Team Program. The field guide provides educational material about the natural processes of the Malibu Creek Watershed including the changes caused by extensive development in the region. The field guide was created to be inspirational, educational, and easily comprehended by the volunteer. The Stream Team Field Guide is intended to complement hands-on field training.

Keeping Volunteers Interested and Motivated

The Coyote Creek Riparian Station, located in Santa Clara County, invites speakers to address their volunteers from various environmental disciplines. This affords volunteers the opportunity to meet and learn from environmental professionals. Opportunities for volunteers to participate in field activities other than the Stream Team include the California Department of Fish and Game, California Department of Parks and Recreation, National Park Service, and the Resource Conservation District of the Santa Monica Mountains. These groups all have opportunities that could benefit these organizations as well as the volunteers.

Stream Team T-shirts should be designed and distributed to volunteers. Certificates of Training and awards acknowledging outstanding volunteers should be regularly distributed and signed by the Executive Director of Heal the Bay. An annual awards party for the Stream Team which includes a presentation by Heal the Bay's Executive Director about the progress of the program and how it is making a difference in the Malibu Creek Watershed is recommended. An outstanding Stream Team member should be selected every month and their image posted on the website.

Organizational Structure

All persons wishing to volunteer at Heal the Bay are asked to attend a volunteer orientation, run by Heal the Bay's Volunteer Coordinator. During this volunteer orientation, all the volunteer opportunities available at Heal the Bay are presented. Those who are interested and willing to invest the time required, should be referred to the Stream Team Program Coordinator.

The Program Coordinator is the liaison between Heal the Bay and the volunteers. This person is responsible for organizing the training and monitoring events, keeping volunteers informed about activities, and ensuring that volunteer input is heard and incorporated into the program. The volunteers and their commitment are what determine the difference between a program that fails and one that makes a difference. The Program Coordinator must meet the needs of the volunteers including praise, acknowledgment, rewards, parties, and social interactions, as well as letting those people know how important their efforts are and how much they are appreciated by Heal the Bay.

The Program Coordinator will:

- Maintain close contact with the pool of volunteers
- Schedule and over see training events
- Ensure that the information collected is distributed to stakeholders and decision-makers
- Ensure that volunteers are aware of their contribution to the overall monitoring effort and are aware how the information they collect is making a difference in the Malibu Creek Watershed
- Stay abreast of the latest developments, techniques, and methods for collecting and analyzing data, through contact with other monitoring efforts and continuing education.

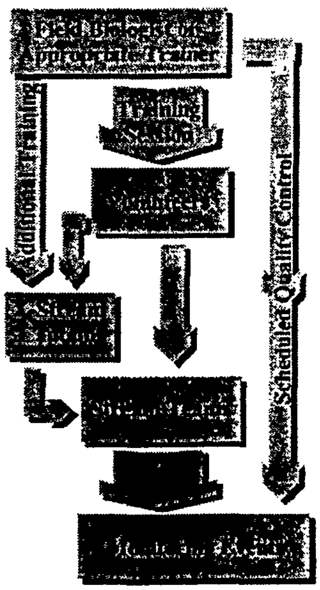

Figure 4-7: Training Flow

The Organization of the Stream Team

A field biologist or other appropriate trainer approved by the science and technical staff at Heal the Bay should train the Program Coordinator and the Stream Team Captains and be present at regularly scheduled quality assurance and quality control events (Figure 4-7). These events are designed to evaluate volunteers on their adherence to monitoring protocols and their familiarity with proper use of the equipment.

The Program Coordinator is ultimately responsible for the safety, training, and day-to-day management of the Stream Team Program. This person should be supported with technical and scientific expertise from within Heal the Bay or from outside consultants. The Program Coordinator should be well versed in all monitoring protocols, procedures, and safety issues, as this person will oversee the training of volunteers. The Program Coordinator must be approachable and accessible for volunteers to express their concerns and provide suggestions regarding the Stream Team.

A core of dedicated volunteers will serve as Stream Team Captains. Stream Team Captains serve as vital link between the Stream Team volunteers and the Program Coordinator. The Stream Team Captains will be organized into a group known as the X-Stream Team and will be identified as X-Stream Team Captains. This group should attend two training events and be accompanied into the field by the field biologist and Program Coordinator for the first three monitoring events. Captains should receive additional training about safety issues. Captains serve as technical advisors in the field and ensure the consistency of the data collected. Having a Captain on each team will ensure that the program is safer, that monitoring protocols are being followed, and the quality of the data is good. Captains will have the responsibility of making sure the equipment

R0016907

is treated appropriately, and returned to the Program Coordinator following the monitoring event. An X-Stream Team Captain should be assigned to every team. X-Stream Team Captains must ensure that volunteers are not placed into situations that are unsafe and should brief their team before every event about safety issues. Captains must be reliable, approachable, and able to communicate with their team.

Stream Team Volunteers should be accompanied by an X-Stream Team Captain at every monitoring event. X-Stream Team Captains and Stream Team Volunteers should be periodically checked and evaluated on their familiarity with the equipment, and information collection procedures.

How Data Can Be Used

The data collected should be very useful to local government agencies and organizations, including Heal the Bay, the Regional Water Quality Control Board, California Department of Fish and Game, California Department of Parks and Recreation, the National Park Service, the Resource Conservation District of the Santa Monica Mountains, and other stakeholder agencies working to protect the natural environment. These groups are very interested in using the collected data to track trends in water quality, and in assisting local planning agencies to develop future water quality protection goals and land use management strategies. This data will also be uploaded to a Regional Data Base maintained by the Regional Water Quality Control Board.

Heal the Bay will use the information gathered during the Stream Walking in Phase 1 to create a map of potential restoration sites, discharge points and outfalls, sites that need clean up activities, and potential barriers to fish passage. This mapped information can assist local planning agencies and other concerned organizations in developing future watershed protection goals and restoration strategies.

Monitoring Activities

The following is a more detailed account of the various monitoring activities

Stream Walking

Stream Walking is the starting point for monitoring in the Malibu Creek Watershed. Stream Walking is an active task that requires the volunteer to get down into the riparian corridors and explore with an acute attention to visual details. The goal of Stream Walking is to provide an overall impression of the stream reaches within the watershed as well as identify key elements of concern. Stream Walk teams will be comprised of an X-Stream Team Captain and two Stream Team Volunteers.

What to Monitor

The collection of the following information should provide Heal the Bay with an overall view of the Malibu Creek Watershed. Analysis of the data should help Heal the Bay chart a course of action geared at improving the ecological function and water quality within the watershed. Heal the Bay should distribute this information to the many agencies with responsibility over the area so that they can make informed planning decisions and take necessary corrective actions.

Volunteers are asked to record information about each of these physical parameters:

1. Discharge Points and Outfalls
2. Unstable Bank Conditions
3. Artificial Streambank Modifications
4. Impacting Land Uses
5. Large Patches of Exotic and/or Invasive Vegetation
6. Possible Barriers to Fish Passage
7. Dump Sites

1. Discharge Points and Outfalls
Discharge points and outfalls are pipes and culverts that carry storm water runoff into a stream at a single point (Figure 4-8). This may cause water quality and stream morphology to be impacted, especially at the point of discharge into the creek. Not all discharges are legal, and information regarding the current location of all outfalls to the creeks is limited. This information will help Heal the Bay update available mapped information.

Figure 4-8: Storm drain discharge point

2. Unstable Bank Conditions
Unstable bank conditions are a common problem along local streams, particularly ones that are subject to upstream development. Banks that are eroding or collapsing into the stream do not have stable soil for vegetation to establish (Figure 4-9). Eroding banks contribute sediments that can impact the habitat of steelhead trout and macroinvertebrates, and collapsing banks can block stream flows, causing flooding and damage to nearby property.

Figure 4-9: Collapsing streambanks and vegetation.

3. Artificial Streambank Modifications
Artificial streambank modifications often are used in urbanized or developing watersheds to prevent flooding (Figure 4-10). This method of streambank stabilization and flood control eliminates the natural vegetation. Vegetation provides food and habitat for aquatic and land-based birds and wildlife, slows the flow of surface runoff, and balances the nutrient levels of streams. Alteration of streambanks is often necessary when private property backs up to stream and structures are built close to the stream.

[redacted]

edge. While artificial bank modification may solve the problem of one property owner, the results are a funneling of problems further downstream to the next property owner, and beyond.

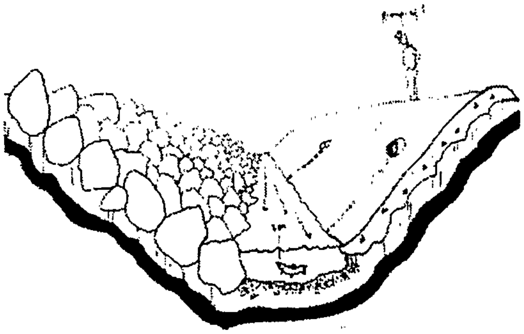

Figure 4-10: Artificially lined streambanks

4. Impacting Land Uses

Impacting land uses that are adjacent to streams can potentially affect the stream environment. The land uses of concern are those that have replaced riparian vegetation. For example, some places in the watershed have horses or other animals that graze right at the edge of the streambank (Figure 4-11). In other locations shopping centers or houses may be located right on the streambank edge. While these land uses may not have a discharge directly to the stream, runoff from these areas could have an effect on stream health.

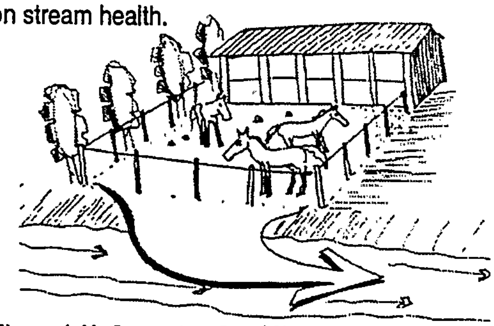

Figure 4-11: Impacting Land Use

5. Large Patches of Exotic and/or Invasive Vegetation

Large patches of exotic and/or invasive vegetation are non-native plants introduced to the Malibu Creek Watershed from other parts of the country or from other regions of the world. Many of these plants are well adapted to local climate and soil conditions; some are aggressive and may out-compete and displace native vegetation (Figure 4-12). Problems arise when these plants do not provide the food and habitat required by the native species of birds and wildlife.

Figure 4-12: Identifying patches of invasive vegetation.

6. Possible Barriers to Fish Passage

Possible barriers to fish passage potentially affect the passage of steelhead trout and other fish to protective spawning ground within the upper watershed (Figure 4-13). Currently, the annual steelhead run is restricted to the lowest 2.5-mile stretch of Malibu Creek, below Rindge Dam. Healthy fish habitat is usually productive habitat for many other aquatic species.

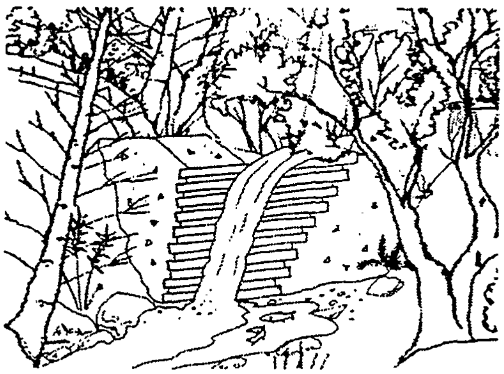

Figure 4-13: Constructed check dams can pose obstacles to fish migration.

7. Illegal Dump Sites

Illegal dumpsites exist partially because dumping is cheaper than legal disposal of waste. Frequently dumped wastes include hazardous chemicals, or large items like appliances (Figure 4-14). The problem is compounded when certain areas become recognized as places to dispose of waste. Areas in and around streams are frequently used as dump sites because they are off the beaten track, lessening the likelihood of the perpetrators being caught in the act.

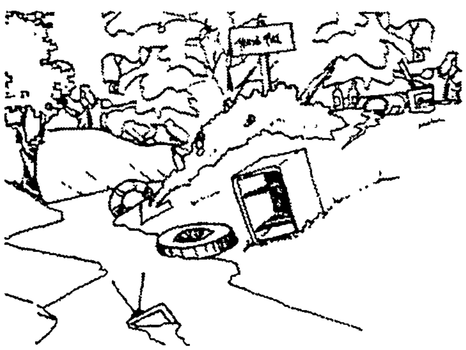

Figure 4-14: Illegal dump sites

When any of the seven listed parameters is identified, a Global Positioning Unit (GPS) will be used to recor its precise location. The location will be added to GIS database that is owned by Heal the Bay. This information will be analyzed by Heal the Bay an suggestions will be made to correct the problem identified during the Stream Walk. Maps that identify the locations of these items along the streams an creeks throughout the watershed should b distributed to interested agencies. By summarizing the information collected during the Stream Walk int a GIS, the data becomes usable by a wide range groups and agencies.

Quality Control and Quality Assurance

The Program Coordinator and a field biologist should provide training to the X-Stream Team Captains an to Stream Team Volunteers. X-Stream Tea Captains should receive two intensive field trainings by the Program Coordinator and a field biologis Captains should be accompanied in the field on th first three monitoring events. Stream Team Volunteers should also attend two training event with either the Program Coordinator or a field biologis All teams should have an X-Stream Team Captain plus two volunteers. All volunteers should be able t demonstrate the ability to follow monitoring protocol and proficiency with using the equipment provided in the field kit. Each team should be recertified onc every six months on their proficiency with dat collection methods and their ability to use the equipment. The field biologist and the Prograr Coordinator should be present during recertificatior

Water Chemistry Testing

If the overall goal of the monitoring program is to improve water quality, then Water Chemistry Testing provides the springboard of data from which further action can be taken. Specifically, the objectives include:

- To establish current baseline conditions within the various subwatersheds of the Malibu Creek Watershed.
- To determine how much each subwatershed contributes to poor downstream water quality.
- To explore the ability of streams to support native plants, and aquatic wildlife such as steelhead trout.

Water quality that is good for aquatic life is often good for humans as well. The overall goal of water chemical testing is to ultimately improve water quality throughout the watershed.

What to Monitor

The specific parameters to be monitored are selected based on issues cf concern and the analysis conducted of the Malibu Creek Watershed. Detecting the presence of pollutants and their potential sources should lead to actions that improve the water quality throughout the Malibu Creek Watershed. Each test is to be conducted twice. If the second result does not closely coincide with the first result, a third test must be performed. Double-checking results in this way will ensure higher quality data.

The following parameters will be measured for the Malibu Creek Watershed Stream Team Pilot Project:

Physical Parameters

1. Site Conditions (weather conditions, debris, and stream properties like color and odor)
2. Stream Flow
3. Air Temperature
4. Water Temperature

Chemical Parameters

5. Dissolved Oxygen
6. pH
7. Turbidity
8. Conductivity
9. Phosphorous
10. Nitrate-Nitrogen
11. Ammonia-Nitrogen

For purposes of the program, Site Conditions are visual observations that do not require quantitative measurements, but do require a general agreement on observation conclusions. Items three through eight are either measured chemically or with meters, and require patience and acute attention to detail. Water Chemistry Teams will collect water samples for items nine through eleven, but will not perform the actual tests. Measuring phosphorous, nitrogen, and ammonia involve complicated procedures. To ensure high quality information, these measurements should be performed by Heal the Bay's Program Coordinator or a field biologist.

1. Site Conditions

The site conditions of the monitoring location will aid Heal the Bay in analysis of the data. These parameters are generally brief, but careful observations should be noted on the "Site Conditions" field sheets. Included among these are weather conditions, presence of debris, and properties of the stream, like presence of algae, water color, appearance, and odor. Observations can be noted at any time during the monitoring event.

2. Stream Flow

Stream flow is the volume of water that moves past a fixed point in a specific interval of time. The amount of water (volume) and how fast it is traveling (velocity) determines the flow of a stream (Figure 4-15).

Stream flow is an important indicator of water quality. It affects the available oxygen level in water that fish and other aquatic wildlife depends on to live. Generally, streams with higher flows have more oxygen available for aquatic wildlife. Stream flow also controls the amount of sediment that is transported in a stream. Streams with higher velocities and larger flows transport greater amounts of sediments than streams with lower flows. In addition, stream flow determines how pollution is transported downstream, and influences the ability of a stream to dilute pollution.

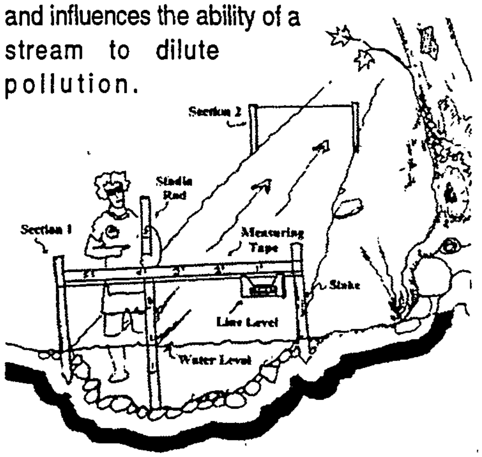

Figure 4-15: Measuring Stream Flow.

Large, swift rivers have a greater ability to dilute and degrade runoff pollutants, unlike smaller stream

3. Air Temperature

Air temperature can influence water temperatur Air temperature measurement should be taken the beginning and end of the monitoring event.

4. Water Temperature

Temperature of the water directly affects biological and chemical processes. Some fish species pref colder waters than other species. Macroinvertebrate will move in the stream in order to find their optimal temperature. Water temperature should be take twice, once at the beginning of the monitoring even, and once at the end.

5. Dissolved Oxygen (DO)

Aquatic organisms rely on the presence of oxygen in streams. Water temperature and altitude, time day, and seasons can all affect the amount dissolved oxygen. Oxygen is both produced and consumed in a stream. Because of constant churning, running water, especially in riffles, dissolves more oxygen

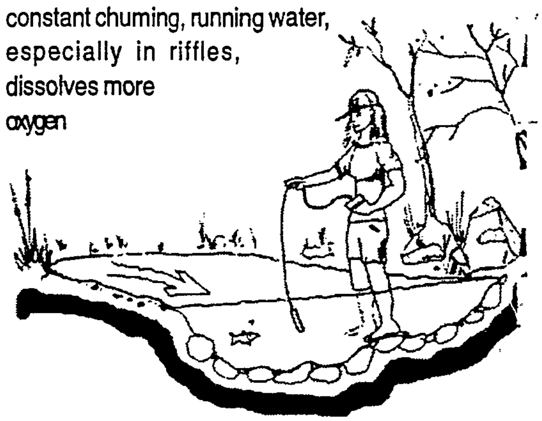

Figure 4-16: Measuring Dissolved Oxygen

R0016913

than the still water often found in a lake or stream pool (Figure 4-16) (US EPA 841-B-97-003 1997, p. 139). The presence of aquatic plants also affects dissolved oxygen concentrations. Green plants release oxygen underwater during photosynthesis. Maximum amounts of DO are produced with the energy of the late afternoon sun. By early morning, the same plants may have taken up the oxygen, making levels of DO lowest at this time. Because DO is lowest in the morning hours, it is one of the first tests performed at the sampling station.

6. pH

pH is a measure of how acidic or alkaline the water is at the time of testing. The pH of a stream affects the ability of plants and wildlife to function and live. pH is measured on a scale from 1.0 to 14.0. Neutral pH is 7.0. Acidic pH is less than 7.0, and alkaline is greater than 7.0. A wide variety of aquatic animals prefer a range of 6.5-8.0 pH. A pH meter measures the electric potential of water in millivolts or pH units.

7. Turbidity

Turbidity is a measure of water clarity. Insoluble solids or suspended particles such as clay, silt, sand, algae, plankton and other substances affect the clarity of the water. High levels of turbidity affect the ability of steelhead trout and other aquatic organisms to survive. Water temperature is increased when suspended particles absorb more heat. Also, when turbidity is high, photosynthesis is reduced, due to the decrease in the amount of light traveling through the water (Figure 4-17). Sources of turbidity include soil erosion, waste discharge, urban runoff, eroding streambanks, large numbers of bottom feeders that stir up sediments, and excessive algal growth.

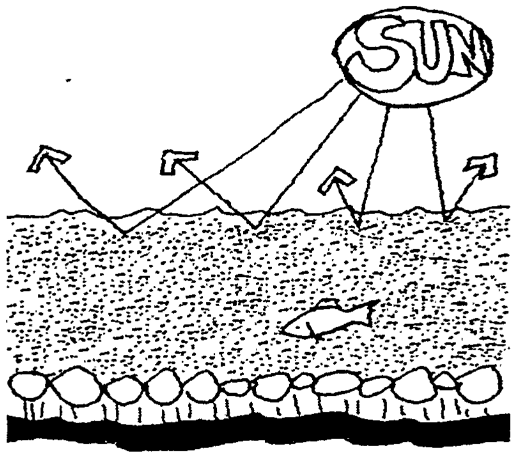

Figure 4-17: Dissolved sediments blocking sunlight

8. Conductivity (Total Dissolved Solids)

Conductivity is a measure of the ability of water to pass an electrical current. The concentration of dissolved solids or the conductivity of streams is directly affected by the substrate or stream bottom material. Conductivity indirectly indicates the presence of inorganically dissolved solids such as chloride, nitrate, sulfate, phosphate, sodium, magnesium, calcium, iron, and aluminum (Murdoch, Cheo, and O'Laughin. 1996, p. 181). These substances and seawater enhance the ability of water to conduct electricity. Failing septic tanks, sewage spills, and agricultural runoff containing phosphates and nitrates are indicated by high conductivity measurements. In general, conductivity is higher in areas with clay soils because these soils tend to dissolve in water. Conversely, organic substances like oil, alcohol, and grease are poor conductors of electricity and will yield low conductivity measurements. Excessive amounts of dissolved solids leads to poor tasting drinking water with laxative effects (Murdoch, Cheo, and O'Laughin. 1996, p. 181).

9, 10, & 11. Phosphorus, Nitrate-Nitrogen & Ammonia-Nitrogen

Phosphorus and nitrogen are both nutrients occurring in streams, and are essential for plants and animals in an aquatic ecosystem. These nutrients originate from both naturally occurring sources and from areas of human development. Naturally occurring sources include soils, eroding rocks, and terrestrial animal and plant waste washing into the streams. Problems occur when large amounts of phosphorous and nitrogen is introduced into the stream ecosystem, results in excessive algal growth depleting the available oxygen in the stream that fish and other aquatic organisms depend upon. Sources of nutrients from human development include wastewater treatment plants, runoff from fertilized agricultural lands, lawns, and golf courses, runoff from grazing animals, commercial cleaning activities, and other similar sources.

Phosphorous is a useful indicator of potential problems associated with excessive plant growth. High amounts of dissolved phosphorous may indicate a pollution source such as chemical fertilizers or septic system leachate. Insoluble phosphorous can be due to excessive erosion, animal waste, or sewage (Murdoch, Cheo, and O'Laughin 1996, p. 180). Two field tests are used to measure the nitrogen content in streams: nitrate-nitrogen (N_2 + NO_3), and ammonia-nitrogen. Although nitrogen (N_2) is the gas that composes 80% of the air we breathe, most plants cannot use nitrogen in this form. N_2 is converted into nitrates, a form that can be used by plants to build proteins. It is this form of nitrogen that the Stream Team will measure. In streams with low levels of dissolved oxygen and elevated levels of nitrates, nitrogen will be found in the form of ammonia. Ammonia is extremely toxic to aquatic life, as compared to nitrates. Sources of nitrogen include wastewater treatment plants, runoff from animal manure storage areas, runoff from fertilized lawns and croplands, failing or improperly maintained septic systems, and industrial discharges containing corrosion inhibitors.

Water Chemistry Monitoring Locations

The long-term goal of the program is to have monitoring locations in each of the seven subwatersheds within the larger Malibu Creek Watershed. Monitoring sites will be at a minimum of two fixed locations in each subwatershed of concern. These two sites will be upstream and downstream of pre-determined land use impacts. The fixed monitoring location above the pre-determined land use will be in a relatively pristine section of the stream. The second fixed monitoring site will be located at the base of the subwatershed, where a stream leaves that particular subwatershed and enters another one.

Comparing the results from these sampling sites should help Heal the Bay determine the effects of land uses and impermeable area on water quality, and to what extent a given subwatershed is contributing to downstream pollution. Based on the results of the work, Heal the Bay and other agencies should be able to determine which subwatersheds require immediate attention and future action.

Because each subwatershed has its own unique natural features and land uses, the impacts to water quality differ between them. For example, the impacts to water quality may be more obvious in the highly developed Westlake and Agoura Hills subwatersheds than in the largely rural Malibou Lake and Cold Creek subwatersheds.

Water Quality Monitoring will occur once a month at each monitoring station. To accurately sample for trends over time, monitoring must take place at the same location, and at the same time of day. This is because concentrations of the substances being tested for vary according to season, time of day, and temperature. A schedule of Water Chemistry Testing events, including the dates and times will be created.

Quality Control and Quality Assurance

Heal the Bay is part of the Southern California Volunteer Monitoring Quality Assurance Project Plan that details testing methods and accuracy requirements of the Water Chemistry Procedures. This section provides recommendations to Heal the Bay that will improve data quality and the time it takes to conduct test procedures.

1. All water chemistry testing volunteers should attend two training events with each volunteer having the opportunity to conduct the tests and use the equipment.
2. X-Stream Team Captains should be accompanied into the field by the field biologist or the Program Coordinator for the first three monitoring events.
3. All tests should be performed twice and if the data does not agree, a third time.
4. Recertification should occur every six months at which time volunteers must demonstrate their proficiency in using the equipment, following the protocols, and accurately collecting analyzing the water samples.
5. Side by side sampling should occur at the same time to ensure the accuracy of the equipment and reagents in the field kit.
6. A strict schedule for replacing reagents in the field kit should be maintained, and the lower expiration limits on those reagents should be used.
5. One person should be in charge of maintaining equipment and ensuring that the equipment is properly cleaned, calibrated, and maintained.
6. The Program Coordinator should be well versed in calibration procedures and life expectancy of all field equipment. A replacement schedule and funding for new equipment should be in place.

Water Chemistry Recommendations:
The following recommendations regard the field kit.

1. Heal the Bay should purchase the testing modules for the field kit packaged individually and not in the current package case format. By modularizing the purchases it will be easier to customize or modify this kit in the future as better testing procedures and methods become available.
2. By modularizing the field chemistry kit, the kit can be assembled in a backpack unit that will be easier for volunteers to

transport.

