The modeling system is being tested and refined sequentially on three test sites. The paper presents the results of testing to date on a specific case study: Lake Thonotosassa, a hypereutrophic, 800-acre lake in Hillsborough County, Florida. The objective of the modeling is to allow for the assessment of various restoration strategies for improving in-lake water quality. The modeling system, which is PC based and in the public domain, will be available for public release in the fall of 1993, along with a user's manual.

Introduction

With passage of the state's Surface Water Improvement and Management (SWIM) Act of 1987, the Southwest Florida Water Management District (SWFWMD) realized a need for an integrated eutrophication model incorporating both a watershed pollutant loading model and a water-body response model. In addition, because many watershed models depend on land use and soils mapping data, a modeling system that could take advantage of data already stored in the district's geographical information system (GIS) would be useful. The stated objective of the watershed/water-body modeling project was "to select and/or link a watershed(s) and water-body eutrophication model for use in prioritizing land-use management and pollution control strategies and evaluating the effects of implementation of best management practices (BMPs) on in-lake water quality and natural systems."

A variety of watershed models exist that make it possible, within limited degrees of certainty, to evaluate the effects of land-use practices on receiving waters. These models are used to prioritize watersheds that contribute the greatest loading to a water body. When coupled with an appropriate model of the receiving water body, the model system can be used to predict how changes in land use will affect the receiving body, both in terms of water quantity and quality.

A watershed model is an important planning tool for evaluating the contributions from existing conditions and projecting contributions under different scenarios. A watershed/water-body model system allows those using them to make decisions regarding alternative land use, zoning, treatment, and BMP options, thus altering constituent loadings to a receiving water body.

Water quality/ecological models are designed to mimic in-waterbody dynamics as the result of inputs and to predict trophic state or other conditions of interest. These models allow the modeler to predict lake conditions based on known or projected inputs, and thus evaluate how changes in loading will affect the overall health of a water body. Decisions with regard to how much of a load reduction is required to produce desired in-lake effects can be made, and the benefits of implementing a particular corrective strategy can be assessed.

From a water-body management perspective, it is desirable to have as a decision tool a linked model that couples the attributes of both watershed and water-body models. With such a model, it would be possible to evaluate how changes in land use will, for example, affect the trophic state (and other states) of a surface water body.

Model Attributes

Prior to selecting a consultant, district staff developed a list of 13 desirable attributes of a linked watershed/water-body model (LWWM):

- Data can be input directly into the linked model from the district's GIS (ARC/INFO) database.
- The model system should consist of "off the shelf" watershed and water-body models, although some customizing may be required. (Proprietary software is not acceptable.)
- Calibration and validation data requirements should not be excessive.
- The model can be applied to most Florida aquatic systems with the watershed component suitable for estuarine systems.
- The model has a storm event or seasonally based watershed component, yet it is capable of yielding annualized values.
- The output of the watershed model component should be fully compatible with the input of the water-body model component.
- The model should be user-friendly, menu-driven, interactive, and fully documented.
- The water-body model considers the physical, chemical, and biological parameters and processes necessary to simulate the eutrophication process and attendant water quality conditions.
- The model is sensitive to eolian, sediment, and ground-water inputs.
- The water-body model should consider the temporal and spatial variation as required to simulate critical water quality conditions and processes.
- The model should be sensitive to trophic dynamics and exchanges between trophic levels.
- The water-body model should predict the trophic state using existing empirical relationships already developed for Florida lakes.

Model Selection

Dames and Moore, Inc., was selected to develop the district's LWWM. The district also established a modeling technical advisory committee (TAC) composed of various recognized modeling and GIS experts from other agencies, academia, and private consulting firms. The primary goal of the TAC was to aid the district and its consultant in finalizing modeling goals and the list of desirable model attributes to be used in an evaluation of existing candidate models. One of the initial tasks accomplished by Dames and Moore was a literature and model comparison report (1) with recommended models to be used in the proposed LWWM. This review focused on model capabilities with regard to the overall LWWM project objectives and did not include a rigorous investigation of the background and theory behind each model.

Dames and Moore, following the examples of Basta and Bower (2) and Donigian and Huber (3), developed specific evaluation criteria to objectively review candidate models consistent with district objectives. Dames and Moore, with the aid of the TAC and before identifying available models, developed four criteria to be used on a preselection basis to identify candidate models for further consideration:

- The models must have written documentation.
- The models must be maintained, either formally (i.e., funded model caretaker) or informally (through active use and application).
- The models must be PC based or have the capability of being easily transportable to the PC environment.
- The models must be nonproprietary.

Based on the above criteria and considering district requirements for review of certain specifically named models, a first-cut list of candidate models was developed followed by a final list of candidate models (Table 1).

The modeling TAC was relied on heavily to eliminate models from further consideration and ultimately arrived at the two selected models, SWMM and WASP4. The rationale for eliminating certain models is detailed by Dames and Moore (1); it was decided that the modeling system should rely on a single watershed model. After considerable discussion, certain models were

eliminated because of their primarily rural or agricultural applicability, other models were eliminated on the basis of limited maintenance, and considerable in-house debate and discussion centered on the advantages and disadvantages of "mechanistic" versus "empirical" type models. Despite its selection, there was concern that SWMM was too complicated to use without extensive training and experience and that this would affect the desirable attribute of being user friendly and easy to apply (or misapply); this was considered a disadvantage common to all "mechanistic" models considered. SWMM is primarily an urban model, and although it has been applied in nonurban areas successfully, the erosion and sedimentation capabilities are not as detailed as most rural or agricultural models. Another disadvantage of SWMM is that subbasins must be defined homogeneously with respect to land use for the water quality routines, and this restriction would limit to some extent the enhancement that could be easily afforded by a GIS linkage (1). Similar type considerations as those mentioned above were used to eliminate candidate water-body models from further consideration.

Eventually, WASP4 was selected as the appropriate "mechanistic" model to complement the watershed loading model. The TAC noted that the model was well maintained, tested, and documented. Although identified as the most complex of the selected water-body models, it was also the most flexible because of its ability to simulate processes, which allows it to be used at either a screening or predictive level depending on the availability of data, the experience of the user, and the objective of the application. Although flexible, the TAC indicated that WASP4 was still perceived as being extremely data intensive (1).

Ultimately, SWMM and WASP4 were selected because these models were determined to be "sufficiently complex to be usable for the most data intensive studies, but have the capability of 'turning off' or 'zeroing out' components such that the model can be made simple. The models are public domain, and both are supported by the EPA. In addition, full documentation is available for both models, and they have each been well tested, including several applications in the southwest Florida area" (1). The models selected were not the best for every application; however, they were considered to be those that best met the objectives of the SWFWMD.

Linked Watershed/Water-Body Modeling System Development

The LWWM incorporates three major environmental modeling components:

- Runoff (point and nonpoint)
- Hydrodynamic/Hydraulic routing
- Time variable water quality modeling

In essence, the LWWM operates as follows:

- It obtains land-use and soil-type information from ARC/INFO coded output.
- It incorporates this information into the runoff component of SWMM.
- SWMM calculates event-driven runoff loads of both point and nonpoint sources.
- The LWWM uses the hydrodynamic model, RIVMOD, to describe the longitudinal distributions of flow in the investigated water body.
- WASP4 incorporates these loads, flow distributions, and water quality information and simulates water-body interactions.

A schematic of the above program linkage is shown in Figure 1.

The LWWM was developed to allow engineers and scientists to rapidly evaluate the effects of both point and nonpoint source loads on receiving waters. The LWWM model obtains land-use information from a GIS that can be used to swiftly generate land-use and soil-type data for the runoff component of the LWWM system, SWMM. The SWMM model calculates event-driven runoff loads for both nonpoint and point sources. This time series of loads and water quantity runoff is then used as input for the receiving water model, WASP4 (EUTRO4). The information generated by the models will be accessible to users via interactive graphs and other user-friendly interfaces.

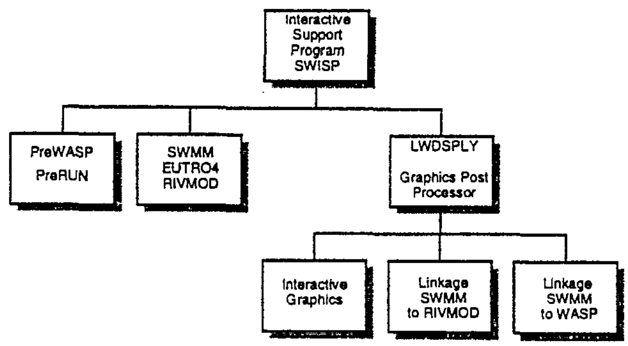

Figure 1. Linked watershed/water-body model (LWWM).

Geographical Information System Interface

A GIS is a computer program used for the entry, management, analysis, and display of geographic or mappable information. GIS systems typically include all of the functions of a computer-aided design (CAD) system, as well as the powerful analytical and modeling capabilities of a full-featured relational database. The power of a GIS lies in its ability to derive problem-solving information from existing data through such techniques as map overlays and modeling, and to store this information in an organized, usable form.

GIS analytical techniques are applied to generate automatically the input data sets for the SWMM watershed model. The software used for development of these data sets is ARC/INFO, an industry-standard GIS from Environmental Systems Research Institute (ESRI). This software is the primary GIS platform in use at the SWFWMD and at all other water management districts throughout the state. Several other federal, state, regional, and local agencies have also adopted ARC/INFO as a standard and are preparing comprehensive geographic databases in this format. The SWFWMD has compiled an extensive geographic database of the entire district in an ARC/INFO format, including detailed coverages for the U.S. Department of Agriculture Soil Conservation Service (SCS) soils, land use and cover, and basin boundaries. These data are compiled using automated ARC/INFO techniques to generate an input data file for the LWWM.

SWMM

SWMM (4) is a comprehensive mathematical model for the simulation of urban water quantity and quality in storm and combined sewer system. All aspects of urban hydrologic and water quality cycles are simulated. SWMM was developed between 1969 and 1971 by a consulting team under contract with the U.S. Environmental Protection Agency (EPA). It was one of the first such models and has been continually maintained and updated. The SWMM model is perhaps the best known and most widely used urban quantity/quality models in existence today.

SWMM simulates real storm events on the basis of rainfall hyetographs, land use, topography and system characterization to predict outcomes in the form of quality and quantity values. SWMM is composed of various computational blocks that can be run as stand-alone programs. The LWWM simplifies this process by selecting the appropriate blocks to run. The blocks used by LWWM and their function are as follows:

- *Runoff block:* Performs hydrologic and water quality modeling with elementary hydraulic routines.
- *Combine block:* Combines interface files to aggregate results of multiple runs.
- *Rain block:* Processes National Weather Service (NWS) precipitation data from magnetic tape or disk.

All other computational blocks within SWMM are either not applicable to the LWWM model or their function is already incorporated within the LWWM (i.e., graphic and tabular processing of output).

The LWWM model uses SWMM Version 4.2 but has been tested successfully with older versions.

RIVMOD Implementation

RIVMOD is a dynamic numerical, hydrodynamic riverine model that describes the longitudinal distributions of flows in a one-dimensional water body through time. The primary criteria for selecting RIVMOD is the need to describe spatially varying flows in a water body through time. The model is applicable to rivers, streams, tidal estuaries, reservoirs, and other water bodies where the one-dimensional assumption is appropriate. RIVMOD solves the governing flow equations in a manner that allows prediction of gradually or highly varying flows through time and space. The model has the capability of handling flow or head as boundary conditions. The specification of head as a boundary condition allows use of the model where an open boundary is required (e.g., an estuary or a river flowing into a lake). Algorithms are employed in RIVMOD to allow it to provide WASP4 with flows, volumes, and water velocities.

WASP Implementation

The WASP4 modeling system (5) was designed to provide the generality and flexibility necessary for analyzing a variety of water quality problems in a diverse set of water bodies. The model considers the hydrodynamics of large branching rivers, reservoirs, and estuaries; the mass transport in ponds, streams, lakes, reservoirs, rivers, estuaries, and coastal waters; and the kinetic interactions of eutrophication-dissolved oxygen and sediment-toxic chemicals.

WASP4 is a dynamic compartment modeling program for aquatic systems, including both the water column and the underlying benthos. The time-varying processes of advection, dispersion, point and diffuse mass loading, and boundary exchange are represented in the basic program. The flexibility afforded by the Water Quality Analysis Simulation Program is unique. WASP4 permits the modeler to structure one-, two-, and three-dimensional models; allows the specification of time-variable exchange coefficients, advective flows, waste loads, and water quality boundary conditions; and permits tailored structuring of the kinetic processes, all within the larger modeling framework, without having to write or rewrite large sections of computer code.

WASP4 simulates the movement and interaction of pollutants within the water using two programs to simulate two of the major classes of water quality problems: conventional pollution (involving dissolved oxygen, biochemical oxygen demand, nitrogen, phosphorus, and eutrophication) and toxic pollution (involving organic chemicals, metals, and sediment).

Because of WASP4's generalized framework and dynamic structure, it is relatively easy to link it to other simulation models. WASP4 was modified to read loads from an external file created by SWMM. This allows WASP4 to update its point and nonpoint source loading information daily.

SWMM/WASP Interactive Support Program (SWISP)

SWISP (Figure 2) is an interactive, menu-driven user environment that allows for the easy execution of the LWWM system of programs. SWISP allows you to view and edit WASP/RIVMOD/SWMM input datasets as well as execute and postprocess the results. SWISP is the Windows of the LWWMs; once the user executes SWISP, the user can perform all functions related to all the simulation models. SWISP provides file management, which allows the user to select a file or a set of

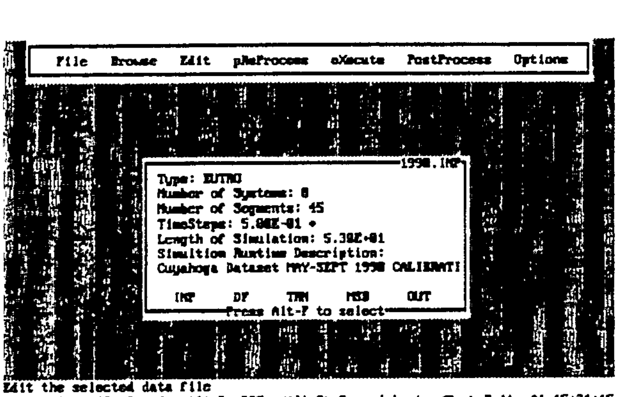

Figure 2. SWMM/WASP Interactive Support Program (SWISP).

files to activate for manipulation and/or execution. SWISP automatically loads the correct simulation model based on the type of input dataset selected; upon execution of the model, SWISP provides the input data file names that will be executed. When the simulation is completed, SWISP is automatically reloaded so that the results may be postprocessed.

SWMM Runoff Preprocessor (PreRUN)

The PreRUN program (Figure 3) was developed to aid the user in the development of SWMM RUNOFF block input datasets (SWMM Version 4.2x and higher). PreRUN provides intuitive data entry forms that successful guide the user through the development of syntactically correct datasets. Additionally, the PreRUN program can import a GIS file that is created before executing the preprocessor. The GIS interface file provides soil-type and land-use classifications to the PreRUN program so that the user can quickly give parameters to the SWMM Runoff block. PreRUN is designed to work with or without the GIS interface file.

Sub-basin area in acres

Figure 3. SWMM Runoff Preprocessor (PreRun).

The power of the PreRUN preprocessor lies in its ability to import a GIS interface file. The GIS file contains land-use and soil classification data for user-delineated watershed subbasins; this information is used by PreRUN to develop area weighted calculations for the SWMM model.

PreWASP Interactive Preprocessor (PreWASP)

The PreWASP program (Figure 4) aids the user in the development of a WASP4 eutrophication input dataset. The preprocessor provides predefined environments (ponds, lakes, rivers, estuaries) that can be modified to match site-specific geometries, or the user may elect to build one from scratch. The PreWASP program allows the user to rapidly develop an input dataset by providing forms that can be filled out quickly using several "Quick Fill" edit functions. The PreWASP program allows the user to select the level of complexity at which to apply

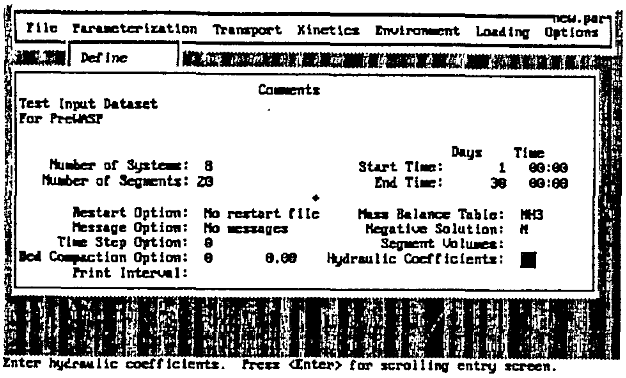

Figure 4. PreWASP Interactive Processor (PreWASP).

the model and provides data forms that are needed to accomplish that level of complexity.

Linked Water-Body/Watershed Postprocessor (LWDSPLY)

The interactive graphical postprocessor LWDSPLY allows the user to rapidly visualize the results of WASP, RIVMOD, DYNHYD, and SWMM simulations. LWDSPLY and SWISP are the only software needed to process the large array of result files that can be produced from simulations of the models contained in the LWWM. LWDSPLY allows the user to view the results both graphically and tabularly and has options for exporting data to spreadsheets. LWDSPLY has the capabilities to process more than one simulation result file at a time (the files must be from the same model), and allows the plotting of up to four graphs on the screen simultaneously. These four plots (view ports) can be manipulated individually to show different results. As with all the programs, context-sensitive help is available at any time within the program by simply pressing F1 for help or ALT-H for a listing of the keyboard map (Figure 5).

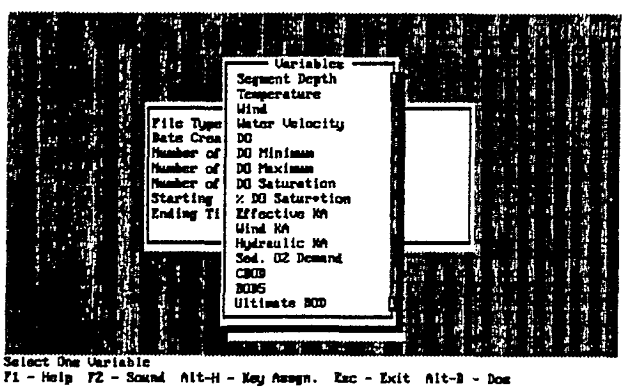

Figure 5. Linked Water-Body/Watershed Postprocessor (LWDSPLY).

The LWDSPLY program allows the user to view (Figure 6), plot, and export information very rapidly. All simulation results can be plotted or written to an ASCII text table or exported to a spreadsheet file. LWDSPLY also provides the algorithms for formatting the output of one model into the input of another.

Linking SWMM to WASP4

SWMM and WASP4 are linked using the LWDSPLY program. The linkage is generic and allows the user to link SWMM results to either the WASP organic or eutrophication model. This linkage is accomplished by creating a SWMM combine block interface using the ASCII combine block option. PreRUN is set to create this file by default. The user must select the WASP4 (TOXI or EUTRO) model with which the SWMM file is to be linked; this allows LWDSPLY to configure itself for the correct output.

Once the appropriate linkage type has been selected, the user is then required to map the appropriate SWMM conduit IDs to WASP segments (Figure 7). Note that you can map more than one conduit's ID to a WASP segment; LWDSPLY will combine the output. LWDSPLY will not check any errors regarding the mapping, so the burden is on the user to fill this table out correctly. The figure below shows the data entry screen for the basin to segment mapping. Note that all the conduit IDs do not need to be mapped out to WASP segments; the user only needs to be concerned with the conduits that affect the water body.

Once the conduit to segment mapping has been completed, the SWMM runoff constituents must be mapped to the WASP4 state variables. The user must map the SWMM state variables to the WASP state variables. The linkage allows the user to fractionate a SWMM state variable to several WASP state variables. The example given below shows the mapping of total nitrogen (calculated by SWMM) into three state variables of WASP's EUTRO4 (NH_3, NO_3, and organic nitrogen). To accomplish this, the user must specify the percentage of the total SWMM constituent runoff mass that will go into each WASP system. This option is presented to the user because SWMM typically calculates mass runoff for total nitrogen and total phosphorus, while WASP needs nitrogen loaded as ammonia, nitrate, and organic nitrogen, as well as phosphorus loaded as orthophosphate and organic phosphorus. There is no error checking done here. The percentages converted can be less than or greater than 100 percent.

When the user is completed with the mapping functions, LWDSPLY will prompt the user for a filename to which to write the nonpoint source interface file. WASP expects the nonpoint source files to have the extension .NPS.

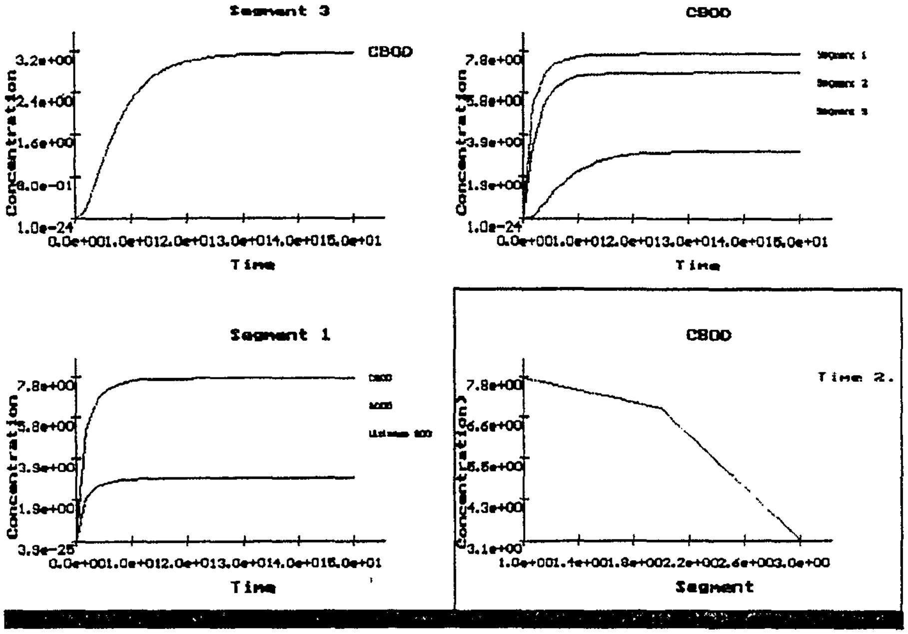

Figure 6. Viewing data in the LWDSPLY.

Model System Application—Lake Thonotosassa, Florida

Study Area Description

Lake Thonotosassa is located in northeast Hillsborough County, Florida (Figure 8). The lake has a surface area of 813 acres, with a maximum depth of approximately 16 feet. It is tributary to the Hillsborough river system, a source of water supply for Tampa, and a part of the Tampa Bay ecosystem providing freshwater to the estuary.

The watershed is approximately 55 square miles and extends east to Plant City and south to Sydney (Figure 8). Elevation in the watershed ranges from 35 ft National Geodetic Vertical Datum (NGVD) along the shoreline of the lake to 145 ft in the eastern section of the catchment. The area in general has relatively mild slopes but is steeper on the eastern section when compared with the southern and western sections. This lake was chosen in part due to the relatively large database available as a result of recently completed diagnostic/feasibility studies (6).

Modeling

Available data included topographic maps, land use, soils, rainfall, wind, solar radiation, water levels, and water quality. These data were utilized in the model setup and calibration processes. Modeling consisted of developing a database linkage from the GIS, watershed modeling with the SWMM model, and water-body modeling with RIVMOD and WASP4. The modeling scenarios are described below.

Digitized land use and soils data were obtained from the SWFWMD on magnetic tapes and downloaded to the Dames and Moore ARC/INFO system. Drainage divides that define subbasins were digitized as an additional overlay. These data provided the basis for developing the *.GDF file, which was linked with the SWMM model via the PRESWMM program package. These maps were directly output from the GIS. In addition, the GIS was used to provide aggregate maps for soils and land use.

The GIS identified 42 land uses at up to Level III for the watershed. SWMM is capable of utilizing five land uses in its watershed modeling. A decision was therefore made to aggregate land uses to provide five classes with similar characteristics. The classes selected were urban, agriculture, open, wetlands, and uplands. To maintain flexibility in redefining aggregates during the

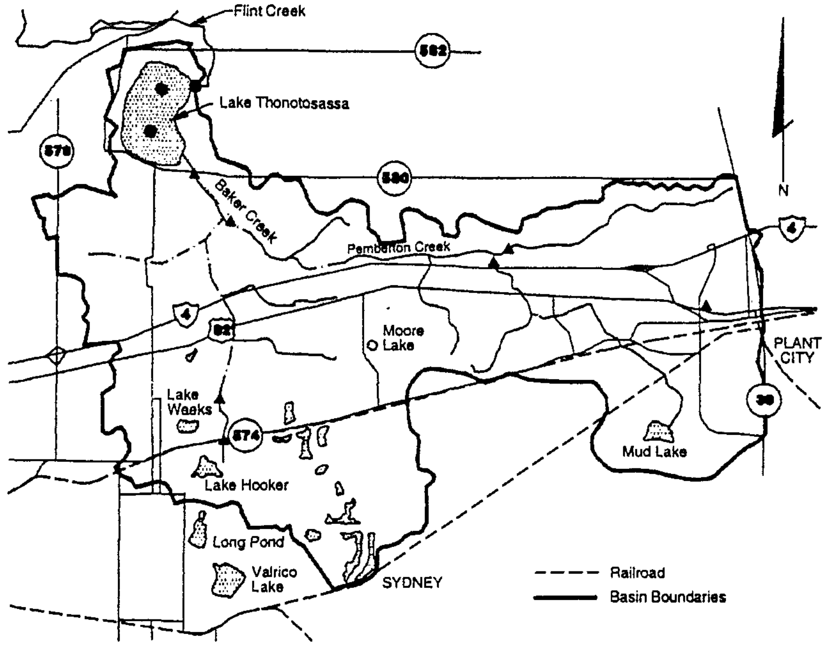

Figure 8. Lake Thonotosassa location map.

modeling process, the unaggregated GIS database served as model input to PRESWMM. PRESWMM then provided the aggregated land-use data for modeling purposes.

SCS soils data on the GIS are more detailed than required for modeling purposes. These data were aggregated in the GIS to provide mapping of hydrologic soil groups A, B, C, or D, as provided by the Hillsborough County soils map and document (7).

The SWMM model (RUNOFF block) was used to simulate both water quantity and water quality inflows to the lake. Before the input file was set up, the watershed was segmented into 34 subbasins. The subbasins were defined by examining topographic, land-use, and soils maps.

To set up SWMM, PRESWMM was used to create an input file consisting of information from the GIS system and user control input (UCI). The GIS system provided land-use and soils information, as previously discussed. These data served as input to PRESWMM, which created the input file for SWMM. In addition, UCIs were input into the PRESWMM interactive program. These UCIs include data on catchment slopes, overland Mannings roughness coefficient (n), evaporation, infiltration rates, basin widths, percent of directly connecting impervious area (DCIA), depression storage, channel slopes, channel lengths, channel geometry, and channel Mannings roughness coefficient (n). Channel basin linkages are also defined so that the model can route flows from the land segment to channels, and from channels to other channels.

After the model was set up, a data period was selected for calibration. The period was from June 11, 1991, to April 24, 1992, and was selected to coincide with available discharge measurement records. The model was calibrated by conducting a series of model runs, comparing simulated and measured data, and adjusting parameters.

The calibration was based primarily on data collected at two stations, LT-4 and LT-5. Station LT-5 is located on Pemberton Creek just upstream of the Baker Creek confluence, which represents 40 percent of the total watershed. The other calibration point is station LT-4, which covers 98 percent of the lake's watershed. The difference in flows between these stations is that contributed by Baker Creek draining the southern portion of the catchment. The final calibration plot for LT-4 is shown in Figure 9.

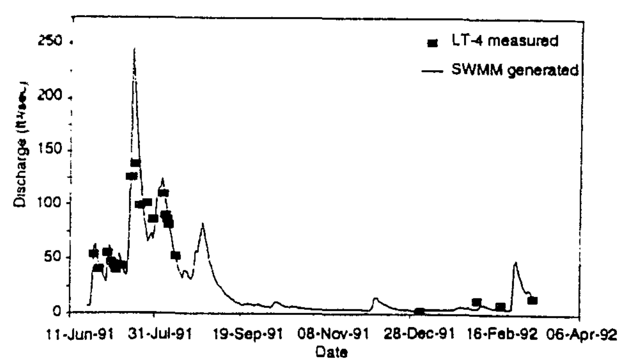

Figure 9. Lake inflow calibration.

The SWMM water quality setup used the same setup as for the water quantity except that coefficients that define buildup/washoff rates and rating curves were added to the routine. The calibration was performed by comparing water quality concentrations for measured and simulated total nitrogen and total phosphorus. The procedure was a sequence of model runs, comparing results, and adjusting parameters.

Water-Body Modeling

Water and pollutant loading inflows generated by SWMM were used as input to the lake, and the lake water quality was simulated. The following two models were used: 1) RIVMOD was used to simulate the dynamics of the inflows, outflows, and change storage in the lake, and 2) EUTRO4 used the simulated hydrodynamics and relevant quality parameters to simulate the lake's water quality.

Sources of pollutants to the lake were identified, with emphasis on nutrient loading. An in-lake model was applied by utilizing ambient water quality data and flows and pollutant loadings from the watershed to model current in-lake processes. The model was calibrated for nitrogen, phosphorus, and chlorophyll-*a*. WASP4 was the lake model used in simulating the in-lake processes.

The lake and inlet channel was subdivided into 10 segments. Four of the segments were in the inlet channel (Baker Creek). These segments were included to allow some flexibility in modification, if necessary, of the nutrient input to the lake during the lake water quality calibration process. The lake had six segments; this was believed to be adequate considering that there were only two water quality data collection stations. The final segment represents the lake outflow point. The segmentation is shown in Figure 10.

The eutrophication water quality model (EUTRO4) was set up as a system of 10 water column segments (Figure 10) to coincide with the hydrodynamic setup. Model time step was one day, with simulation for all eight systems of the WASP4 Intermediate Eutrophication Kinetics package. The eight systems are ammonia, nitrate+nitrate, orthophosphate, chlorophyll-*a*, biochemical oxygen demand, dissolved oxygen, organic nitrogen, and organic phosphorus. Water column segments interact with each other both by advective flows and diffusive exchange.

The SWMM model generated loads of total nitrogen, total phosphorus, and biochemical oxygen demand (BOD). For water quality modeling, data on nitrate-nitrate nitrogen, organic nitrogen, ammonia nitrogen, orthophosphate, and organic phosphorus were required. These constituents were estimated by applying stoichiometric ratios obtained from the data collected during the extensive data collection period. Loads of

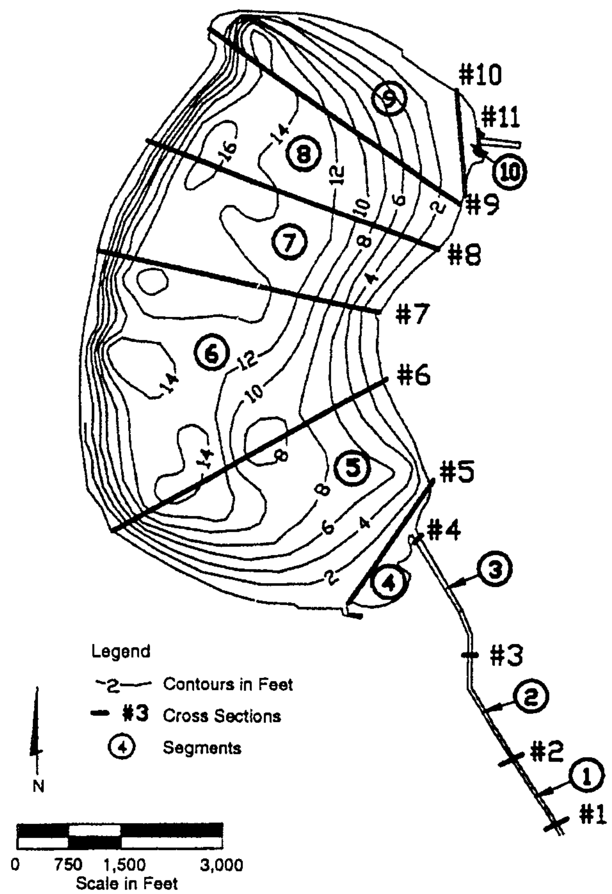

Figure 10. Lake Thonotosassa modeling segmentation and bathymetric map.

dissolved oxygen were also included in the model. These were obtained by applying monthly dissolved oxygen data to SWMM simulated flows.

Seven environmental parameters were included in the setup. The parameters defined values for salinity, segment temperature, ammonia flux, phosphate flux, and sediment oxygen demand. Salinity and temperature were derived from field measurements. Some of the constants associated with the environmental parameters were pointers used in combination with various time functions to define time series of water temperature, solar radiation, fraction daylight hours, and wind velocity. Time series of water temperature, solar radiation, and wind velocity were derived from the available data discussed above. Fraction of daylight hours was obtained from latitude-dependent information presented in Chow (8).

Initial constituent concentration was based on the measurements of June 26, 1991, and initial model time. Organic phosphorus was assumed to be the difference between total phosphorus and orthophosphate. It is recognized, however, that organic phosphorus may be overestimated because of particulate forms of inorganic phosphorus. Organic nitrogen was calculated from total Kjeldahl nitrogen and ammonia.

The model was set up with the constants required for eutrophication simulation. Values for these constants were derived primarily from the literature (9), although some field measurements were used as guidance to determine constants. These constants were primarily calibration factors.

Calibration was accomplished by adjusting constants within reasonable limits until a satisfactory fit between measured and simulated data was obtained (Figures 11 to 13). In some instances, although the model fit was by no means perfect, the model was considered calibrated within the constraints of the various estimates of inflows and environmental parameters. Constraints were associated with each of the eight systems in the eutrophication package: ammonia, nitrate-nitrate, orthophosphate, phytoplankton, BOD, dissolved oxygen, organic nitrogen, and organic phosphorus. Ammonia, nitrate-nitrate, and organic nitrogen are subsystems of the nitrogen cycle; orthophosphate and organic phosphorus are subsystems of the phosphorus cycle; and BOD and dissolved oxygen are subsystems of the dissolved oxygen balance. All systems interact.

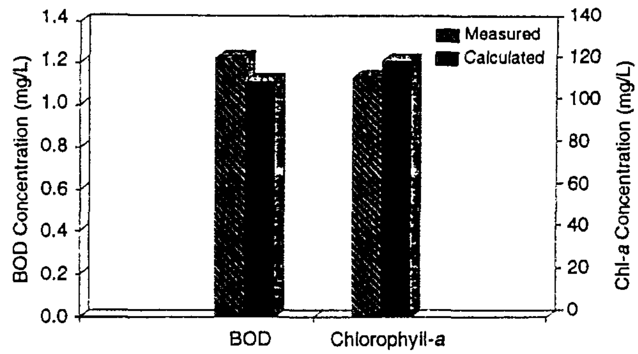

Figure 13. BOD and chlorophyll-*a* calibration, Lake Thonotosassa.

Summary

The development and model components of the LWWM system and its user environment, SWISP, have been described. The LWWM has been applied to Lake Thonotosassa and its watershed. Water quantity and quality originating from the watershed were modeled as pollutant loading to the lake. In-lake processes were then simulated. Refinements are being made to the LWWM system in anticipation of project completion in September 1993. The resultant modeling system will be tested on two other systems, one a river flowing into an estuary (i.e., Little Manatee) and one a series of 19 interconnected lakes (i.e., the Winter Haven chain of lakes). It is anticipated that the resultant modeling system will become the district standard for eutrophication modeling of its surface water bodies. The final code and user's manual for SWISP will be public domain, and it is hoped that this modeling system will be used by other water resource managers in developing pollutant load reduction strategies for their water bodies.

AUTO_QI: An Urban Runoff Quality/Quantity Model With a GIS Interface

Michael L. Terstriep and Ming T. Lee
Office of Spatial Data Analysis & Information,
Illinois State Water Survey, Champaign, Illinois

Abstract

This paper describes the development and application of the AUTO_QI model, which the authors developed at the Illinois State Water Survey in Champaign, Illinois. The paper includes background information on the Illinois Urban Drainage Area Simulator (ILLUDAS), on which AUTO_QI is hydrologically based. AUTO_QI stands for AUTOmated Quality-ILLUDAS. The model is automated in the sense that it includes an optional geographic information system (GIS) interface using ARC/INFO software. The Quality-ILLUDAS portion of the name indicates that the model simulates quality as well as quantity of runoff from an urban area.

AUTO_QI uses a continuous simulation of soil moisture to provide reliable estimates of antecedent moisture conditions for the simulation of selected runoff events. The soil moisture simulation requires a continuous precipitation record for the period of interest. The user may then specify some base rainfall above which the runoff volume and pollutant loading are then simulated for each event in the record. The resulting series of runoff volumes or pollutant loadings may then undergo statistical analysis. For each catchment in the study area, the user must provide soils and land cover information as well as buildup and washoff factors for each pollutant of interest. The model can simulate multiple drainage outfall points for a given rainfall record and group the results for different receiving waters. The user may incorporate specific best management practices (BMPs) into the simulation for comparison of loadings with and without BMPs. The paper also discusses use of the GIS interface including processing of remotely sensed data.

Introduction

Models for simulation of urban runoff hydrographs such as the Illinois Urban Drainage Area Simulator (ILLUDAS) (1), Stormwater Management Model (SWMM) (2, 3), and Storage, Treatment, Overflow, Runoff Model (STORM) (4) have been used for some time. Their wide usage reflects their reliability for stormwater drainage design. Models that incorporate urban runoff water quality are available but are less common. The main reasons for this are:

- The water quality component is less reliable.
- The models require extensive input data.
- The models lack verification.

The relatively infrequent use of a water quality component is unfortunate because urban water quality modeling is a convenient tool for assessing pollutant loadings. Considering the high cost of monitoring and the lack of extensive data for using a statistical approach, the proper model with field data verification is a logical and feasible method for water quality assessments.

The principal investigators have developed an approach (5) that greatly reduces the cost of applying a deterministic model Q-ILLUDAS (6) to a relatively large area. This approach incorporates the ARC/INFO geographic information system (GIS) for data management. The savings comes from automation of input files. Readily available automated data include the U.S. Geological Survey (USGS) LUDA Level II land use data and the U.S. Census Bureau's DIME or TIGER/LINE file for population, housing, and street density. The streams, soils, and other data are also available in the Illinois and other state and federal GIS databases. This method is very effective for simulating regional urban runoff loadings that involve large databases and multiple outfalls. The model and GIS interface are known as AUTO_QI.

Literature Review

Shaw (7) describes the special hydrologic problems of urban runoff as follows. The problem of estimating runoff from storm rainfall depends on the character of the catchment surface. The degree of urbanization (extent of impervious area) greatly affects the volume of runoff obtained from a given rainfall. Retention of rainfall by initial wetting of surfaces and absorption by vegetation and pervious areas reduces the amount of storm runoff. These surface conditions also affect the time distribution of the runoff. Computational methods used to obtain runoff from the rainfall should allow for the characteristics of the surface area to be drained. Thus, the first efforts in urban runoff modeling were to relate runoff from storm rainfall to the catchment characteristics.

The first stormwater sewer design method was the rational method by Kuchling (8). Sherman (9) introduced the unit hydrograph method. After the development of digital computers, early urban hydrologic models were developed, such as those by James (10), Papadakis and Preul (11), Terstriep and Stall (1), and McPherson and Schneider (12). One characteristic of urban runoff is that during the early minutes of a storm, urban runoff mainly derives from the impervious surfaces. Contributions from the pervious portion of the basin are highly variable and more difficult to define. Other research results may be found in Novotny and Chesters (13), Hann et al. (14), and Shaw (7).

Many conducted early urban runoff water quality modeling research, including Sartor and Boyd (15), Hydrologic Engineering Center (4), McPherson (16), Sutherland and McCuen (17), U.S. EPA (18-20), and Noel and Terstriep (6). Donigian and Huber (21) prepared a comprehensive review of modeling of nonpoint source water quality in urban and nonurban areas. Other reviews that consider surface runoff quality models include Feldman (22), Huber and Heaney (23), Kibler (24), Whipple et al. (25), Barnwel (26, 27), Huber (28, 29), Bedient and Huber (30), and Viessman et al. (31).

Table 1. Urban Runoff Quality Model

Model	Authors	Year
QUAL-II	Hydrologic Engineering Center	1975
SWMM	Huber et al.	1975
STORM	Hydrologic Engineering Center	1977
MUNP	Sutherland and McCuen	1978
Q-ILLUDAS	Noel and Terstriep	1982
QQS	Geiger and Dorsh	1980
HSPF	Johanason et al.	1980

Table 1 shows a partial list of urban water quality models.

For a detailed description of each of the models, the reader may review the respective references. This section will limit its discussion to the deposition and accumulation of pollutants on impervious surfaces and removal of solids from the street surface.

As reported by Sonnen (32), the state of the mathematical urban water quality model was fairly dismal a decade ago. Little has changed since then because the physical processes are so complex that they defy efforts to reduce them to mathematical statements. Consequently, semiempirical methods are often used.

Deposition and Accumulation of Pollutants on Impervious Surfaces

As described by Novotny and Chesters (13), the primary sources of pollutants are wet and dry atmospheric deposition, litter, and traffic. Pollutants deposited on the surface during a dry period can be carried by wind and traffic and accumulate near the curb or median barrier. Thus, many studies report the street pollutant loading by unit length of curb.

The street refuse that runoff washes to storm sewers contains many contaminants. Significant amounts of organics, heavy metals, pesticides, and bacteria are commonly associated with street refuse. Factors that affect the pollutant accumulation rates are atmospheric fallout, wind, traffic, litter deposition, vegetation, and particle size distribution.

Pollutant accumulation in an urban area has a significant random component; thus, no mathematical model yields totally reliable results. Consequently, one common concept used is the storage-input-output schematic approach, which assumes that the amount of accumulated pollutants on a surface can be described as a simple mass balance formula:

$$dP/dt = A - r \qquad \text{(Eq. 1)}$$

where

A = pollutant accumulation rate (lb/day)
r = pollutant removal rate (lb/day)
P = amount of street refuse or dust/dirt present on the street (lb)
t = time in days

Integrating Equation 1, then:

$$P = A/r\,[1 - \exp(-rt)] + C \qquad \text{(Eq. 2)}$$

where

exp = exponential function
C = undefined constant

Using the empirical data from U.S. EPA (33), the parameters were defined for the Washington, DC, area as follows:

$$A = (ATMFL + LIT)\,(SW/2) + 1.15\,TD$$

$$r = 0.00116 \exp [0.0884 (TS + WS)]$$
$$C = 0$$

where

ATMFL = atmospheric fallout rate (g/m²/day)
LIT = litter deposition rate (g/m²/day)
SW = street width (m)
TD = traffic density (thousand axles/day)
TS = traffic speed (km/hr)
WS = wind speed (km/hr)

Sutherland and McCuen (17) made another attempt by developing a set of refuse accumulation functions using average daily traffic volume and pavement condition expressed by the present serviceability index (PSI). The results are a set of accumulation equations in terms of these input factors.

The accumulation of street refuse is the main pollution source in urban areas. Novotny and Chesters (13) reported on typical urban street refuse. Table 2 also presents findings from research on this topic.

The Chicago results indicate that multiple-family areas generate about three times more street dirt than single-family areas. The commercial and industrial areas generate about five and seven times more than the single-family areas.

The street refuse accumulation rate based on the eight American cities (15, 35) is two to four times higher than the Chicago dust/dirt accumulation rate. This reflects the wide variations in pollutant accumulation rates in existing measured field data for different cities.

Refuse Washoff by Surface Runoff

When surface runoff occurs on impervious surfaces, the splashing effect of rain droplets and the drag forces of the flow put particles in motion. Sedimentation literature includes many hydraulic models that are potentially applicable to the problem of particle suspension and transport. Two models used frequently in urban runoff modeling are described below.

Yalin Equation

Of numerous equations published in the literature, the Yalin equation (36) is probably one of the best for describing suspension and transport of particles by shallow flow typical for rills and street gutters. The equation has been reported in the following form:

$$p = 0.635\, s\, [1 - \ln (1 + as) / (as)] \qquad \text{(Eq. 3)}$$

where

p = particle transport per unit width of flow (g/m/sec)
$s = (Y/Ycr) - 1$
$a = 2.45 r_s^{-0.4} \sqrt{Ycr}$
ln = natural log function

The variables are defined as follows:

Y = particle bed load tractive force $= \dfrac{\mu^*}{[(\rho_s - 1)gD]}$
ρ_s = particle density (g/c-cm³)
Ycr = the critical tractive force at which sediment movement begins (newton/m²)
D = particle diameter (m)
μ^* = sheer velocity (m/sec)
g = gravity acceleration (m/sec²)

Based on Yalin's equation, Sutherland and McCuen (17) developed a washoff model. The model is based on the relationship between percentage removal of total solids in a particle range (0.001 to 1.0 mm) due to a total rainfall volume of 1/2 in. and correlation factor Kj such that:

$$TSj = Kj\,(TSi) \qquad \text{(Eq. 4)}$$

where

TSj = percentage removal of total solids in a particle range due to total rainfall volume j, measured in mm

Table 2. Street Refuse Accumulation

	Solids Accumulation			
	Chicago (34) Dust and Dirt		Eight American Cities (15, 35) Total Solids	
Land Use	g/curb miles/day	lb/acre/day	g/curb miles/day	lb/acre/day
Single family	10.4	2.1[a]	48	9.5[a]
Multiple family	34.2	6.8[a]	66	13.1[a]
Commercial	49.1	9.7[a]	69	13.7[a]
Industrial	68.4	13.5[a]	127	25.1[a]

[a]The curb density in Chicago and eight American cities was assumed by the authors to be 90 m/acre.

Kj = factor relating TSj and TSi
TS = percentage removal of total solids in the particle range due to a total rainfall of 1/2 in.

Sartor et al. Washoff Function

The Sartor et al. washoff function is based on the first-order washoff function (15, 35):

$$dP/dt = - Ku\ r\ P \qquad \text{(Eq. 5)}$$

where

P = amount of solids remaining in pounds
t = time in days
Ku = constant depending on street surface characteristics (called urban washoff coefficient)
r = rainfall intensity (in./hr)

The constant Ku was found independent of particle size within the studied range of 10 to 1,000 μm. The integrated form of the equation can be expressed as:

$$P_t = P_o\ [1 - \exp\ (-Ku\ r\ t)] \qquad \text{(Eq. 6)}$$

where

P_o = initial mass of solids in the curb storage
P_t = mass of material removed by rain with duration t
exp = exponential function

In spite of the Sartor concept's highly empirical nature and arbitrarily chosen constants, many urban runoff models such as SWMM (2, 3) and STORM (4) have incorporated it.

AUTO_QI Model

Model Overview

AUTO_QI actually comprises three programs known as HYDRO, LOAD, and BMP. These programs run in series, each using output from the previous program as input along with additional information from the user. HYDRO performs a continuous simulation of soil moisture based on a daily and hourly rainfall record that the user provides. It also computes runoff volume for each event above some user-specified rainfall amount. LOAD uses these runoff volumes along with additional pollutant accumulation and washoff information to calculate pollutant loadings for each runoff event. The BMP program then reduces these loadings in accordance with user-specified best management practices (BMPs) and reports the results both with and without BMP conditions. The simulation process may be examined by looking at wet and dry periods.

Runoff

Runoff may only occur during a "wet period," a day during which rainfall occurs. During these potential runoff periods, the model requires hourly rainfall amounts. The basin is assumed to have three types of area: directly connected paved area, supplemental paved area, and contributing grassed area. As the name implies, runoff from the directly connected paved area flows directly to the storm system. Runoff from the supplemental paved area flows first across the grassed area and is thus subjected to infiltration losses. The remainder of the basin is assumed to be grassed area, so all rain falling on this surface is also subjected to infiltration losses.

Paved Area Runoff

The model distinguishes between directly connected paved area and supplemental paved area. The losses from directly connected paved area consist of initial wetting and depression storage. These losses are combined and treated as an initial loss; they are subtracted from the beginning of the rainfall pattern. After subtracting these losses from the rainfall pattern, the remainder of the rainfall appears as effective rainfall and thereby as runoff from the paved area.

Grassed Area Runoff

Computation of grassed area runoff includes runoff from the supplemental paved area because both are subjected to infiltration. As in the case of paved area runoff, rainfall is the primary input for grassed area runoff calculations. The modifications that must change the rainfall pattern to grassed area runoff are much more complex than in the paved area case. The procedure followed here first adds in supplemental paved area runoff, then subtracts initial and infiltration losses.

In this model, rainfall on the supplemental paved area is simply distributed by linear weighting over the entire grassed area, thereby modifying the actual rainfall for grassed areas such that:

$$R' = R\ (1.0 + SPA/CGA) \qquad \text{(Eq. 7)}$$

where

R′ = effective rainfall on the grassed area
R = actual rainfall
SPA = supplemental paved area
CGA = contributing grassed area

In an urban basin, bluegrass turf most often covers the area that is not paved. When rain falls on this turf, there are two principal losses. The first is associated with depression storage and the second with infiltration into the soil. In this model, depression storage fills and maintains, and infiltration is satisfied before any runoff takes place. Depression storage is normally considered to be 0.20 in., but the model provides for this to be varied.

The dominant and far more complex loss of rainfall on grassed areas is caused by infiltration. The theoretical approach to evaluating infiltration rates uses the physical properties of the soil to estimate the water storage available in the soil mantle, and evaluates the role of this water storage as rain water infiltrates into and through the soil mantle. The original ILLUDAS manual provides details of water storage in soil and infiltration rates through soil. The following text offers only brief descriptions.

Water Storage in Soil

The amount of water that the soil mantle can store depends on the total pore space available in the soil between the soil particles. This model divides the total water stored in the soil mantle into two principal parts. The first of these is gravitational water. This is the water that will drain out of soil by gravity. The second is evapotranspiration (ET) water. This is the water that plants can remove through evapotranspiration.

Soil moisture storage capacity varies with soil type and may be classed by hydrologic soil group. This model considers seven hydrologic soil groups. The U.S. Soil Conservation Service describes the hydrologic soil groups as follows:

A = low runoff potential and high infiltration rate (consists of sand and gravel)
AB = soil having properties between soil types A and B
B = moderate infiltration rate and moderately well drained
BC = soil having properties between soil types B and C
C = slow infiltration rate (may have a layer that impedes downward movement of water)
CD = soil having properties between soil types C and D
D = high runoff potential and very slow infiltration rate (consists of clays with a permanent high water table and high swelling potential)

Appendix B supplies default values of soil moisture storage capacity for different soil types. Users can change these values to suit their own experience. For further references, see Eagleson (37) and Richey (38).

Infiltration Rate

Knowing the water storage available for infiltration within a soil mantle makes it possible to compute the infiltration rate at any time from the Horton equation, as given by Chow (39):

$$f = f_c + (f_0 - f_c)\ \exp(-kt) \qquad \text{(Eq. 8)}$$

where

f_c = final infiltration rate (in./hr)
f_0 = initial infiltration rate (in./hr)
k = shape factor
t = time from start of rainfall (hr)
exp = exponential function

This equation is solved by the Newton-Raphson technique for given f_c and f_o values that depend on soil properties supplied by the user. A shape factor (k) of 2 was used to provide the shape best reflecting natural conditions.

The total amount of infiltration during a storm event depends on the total amount of soil moisture (ET water and gravitational water) in storage. The higher the amount of available soil moisture, the lower the amount of infiltration, and vice versa. This model distributes the total amount of infiltration among ET storage and gravitational storage in a preassigned 60:40 ratio. AUTO_QI continuously simulates soil moisture so that a reliable soil moisture is available at the beginning of any event.

During dry periods, the model operates on two different time steps: daily if there is no rainfall on the current day and hourly if there is rainfall at some time during the current day. During dry periods, depression storage and soil moisture depend on:

- Evaporation, at a user supplied rate, from depression storage.
- Infiltration from depression storage, with the infiltration volume separated in a 60:40 ratio into ET water and gravitational water.
- Evapotranspiration, at a user specified rate, from ET water storage.
- Percolation, at a constant rate f_c, from gravitational water storage.