3. Specialized cases for sensitive equipment like GPS units, electronic water chemistry equipment, and digital cameras can be integrated into a single Stream Team field kit which will be better protected from unforeseen accidents.
4. Volunteers will be more productive and the data collected will be of more value if the field kits incorporate dissolved oxygen meters and turbidity meters instead of the titration method currently being utilized.
5. The nitrate test, nitrogen as ammonia test and phosphate test may not be accurate enough to make the data collected useful in analysis. Water samples should be collected by volunteers, labeled and put into a full ice chest. The sample should be transported to the central meeting place and analyzed using a colorimeter by the Program Coordinator or field biologist. By using a central meeting place, the samples can be analyzed in a more timely manner and only one colorimeter need be purchased.
6. Training and monitoring events should be scheduled far in advance at regular intervals, e.g. the first Saturday of every month.
7. Volunteers should gather at a central meeting place prior to each event and at the end of each event. This can be used to pass out and collect equipment, to ensure that all volunteers are safe, and to perform the nutrient testing.

Phase 2

Phase 2, if implemented, would provide supplemental data regarding the effects of development and urbanization on stream health. This phase would include macroinvertebrate sampling and stream reach surveying. Biological monitoring could be integrated into the Stream Team Program, or be a supplement program conducted by an outside agency. If an outside group samples for macroinvertebrates, they should choose sites detailed in section 5 of this document. This will enhance the monitoring program and ensure the data collected is most useful.

The Stream Reach Survey should be implemented in Phase 2 and should build on the Stream Walk information. This tiered approach allows Heal the Bay time to develop a volunteer pool and develop a well-organized program based on field experience. This approach should allow Heal the Bay to better evaluate if volunteers are able to accurately collect this more complex data.

Macroinvertebrate Sampling

Biological monitoring is a monitoring tool for testing water quality and assessing the health of the watershed. Biological testing depicts water quality over a longer period of time, since the biological components of a stream live in direct contact with water and are affected by the quality of that water. These organisms are the continuous indicators of water quality. An integrated approach using chemical testing, biological testing, and assessing the physical components of a stream, can result in a more comprehensive evaluation of stream and watershed health.

Why Monitoring for Macroinvertebrates is Important

A common way that volunteers can test the biological health of a stream is by monitoring for aquatic macroinvertebrates. Since riparian macroinvertebrates are largely immobile and spend part or all of their life within water, they are continuous indicators of water quality. Some macroinvertebrates are highly pollution-sensitive while others are more pollution-tolerant. They can react to changes in water temperature, dissolved oxygen levels, chemical and organic pollution, and sedimentation. If a monitoring sample shows a great number of pollution-tolerant macroinvertebrates and very few, if any, of the pollution-sensitive macroinvertebrates, it can be an indication that water quality is poor.

What are Macroinvertebrates?

Macroinvertebrates are organisms that have no backbone and can be seen with the unaided eye. These can be aquatic clams, snails, worms, and insects. Many of the macroinvertebrates live the majority of their life within water. For many this is their aquatic stage. They include organisms such as mayflies, dragonflies, and caddisflies (Figure 4-18). Once they enter the adult stage they develop wings and are able to fly, mate, and deposit eggs for another generation to form and develop. The aquatic stage can last a few weeks or up to a few years, depending upon the organism. Other types of macroinvertebrates, such as aquatic worms and snails, live all of their life within water.

The macroinvertebrates to be monitored are benthic macroinvertebrates. These are macroinvertebrates that live on the bottoms of streams and watercourses. Benthic macroinvertebrates can be divided into functional feeding groups. These groups are collectors, shredders, scrapers, and predators. Collectors feed on tiny pieces of organic material, and can be further divided into collector-filterers and collector-gathers. Shredders feed on coarser pieces of organic material such as leaves, algae, and twigs. Shredders break down these larger pieces which other macroinvertebrates can then feed on. Scrapers feed on algae attached to stones and other surfaces found on the stream bottom. Predators directly feed on other aquatic organisms found within the aquatic environment. Each of these functional feeding groups plays a vital role in breaking up organic material and contributing food and nutrients along the food chain.

Selecting Monitoring Sites

Two types of monitoring sites should be chosen in the watershed. These two sites are reference sites and monitoring sites. A reference site is needed to compare other monitoring sites against. It is a site that is minimally impacted by human use and similar in characteristics to the monitoring site. Since the reference site is minimally impacted, it should show what a healthy stream in the watershed looks like, and the mixture and diversity of macroinvertebrates that can be expected. Monitoring sites are picked because of their strategic location and their ability to indicate what is happening in various parts of the watershed.

Monitoring for macroinvertebrates normally takes place in areas of the stream that have riffles. Riffles are areas where water flows rapidly over rocks in a shallower part of the stream. This is a good area to monitor because macroinvertebrates find this

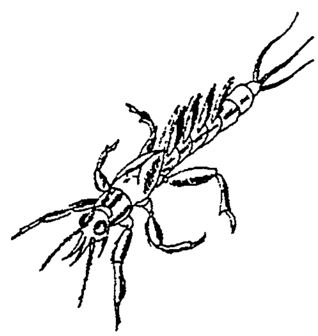

Figure 4-18: Sample macroinvertebrate: a common burrower.

R0016918

environment a favorable place to live. The fast moving water captures oxygen from the air, increasing the dissolved oxygen content of the water. The large stones and rocks create niches where macroinvertebrates attach their homes or find shelter from predators in the rapidly moving stream. This environment also creates nooks and crannies where organic material and other food can be trapped. The riffle part of a stream is where a great degree of diversity in the types of macroinvertebrates is found.

Most organisms have been categorized into the following six functional feeding groups based on their method of acquiring food; shredders (SH), predators (P), scrapers (SC), filtering collectors (FC), collector gathers (CG) and piercers (PI). The composition of functional feeding groups will change depending on the type and degree of disturbance to the stream. For example, absence of riparian canopy will allow more sunlight to enter the stream producing more periphyton and more scrapers, which eat periphyton. Macroinvertebrate abundance varies with the type of pollution affecting the stream.

Creating a Monitoring Protocol

Currently the California Department of Fish and Game (CDFG) is revising their protocol to be more user-friendly and geared towards volunteer monitoring programs. CDFG will be publishing a key that will be helpful for monitoring for macroinvertebrates in the Malibu Creek Watershed. Heal the Bay should use CDFG's protocols and the macroinvertebrate key for Phase 2 of the Stream Team Program.

Stream Reach Surveying

Stream reach surveying measures the physical forms and characteristics of a particular section of a stream and provides a documented record that can be compared over time. The idea behind the stream reach survey is to take a representative sample of an entire stream or creek, such as 15% of the total length, and apply the findings to the whole stream. The stream reach survey collects specific information about the channel shape, size, the meander pattern, bankfull width and depth as well as measuring average depth of pools, and characterizing the instream habitat, substrate, and overhead cover. This procedure collects detailed information that can be checked year after year to determine if the stream has been changed due to factors upstream. This procedure will allow the monitoring program to sample the effects of sedimentation on the watershed, whereas the other procedures will only provide limited data regarding sediments.

Stream reach survey design should include collecting data as teams move upstream to the next survey site. It is a logical extension of the Stream Walk procedures used in Phase 1 and provides more detailed quantifiable information about the stream. This method is used by the California Department of Fish and Game and the Forest service, making the information collected extremely useful for analysis and planning.

Why Stream Reach Surveying is Important

Using stream reach survey to chart "change over time," would allow Heal the Bay to discern the effects of development upon the physical character of a stream. This procedure further allows various agencies and users of the information collected to accurately characterize the stream using Rosgen's stream classification technique. The Rosgen system is considered very valuable in restoration work.

The objectives include:

- To accurately map the physical properties of a stream
- To establish current baseline conditions within the various subwatersheds of the Malibu Creek Watershed.
- To compare areas upstream and downstream of urbanization to help determine impacts associated with urbanization.

What to Expect When Stream Reach Surveying

Stream Reach Surveying will occur monthly following the completion of the Phase 1, Stream Walk. Teams consist of an X-Stream Team Captain and three volunteers.

The specific protocols for the stream reach survey should fit the information needs of stakeholders in the watershed at the time Phase 2 is ready to begin. A consultation with Fish and Game will determine the information needs and appropriate methods to collect information. Many volunteer programs are using the Stream Reach Survey to collect information. Care must be taken by the volunteers because many of the field procedures are complex and may be difficult.

This Monitoring Program section details the monitoring program and recommended monitoring protocols for the Stream Team. Special emphasis has been placed on identifying and avoiding potential pitfalls, maintaining high levels of volunteer enthusiasm and participation, and ease of procedures. The Stream Team Program will identify problem areas and provide good quality baseline data about the seven subwatersheds within the Malibu Creek Watershed. The information collected will be in a form that is usable by other groups and agencies charged with protecting the environmental resources of the Malibu Creek Watershed. The program has been designed to educate volunteers about the watershed and provide information that will help identify problems and keep decision-makers better informed. The flexibility of the program, and the two-phased approach, should help Heal the Bay to achieve the monitoring goals and in the long-term improve water quality and enhance the ecological functioning of the watershed.

Section 5

ANALYSIS, SITE SELECTION, and MONITORING PROGRAM

Models are used to better understand where and how key issues function within the watershed. The models created for this project analyzed each subwatershed in terms of land uses, surface water features, and water quality issues. To better understand water quality throughout the watershed, the key components are modeled. These maps predict probable source areas of urban runoff associated with impervious surfaces, nutrient loading, and sedimentation. Areas of recreational resources are mapped to predict areas most likely to receive recreational use. Finally, using these predictive models and criteria, the best monitoring sites are located, and recommendations are made concerning existing and future monitoring sites.

ANALYSIS AND MODELING

Water quality within the Malibu Creek Watershed is a major contributing factor to the overall ecological functioning of the area and the biggest threat to the health of recreational users. Malibu Creek ranked second on a study listing water bodies contributing contaminants to Santa Monica Bay (Santa Monica Bay Restoration Project 1994, pp. 13-14). In 1992, a survey of 5,800 residents within the watershed was conducted by the City of Malibu's General Plan Task Force. Of 406 respondents, 95% felt that the prevention of pollutants to the creeks, lagoon, and ocean should be of the highest priority (Schmidt 1992, p. A3). Achieving water quality that is capable of sustaining a healthy population of aquatic wildlife that does not pose any human health risks is a highly desired goal.

Subwatersheds

To better understand the watershed, and to consider the potential effects of impervious surfaces on each of the major tributaries that drain the watershed, the watershed has been broken down into seven smaller subwatersheds. These seven subwatersheds are Agoura, Cold Creek, Hidden Valley, Las Virgenes, Malibu Creek, Malibou Lake, and Westlake.

Hidden Valley Subwatershed

The Hidden Valley subwatershed is located at the eastern end of the Malibu Creek Watershed in a large fertile valley. Potrero Creek is the major tributary draining this area. Prior to development, this area likely served as a floodplain for Potrero Creek and therefore has collected large deposits of alluvial materials that make up the fertile soils. Hidden Valley subwatershed is 16.9 square miles and is predominantly rural in nature, with an estimated population of 1,200 people. With the exception of vacant land, agriculture is the dominant land use, comprising 1.87 square miles.

Lake Sherwood is located at the outlet, or base, of this subwatershed and was constructed in 1904 to serve as a source of water for the ranches in the area. The lake can store 2,600 acre-feet of water and has an estimated surface area of 163 acres (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 55). The staff of Lake Sherwood Ranch, which manages the lake, uses copper sulfate to minimize algae growth. Since the mid-1980s, wastewater treatment has occurred through connection to a sewer system, while the potable water supply continues to come from well water (Hidden Valley Municipal Water District 1998). There are numerous ranches in the area with much of the area being used for raising livestock, agriculture, and pastures for horses (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 58). Water samples taken by the NRCS indicate that above acceptable levels of phosphate are present in the receiving waters that drain this subwatershed.

Westlake Subwatershed

Westlake subwatershed is 13.0 square miles in area. Being predominantly urban, the highest land use is high density single family residential, comprising approximately 1.96 square miles. Two constructed lakes and one reservoir are contained within this subwatershed. Westlake Lake is 18 feet deep near the dam, and can store approximately 791 acre-feet of water with a surface area of 95 acres (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 57). Westlake Lake empties into Triunfo Creek and is required to discharge water from May 1 to September 1. Las Virgenes Reservoir (Westlake Reservoir) drains approximately 0.9 square miles with a storage capacity of 10,000 acre-feet or 3.3 billion gallons, and is used by the Las Virgenes Municipal Water District to store imported water (LVMWD 1994, p. 30). Lake Eleanor drains 1.2 square miles and has a surface area of 9 acres that stores approximately 104 acre-feet of water. The channel between Lake Sherwood and Westlake Lake is almost completely altered with either riprap or concrete for flood control purposes (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 57). The population for the city of Westlake Village is estimated at 7,640 residents, which is predicted to grow to 12,200 by the year 2015 (Bauer Environmental Services March 1996, p. 5).

Agoura Subwatershed

Agoura subwatershed contains 180 acres of golf courses and a large single family residential population. Lake Lindero is located within this subwatershed, and drains 5 square miles with the capacity to store 90 acre-feet of water with a surface area of 14 acres (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 59). The total area is 21.6 square miles, with high-density single family residential being the largest land use, totaling 3.4 square miles excepting vacant land. The major tributary is Medea Creek, which is fed by Lindero, Palo Commado, and Cheseboro Canyons. The majority of the 21,000-person population, according to 1993 estimates, resides in the city of Agoura Hills (Bauer Environmental Services March 1996, p. 5). The city of Agoura Hills is expected to increase in population to 27,330 based on SCAG projections for the year 2015. Sampling and modeling conducted in the Agoura subwatershed in 1993 found both high salt levels and high concentrations of coliform. Confined livestock near the Palo Commado area are thought to be a problem regarding water quality.

Land Use of the Watershed

Universal Transverse Mercator Projection
North American Datum, 1927

Malibu Creek Watershed: A Framework for Monitoring, Enhancement and Action

606 Studio **California State Polytechnic University, Pomona** **August 1998**

Las Virgenes Subwatershed

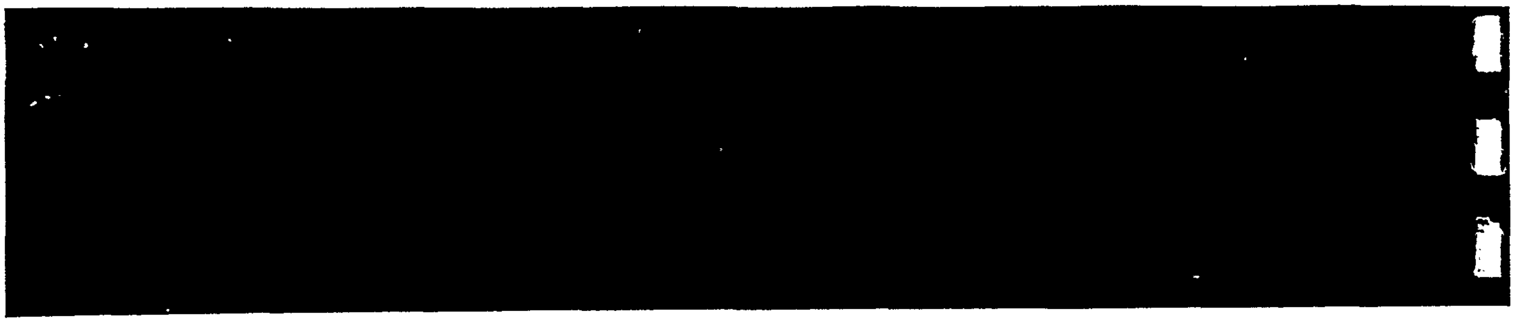
Las Virgenes subwatershed is 24.3 square miles in area with the largest land use being high density single family residential (0.8 sq. mi.). 300 of the 3,766 households in Calabasas are on septic systems, the majority of which are in Stokes Canyon towards the base of the subwatershed. This area has had high nitrogen, phosphorous, and fecal coliform concentrations that may indicate malfunctioning septic systems (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 59). Las Virgenes Creek is the major tributary that drains this area. The remainder of the subwatershed is largely rural in character. This subwatershed also has orchards, pastureland, and field crops but predominantly consists of open space. This subwatershed is not yet heavily developed, and may be undergoing development pressures due to the large amount of undeveloped private land. During May and September, sampling events conducted by NRCS, upper Las Virgenes Creek showed high concentrations of phosphates above the acceptable level and were considered high enough to impact downstream water (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 62).

Malibou Lake Subwatershed

Malibou Lake subwatershed is 13.2 square miles. Rural residential comprises 0.677 square miles and is the dominant land use, with some homes located along creeks and surrounding the lake. This subwatershed receives water from the Agoura and Westlake subwatersheds. Malibou Lake is fed by Triunfo Creek to the west and Medea Creek from the north. The lake drains 64 square miles and has a surface area of 55 acres with a storage capacity of 500 acre-feet. This subwatershed has an estimated 2,978 households with 625 on private septic systems (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 63). Previous water chemistry sampling done by the United States Geological Survey (USGS), from 1985-1987, and those done in 1993 by the NRCS demonstrate high levels of phosphorous in Triunfo Creek and high phosphorous levels and fecal coliform at the base of Medea Creek and in Malibou Lake (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 64). Both Triunfo Creek and Malibou Lake were designated as impaired at least some of the time by the 1994 California State Water Quality Assessment. Malibou Lake opens the outlet valves to the dam annually to expel sediments as well as periodically dredging to remove sediments. The lake is also treated with copper sulfate to minimize algae growth (Trim 1994, p. 36).

Cold Creek Subwatershed

Cold Creek subwatershed, at 8.2 square miles, is predominantly open space with the exception of rural residential land uses on private septic systems comprising 0.8 square miles. In addition, this subwatershed has 34 acres of confined animal units concentrated towards the lower part of the subwatershed (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 65). Sampling conducted by the USGS from 1982 to 1988, and one site survey by the NRCS in 1993, demonstrated consistently high levels of phosphorous averaging in excess of 5.6 mg/l which are high enough to impact downstream water quality (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 65).



Malibu Creek Subwatershed

Malibu Creek subwatershed is 12.8 square miles and comprised mostly of mountainous open space. Low density, single family residential comprises 0.2 square miles and is the predominant land use in this subwatershed. Malibu Creek is subject to receiving waters from the other six subwatersheds. Tapia is located in this subwatershed. Treated water has been discharged from this facility into the creek since 1961 and has altered the dynamics of both surface water quality and quantity. Malibu Creek was listed as having intermediate impairments in the 1994 California State Water Quality Assessment (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 66). Areas tested above Tapia were below the 10-mg/l threshold set by the Regional Water Quality Control Board (RWQCB) for concentrations of nitrates. Measurements taken below Tapia have been recorded in excess of 16 mg/l (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 48).

The Century Reservoir is located in the Malibu Creek subwatershed. This reservoir drains 68.1 square miles and has a surface area of seven acres that can store 70 acre-feet of water. Located within this subwatershed is the 102 foot tall Rindge Dam. This dam is completely full from sedimentation, serving as a testament to the highly erodible soils in the area. Where Malibu Creek empties into the lagoon as it passes through the City of Malibu, a small portion of mainly commercial property is evident. The wastewater at the base of the Malibu Creek subwatershed in the City of Malibu is handled by private septic systems. There is strong public opinion that these septic systems are a major contributing factor to the consistently poor water quality in the lagoon and at Surfrider Beach. Currently, UCLA is studying the lagoon with funding from the California Coastal Conservancy.

The RWQCB has established a list of designated beneficial uses for various water bodies in the Malibu Creek Watershed. The RWQCB has set measurable water quality objectives that ensure that these beneficial uses do not become impaired (USDA, NRCS Malibu Creek Watershed Natural Resources Plan 1995, p. 42). These lists can be obtained in the RWQCB's 1994 Basin Plan.

Impervious Surfaces

Mapping areas of impervious surfaces can be used as an effective tool to predict impacts of development within the watershed. There is a strong relationship between the percentage of impervious surface in a watershed and the quality of stream habitat and water quality. Mapping impervious areas can be useful as a planning tool to help assess and manage impacts development will have in the watershed.

Measuring the percent of impervious coverage is best done at the subwatershed level. Impacts associated with impervious surfaces are likely to occur in the tributary that drains these impervious surfaces. Headwater subwatersheds can be organized into three different categories, depending upon the percent of impervious coverage. These categories are sensitive, degrading, and non-supportive subwatersheds. The sensitive subwatershed has about 1% to 10% impervious cover (Schueler 1995, p. 42). Water quality and stream biodiversity is normally good to excellent, and stream channel stability is stable. The resource objective in the sensitive subwatershed is to preserve and protect biodiversity and channel stability. The next category is the degrading subwatershed, with 11% to

25% impervious cover. Water quality and stream biodiversity is fair to good. Stream channel stability is unstable and the resource objective is to maintain or restore the key elements of stream quality. The last category is the non-supporting subwatershed. This subwatershed has 26% to 100% impervious cover. Water quality is fair to poor, and stream biodiversity is poor. Stream channel stability is highly unstable. The resource objective within the non-supportive subwatershed is to minimize pollutant loads to protect downstream waters.

There are two methods of measuring the amount of impervious surfaces. These are mapped impermeability and effective impermeability. Mapped impermeability includes all impervious surfaces within a subwatershed. Effective impermeability includes only impervious surfaces that are directly connected to the storm water drainage system or to streams. Effective impervious surfaces does not include surfaces such as rooftops where runoff may flow onto landscaped areas and infiltrate into the soil (Figure 5-1). These surfaces have less of an impact upon the watershed. A large percentage of storm water runoff from these disconnected impervious areas flow onto landscaped areas and infiltrate into the soil before reaching the storm water drainage system. This is especially true during smaller storm events. Unlike disconnected impervious surfaces, nearly all runoff from directly connected impervious areas, such as roads and parking lots, flows directly into the storm water drainage system.

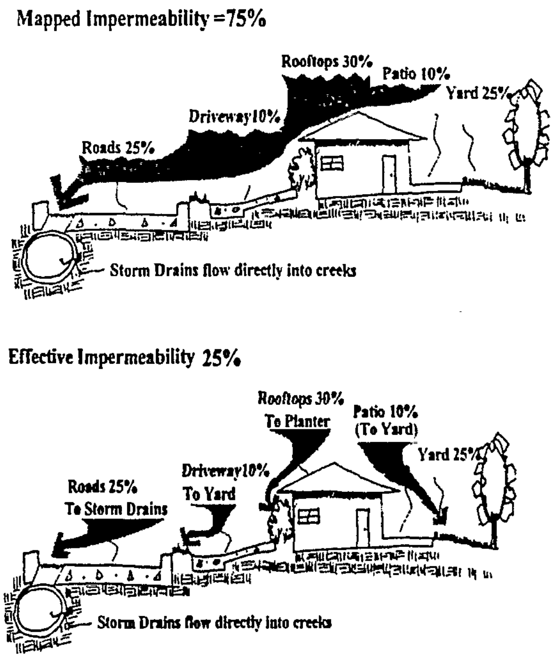


Figure 5-1: Mapped versus Effective Impermeability.

One method of mapping the effective impermeability of an area is by ground truthing or checking data out in the field. Due to the size of the watershed and the limited time of this study, ground truthing for this project was not feasible. The approach used by the Cal Poly team was to calculate the overall area of individual land uses that are known to have impervious surfaces in each subwatershed. These land use areas were then multiplied by an imperviousness factor to come up with the effective impermeability for that land use. The effective imperviousness factor represents the amount of runoff a particular land use generates. Effective impermeability gives a more accurate account of runoff than does mapped impermeability. Imperviousness factors used are from a study done for the cities of Los Angeles County by Heal the Bay (Urban Runoff: A Pollution Abatement Program 1992). Land use categories used in this analysis are based on the maps provided by Los Angeles County Department of Public Works. These maps were updated in ArcView v 3.0a using a digital orthographic aerial photograph taken in April and October 1997. The land use map was placed on top of and compared to the aerial photograph. Adjustments were made so that land use reflected the most current data.

The Impervious Surfaces map shows the effective impervious surface area for each of the seven subwatersheds in the Malibu Creek Watershed. Westlake subwatershed has the largest percentage of impervious surfaces with just over 23%. Agoura subwatershed is second with 18.4% impervious

Mapped Impervious Surfaces

Universal Transverse Mercator Projection
North American Datum, 1927

Malibu Creek Watershed: A Framework for Monitoring, Enhancement and Action

606 Studio **California State Polytechnic University, Pomona** **August 1998**

surfaces. These subwatersheds fit into the degrading category, and should have fair to good water quality and stream biodiversity. The objective is to maintain or restore the key elements of stream quality in degrading streams. Within these two subwatersheds, large segments of their tributaries are channelized with concrete or other materials. This suggests that subwatersheds that will potentially reach these percentages of impervious surface area are likely to become channelized and thereby transfer their problems downstream. Westlake subwatershed is dangerously close to reaching a non-supporting level with poor to fair water quality, poor biodiversity, and highly unstable streambanks.

Based upon percent of impervious surfaces, each subwatershed was placed into one of the three categories: sensitive, degrading, and non-supportive (Figure 5-2). The volunteer monitoring program will gather information that will serve as baseline data to further support and identify sensitive, degrading, and non-supportive subwatersheds. Gathering this data will also help to confirm and refine the impervious surface, water quality, and stream habitat relationship.

The Cold Creek, Hidden Valley, and Las Virgenes subwatersheds are all below 9% impervious surfaces. They are considered sensitive subwatersheds, with good to excellent water quality, biodiversity, and stable streambanks. The resource objective in the sensitive subwatershed is to protect and preserve biodiversity and channel stability. The Malibou Lake and Malibu Creek subwatersheds are also within the sensitive subwatershed category. These subwatersheds are not headwater subwatersheds and receive inputs from subwatersheds upstream. Malibou Lake receives water that passes through the Hidden Valley subwatershed into Westlake. The Malibu Creek subwatershed receives water from all of the subwatersheds; therefore the water quality, biodiversity, and stability of their streambanks are subject to upstream levels of impervious surfaces.

In order to preserve the Malibu Creek Watershed and the biodiversity that makes this watershed special, the ever-increasing amounts of impervious surfaces must be addressed. Continued development and build out of the watershed will cause further channelization of creeks and streams, degraded water quality, less abundant populations of fish and wildlife, and will alter the natural character that attracts millions of visitors and thousands of residents to this area.

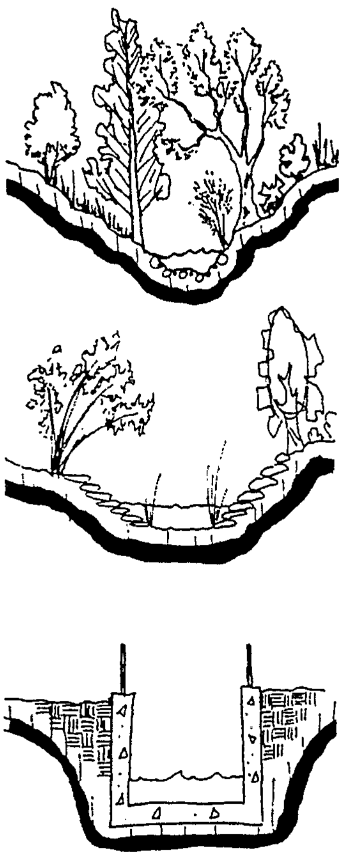

Figure 5-2: The conceptual sketch above shows the condition of riparian corridors in a: A) sensitive, B) degrading, and C) non-supporting, watersheds.

Probable Pollution Sources

This model examines three key issues: urban runoff, nutrient loading, and sedimentation, in terms of their water quality pollution potential. Probable pollution sources was derived from the various land uses. Each land use was weighted for its most likely type of pollutant. The map on the next page highlights potential pollution sources.

Urban Runoff Pollution Sources

The urban runoff pollution source model is based on the following land uses that were considered likely to contribute pollutants to receiving waters: Transportation, Retail/Commercial, Other Commercial, Multiple Family Residential, Mixed Transportation, Mixed Commercial and Industrial, Maintenance Yards, Institutional, Heavy Industry, High Density Single Family Residential, and General Office. All urban land uses have a 30% or greater imperviousness factor, and were considered heavily utilized by automobile traffic.

Areas Likely to Contribute Pollution

Universal Transverse Mercator Projection
North American Datum, 1927

Malibu Creek Watershed: A Framework for Monitoring, Enhancement and Action

606 Studio California State Polytechnic University, Pomona August 1998

Nutrient Sources

The following land uses were considered likely sources of nutrient loading: Nurseries and Vineyards, Golf Courses, Animal Husbandry, and Agriculture. Areas of known septic systems that were located within 300 foot from a water body were also included. Areas with high density septic use like Monte Nido, Cross Creek Plaza, the Malibu Civic Center, and Serra Retreat were considered probable sources due to the volume of wastewater treated and the cumulative effect of long-term treatment.

Erosion and Sedimentation Sources

A model was created to reveal probable sources of erosion and sedimentation. The criteria used to create this model are land uses that are considered likely to supply sediments to surface waters. Land uses such as, Under Construction, Nurseries and Vineyards, Animal Husbandry, and Agriculture were all considered for this model. The latest fire to occur in this watershed took place in 1996 and areas affected by this fire were also considered to be likely sources of erosion and sediments. Finally, soil types rated as severe to very severe, and very severe based on their erodibility, were used as probable sources of erosion and sedimentation. Soil types were based on studies done by USDA-SCS and the University of California Agricultural Experiment Station (Soil Survey, Ventura Area, California. April 1970. USDA-SCS and the Topanga-Las Virgenes Resource Conservation District and the Los Angeles County Department of County Engineer. Soils of the Malibu Area, California with Farm and Non-Farm Interpretations, October 1967).

Site Selection Process

It is important that the monitoring program is well organized and steady progress is made in achieving the objectives set by Heal the Bay. This section provides Heal the Bay with two monitoring program options. This flexibility will allow the Stream Team Program to start slowly and progress and expand, as the information base and the experience level of volunteers grows. The two different programs were designed to take advantage of the growing wealth of knowledge about the watershed, the differing skill levels of volunteers, and the growing interest and funding as the program matures.

The site selection process first involves examining existing monitoring efforts within the watershed. Next, streams are classified according to their physical characteristics. Then criteria are established for choosing the different types of monitoring sites. Finally, monitoring sites are selected. A description of the monitoring program follows the monitoring site selection, and the monitoring program options are defined.

Existing Monitoring Sites

The bulk of existing monitoring efforts are at the bottom of the watershed (see map on next page). Very few monitoring stations are located in the upper portion of the watershed, where the probable sources of water quality degradation occur. Currently, four groups are engaged in regular water quality monitoring programs that sample at least once a month. These are the Las Virgenes Municipal Water District, Resource Conservation District of the Santa Monica Mountains, Los Angeles County Department of Health Services, and Los Angeles County Department of Public Works.

R0016931

There are redundancies and overlaps between the different agencies with their monitoring efforts. This project recommends coordinating the monitoring efforts and relocating some monitoring sites to collect more comprehensive and useful data. These recommendations can be found in Appendix B–Existing Monitoring Efforts.

Stream Classification

As part of the site selection process, the streams within the Malibu Creek Watershed were classified. The first level stream typing method, based on techniques developed by Dave Rosgen of Wildland Hydrology, was used on all second order and above streams. Each stream fits into one of eight distinct types. Stream classification allows monitoring programs to minimize the number of baseline, or reference, monitoring sites. For example, a "B" type stream in one location should look and behave in the same manner elsewhere in the watershed. Stream classification is also useful for future restoration efforts. This technique allows comparison of a pristine stream of a certain type to a stream of the same type that is influenced by development to determine any differences. Stream classification was done by the Cal Poly Team using 3-D modeling to determine the shape of the landscape, and then calculating the slope and sinuosity of the stream itself using the aerial photograph and USGS 7.5 minute topographic maps. Further details about first level stream typing can be found in Rosgen's book, *Applied River Morphology* 1996.

Overview and Criteria

The site selection process for monitoring sites was begun by overlaying the digital aerial photograph, the probable pollution sources model, and land use maps. Using this information, all possible monitoring sites were located, resulting in the Maximum Monitoring Sites Model. These include Reference Sites, General Impact Sites, Recovery and Outlet sites. All streams of less than second order were automatically eliminated from consideration, as it is unlikely that these streams would have adequate water supply to sustain a year round monitoring effort. Using the preliminary first level stream classification discussed earlier, streams of A or AA+ types were eliminated as potential monitoring sites, due to their overall long term stability that, if monitored, would not show changes influenced by development practices. Finally, all monitoring sites chosen had to be located near a road and appear to have access, based on the aerial photo. These sites were also compared against a land ownership map to determine which sites were privately held and those that were public.

Maximum Monitoring Sites Model

Using the above criteria, the maximum number of potential monitoring sites was selected. With all potential sites identified, the monitoring program can expand in the future if changes occur, such as upstream development. When this occurs, this model allows the monitoring program the flexibility of finding new reference locations. The maximum monitoring sites map can be seen on the next page.

Reference Sites are upstream from impacts identified on the Probable Pollution Sources Model and aerial photograph. Reference sites are typically located in relatively undisturbed areas of the watershed (Figure 5-3).

General Impact Sites are located downstream from probable pollution sources. Sites were selected as much as possible to locate and isolate the pollution

source to a specific tributary. General Impact Sites will help Heal the Bay determine what impacts are being caused by upstream land uses. General Impact Sites were subjected to the same criteria as the reference sites, with the exception that they must be downstream of a suspected impact.

Recovery Sites are located at least 500 yards downstream from General Impact Sites. The goal is to determine how long it takes water quality to recover from probable pollution sources. Recovery Sites were subjected to the same criteria as the previous two types of monitoring sites.

Outlet Sites were chosen for each of the seven subwatersheds. Outlet sites are located where the tributary exits a subwatershed just prior to entering the adjoining downstream subwatershed. Outlet Sites will allow Heal the Bay to determine the contribution of each subwatershed to water quality and quantity.

Monitoring Program Options

From the Maximum Monitoring Sites Model, two potential programs were created, the Overview Program, and the General Impacts Program. The criteria used for each monitoring program alternative are summarized in the Monitoring Sites Selection Criteria chart (Table 5-1). These criteria are to be used by the program coordinator to assist in determining where to set up monitoring stations. The goal for each program differs, depending on what type of information is desired by Heal the Bay.

Overview Monitoring Program

This is a program designed to test the general water quality of each of the seven subwatersheds within the Malibu Creek Watershed (see map on next page). This program measures the contribution that each subwatershed has on the overall water quality and quantity within the watershed. Each subwatershed contains two sampling stations, one at the base where the waters leave that particular subwatershed, an Outlet Site, and another Reference Site, upstream of all impacts. Sites selected were located on the tributary in each subwatershed that drained the largest land area. By monitoring these two points in each subwatershed, the results can be compared to each other to determine if land uses are affecting the water quality at the outlet. The Overview Program consists of a total of fourteen sites, two per each subwatershed.

Type of Monitoring Site	Monitoring Program Option	Criteria Used for Site Selection	Information Sources
1) Reference 2) General impact 3) Recovery 4) Outlet	Maximum # of Monitoring Sites	1) Above suspected pollution sources and impacts 2) Below probable pollution sources or impacted areas 3) downstream of an unaltered reach, downstream of an impact site 4) Base of a Subwatershed	1-4) probable pollution source model, land use map, aerial photo, streams map, subsheds map
1) Reference 2) Outlet	Overview Monitoring Program	1) Above suspected pollution sources and impacts on largest subshed tributary 2) Base of Subwatershed	1-2) Maximum number of monitoring sites model, subsheds map and stream map
1) Reference 2) General impact 3) Outlet	General Impacts, Minimal Monitoring Program	1) Directly above suspected pollution sources and impacts 2) Downstream of dominant pollution source 3) Base of Subwatershed	1-3) Maximum number of monitoring sites model, subsheds map and stream map

The Overview approach is recommended for Phase 1 of this pilot program. The Overview Monitoring Program will allow Heal the Bay to determine how each of the seven subwatersheds is contributing to flow and/or degraded water quality within the overall watershed. The weakness of this approach is that it only isolates problems to the subwatershed level. It is a useful approach for Phase 1 and will allow Heal the Bay to determine which subwatersheds are having problems. In Phase 2, Heal the Bay can focus their efforts to target specific areas.

General Impacts Monitoring Program

There are two options within the General Impacts Monitoring Program, Optimal and Minimal. With this program, the maximum numbers of sampling stations are selected based on their ability to isolate the general impacts. These impacts are based on the Probable Pollution model, which highlights areas that are likely contributors of pollution for each of the key issues of sedimentation, nutrient loading, and urban runoff. Additional reference sites were chosen if they were situated immediately upstream of the general impact and were minimally influenced by upstream factors. This was done to help isolate the suspected impact. All sites selected were located near a road on a second order or higher stream, and appeared accessible from aerial photography. As always, A and AA+ stream types were eliminated from consideration. Using these criteria, the program can grow in the future and adapt to unforeseen change.

General Impacts–Optimal

The Optimal option chooses land uses that can be isolated and are potentially impacting major tributaries within each subwatershed. This would allow the monitoring program to generally locate the source of the problem based on the three key issues. Where possible, reference sites were located directly upstream of the suspected impact. When this was not possible, a reference site with the same stream classification was used. Recovery Sites were selected downstream of a location of a likely impact to determine if the stream and water quality has recovered at this lower point and to what extent. This scenario also locates Outlet Sites at the base of each subwatershed to determine the overall contribution to water quality and quantity of each subwatershed. The General Impacts Optimal map can be seen on the next page.

General Impacts–Minimal

The minimal scenario is the fewest number of stations that would determine the effects of pollution on water quality directly above and below an area. This option chooses a Reference Site and a General Impact Site below the suspected dominant pollution source in each subwatershed. An Outlet Site is selected as well. This scenario will isolate pollution sources to a general area and compare the difference between water quality upstream and downstream of the impact. The General Impact Sites, Minimal Monitoring Program map can be seen on page 5-19.

Watershed Monitoring Framework

The Watershed Monitoring Framework section contains three important components of this monitoring program. Prioritizing Subwatersheds provides a framework from which to build a monitoring program. The Recommendations for Future Monitoring contains suggestions on ways to organize the sampling options

outlined above. Recommendations for Existing Monitoring Efforts details ways in which current monitoring efforts could potentially be more effective.

Prioritize Subwatersheds

The subwatersheds have been prioritized for each monitoring procedure based on how critical the extent of probable impacts are to the streams. Prioritizing provides flexibility for the implementation of the monitoring procedures. This is due to the unpredictability of volunteer participation and the resources available to create field kits for Stream Walking and Water Quality Teams. Each subwatershed is assigned a number, one through seven, one being most critical, seven being the least critical. Subwatersheds were prioritized with regard to Stream Walking and Water Quality Monitoring. Stream Walking was prioritized using the following criteria: which subwatershed is the most critical to locate barriers to fish passage, which subwatershed should have the most unstable streambanks and outfalls into the streams, and which subwatershed should suffer from the greatest impacts from development (Table 5-2). Water Quality was evaluated in terms of most susceptible to pollutants from urban runoff, sediment loading, and nutrient loading (Table 5-3). The ranking and priority for each category can be seen in the tables below.

Recommendations for Future Monitoring

The models created for the General Impacts Monitoring Program should be used to incorporate any future monitoring efforts within the watershed. If a high school or other organization wants to conduct monitoring, water quality sites should be added in accordance with these models. It is recommended that the General Impacts Minimal option be used prior to using the General Impacts Optimal option. By following this plan, the data collection in this watershed will be maximized and redundancy will be minimized. These models should also be used to implement any biological monitoring procedures. By doing so, this data can enhance the overall knowledge about the watershed.

Criteria / Subwatersheds	Fish Migration Potential	Degraded Habitat (based on impermeability)	Greatest Threat from Future Development	Priority of Subwatershed (lowest number equals highest priority)
Malibu Creek	1	6	7	14
Cold Creek	2	7	6	15
Las Virgenes	3	3	1	7
Malibou Lake	4	5	5	14
Agoura	6	2	3	11
Westlake	7	1	4	12
Hidden Valley	8	4	2	14

Table 5-2: Priority chart for Stream Walking

Criteria / Subwatersheds	Likely Pollution from Urban Runoff	Likely Pollution from Nutrients	Likely Pollution from Sediments	Priority of Subwatershed (lower number equals higher priority)
Malibu Creek	4	1	6	11
Cold Creek	7	6	7	20
Las Virgenes	3	4	3	10
Malibou Lake	5	7	5	17
Agoura	2	5	2	9
Westlake	1	3	4	8
Hidden Valley	6	2	1	9

Recommendations for Existing Monitoring Efforts

Current monitoring efforts could potentially be more effective with a few modifications. There is an overlap of monitoring sites by different agencies. Monitoring efforts, including the efforts of the Malibu Creek Watershed Stream Team volunteers, must be coordinated to maximize resources and enhance the quality of data gathered in the watershed.

Monitoring should be done at the same time or at least on the same day at sampling stations that have overlaps. On Malibu Creek at Cross Creek Road, the Department of Health Services (DHS) is testing bacteria, and Las Virgenes Municipal Water District (LVMWD) and LA County Department of Public Works (DPW) are testing conventional, nutrients, bacteria, organic chemicals and making visual observations on a monthly basis (Trim 1994, pp. 12-15). It is recommended that the DHS should consider discontinuing monitoring at the Cross Creek Station. Instead, resources should be re-allocated to include conventional testing, nutrient testing, and bacteria testing at the Salvation Army station on Malibu Creek, so that DHS can quality check LVMWD's data. Currently, DHS is only monitoring bacteria at the Salvation Army Camp station while LVMWD monitors for conventional nutrients, bacteria, organic chemicals, and makes visual observations.

Two ocean sites, 50 yards east and west of the mouth of Malibu Lagoon, are also being monitored by DHS and LVMWD. A schedule should be established to encourage monitoring at the same time that would serve as a quality assurance check. These sites should be monitored ideally in the morning on the first Friday of every month. This schedule will more closely correlate with volunteer monitoring efforts and make the data collected more comparable. Ideally, monitoring would begin at the Salvation Army Site, proceed downstream to Cross Creek, and then end at the two ocean sites. Resource Conservation District (RCD) should work on this same schedule at the lagoon. Further, the RCD should add a monitoring station at Cross Creek Road that is monitored at the same time as LVMWD and DPW. This would be an effective way to verify the accuracy of their data.

The RWQCB Planning Division monitors four surface water sites within the watershed, but does so on an annual basis (Trim 1994, pp. 12-14). This data is of limited use at such an infrequent level of monitoring. The RWQCB Planning Division should discontinue their current monitoring sites and re-allocate those resources to supplying quality control and quality assurance to the volunteer monitoring program. The RWQCB could join the monitoring teams on three Saturdays and three Sundays and take side by side samples to provide quality assurance checks. Further, they could test those samples for bacteria. The Ventura County Department of Public Works monitors three stations on a quarterly basis, testing for conventional nutrients and bacteria. The Cal Poly team recommends that these sites be monitored on a monthly basis–the first Saturday (preferred), or Friday. Finally, Ventura County should add an additional monitoring site to serve as a reference on Cheseboro Road.

Section 6

Beyond Monitoring

The most effective way to improve ecological functioning within the watershed is to take action at the sources of the problems. New construction and renovation provides an opportunity for developers, architects, landscape architects, engineers, planners, and others to integrate designs that combine function, form, and ecological sensitivity. The following section is a catalog of planning and development recommendations, and design alternatives or Best Management Practices (BMPs) for consideration and action.

The monitoring program will advance the understanding of water quality issues, track trends, and identify source areas of pollutants. As long as urban runoff flows untreated and unfiltered directly into streams, water quality will not significantly improve at Malibu Lagoon and Surfrider Beach. By implementing the following action items, the health of stream corridors and ultimately water quality, can improve, fulfilling the vision of the watershed presented at the beginning of this document.

The following recommendations are divided into sections by key issues related to water quality. These are impervious surfaces, nutrient loading and sedimentation, water quantity, riparian habitat conservation, and development. Overall goals describe the conditions for optimal ecological functioning without sacrificing human needs. Objectives contribute towards the improvement of an issue if action items are implemented.

Planning & Development Recommendations could be turned into planning and zoning ordinances for local cities, counties, or regional agencies to implement and enforce. Design Alternatives are land-based actions that an individual or developer could implement on their property or in their community. Reference sections provide specific sources of information relating to a particular objective.

Impervious Surfaces

Reducing the effective level of impervious surfaces can improve water quality. This will increase infiltration, and ultimately reduce not only the volume and intensity of surface flows, but also the pollutants associated with urban runoff within the watershed. Reducing impervious surfaces would diminish future impacts to stream ecosystems. At the site scale, the goal for reducing the effects of impervious surfaces is slightly different than that for the whole watershed. The goal would be to achieve a "no net increase" in the amount of storm water runoff that leaves a given site. This means that the amount of storm water flow off of a site is the same as its pre-development, naturally vegetated state.

Planning and Development Recommendations

Limiting construction of impervious surfaces and promoting the use of permeable surfaces for all current and future projects can help restrict the amount of urban runoff in the watershed. Use of different products and technologies that allow the infiltration of water must be considered for all new developments, whether they are small-scale improvements such as a drainage swale, or a newly planned commercial and residential developments. By enhancing infiltration, the impacts to streams and water quality can be reduced.

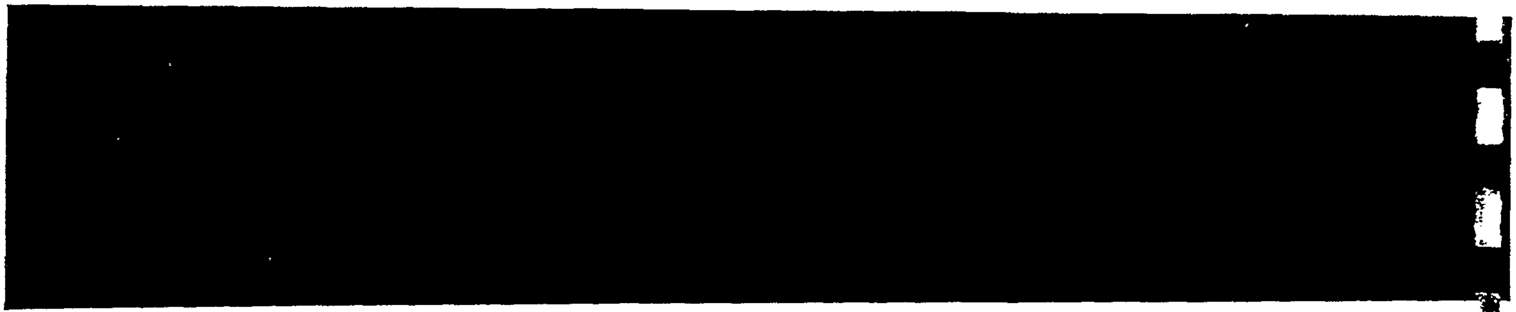
One way to lessen the impact of impervious surfaces is to concentrate development in higher density clustered housing (25% to 100% impervious surfaces) in some of the subwatersheds, in order to limit development in other subwatersheds to 10% impervious surfaces (Schueler 1995, p. 38). Clustered development lessens road length and reduces the amount of other impervious surfaces required to support a development. Reductions of impervious surfaces between 10% to 50% from traditional layouts can be accomplished depending upon the configuration of the clustered development (Schueler 1995, p. 61). Substantial savings in infrastructure costs are a direct benefit to the developer.

Land use zoning and other regulations can be used to limit the amount of impervious surfaces. Positive incentives and flexible codes encourage creative strategies for reducing the amount of impervious surfaces. This zoning should be done at the subwatershed scale and should be based upon the subwatershed classification: sensitive, degrading, and non-supporting. The sensitive subwatershed should have an upper limit of 10% impervious surfaces, degrading a 25% limit, and non-supporting no upper limit on impervious surfaces. Non-supporting subwatersheds have poor water quality and highly unstable streambanks. Future development and growth should be designated to occur in non-supporting subwatersheds in order to protect the sensitive and degrading subwatersheds.

Recommendations regarding specific subwatersheds in the Malibu Creek Watershed include:

- Focus development in the Westlake and Agoura subwatersheds and limit this to no more than 25% mapped impermeable surfaces.
- Change the zoning regulations to ensure that Las Virgenes, Malibou Lake, Malibu Creek, and Hidden Hills subwatersheds never exceed the 10% threshold for impervious surfaces.
- Reduce the level of effective impermeability in the Westlake and Agoura subwatersheds. This can be done through ordinances, building codes, and implementing new technologies to handle development.

Studies, such as Schueler's, have shown that it is more effective to reduce the amount of impervious surfaces related to the transport system (roads, parking lots, etc.), since these tend to have higher concentrations of pollutants than do rooftops or other impervious surfaces. These include reducing driveway length, width of streets and amount of impervious parking area.



Design Alternatives–Impervious Surfaces

The keys to mitigating the amount of storm water runoff are to slow down, capture, store, filter, and release storm water runoff. The most effective strategy, of course, is to limit or reduce the amount of impervious surfaces in the watershed. In addition to limiting or reducing impervious surfaces, it is recommended that design alternatives or Best Management Practices (BMPs) be implemented to reduce the amount and filter pollutants out of urban runoff.

The BMPs strategy will depend upon the subwatershed classification. Sensitive subwatershed BMPs should try and maintain pre-development hydrology and reduce sediment loading. BMPs such as biofilters, swales, and sand filters should be located away from streams to protect the hydrology of streams. BMPs for degrading subwatersheds should be implemented to remove pollutants and to reduce the frequency of bankfull and sub-bankfull floods. Pond or wetland designs can be implemented to achieve these goals. Non-supporting subwatershed BMPs objectives are to reduce pollution loads and prevent pollution.

The amount of impervious surfaces can vary greatly depending upon the development strategies and requirements for an area. The width of streets, the density of buildings, parking lot requirements, and the materials specified for such surfaces all contribute to the amount of impervious surfaces within a development. The amount of actual impervious surfaces can vary from 25% to 60% for medium density, single-family homes (Schueler 1995, p. 21). This all depends upon layout of streets, parking lots, and the overall layout and design of the site.

Recommendations

The following are specific actions that can be used to diminish the amount and effects of impervious surfaces.

Overall Recommendations

- Minimize the pollutants, and volume, and intensity of stream flows by restoring channelized portions of the creek throughout the Westlake and Agoura subwatersheds. Efforts to recapture the natural creek should start at the top and work down.
- Implement Best Management Practices throughout the entire watershed.
- Create a system of freshwater wetlands that biologically cleanses the water and regulate the volume and intensity of stream flows into downstream subwatersheds.

Streets, Driveways & Sidewalks

- Narrow width of streets.
- Use bioswales (vegetated depressions) that collect storm water and create visual separation, instead of creating elevated median strips to separate the traffic on two-way streets.
- Create streets and driveways that combine vegetative materials like grass, and ground covers with porous concrete, cobblestones or other materials that allow for the infiltration of water.
- Reduce the size of driveways for single family homes by sharing driveway

entrances. Create permeable extra parking spaces for visitors.

- Install French drain filter strips at the bottom of driveways or parking lots that collect and filter onsite runoff, then disperse water into planted collection areas.
- Use driveway strips with vegetation in the center to absorb leaks from automobiles and increase infiltration.
- Use permeable surface materials, such as cobbles, bricks or concrete paving blocks laid in a sand bed with mortarless joints, decomposed granite, and gravel.
- Design residential streets that receive little traffic with porous pavement to accommodate one way traffic, and use grass pavement for times when two-way traffic is needed.

Parking Lots

- Maximize how parking lots are used by using permeable surface materials on overflow areas or outer edges that are only used during busy holiday seasons.
- Use bioswales to collect runoff from parking, with plants and soil to filter pollutants associated with cars, before entering into the stream system.
- Support and use public transportation; ride bicycles for shorter trips.
- Create pedestrian-friendly malls that encourage strolling, not driving, between stores.
- Require underground parking beneath large structures, such as commercial buildings or apartment complexes.

Rooftops

Rooftop drainage is often sent directly to driveways and streets to rapidly flow into the storm drain system. Collecting, dispersing and filtering rooftop runoff before it reaches the storm drain system is a simple way of reducing negative effects of runoff.

- Drain roof runoff onto permeable areas such as planter beds. Use gravel to disperse gutter flows and to prevent erosion, or trench drains of gravel.
- Collect rooftop runoff from gutters into underground cisterns for future irrigation use.

Drainage Structures

- Retrofit existing storm water channels with pervious surfaces, where safe, to slow velocity of runoff.
- Create soft-bottom channels in place of concrete or pipes.
- Widen channels where possible.
- Establish retention/detention ponds, filters and infiltration systems.
- Create alternate routes for heavier flows through unused corridors or lots.
- Retrofit areas of high runoff due to impervious surfaces.
- Construct wetlands, where hydrology permits, for the enjoyment of residents.

Nutrient-Loading

Mitigation measures can decrease the impacts of pollutants to water quality. The key to preventing excess nutrients from reaching the water is to mitigate them at their source. The intent of this section is to recommend ways to reduce effects of polluted runoff into streams. New developments represent a good opportunity to implement some of these measures.