Spatial Distribution of Runoff Processes

The model assumes all of the wet period and dry period processes are spatially distributed, and simulates by the use of a triangular distribution. Figure 1(a) shows a distribution assumed to vary linearly from zero to twice

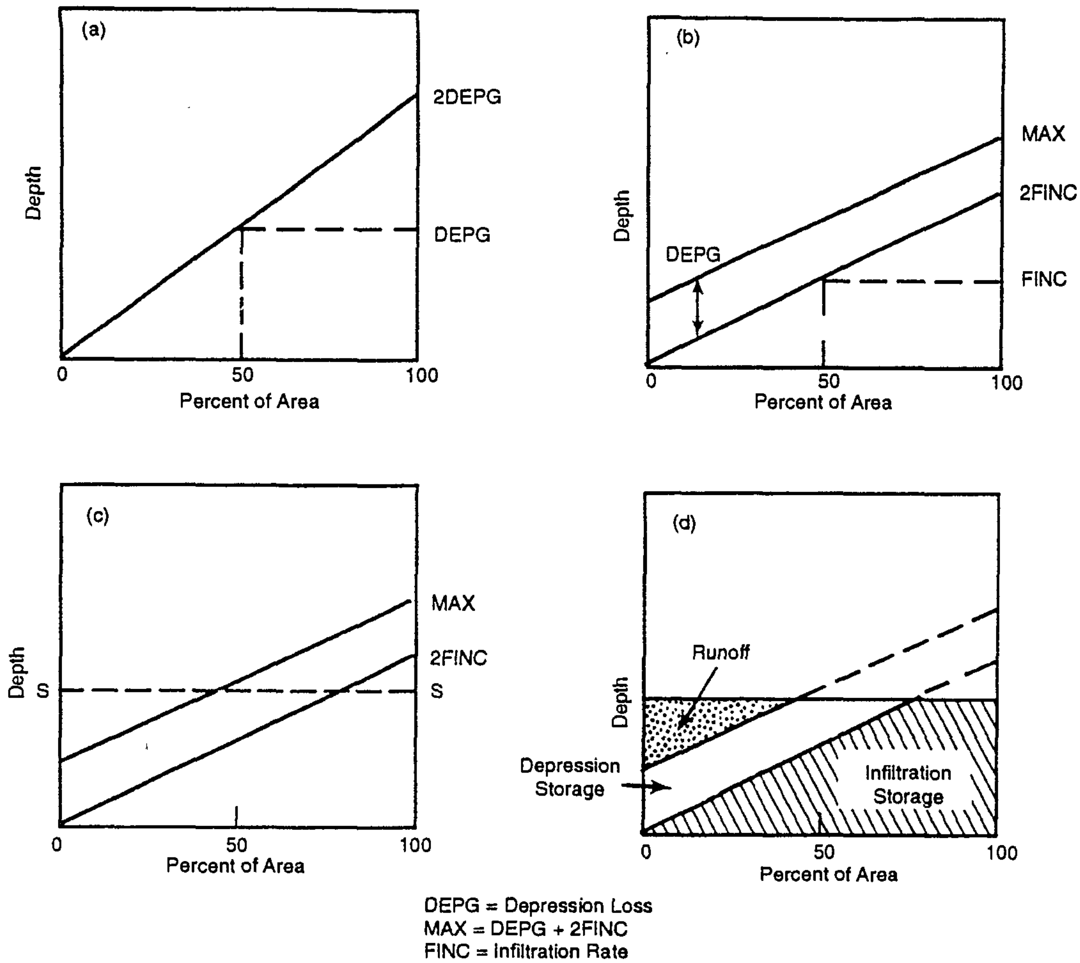

Figure 1. Triangular spatial distribution of runoff.

the user-specified mean value over the subcatchment area. DEPG, as an example, is the mean pervious depression storage. Figure 1(b) shows the concurrent processing of depression storage and infiltration potential. Although both filling of depression storage and infiltration are assumed to be spatially distributed, they are also assumed to be totally independent of one another physically. Depression storage may therefore have a uniform distribution with respect to infiltration potential.

The concurrent processing of infiltration and depression storage, Figures 1(c) and 1(d), assumes that infiltration potential varying from zero to 2FINC is satisfied for a particular level of supply, S, before considering depression storage. The supply rate S is defined as the sum of the rainfall and the uniformly distributed volume of depression storage at the start of the interval. The volume below S and between curves 2FINC and MAX represents the moisture supply to depression storage in the interval and is processed according to the above discussion of Figures 1(a) and 1(b). The volume remaining below S and above the curve bounded by MAX is the surface runoff volume for the hour.

Pollutant Generation

After generating an effective hyetograph for both pervious and impervious areas, these rainfall depths are supplied as input to the program LOAD. LOAD then generates the washoff of different pollutants from the storm event. LOAD uses linear accumulation and exponential washoff equations. The user supplies the number of pollutants and associated characteristics such as daily accumulation rate and daily removal rate.

Dry Periods

One form of mass balance formula in discrete form is the linear accumulation equation, which generates the antecedent pollutant load at the beginning of an event as follows:

$$P_t = P_{t-1}(1-r) + A \qquad \text{(Eq. 9)}$$

where

P_{t-1} = initial load at time t-1

R0015847

P_t = load at time t
r = background removal rate
A = daily accumulation rate

Wet Periods

At the start of rainfall, the amount of a particular pollutant on a surface that produces runoff will be Po, in lb/acre. Assuming that the pounds of pollutant washed off in any time interval, dt, are proportional to the pounds remaining on the ground, P, the first order differential equation is:

$$-dP/dt = kP \quad \text{(Eq. 10)}$$

When integrated, this converts into the exponential washoff function for the removal of the surface loads as follows:

$$P_0 - P = P_0(1 - \exp(-kt)) \quad \text{(Eq. 11)}$$

where

$P_0 - P$ = washoff load (lb/acre)
k = proportionality constant
t = storm duration in hours

To determine k, the model uses the same assumption as the SWMM model. Therefore, k varies in direct proportion to the rate of runoff such that:

$$k = iB$$

where

i = runoff (in./hr)
B = constant

To determine B, it was assumed that a uniform runoff of 1/2 in./hr would wash away 90 percent of the pollutant from paved areas and 50 percent of the pollutant from grassed areas in 1 hour. That leads to a value for B of 4.6 for paved areas and 1.4 for grassed areas. These are default values that the user can modify.

To find the washoff load, apply each constituent's loading parameters to the buildup function to determine the initial load (by land use). Then apply the exponential washoff equation for impervious and pervious areas. The event mean concentration (EMC) is determined by dividing the total washoff loads by the runoff volume for each land use.

Best Management Practices

BMPs are the measures implemented to reduce pollutants from source areas, or in streams and receiving waters. Many factors govern BMP pollutant removal ability. Schueler (40) outlined three primary interrelated factors:

- The removal mechanisms used.
- The fraction of the annual runoff volume that is efficiently treated.
- The nature of urban pollutants being removed.

The AUTO_QI model does not model specific BMP processes but represents the effectiveness of BMPs by a removal efficiency factor. The model can handle one or more BMPs in a catchment or portion of a catchment. The pollutant removal factor may be inferred from field performance monitoring, laboratory experiments, modeling analyses, or theoretical considerations. Most model users, however, must rely on literature values as a starting point.

The particulate related pollutants, such as sediment and lead, are relatively easy to remove by common removal mechanisms, such as settling. Soluble pollutants, such as nutrients, are much more difficult to remove. The settling mechanism has little or no effect on these pollutants. Therefore, biological mechanisms, such as uptake by bacteria, algae, rooted aquatic plants, or terrestrial vegetation, are often used. A detailed description of individual BMPs can be found in Schueler (40) and Novotny and Chesters (13).

The model allows users to test the potential enhancement of water quality by implementing one or more BMPs in a catchment or group of catchments. The user specifies what portion, in percent, of a catchment the desired BMPs will affect and the removal efficiency of the BMPs. The model output lists the load and EMC without BMPs, followed by the load and EMC expected with BMPs. The user may apply this same procedure to reflect existing conditions if one or more BMPs are already in place.

Data Preparation

Interfacing the GIS Database and AUTO_QI

Urban runoff quantity and quality are highly dependent on the land use and hydrologic soil type. To tabulate the land use/soil complex for a large basin is a time-consuming process. To simplify the data collecting process, an optional ARC Macro Language (AML) program was developed to retrieve the land use/soil layers in a format suitable for model input.

The AML includes a menu-driven data review feature with two windows on the screen. The right window displays an index map of the whole drainage basin and the subbasin boundaries. The user can select a subbasin and display the land use, soil layers, streets, and storm sewers. If the user wants the land-use input file of a specific subbasin, the AML retrieves the attribute data and generates an ASCII file for the model input.

AML Programs

The AML programs link and provide the user interface between the GIS, which runs on a PRIME, and the AUTO_QI program, which runs on a PC. These programs process the data that AUTO_QI uses and also enable the user to view the graphic data at the subbasin level via a menu. The programs should be used with ESRI's ARC/INFO software on a PRIME computer and are grouped into two functions: the preprocessor programs and the menu system programs. PREPROCESSORLANDSOIL.AML, PREPROCESSORBMP.AML, and RUNIT.AML are the names of the three main programs.

PREPROCESSORLANDSOIL.AML uses the soil, land use, and BMP coverages to create a soil/land-use file for input to the AUTO_QI model. PREPROCESSORBMP.AML uses land-use and BMP coverages to create BMP application files for the AUTO_QI model. RUNIT.AML accesses the ARC/INFO menu system to view the coverages and INFO data. This menu also allows the user to choose and view individual subbasins and their data layers.

GIS Database Layers

Soil Layer

In 1985, funding from the Illinois Department of Mines and Minerals (IDMM) allowed for the digitization of the statewide "General Soil Map of Illinois" for the Illinois GIS system. This map contains 57 general soil associations in Illinois. The attribute data include the soil surface color, surface code, and the hydrologic class (well drained, moderately well drained, somewhat well drained, and poorly drained). The AUTO_QI model needs this hydrologic soil classification for hydrologic modeling. The source map scale for the soil associations is 1:500,000.

Land Use Layer

The statewide land-use maps are available from the U.S. Geographical Survey LUDA digital database (41). The land uses are classified based on LUDA Level II, which contains 37 land-use categories (Appendix D). Digital Landsat image data or scanning aerial photographs have updated land-use/cover information (42-44). The Illinois State Water Survey has developed image analysis capability using the ERDAS image processing package (45). The results of a classified land use can easily be transferred to the ARC/INFO system.

Street Layer (DIME file/TIGER/LINE file)

Either the 1980 DIME file or the 1990 TIGER/LINE file, which were created by the U.S. Census Bureau, can provide the street coverage. The DIME and TIGER/LINE files comprise street segment records. A segment is defined as the length of a street feature between two distinct vertices or nodes. Other features are political boundaries and topologic features (e.g., rivers, shorelines, canals, railroads, airports). Additional demographic information is also available in the attribute data. This includes state, county, and standard metropolitan statistical area codes, aggregate family income, aggregate rental cost for occupied dwelling units, and numerous other demographic statistics. The data can be plotted by census tract. The source map scale is 1:100,000. The street layer is valuable for estimating the pollutant accumulation rate and the imperviousness of the drainage basin.

Sewer Network

The database may also include an automated storm sewer network. The AML menu system provides for this coverage. The coverage is not required by the AML, however, and is not needed by AUTO_QI.

Model Verification

Overview

Due to the lack of observed data in the Lake Calumet area, the AUTO_QI model was verified by using the Boneyard Creek Basin in Champaign-Urbana, Illinois. The USGS has continuously gauged this station since 1948. The watershed area was reduced from 4.7 to 3.6 square miles in 1960 by a diversion. The basin contains a portion of Urbana, the commercial center of Champaign, and the University of Illinois campus. The central business district of Champaign makes up 7.5 percent of the drainage area and is nearly 100 percent impervious. Other city properties, including predominantly residential along with some commercial and light industrial, constitute an additional 81.2 percent of the basin. The remaining 11.3 percent of the basin is in parks, open space, and other land-use classes. Measurements have found the basin to be approximately 44 percent total paved area, which includes approximately 24 percent of direct connected paved area, 13 percent of supplemental paved area, and 7 percent of nonconnected paved area. The soils of the basin are predominantly Flanigan silt loam of hydrologic class B (8).

Runoff Simulation

For runoff simulation, rainfall data for 3 years were chosen. These years represent low (25 percent), average (50 percent), and high (75 percent) annual exceedence of rainfall. Table 3 displays these data.

Land uses in the basin were simplified into two categories. Table 4 lists the land-use parameters for these categories which were used to verify the model.

Table 3. Selected Years and Total Annual Rainfall

Year	Total Rainfall (in.)	Chance of Exceedence (percent)	Comments
1959	35.94	50	Average year
1976	32.63	75	Dry year
1977	42.44	25	Wet year

Table 4. Land-Use Parameters

Land Use	USGS Land Use Level 2 Code	% PA	% SPA	DEPI (in.)	DEPG (in.)
Residential	11	15	20	0.1	0.1
Commercial	12	90	5	0.1	0.1

% PA = paved area in percent
% SPA = supplemental paved area in percent
DEPI = impervious depression storage depth
DEPG = pervious depression storage depth

Results of Runoff Simulation

The events selected allowed the actual event runoff volume to be distinguished with reasonable confidence from the continuous runoff data. Table 5 presents the actual events for the "average year" of 1959.

Figure 2 shows that AUTO-QI does an acceptable job of reproducing runoff volumes for dry, average, and wet years. The simulated runoff/rainfall ratio for these 3 years is approximately 20 percent, which is consistent with the observed data and with what has been found previously (1).

Water Quality Simulation

Water quality data for Boneyard Creek were available for eight events in 1982 from a study by Bender et al. (46). Simulated water quality data were compared with those 1982 data.

Water Quality Parameters

Table 6 tabulates the pollutant accumulation/decay parameters required by the model and used in this study.

The accumulation rate and removal rate were selected based on typical Midwest urban runoff basins. No attempt was made to adjust these parameters to fit the observed data.

Table 7 tabulates the comparisons between simulated washoff and actual washoff of total suspended solids (TSS), phosphorus (P), and lead (Pb). The results of this verification are disappointing. They demonstrate, however, the problems of water quality simulation without verification and calibration data. The buildup and washoff factors in the model could be adjusted to "calibrate" the model to this data set and produce better results, but that was not the intent here.

Table 6. Water Quality Parameters

	ARi (lb/acre/day)	ARp (lb/acre/day)	RRi (%)	RRp (%)
For residential land use:				
Suspended solids	7.6300	3.9900	4.50	4.50
Phosphorus	0.0138	0.0070	6.00	5.00
Lead	0.0100	0.0053	6.00	5.00
For commercial land use:				
Suspended solids	9.5500	5.5500	3.00	4.50
Phosphorus	0.0100	0.0053	4.50	4.50
Lead	0.0110	0.0060	6.00	5.00

ARi = Accumulation rate for impervious area
ARp = Accumulation rate for pervious area
RRi = Removal rate for impervious area
RR = Removal rate for pervious area

Table 5. Summary of Runoff Simulation for Selected Events in 1959

Date	Dry Days	Rainfall (in.)	Event Duration (hr)	Observed Runoff (in.)	Simulated Runoff (in.)	Simulated Grass Runoff (%)

Summary

A new comprehensive computer package was developed on the basis of two proven models for urban water quantity/quality assessment, ILLUDAS and Q-ILLUDAS. The package consists of three main parts:

- Water quantity/quality model, called AUTO_QI.
- A convenient menu system called QIMENU for preparing and editing inputs, viewing the outputs, running the model, and assisting users.
- A GIS interface called RUNIT, and other GIS processing programs.

The AUTO_QI model, which provides continuous simulation, consists of three main components: HYDRO, LOAD, and BMP. HYDRO uses a runoff/soil moisture accounting procedure, pervious and impervious depression storage, interception, Horton infiltration curves, and water storage in the soils to generate runoff volumes for each event in the record. LOAD is the water quality simulator that uses the output from HYDRO along with the pollutant accumulation and exponent washoff functions to generate loads and EMCs. BMP is the best management practices simulator that handles numerous separate or overlapping BMPs and produces the model output. The user may simulate the impacts of pollution reduction at multiple stormwater outfall points. The results can be viewed at one outfall point or multiple outfall points.

QIMENU aids users with preparation of input files, selection of parameters, running the model, testing the BMPs, and viewing the output.

The GIS interface uses the AML and automates the generation of the major input files for AUTO_QI. It also provides the user with a menu-driven program to review GIS coverages on the screen.

The model was verified by using data from the Boneyard Creek drainage basin in Urbana, Illinois. The three sets of rainfall data selected represent wet, average, and dry years. The input data consist of daily and hourly rainfalls, percent impervious and supplemental paved areas, depression storage, initial and final infiltration rates, gravitational and evapotranspiration soil storage, pollution accumulation and removal rate, and washoff factor. When comparing the outputs with the observed data for the Boneyard Creek basin, the results indicated that the model performed well for runoff volume. The simulations of pollutant loadings using the uncalibrated model were poor and indicate the need for further testing and calibration.

Acknowledgments

This research was funded by Region 5 Water Division, Watershed Management Unit, EPA, Chicago, Illinois, and the Great Lakes National Program Office, EPA, Washington, DC. The EPA Project Officer was Thomas E. Davenport.

The principal investigators of this report were Michael L. Terstriep and Ming T. Lee. Thomas Davenport, EPA Regional Nonpoint Source Coordinator, reviewed the early versions of this report and provided a number of helpful comments and suggestions. Douglas Noel developed the program for the original Q-ILLUDAS model, consulted on this project, and provided a general outline for the revised computer program. M. Razeur Rahman wrote the LOAD and BMP portion of the model. Evan P. Mills wrote the menu-driven program QIMENU for handling the inputs and outputs. Amelia V. Greene wrote the AML program for the GIS interface. John Brother prepared the graphical work.

Source Loading and Management Model (SLAMM)

Robert Pitt
Department of Civil Engineering, University of Alabama at Birmingham, Birmingham, Alabama
John Voorhees
Johnson Johnson & Roy/Inc., Madison, Wisconsin

Introduction

The Source Loading and Management Model (SLAMM) was developed to more efficiently evaluate stormwater control practices. It soon became evident that to accurately evaluate the effectiveness of stormwater controls at an outfall, the sources of the pollutants, or problem water flows, must be known. SLAMM has evolved to include a variety of source area and end-of-pipe controls and the ability to predict the concentrations and loadings of many different pollutants from many potential source areas. SLAMM calculates mass balances for both particulate and dissolved pollutants and runoff flow volumes for different development characteristics and rainfalls. It was designed to give relatively simple estimates (pollutant mass discharges and control measure effects) for a very large variety of potential conditions.

SLAMM was developed primarily as a planning level tool, for example, to generate information needed to make planning level decisions while not generating or requiring superfluous information. Its primary capabilities include predicting flow and pollutant discharges that reflect a broad variety of development conditions and the use of many combinations of common urban runoff control practices. Control practices evaluated by SLAMM include detention ponds, infiltration devices, porous pavements, grass swales, catchbasin cleaning, and street cleaning. These controls can be evaluated in many combinations and at many source areas as well as the outfall location. SLAMM also predicts the relative contributions of different source areas (e.g., roofs, streets, parking areas, landscaped areas, undeveloped areas) for each land use investigated. As an aid in designing urban drainage systems, SLAMM also calculates U.S. Department of Agriculture Soil Conservation Service (SCS) curve numbers (CNs) that reflect specific development and control characteristics. These CNs can then be used in conjunction with available urban drainage procedures to reflect the water quantity reduction benefits of stormwater quality controls.

SLAMM is normally used to predict source area contributions and outfall discharges, but SLAMM (1) has also been used in conjunction with a receiving water model (HSPF) to examine the ultimate effects of urban runoff.

The development of SLAMM began in the mid-1970s, primarily as a data reduction tool for use in early street cleaning and pollutant source identification projects sponsored by the U.S. Environmental Protection Agency's (EPA's) Storm and Combined Sewer Pollution Control Program (2-4). Much of the information contained in SLAMM was obtained during EPA's Nationwide Urban Runoff Program (NURP) (5), especially the early Alameda County, California (6), and the Bellevue, Washington (7) projects. The completion of the model was made possible by the remainder of the NURP projects and additional field studies and programming support sponsored by the Ontario Ministry of the Environment (8), the Wisconsin Department of Natural Resources (9), and EPA Region 5 (this report). Early users of SLAMM included the Ontario Ministry of the Environment's Toronto Area Watershed Management Strategy (TAWMS) study (8) and the Wisconsin Department of Natural Resources' Priority Watershed Program (9). SLAMM can now be effectively used as a tool to enable watershed planners to obtain a better understanding of the effectiveness of different control practice programs.

A logical approach to stormwater management requires knowledge of the problems that are to be solved, the sources of the problem pollutants, and the effectiveness of stormwater management practices that can control the problem pollutants at their sources and at outfalls. SLAMM is designed to provide information on the last two aspects of this approach.

Stormwater Problems

Before stormwater control programs can be selected and evaluated, it is necessary to understand the stormwater problems in local receiving waters. Table 1 lists typical receiving water problems associated with both the long-term accumulation of pollutants and the short-term (event-related) buildup of pollutants. Many of these problems have been commonly found in urban receiving waters in many areas of the United States (10). Because these problems are so diverse, an equally wide variety of individual stormwater controls must usually be used together. Unfortunately, combinations of controls are difficult to analyze using conventional stormwater models or the results of monitoring activities. SLAMM was developed to effectively examine control practices and land uses that may affect these receiving water problems.

Table 1. Typical Receiving Water Problems

Long-Term Problems Associated With Accumulations of Pollutants	• Sedimentation in stormwater conveyance systems and in receiving waters. • Nuisance algae growths from nutrient discharges. • Inedible fish, undrinkable water, and shifts to less sensitive aquatic organisms caused by toxic heavy metals and organics.
Short-Term Problems Associated With High Pollutant Concentrations or Frequent High Flows (Event Related)	• Swimming beach closures from pathogenic microorganisms. • Water quality violations. • Property damage from increased flooding and drainage system failures. • Habitat destruction caused by frequent high flow rates (e.g., bed scour, bank erosion, flushing of organisms downstream).

SLAMM Computational Processes

Figure 1 illustrates the development characteristics that affect stormwater quality and quantity. This figure shows a variety of drainage systems, from concrete curb and gutters to grass swales, along with directly connected roof drainage systems and drainage systems that drain to pervious areas. "Development characteristics" define the magnitude of these drainage efficiency attributes, along with the areas associated with each surface type (e.g., road surfaces, roofs, landscaped areas). The use of SLAMM shows that these characteristics greatly affect runoff quality and quantity. Land use alone is usually not sufficient to describe these characteristics. Drainage type (curbs and gutters or grass swales) and roof connections are probably the most important attributes affecting runoff quantity and quality. These attributes are not directly related to land use, but some trends are obvious; most roofs in strip commercial and shopping center areas are directly connected, and the roadside is most likely drained by curbs and gutters, for example. Different land uses, of course, are also associated with different levels of pollutant generation. For example, industrial areas usually have the greatest pollutant accumulations.

Figure 2 shows how SLAMM considers a variety of pollutant and flow routings that may occur in urban areas. SLAMM routes material from unconnected sources directly to the drainage system or to adjacent directly connected or pervious areas, which in turn drain to the collection system. Each of these areas has pollutant deposition mechanisms in addition to removal mechanisms associated with them. As an example, unconnected sources, which may include rooftops draining to pervious areas or bare ground and landscaped areas, are affected by regional air pollutant deposition (from point source emissions or from fugitive dust) and other sources that would affect all surfaces. Pollutant losses from these unconnected sources are caused by wind removal and rain runoff washoff, which flows directly to the drainage system or to adjacent areas. The drainage system may include curbs and gutters, where there is limited deposition, and catch basins and grass swales, which may remove substantial participates that are transported in the drainage system. Directly connected impervious areas include paved surfaces that drain directly to the drainage system. These source areas are also affected by regional pollutant deposition, in addition to wind removal and controlled removal processes, such as street cleaning. Onsite storage is also important on paved surfaces because of the large amount of participate pollutants that are not washed off, blown off, or removed by direct cleaning (2, 4, 6).

Figure 3 shows how SLAMM proceeds through the major calculations. There is a double set of nested loops in the analyses where runoff volume and suspended solids (particulate residue) are calculated for each source area and then for each rain. These calculations consider the effects of each source area control, in addition to the runoff pattern between areas. Suspended solids washoff and runoff volume from each individual area for each rain are summed for the entire drainage system. The effects of the drainage system controls (catch basins or grass swales, for example) are then calculated. Finally, the effects of the outfall controls are calculated.

SLAMM uses the water volume and suspended solids concentrations at the outfall to calculate the other pollutant concentrations and loadings. SLAMM keeps track of the portion of the total outfall suspended solids loading and runoff volume that originated from each source area. The suspended solids fractions are then used to develop weighted loading factors associated with each pollutant. In a similar manner, dissolved pollutant concentrations and loadings are calculated based on the

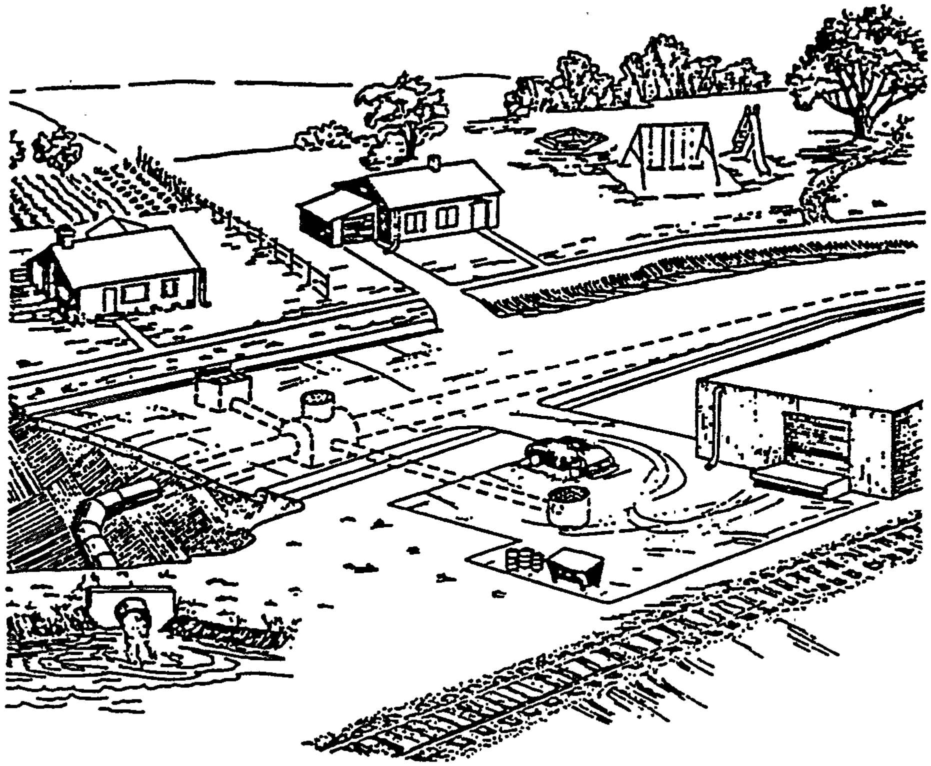

Figure 1. Urban runoff source areas and drainage alternatives (9).

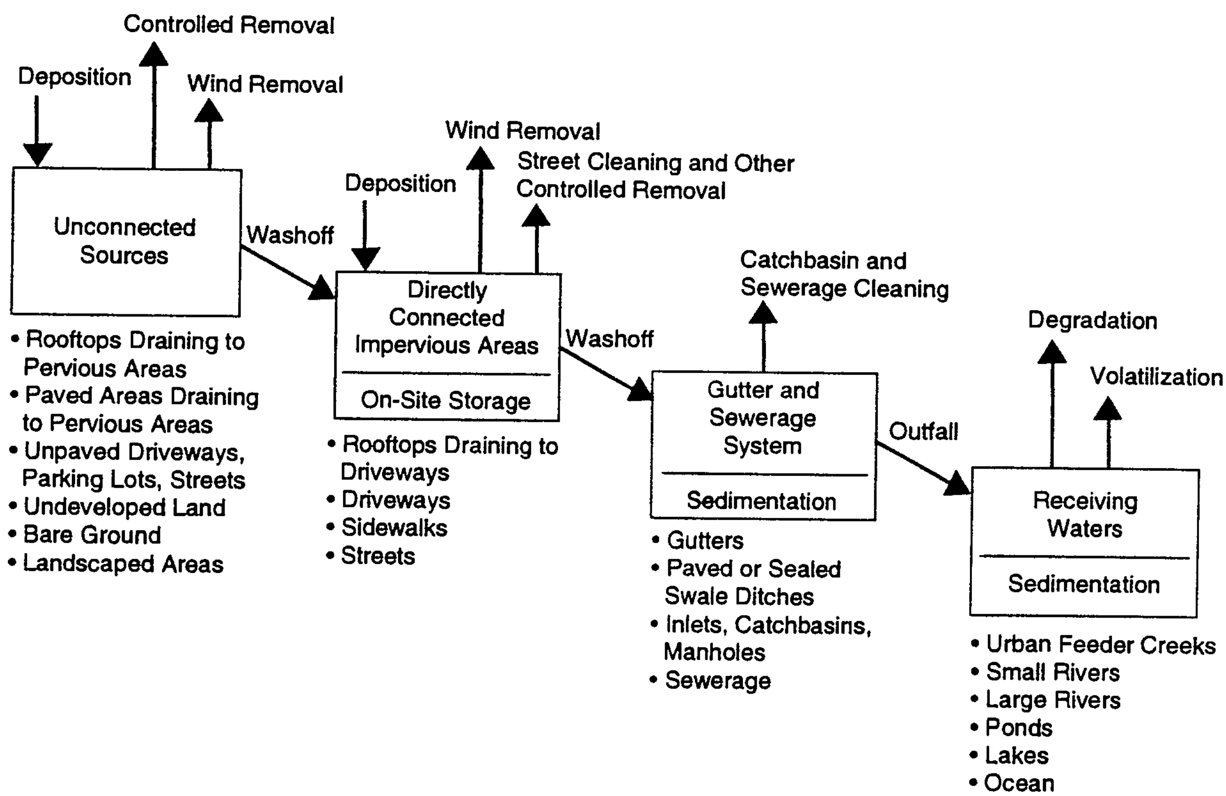

Figure 2. Pollutant deposition and removal at source areas (9).

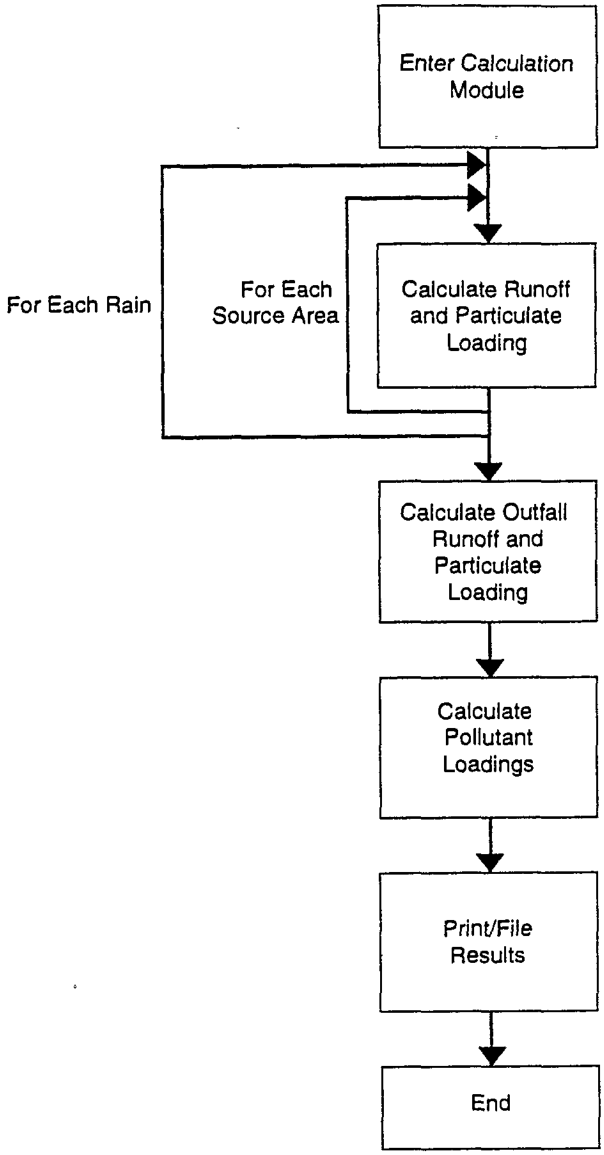

Figure 3. SLAMM calculation flow chart.

percentage of water volume that originates from each of the source areas within the drainage system.

SLAMM predicts urban runoff discharge parameters (total storm runoff flow volume, flow-weighted pollutant concentrations, and total storm pollutant yields) for many individual storms and for the complete study period. It has built-in Monte Carlo sampling procedures to consider many of the uncertainties common in model input values. This enables the model output to be expressed in probabilistic terms that represent the likely range of results expected.

Unique Aspects of SLAMM

SLAMM is unique in many aspects. One of the most important aspects is its ability to consider many stormwater controls (affecting source areas, drainage systems, and outfalls) together, for a long series of rains. Another is its ability to accurately describe a drainage area in sufficient detail for water quality investigations without requiring a great deal of superfluous information that field studies have shown to be of little value in accurately predicting discharge results. SLAMM also applies stochastic analysis procedures to represent actual uncertainty in model input parameters to better predict the actual range of outfall conditions (especially pollutant concentrations). The main reason SLAMM was developed, however, was because of problem areas in many existing urban runoff models. The following paragraphs briefly describe small storm hydrology and particulate washoff, the most significant of these problem areas.

Small Storm Hydrology

One of the major problems with conventional stormwater models concerns runoff volume estimates associated with small storms. Figures 4 and 5 show the importance of common small storms when considering total annual pollutant discharges. Figure 4 shows the accumulative rain count and the associated accumulative runoff volume for a medium density residential area in Milwaukee, Wisconsin, based on 1983 monitored data (11). This figure shows that the median rain, by count, was about 0.3 in., while the rain associated with the median runoff quantity is about 0.75 in. Therefore, more than half of the runoff from this common medium density residential area was associated with rain events that were smaller that 0.75 in. The 1983 rains (which were monitored during the Milwaukee NURP project) included several very large storms, which are also shown on Figure 4. These

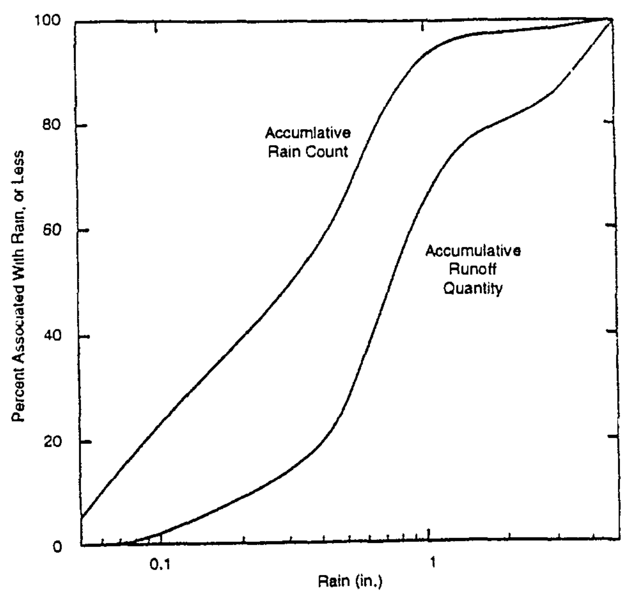

Figure 4. Milwaukee rain and runoff distributions (medium-density residential area).

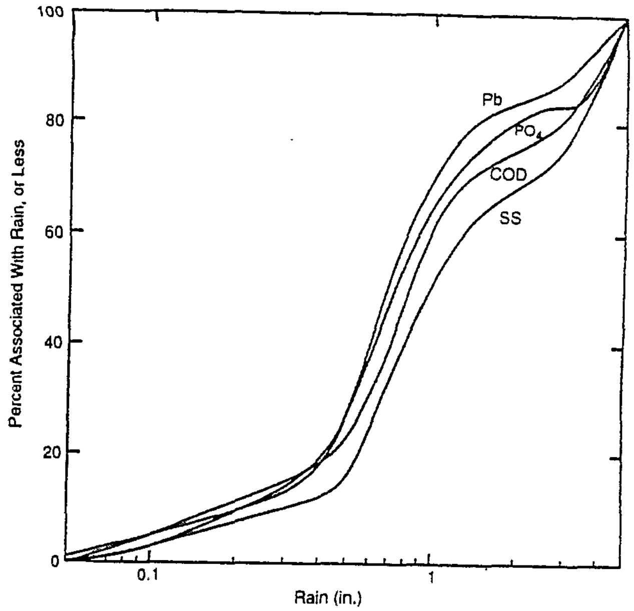

Figure 5. Milwaukee pollutant discharge distributions (medium-density residential area).

large storms (3 to 5 in. in depth) distort Figure 4 because, on average, the Milwaukee area only can expect one 3.5-in. storm every 5 years. If these large rains did not occur in most years, then the significance of the small rains would be even greater.

Figure 5 shows the accumulative loadings of different pollutants (suspended solids, chemical oxygen demand, phosphates, and lead) monitored during 1983 in Milwaukee at the same site as the rain and runoff data shown in Figure 4 (11). When Figure 5 is compared with Figure 4, runoff and discharge distributions appear very similar. This is a simple way of indicating that no significant trends of stormwater concentrations were observed for different size events. Substantial variations in pollutant concentrations were observed, but these were random and not related to storm size. Similar conclusions were noted when all of the NURP data were evaluated (5). Therefore, accurately knowing the runoff volume is very important when studying pollutant discharges. By better understanding the significance and runoff generation potential of these small rains, runoff problems will be better understood.

Figure 6 illustrates the concept of variable contributing areas as applied to urban watersheds. This figure indicates the relative significance of three major source areas (street surfaces, other impervious surfaces, and pervious surfaces) in an urban area. The individual flow rates associated with each of these source areas increase until their time of concentrations are met. The flow rate then remains constant for each source area until the rain event ends. When the rain stops, runoff recession curves occur, draining the individual source areas. The three component hydrographs are then added together to form the complete hydrograph for the

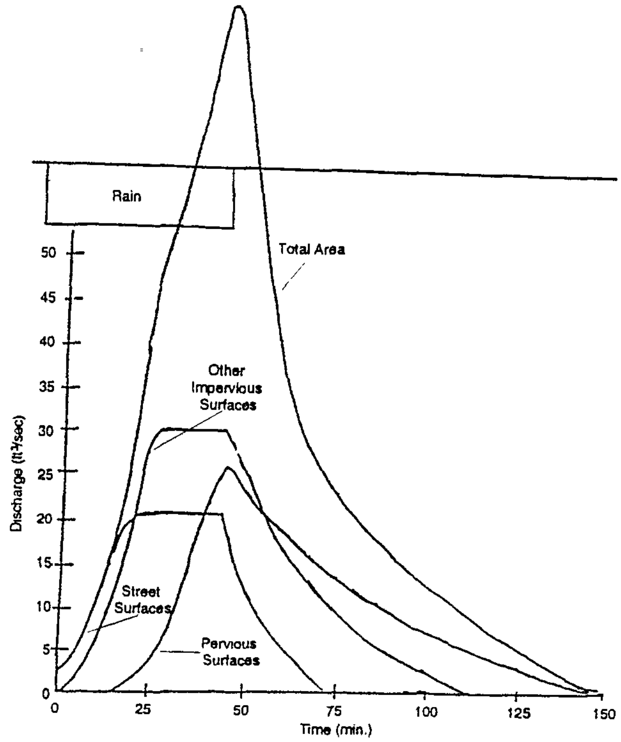

Figure 6. Variable contributing areas in urban watersheds.

area. Calculating the percentage of the total hydrograph associated with each individual source area enables estimates of the relative importance of each source area to be quantified. The relative pollutant discharges from each area can then be calculated from the runoff pollutant strengths associated with each area.

When the time of concentration and the rain duration are equal for an area, the maximum runoff rate for that rain intensity is reached (12). The time of concentration occurs when the complete drainage area is contributing runoff to the point of concern. If the rain duration exceeds the time of concentration, then the maximum runoff rate is maintained until the rain ends. When the rain ends, the runoff rate decreases according to a recession curve for that surface. The example shown in Figure 6 is for a rain duration greater than the times of concentrations for the street surfaces and other impervious areas, but shorter than the time of concentration for the pervious areas. Similar runoff quantities originated from each of the three source areas for this example. If the same rain intensity occurs but lasts for twice the duration (a less frequent storm), the runoff rates for the street surfaces and other impervious surfaces will be the same until the end of the rain, when their recession curves would begin. The pervious surface contribution would increase substantially, however, because its time of concentration may be exceeded by the longer rain duration. If the same rain intensity occurs but only for half of the original duration, the street surfaces time of concentration is barely met, and the other impervious surfaces would not have reached their time of concentration. In this last example, the pervious surfaces would barely begin to cause runoff. In this last case, the street surfaces are the dominant source of runoff water. By knowing the relative contributions of water and pollutants from each source area, it is possible to evaluate potential source area runoff controls for different rains.

Figure 7 shows monitored rainfall-runoff results from one of a series of tests conducted to investigate runoff losses associated with common small rains on pavement (13). This figure indicates that initial abstractions (detention storage plus evaporation losses) for this pavement totaled about 1 mm, while the total rainfall losses were about 6 mm. These maximum losses occurred after about 20 mm of rain. For a relatively small rain of about 7 mm, almost one-half of the rain falling on this pavement did not contribute to runoff. During smaller storms, the majority of the rainfall did not contribute to runoff. These rainfall losses for pavement are substantially greater than commonly considered in stormwater models. Most stormwater models use rainfall-runoff relationships that have been developed and used for many years for drainage design. Drainage design is concerned with rain depths of at least several inches. When these same procedures are used to estimate the runoff associated with common small storms (which are the most important in water quality investigations), the runoff predictions can be highly inaccurate. As an example, Figure 8 is a plot of

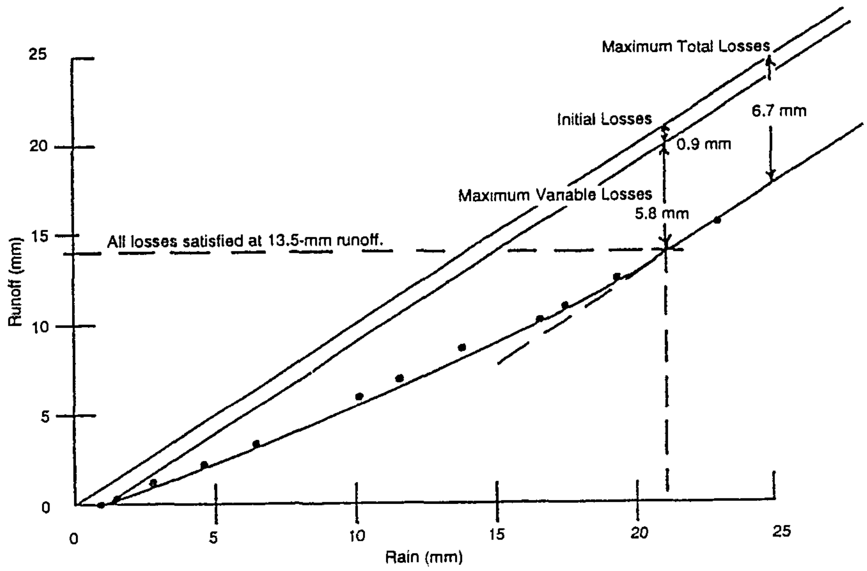

Figure 7. Rainfall-Runoff plot (example for high-intensity rains, clean and rough streets) (13).

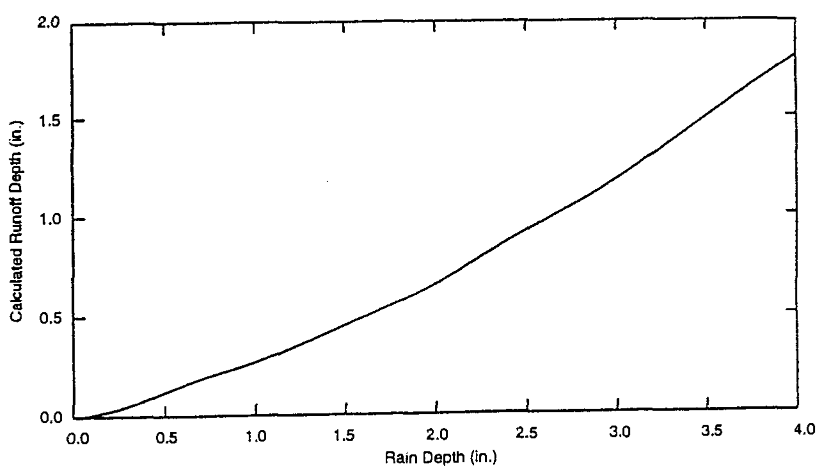

Figure 8. Rainfall-Runoff plot (medium-density area with clayey soils).

the observed runoff for different rain depths in Milwaukee during the 1983 NURP investigations. It was noted previously that several storms were monitored during this period that were very large. The volumetric runoff coefficient (the ratio of runoff to rain depth) observed varies for each rain depth. This ratio can be about 0.1 for storms of about 0.5 in. but may approach 0.4 for a moderate size storm of 2.5 in. or greater which is typically associated with drainage events. The NURP study (5), however, recommended the use of constant (average) volumetric runoff coefficients for the stormwater permit process. Therefore, the runoff volumes of common small storms would most likely be overpredicted.

Figure 9 shows the calculated SCS (14) CNs associated with different storms at a medium density residential site in Milwaukee. This figure shows that the CN values vary dramatically for the different rain depths that actually occurred at this site. The CN values approach the CN values that would be selected for this type of site only for rains greater than several inches in depth. The CN values are substantially greater for the smaller common storms, especially for rains less than the 1-in. minimum rain criteria given by SCS (14) for the use of this procedure. These results are similar to those obtained at many other sites. In almost all cases, the CN values for storms of less than 0.5 in. are 90 or greater. Therefore, the smaller storms contribute much more runoff than would typically be assumed if using SCS procedures. The CN method was initially developed, and is most appropriate, for use in the design of drainage systems associated with storms of much greater size than those of interest in stormwater quality investigations.

SLAMM makes runoff predictions using the small storm hydrology methods developed by Pitt (13). Figure 10

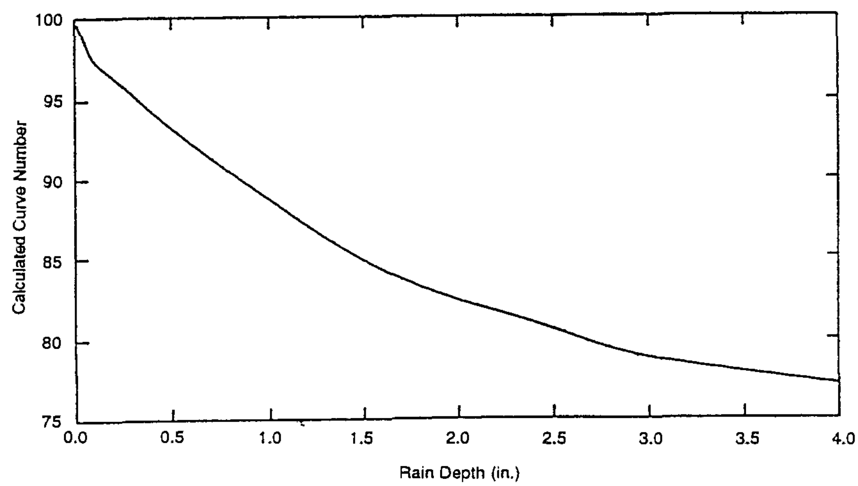

Figure 9. Curve number changes for different rain depths (medium-density area with clayey soils).

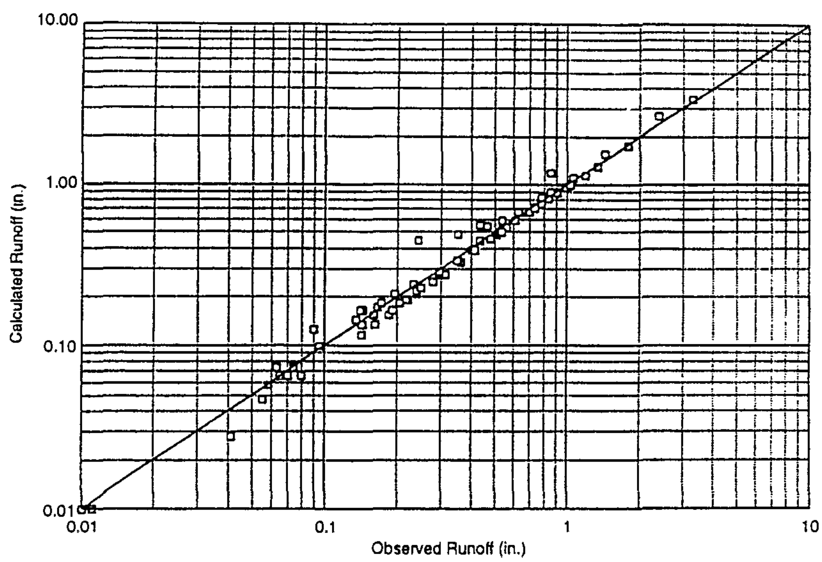

Figure 10. Commercial shopping center runoff verification.

shows the verification of the small storm hydrology method used in SLAMM for storms from a commercial area in Milwaukee. This figure shows that the calculated runoff for many storms over a wide range of conditions was very close to the actual observed runoff. Figure 11 shows a similar plot of the predicted versus observed runoff for a Milwaukee medium density residential area. These two sites were substantially different from each other in the amount of impervious surfaces and in the way these areas were connected to the drainage system. Similar satisfactory comparisons using these small storm hydrology models for a wide range of rain events have been made for other locations, including Portland, Oregon (15), and Toronto, Canada (8).

Particulate Washoff

Another unique feature of SLAMM is its use of a washoff model to predict the losses of suspended solids from different surfaces. Figure 12 is a plot of the suspended solids concentrations for different rain depths for sheetflow runoff from paved surfaces during controlled tests in Toronto (13). This figure shows local "first-flush" effects, with a trend of decreasing suspended solids concentration with increasing rain depth. During the smallest rains, these concentrations are shown to be about several hundred milligrams per liter, and as high as 4,000 mg/L. The suspended solids concentrations during the largest events (about 1 in. in depth) decreased

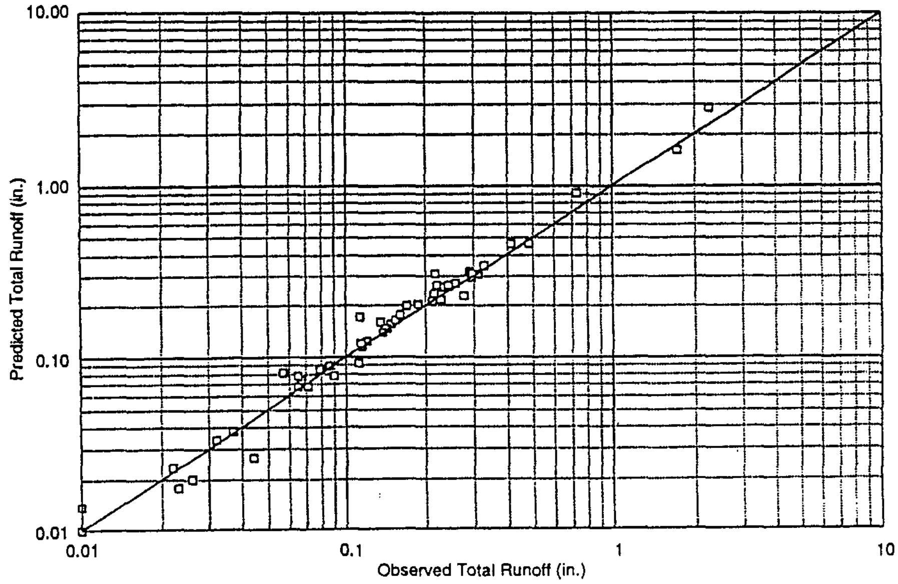

Figure 11. Medium-density residential area runoff verification.

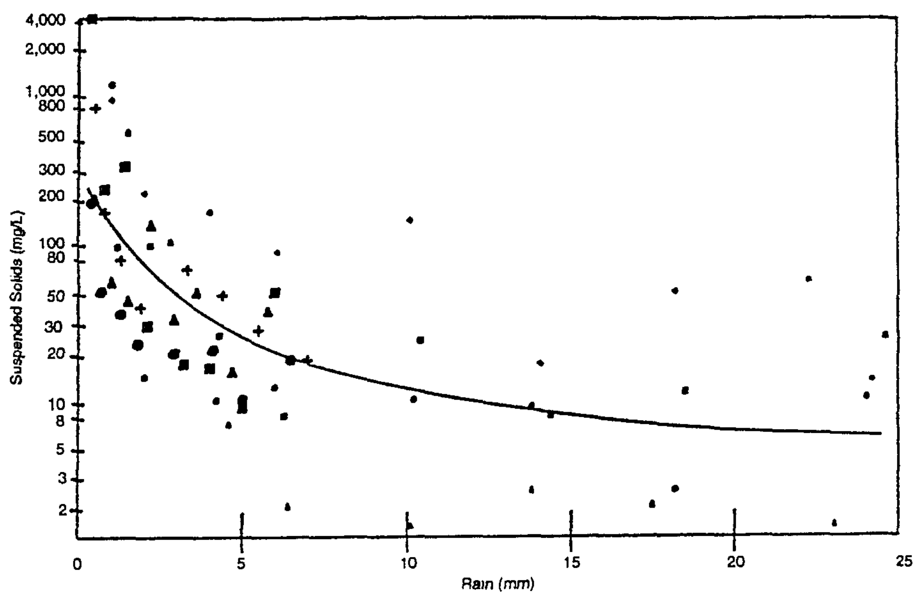

Figure 12. Pavement "first-flush" suspended solids concentrations (13).