The following are specific actions that can be used to diminish the amount and effects of nutrient loading:

Recommendations

- Treat runoff onsite in bio-retention ponds or wetlands, before being released into public storm drain system.
- Collect runoff in parking lots into bio-retention ponds such as tree planters, median strips, or bioswales.
- Line streets and parking lots with bioswales to collect and filter runoff.
- Educate the public on ways they can lessen pollution runoff and impacts to the watershed.
- Maintain a water quality monitoring program to give feedback to the public and to agencies responsible for maintaining water quality.
- Lessen the amount of inputs into managed landscapes, such as pesticides, fertilizers and herbicides.
- Restore riparian vegetation.
- Minimize inputs to the wastewater treatment facility by promoting the use of gray water.
- Minimize the use of detergents containing phosphates that are hard to filter.
- Tapia should utilize wetlands that cool, store, and polish wastewater to be delivered during the summer when demand for reclaimed water exceeds supply.
- Begin a regional horse ownership educational program to encourage composting manure, pasture rotation, and proper planting techniques for grazing areas. Encourage the use of bioswales and filter strips to capture runoff leaving areas where horses are kept.
- Establish ordinances requiring a minimum 200-foot riparian buffer zone between areas where horses are kept and the stream.
- Permit no animal grazing within 200-foot of the riparian zone.
- Properly maintain septic systems; require inspections every two years. Require systems that do not pass inspection to be retrofitted with new septic systems that treat and reuse water for landscape irrigation.
- Pass ordinances that require new construction to meet these same requirements. Utilize computer-type systems to monitor the effectiveness of leach fields.

Recommendations for Steelhead Trout Enhancement (see Appendix E for more details)

- Remove the Rindge Dam to enable steelhead trout to migrate further upstream.
- Designate and protect critical habitat for steelhead trout.
- Require Tapia to cool, store, and polish wastewater using wetlands prior to any creek discharge.

- Implement construction BMPs on all projects requiring grading.
- Establish a no-build riparian buffer zone of at least 200-foot from the stream throughout the entire watershed.
- Reduce the effective impermeability of upstream cities through new zoning ordinances, building codes, and implementing structural BMPs.

Sedimentation

With the soils of the watershed being highly erodible, the goal regarding erosion and sediment loading is to minimize its occurrence. The following are specific actions that can be used to diminish the amount and effects of sedimentation:

Recommendations

- Reduce erosion and sedimentation at all construction sites with erosion and sedimentation control measures.
- Require Storm Water Pollution Prevention Plans (SWPPP) at all construction sites. These SWPPPs should be checked along with all sedimentation control measures during the construction process.
- Enforce compliance for all construction sites that do not display a SWPPP or have not implemented the erosion control measures.
- Limit clearing of native vegetation on construction sites.
- Require new construction projects of all sizes to implement sediment and erosion control devices at the construction site (such as silt fences, straw bales, etc.).
- Install terraces, temporary dams, sediment traps, or wetlands, that capture, store, and slowly release sediments over time.
- Protect soil from erosion during construction activities. Soil is highly vulnerable to erosion when vegetation has been removed during construction.

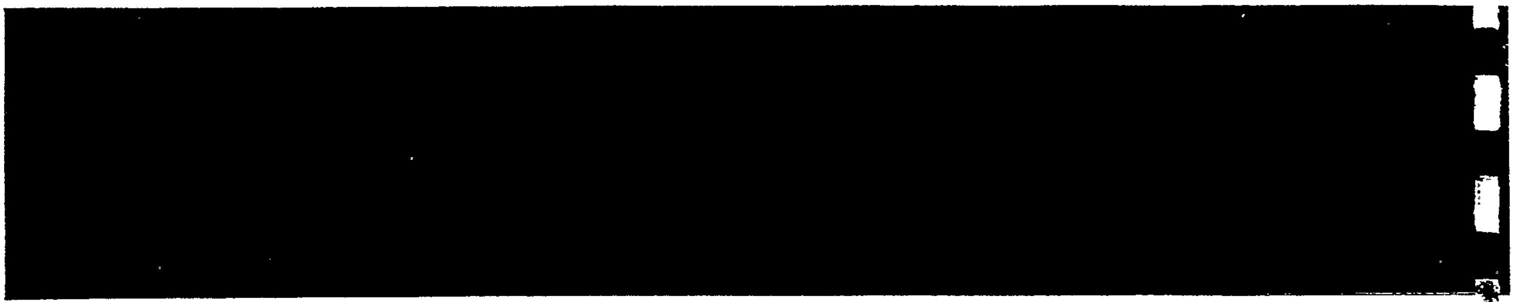
Water Quantity

The ultimate goal regarding water quantity is reducing the amount of imported water to be used, while accommodating population growth and development. With the continued consumption of imported water, the quantity of treated water being stored and released into Malibu Creek will continue to increase.

The following are specific actions that can be used to diminish the amount and effects of water quantity:

Recommendations

- Reduce imported water consumption through more efficient irrigation practices and low flow devices.
- Educate residents on the effects of imported water and provide incentives for reduced consumption.
- Increase the re-use of reclaimed water by allowing the distribution of reclaimed water to more customers, including residential users.
- Encourage the use of gray water systems through better landscape ordinances and rebates to supplement the initial costs.



- Encourage the use of drought tolerant and native vegetation.
- Create a series of wetlands throughout the watershed that would increase groundwater recharge, and decrease the intensity and volume of flows associated with impervious surfaces. Enhance water quality through biological filtration, and increase the available habitat for birds and other wildlife.

Riparian Habitat Conservation

Healthy stream habitats can help to reduce and mitigate problems associated with impervious surfaces, sediment loading, and nutrient loading.

The following are specific actions that can be used to enhance and protect riparian habitats.

Recommendations

- Protect existing riparian habitats.
- Preserve existing riparian corridor habitat.
- Preserve remaining native vegetation patches adjacent to riparian corridors.
- Protect sensitive areas from being developed. These include areas near streams, steep slopes, land on highly erodible soil, and areas with well established native vegetation.
- Protect existing vegetation that is covering the soil and holding the soil together.
- Protect soil from erosion by planting disturbed sites with native vegetation.
- Establish buffer zones between developed areas and streams. Reducing the amount of impervious surfaces near streams will help the vegetated buffer zone absorb and filter storm water runoff. The best strategy is to create a vegetated buffer zone by protecting existing native vegetation.
- Protect existing wildlife habitat corridors.
- Designate additional open spaces that link existing private and public open space.
- Re-establish the natural fire cycle to minimize the intensity, and associated sediment loading, from large intense wildfires.

This section contains recommendations and design ideas that if implemented, could aid in the restoration and enhancement of the ecological functions of the watershed. It is up to concerned citizens and stewards of the watershed to take action and help restore this diverse and spectacular watershed. These ideas are only a smattering of the various opportunities that can help solve the water quality problems of the watershed. Stewardship and design are a strong combination that, together, can result in positive change.

Recommendations and Project Limitations

RECOMMENDATIONS

Any efforts to correct existing digital storm drain data that currently is in a form that is unusable, should consider the Malibu Creek Watershed a high priority. Many groups and agencies currently monitor in the area and can immediately utilize this information to isolate the sources of pollution. An opportunity exists to use the volunteer monitoring program as a way to collect locations of storm drain outfalls by using global positioning systems. This alternative would enable the county to accurately locate storm drain outfalls for a fraction of the cost and time it would take for county employees to accomplish this task. While this would require funding for equipment and training, this is a viable alternative that would mutually benefit both groups.

An important element to any monitoring program is the ability to isolate the sources of pollution problems. Isolating sources of pollution would be more effective if storm drain locations were mapped. The Los Angeles County Department of Public Works, and Ventura County Department of Public Works, should create a single comprehensive digital storm drain map for the Malibu Creek Watershed. This storm drain map must identify storm drain outfalls and the areas drained by each outfall, and identify who is responsible for maintaining each storm drain. In addition, to ensure that digital data is readily available, and to increase the effectiveness of management of this complex system, this information must be compatible with the GIS employed by these counties. Without this type of information, locating the sources of water pollution problems will be impossible.

Existing information exists regarding monitoring throughout the watershed. This data should be synthesized and kept in one location that is accessible by the public and agencies in the watershed. This data can be helpful in making decisions concerning the watershed.

At the current time, Heal the Bay has the facilities to ensure the timely dissemination of the information collected by the Stream Team. As a non-profit agency, they can distribute this information at little to no cost. As the data base grows, Heal the Bay will be forced to upgrade their computer hardware to accommodate the increased volume of stored data. Beyond the time frame of the pilot project, it is recommended that funding to upgrade the computer hardware and software be acquired. Further, Heal the Bay should purchase a new orthographic digital aerial photograph every three years. Funding should be secured to accommodate additional Stream Walk Teams during the course of Phase 1. If Heal the Bay decides to expand the program into Phase 2, the person running the program should receive specific training for Macroinvertebrate Sampling and Stream Reach Surveying.

Flow data at the two stream gages in the watershed does not provide a picture of the contribution from each subwatershed. It is felt that many of the streams that were once intermittent are now perennial from artificial inputs into the streams. Installation of stream gages and rain gages at the base of each subwatershed, that accurately measure low flows would be beneficial to the area.

Project Limitations

Data from this study is based on the most current available information. The soils map received in digital form is considered obsolete and unreliable for this area. The Natural Resource Conservation Service is currently conducting a detailed soil survey for the area, and they have already discovered eight new soil types (Koeneker 1998, p. 5). When this new study is ready, the model should be updated. Land Use data has been revised by the project team from a digitally rectified orthographic aerial photo to reveal the newest information. The aerial photo is a blend of photos taken in April and October of 1997. Sites chosen for the monitoring, and stream classifications are based on observations from the aerial photo, USGS Topographic Maps, and street maps. These sites have not been field checked. The data provided in the digital data set should not be used for building, precise modeling, or any activity that needs data at higher accuracy than 30 meters.

Appendix B

Runoff Analysis for the Malibu Creek Watershed

by Bradley B. Owens

Introduction

The software used for modeling the watershed is called Watershed Modeling System (WMS) created by Environmental Computer Graphics Laboratory (ECGL) of Brigham Young University. With this model, runoff was estimated utilizing data supplied by Los Angeles County Department of Public Works and digital elevation data from DEMs. The watershed was modeled for two conditions– pre-development and current development. Results show a dramatic increase in runoff from pre-developed conditions to the current developed condition.

WMS provides a graphical interface for standard computer models such as HEC-1 and TR-20; HEC was developed by the United States Army Corps of Engineers, and TR-20 was developed by the Soil Conservation Service (SCS, now the Natural Resource Conservation Service or NRCS). When using this software program, the model can be updated and refined as new information becomes available, thus adding to the effectiveness of analyzing and predicting changes in the watershed.

Peak Runoff Explanation

A hydrograph is a graphical representation of a volume surface flow at a common point, such as a stream gage, in a given time period (cubic feet per second). For this model, a 24-hour storm was used as the time period. After the initial infiltration of rain into the topsoil, overland flow, or runoff, will occur and a peak will also occur at some point when the flows are greatest due to factors such as subwatershed geometry (area, slope), soil types, cover (land use, vegetation), and storm pattern.

The WMS software requires that certain data sets are available, depending on the model type and accuracy desired. Data was collected from a variety of different sources listed in table 1.

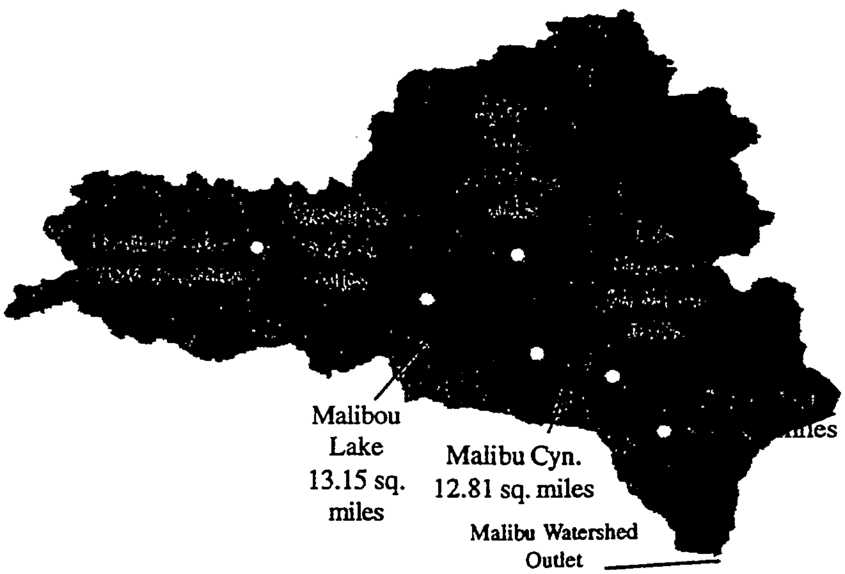

Figure B-1: Malibu Creek Watershed, Boundaries, and Area

Model Inputs and Methods

HEC-1 was chosen as the hydrograph method within WMS due to its ability to utilize the land use and soils data, thus providing more precision than other models such as TR-20. Within HEC-1, the NRCS curve number method was chosen to compute losses (runoff) for the same reason. The curve number method was developed by the NRCS as a way to index various surface runoff conditions based on land use conditions and soil characteristics.

The model was run for intervals of 2, 5, 20, 25, 50, and 100 year storms, based on rain data available from the National Oceanic Atmospheric Agency (NOAA) and applied to two conditions. Current developed conditions and predevelopment conditions were based on a vegetation survey done from 1930 to 1934 by A. E. Wieslander of the United States Forest Service. For predevelopment land use conditions, the Wieslander survey was used to visually estimate the percentages of different vegetation type. These were averaged together to generate predevelopment curve numbers.

Dams

There are at least six dams/reservoirs in the watershed; of these, four were used in the model due to their size and/or location within the watershed. The dams used (with the DWR number) for this model are Lake Sherwood (765-000) in Hidden Valley, Westlake Lake (786-000) in Westlake, Lindero Lake (785-000) in Agoura Hills, and Malibou Lake (771-000) in the Malibou Lake subwatershed. Information about the dams is available on the World Wide Web (see references).

Assumptions, Limitations

This model is dependent on the available primary data; it is assumed that this is the best available at this time. It is known that the soil survey on which the

Primary Data	Source	Notes
Rainfall	NOAA	24hr. 2-5-10-25-50-100 year storms.
Soils	National Park Service	Modified by Suzanne Dallman, UCLA to reflect new information.

Table B-1

GIS shapefile was based is an interim survey by the NRCS and is currently being updated for official release due in year 2001 (personal communication, Al Wasner, NRCS). In addition, the land use categories supplied did not have direct correlation to the SCS curve number table and this was manually interpolated.

As stated previously, this model has many inputs so modification and refinement over a long period of time will return the best results. Additional information useful would be channel geometry, reservoir geometry and conditions, and more exact soils data. Hydrologic modeling is both art and science, so the results are assumed to be estimates, and will differ from actual conditions.

Results

The runoff analysis resulted in two primary results, predevelopment and current developed conditions with modeled estimates of peak runoff (cubic feet per second) for each subwatershed and a total at the ocean outlet for each storm interval. The data is presented on the following pages in tabular form with a hydrograph for the outlet. Figure 1 represents predevelopment conditions and Figure 2 represents current conditions.

Conclusion

The modeling has shown that the watershed is yielding a large increase in runoff since predevelopment conditions have changed. Increases greater than 100% are seen in every subwatershed, most approaching 200% for a two year storm, and the Westlake subwatershed showing an over 700% increase. Figure 3 shows the relationship between the increase in mapped impervious surfaces and the increase in the amount of runoff is highly correlated.

Table 2 shows that the increase in impervious surface area in each subwatershed has increased the runoff into Malibu Creek (with the assumption being that the predeveloped condition had zero impervious surface). The clearest example is in the Westlake subwatershed where a 22.89% increase in impervious surface has led to a 722.01% increase in runoff. The linear graph also shows that the increase is a logarithmic relationship; small incremental increases of impervious surface leads to greater and greater amounts of runoff (Figure 4).

Although typical (and costly) structural devices such as dams and weirs can be used to control runoff, it is clear that this watershed will yield extreme amounts of runoff as impervious surfaces increase, and due to the erosive nature of the soils, will render these devices largely ineffective in relatively short periods of time as seen with Rindge Dam which has completely filled with sediment.

Appendix C

Within Every Healthy Watershed Dwell Citizen Stewards

by Eileen Takata Schueman

Introduction

Human beings have altered natural systems by dredging wetlands, channeling streams, damming rivers, and by increasing impervious surfaces by paving over porous soils. Over time, the accumulated effects have altered the natural hydrologic cycle, degraded habitat for native plant and animal species, and strained precious water resources. Government agencies alone can not bring changes to the current situation. Banded together, however, private citizens are capable of improving conditions of these altered streams, rivers, lakes, wetlands, and estuaries in and around their neighborhoods, towns, cities, and counties. Citizen stewards, who participate in monitoring the current health of these ecosystems, contribute to the future health of their natural resources.

Overview of Existing Monitoring Programs

It is not clear how many volunteer monitoring programs exist or how many participants are active in this country. The U.S. Environmental Protection Agency reports that over 24,000 volunteers involved with state-supported programs monitor more than 985 streams and rivers, nearly 2800 ponds, lakes, and wetlands, and four major estuaries. Throughout Pennsylvania, 60 groups and over 6,000 volunteers sample surface and groundwater. California's Directory of Volunteer Monitoring Organizations (1997) list over 50 groups around the state. What is clear is that the numbers are rising. Internationally, Australia and the United Kingdom support many stream-monitoring programs, and a joint program exists between Mexico and the U.S.

In the past, coastal lagoons and wetlands had been the focus of citizen monitoring efforts. Isolated streams and rivers have also been monitored extensively. More recently, watershed management has become the impetus behind new grassroots organizations and projects. This holistic approach addresses multiple issues affecting the complex system of streams, wetlands, and creeks. Watershed-wide monitoring addresses problems at their source, and can be effective in integrating multiple solutions to the complex problems.

WHO Is Monitoring?

Volunteers are either local concerned citizens of all ages, elementary through college students. They share a sense of wanting to contribute to "the environment." Monitoring groups call themselves Stream Team, X-Stream Team, Stream Keepers, Stream Watch, Watershed Watch, Texas Watch, Friends of the Estuary, and Riparian Station. Naming ensures a "team spirit" and contributes to the motivation factor, which will be discussed later.

Statewide programs such as Kentucky Water Watch and Hoosier Riverwatch in Indiana are run through their respective Department of Natural Resources. Auburn University's Alabama Water Watch is an example of a collaborative effort between Federal, State, and local agencies. Non-profit organizations coordinate local, regional, or statewide monitoring efforts. In Virginia, the Izaak Walton League's Save Our Stream Program (SOS) supplies its data to the Virginia Department of Conservation and Recreation, Division of Soil and Water Conservation. The Bay Area Regional Watershed Network promotes watershed stewardship by acting as a facilitator and regional funding base for different groups in the San Francisco Bay Area. students at Sequoia Elementary School in Pleasant Hill, California monitor Murderer's Creek.

WHAT Is Being Monitored?

Every project is unique in terms of what is being monitored, and depends largely on the goals and objectives of that particular program. The name Stream Team implies stream quality monitoring, but could easily include wetlands, lakes, vegetation and habitat restoration or watershed surveying. Friends of the Santa Margarita River in southern California are concerned about the health of the entire watershed. In northern California, the Lindsay Museum Watershed Watchers monitor Walnut and Pine Creeks.

Each program samples one or a combination of several stream and watershed parameters. A large number of programs train for chemical sampling of water quality. Physical stream characteristics and biological sampling of benthic macroinvertebrates are also common. Other parameters include bacterial, habitat assessment, illegal dumping, discharges, vegetation, stream/beach cleanup, erosion, or sedimentation. More and more groups are realizing the importance of setting goals for a holistic monitoring program. This ensures that the overall health of a watershed is being measured, not just one particular stream or river.

WHY Monitor?

Volunteers monitor in their community to contribute to society, to do something "good for the environment", and to gain something back. School children gain hands-on educational experience in the natural sciences. Adults gain satisfaction knowing their monitoring results will be used to make improvements to the health of surrounding ecosystems. Many organizations offer training workshops and informational lectures for their volunteers. In this way, volunteers learn new skills and techniques that are essential for high quality data collection.

Programs originate because of one or a combination of three general categories. The U.S. Environmental Protection Agency, Non-Point Discharge Elimination Survey (NPDES) compliance is a primary impetus for starting a program. Many programs have begun due to citizens organizing for a specific reason, such as to take action against a known point-source polluter, or to save an endangered species, or to combat invasive exotic vegetation which has taken over a stream bank. Lastly, effects of degradation and human-induced alterations of riparian ecosystems or watersheds prompt citizens and professionals to organize and develop a comprehensive monitoring program.

Key Issues in Monitoring Programs

In order to gain first hand insight into key issues in monitoring and program planning, I developed a questionnaire which guided telephone interviews. A sample copy is included and follows the bibliography. There are eighteen questions, relating to four general categories: The Program Goals & Objectives, Program Organization and Change, Data Collection and Dissemination, and Volunteers. Talking to actual monitors and program coordinators has unveiled some interesting insights, especially on the importance of volunteers, and reinforced existing knowledge.

Seven organizations have been contacted. Interviews were conducted with Hoosier Riverwatch in Indianapolis, IN, River Watch Network in Montpelier, VT, Kentucky Water Watch in Frankfort, KY, Sonoma Ecology Center in Sonoma, CA, Coyote Creek Riparian Station in Alviso, CA, Bay Area Action out of Palo Alto, CA, and the Mill Valley Watershed Organization out of Fairfax, CA. The contacted persons are program coordinators, office managers, or technical advisors to the project. These contact persons represent either state-sponsored programs, or regional and local non-profit agency-sponsored programs. The one exception is River Watch Network, a non-profit organization that assists in the development of new monitoring programs around the country.

Program Goals and Objectives

Goals for existing monitoring programs surveyed to date serve two primary purposes. The first goal serves the needs of humans, namely the volunteers and the public at large. Monitoring provides educational opportunities for teachers and students of all ages, and provides opportunities for citizen stewardship. Hoosier Riverwatch aims to increase public awareness. The second goal addresses ecological concerns. The need to improve water quality ranks high among these groups. Physical degradation of stream banks, habitat and or species loss, native vegetation concerns, and overall watershed health are other examples of goals stemming from ecological concerns.

What a group monitors depends largely on these goals and objectives. Bay Area Action is concerned with bird and wildlife habitat quality, and the control of invasive plants, as well as the restoration of native vegetation. The Mill Valley Watershed Organization surveys habitat, vegetation, sedimentation, and stream substrate. Watershed survey data is also an important component of data collection. Hoosier Riverwatch sends students out to collect chemical and biological data for school projects.

Program Organization and Change

The individuals that were interviewed have one of four roles within their organization. They are either a Volunteer/Program Coordinator, technical advisor, student intern, or volunteer. Being a program coordinator is a full-time paid position at Kentucky Water Watch and Hoosier Riverwatch, which are also state-funded programs. As for the non-profit organizations, it is not clear if program coordinators are paid or volunteer positions. The Sonoma Ecology Center utilizes a volunteer technical advising committee. Bay Area Action employs a few staff members, engages six student interns for specific projects, coordinates with five to six key managers, and oversees about twenty to thirty citizen volunteers on a typical work day.

Collaboration among agencies on goals and program elements are important to the Sonoma Ecology Center, Coyote Creek Riparian Station/Watershed Initiative Pilot Program, and Bay Area Action. These three groups work with agency partners and local community organizations to plan current projects and future directions. Bay Area Action is involved with the Coordinated Resource Management Process (C.R.M.P.) project, a group of stakeholders interested in an integrated approach to solving watershed-wide problems. Issues range from biodiversity, flood control, and pollution, to the homeless living in creek corridors.

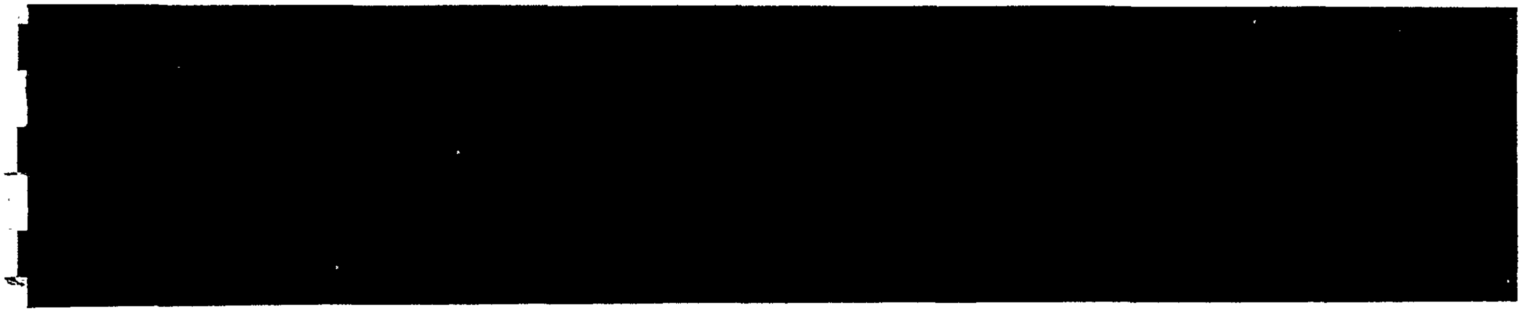
Program objectives change over time for some organizations. Hoosier Riverwatch began as a trash clean-up and awareness program, and has since expanded to include biological and chemical testing. Another group, the Coyote Creek Riparian Station is undergoing a transition because their goals and resource needs have changed. Originally they monitored riparian habitats of several creeks. However, focus has recently shifted towards watershed monitoring, recognizing the need to understand the entire ecosystem, rather than single creek riparian systems. From this reassessment of program goals, the interagency Watershed Initiative Pilot Program was born. This program is collaborative, potentially allowing more access to funding and technical resources through its partner organizations.

Data Collection and Dissemination

A volunteer will record his or her data onsite. The forms that they use vary with each program. Once sampling is complete, forms are turned in to the monitoring organization for data entry and analysis. In the case of Kentucky Water Watch, their World Wide Web site contains an electronic submittal form similar to the paper one, which approximately 20% of volunteers use. The only problem seems to be duplicate submissions; users frequently hit the "submit" button more than once, sending duplicate sets of data to be analyzed. More and more groups are giving volunteers the opportunity to submit data electronically.

Volunteers like to know that their hard work will result in some positive action. Understanding how data will be used is an important part of program planning. Many programs make their data readily available on the internet. The Hoosier Riverwatch program does not know whether or not their Internet database is used. Their goal is to make the information readily available for interested persons, rather than to target specific users. Quality Assurance/Quality Control (QA/QC) methods are employed by various organizations to ensure high quality data. Data collected by school children tend not to be accurate, so it is not released to the general public. Trained adults collect data that is more trusted, therefore, more likely to be used in studies and management decisions. In addition to data quality, Environmental Protection Agency and state agencies will consider funding programs that have a QA/QC plan in place.