R0015861

dramatically to about 10 mg/L. These data were obtained during controlled small storm hydrology and particulate washoff tests using carefully controlled and constant rain intensities. A first flush of pollutants, as seen in this figure, is likely only to occur for relatively small homogeneous surfaces subjected to relatively constant rain intensities. First flushes at storm drain outfalls may not be commonly observed because of the routing of many different individual first-flush flows that are mixed. Because the highest concentrations associated with these individual flows reach the outfall at different times, these individual first flushes are mixed and lost. More significantly, later times during a rain may have much higher periods of peak rain intensities, resulting in peak washoff late in a storm. Intermittent periods of high rain intensities later in rains likely cause localized periods of high runoff pollutant concentrations that may occur long after the beginning of the rain. Therefore, first-flush situations are most likely to occur for homogeneous drainage areas (such as for large paved areas or roofs) during relatively constant rain intensities.

SLAMM calculates suspended solids washoff based on individual first-flush (exponential) plots for each surface. These plots are derived from observations during rains and during controlled tests (8). The use of individual surface washoff plots has been verified using runoff observations from large and complex drainages (13). Figures 13 through 15 show washoff plots for total solids, suspended solids (>0.45 µm), and dissolved solids (<0.45 µm) during an example controlled street surface washoff test (13). These plots indicate the accumulative gram per square meter washoff as a function of rain

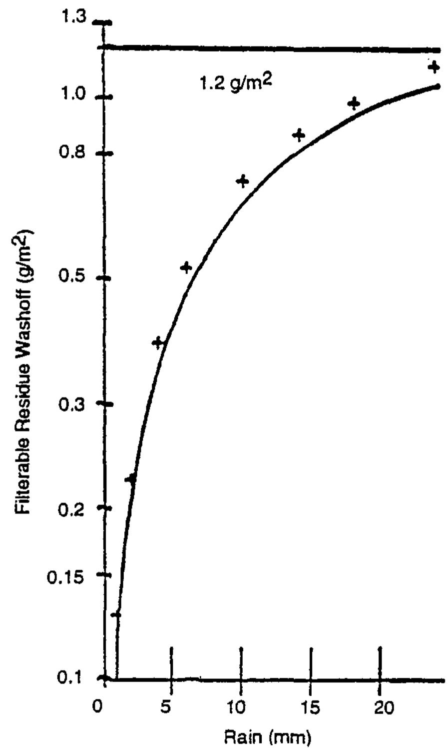

Figure 14. Dissolved solids washoff test results (13).

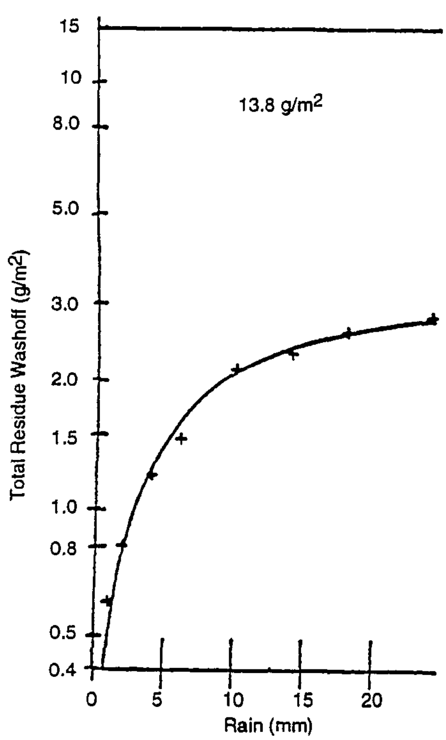

Figure 13. Total solids washoff test results (13).

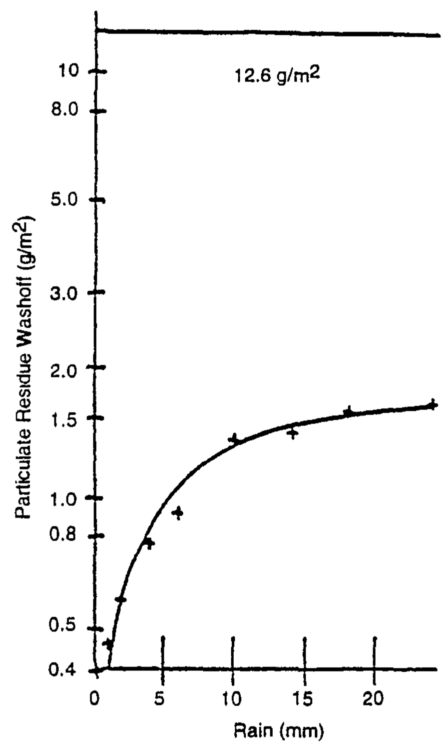

Figure 15. Suspended solids washoff test results (13).

R0015862

depth. Also shown on these figures are the total street dirt loadings. As an example, Figure 13 shows that 13.8 g/m^2 of total solids were on the street surfaces before the controlled rain event. After about 15 mm of rain fell on the test sites, almost 90 percent of the particulates that would wash off (about 3 g/m^2) did, similar to the rain depth needed for "complete" washoff as reported by earlier studies by Sartor and Boyd (16). The total quantity of material that could possibly wash off (about 3 g/m^2), however, is a small fraction of the total loading that was on the street (13.8 g/m^2). If the relationship between total available loading and total loading of particulates is not considered (as in many stormwater models), then the predicted washoff would be greatly in error.

Figure 14 is similar to Figure 13 but shows the smallest particle sizes ("dissolved solids," < 0.45 μm) as a function of washoff. Here, the total loading of the filterable solids on the streets was only about 1 g/m^2, and almost all of these small particles were available for washoff during these rains. Figure 15 shows the washoff of largest particles ("suspended solids," > 0.45 μm) on the street. Here, the street loading was 12.6 g/m^2, with only about 1.8 g/m^2 available for washoff. The predicted washoff of suspended solids could be in error by 700 percent if the total loading on the street was assumed to be removable by rains. SLAMM uses test results from Pitt (13) that measured the washoff and street dirt loading availability relationships for many street surfaces, rain intensities, and street dirt loadings to more accurately predict the amount of washoff.

Another common problem with stormwater models is the use of incorrect particulate accumulation rates for different surfaces. Figure 16 shows an example of the accumulation and deposition of street surface particulates for two residential areas monitored in San Jose, California (2). The two areas were very similar in land use but the street textures were quite different. The good condition asphalt streets were quite smooth, while the oil and screens overlaid streets were very rough. Immediately after intensive street cleaning, the rough streets still had substantial particulate loadings, while the smooth streets had substantially less. The accumulation of debris on the streets also increased the street dirt loadings over time.

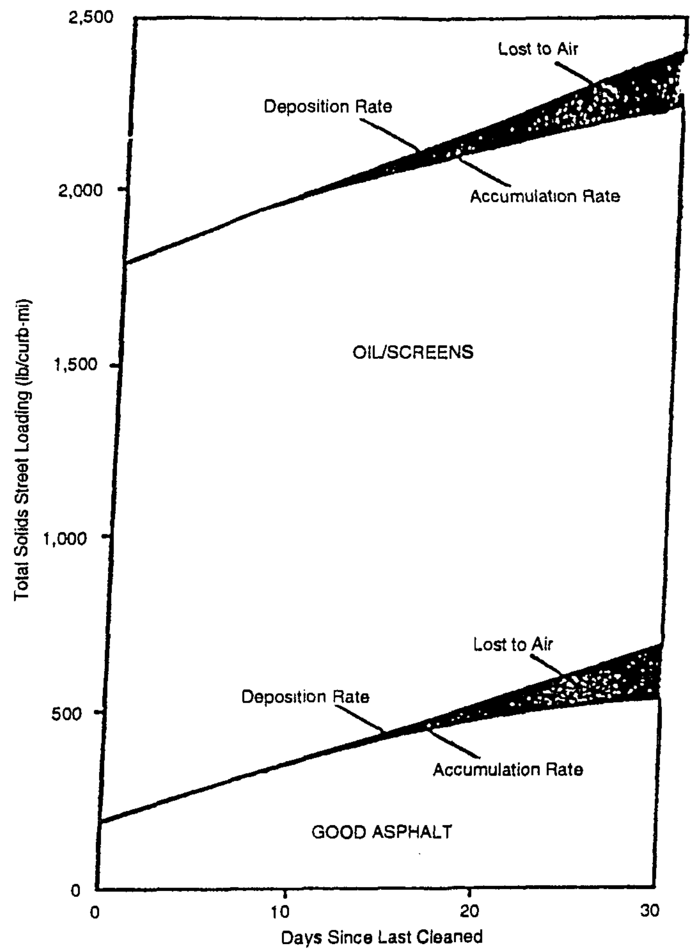

Figure 16. Deposition and accumulation rates of street dirt (13).

R0015863

The accumulation rates were very similar for these two different streets having the same land uses. The loadings on the streets at any given time, however, were quite different because of the greatly different initial loading values (permanent storage loadings). If infrequent street dirt loading observations are made, the true shape of the accumulation rate curve may not be accurately known. As an example, the early Sartor and Boyd (16) test results that have been used in many stormwater models assumed that the initial loading values after rains were close to zero, instead of the actual substantial initial loadings. The accumulation rates were calculated by using the slope between each individual loading value and the origin (zero time and zero loading), rather than between loadings from adjacent sampling times, which can easily result in accumulation rates many times greater than actually occurred.

The street dirt deposition rates were found to be only a function of the land uses, but the street dirt loadings were a function of the land use and street texture. The accumulation rates slowly decreased as a function of time and eventually became zero, with the loading remaining constant after a period of about 1 month of either no street cleaning or no rains. Figure 16 shows that the deposition and accumulation rates on the streets were about the same until about 1 or 2 weeks after a rain. If the streets were not cleaned for longer periods, then the accumulation rate decreased because of fugitive dust losses of street dirt to surrounding areas by winds or vehicle turbulence. In most areas of the United States (having rains at least every week or two), the actual accumulation of material on street surfaces is likely constant, with little fugitive dust losses (2).

SLAMM includes a large number of street dirt accumulation and deposition rate relationships that have been obtained for many monitoring sites throughout the United States and Canada. The accumulation rates are a function of the land uses, while the initial loadings on the streets are a function of street texture. The decreasing accumulation rate is also a function of the time after a street cleaning or large rain event.

Monte Carlo Simulation of Pollutants Strengths Associated With Runoff From Various Urban Source Areas

Initial versions of SLAMM only used average concentration factors for different land-use areas and source areas. This was satisfactory for predicting the event mean concentrations (EMC, as used by NURP [5]) for an extended period and for calculating the unit area loadings for different land uses. Figure 17 is a plot of the event mean concentrations at a Toronto test site (8). The observed concentrations are compared with the SLAMM predicted concentrations for a long-term simulation. All of the predicted EMC values are close to the observed EMC values. To predict the probability distributions of the concentrations, however, it was necessary to include probability information for the concentrations found in the different source areas. Statistical analyses of concentration data (attempting to relate concentration trends to rain depths and season, for example) from these different source areas have not been able to explain all of the observed variations in concentration. The statistical analyses also indicate that pollutant concentration values from individual source areas are distributed log normally. Therefore, log-normally distributed random concentration values are used in SLAMM

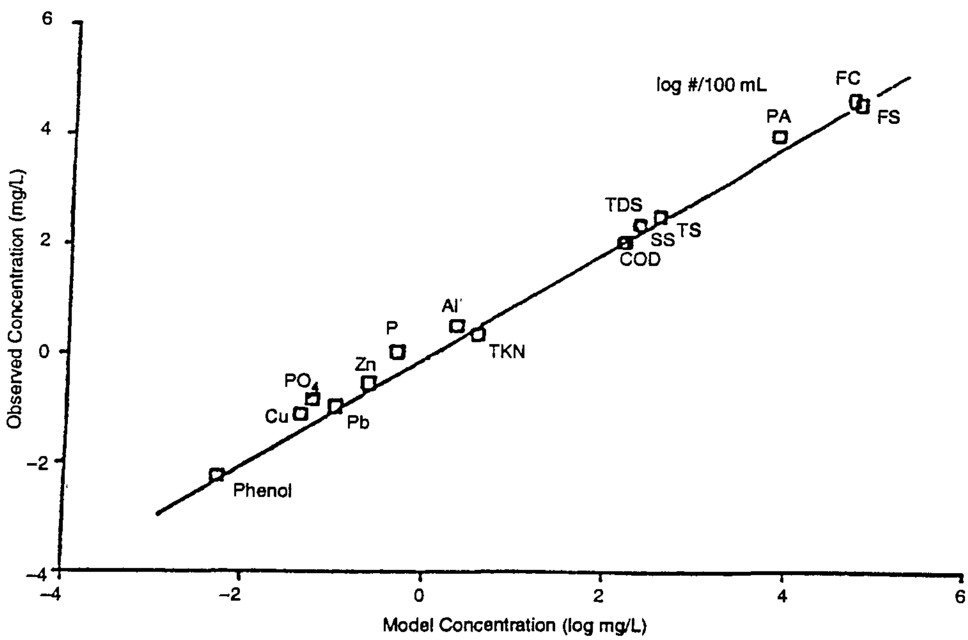

Figure 17. Observed and modeled pollutant concentrations (Toronto industrial site) (8).

R0015864

for these different areas. The results are predictions for concentration distributions at the outfall. This can provide estimates of criteria violations for different stormwater pollutants at an outfall for long, continuous simulations.

An Example Analysis Using SLAMM To Identify the Sources of Pollutants and To Evaluate Different Control Programs

Table 2 is a field sheet that has been developed to assist users of SLAMM to describe test watershed areas. This sheet is used to evaluate stormwater control retrofit practices in existing developed areas, and to examine how different new development standards effect runoff conditions. Much of the information on the sheet is not actually required to operate SLAMM but is very important when considering additional control programs, such as public education and good housekeeping practices, that are not quantified by SLAMM. The most important information shown on this sheet is the land use, the type of the gutter or drainage system, and the method of drainage from roofs and large paved areas to the drainage system. The efficiency of drainage in an area, specifically if roof runoff or parking runoff drains across grass surfaces, can be very important when determining the amount of water and pollutants that enter the outfall system. Similarly, the presence of grass swales in an area may substantially reduce the amount of pollutants and water discharged. This information is therefore required to use SLAMM.

The areas of the different surfaces in each land use are also very important for SLAMM. Figure 18 is an example showing the areas of different surfaces for a medium density residential area in Milwaukee. As shown in this

R0015866

example, streets make up between 10 and 20 percent of the total area, while landscaped areas can make up about half of the drainage area. The variation of these different surfaces can be very large within a designated area. The analysis of many candidate areas may therefore be necessary to understand how effective or consistent the model results may be for a general land-use classification.

Control practices evaluated by SLAMM include infiltration trenches, seepage pits, disconnections of directly connected roofs and paved areas, percolation ponds, street cleaning, porous pavements, catchbasin cleaning, grass swales, and wet detention ponds. These devices can be used singly or in combination, at source areas or at outfalls, or, in the case of grass swales and catchbasins, within the drainage system. In addition, SLAMM provides a great deal of flexibility in describing the sizes and other design aspects for these different practices.

One of the first problems in evaluating an urban area for stormwater controls is the need to understand where the pollutants of concern are originating under different rain conditions. Figures 19 through 22 are examples for a typical medium density residential area showing the percentage of different pollutants originating from different major sources, as a function of rain depth. As an example, Figure 19 shows the areas where water is originating. For storms of up to about 0.1 in. in depth, street surfaces contribute about one-half to the total runoff to the outfall. This contribution decreased to about 20 percent for storms greater than about 0.25 in. in depth. This decrease in the significance of streets as a source of water is associated with an increase in water contributions from landscaped areas (which make up more than 75 percent of the area and have clayey soils). Similarly, the significance of runoff from driveways and roofs also starts off relatively high and then decreases with increasing storm depth. Figures 20 and 21 are similar plots for suspended solids and lead. These show that streets contribute almost all of these pollutants for the smallest storms up to about 0.1 in. The contributions from landscaped areas then become dominant. Figure 22 shows that the contributions of phosphates are more evenly distributed between streets, driveways, and rooftops for the small storms, but the contributions from landscaped areas completely dominate for storms greater than about 0.25 in. in depth.

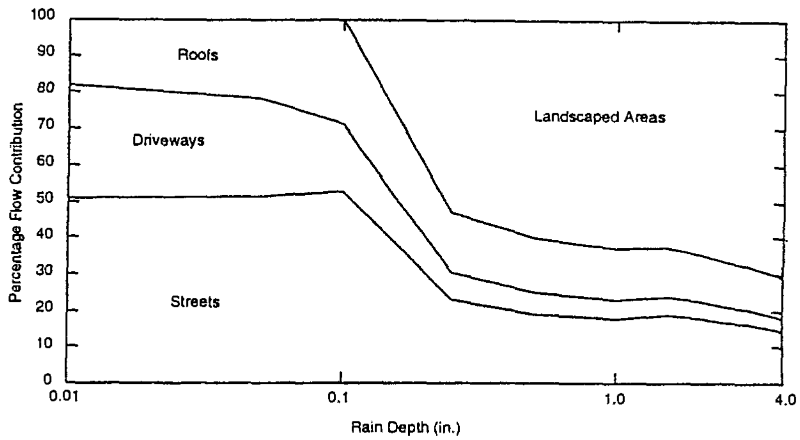

Figure 19. Flow sources for example medium-density residential area having clayey soils.

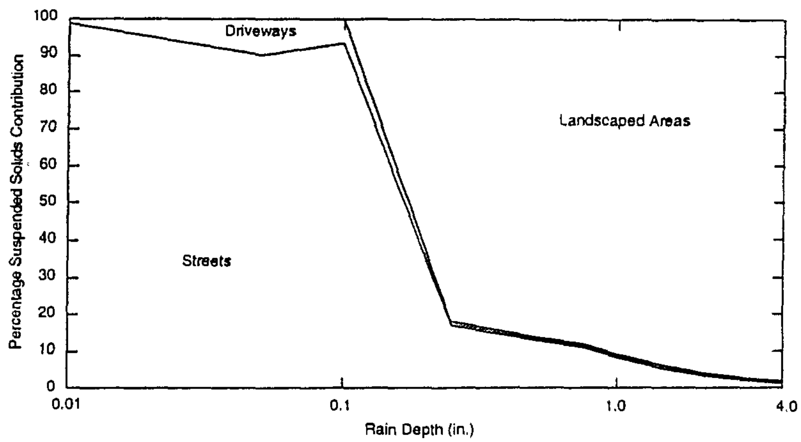

Figure 20. Suspended solids sources for example medium-density residential area.

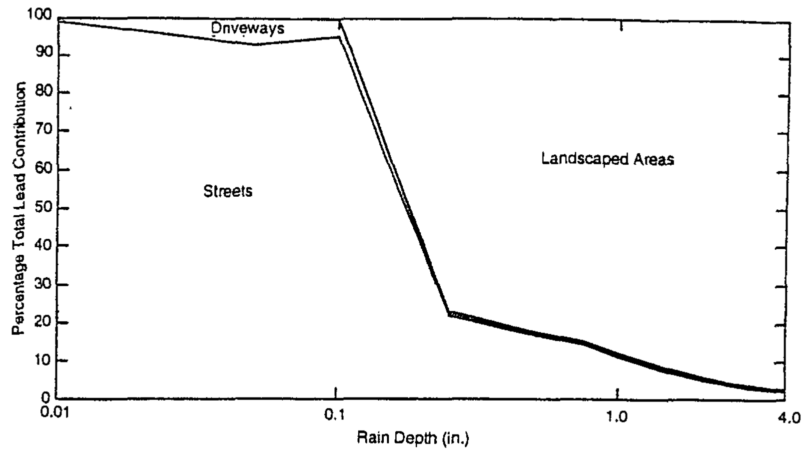

Figure 21. Total lead sources for example medium-density residential area.

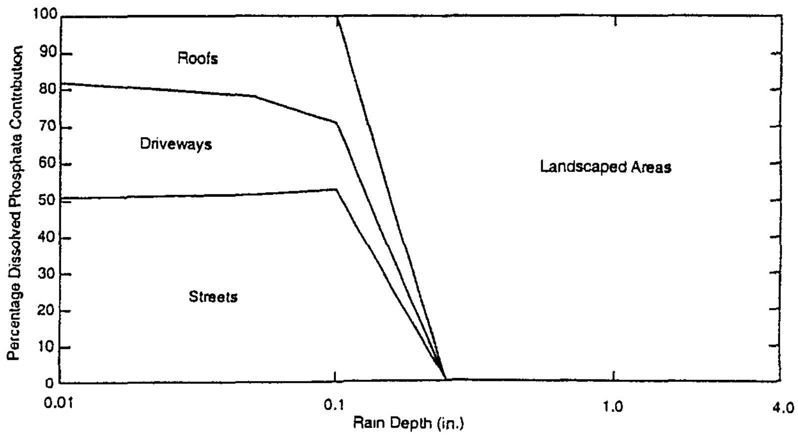

Figure 22. Dissolved phosphate sources for example medium-density residential area.

Obviously, the specific contributions from different areas and for different pollutants vary dramatically, depending on the characteristics of development for the area and the source controls used. Again, a major use of SLAMM is to better understand the role of different sources of pollutants. As an example, to control suspended solids, street cleaning (or any other method to reduce the washoff of particulates from streets) may be very effective for the smallest storms but would have very little benefit for storms greater than about 0.25 in. in depth. Erosion control from landscaped surfaces, however, may be effective over a wider range of storms.

The following list shows the different control programs that were investigated in this hypothetical medium density residential area having clayey soils:

- Base level (as built in 1961 to 1980, with no additional controls).
- Catchbasin cleaning.
- Street cleaning.
- Grass swales.
- Roof disconnections.
- Wet detention pond.
- Catchbasin and street cleaning combined.
- Roof disconnections and grass swales combined.
- All of the controls combined.

This residential area, which was based on actual Birmingham, Alabama, field observations for homes built between 1961 to 1980, has no controls. The use of catchbasin cleaning and street cleaning in the area was evaluated. Grass swale use was also evaluated, but swales are an unlikely retrofit option and would only be appropriate for newly developing areas. It is possible, however, to disconnect some of the roof drainages and divert the roof runoff away from the drainage system and onto grass surfaces for infiltration in existing developments. In addition, wet detention ponds can be retrofitted in different areas and at outfalls. Besides those controls examined individually, catchbasin and street cleaning controls combined were also evaluated, in addition to the combination of disconnecting some of the rooftops and the use of grass swales. Finally, the prospect of using all of the controls together was examined.

The following list shows a general description of this hypothetical area:

- All curb and gutter drainage (in fair condition).
- 70 percent of roofs draining to landscaped areas.
- 50 percent of driveways draining to lawns.
- 90 percent of streets of intermediate texture (remaining are rough).
- No street cleaning.
- No catchbasins.

About one-half of the driveways currently drain to landscaped areas, while the other half drain directly to the pavement or the drainage system. Almost all of the streets are of intermediate texture, and about 10 percent are rough textured. There currently is no street cleaning or catchbasin cleaning.

The level of catchbasin use that was investigated for this site included 950 ft^3 of total sump volume per 100 acres (typical for this land use), with a cost of about $50 per catchbasin cleaning. Typically, catch basins in this area could be cleaned about twice a year for a total annual cost of about $85 per acre of the watershed.

Street cleaning could also be used, with a monthly cleaning effort of about $30 per year per watershed acre. Light parking and no parking restrictions during cleaning are assumed, and the cleaning cost is estimated to be $80 per curb mile.

Grass swale drainage was also investigated. Assuming that swales could be used throughout the area, there could be 350 ft of swales per acre (typical for this land use), with swales 3.5 ft wide. Because of the clayey soil conditions, an average infiltration rate of about 0.5 in./hr was used in this analysis based on many different double-ring infiltrometer tests of typical soil conditions. Swales cost much less than conventional curb and gutter systems but require increased maintenance. Again, the use of grass swales is appropriate for new development but not for retrofitting in this area.

Roof disconnections could also be used as a control measure by directing all roof drains to landscaped areas. The objective would be to direct all the roof drains to landscaped areas. Because 70 percent of the roofs already drain to the landscaped areas, only 30 percent could be further disconnected, at a cost of about $125 per household. The estimated total annual cost would be about $10 per watershed acre.

An outfall wet detention pond suitable for 100 acres of this medium density residential area would have a wet pond surface of 0.5 percent of drainage area for approximately 90 percent suspended solids control. It would need 3 ft of dead storage and live storage equal to runoff from 1.25-in. rain. A 90-degree V notch weir and a 5-ft wide emergency spillway could be used. No seepage or evaporation was assumed. The total annual cost was estimated to be about $130 per watershed acre.

Table 3 summarizes the SLAMM results for runoff volume, suspended solids, filterable phosphate, and total lead for 100 acres of this medium density residential area. The only control practices evaluated that would reduce runoff volume are the grass swales and roof disconnections. All of the other control practices evaluated do not infiltrate stormwater. Table 3 also shows the total annual average volumetric runoff coefficient (Rv) for these different options. The base level of control has an annual flow-weighted Rv of about 0.3, while the use of swales would reduce the Rv to about 0.1. Only a small reduction of Rv (less than 10 percent) would be associated with complete roof disconnections compared with the existing situation because of the large amount of roof disconnections that already occur. The suspended solids analyses shows that catchbasin cleaning alone could result in about 14 percent suspended solids reductions. Street cleaning would have very little benefit, while the use of grass swales would reduce the suspended solids discharges by about 60 percent. Grass swales would have minimal effect on the reduction of suspended solids concentrations at the outfall. (They are primarily an infiltration device, having very little filtering benefits.) Wet detention ponds would remove about 90 percent of the mass and concentrations of suspended solids. Similar observations can be made for filterable phosphates and lead.

Figures 23 through 26 show the maximum percentage reductions in runoff volume and pollutants, along with associated unit removal costs. As an example, Figure 23 shows that roof disconnections would have a very small potential maximum benefit for runoff volume reduction, at a very high unit cost compared with other practices. The use of grass swales could have about a 60-percent reduction at minimal cost. The use of roof disconnection plus swales would slightly increase the maximum benefit to about 65 percent, at a small unit cost. Obviously, the use of roof disconnections alone, or all controlled practices combined, is very inefficient for this example. For suspended solids control, catchbasin cleaning and street cleaning would have minimal benefit at high cost, while the use of grass swales would produce a substantial benefit at very small cost. If additional control is necessary, however, the use of wet detention ponds may be necessary at a higher cost. If close to a 95-percent reduction of suspended solids was required, then all of the controls investigated could be used together, but at substantial cost.

Conclusions

This paper has shown how SLAMM can be used to estimate the relative contributions of different pollutants from different areas within a complex watershed. SLAMM can also be used to examine the cost effectiveness of different individual control programs, or combinations of control programs, that could be located at source areas or at the outfalls.

SLAMM is unique compared with most stormwater models. Specifically, the use of small storm hydrology to predict the contributions of runoff from different source areas and the use of particulate washoff algorithms have greatly enhanced the accuracy of SLAMM. In addition, SLAMM requires a minimum amount of information to describe the area under consideration and engineering design parameters for different control practices. SLAMM is a very useful tool in guiding planners and watershed managers in devising control strategies. It has also been used to quantify and justify the benefits associated with stormwater controls for newly developing areas.

Department of Environmental Resources, Division of Environmental Management, Watershed Protection Branch, Prince George's County, Landover, Maryland

Abstract

A geographic information system (GIS) based Watershed Simulation Model (GWSM) was developed for stormwater pollution control in Prince George's County, Maryland, using the Stormwater Management Model (SWMM 4.2), ARC/INFO (6.1), and data postprocessors. The GWSM was designed to perform planning level assessments of water quality concentrations and loadings for 12 water quality parameters in 41 primary watersheds within the county. The model combines continuous watershed modeling and the spatial analysis capabilities of a GIS in a single, integrated system operating on a Sun Sparc 2 workstation. The user selects a watershed to determine daily, monthly, seasonal, or annual stormwater pollutant loadings using the SWMM output. Additional routines analyze stormwater control structures and user-defined subbasins. GWSM output is saved for watershed comparisons using both graphical and tabular formats.

GWSM allows county water resources planners to perform analyses in the following areas:

- *Prioritize problem watersheds:* Identify where impacts are most severe based on pollutant-specific data. Both temporal and spatial problems and trends are identified.
- *Integration with water quality databases:* Data from national databases, including STORET, WATSTORE, and Reachfile III streams, are used in characterizing the water resources of the study area.
- *Alternative land use assessment:* Water quality impacts and trends, based on land use changes or future master planning scenarios, can be evaluated.
- *Screening solutions/microscale analysis:* Management assessment tools provide planning level screening of controls designed to cost-effectively manage the pollutants of concern. This allows determination of which flows and loads need to be controlled. Smaller, 100- to 400-acre drainage basins can also be evaluated with alternative land uses and management practices.

Introduction

The National Pollutant Discharge Elimination System (NPDES) municipal stormwater permit regulations resulting from the Clean Water Act Reauthorization of 1987 require large counties and municipalities to develop comprehensive stormwater management programs. For complex urban fringe areas such as Prince George's County, Maryland, prioritizing stormwater problems and developing cost-effective management techniques is a primary objective if program resources are to be efficiently allocated. The geographic information system (GIS) based Watershed Simulation Model (GWSM) was designed to support the development and implementation of the county's stormwater management program. GWSM enables planning assessment at the watershed level through estimation of pollutant loads and flows for current land use conditions and future buildout scenarios, with or without structural controls. At the small basin level, alternative stormwater control scenarios can be evaluated for user-defined areas.

Existing Watershed Models

A variety of models are available for simulating water quantity and quality on a watershed scale (1). These range from relatively simple empirical models that predict annual or storm loads to deterministic models that yield flow and pollutant loads for a variety of flow conditions.

R0015873

Simple models, such as the U.S. Environmental Protection Agency (EPA) Screening Procedures (2) model and the Simple Method (3), commonly aggregate the physical parameters for an entire watershed and calculate loads on an annual or seasonal time step. Although this reduces the amount of input data and time required to apply the model, it does not allow for an examination of the variations between storm events or water quality problems occurring over a wide range of hydrologic conditions.

Complex models, such as SWMM (4) and the Hydrologic Simulation Program-Fortran (HSPF) (5), simulate hydrologic processes that generate runoff and pollutant loads in a continuous manner rather than relying on simplified rates of change (1). This class of model can use time series climatic data for continuous simulation over several years, enabling analysis of not only annual loads and flows but also of single events or a series of storms.

Previous Studies

GIS is increasingly used for watershed assessment in support of various water resources programs (6). A review of available literature shows that the use of GIS in conjunction with hydrologic models comprises a major part of the current activities. The use of GIS for hydrologic modeling can be divided into two general approaches: 1) performing watershed modeling analyses directly within a GIS package using empirical or lumped models and 2) processing input data for use with a separate or partially linked watershed model.

Empirical modeling within a GIS environment includes an approach using the modified Universal Soil Loss Equation (USLE) for evaluating silvicultural activities and control programs in Montana (7). Tim et al. (8) coupled empirical simulation modeling with a GIS to identify critical areas of nonpoint source pollution in Virginia. On the other hand, linked GIS and hydrologic modeling approaches include a study by Ross and Tara (9) using a GIS to perform spatial data referencing and data processing while traditional hydrologic codes performed the calculations for time-dependent surface- and ground-water simulations. Terstriep and Lee (10) developed AUTO_QI, a GIS-based interface for watershed delineation and input data formatting to the Q-ILLUDAS model.

Modeling Approach: The Prince George's County GIS-Based Watershed Simulation Model

The GWSM developed for the Prince George's County stormwater program combines results from a watershed model with GIS analytic routines. Figure 1 illustrates this modular modeling approach. The GWSM uses a continuous simulation model to generate single land-use water quality and quantity time series data. ARC/INFO,

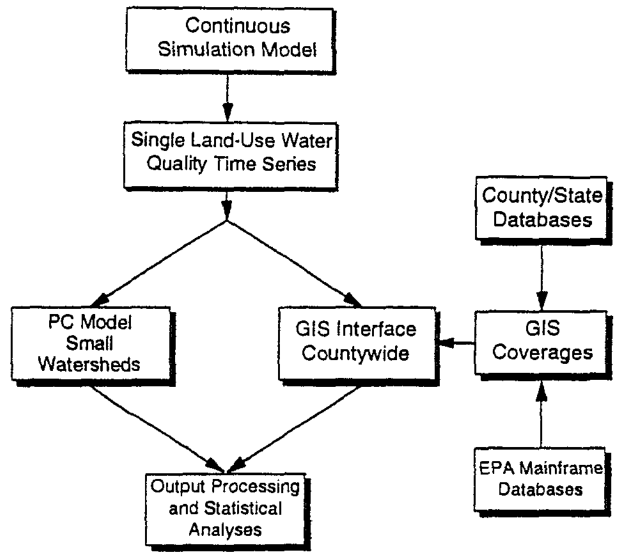

Figure 1. Watershed modeling approach.

combining GIS coverages from various databases, is used to select a watershed and determine its physical characteristics, including drainage area and land-use distribution. The single land-use time series, along with the land-use and drainage area files, are processed by a series of Fortran routines to determine watershed loads and summary statistics (Figure 1). Results can be interactively displayed for watershed comparisons and management assessment. As with AUTO_QI (10), the GWSM modeling approach uses the GIS to furnish data for use with a continuous simulation model. Unlike other approaches, however, GWSM uses preprocessed output from a watershed model to calculate storm flows and pollutant loads for the study watershed.

Although SWMM was used for this application of GWSM, results from other continuous simulation models can also be included in the model. This modular approach enables increased simulation accuracy as calibrated models become available. Further, several models can be used within a single application, combining the strengths of each. For instance, SWMM could be used for urban areas, while HSPF could be applied to agricultural lands within a single study area.

Input Data Requirements

GWSM requires both ARC/INFO vector coverages and continuous simulation model output for each land-use type modeled. Coverages include watershed boundaries and current land-use files. Input data for SWMM include parameters for the rainfall, temperature, and runoff blocks for each of the nine homogenous land-use basins.

A Case Study: Collington Branch Watershed

Water resource managers face multiple questions on how best to manage stormwater on a regional, watershed, and subbasin scale. In Prince George's County, an area covering over 480 square miles, there are 41 watersheds of varying size and land-use distribution. The proximity of the county to the fast-growing metropolitan Washington, DC, area makes stormwater management a complex and pressing problem.

An assessment of the predominantly forested and agricultural Collington Branch watershed, covering approximately 14,820 acres and draining to the Western Branch and to the Patuxent River, was performed as a demonstration of the GWSM. Figure 2 is the watershed selection screen from the GWSM, including the land-use distribution for the Collington Branch watershed. This case study demonstrates how the GWSM can be applied using a three-step approach: 1) identify and target problem watersheds, 2) identify pollutant sources and characterize pollutants, and 3) conceptually identify control measures and evaluate future land-use changes.

Watershed Problem Identification and Targeting

Often, the first questions that water resource managers ask are, How can problem watersheds be identified, and how do watersheds compare with each other in terms of pollutant loads and flows? GWSM enables the rapid analysis of the relative contributions of each watershed to the total load, performing a complete assessment and interpretation of the data within 10 minutes. The results

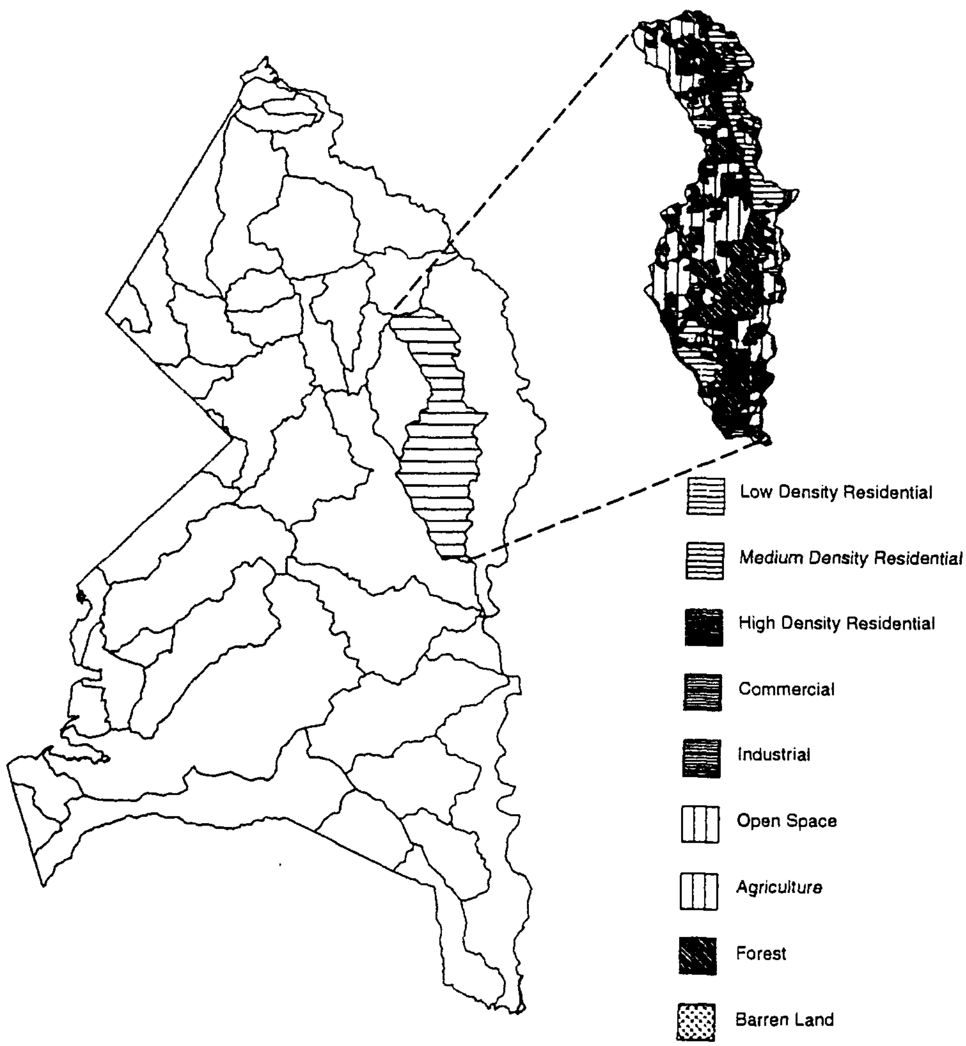

Figure 2. Watershed selection screen for the Collington Branch watershed, including land-use distribution.

R0015875

include estimates of annual, mean monthly, and monthly loads for the watershed for 12 parameters. Each constituent may be viewed either as a percentage of the total load or in actual units (pounds or cubic feet). Figure 3 presents the graphical display from GWSM showing the total nitrogen load for the Collington Branch, illustrating the changes in loads due to climatic variability.

A comparison between two watersheds is easily performed to assess load and flow estimates and review results graphically. Multiple applications provide a rapid assessment of all the major watersheds in the county. This phase of the GWSM analysis provides information to answer the questions, Which are the likely water quality impacts, and how significant are they compared to other watersheds?

Identify Pollutant Sources and Characterize Pollutant of Concern

Once problem watersheds are identified and targeted for further analysis, the water quality problems must be clearly defined. What are the sources of the pollutants of concern? An analysis of the pollutant contribution by land use is included in GWSM, calculating constituent load by land use for each of the 12 parameters. Figure 4 shows total nitrogen contributions for each land use in the Collington Branch, indicating that agricultural areas are the primary source. This provides important information for targeting control programs throughout the watershed. Characterizing the pollutant loads is an important issue for developing management programs. The following questions are answered at this phase: What pollutants are of primary concern? What are their sources and spatial and temporal characteristics? How do their loads vary seasonally and annually? What are the temporal variations between pollutants? To answer these questions, GWSM provides graphical displays of mean monthly, mean annual, and annual pollutant loads for each pollutant.

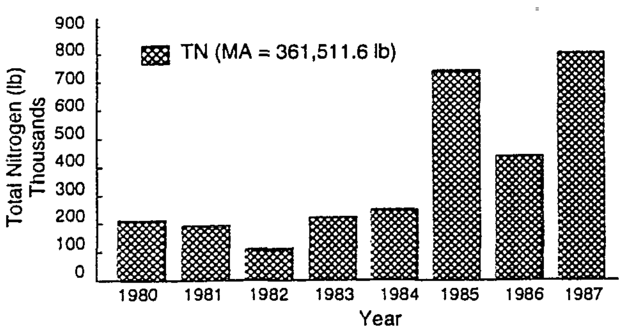

Figure 3. Annual summary of total nitrogen load, Collington Branch watershed, illustrating changes in loads due to climatic variability.

Management Screening

In this phase, implementing the most cost-effective controls is addressed. To address control measures, the relationship between storm size, runoff volume, and pollutant load must be assessed. For example, what storm sizes contribute the largest pollutant loads, and which storm size should be targeted? The analytic routines in GWSM provide graphical answers to these questions. Figure 5 presents lead loads by storm size, indicating that targeting only a percentage of runoff will control over half of the total load. Figure 6 illustrates the rainfall/runoff characteristics of the watershed, with the majority of storms generating less than 0.05 in. of runoff. These estimates will vary by watershed and type of pollutant, but GWSM allows rapid analysis of each pollutant and multiple watersheds.

Management evaluation is done at both watershed- and site-specific levels. Over an entire watershed, what is the optimal control level for structural water quality facilities? GWSM includes a stormwater pond routine that calculates the pollutant mitigating effects of different

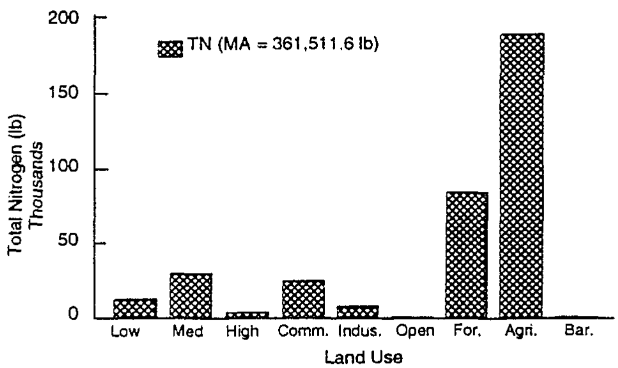

Figure 4. Total nitrogen load by land use, Collington Branch watershed.

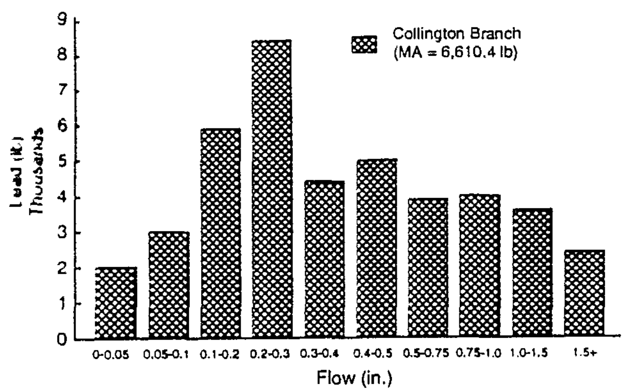

Figure 5. Lead distribution by storm size, Collington Branch watershed.

R0015876

control levels and retention times. At a site-specific level, such as a proposed new subdivision, similar structures can also be evaluated to allow optimal design criteria to be selected. Figure 7 illustrates the phosphorus contribution for a simulated residential subdivision, and the pollutant reduction from a stormwater pond designed to control for 0.3 in. of runoff. As seen in Figure 7, the mean annual phosphorus load was reduced from 453 to 277 lb by the simulated structure.

Managers must address how future changes will affect water quality. On the watershed level, what will be the impact of urbanization on flow and pollutants loads? At the subbasin level, how will proposed projects change the runoff characteristics? Both land use scenarios can be evaluated in GWSM. On the watershed scale, the current land use can be interactively changed with a "point-and-click" menu. At the subbasin level, a user-defined basin may be modeled, with the land-use distribution entered into a pulldown menu. At both watershed and subbasin levels, once a land-use scenario is selected, GWSM calculates the anticipated pollution loads. The results can then be compared with preexisting conditions. The following questions are answered during the final phase of GWSM: How do pollutant loads relate to rainfall and runoff distribution and intensity?

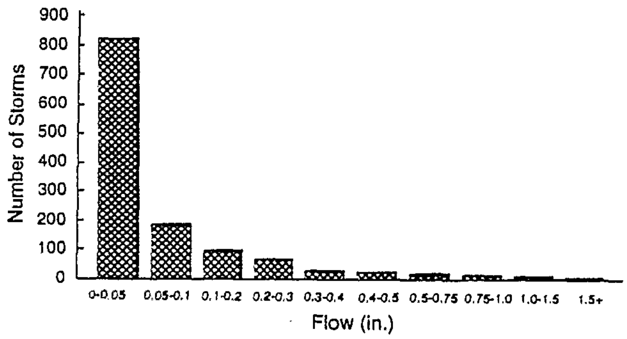

Figure 6. Flow (frequency) distribution by storm size, Collington Branch watershed.

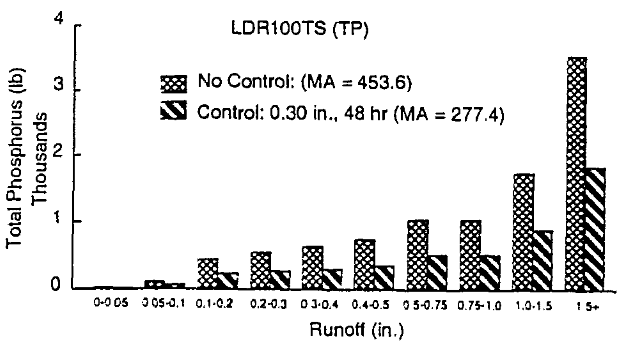

Figure 7. Phosphorus contribution for a simulated residential subdivision with a stormwater pond designed to control for 0.3 in. of runoff.

What is the optimal control level for structural practices? What are the likely impacts of future land-use changes on water quality?

Stormwater Management: Future Model Applications

The NPDES stormwater permit regulations have created new challenges and opportunities for state, county, and city water resource programs. Water resource managers are faced with often conflicting stormwater management objectives and forced to make decisions that weigh the costs and benefits of each. For instance, water quality and flood control objectives do not always coincide. The design and management of regional stormwater ponds will vary depending on whether water quantity control or water quality control is the primary objective.

To address the complex array of stormwater issues, more sophisticated analytical tools and techniques are needed. Watershed models that effectively evaluate alternative scenarios and allow for optimization routines for differing management objectives are in demand. Integrating environmental data, such as wetland areas, bioassessment information, structural and nonstructural best management practice (BMP) optimization, and permit and monitoring information will be required in a user-friendly GIS package.

As the NPDES stormwater regulations are implemented at the county and local level, unique management programs will develop according to specific water quality and resource availability issues. As these programs take shape, GIS and GIS-based models and information management systems are likely to play larger roles in assessing problems and crafting solutions.

Conclusions

The GWSM enabled the rapid assessment of Prince George's County's stormwater problem areas and the evaluation of control measures. GWSM was developed to support the development of the county's stormwater management program. The model incorporates the strengths of continuous simulation modeling with the spatial analysis techniques of GIS in an integrated system. Together, the GIS and data processing routines allow for further analysis and interpretation of time series data from the SWMM model. Combining continuous time series data with georeferenced watershed/land-use data allows for the further analysis and interpretation of the results. As additional data from monitoring both homogenous land-use basins and in-stream locations becomes available from the long-term monitoring program developed as part of the NPDES Part 2 permit, the accuracy of the model will increase.

As technologies for developing and evaluating stormwater programs increase in sophistication, the questions asked of water resource managers are likely to become more difficult. The GWSM will continue to develop to incorporate more functions designed to assist managers to make the best, most informed decisions.

Acknowledgments

The authors thank the Prince George's County Watershed Protection Branch for its support of the model development; Prince George's County Park and Planning for watershed delineation coverages; and the Maryland Department of Planning for 1990 land-use coverages of Prince George's County.

Watershed Screening and Targeting Tool (WSTT)

Leslie L. Shoemaker and Mohammed Lahlou
Tetra Tech, Inc., Fairfax, Virginia

Abstract

Screening-level tools allow managers to understand, evaluate, and compare the water quality problems of watersheds so that they can be prioritized. The Watershed Screening and Targeting Tool (WSTT) makes it easier for watershed managers in federal, state, and local agencies to conduct these evaluations by providing access to the necessary data and information and facilitating the assessment itself. This prototype has been developed as a cooperative project for the U.S. Environmental Protection Agency (EPA) Region 4 and the Office of Wetlands, Oceans, and Watersheds in support of the Total Maximum Daily Load (TMDL) program.

The WSTT is an interactive, user-friendly, two-step evaluation and targeting process. The first step allows for preliminary screening based on multiple criteria. Each criterion can be compared with a default or user-defined reference value. Data from EPA mainframe databases allow the user to compare reference values with land-use and water quality observations from watersheds under consideration. The second level of targeting, comparative analysis, allows for a more detailed examination of watersheds. In addition, this analysis permits the user to include subjective weights and additional data to the targeting procedure. The algorithms for this targeting system are based on a hierarchical structure of objectives and criteria, where a set of up to seven criteria can be used to describe the comparison objectives. Although the analysis objectives are project specific, the procedures are developed to use either user-specified data or information from provided databases. Weights can be entered to give greater or lesser value to particular criteria. This paper presents examples of the application of these techniques to sample watersheds in Alabama.

Introduction

Targeting of watersheds is used to allocate increasingly scarce water management resources for data collection, modeling studies, and management assessment, design, and construction. Water resource managers can use screening-level evaluations to help assess, compare, and prioritize the water quality problems of watersheds within their jurisdictions. The Watershed Screening and Targeting Tool (WSTT) makes it easier for watershed managers in federal, state, and local agencies to conduct these evaluations by providing easy access to the necessary data and facilitating targeting assessments. A prototype of WSTT has been developed that allows access to data for Alabama and Georgia. WSTT operates on a personal computer (286+) in a DOS environment.

WSTT provides an interactive, user-friendly, two-step evaluation and targeting process (Figure 1). The first allows for preliminary screening based on multiple criteria. Each criterion can be compared with a default or user-defined reference value. Data from U.S. Environmental Protection Agency (EPA) mainframe databases allow the user to compare reference values with land-use and water quality observations from watersheds under consideration. The second level of targeting, comparative analysis, allows for a more detailed examination of watersheds. In addition, this analysis permits the user to include subjective weights and additional data in the targeting procedure. The algorithms for this targeting system are based on a hierarchical structure of objectives and criteria, where a set of up to seven criteria can be used to describe the comparison objectives. Although the analysis objectives are project specific, the procedures are developed to use either user-specified data or information from provided databases. Weights can be entered to give greater or lesser value to particular criteria.

Watershed prioritization and targeting involve a multistep decision-making process using both technical criteria and subjective judgement. The use of formal targeting procedures throughout this process can assist in structuring the problem while taking into account all pertinent and site-specific concerns.

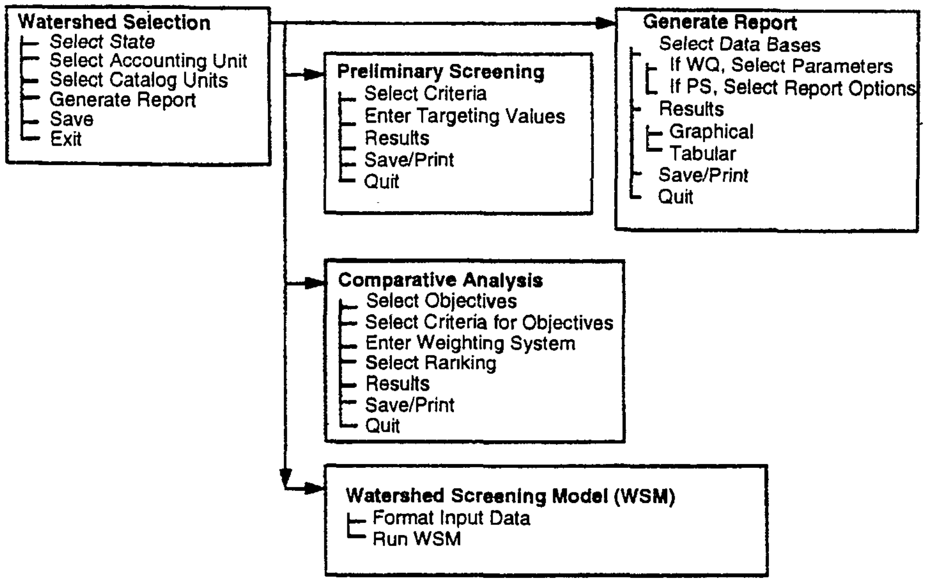

Figure 1. Schematic of WSTT components.