The World Wide Web provides opportunities for sharing information across long distances. Information networks are designed for local, regional, or global use. Hoosier Riverwatch plugs their data into the RiverBank database maintained by Global Rivers Environmental Education Network or GREEN. RiverBank is a database that allows volunteers and schools to record and store data. The Coyote Creek Riparian Station/Watershed Initiative Pilot Program will



be adding data to the Bay Area EcoAtlas database. EcoAtlas is a Geographic Information Systems (GIS) database available online used to support local and regional environmental planning and management.

During the Fifth National Volunteer Monitoring Conference in August 1996, a special discussion planning session focused on the topic of "Turning data into action" (Proceedings, 1996). The discussion outlined "burning issues" such as making the data available and finding better ways to put the data to use, and improving volunteers' ability to follow up on monitoring results themselves for increased citizen action. Key recommendations involved empowering the citizen monitors by involving them in the decision-making process of how the data will be used by various stakeholders.

Volunteers–The Human Component

The most important information gathered during the interviews relates to the human component of monitoring programs - finding, keeping, and motivating volunteers. Each person interviewed had advice to give on some aspect of the issue of human involvement in the program. Clearly, monitoring programs would not be successful without meeting the needs of volunteers. Background education on why they are monitoring, what they are monitoring for, when they are expected to participate, and where the monitoring will take place is important to convey to volunteers. In turn, they are more motivated, better prepared, and capable of contributing to the best of their abilities. The relationship between volunteers and monitoring agencies or organizations is symbiotic; each is concurrently teaching or learning from the other.

Finding volunteers required some work for one non-profit organization. Once the monitoring creeks were selected, homeowners on or near the creeks were contacted. Information packets were mailed containing monitoring information, meeting or training session information, phone numbers to call in case of illegal dumping, etc. The purpose of these packets is to promote a sense of ownership and to arm creek-side homeowners with basic tools to become active stewards. In addition to adjacent landowners, recreationists are another potential pool of volunteers.

Motivating volunteers through education and training ensures a well-informed, committed volunteer base. A successful program will attempt to explain the "interconnectedness" between the volunteer and their everyday life, as one program coordinator suggested. Keeping volunteers can also mean simply taking care of them by bringing food and drinks to work days and training sessions. In the case of Kentucky's Water Watch program, keeping volunteers means addressing issues of "safety and access first." According the program coordinator Ken Cooke, the following list contained his words of serious advice (Cooke, 1998): (1) Safe parking place; (2) Clear path to river or creek; (3) Comfortable place to stand/sit during testing; (4) Will anyone shoot me while I'm monitoring? If yes, select different site; (5) THEN review hydrologic schematic of watershed to see if location is significant.

River Watch Network, an agency experienced in setting up volunteer programs stressed the need for a committed sponsoring group to take the responsibility for a successful program. Within that group, a "star" person is needed to take the lead. Alabama Water Watch calls this person the Volunteer Monitor Coordinator. River Watch Network recommends that volunteers be given the opportunity to assist in shaping the goals and objectives of the program. Also, they should be encouraged to give their insight into land uses, preferably on a land use map. This way, the citizen who is aware of the "important swimming hole" is contributing to the overall success of the monitoring project.

Towards Watershed Health

According to the Streamkeeper's Field Guide, "A stream is only as healthy as its surrounding watershed." This delightful book, subtitled *Watershed Inventory and Stream Monitoring Methods*, covers overall understanding of watersheds and their investigation in the first two chapters. Many other programs are beginning to see the importance of planning and taking action at the scale of the watershed, versus at a single creek, river, lake, wetland or estuary. Every single person lives in a watershed. Citizens who monitor their local creek ensure the future health of their surrounding watershed.

Appendix D

Ecological Engineering Planning Process for Designing Constructed Wetland Storm Water Systems

by Chris Padick

In undeveloped areas, storm water runoff is managed through the natural hydrological cycle, effectively accommodating even severe storm events. As in the Malibu Creek Watershed, land-use changes associated with urbanization alter the natural hydrology by changing peak flow characteristics, total runoff, and water quality. With a traditional storm water management regime being one of getting the water off site as quickly as possible, the resulting condition is a degraded watershed, poor water quality, erosion and flooding.

Within the Malibu Creek Watershed, the rapid expansion of urban development is having a tremendous impact on the Malibu Creek ecosystem. As levels of impermeability rise, the resulting increase in urban storm water has a direct impact on the water quality of the watershed, primarily in the form of non-point pollution, sedimentation and increased peak water flows. As the watershed continues to be developed, these problems will only continue to increase. The result of these problems is a degraded creek ecosystem. Once the impermeability of a watershed reaches 10-15 % of the total watershed area, we begin to see degradation on the creek ecosystems, primarily in the form of degraded water quality and the erosion of stream beds and banks due to dramatically higher intensity peak flows (Schueler). Though only about 12% of the total Malibu Creek Watershed is developed, development tends to be highly concentrated along many of the upper reaches of the Malibu Creek ecosystem, including some subwatersheds reaching 45% total developed area. The result is a stream system impact that has an effect throughout the watershed.

To deal with these development issues, ecological engineered solutions are proving to be both very effective and environmentally sensitive. Ecological engineering is the design of human environment within the natural environment for the benefit of both (Mitcsh 1989, p.4). Defined, it is engineering that involves the design of natural environments using quantitative approaches and basing approaches on basic science (Mitcsh 1989, p.4).

As the understanding of ecosystem functions and structure drives ecological engineering, ecology is the basic science driving design. Well defined by Odum in 1962 as "environmental manipulation by man using small amounts of supplementary energy to control systems in which the main energy drives are still coming from natural sources", ecological engineering is the design of ecosystems that, once created, rely on the self designing properties of natural ecosystems with a minimum of maintenance. Key to the process is that ecologically engineered designs need to be solar-based, requiring little intervention, thus based on natural ecosystems that are self-sustaining systems running on solar energy (Mitcsh 1989, p.7).

Ecological engineering, with its roots in ecology, is quickly proving to be a significant alternate solution to some of the pressing problems associated with the impacts of human development on the environment. The goal of this appendix will be to introduce the field of ecological engineering as a guiding force for design opportunities concerning constructed wetland applications within the Malibu Creek Watershed for the treatment of non-point pollution sources associated with urban runoff.

When making design decisions for alternative storm water treatment applications, it is important to first understand the key principles driving an ecologically engineered design. The following are in essence, guidelines for a design process.

1. Ecosystem structure and function are determined by the forcing functions, such as temperature, nutrient imports, and water flows, of the system. Alteration of the forcing function causes the most dramatic changes on an ecosystem. Structure of an ecosystem is ultimately controlled by forcing functions. As the driving forces behind an ecosystems function, an in-depth understanding is critical for a successful design (Mitcsh 1989, p.22).

2. Ecosystems are self-designing systems. The more one works with the self-designing ability of nature, the lower the cost of energy to maintain that system. An ecosystem's regulation and feedback mechanisms give it the ability to adapt and self-design to the environment and minimize changes in the function of the ecosystem. It is here that ecosystems and ecological processes are used, not replaced as a primary guiding force in ecological engineering (Mitcsh 1989, p.24)

3. Elements are recycled in ecosystems. Matching humanity and ecosystems in recycling pathways will ultimately reduce the effects of pollution. Elements cycle in all ecosystems, an example of this would be the nutrient cycle. Of primary importance in an ecologically engineered application is understanding the individual cycles of the ecosystem and their rates (Mitcsh 1989, p.25).

4. The processes in ecosystems have characteristic time scales that may vary over several orders of magnitude. For optimal performance, manipulation of ecosystems must be adapted to the ecosystem's natural dynamics (Mitcsh 1989, p.29).

5. Ecosystem components have characteristic space scales. Manipulation of ecosystems should take into account the appropriate size necessary to achieve the desired results (Mitcsh 1989, p.30).

6. Chemical and biological diversity contributes to the buffering capacity of ecosystems. When designing ecosystems, one should introduce a wide variety of parts for the ecosystem's self designing ability to choose from. The more possibilities an ecosystem has, the higher its buffering capacity. This is especially true for the buffering capacities related to the function of the system. A system with a high diversity may change

[redacted]

species composition radically and therefore be considered unstable yet still have a high buffering capacity related to its function. The higher the diversity, the more capable an ecosystem is in handling fluctuations of its force flows (Mitcsh 1989, p.33).

7. Ecosystems are most vulnerable at their geographical edges. Ecological management should take advantage of ecosystems and their biota in their optimal geographical ranges. As ecosystems have defined ranges in which they are tuned to the climatological and geological features of the landscape, these should be primary considerations in the design process. As ecological engineering involves manipulation of ecosystems, the stability of the system will be enhanced if the species are in the middle of their environmental tolerances (Mitcsh 1989, p.33).

8. Ecotones are formed at the transition zones between ecosystems. The interface between human settlement and nature should be designed as gradual transitions, not as sharp boundaries. Nature has developed transition zones, between ecosystems, to make soft transitions. Ecotones may also be considered buffer zones between ecosystems that are able to absorb undesirable changes imposed on an ecosystem from neighboring ecosystems. (Mitcsh 1989, p.34)

9. Ecosystems are coupled with other ecosystems. This coupling should be maintained wherever possible and ecosystems should not be isolated from their surroundings. Ecosystems are open systems, and as such, exchange mass and energy with their environment. Thus it is important in ecological engineering to take this into consideration. If a component is removed from one system, the problem is not solved if the component then harms another system (Mitcsh 1989, p.35).

10. Ecosystems with pulsing patterns are often highly productive. The importance of pulsing subsidies should be recognized and taken advantage of wherever possible. Ecosystems with pulsing pattems often have greater biological activities and chemical cycling than systems with relatively constant patterns. But careful understanding is required to ensure proper frequency and duration to allow a system to operate at optimal levels (Mitcsh 1989, p.36).

11. Everything is linked to everything else in the ecosystem. It is impossible to manage one component of an ecosystem without affecting other parts. As all components of an ecosystem are linked in one way or another, it is particularly important to understand these connections in ecological engineered designed solutions (Mitcsh 1989, p.36).

12. Ecosystems have feedback mechanisms, resilience and buffer capacities in accordance with their proceeding evolution. And understanding of these characteristics will ensure greater success (Mitcsh 1989, p.36).

With these principles guiding the design process, there is a greater chance of understanding the ecosystems involved. With this better understanding, adopting an appropriate design will blend the needs of humanity with the needs of the ecosystem for the benefit of both.

With this in mind, we can now address one of the major issues concerning water quality with in the Malibu Creek Watershed. Non-point pollution sources (NPS), especially those associated with urban runoff, are considered among the nations leading source of surface water and ground water quality impairment (www.epa.gov). Urban storm water runoff, as well as being a major NPS, also contributes to water quality problems through increased peak flows that degrade streams and erode stream banks. The first step in designing the solution is understanding the problem.

In the Non-point pollution associated with urban storm water runoff, the following are the pollutants of concem.

- Biological Oxygen Demand (BOD): Organic molecules and other substances that require large amounts of oxygen to be broken down constitute BODs. Because of this high O2 demand, when released into the environment, those organics can have a detrimental effect on fish and wildlife by robbing them of the available dissolved oxygen.
- Nutrients: When high level of nutrients accumulate in waterways, it creates algae blooms that depletes oxygen needed by fish and other wildlife.
- Suspended Solids (SS) Suspended solids are insoluble materials, sediment particles that cloud water when suspended preventing light and oxygen from reaching aquatic life. Increased sediment settling can also degrade wildlife habitat, especially that of the steelhead trout that needs gravelly bottoms for breeding success.

Along with NPS pollutants, the other major problem associated with urban storm water runoff is the increase in peak water flows during storm events. The result is an overloading of the stream system to the point of downstream flooding and accelerated stream bank erosion.

Here is where ecological engineered solutions can play a vital role in the mitigation of these problems. Showing itself as being a very effective solution is the use of a variety of constructed wetlands. Basically, constructed wetlands are created ecosystems, modeled after natural systems and designed to mimic the natural processes of these ecosystems. Evidence is showing that these artificially created ecosystems, depending on type, are very efficient at filtering out most solid BOD as it passes through sand, soil, crushed rock or brick elements of the wetland substrate, while dissolved BOD is eaten by microbes. Microbes colonize on the surface of plant roots where oxygen is made available as plants photosynthesize and transport oxygen from their leaves to their roots. Constructed wetlands filter these nutrients by using them for vegetative growth. Sediments are also trapped within the wetland systems, primarily from settlement due to slow water flows through the system.

There are several basic types of constructed wetlands to be considered. Some resemble traditional wetlands in character while others are more marshlike. The basic types of constructed wetlands that are being used for storm water treatment consist of Free Water Surface Wetlands (FWSW) and Subsurface Flow Wetlands (SFW).

Free Water Surface Wetlands consist of basins or channels with suitable mediums to support the growth of emergent vegetation, with open areas and with water flowing at relatively shallow depths. The key feature is the presence of free water surfaces. These can include a variety of substrate and are designed as ground water recharging or non-recharging systems. Very similar to natural wetlands, these types often provide wildlife habitat as well.

Subsurface Flow Wetland (SFW), also known as rock reed systems or root zone systems and sometimes interchangeable with the term bio-filter, involve shallow basins or channels planted with suitable vegetation growing in a variety of media designed so that the runoff water flows horizontally through the media with no above surface flow or open surface flow. In SFW systems, runoff is applied to flow horizontally through basins or channels filled with rock or sand. In SFW systems, specific surface area and the porosity of the medium are important variables (Etnier 1996, p.29).

Within both of these systems, vegetation plays a critical role. Wetland vegetation is a function of climate, hydrology and nutrient availability. In a constructed wetland, climate, hydrology and pollutant response influence the selection of plant species. Wetland plants have specific tolerances to the levels and types of pollutants, which could be altered by varying storm water quality. This in turn could alter the plant community. Since new dominants reflect more efficient use of nutrients or more tolerance to pollutants, these plant changes should benefit overall pollutant removal (Hammer 1989, p.258). When referring to the considerations of an ecologically engineered design approach, an understanding of the plant palette is critical. In determining which plants are appropriate for the type of constructed wetland design, it is crucial to look at known efficiency of a plant type in pollutant removal and more importantly, appropriateness of a plant type for survival in local conditions.

As well as vegetative considerations, relationships between the hydrology and wetland characteristics must be included in the design to ensure long term effectiveness. The source of water, volume, renewal rate and frequency of inundation influences the chemical and physical properties of the wetland substrate, which in turn influences species diversity and abundance, primary productivity, organic deposition and flux and nutrient cycling. Hydrology also influences sedimentation, aeration, biology transformation and soil absorption processes. Critical factors that must be evaluated include velocity and flow rate, water depths and fluctuations, detention time, circulation and distribution patterns, seasonal and climatic influence, groundwater conditions and soil permeability. This also includes establishing wetland hydro-period to determine form, nature and function of the wetland. Hydro-period is the depth and duration of inundation measured over the annual wet or dry cycle. Acceptable high and low water elevations will determine the storm water treatment volume capacity of the wetland. Water depth and inundation period can change the plant community, with beneficial or detrimental effects on the wetland or storm water pollutant removal (Hammer 1989, p.225).

It is a solid understanding of both the structure and function of the wetland processes as well as an understanding of the local environmental conditions

Appendix E

Malibu Creek Steelhead

by Mark J. Abramson

It's early morning. The sky is gloomy and threatening as I stand in the shallow waters of a stream in the Santa Cruz mountains. The air on my face is brisk and invigorating. Suddenly, as if attacked by a shark, my rod tip is nearly touching the water. The fight is on and my heart and mind begin to race. I see the shimmering silver-blue green of the majestic steelhead trout and imagine the perilous journey this fish has gone through. Emerging as a tiny fry in this very stream it must survive threats from both native and exotic aquatic species to reach a size and maturity where it can eventually migrate to the ocean. The fish must survive fishing and other threats from marine species to return to its native stream to spawn and continue the life cycle. At times this migration route can be blocked by drought for years at a time, not allowing smolt to leave or adults to return and spawn. The ability of a fish to survive in both fresh and salt water is extraordinary. As I release this fish and admire the pristine natural beauty of the surrounding stream, a feeling of deep respect for this worthy fish floods over me.

A century of water diversions, pollution, dam building, urbanization, and degradation of creeks, streams and rivers have hit California steelhead populations hard. Steelhead trout (Oncorhynchus mykiss), the anadromous form of rainbow trout, were once abundant up and down coastal streams draining mountains throughout the state including the Santa Monica Mountains. "California steelhead populations have dropped by more than 90 percent statewide and estimates of the adult steelhead population is only 250,000, less than half of estimates from 30 years ago."[1] "Historically over one hundred and twenty-two streams south of San Francisco Bay are known to have once contained steelhead populations; 33 percent no longer have any, and all the remaining streams are in decline, some of them in population nosedives."[2] These startling statistics have instigated the National Marine Fisheries Service (NMFS) to list the southern coast populations, those found from the Santa Maria River to Malibu Creek, as endangered.

Life History:

Steelhead is the anadromous form of rainbow trout. They are born in fresh water, then immigrate to the ocean where a majority of their growth occurs. When a storm event provides sufficient flow to breach the sandbars that close the mouths of coastal streams, mature steelhead return to their native streams to spawn. Unlike the salmon, steelhead do not necessarily die after spawning and may make numerous round trips or may spawn and then remain in the stream.

The female selects a site having good intergravel flow, to ensure that oxygen is available for eggs and small hatchlings, and then digs a redd (nest) to deposit eggs. After being fertilized by the male, the eggs are then covered with gravel and the female swims upstream to repeat the process. Hatching time is dependent

R0016975

mostly on water temperature. Studies conducted by Leitritz and Lewis in 1980 record eggs hatching in about 30 days in water temperatures of 51 degrees F. The young hatchlings live in the protective gravel for approximately 4-6 weeks after hatching, depending on the depth of the redd, gravel size, siltation, and temperature, before the emerge as fry.[3] Newly emerged fry move to shallow, protected areas associated with stream margin.[4] Fry soon will find feeding locations in areas of the stream. Juveniles will inhabit riffles but larger ones often inhabit deeper runs or pools.[5] South coast steelhead like those of Malibu Creek, are ocean maturing (winter steelhead). South coast steelhead typically begin their spawning migration in fall through winter and spawn January through March, within a few weeks to a few months of entering fresh water.

Non-anadromous or resident forms of rainbow trout (O.m. irideus) are now believed to be a critical component of the adaptability of steelhead and integral to any type of management plan. It was once believed that they were two distinct subspecies but genetically there are little to no differences between resident and anadromous forms. It is not uncommon for anadromous forms for males to mature as parr then assume a resident life style.[6] Mature male parr rainbow trout have been observed spawning with female steelhead in Waddell Creek.[7] Steelhead are dependent on a variety of conditions in order to successfully migrate to the ocean. Malibu Creek is subject to extreme variations in rainfall and droughts that may last years. These variations may force steelhead to remain in streams for several years at a time. Sufficient stream flow is required to breach sandbars and allow access to stream headwaters or the ocean. During a storm event with sufficient flow, only a brief window allows steelhead to transfer between the ocean and freshwater environments. This flexibility in life history, which allows steelhead to survive and spawn until a time when a migration route is opened, is critical, particularly in the harsh southern geographic limit.

Steelhead must be adaptable in order to exploit resources in rivers, streams, and the ocean as few species do. Southern populations are the most adaptable of all steelhead. Studies of the Malibu fish show them to be the most genetically diverse of any known trout population. For this reason the southern steelhead is considered critical for the survival of the entire species due to their unique ability to adapt to marginal conditions such as high temperatures, and unpredictable water flows.

Instream Habitat

Following are the types of instream habitat preferred by the steelhead trout:

Depth: Steelhead prefer to spawn in depths between 6-24 inches. Fry will utilize water between 2-14 inches deep, while parr utilize water depths between 10-20 inches. In a 1972 study, Thompson reports that seven inches of water is the minimum depth required for successful migration of adult steelhead.

Velocity: Velocities in excess of 10 –13 feet per second hinder the swimming ability of adult steelhead and may slow migration (Reiser and Bjorn 1979).[8] The larger the fish the higher the velocity of water that can be utilized for spawning. Steelhead will spawn with water velocities ranging from 1- 3 cubic feet per second (Barnhardt 1986).[9]

Substrate: Adult steelhead have been reported to spawn in substrates between .2- 4 inches in diameter. The Unified Soil Classification System classifies sand as particles with diameters from .003- .19 inches, gravel as .19- 3 inches, and cobble as 3- 11.8 inches. Gravel must be highly permeable to keep incubating eggs well oxygenated and contain less than 5 percent sand and silt. Fry and juvenile steelhead prefer slightly larger gravel and cobble than spawning adults.

Temperature: While temperature preferences are well documented for northern streams less is known about southern streams. Egg mortality begins to occur at 56 degrees F and steelhead have difficulty getting adequate oxygen from water with temperatures above 70 degrees F.

The type of habitat required by juvenile steelhead varies with lifestage. Younger smaller fish prefer slower shallower water than larger fish.

MALIBU CREEK STEELHEAD

Malibu Creek has been listed as the southern most geographic area to support a self-propagating run of steelhead trout. "This run has adapted to drastic changes in flow, water quality and population expansion occurring within the Los Angeles basin."[10] There is a concerted effort by local citizens, and local, state and federal responsible agencies to prevent this run from becoming extinct. The Malibu Creek Watershed does have certain benefits that may help protect steelhead trout and other wildlife in the future. Large partitions of land are owned by California Department of Parks and Recreation as well as the National Park Service, which will ensure that these areas are not developed.

The native fish community include steelhead trout, Arroyo Chub (*Gila orcutti*), and Pacific Lamprey (Lampetra tridentatta) another native anadromous species. Introduced species include bluegill (Lepomis macrochirus), green sunfish (Lepomis cyanellus), largemouth bass (Micropterus salmoides), brown bullhead (Ictalurus nebulosus), and channel catfish (Ictalurus punctatus).[11]

The water regime within Malibu Creek has been drastically altered as a result of dependence on imported water. The coastal Mediterranean climate results in approximately 16 inches or 41cm of rainfall annually, with nearly all precipitation occurring from November through April. Stream flows typically range from summer lows of 6-10 cubic feet per second (cfs) to storm flow peaks above 600 cfs. Extreme flows include historic no-flow conditions, prior to discharge of treated effluent by Tapia in the late 1960s, and peak flows of 33,800 cubic feet per second were recorded in January 1969.[12]

Accessible Steelhead Habitat

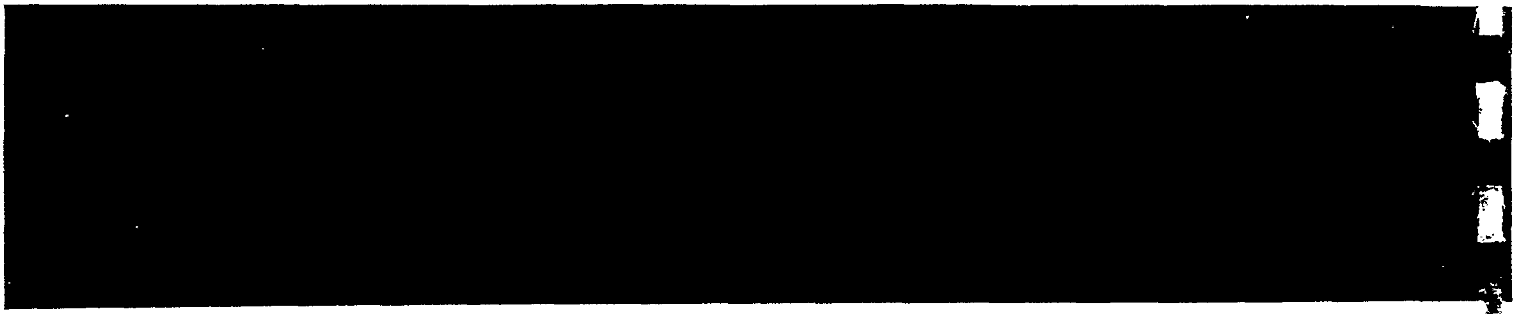
Currently, useable steelhead habitat occurs on an approximately 2.6 mile stretch below Rindge Dam. This stretch of Malibu Creek is characterized as a steep gradient gorge nearest the dam that gradually flattens out into a valley section and eventually flows to the Malibu Lagoon. Steep canyons walls provide topographic shading in the gorge nearest the dam, which serves to regulate water temperature. The gorge has a pool riffle ratio of 1:1 with pools as deep as 5 feet and with more frequent and longer riffles than in the valley section. Dominant substrates in the gorge section range from small cobbles to large boulders, which serve to cool water and provide shelter from predators.[13] As the gradient flattens out, sediments in the slower moving water have the opportunity to settle and particle size decreases to smaller gravel and sand. A >6:1 pool riffle ratio occurs in the low gradient valley section, which has many long pools from 1-3 feet in depth.[14]

Good quality adult and juvenile steelhead habitat is found in the steep canyon for about the first two kilometers heading to the ocean from the dam. Excellent gravels, appropriate channel morphology and abundant cover in the form of boulders, deep water, and surface turbulence, provide good habitat for spawning fish in this section. Good rearing habitat occurs in pockets most abundantly in the gorge where deep pools and larger substrates provide cover, food-producing riffles are more abundant, and canyon walls provide shade and maintain cooler water temperatures of 12.2 degrees Celsius, 100 meters below Rindge Dam.[15]

Largemouth bass thrive on warmer water temperatures and are believed to be a predator of juvenile steelhead trout. Largemouth bass abundance increases with distance downstream, the opposite of steelhead distribution and accounts for 80 percent of the total fish community in the valley section. This section is characterized by low gradients with long pools and runs separated by short riffle sections and increased settlement of sediments. This section had only 3.5 fish per 100m of pool/run habitat due to poor marginal rearing habitat associated with that section. Rearing steelhead seem to prefer pool habitat to run habitat showing 50 percent more utilization of pools than runs.[16]

Several issues are contributing to the severely decreased steelhead run on Malibu Creek. These issues are exotic invasive predator fish species, loss of suitable spawning and rearing habitat, and water quality. The California Department of Fish and Game identifies freshwater habitat loss and degradation resulting from inadequate stream flow, blocked access to historic spawning and rearing areas, and human activities that discharge sediment and debris into water courses as the main factors contributing to the decline of steelhead trout populations.