Multicriteria analysis techniques can aid in processing available information in a more structured framework, leading to a rational prioritization of watersheds. These procedures can be used in the Total Maximum Daily Load (TMDL) process to identify data sources, retrieve relevant water quality and watershed data, and analyze these data within a structured framework to determine which watersheds require management. The advantages of structured decision-making techniques—especially when dealing with numerous watersheds where the ranking in order of priority is not obvious *a priori*—include analysis directed toward the selection of pertinent decision criteria and identification of potential candidate watersheds; credibility of the selection process by the use of demonstrated and valid decision-making techniques; reductions in the cost and time for data collection and processing through a multiphase screening process; iterative evaluation of watersheds; and increased understanding of the various tradeoffs.

For the incorporation of targeting criteria and the generation of reports, WSTT is distributed with and relies on data that were selectively downloaded from EPA's mainframe computer. The databases that it uses include an accounting unit/catalog unit (CU) summary table, land use (U.S. Department of Agriculture Natural Resource Inventory summary of acres per land-use category), water quality (EPA STORET ambient water quality data summarized by CU for 50 parameters), reference levels (based on EPA water quality criteria), water supplies (number, flow, location, and type), point sources (number, flow, location, and type), and water bodies (number and size). These data, always available to the public, have traditionally been difficult to access without familiarity with EPA's mainframe. Through WSTT, these data are readily accessible. Using these databases, WSTT can generate reports, in table or graph form, on land use, water quality, water supplies, impoundments, and point source facilities in each of the selected areas.

The data that are distributed with WSTT can also be used to prepare preliminary data input files for a watershed screening model (WSM) which, for this prototype version, can be run for CUs within Georgia and Alabama. The watershed screening methodology permits simple watershed assessments that predict daily runoff, streamflow, erosion, sediment load, and nutrient washoff. The WSM relies on observed precipitation and temperature data from local meteorologic stations, municipal point source load estimations from pollutant concentrations in the literature, and nonpoint source loading functions for selected land uses based on literature values. Users can readily modify or revise the input data to reflect site-specific conditions. Output data from the model simulations can be used to augment information provided by the other databases.

Review of Potential Targeting Procedures

Most multicriteria decision techniques with potential application to the prioritization and targeting process can be grouped into three categories:

- *Sequential elimination:* Techniques to eliminate watersheds that do not show any need for controls.
- *Dominance theory:* Techniques to eliminate inferior or dominated watersheds that demonstrate a need for

pollution control but do not present a character of relative urgency.

- *Ranking procedures:* Techniques to prioritize remaining watersheds.

Sequential Elimination

The first group of analytical procedures target nonpriority watersheds or the nonfeasible set of watersheds. These procedures are typically referred to as sequential elimination techniques. Each watershed is compared with a hypothetical watershed using an amalgamation of standards and criteria. Watersheds that are better than the hypothetical watershed form the nonfeasible set and can be eliminated from further analysis. These techniques provide a preliminary filtering system to ensure the legitimate acceptability of the remaining set of watersheds. Sequential elimination techniques do not differentiate on the basis of relative importance, only on the ability to satisfy a condition of preset limits. Four relevant sequential elimination techniques, available for application in the prioritization process, include the conjunctive approach, the disjunctive approach, the lexicographic approach, and the compensatory approach (1).

The conjunctive approach screens out watersheds by establishing minimum cutoff levels for each discriminating criteria. Depending on the type of criterion and its method of measurement, the constraint or "cutoff level" is defined as either a categorical exclusionary or inclusionary limit. The application of a conjunctive scheme relates the decision criteria and their constraint with the logical "and" so that all constraints must be satisfied for a watershed to be eliminated from further consideration. Evaluation scales do not have to be homogeneous across criteria and can include logical, numeric, or natural scales. Because decision criteria and the set of watersheds are independent, each watershed is compared individually with a hypothetical set of constraints rather than with other watersheds. In general, decision criteria in the conjunctive approach should be carefully selected to focus on criteria with a strict regulatory requirement and technical constraints that cannot be relaxed or are not subject to tradeoffs.

The disjunctive approach is similar to the conjunctive scheme, but it requires that only one criterion be satisfied for a watershed to be eliminated from further consideration. Because this process is characterized by the logical relation "or," problem formulation must be defined in terms of the level of substitutions among the selected decision criteria.

Lexicographic screening differs from the previous techniques in that the value of each criterion is compared across watersheds (2). The criteria are first ordered in terms of their relative importance, and watersheds are then screened, starting with the most important criteria. Watersheds that pass this preliminary test are screened with the next highest ranked criteria until either all criteria are evaluated or the number of watersheds selected for further analysis is sufficiently reduced.

Compensatory analysis is a more elaborate form of conjunctive and disjunctive screening and deals primarily with preferential constraints where the cutoff levels are set by the objectives rather than by the criteria themselves (3). The analysis develops constraints on selected objectives that are represented in the decision problem by a group of two or more criteria. For each identified objective, the corresponding criteria are combined into a discriminating model expressing the degree to which each criterion achieves the objective. The discrimination process can be inclusionary, exclusionary, or both, depending on the screening model.

Dominance Theory

The second group of analytical tools with potential for application in the watershed prioritization and targeting process consist of techniques developed from the dominance approach. This approach serves to identify poorer watersheds rather than rank them completely. In this case, when the first watershed that has criterion values at least as poor as those of a second, as well as one or more values that are poorer, the first watershed will be selected for further analysis rather than the second. The first watershed is said to dominate the second. These techniques add some capability of determining which watersheds are worse than others beyond the simple comparisons offered by the sequential elimination schemes. Although several techniques have been developed based on this decision rule, their application to discrete decision space, such as watershed targeting applications, may not be effective in eliminating many watersheds. Among these techniques are the noninferior curve technique, the indifference map technique, and fuzzy outranking approaches.

The noninferior curve technique uses the distribution of the feasible set of watersheds within the decision space to identify inferior and noninferior sets (4). The curve defines the level of tradeoff between decision criteria where any incremental improvement in one criterion results in a balanced incremental decrease in other criteria. Application of this technique may require excessive computational time and professional training for interpretation of the results (5).

The indifference map technique relies on the representation of the preference structure to determine the family of indifference curves (6). An indifference curve represents points in the decision space for which the preference is equivalent among all criteria. This approach can be used in combination with the noninferior curve technique. Theoretically, if the one indifference curve tangent to the noninferior curve can be located, then watersheds lying farthest from the point of tangency form the set with the highest priority for controls.

Outranking techniques analyze sets of watersheds to derive binary relationships on the set rather than a function from this set to the real numbers, as in the case of the classical theory of decision analysis. This binary relationship also differs from classical decision analysis in the sense that it does not necessarily require a strict transitivity condition (7, 8). Outranking procedures can be used to select one and only one watershed, a set of acceptable watersheds, or a cluster of watersheds in an ordered sequence of indifference classes ranging from best to worst.

Ranking Procedures

The third group of analytical decision techniques ranks the set of watersheds under consideration. Several algorithms with potential application to discrete situations include utility theory, compromise programming and displaced ideal techniques, cooperative game theory, and the analytic hierarchy process.

Decision techniques developed based on the theory of utilities assign a utility function to each decision criterion, then compute the expected utility for each watershed using either an additive or multiplicative model (9). Watersheds that maximize the expected utilities may be eliminated from further analysis, and those with low ranking values form the set to be considered. The difficulties associated with application of the utility models reside in the development of representative utility functions for each criterion and the insurance that all criteria satisfy both preference and utility independence axioms. A utility function refers to a mapping of the values in the range of natural criteria scale to a bounded cardinal-worth scale reflecting the preference structures associated with that criteria as perceived by the decision-maker(s).

Compromise programming techniques have been applied extensively to water resources projects. These techniques attempt to identify watersheds that approach an ideal case (10), assuming that the watershed located the closest to the ideal watershed in the decision space can be eliminated from further consideration. The computation algorithms rank watersheds based on the normalized distance between each watershed and this ideal point. This approach can also be applied to identify watersheds that are the closest to an anti-ideal point using a similar minimization scheme.

Cooperative game theory is a representation of a conflict situation based on the general concepts of rational behavior. Optimization of a set is sought by well-informed decision-makers with conflicting objectives who are aware of their preference structure. The objective of each participant in the game is to identify solutions that are high on the preference scale. A generic algorithm based on this theory for an n-person game was developed by Harsanyi (11). This algorithm was generalized for a regional ground-water pollution problem (12) and for the analysis of wastewater management alternatives (13).

The analytic hierarchy process was developed in an effort to expand the classical decision models to include subjective analysis of multilevel or hierarchical systems (14, 15). The process consists of decomposing the decision problem into smaller subproblems, analyzing each subproblem individually, and then recomposing the results to reach a complete ranking of the set of watersheds considered. It relies strongly on the structuring of the decision problem into an intuitively logical hierarchy of objectives and criteria. The hierarchical structures express the factual relationships between the decision elements (objectives, criteria, and alternatives). This decision process parallels the principles of analytical thinking (16): constructing hierarchies, establishing priorities, and logical consistency.

Targeting Techniques in WSTT

The review of decision analysis techniques, briefly described above, provided the background for the development of the targeting tools used in the WSTT. The development of decision-making techniques for watershed prioritization and targeting was based on the following:

- Ability to perform a multicriteria analysis.
- Applicability to discrete situations with a limited number of watersheds.
- Applicability to selecting the worst watersheds rather than the preferred conditions, as is the case in most decision situations for TMDLs or watershed management.
- Flexibility of problem structuring, data processing, and the ability to decompose the problem into smaller and more homogeneous components.
- Stability of the final ranking using simple scaling procedures.
- Ease of interpreting the rankings.
- Ability to perform sensitivity analysis and consistency testing of the value judgment.

These considerations led to the development of a two-step targeting approach consisting of both a preliminary screening and a formal comparative analysis. A test watershed is used for illustrating examples of the two types of screening techniques (Figure 2).

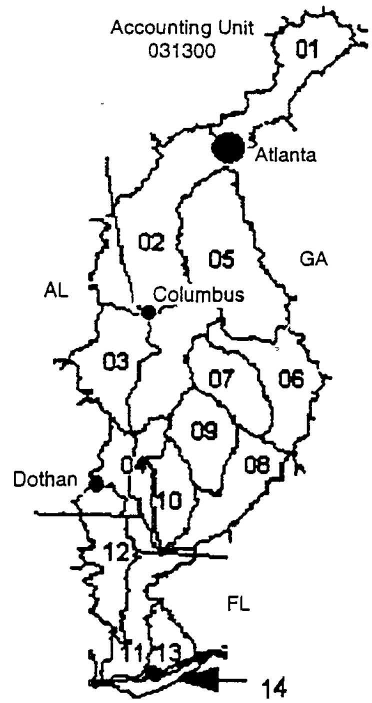

Figure 2. Watersheds selected for preliminary screening.

Preliminary Screening Analysis

The screening level analysis of watersheds at a regional or accounting unit scale is designed to help users understand what the water quality conditions are in each watershed and how the factors governing quality vary from one watershed to the next. The advantage of this procedure is its ability to operate under the WSTT environment, using automatically retrieved values for the desired decision criteria, and iteratively screen out watersheds that do not represent a significant water quality problem.

The screening algorithm used in WSTT consists of a sequential elimination scheme adapted from the conjunctive approach described in the previous section. The objective of this process is to identify watersheds that do not represent a significant water quality problem and consequently reduce the set of watersheds to a workable number. The significance of the water quality problem is, however, indirectly introduced into the analysis through the selection of screening criteria indicative of the problem under consideration and the magnitude of each criterion cutoff level. Figure 3 illustrates this process using a single water quality criterion, and Figure 4 presents the case of a two-criteria screening. Based on the sample cutoff limit shown in Figure 3, six watersheds (1, 2, 3, 4, 5, and 13) would be selected for further analysis. In Figure 4, two criteria are examined. In this case, both acres of urban land and BOD_5 concentrations are selected for examination. Values outside the upper limits for either of the two criteria would be selected for

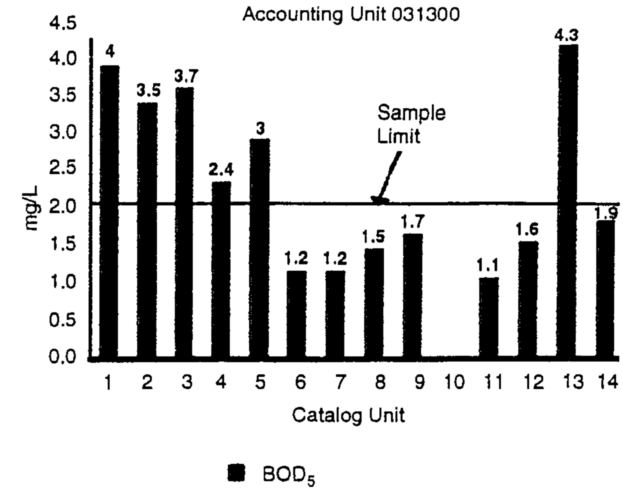

Figure 3. Preliminary screening example with one criterion.

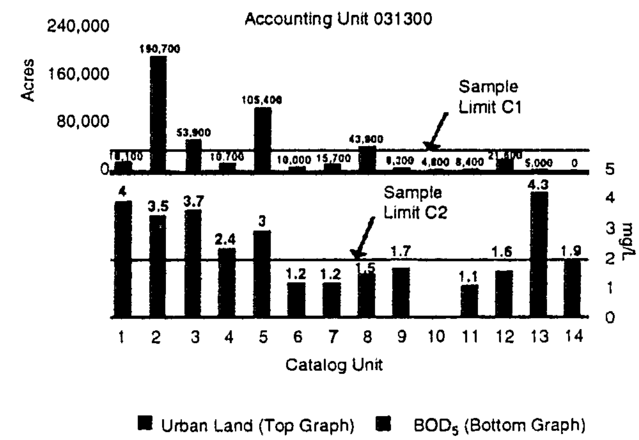

Figure 4. Preliminary screening example with two criteria.

further examination. In this case, seven watersheds (1, 2, 3, 4, 5, 8, and 13) would be selected. The user can select the cutoff limits in an iterative fashion to examine the differences between the watersheds. Multiple criteria can be selected for evaluation, depending on data availability and watershed characteristics. This provides a quick and easy approach for preliminary evaluation of the differences between the watersheds selected for examination.

For a multidimensional problem, each criterion is defined in terms of a cutoff limit representing a vector of threshold values. Depending on the type of criterion and its measurement scale, each value in this vector may either represent an upper or a lower limit. Examples of criteria with an upper limit are water quality parameters for which the cutoff limit represents a concentration that should not be exceeded. On the other hand, criteria with a lower limit include those with ascending scales in which the higher values are better, such as in the case of dissolved oxygen concentration.

The watershed screening level analysis in WSTT allows users to retrieve screening criteria and their values automatically from available, preprocessed databases. When the criteria represent water quality parameters, watershed rating with respect to each criterion can be expressed in terms of a mean value, a median, or a quartile. Multiple databases can be accessed sequentially. Access to the water quality and land-use databases is enabled at the present time. Cutoff limits are user specified and can be modified in an iterative scheme by either relaxing the criteria's cutoff limit and consequently decreasing the set of selected watersheds or by making them more stringent. Watersheds eliminated during this screening level analysis can still be considered in the comparative analysis phase. The output of this algorithm generates a list of watersheds that do not satisfy the criteria's cutoff levels. For these watersheds, the corresponding input data (payoff-matrix) can be accessed through the reporting option of the WSTT. Watersheds that satisfied all user-specified constraints are also tabulated. As noted earlier, the screening analysis does not take into consideration the relative differences in the exceedence of the observations beyond the upper limit. For examination of the relative importance and actual ranking of the watersheds, the comparative analysis technique is used.

Comparative Analysis in WSTT

The objective of the comparative analysis is to provide a system that captures both the importance of the selection objectives and that of the criteria describing these objectives. Comparative analysis can provide a complete ordering of watersheds. The process requires that the targeting problem be formulated in terms of a decision situation and that judgement values be incorporated into each phase of analysis. At this level of analysis, additional measurable and subjective criteria are usually incorporated into the analysis; therefore, the algorithm provides a logical scaling system to evaluate the importance of these objectives on a common basis. The algorithm also incorporates a mathematical framework to amalgamate the value judgement and the watershed observations with respect to each criterion or objective in terms of a ranking index.

Four subroutines incorporated in the development of the comparative analysis algorithm in the WSTT are described below.

Structuring of the Targeting Problem

The formulation of watershed prioritization problems in WSTT consists of a multilevel hierarchical structuring of the selection objectives, the decision criteria, and the alternative watersheds. This formulation separates the selection problem into several smaller and homogeneous subproblems which can be easily compared. Figure 5 illustrates a generic representation of a clustered hierarchy in which the project is decomposed into a set of simple and smaller subprojects. Each subproject can be analyzed separately, and the results can be reintegrated to obtained an overall ranking of the watersheds.

Value Judgment

The decision-maker's value judgment is introduced in terms of the importance weight coefficients of the objectives and criteria. The derivation of criterion importance weights proceeds according to the hierarchical structure of the decision problem, starting from the higher level objectives. This routine takes the decision-maker through a series of paired comparisons cluster by cluster in the order shown by the roman numerals in Figure 5. For each paired comparison between two criteria, the decision-maker defines which criterion of the pair is more important and determines the magnitude of the importance using the integer ratio scale presented in Table 1. The magnitude of importance is not the desired importance weight but rather a measure of a pairwise ratio defined as follows:

$$a_{ij} = \frac{W_i}{W_j} \qquad \text{(Eq. 1)}$$

where a represents the ratio of importance weight W of criterion i over that of criterion j.

The use of the ratio scale defined in Table 1 generates a square, positive, and reciprocal matrix in which the importance weight coefficients consist of the entries of the eigenvector corresponding to the maximum eigenvalue of the this matrix. The characteristics of the resulting comparison matrix are summarized as follows:

$$a_{ij} = \frac{1}{a_{ji}} \qquad \text{(Eq. 2)}$$

for all i and j;

$$a_{ii} = 1 \qquad \text{(Eq. 3)}$$

for all i=1 to n where n is the number of criteria; and

$$a_{ik} = a_{ij} + a_{ik} \qquad \text{(Eq. 4)}$$

The rationale for determining the eigenvector corresponding to the maximum eigenvalue as the importance weight coefficient vector derives naturally from the type of scale used in the pairwise comparisons and the as-

R0015884

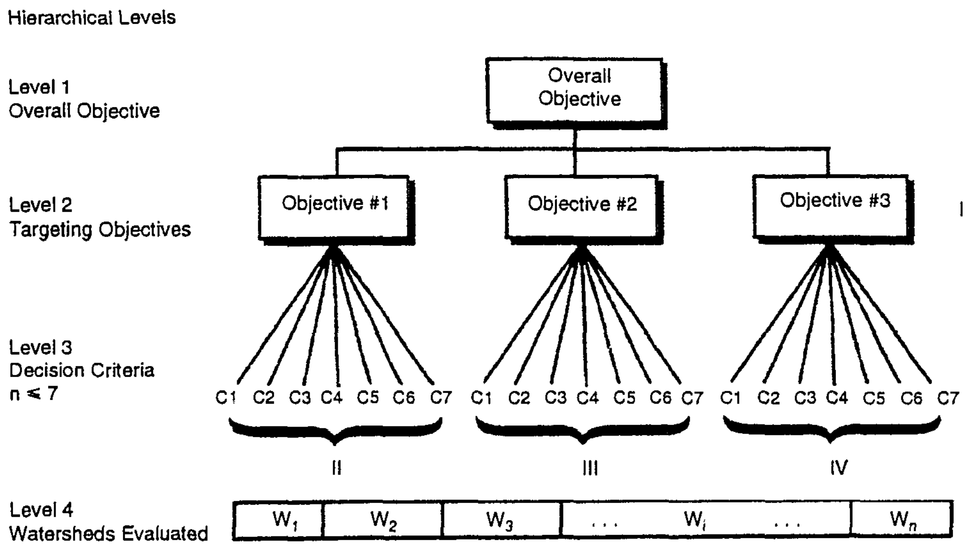

Figure 5. Generic representation of the watershed targeting problem in WSTT.

Table 1. Evaluation Scale Developed by Saaty (14) for Use in the Analytic Hierarchy Process

Intensity of Importance	Definition	Explanation
1	Equal importance	Two activities contribute equally to the objective.
3	Weak importance of one over another	Experience and judgment slightly favor one activity over another.
5	Essential of strong importance	Experience and judgment strongly favor one activity over another.
7	Demonstrated importance	An activity is strongly favored, and its dominance is demonstrated in practice.
9	Absolute importance	The evidence favoring one activity over another is of the highest possible order of affirmation.
2, 4, 6, 8	Intermediate values between the two adjacent judgments	Compromise is needed.
Reciprocal of above nonzero	If activity i has one of the above nonzero numbers assigned to it when compared with activity j, then j has the reciprocal value when compared with i.	
Rational	Ratio arising from the scale	Consistency is forced by obtaining n numerical values to span the matrix.

sociated matrix theory used in solving nonlinear systems, expressed in matrix form as

$$A \cdot W = n \cdot W, \quad \text{(Eq. 5)}$$

where A is the comparison matrix with n entries, n is the number of criteria, and W is the vector of importance weight coefficients. The solution of the above eigenvalue problem for each cluster in the order shown in Figure 5 provides a partial weight coefficient for each criterion. The overall weight can be derived by multiplying the partial weight of the dominant objective by that of the criteria:

$$W_i = W_p\,(objective) \cdot W_p(criteria_i). \quad \text{(Eq. 6)}$$

Consistency of the Preference Structure

When dealing with large numbers of objectives and criteria, the preference structure tends to lose its transitive character. As intransitive comparisons are introduced, the resulting matrices become less consistent, and the importance weight coefficients may not represent the true preference structure.

For a perfectly consistent positive reciprocal matrix, the maximum eigenvalue should equal the order of the matrix. This suggests that the remaining eigenvalues are equal to zero. As small inconsistencies are introduced into the matrix because of intransitive judgements, they lead to very small perturbations in the original set of eigenvalues. This represents the fundamental theory of consistency measurement in positive reciprocal matrices (14). The more the maximum eigenvalue deviates from that of a consistent matrix, the less consistent the pairwise comparisons are. A consistency index developed by Saaty (14) was introduced into the targeting subprogram in WSTT to indicate the degree of consistency at the end of each series of pairwise comparisons. A consistency index of 0.0 indicates a perfect consistency, and a value of 1.0 indicates a fully inconsistent matrix. Because of the use of an integer scale in addition to the nonlinearity of certain subjective judgments, a slight nonconsistency in developing importance weight coefficients is common. In fact, a fully consistent comparison is not required to reach the desired accuracy. Analysis of the sensitivity of eigenvalue solution shows that matrices with a consistency ratio of up to 0.1 are acceptable (17).

Ranking of Watersheds

The hierarchic representation of the watershed targeting process is a logical structure for integrating the decision elements into a single problem and deriving the selection priorities defined in terms of objectives, criteria, and their respective weight coefficients. To derive the overall ranking of the watersheds, a simplified form of the additive utility model is used. This model is described in much of the relevant literature as the best known of the multiattribute utility functions because of its relevance to a wide range of decision problems, its stability in ranking alternatives, and its simplicity of application. This model is also used in most index calculations. Its generic expression when applied to a hierarchic problem takes the following form:

$$U_i = \sum_{j=1}^{N} W_j \cdot \sum_{k=1}^{M} W_k \cdot V_k, \qquad \text{(Eq. 7)}$$

where

W = weight coefficient
N = number of objectives
M = number of criteria under each objective
U = ranking of watershed i
V = measurable value of lower level criteria

This model uses normalized values of the criteria in an ascending scale, meaning that the higher values are better. The ranking is therefore performed on a descending scale so that watersheds with the lowest scores are identified as the priority watersheds.

The results of a sample application are shown in Table 2 below. For illustration purposes, a comparative analysis was applied, using WSTT, to six watersheds in Alabama. Three criteria were selected for examination—BOD5, ammonia, and iron—based on the 85th percentile of all data available on STORET since 1980. The values used for the comparative analysis are shown first. Three types of weights are shown: equal weights and two variable options. The final section of Table 2 shows how the changes in weights affect the resulting ranking of the watersheds. The ability to adjust weights and test a variety of user- and system-provided criteria allows for a wide range of flexibility in the assessment of watershed ranks. Users can thereby incorporate best professional judgement and local knowledge into the targeting procedure in a systematic fashion.

Table 2. Description of Comparative Analysis Application

Values Used for Comparative Analysis (Payoff Matrix)

Catalog Unit	Criterion 1 BOD_5 (mg/L)	Criterion 2 NH_4 as N (mg/L)	Criterion 3 Fe (µg/L)
0313001	4.0	0.27	1,100
0313002	3.5	0.62	1,600
0313003	3.7	0.30	315
0313004	2.4	0.14	680
0313005	3.0	0.66	2,900
0313013	4.3	0.16	370

Calculated Importance Weight Coefficients

Criteria	Equal	Variable 1	Variable 2
1 (BOD_5)	0.333	0.122	0.637
2 (NH_4 as N)	0.333	0.648	0.258
3 (Fe)	0.333	0.230	0.105

Final Watershed Ranking

Catalog Unit	Equal	Variable 1	Variable 2
0313001	3	3	3
0313002	4	2	1
0313003	5	4	5
0313004	6	6	6
0313005	1	1	4
0313013	4	5	2

Application of the comparative analysis requires users to evaluate which criteria are relevant and significant to the local watershed conditions. Often, application will be constrained by the availability of water quality sampling information or other data. Consideration should also be given to possible dependence between two criteria selected. Criteria should be independent for accurate assessment of watershed ranking.