The Malibu Creek steelhead population is currently relegated to approximately 2.5 miles (4.2 kilometers) representing approximately 35 percent of total available stream habitat below the Rindge Dam. The Rindge Dam is considered the primary obstacle or barrier to steelhead in Malibu Creek. Rindge Dam was originally constructed to provide agriculture irrigation and domestic water supply for the Rindge Ranch. Rindge Dam was built between 1924 and 1926 with private funds from the Rindge family, and was authorized for use on January 31,1933. The original storage capacity was 574-acre feet of water. As a result of the highly erodable soils and fire frequency throughout the watershed, the reservoir was completely filled with sediments and decommissioned by the State of California in 1967. The reservoir is estimated to contain approximately 1.6 million cubic yards of sediment. In 1984, 960 acres of Malibu Canyon, including Rindge Dam were sold to the State of California to become part of Malibu Creek State Park. California Department of Parks and Recreation, manages Malibu Creek State Park and the Rindge Dam, and one mission of that organization is to increase the native biological diversity of the lands they own and manage.



Potential Steelhead Habitat

Entrix investigated the potential of steelhead habitat above Rindge Dam in an effort to determine if removal of the dam would increase available habitat, and likely increase the steelhead population. From Rindge Dam to the Los Angeles County stream gauge, good quality steelhead habitat for both spawning and rearing were found. The entire stream reach is well confined by the steep sided canyon, which provides topographic shading to the stream except for in the lower .4 mile stretch of the stream, which meanders through the sand and gravel deposited behind the dam.[17] In the flatter lower third of the stream reach nearest the dam, substrate is composed of sands and small gravels with a pool/riffle ratio of 4:1. This section has abundant overhanging tree cover and shading. This area has outstanding spawning sites.[18] The remaining section of this stream reach is steeper and has larger substrates of gravels, cobbles and boulders that provide excellent opportunities for escape and instream cover. This section of the stream reach provides good quality rearing habitat. Directly adjacent to the tunnel on Malibu Canyon Rd., is a natural fall of approximately 18-feet that creates a barrier to upstream passage. To provide fish passage around this barrier using a concrete flume, was estimated at a cost of $120,000 in 1989.[19]

The stream reach that starts at the stream gauge and ends at Las Virgenes Creek is characterized by a wide flat valley section moving upstream from the confluence at Cold Creek followed by a more narrow valley section that widens out as Las Virgenes Creek and Malibu Creek converge. Topographic shading is less in this stream section, which has a pool to riffle ratio averaging 5:1. Substrates are filled with fine sediments estimated at 40 percent embeddedness throughout this stream section. Evidence of pools being filled and high degrees of embeddedness suggest that sediments are being transported down Las Virgenes Creek and into Malibu Creek which are impacting potential steelhead habitat. "In the section of stream below Tapia foam appeared on the water beneath each riffle and there was a total lack of attached algae on the stream bottom, algae was present at all the other sites surveyed. The water had an acrid odor and kick samples produced almost no macroinvertebrates."[20] Along this stream reach are two small sections between Cold Creek and Tapia, and adjacent to Tapia Park that exhibit suitable steelhead habitat. These sections have a steeper gradient and therefore have larger substrates with 25 percent embeddedness, and a pool to riffle ratio of 1:1. This area has deeper pools, greater water velocities, and greater amount of cover overhead and instream.[21] The researchers who conducted this survey evaluate the overall habitat quality along this stream reach as ranging from poor to fair.

The stream reach that runs from Las Virgenes Creek to Century Dam flows in a wide valley between gentle hillslopes heading upstream from the confluence of Malibu Creek and Las Virgenes Creek. Triunfo Canyon, in the upper third of the reach, is confined by a deep narrow gorge heading towards Century Reservoir.[22] The bottom section of the reach has a pool to riffle ratio of 8:1, no topographic shading or substantial riparian cover, and small substrates. It is suspected that water temperatures in the lower .5 mile of this reach may exceed the levels tolerable for steelhead. [23] The best steelhead habitat occurs in the upper third of this reach in Triunfo Canyon. This section has large deep pools and excellent topographic shading. Field investigations reveal the substrates in the canyon section range from boulders to bedrock with low percentages of embeddedness.

The stream reach from the mouth of Cold Creek to Stunt Ranch Road is confined by a narrow valley which widens out in short stretches near the mouth and below Stunt Ranch. The canyon is well shaded from a combination of topographic shading and riparian cover. Average pool depths were about 6 inches with the deepest pool measuring 3.6 feet. Pool to riffle ratios ranged from 4:1 in flatter sections to 1:1 in steep sections.[24] Substrates were smaller towards the mouth of the creek with bedrock and boulders in the steepest portions of the reach. The lower third of the creek had 35 percent embeddedness in contrast to the steeper upper reaches that had less than 10 percent.[25] Flows were a limiting factor for upstream migration. Cold Creek has a substantial amount of useable habitat for steelhead during their first most vulnerable year, beyond that age class, only a few deep pools in steeper parts of the reach provide adequate habitat.[26] Three barriers are located on Cold Creek that would prevent upstream migration.

Extensive site investigations were conducted for this project by the research team from Cal Poly, Pomona. The 1998 El Nino year yielded above average rainfall. Site visits in the later months of 1997 confirm the Entrix findings along Cold Creek, and on Malibu Creek from the stream gauge to Las Virgenes Creek. Subsequent visits in March-May of 1998, following several large storm events, revealed lower percentages of embeddedness along both of these stream reaches and pools that were much deeper. Embeddedness on the lower portions of Cold Creek were estimated at 15-25 percent and 20-30 percent from the stream gauge to Malibu Creek. This suggests that sediment deposits had been scoured out during high creek flows. The investigators estimate the average depth of flow beteween 10-18 inches along Cold Creek and average pool depths between 12-18 inches.

The Cal Poly team also investigated the last mile of Las Virgenes Creek where it converges with Malibu Creek. The numerous site investigations reveal that prior to the substantial creek flows in the winter of 1998, the average water depth on this section of Las Virgenes Creek was between 8-12 inches and embeddedness was estimated at 35-40 percent. Following the El Nino winter, average water depth increased to greater than 12 inches and embeddedness decreased to between 20 and 25 percent. Further, the team identified habitat that would be useable for both spawning and rearing.

Currently 65 percent of usable rearing habitat and 86 percent of the spawning habitat in Malibu Creek are inccessible.[27] Four fish barriers have been identified that significantly reduce access to prime steelhead habitat within the Malibu Creek Watershed:

1) Rindge Dam.
2) Tunnel Falls, a natural falls near the tunnel on Malibu Canyon Road.
3) A concrete apron at the county-operated stream gauge below the mouth at Cold Creek.
4) A concrete road crossing in Century Ranch State Park.

According to the 1989 Entrix Steelhead Habitat assessment, by allowing fish passage at these four barriers, the watershed will realize a 590 percent increase in spawning habitat and a 180 percent increase in rearing habitat for steelhead trout or about 4.8 miles of new habitat. "A healthy population of 145

Malibu Creek Watershed: A Framework for Monitoring, Enhancement and Action

606 Studio **California State Polytechnic University, Pomona** **August 1998**

juveniles of three year classes of steelhead utilize Malibu Creek downstream from Rindge Dam, which is particularly significant because the study was conducted in August during the third year of drought conditions."[28] This study suggests that the steelhead population declines as you move further downstream closer to the ocean as a result of declining habitat quality in the lower reaches of Malibu Creek and increased numbers of largemouth bass, a predator to juvenile steelhead. The Steelhead investigations, conducted by Entrix Incorporated, suggest that the steelhead population in Malibu Creek can expect at least a three-fold increase if full habitat is utilized both above and below Rindge Dam.

The best available spawning habitat on Malibu Creek occurs 2 kilometers below Rindge Dam stretching above the dam to the confluence at Cold Creek. These locations were selected because they have adequate water depths and velocities, accessible cover, excellent grain size distribution of substrate materials, low degrees of embeddedness.[29]

The best available rearing habitat was focused in narrower canyon stretches having deeper, swifter flowing water and provided better cover than was found in valley sections. These areas also exhibited more abundant and diverse populations of aquatic macroinvertebrates, and shorter pool lengths ensuring adequate transport of food downstream.[30]

Further, several studies have been conducted regarding fish passage over the Rindge Dam. The Army Corps of Engineers recently completed a reconnaissance study to determine the plausibility of providing access to steelhead above Rindge Dam. If they receive approval and $ 750,000 of funding from Congress the following alternatives will be researched:

1. Complete removal of the dam with the sediments being disposed of in a landfill. The cost of this alternative is estimated at 40 million dollars. If sediments can be used to replenish beach sands or create shallow water habitat nearby, the cost estimate drops to 25 million dollars.
2. Installing a conduit or pipe through the dam which will provide passage. The estimated cost is 10 million dollars.
3. Constructing a hydraulic lift to allow access is estimated to cost 1 million dollars.[31]

Alternatives that have been previously considered include:

1. Notching the dam in intervals and allowing the sediments to flow downstream in a semi-regulated manner.
2. Reestablishing the reservoir for use as fire suppression water storage.
3. Drilling into the top 10 feet of sediments and installing pipes to utilize the dam as a giant sand filter for treatment of surface water during dry weather. This last alternative is proposed until a time when the dam could be removed.

The current consensus among knowledgeable stakeholders is the dam needs to be removed and that lifts to provide passage over the dam will be too unreliable, and, due to poor road access, impossible to maintain. Opposition by Ron Rindge, a descendent of the Rindge family, to keep the dam and get it registered, as a historic structure is ongoing.

Restoration of California's anadromous fish populations is mandated by The Salmon, Steelhead Trout, and Anadromous Fisheries Program Act of 1988 (SB 2261). This act establishes State policy to increase significantly the natural production of salmon and steelhead and directs the California Department of Fish and Game to develop a program that strives to double the naturally spawning anadromous fish populations by the year 2000. Governor Wilson, in his April 1992 Water Policy Statement, specifically states the urgent need to provide safe reliable water supplies to restore fish and wildlife resources among other things.

Recommendations to Increase and Enhance Steelhead Habitat

This section makes recommendations, that if implemented, will increase and enhance steelhead habitat throughout the Malibu Creek Watershed. Section 6 details recommendations that address the issues identified during the course of this project. Implementing these alternatives will improve water quality and decrease the concentration of pollutants that reach receiving waters. These issues need to be addressed over the entire watershed.

The different alternatives on how to address Rindge Dam have been researched with the following conclusion. The dam is a significant feature of Malibu but serves no useful function at present time. It is not practical and would likely be costly to revitalize the structure to be used for fire protection or irrigation. To maintain the dam would require frequent dredging of sediments due to the highly erodable soils and frequent fires in the area. Removal of the dam is the preferred option. Leaving the spillways and creating an overlook site on Malibu Canyon Road that provides information about the dam is recommended. Ideally, a use for the sediments contained by the dam would be found. This project should also include habitat restoration in the flat area immediately preceding the dam and the riparian zone directly above and below the dam. Further, the restoration and any feasibility study should include passage over tunnel falls.

Quickly designate Malibu Creek, Las Virgenes Creek, Cold Creek, Triunfo Creek and their tributaries as critical habitat areas. This should include at minimum a 200-foot buffer zone on each side of the creek.

Cold Creek has been identified as suitable rearing habitat for juvenile steelhead in their first year when they are most vulnerable. Following winters with significant rainfall, migration corridors are more than deep enough to accomodate steelhead trout. The diversity of macroinvertebrates was greater on Cold Creek as compared to Malibu Creek. The barriers to fish passage are relatively small and could be overcome with small inexpensive projects. Cold Creek offers a perennial source of cool clean water that must be protected to enhance the ability of species survival.

Triunfo Creek has the best diversity and abundance of macroinvertebrates of all areas studied. While Century Dam currently poses an obstacle to the best habitat along this reach, it is owned and operated by California Department of Parks and Recreation. Fish passage can be easily and inexpensively accomplished through removal of the dam or using a fish ladder.

Small pockets of useable spawning and rearing habitat were identified on lower Las Virgenes Creek. This section of the creek has excellent riparian overhead canopy, significant amounts of large woody debris and instream habitat. The majority of this reach is owned by California Department of Parks and Recreation and will never be developed.

The findings recorded by the Cal Poly team suggest that periodically sediments are flushed from the substrate, and pools are scoured creating better and more useable habitat. Although Triunfo Creek, Las Virgenes Creek, and Cold Creek have limited useable habitat, they empty into the best available spawning and rearing habitat along Malibu Creek. Sediments being transported by Las Virgenes Creek are already causing pools to fill and substrate embeddedness of 40 percent where it converges with Malibu Creek. Critical habitat designation will ensure that future construction projects are sensitive to steelhead trout and the habitat they depend upon.

Implement Best Management Practices to reduce the impacts of upstream development, nutrient loading, and sediment loading to the watershed (See Beyond Monitoring, Section 6).

Zoning Ordinances must be changed to prevent the Agoura and Westlake subwatersheds from exceeding 25 percent impervious surfaces. Hidden Valley, Malibou Lake, Cold Creek, Las Virgenes, and Malibu Creek subwatersheds should be maintained at less than 10 percent impervious surfaces. If sensitive building practices are adopted throughout the watershed and these levels of impervious surfaces are maintained water quality and channel stability will be good.

Require all future building to address the needs of fish passage like properly designed culverts. This should be required in the Malibou Lake, Las Virgenes, Agoura, Malibu Creek, and Cold Creek subwatersheds. This will ensure that costly projects to provide fish passage are not necessary when passage above Rindge Dam is realized.

Do not channelize any more of the streams or creeks in the watershed. This increases the velocity of stream flows and can cause downstream erosion of streambanks.

Tapia should be required to further polish and cool reclaimed water before releasing it into Malibu Creek. Reclaimed water has higher than normal levels of nutrients, which can be removed, through biological treatment using a wetland. If properly designed this wetland would also cool water before it is released. This should benefit Tapia by allowing them to store water during the rainy season when the demand for reclaimed irrigation water is low, to be sold when demand increases. Dry season releases to the creek should only be permitted during sustained periods of drought to sustain a creek flow of 1 cfs. LVMWD is currently funding a research project to determine which substrate materials most effectively infiltrate and filter water.

Potential Funding Sources

The following are potential funding sources that could be used to pursue steelhead habitat monitoring and assessment programs. These funds may also be available to organizations that have identified problems that are affecting steelhead or critical steelhead habitat that wish to undertake restoration projects.

Wildlife Conservation Board Funding is authorized to make grants to public organizations and private nonprofit groups for fish and wildlife habitat restoration. This Board has the legal responsibility for disbursement of the following funds:

- California Riparian Habitat Conservation Program, are funds to protect and restore riparian habitat throughout the State through acquisition of interests and rights in land and waters.
- California Wildlife Protection Act of 1990. The Board is responsible for administering annual appropriations to the Habitat Conservation Fund of up to 11.5 million dollars. Funds may be used for acquisition, restoration, or enhancement of aquatic habitat for spawning and rearing of anadromous trout resources.
- Cal Trans Environmental Enhancement and Mitigation Program.
  Funds are available to local, state and federal agencies and nonprofit entities to mitigate impacts of modified or new public transportation facilities. Grants for individual projects are generally limited to $500,000 each but may be larger if certain criteria are met. Eligible projects include the acquisition, restoration or enhancement of resource lands (natural areas, wetlands, forests, woodlands, meadows, streams or other areas containing fish or wildlife habitat) to mitigate the loss or detriment to, resource lands within or near the right-of-way acquired for proposed transportation improvements.

Appendix F

Common Riparian Plants of the Malibu Creek Watershed

by Gerald O. Taylor, Jr.

Purpose

The purpose of this appendix is to help volunteers involved in the Stream Team monitoring program identify plant species that are found near riparian areas in the Malibu Creek Watershed. This will be especially useful in distinguishing non-native plant species from native plant species. The long term goal is to identify and map significant patches of exotic and/or invasive vegetation and areas that are degraded which may contribute excess sediments into the receiving waters throughout the Malibu Creek Watershed. The information collected will be stored on a GIS system at Heal the Bay and made available to all agencies that work in this watershed. Ideally, maps that accurately locate degraded habitat and large patches of exotic and/or invasive vegetation can be used by local agencies and organizations to develop restoration strategies and to improve water quality throughout the watershed.

The Riparian Zone within the Malibu Creek Watershed

Within the Malibu Creek Watershed there are many areas that can be described as riparian. Riparian areas are commonly found adjacent to intermittent or perennial sources of water, such as creeks, streams, ponds, lakes, springs, or seeps. This field guide covers plants found in riparian habitats and includes plants found along streams, lakes, ponds, and freshwater marshes.

Specific types of plants have evolved within riparian and wetland environments. These plants need access to the additional soil moisture that is available in these areas for their survival. Within the riparian zone, plants have varying water needs. Some plants may be located in soil that is saturated with water (cattails) or on soil that is seasonally saturated with water (alders, sycamores). Others will be located where the soil does not stay saturated (oaks, walnuts). A profile of a stream in the Malibu Creek Watershed may show willows and alders closest to the stream, sycamores a little further away, and oaks on the bank away from the stream. Intermixed among these trees may be a variety of shrubs, perennials, or annuals, each having special needs for location. The arrangement of plants along the riparian profile is never exact and there can be much variation depending upon soils, moisture, aspect, slope, geology, and other factors.

Riparian Vegetation and Stream Ecosystems

Riparian vegetation plays a vital role in the health of a watershed. The canopies of plants help to decrease the direct impact of raindrops onto the soil. Roots bind and hold the soil together. Plants aid in the improvement of water quality by slowing runoff, allowing deeper infiltration and filtering of water. With deeper infiltation and a slower release of water, the watershed is sustained with moisture over a longer period of time.

Vegetation also influences sedimentation flow. Along stream banks, the roots of plants help hold and stabilize the soil. Streamside vegetation and debris helps moderate the flow of water, creating diverse habitats where water flow is varied and aquatic life can find protected places. Organic matter from vegetation that falls into the water also provides nourishment for a wide variety of insects and aquatic wildlife. Foliage canopies of larger trees or shrubs help to shade creeks or ponds, thus keeping the water cool, increasing dissolved oxygen, and making the water more hospitable to the plants and animals that live in this environment.

The Malibu Creek riparian ecosystem has evolved over time to create beneficial relationships between plants and animals and has adapted to the geology and other natural forces of the Santa Monica Mountains. Today, great changes are taking place with human development of the watershed. Changes in the natural, seasonal flow of streams and creeks takes place because of the year-round use and runoff of water into the watershed by humans. Plants not native to the area have been introduced, and many of these, for example Giant Reed and Algerian Ivy, are out-competing and displacing native plants. Riparian areas are especially vulnerable to the invasive character of some non-native plant species, because these species choke up streams, transpire great amounts of water, change water temperature by not providing adequate shading, and develop monocultures and damaged habitats for animals. These changes affect the delicate balance and beneficial aspects of the native plant/animal relationship that has evolved over time.

Illustrations and Descriptive Information

The following plant images and descriptions represent some of the plants Stream Walk volunteers may encounter as they perform their monitoring duties. These plants are commonly found near creeks, seeps, ponds or other riparian areas and include both native and non-native plant species. The illustrations and descriptions are meant to help volunteers identify plant species during the monitoring process.

The plants are arranged alphabetically by their botanical name (genus and species). Common names for plants are also included. It is important for volunteers to list a plant by its botanical name on the monitoring form. A plant will have only one botanical name (synonyms or old names are in parentheses), but may have numerous common names that have arisen over time. Knowing the botanical name is also helpful for finding additional information on these plants, since most reference books list plants by their botanical name.

Each plant in the illustrated compendium has a scanned image and a physical description. The scanned images were created by digitally scanning leaves, flowers, or fruit into a computer desktop program. A ruler is added to show relative scale between the different images.

A listing of key species and non-native riparian and related plant species found in the Malibu Creek Watershed follows the illustrated compendium.

Exotic and/or Invasive Plants

The following are images and descriptions of seven non-native plants found in the Malibu Creek Watershed. Most of these are aggressive plants that can out-compete and displace native plants.

Giant Reed

Arundo donax

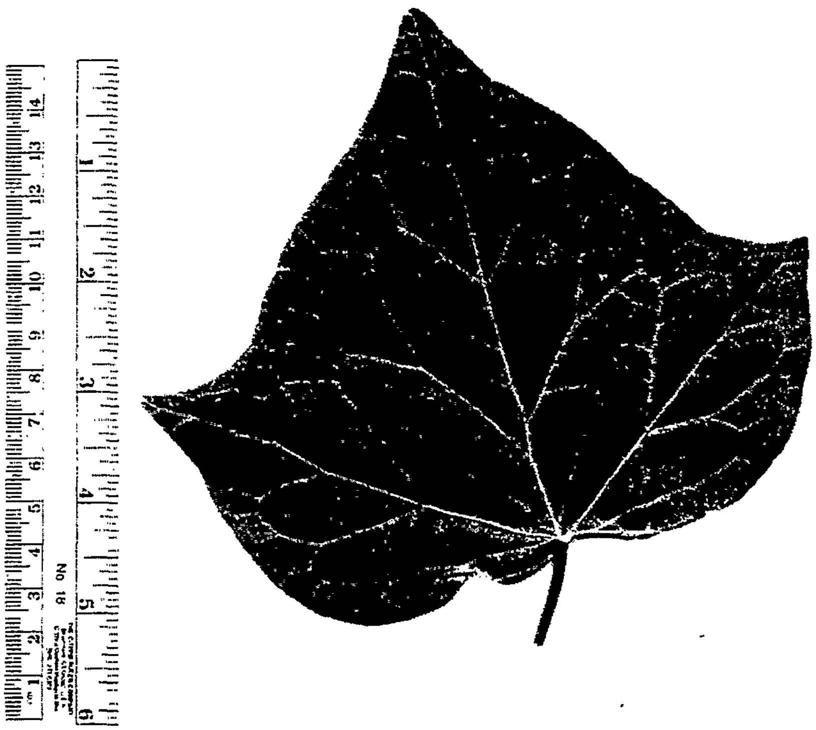
Family: Grass Family (Poaceae)
Type: An invasive, non-native, tall perennial grass.
Height: 6' to 20'
Leaves: Large, flat leaves can get up to 2' long, 1 1/2" wide.
Trunk: Thick, bamboo-like woody stems.
Flowers: Flowers occur on large flowering stalks, blooming from spring into late fall.
Fruit: Seeds
Other information:
Giant Reed is an aggressive, non-native plant that has become extremely invasive throughout the watershed. It likes moist soil and is commonly found along riparian areas, often out-competing and displacing native plants. It can uptake and transpire large quantities of water. The dried leaves can create a fire hazard. It can spread vegetatively, often becoming established when pieces of the plant break off and float downstream. Removal of this plant in upstream locations is essential for the complete eradication of this species.

Giant Reed **R0016989**

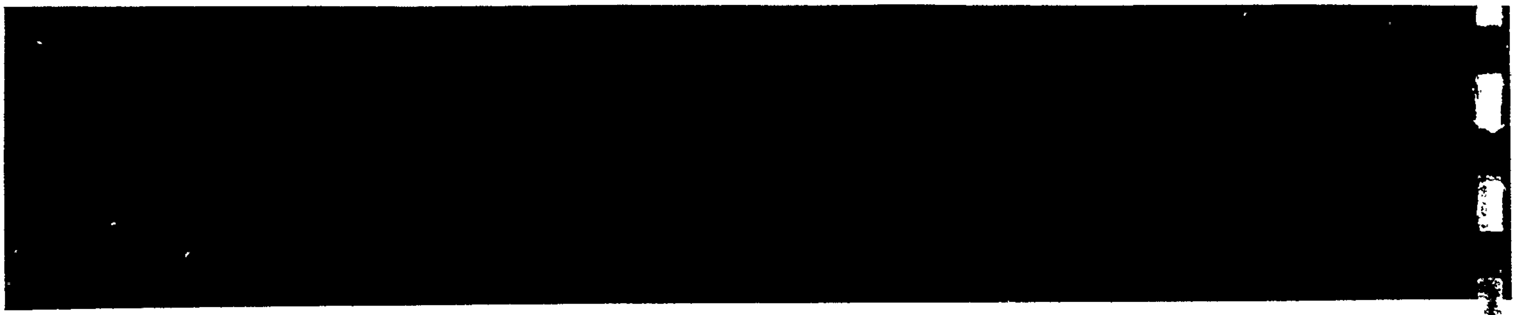
Algerian Ivy

Hedera canariensis

Family: Ginseng Family (Araliaceae)
Type: An invasive, non-native, evergreen woody vine
Height: 1' to 2'
Spread: 10' to 15'+
Leaves: 5" to 8" wide, leaves are dark green with lighter veins. Usually has 3 to 5 lobes.
Flowers: Small, greenish flowers during spring.
Fruit: A small, black berry. Berries and leaves are toxic if eaten.
Other information:
Algerian Ivy can be found in shady areas near streams or other moist places. It spreads by rooting along stems. It is aggressive often spreading and climbing over other plants.



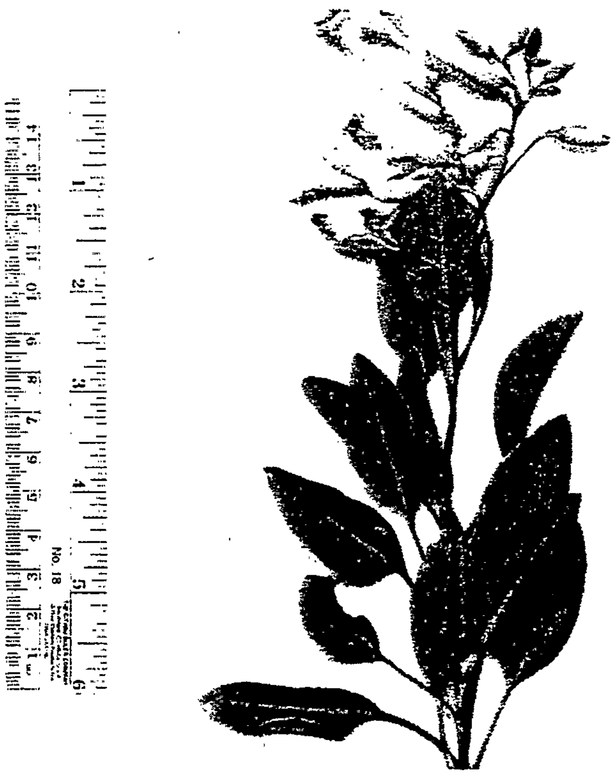
Algerian Ivy



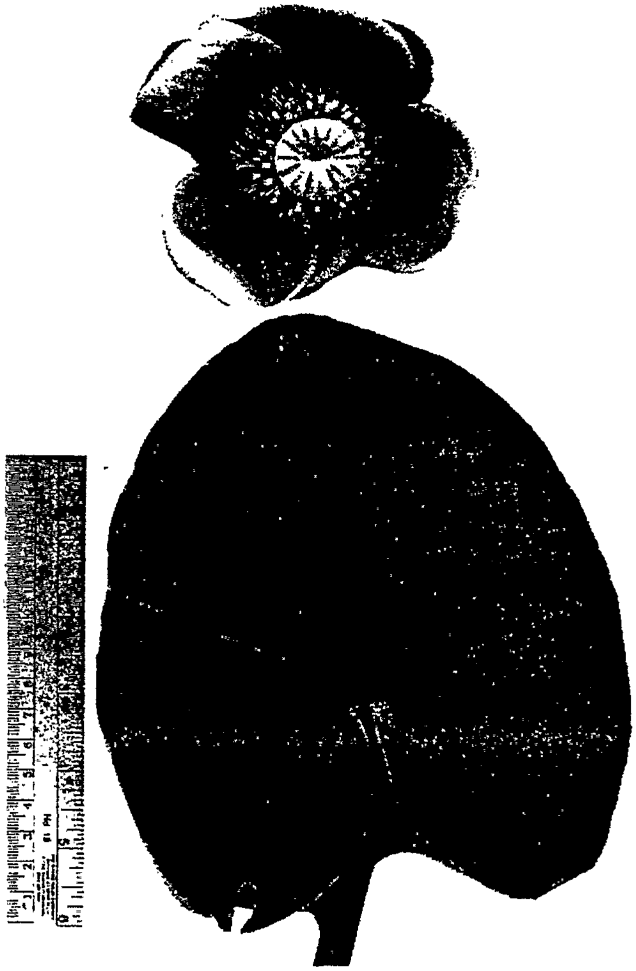
Tree Tobacco

Nicotiana glauca

Family: Nightshade Family (Solanaceae)
Type: An invasive, non-native, evergreen shrub to small tree
Height: Upright to 8' to 16'
Leaves: Alternate, 1" to 3" long leaves are ovate and bluish green.
Flowers: Yellow-green flowers are tubular shaped with a narrow flare at the tip. Can flower throughout the whole year but most prolifically during spring into summer.
Other information:
Tree Tobacco is a rapid growing, aggressive plant that is commonly found in disturbed areas but can occur along sandy streams. Tree Tobacco is native to South America.



Tree Tobacco



Yellow Pond Lily

Yellow Pond Lily

Nuphar luteum

Family: Water Lily Family (Nymphaeaceae)

Type: A non-native, aquatic, herbaceous perennial

Height: Floating on surface of water or held up to 1' above water.

Leaves: Large, 12" wide, round, green leaves with long stems.

Flowers: Yellow, 4" to 6" wide flowers occur individually on long stems held above surface of water. Flowers spring through summer.

Other information:

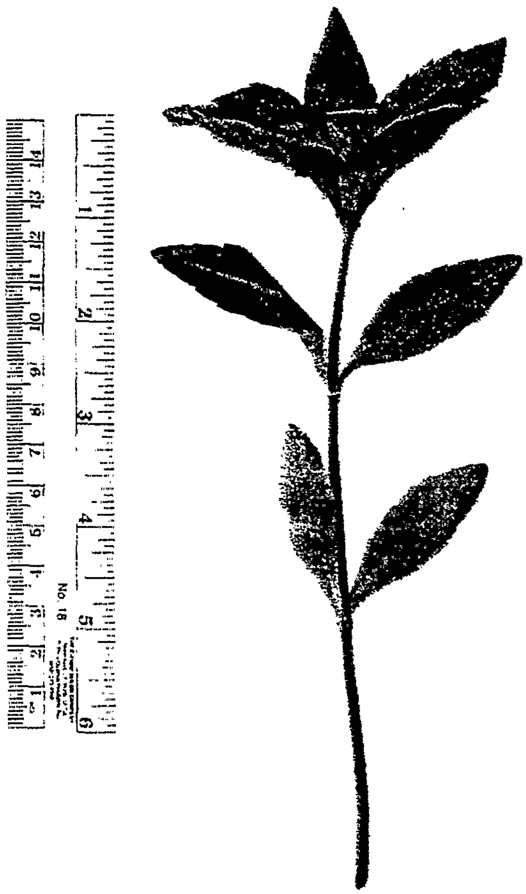
Yellow Pond Lily occurs in shallow areas of freshwater ponds and in slow moving streams. It can be seen in Malibu Lake and in Century Lake in the Malibu Creek watershed.

Castor Bean

Ricinus communis

Family: Spurge Family (Euphorbiaceae)
Type: An invasive, non-native, evergreen shrub.
Height: 5' to 15'
Spread: 5' to 15'
Leaves: Large, 1/2' to 3' wide, palmately lobed leaves on reddish stems.
Flowers: Small, greenish white flowers in clusters can occur throughout the year.
Fruit: Extremely poisonous seeds. One seed can be fatal.
Other information:
Castor Bean is an aggressive plant growing mostly in disturbed areas. It can be found in ravines or near riparian areas. Besides the seeds being extremely poisonous (one seed can be fatal), the foliage and seeds can cause allergic reactions in some people if touched.

Castor Bean



Watercress

Watercress

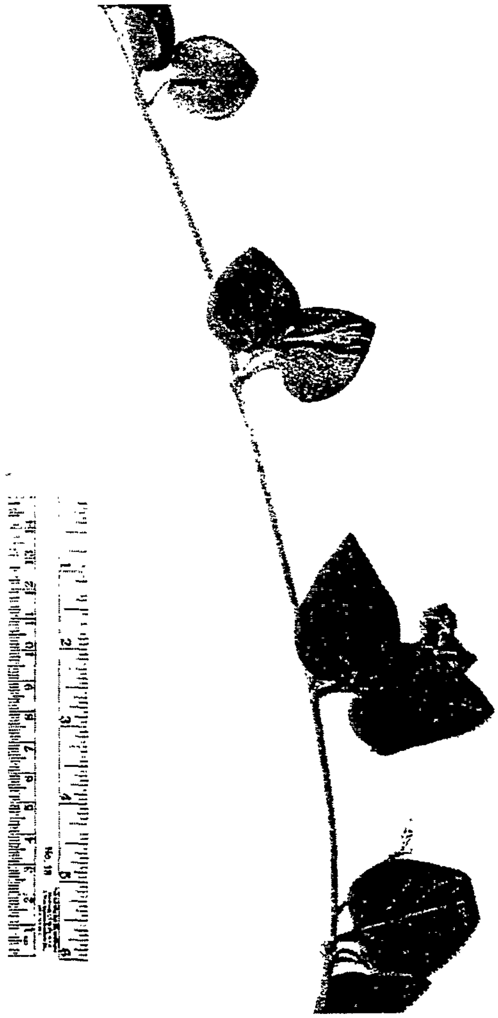
Rorippa naturtium-aquaticum

Family: Mustard Family (Brassicaceae)
Type: Non-native, aquatic, herbaceous perennial
Height: Prostrate stems can get 2' long.
Leaves: 2" to 4" long, alternate leaves are compound with 3 to 11 ovate leaflets. Stems are free rooting at leaf nodes.
Flowers: Small white flowers occur in clusters at ends of stems, spring to fall.
Fruit: Linear capsule with many seeds.
Other information:
Watercress is found on wet banks, in lakes, ponds and in slow-moving creeks. It is a native of Europe and northern Africa that has naturalized and become established throughout the Malibu Creek watershed. Its leaves are edible and are cultivated for use as edible greens. Watercress is also eaten by wildlife.

Periwinkle

Vinca major

Family: Dogbane Family (Apocynaceae)
Type: An invasive, non-native, evergreen perennial with a vine-like habit.
Height: 1' to 2'
Spread: 10' – 15'+
Leaves: 1" to 3", dark green, oval leaves.
Flowers: Attractive, 1" to 2" wide, lavender blue flowers occur during spring and summer.
Other information:
Long, trailing stems root as they spread. Periwinkle can become extremely invasive in shady, moist areas often displacing other plants. Can often be found growing near streams.



Periwinkle

R0016995

The following pages contain images and descriptions of some of the native riparian plants you may come across during your stream walk. These plants can be good indicators of a healthy riparian zone.

White Alder

White Alder

Alnus rhombifolia

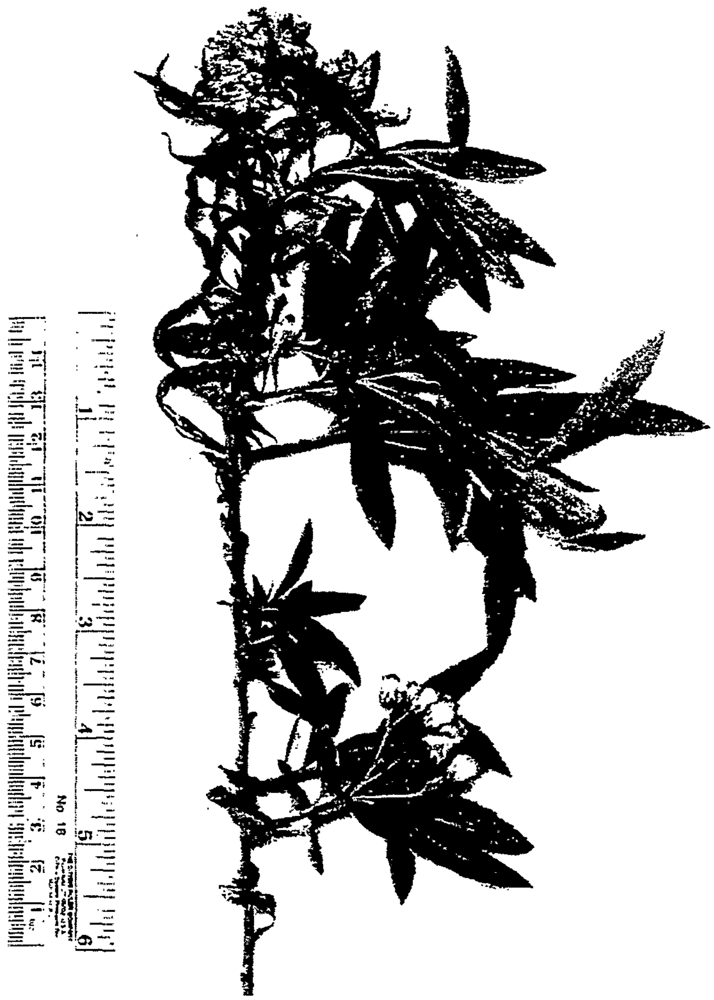
Family: Birch Family (Betulaceae)
Type: Winter deciduous tree
Height: 20' - 50'
Spread: 20' - 35'
Leaves: 2" - 4" long ovate leaves with fine or coarsely toothed margins. Dark green above, light yellowish green beneath with prominent veins.
Trunk: Single-trunk with usually smooth, whitish bark when young. Develops a brownish, fissured trunk with age.
Flowers: Female catkins and pendulous male catkins occur in early spring.
Fruit: 1" long, small woody cones develop from female flowers. These persist on tree through winter.
Other information:
A distinctive characteristic of White Alder is the "eyes" that develop along the trunk. These occur when branches fall off and leave markings that look like "eyes". Native Americans used the inner bark to make a red dye for baskets and for tanning buckskins. A tea made from the plant was used as a blood purifier, to relieve diarrhea, to ease stomachache, and to facilitate childbirth. White Alder can be found along permanent streams and creeks, close to the water's edge usually occurring in masses and groves. It has a rapid growth rate and can grow 30' in 5 - 6 years.

[redacted]

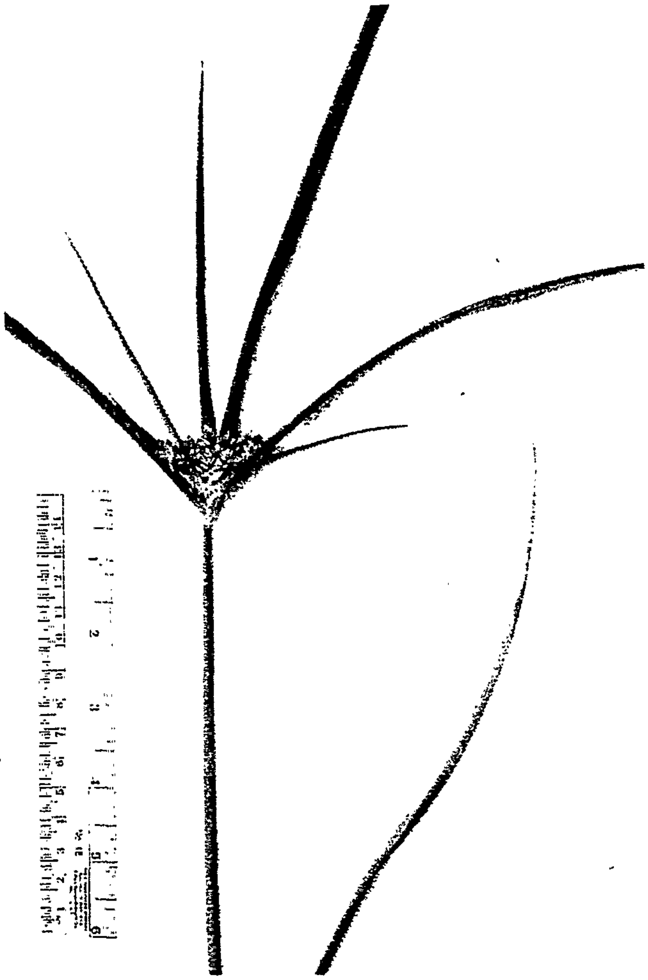
Mule Fat, Seep Willow

Baccharis salicifolia
(B. glutinosa)

Family: Sunflower Family (Asteraceae)
Type: Evergreen, erect woody shrub
Height: 6' to 12'
Spread: 6' to 10'
Leaves: Alternate 2" to 6" long, lance-shaped leaves have saw-toothed margins and are 3-veined.
Flowers: Small, whitish flowers occur in clusters at ends of stems spring into fall. Male and female flowers occur on separate plants.
Fruit: Small seeds develop on female plants.
Other information:
Mule Fat is found along lakes and perennial and intermittent streams throughout the Malibu Creek watershed. Its leaves are willow-like and are sometimes mistaken for a willow at first glance. It used to be listed as *Baccharis glutinosa* and now is known as *Baccharis salicifolia*.



Mule Fat, Seep Willow



Umbrella Sedge

Umbrella Sedge

Cyperus species

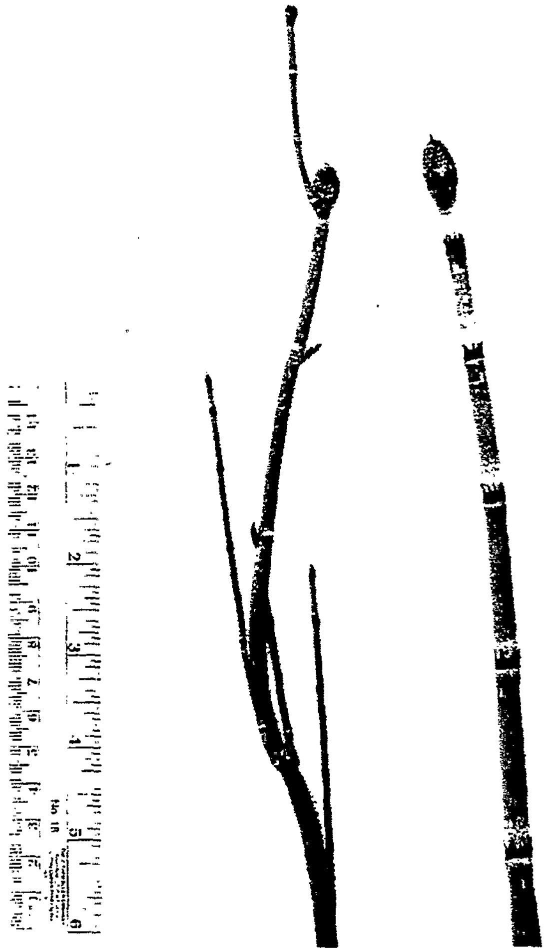
Family: Sedge Family (Cyperaceae)
Type: Annual or perennial grass-like herb
Height: to 5' tall
Leaves: On solid, 3-sided stems.
Flowers: Mostly spring into fall.
Other information:

Umbrella Sedge is found in wet and marshy places. Most of the *Cyperus* species found in the watershed are perennial, except for *Cyperus odoratus* , which is an annual plant. Umbrella Plant (*Cyperus involucratus*) is a non-native, clumping perennial, which can become invasive.

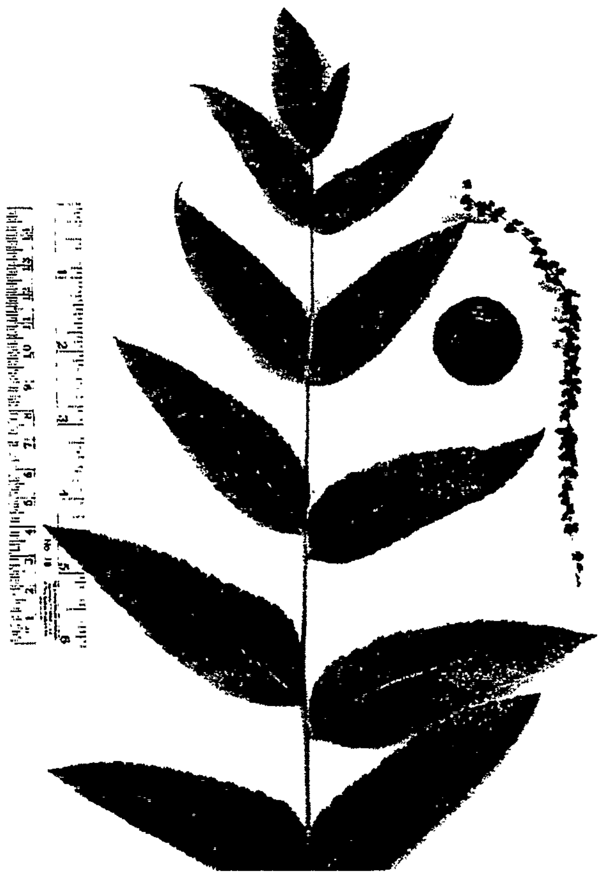
Great Horsetail,
Giant Horsetail

Equisetum telmateia

Family: Horsetail Family (Equisetaceae)
Type: Rush-like perennial
Height: Stems to 8' tall
Leaves: This plant has no leaves. The hollow, green stems with grooves take on the role of photosynthesis. Green, infertile stems branch at nodes. Brown, fertile branches do not branch.
Flowers: On 1 1/2', unbranched, fertile brownish stems, flowers occur at top on 2" to 3" long spikes during spring. Small, green infertile flowers occur on stems that branch. Fertile flowers occur on brownish stems that do not branch.
Other information:
Another plant in the genus *Equisetum* located within the Malibu Creek watershed is Smooth Scouring Rush (*Equisetum laevigatum*). Smooth Scouring Rush reaches a height of about 3' tall. Both Great Horsetail and Smooth Scouring Rush can be found in swampy places and along streams.



Great Horsetail, Giant Horsetail



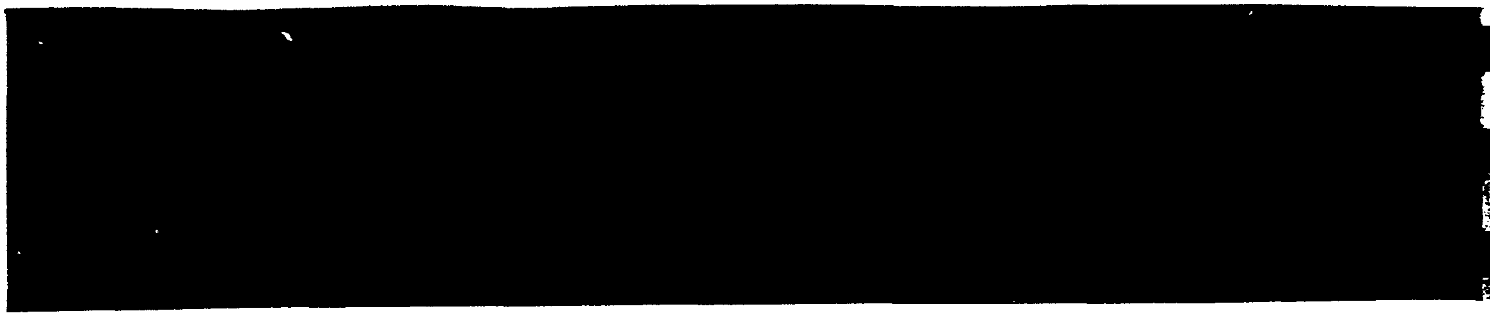
Southern California Black Walnut

Southern California Black Walnut

Juglans californica

Family: Walnut Family (Juglandaceae)
Type: Winter deciduous tree
Height: 15' to 30'
Spread: 15' to 30'
Leaves: Leaves are compound with 11 to 15 leaflets. Leaflets are 2 1/2" long with smooth to finely toothed margins.
Trunk: Can have single or multiple trunks. Trunk is rough and heavily furrowed.
Flowers: Male flower is a drooping 2" to 3" long catkin. Female flowers occur on shorter flower spikes. Flowers during spring.
Fruit: Fruit is a round, 3/4" to 1" diameter nut. The walnuts are edible but have thick shells that are difficult to crack.

Other information:
The Southern California Black Walnut occurs on north-facing slopes or along streambeds throughout the watershed.

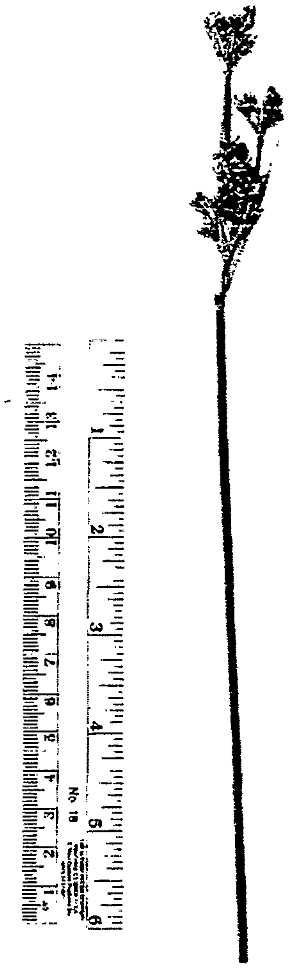


Rush, Wire Grass

Juncus species

Family: Rush Family (Juncaceae)
Type: Grass-like herbaceous perennial
Height: Varies, to 4'
Leaves: Long, round or flat narrow leaves occur from base of plant.
Flowers: Small green flowers grow in clusters, spring to summer.
Other information:

Rush is commonly found near streams, ponds, canyons or other moist areas. Baltic Rush (*Juncus balticus*) is 1' to 3' tall and can be found along Lake Sherwood. *Juncus macrophyllus* grow's up to 4' tall and can be found along streams at lower elevations within the Malibu Creek watershed.



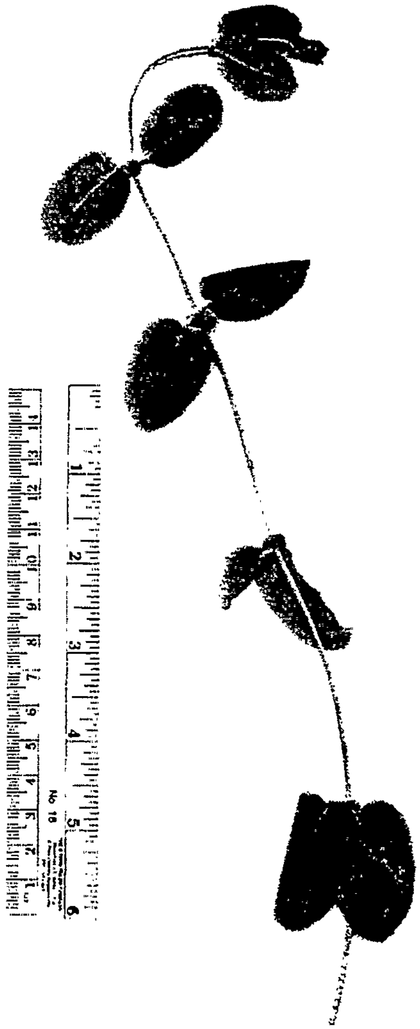
Rush, Wire Grass

R0017001

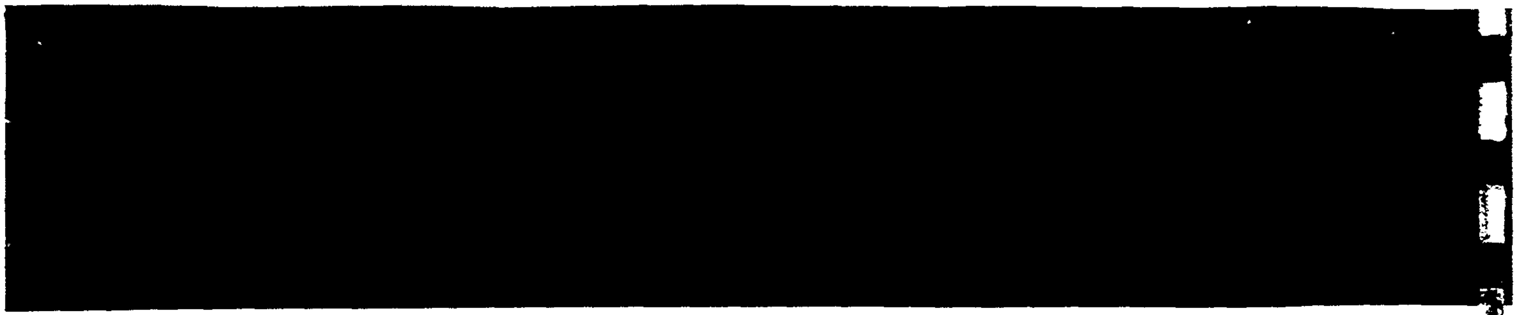
California Honeysuckle

Lonicera hispidula var. vacillans

Family: Honeysuckle Family (Caprifoliaceae)
Type: Climbing vine
Height: Can climb 6' to 18'
Leaves: Opposite, roundish, 1" to 3" long leaves. Leaves are green above and whitish and hairy beneath. Leaves near ends of stems tend to fuse together around stem.
Flowers: Large pink or purplish flowers in whorls at ends of stems occur late spring to early summer. Hummingbirds are attracted to flowers.
Fruit: Fruit is a round red berry that is edible but has a bitter taste.
Other information:
California Honeysuckle occurs near creeks and in deep canyons. Examples can be found south of Tapia Park within the Malibu Creek watershed.



California Honeysuckle



Western Sycamore

Platanus racemosa

Family: Sycamore Family (Platanaceae)
Type: A large, winter-deciduous tree
Height: 30' to 90'
Spread: 30' to 70'
Leaves: Large, broad, 10" - 12" wide, palmate leaves with 3 to 5 deep lobes. Leaves are woolly when young.
Trunk: Can have single or multiple trunks that often grow at angles to the ground. Trunk has distinctive bark that flakes leaving a smooth, whitish trunk with an attractive, mottled appearance.
Flowers: Small flowers occur in ball-like clusters in spring.
Fruit: 3/4" diameter fruit occurs in ball-like clusters of 2 to 7 per stalk and persist into fall after leaves drop.
Other information:
Western Sycamore can usually be found along perennial and intermittent streams in the Santa Monica Mountains, often occurring in large groves. Good examples can be found at Rock Pool and along Malibu Creek near the visitor's center in Malibu Creek State Park.

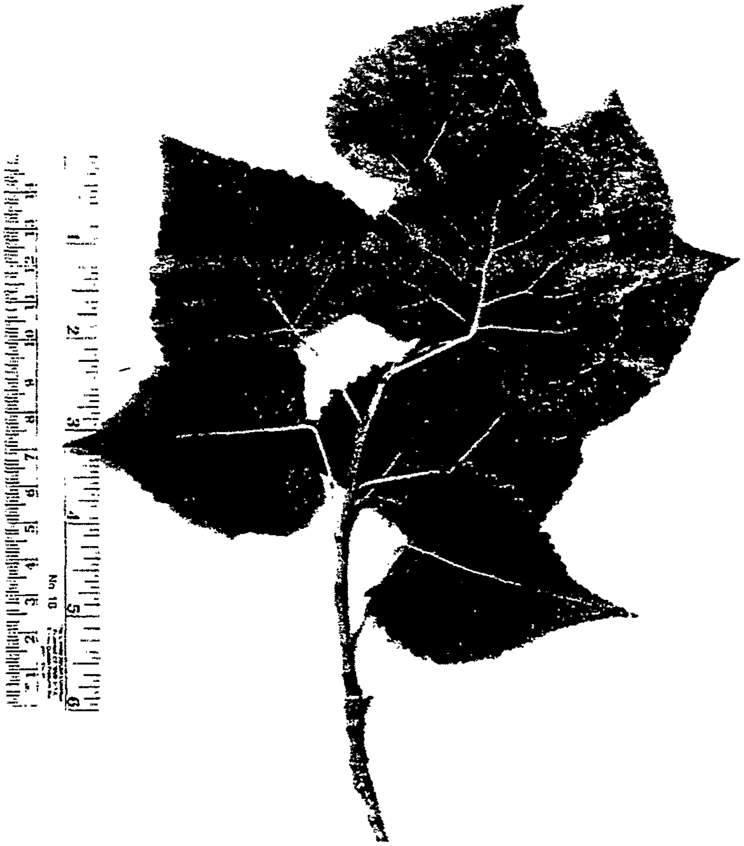
Western Sycamore

R0017003

Fremont Cottonwood, Western Cottonwood

Populus fremontii

Family: Willow Family (Salicaceae)
Type: Large, winter-deciduous tree with a very rapid growth rate of over 5' per year.
Height: 40' to 60'
Spread: 40' to 60'
Leaves: Alternate, 2" to 4" long leaves are bright green to yellowish green on both sides. Leaves are triangular shaped and occur on flattened stems. Leaves are shiny with coarsely toothed margins and turn a bright yellow color during fall before they drop.
Trunk: Trunks can develop whitish, roughly cracked bark.
Flowers: Small, inconspicuous yellowish green flowers occur during spring. Male and female flowers occur on separate plants.
Fruit: On female trees, white, cotton-like seeds develop during spring.
Other information:
Cotton-like seeds on female trees can become quite prolific and when wind-borne can cover large areas. These cottony seeds have been used for stuffed animals and for pillows. Leaves tend to flutter in the wind due to flattened leaf stems. Fremont Cottonwood can be found along permanent streams and in other moist places.



Fremont Cottonwood, Western Cottonwood

R0017004

Western Bracken Fern

Pteridium aquilinum* var. *pubescens

Family: Bracken Fern Family (Dennstaedtiaceae)
Type: Winter deciduous fern.
Height: 1' to 4'
Leaves: Large fern fronds arising upright or reclining from a spreading rhizome at base of plant. Leaves are slightly hairy beneath.
Sori: Spores occur late summer into fall.
Other information:
Western Bracken Fern is found in moist shady canyon areas at lower elevations on the coastal side of the mountains. They often occur in large masses.

Western Bracken Fern

Coast Live Oak

Quercus agrifolia

Family: Oak/Beech Family (Fagaceae)
Type: Large, evergreen tree.
Height: 30' to 70'
Spread: 40' to 80'+
Leaves: 1" to 3" long, oval leaves with spiny margins ("agrifolia" means "with spiny leaves"). Leaves are dark green above and lighter green beneath. The underside of leaf has minute brownish hairs where the lateral veins intersect with the midvein. Leaves at the outer surface of the tree canopy tend to be thick, hard and convex. Leaves in shadier interior canopy are larger, thinner and flatter.
Trunk: With age, trunks can become quite massive, up to 8' to 12' in diameter with heavily fissured bark.
Flowers: Small, reddish brown flowers occur in 1" to 2 1/2" long clusters during spring. Male and female flowers are separate but occur on same plant.
Fruit: 1" to 1 3/4" long, slender and pointed acorns with thin caps covering upper 1/3 of acorn.
Other information:
These oaks provide habitat for a wide variety of animals. Native Americans have harvested the acorns from these trees, leaching and cooking them into a mush. Early pioneers used oaks for firewood, tools, and wagons and in the production of charcoal for limekilns. They are commonly found throughout the watershed on north facing slopes, canyons, and near streams.

Coast Live Oak

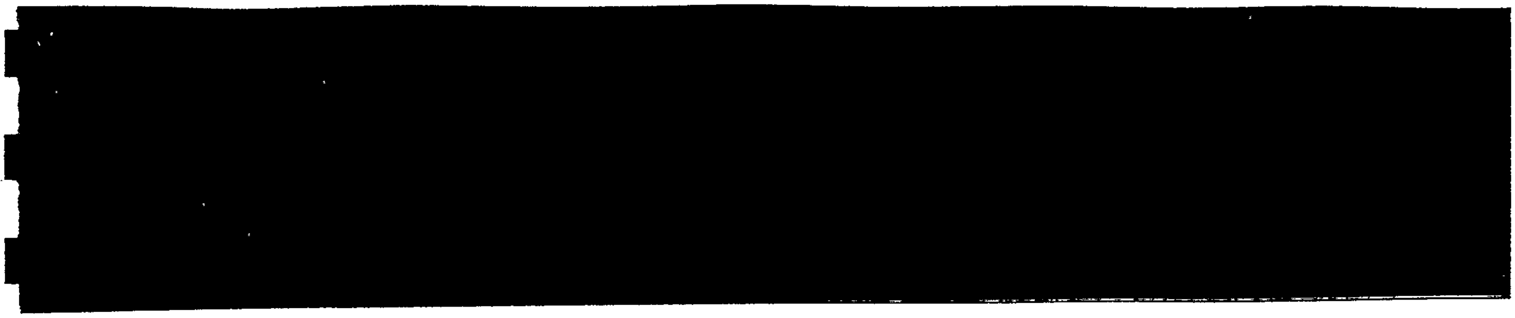
R0017006

Narrow-Leaved Willow

Narrow-Leaved Willow

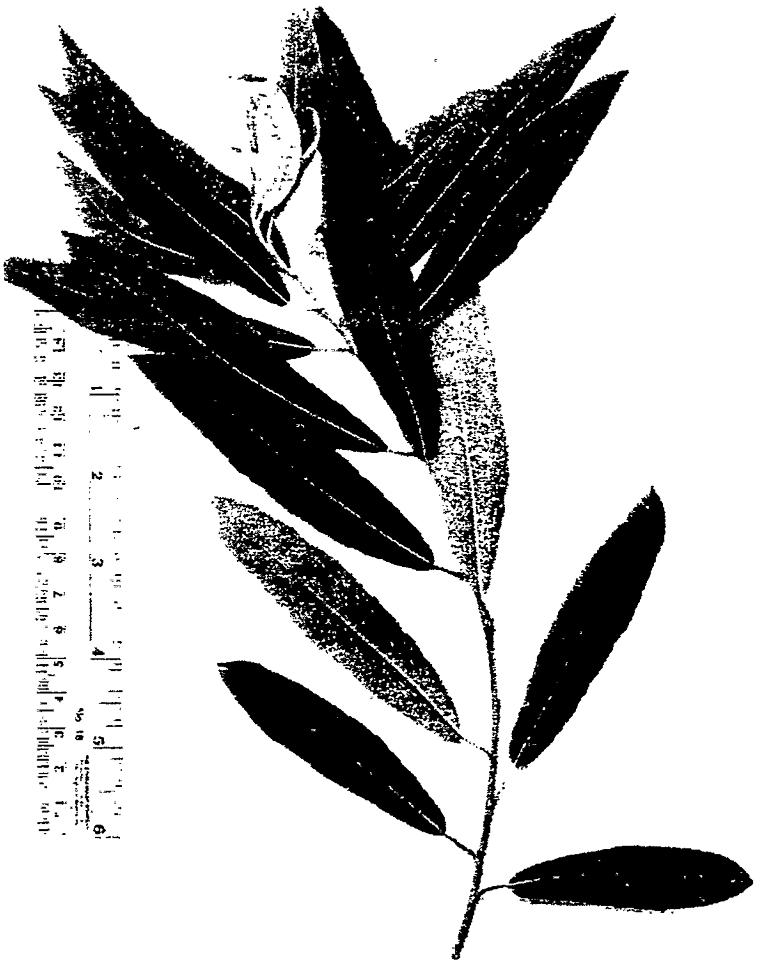
Salix exigua (S. hindsiana)

Family: Willow Family (Salicaceae)
Type: Winter deciduous erect shrub or small tree.
Height: 6' to 20'
Spread: 6' to 15'
Leaves: Narrow, linear to lanceolate leaves are 1 1/2" to 3" long and less than 1/3" wide and have short stems. Grayish hairs giving the leaf a grayish or bluish appearance cover the leaves on both sides. Leaf margins are smooth to finely toothed. Leaf twigs are brownish.
Trunk: Multiple, grayish trunks with furrowed bark.
Flowers: Flower clusters occur at the same time or after leaves appear during winter to early spring. Male and female flowers occur on separate plants. Male flowers have two stamens.
Fruit: Seeds on female plants.
Other information:
There are three willows native to the Malibu Creek watershed: Narrow-Leaved Willow (*Salix exigua*), Black Willow (*Salix laevigata*), and Arroyo Willow (*Salix lasiolepis*). Of these three, the Narrow-Leaved Willow is the easiest to identify because of its narrow leaves. It can be found in sandy riverbeds nearest to the water's edge, often occurring on sandbars at lower elevations in the watershed.



Arroyo Willow
Salix lasiolepis

Family: Willow Family (Salicaceae)
Type: Winter deciduous shrub to small tree.
Height: 10' to 20'
Spread: 10' to 20'
Leaves: Lanceolate leaves are variable in structure and appearance. They can be up to 4" long and about 3/4" wide. Some leaves may be wider above the leaf middle. Leaf margins tend to be irregular. They are dark green above and a paler whitish color beneath. Upper leaf surface may not be smooth. Leaves usually occur on yellowish twigs, but twigs may also have a reddish color.
Trunk: Usually with multiple trunks. Bark is smooth on younger plants, becoming more furrowed with age.
Flowers: Flower catkins are almost a black color and occur during late winter to early spring before leaves appear. Male flowers have two stamens. Male and female flowers occur on separate plants.
Fruit: Seeds on female plants.
Other information:
Black Willow (*Salix laevigata*) is similar in appearance to the Arroyo Willow (*Salix lasiolepis*), but can reach heights of up to 45'. Leaves throughout the tree tend to be of similar shapes, and male flowers have 4 to 5 stamens. Both can be found along permanent or intermittent streams throughout the Malibu Creek watershed.



Arroyo Willow

R0017008

Blue Elderberry, Mexican Elderberry

Sambucus mexicana

Blue Elderberry, Mexican Elderberry

Family: Honeysuckle Family (Caprifoliaceae)

Type: Winter deciduous to drought deciduous large shrub or small tree.

Height: 15' - 30'

Spread: 15' - 30'

Leaves: Compound leaves are divided into 3 to 5 leaflets. Each leaflet is 1" to 6" long with finely toothed margins. The terminal leaflet tends to be larger than the other leaflets.

Flowers: Small, 1/4" wide, creamy white flowers occur in flat-topped clusters that are 2" to 8" across, during spring into summer.

Fruit: 1/4" round, dark purplish black berries during summer. Berries have a whitish coating and are edible.

Other information:

Blue Elderberry is a distinct plant that is very noticeable especially when it is in flower. The edible berries can be eaten fresh or used to make jam, pies, or elderberry wine. Native Americans, in addition to eating the berries, used the berries for making a purple dye and the stems to make a yellow-orange dye. Blue Elderberry can be found throughout the watershed on slopes or in open riparian washes.

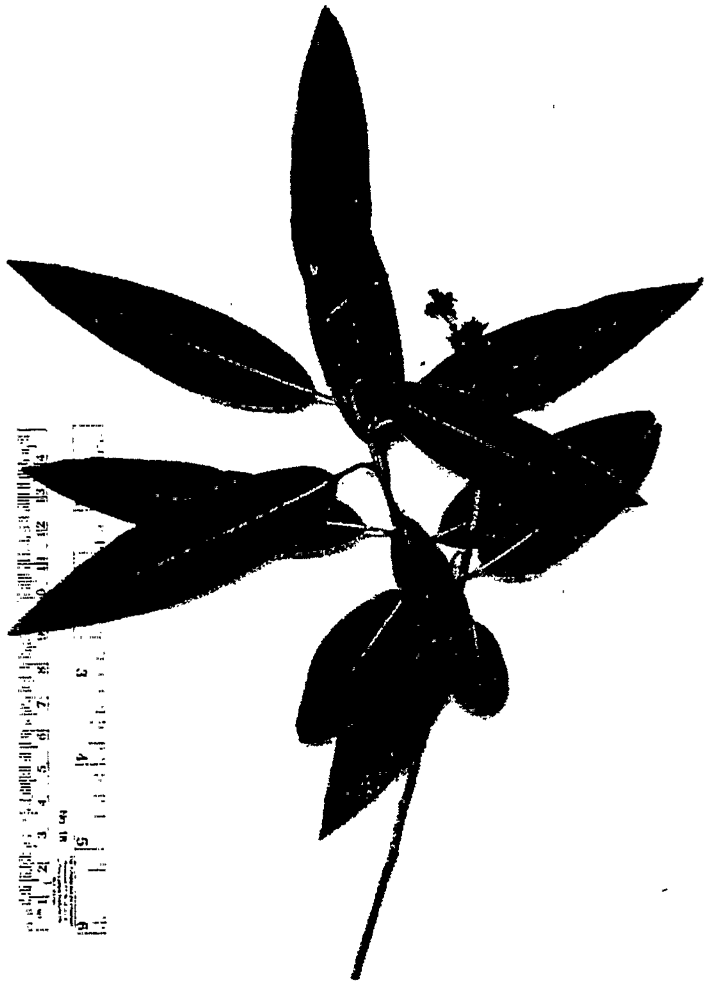
Poison Oak

Toxicodendron diversilobum

Family: Sumac Family (Anacardiaceae)
Type: A winter deciduous shrub that sometimes becomes vine-like in shady areas.
Height: 4' to 8'
Spread: Can spread 15' to 20' as a vine.
Leaves: Shiny, alternate, green leaves have three, 2" long, ovate leaflets. Leaflets usually have lobed margins but can be toothed. New growth during the spring is a shiny bronze color and during fall the leaves often turn red before they drop.
Flowers: Small, white to greenish white flowers appear during spring.
Fruit: 1/4" white berry develops during summer.
Other information:
Poison Oak is found throughout the watershed and is often found near riparian areas or other moist, shady areas. Poison Oak is a plant that everyone should learn to recognize. It secretes a juice that can cause severe blistering and itching of the skin. Look for the distinctive leaflets. Remember: "Leaves of three, let it be!" Also, be careful of contact with this plant during the winter as irritation may occur even when there are no leaves. In spite of this, Poison Oak is nevertheless a plant that deserves much respect for its ability to stabilize the soil, and create wildlife habitat for a wide variety of animals.

Poison Oak

R0017010



California Bay Laurel

California Bay Laurel

Umbellularia californica

Family: Laurel Family (Lauraceae)
Type: Evergreen large shrub to medium size tree.
Height: 20' to 40'
Spread: 20' to 40'
Leaves: 3" to 5" long, aromatic, dark green leaves.
Flowers: Small, yellowish green clusters of flowers appear winter to early spring.
Fruit: Fruit resembles a small, yellow-green, 1" diameter olive that ripens to a dark purple.
Other information:
The California Bay Laurel is a plant that is easy to identify by tearing off a piece of the dark green leaves and smelling the strong aromatic fragrance. California Bay Tree has a long history of many uses. Besides using the leaves for seasoning (use about 1/3 as much as regular bay leaves), Native Americans used the leaves to make a tea for stomach problems, and to repel fleas from their homes. It is often found in canyons and along streams and on shadier slopes throughout the watershed.

Riparian Plant Species List

As a supplement to the illustrated section of this handbook, the following is a comprehensive listing of plants found in riparian areas or nearby zones of the Malibu Creek Watershed. Plants with an asterisk (*) are not native and have been introduced to the Malibu Creek Watershed.

Botanical name	Common Name
Acer macrophyllum	Big Leaf Maple
Acer negundo	Box Elder
Adiantum capillus-veneris	Venus Hair Fern
*Agrostis viridis	Water Bent
Alnus rhombifolia	White Alder
Anemopsis californica	Lizardtail
*Apium graveolens	Celery
Apocynum cannabinum	Indian Hemp
*Artemisia biennis	Biennial Sagewort
Artemisia douglasiana	Mugwort
*Arundo donax	Giant Reed
Aster subulatus var. ligulatus	Slim Aster
Azolla filiculoides	Duckweed Fern
Baccharis douglasii	Douglas Baccharis
Baccharis salicifolia	Mule Fat
Barbarea othoceras	Winter-Cress
Berula erecta	Water Parsnip
Bidens laevis	Bur-Marigold
Carex species	Sedge
Castilleja stenantha	Stream Paint Brush
*Chenopodium ambrosioides	Mexican Tea
Chenopodium macrospermum	Coast Goosefoot
Clematis ligusticifolia	Western Virgin's Bower
Cornus glabrata	Brown Stem Dogwood
*Cotula coronopifolia	Brass Buttons
Cuscuta campestris	Field Dodder
Cyperus species	Umbrella Sedge
*Cyperus involucratus	Umbrella Plant
Datisca glomerata	Durango Root
*Delaireia odorata	Cape Ivy
*Echinochloa crusgalli	Barnyard Grass
Echinodorus berteroi	Bur Head
Elatine californica	California Waterwort
Eleocharis species	Spike Rush
Epipactis gigantea	Stream Orchid
Equisetum laevigatum	Smooth Scouring Rush
Equistetum telmateia	Giant Horsetail
Euphorbia serpyllifolia	Thyme-Leaf Spruge
*Festuca arundinacea	Tall Fescue
*Festuca pratensis	Meadow Fescue
*Ficus carica	Edible Fig
Fraxinus velutina var. coriacea	Arizona Ash, Velvet Ash
Glycyrrhiza lepidota	Wild Liquorice
Gnaphalium palustre	Lowland Cudweed
*Hedera canariensis	Algerian Ivy
Helenium puberulum	Sneezeweed
*Ipomoea purpurea	Common Morning Glory
Juglans californica	S. California Black Walnut
Juncus species	Rush, Wire Grass
Lemna species	Duckweed
Lepidaspartum squamatum	Scale Broom
*Lepidium latifolium	Perennial Pepper Grass
Leptochloa uninervia	Sprangle Top
Lilium humboldtii var. ocellatum	Humboldt Lily
Lonicera hispidula var. vacillans	California Honeysuckle
*Lotus corniculatus	Bird's Foot Lotus
Ludwigia peploides	Yellow Water-Weed
Madia elegans	Common Madia
*Melilotus albus	White Sweet Clover
*Mentha pulegium	Pennyroyal
*Mentha spicata	Spearmint
Mimulus cardinalis	Scarlet Monkey Flower
Mimulus guttatus	Creek Monkey Flower
*Nicotiana glauca	Tree Tobacco
*Nuphar luteum	Yellow Pond Lily
Paspalum distichum	Knot Grass
Petunia parviflora	Wild Petunia
Phacelia ramosissima	Branching Phacelia
Phyla lanceolata	Mat Grass
Phyla nodiflora	Mat Grass
*Plantago major	Common Plantain
Platanus racemosa	Western Sycamore
*Polypogon monspeliensis	Rabbit's Foot
Polypodium californicum	California Polypody
Populus balsamifera ssp. trichocarpa	Black Cottonwood

Botanical name	Common Name
Populus fremontii	Fremont Cottonwood
*Potamogeton crispus	Curled-Leaf Pondweed
Potamogeton pectinatus	Fennel-Leaf Pondweed
Psilocarphus tenellus	Woolly-Heads
Psoralea macrostachya	Leather Root
Pteridium aquilinum var. pubescens	Western Bracken Fern
Quercus agrifolia	Coast Live Oak
*Ricinus communis	Castor Bean
Rorippa curvisiliqua	Yellow Cress
*Rorippa naturtium-aquaticum	Water Cress
Rosa californica	California Wild Rose
Rubus ursinus	California Blackberry
Rumex salicifolius	Willow Dock
Salix species	Willow
Salix exigua	Narrow-Leaved Willow
Salix laevigata	Red Willow
Salix lasiolepis	Arroyo Willow
Sambucus mexicana	Blue Elderberry
Scirpus species	Bulrush, Tule
Scirpus americanus	Three Square
Scirpus californicus	California Bulrush
Scirpus maritimus	Maritime Club-Rush
*Senecio mikanioides	(see Delaireia odorata)
Solidago occidentalis	Western Goldenrod
*Sonchus asper	Prickly Sow Thistle
Stachys albens	White Hedge Nettle
Stachys rigida	Rigid Hedge Nettle
Symphoricarpos mollis	Dwarf Snowberry
Toxicodendron diversilobum	Poison Oak
Trifolium obtusiflorum	Clammy Clover
Trifolim variegatum	White Tip Clover
Typha species	Cat-Tail
Typha domingensis	Slender Cat-Tail
Typha latifolia	Cat-Tail
Umbellularia californica	California Bay Laurel
Urtica dioica ssp. holosericea	Stinging Nettle
*Veronica anagallis-aquatica	Great Water Speedwell
*Vinca major	Periwinkle
Woodwardia fimbriata	Giant Chain Fern

Glossary

Alternate: arrangement of leaves on stems of plant; singularly on one side and then the other; not opposite or whorled.

Catkin: a pendulous, spiked cluster of small, unisexual flowers.

Compound leaf: a leaf that is divided into different segments of two or more leaflets.

Deciduous: leaves falling off at end of a growing season, usually during fall to winter.

Drought deciduous: leaves falling off in response to drought conditions.

Evergreen: leaves remaining on plant throughout the year.

Flower: the assemblage of reproductive structures..

Herb: a plant without a woody stem.

Herbaceous: not woody; like an herb.

Lanceolate: leaves shaped like a lance.

Leaflet: a division of a compound leaf; does not have an axillary bud.

Linear: leaves long and narrow.

Lobe: a rounded division of a leaf or leaflet.

Opposite: arrangement of leaves on stems of plant; in pairs on opposite sides of stem; not alternate or whorled.

Palmate: leaf having lobes or segments radiating from a single point; finger-like.

Perennial: plant living for several years.

Pinnate: leaflets arranged on both sides of a main stem; feather-like.

Shrub: a woody plant smaller than a tree with many stems; usually under 9 feet high at maturity.

Sori: spores on the surface of a fern leaf.

Toothed: leaf margin with small, rounded or pointed lobes.

Tree: a woody plant larger than a shrub usually with a single trunk; usually 9 or more feet in height at maturity.

Winter deciduous: leaves falling off at end of growing season, usually during fall-winter.

Whorled: arrangement of leaves on stems of plant; 3 or more leaves arranged around a stem usually in a circle.

Vine: a plant without a self-supporting stem; usually trailing on ground or climbing on other plants or structures for support.

About the 606 Studio

The 606 Studio is a consortium group of faculty and third-year Master's students in Landscape Architecture at California State Polytechnic University in Pomona. The Studio is interested in the application of advanced methods of analysis and design with particular emphasis on the preservation and restoration of sensitive natural systems. Projects address serious and important ecological, social and aesthetic issues related to urban, suburban, rural or natural landscapes. They generally result in:

- Conceptual or Specific Plans
- Schematic Site Designs
- Land Use Policies
- Land Management Strategies

Approach

Projects are carried out by teams of third-year graduate students and members of the graduate faculty. Working with the direction and continuous participation of the faculty group, graduate students perform the tasks of research, analysis, planning and presentation. Design approaches vary considerably depending on the scope and character of the project. In every case, the approach fits within the framework of Ecosystematic Design as developed by the Cal Poly graduate program. This approach stresses sensitive understanding of principles of ecology, particularly the systematic behavior of material and energy flows, in relation to human uses.

Project Selection

The academic studio environment offers a unique opportunity for graduate students to explore issues and possibilities. Because it functions within an educational institution, the 606 Studio bears the responsibility to maintain academic integrity, advance the state of the art, and contribute to the public well-being. The real nature of these projects and the clients' needs demand that projects have a strong practical base, as well as display technical and professional expertise. Projects undertaken by the Studio are expected to satisfy the following criteria:

- They must address significant issues concerning resources and the physical environment, with broad implications beyond the boundaries of the project site, and sometimes beyond the immediate concerns of the client.

- They must promise to result in significant benefits to the general public.

- They should be complex, requiring the application of advanced methods beyond those routinely used in the field.

- Sufficient time and support must be available to explore all promising approaches, to do a thorough job, and to communicate the results clearly and completely.

- The results must become public information.

Project Team Description

The design team for this project consisted of four members: Mark J. Abramson, Christopher D. Padick, Eileen Takata Schueman, and Gerald O. Taylor.

Gerald Taylor received his B.S. in Landscape Architecture from California State Polytechnic University at Pomona. He is actively involved in issues related to ecological restoration, native plant habitats, and the healing and restorative properties of landscapes.

Chris Padick received his B.A. in Psychology from the University of California Santa Barbara. He is committed to promoting the concepts of sustainable agriculture and ecosystematic design.

Eileen Takata Schueman received her Bachelors of Landscape Architecture from Virginia Polytechnic Institute and State University. She is involved in advancing the profession of Landscape Architecture by applying the principles of ecosystematic design and planning.

Mark Abramson received his B.S. in Accounting from Pepperdine University. He is dedicated to improving water quality and the ecological function of watersheds by promoting biological treatment processes and the reuse of water.