Conclusions

The WSTT program and associated databases provide watershed managers with the tools to effectively target and assess watersheds on a broad scale. The two levels of targeting tools included with the WSTT allow for a range of targeting applications—from simple to sophisticated—depending on project needs. The incorporation of the comparative targeting tool provides the valuable addition of subjective judgement and user-defined parameters to the decision-making structure. This powerful algorithm allows managers to refine decision-making criteria and evaluate multiple and often conflicting objectives. The incorporation of targeting tools and databases into a user-friendly PC environment can make these powerful techniques convenient and accessible to a wide range of water resources professionals.

Acknowledgments

The authors would like to thank Jim Greenfield, EPA Region 4, and Donald Brady, Chief, Watershed Management Section, EPA Office of Wetlands, Oceans, and Watersheds, for their guidance and input into the development of WSTT. Sigrid Popowich and John Craig of Tetra Tech, Inc., provided significant input into both the design of WSTT and the preparation of the databases. Software design and development was performed by Randy French of Isoceles Software, Inc.

Hydrocarbon Hotspots in the Urban Landscape

Thomas Schueler and David Shepp
Department of Environmental Programs,
Metropolitan Washington Council of Governments, Washington, DC

Abstract

This paper reports on a monitoring study that compared hydrocarbon, polycyclic aromatic hydrocarbons (PAHs) and trace metal levels in stormwater runoff captured within standard oilgrit separators (OGSs) serving five automotive-related land uses in the Maryland Piedmont. Composite priority pollutant scans and trace metal samples were collected from the pools and the trapped sediments of 17 OGSs serving gas stations, convenience commercial, commuter parking lots, streets, and residential townhouse parking lots. Previous studies indicated that OGSs were not effective in trapping sediments over the long term, based on sediment accumulation rates over time. Oily sediments, however, were retained over a short term, making the OGS sites useful sampling ports to characterize differences in hydrocarbon and toxic levels in small, automotive-related land uses.

Gas stations had significantly higher hydrocarbon, total organic carbon, and metal levels than all other sites in both the water column and the sediments. Convenience commercial and commuter parking lots had moderate levels of contamination, with the lowest levels recorded for streets and residential townhouse parking lots. Mean hydrocarbon concentrations of 22 mg/L and 18,155 mg/kg were recorded for the water column and the sediments at gas station OGS sites. The priority pollutant scan identified 37 potentially toxic compounds in the sediments and 19 in the pools of gas station OGS sites. This can be compared with non-gas-station sites, which had 29 and 7 toxics in the sediment and water column, respectively. Some of the gas station priority pollutants included naphthalene, phenanthrene, pyrene, toluene, xylene, chrysene, benzene, phenols, acetone, and numerous trace metals.

The source of these pollutants appears to be spillage or leakage of oil, gas, antifreeze, lubricating fluids, cleaning agents, and other automotive-related compounds. The study suggests that numerous "hotspots" exist in the urban landscape that generate significant hydrocarbon and PAH loadings, particularly where vehicles are fueled, serviced, and parked for extended periods. Preliminary computations suggest a possible link between these hotspots and sediment PAH contamination of a local estuary.

Introduction

Over the past decade, nearly one thousand oil grit separators (OGSs) have been installed in the metropolitan Washington area to treat urban stormwater runoff from small drainage areas. These structures consist of two precast chambers connected to the storm drain system (Figure 1). The first chamber is termed the grit chamber and is used to trap coarse sediments. The second chamber, termed the oil chamber, is used to temporarily trap oil and grease borne in urban runoff so that they may ultimately adsorb to suspended sediments and settle to the bottom of the chamber.

Most OGSs control runoff from highly impervious sites of an acre or less and have a storage volume of 0.06 to 0.12 in. of runoff, depending on the local design. As such, OGSs were never expected to achieve high rates of pollutant removal (1). Rather, they are intended to control hydrocarbons, floatables, and coarse sediments from small parking lots that cannot normally be served by other, more effective best management practices.

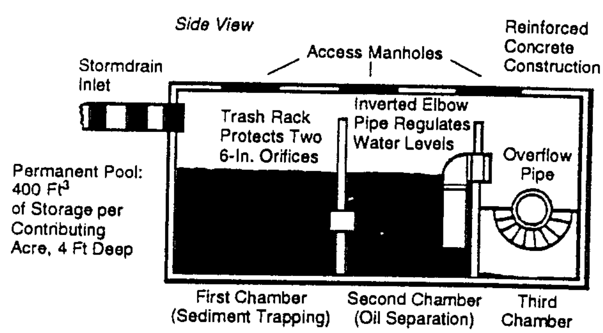

Figure 1. Schematic diagram of an OGS (1).

R0015888

From a monitoring standpoint, OGSs are interesting in that they act as a very useful and standardized sampling port to extract runoff samples from very small areas of differing automotive land use. It was hypothesized that hydrocarbon and trace metal levels might be greater at sites where vehicles were parked, serviced, or fueled. These potential "hotspots" had never been systematically monitored in the metropolitan Washington area before.

Methods

A two-tiered monitoring strategy was employed to test the effectiveness of OGS systems and to detect hydrocarbon hotspots. In the first tier of sampling, 110 OGS systems were surveyed to determine their general characteristics in the field. Each structure was sampled for the mass and particle size distribution of trapped sediments, land use, age, maintenance history, secchi depth, and other engineering parameters (2).

The emphasis on the second tier of sampling was to characterize the range of pool and sediment quality found within OGS and related systems. Nineteen of the Tier 1 sites were selected for additional detailed sampling of the quality of pool water and trapped sediments. The sites were grouped into five land-use categories: townhouse parking lots, streets, all-day parking lots, gas stations, and convenience store parking lots. Sediment and pool samples were collected from each chamber and were subsequently analyzed for nutrients, soluble and extractable metals, total organic carbon (TOC), and total hydrocarbons.

In addition, six priority pollutant scans were conducted based on composite sediment and pool water samples from gas station sites, non-gas-station sites, and all five land-use sites combined. The samples were analyzed for the presence of 128 compounds outlined in the U.S. Environmental Protection Agency's (EPA's) priority pollutant list. A complete description of the sampling and analytical protocol is contained in Schueler and Shepp (3).

Results

Retention of Sediments in OGS

The field surveys indicated that OGS systems had poor retention characteristics. The average wet volume of trapped sediments in 110 OGSs was 11.2 ft^3, with an average sediment depth of only 2 in. If OGS systems were highly retentive, the mass of trapped sediments would be expected to increase with age. No such relationship was evident, however, in the 110 OGSs surveyed (Figure 2), suggesting that frequent scour and resuspension occur.

Monthly sampling of sediment depths in individual OGS systems revealed sharp fluctuations in depth over time (Figure 3), with up to a 50-percent decrease in sediment depths recorded in a single month. Dye tests indicated pool residence times of less than 30 min during storms. Consequently, it is thought that the mass of trapped sediments contained within an OGS at any given point represents only a temporary accumulation of pollutants.

General Characteristics of OGS Systems

Trapped sediments within OGSs were coarse-grained, highly organic, oily in appearance, and interlaced with litter and debris. Sediments were also quite soupy; only 45 percent total mass of sediment existed as dry weight. The proportion of volatile suspended solids, a measure of the general organic content of the sediments, averaged 15 percent of total mass.

OGS pools frequently had a thin oil sheen or surface scum, and oil stains were present on the chamber walls. Despite the sheen, the pool water was relatively transparent, with an average secchi depth of 14 to 22 in. Floatable trash was present in low to moderate quantities.

SCD = soluble cadmium
ECR = extractable chromium
SCR = soluble chromium
ECU = extractable copper
SCU = soluble copper
EPB = extractable lead
SPB = soluble lead
EZN = extractable zinc
SZN = soluble zinc

The influence of contributing land use on the quality of OGS pool water is evident in Table 1. In general, the concentration of conventional pollutants such as nutrients and suspended solids was similar to many other reported urban stormwater runoff datasets (1). The pool water concentrations of total hydrocarbons, TOC, and soluble and extractable trace metals, however, were much higher. In particular, the average concentration of total hydrocarbons exceeded 10 mg/L in three of the five land uses studied. Analysis of variance indicated that gas station OGS sites had significantly greater pool water hydrocarbon, TOC, zinc, copper, lead, and cadmium levels that any other OGS sites.

The influence of contributing site land use was even more pronounced when sediment quality was analyzed (Table 2). OGS sediments were all heavily enriched with hydrocarbons, TOC, nutrients, and metals. The gas station OGS sites had significantly higher hydrocarbon, TOC, phosphorus, and metals concentrations compared with the other four land uses. Convenience commercial and all-day parking sites generally had higher levels than streets and townhouse parking lots.

Effects of Automotive Land Use

Previous priority pollutant scans of stormwater runoff and pond sediments from primarily residential land uses in the metropolitan Washington area had failed to detect the presence of polycyclic aromatic hydrocarbons (PAHs) (4). Numerous PAHs and other compounds on EPA's priority pollutant list, however, were detected in the automotive-influenced sites of the OGS study (Tables 3 and 4).

Table 2. Characterization of the Quality of Trapped Sediments in OGS: Effect of Land Use

Parameter (mg/kg)	All-Day Parking (N = 8)	Convenience Commercial (N = 6)	Gas Stations (N = 7)	Streets (N = 6)	Townhouse/ Garden Apartments (N = 6)
TKN	1,951.0	5,528.0	3,102.0	1,719.0	1,760.0

TKN = total Kjeldahl nitrogen, TP = total phosphorus, TOC = total organic carbon, HC = total hydrocarbons. All metals are extractable.

A total of 19 priority pollutants were detected in pool water at the gas station OGS sites, compared with seven detected at non-gas-station sites, most of which were metals. Thirteen volatile and semivolatile priority pollutant compounds were detected in pool water at the gas station OGS sites. Semivolatile compounds included phenols, naphthalene, and plasticizers, whereas the volatile compounds included acetone, benzene, toluene, xylene, and ethyl benzene. Most, if not all, of these compounds are linked to gasoline and its derivatives, lubricants, and cleaning agents customarily found at gas stations (5).

An even greater number of priority pollutants, 26, were detected in the trapped sediments of gas station OGS sites. An additional 11 priority pollutants were indicated but were below analytical detection limits. Metals and PAHs dominated the list of confirmed priority pollutants. PAHs found at the highest concentrations in the sediment included 2-methylnapthalene, naphthalene, phenanthrene, fluoranthene, pyrone, and christen. Three of these PAHs have been listed as toxics of concern by the EPA Chesapeake Bay Program (5). Most of these PAHs are strongly associated with gasoline and its byproducts. The gas station OGS sites had the highest sediment metals levels, particularly for cadmium, copper, chromium, lead, and zinc.

Only nine PAHs were recorded at the non-gas-station OGS sites, and in nearly all cases the concentration in the sediments was lower. Interestingly, the only pesticides detected in the sampling were discovered at the more residential non-gas-station sites.

Discussion

The monitoring study has several interesting implications for urban stormwater runoff and its effective control, which are discussed below.

Hydrocarbon Hotspots in the Urban Landscape

The results suggest that hotspots of possible hydrocarbon and metal loading do exist in the urban landscape, and that these are likely to occur where vehicles are fueled, stored, or serviced. In this study, gas stations and, to a somewhat lesser degree, frequently used parking lots clearly exhibited greater hydrocarbon and metal loading potential than more residential sites. Future monitoring may reveal other potential hotspots such as bus depots, loading bays, highway rest areas, and vehicle maintenance operations.

The traditional management approach for urban runoff quality has been to specify a uniform treatment standard for all impervious areas across the urban landscape (e.g., the first half inch of runoff). Based on the results of this study, a more effective strategy might be to supplement uniform standards with more stringent treatment requirements when a possible hydrocarbon hotspot may be involved.

Only nine PAHs were recorded at the non-gas-station OGS sites, and in nearly all cases the concentration in the sediments was lower. Interestingly, the only pesticides detected in the sampling were discovered at the more residential non-gas-station sites.

Possible Link to Estuarine Sediment Contamination

The bottom sediments of most of the nation's urban estuaries are frequently contaminated with hydrocarbons, PAHs, and metals. The sources of the ubiquitous and pervasive contamination may include air deposition, fuel spills, leaking underground storage tanks, leachate from landfills or industrial sites, industrial discharges, and waste oil dumping, among others. This study suggests

that the washoff of leaked fuels and fluids from vehicles may also be a key source of sediment contamination.

The significance of runoff from hydrocarbon hotspots in sediment contamination may be great. For example, 12 out of 13 PAHs present in the sediments of the tidal Anacostia estuary were also present in the trapped sediments of gas station OGS sites. On average, the concentration in OGS sediments was seven times greater than that recorded in the tidal estuary. Of even greater interest is the finding that the relative composition of PAHs in both the river and OGS sediments was quite similar (3). While the possible link between runoff from hydrocarbon hotspots and estuarine sediment contamination remains suggestive rather than conclusive at this point, the subject merits further monitoring and analysis.

Opportunities for Pollution Prevention at Hotspots

Because leakage, spills, and improper handling and disposal of automotive products appear to be the key source of many of the pollutants observed at hydrocarbon hotspots, an effective control strategy involves the use of pollution prevention practices. For small vehicle maintenance operations, these may include techniques to run a dry shop, reduce run-on across work areas, use less toxic cleaning agents, control small spills, store automotive products in enclosures, and, perhaps most importantly, train employees to reduce washoff of automotive products from the site (6).

Implications for OGS Cleanout and Disposal

The original purpose of the study was to establish the characteristics of trapped sediments and pool water within OGS sites to determine the most appropriate and safe disposal method. Based on preliminary data, OGS residuals do not quite meet criteria to be considered hazardous for landfilling (7). Many local landfills, however, may set more stringent criteria and will not accept OGS sediments unless they are fully dewatered. Introduction of OGS residuals into the sanitary system appears also to be prohibited due to utility pretreatment requirements.

Regular cleanout of OGS systems appears to be quite rare. For example, none of the 110 OGS systems surveyed in the field appeared to have been maintained in the last year (2). Given the poor retention characteristics of existing OGS designs, a minimum frequency of quarterly cleanouts would seem warranted to ensure that the trapped residuals are removed before they are resuspended. The cost to cleanout an OGS system and safely dispose of the trapped sediments, however, could exceed $400 per site visit. The need for frequent and costly cleanouts, coupled with the ambiguities regarding the possible toxicity of trapped sediments, raises serious concerns about the effectiveness of the current generation of OGS systems.

Outlook for Improvements in OGS Design and Performance

The study indicates that the current generation of OGS systems does not retain trapped pollutants and therefore must be maintained at an unrealistically high frequency. Clearly, the retention characteristics of OGS must be sharply increased if they are to become a credible urban best management practice.

Several design improvements have the possibility of increasing the retention of pollutants. These include designing the OGS to be fully off-line, so that larger runoff events bypass the OGS and reduce the frequency of sediment resuspension; providing larger treatment volumes; using sorptive media, fabrics, or pads within chambers; and modifying the geometry of each chamber to reduce turbulence in the vicinity of trapped sediments. Until the improved retention of these design modifications is confirmed in the field, however, it may not be advisable to use OGS systems on a widespread basis.

Given the possible importance of hydrocarbon hotspots in the urban landscape and the apparent inadequacy of the current generation of onsite best management practices to control them effectively, it is strongly recommended that an intensive research and demonstration program be started to evaluate alternative small-site runoff treatment technologies.

Acknowledgments

The study was sponsored by the Maryland Department of the Environment under an EPA Chesapeake Bay Implementation grant. Sampling and laboratory analyses were conducted by the Occoquan Watershed Monitoring Laboratory.

Design Considerations for Structural Best Management Practices

Joseph J. Skupien
Somerset County Engineering Department, Somerville, New Jersey

Abstract

Upon selection of the appropriate structural best management practice (BMP) to address an urban runoff management need, the design process begins. Successful BMP design does not consist merely of achieving required technical performance levels specified in a government regulation. To meet both the letter and spirit of the regulation and to help encourage the public participation vital to the future of urban runoff management, a responsible BMP designer must also acknowledge and address several other technical and nontechnical considerations.

This paper emphasizes the need for a strong theoretical understanding of standard design models and equations. It also recommends a technique for identifying and evaluating a structural BMP's inherent maintenance, safety, and aesthetic needs that may not be readily apparent when using more conventional design procedures. The paper also identifies the individuals and agencies that will interact with a structural BMP during its design and/or following its construction, and emphasizes the need to include their interests in the BMP design process.

Finally, in recognition of the nascent state of nationwide stormwater management, the paper encourages BMP designers to contribute to the continued development of the field by conducting their designs in an open and objective manner and by continually seeking new and better responses to the many stormwater management challenges we face.

Introduction

> design \di-zine\ vb 1: to conceive and plan out in the mind; 2: to devise for a specific function or end; 3: to conceive and draw the plans for (Merriam-Webster Dictionary)

This definition succinctly describes both the scope and sequence of activities typically undertaken by the designer of a structural best management practice (BMP). Having identified a stormwater management problem or need that can best be solved through the construction of a structural BMP, the designer then selects the most appropriate type of BMP, conceptualizes its function and operation, and determines the specific characteristics necessary for the BMP to achieve its desired performance. Having completed this, the designer must then transform these characteristics into a physical entity. This is done through the development of detailed construction plans and specifications, which are used to construct the BMP in the field.

Throughout the entire endeavor, the structural BMP designer must, of course, fulfill certain technical responsibilities if the BMP is to comply with the standards and requirements of the community's overall stormwater management program. To do so, the designer must be familiar with these program requirements as well as the technical data, equations, and analytic techniques commonly used to meet them. If stormwater management is to grow beyond its traditional concerns for stormwater quantity to address stormwater quality and nonpoint source (NPS) pollution, however, such technical compliance is not enough. Instead, the BMP designer must also recognize his or her unique responsibilities both to the success of the overall stormwater management program and to the people who will live, work, or travel past the structural BMP they are creating. Only by fulfilling these larger design responsibilities will stormwater management be able to achieve and sustain the public support and participation it needs to effectively address the complex problems that lie ahead of it. A description of each of these design responsibilities is presented below, along with recommendations for fulfilling each.

The Responsibilities of the BMP Designer

As noted above, the effective BMP designer must fulfill several levels of responsibility. First and foremost, the designer is responsible for complying with the technical requirements and standards of the overall stormwater management program of which the

R0015893

BMP will be a part. This typically includes achieving the required level and range of peak outflow control necessary to prevent or reduce downstream flooding as well as the detention times and pollutant removal rates necessary for stormwater quality enhancement. Additional technical requirements contained in the stormwater management program may include emergency discharge capacity to insure dam or embankment safety, as well as structural and geotechnical standards to achieve stability and strength. The BMP designer must be familiar with the specific technical requirements of the stormwater management program as well as the theoretical basis for and use of the various hydrologic, hydraulic, structural, and geotechnical analyses typically used to comply with them.

The responsible BMP designer should not only be familiar with the program's technical requirements but also understand the program's overall intent or goals, for the designer must recognize that the program's technical requirements are only the means through which we hope to achieve the program's goals or ends. As such, a structural BMP will contribute more towards those goals if its designer understands, for example, not just what detention time the BMP should have, but why it should have one, why it should be a certain duration, and what will happen if it does not. Such understanding also produces BMP designs that are better able to achieve satisfactory results over a much wider range of real-world conditions than the more limited conditions that are normally analyzed during the design process.

In addition, due to the inherent complexities of stormwater quality and nonpoint source (NPS) pollution, we have not been able in many instances to define the technical requirements of our stormwater management programs as well as we have been able to specify their goals. For example, it is considerably easier to select a goal of 80 percent removal of suspended solids from stormwater runoff than it is to specify the exact technical measures that must be implemented to do so. This disparity between means and ends can be overcome to a great degree by the responsible designer who, aware of the disparity, is willing and able to look behind and beyond the program's somewhat limited technical requirements and produce designs that do a better job of achieving the program's goals.

Another BMP design responsibility is based on the fact that the final product of the designer's efforts will be a real structure that must be constructed and maintained and that will occupy space in a real environment. As such, it is vital that the BMP be both simple and practical in terms of construction, materials, operation, maintenance, and safety. Such characteristics can only be achieved by a designer who is aware of their importance and can define them in physical terms. In addition, such vital characteristics cannot, at times, be achieved by strictly adhering to a stormwater management program's technical standards and may, in fact, require that they even be ignored or broken. Such instances demand the involvement of a responsible designer who will be able to achieve a more informed, effective balance between technical compliance and practicality than is achievable through strict compliance alone.

In the design of any structural BMP, cost must also be an important factor, and the responsible designer not only appreciates this fact but also can accurately and objectively determine both the benefits that a structural BMP provides and the costs of doing so. A true measure of a BMP's cost effectiveness can only be achieved by understanding, quantifying, and comparing both. To do so, the designer has a responsibility to fully understand both the cost of BMP construction, operation, and maintenance and the relative values or benefits to be gained from it. This requires, among other traits, a high degree of objectivity to ensure that the costs and benefits determined by the designer are based on reality and not the interests or desires of his or her client or supervisor, or a government regulator.

Finally, the responsible BMP designer understands the importance of professionalism and will always conduct the design process in an open, honest, and objective manner. In view of the nascent state of stormwater management nationwide, such tenets are particularly vital if we are to close the present gap between what we seek to gain from stormwater management and how we can best achieve it. Such conduct will also enable us to more quickly identify uncertainties, conflicts, and errors in our present understanding of stormwater runoff and NPS pollution and to develop more effective and efficient solutions.

BMP Design Considerations: Points To Ponder

From the above, it can be seen that the responsible BMP designer must not merely be concerned with the technical requirements of a stormwater management program but, instead, must strive to produce facilities that also achieve and even advance the program's goals and intentions. The structural BMPs that result from such an effort will become assets to the community that they serve and promote the public interest and involvement necessary for overall program success. The BMP must also be practical, safe, aesthetically pleasing, easy to build, and even easier to maintain. Faced with such a formidable list of requirements, the responsible designer must not only bring competent technical ability to the design process but also an informed, open attitude and even a sense of mission or purpose. To help promote such an attitude and more fully prepare the BMP designer for the job ahead, the following points regarding BMP design, construction, and operation are offered. The BMP designer should consider these points before undertaking a design effort.

Interested Parties

To produce a BMP design good enough to earn an "approved" stamp from a stormwater management program regulator (who is presumably interested in ensuring compliance with the program's regulations), a BMP designer must identify with those interests and make sure they are reflected on the construction drawings. To further ensure that the BMP will truly be an asset to the community and will make a positive statement about the value of stormwater management, the BMP designer must consider several interested parties.

The Client

Including the client on a list of parties having an interest in a BMP design should not come as a surprise; however, a review of what the client's interests really are just may be. Therefore, the responsible BMP designer will not automatically assume to know the client's interests (however obvious they may appear) but will instead fully discuss them with the client.

The prospect of such a discussion may then lead the designer to ask the following question: What should the client's interests be? Does the client have a misinformed or misguided attitude towards the goals of stormwater management? Is this attitude based on a lack of understanding or information? In such cases, the responsible designer can, through education (and a touch of diplomacy), both expand the client's understanding and improve his or her attitude towards stormwater management, thereby enhancing the designer's own chances of producing a positive BMP design.

The Regulator

Similar to the client, the regulator is also an obvious choice for an interested party list. Once again, the following questions may be raised: What are the regulator's interests, and what should they be? Because a regulator's review of a BMP design can sometimes stray from the program's technical standards into more subjective areas (due, in part, to a lack of such standards), it is often helpful to know what interests the regulator has stored up in those areas. Are those interests both in keeping with the goals of the stormwater management program and within the program's (and, therefore, the regulator's) jurisdiction?

For example, a regulator may have a strong interest in promoting proper land use as a means of achieving a program's goals. If regulating land use is beyond the program's scope or authority, however, then such interests have no rightful place in the regulator's review of the BMP design. Should such interests become part of the review, it is the designer's responsibility to point this fact out and redirect the review back to its proper direction. In doing so, all of the diplomatic skills the designer has developed from educating the client will prove invaluable.

Similar to the client, a BMP designer may also encounter a regulator who, through a lack of knowledge or an abundance of wrong information, either misunderstands the program's requirements or lacks the ability to fully ensure their compliance. Once again, the responsible BMP designer can, through education and a competent, comprehensive design, expand the regulator's understanding and ability so that the designer's intentions can be better understood.

The Constructor

As noted earlier, one of the key responsibilities of the structural BMP designer is to transform the BMP from concept to reality by preparing detailed plans and specifications of how it should be built. It is then up to the constructor to finish the project by actually building the BMP from these plans and specifications. Therefore, the responsible designer appreciates the efforts of the constructor and does not see his or her own efforts as an independent exercise, but rather as an integral part of a much larger process—a process that requires the constructor to complete.

As such, the responsible BMP designer recognizes and responds to the constructor's interests by producing a well thought-out design that can be constructed as easily and simply as possible. Because this may not always be possible, particularly when faced with complex performance requirements or difficult site conditions, the responsible designer also takes extra care to bring any difficult or unusual aspects of the design to the constructor's attention before the start of construction, even consulting with the constructor during the design phase to mutually devise the best construction technique, material, or sequence.

Under ideal circumstances, the BMP designer will also continue his or her involvement in the project throughout the construction phase and will work with the constructor to correct mistakes, address oversights, and develop revised designs as necessary to overcome problems that may be encountered in the field.

The Maintainer

Once construction of the BMP has been completed, the designer's involvement with the process (assuming it lasted through construction) normally ends. However, there are interested parties whose involvement with the BMP is just about to start and whose interests the designer must also consider. These are the maintenance personnel who will be responsible for mowing the grass, removing the sediment, clearing the debris, managing the habitats, and performing the necessary repairs at the BMP for the rest of its serviceable life. Similar to the constructor, the maintainer's actions will be governed by what the designer creates on paper. Because construction has been completed and the designer has moved on to other projects, however, it is considerably more difficult for the maintainer to have deficiencies or oversights in the design corrected.

As such, the designer must understand and address the interests of the maintainer before it is virtually too late. As described in more detail in later sections, this can be accomplished by designing a facility that, optimally, requires a minimal amount of maintenance that can be performed as easily as practicable.

The Resident

This interested party may also be the worker, commuter, shopper, student, or local government official who will interact with the structural BMP on a regular basis. This interaction may be physical (through the sense of touch, sight, hearing, or smell) or psychological (as anyone who has worried about children's safety or the value of his or her property will understand).

In any case, these are the people who have, perhaps, the strongest interest in seeing that a positive BMP design is achieved. These are also the people who will soon be asked to participate in the community's nonstructural stormwater management programs by changing some of their aesthetic values and even their lifestyles. Therefore, the person responsible for producing the BMP design must be aware of their interests and incorporate them into the design as well.

Operating Conditions

Just as a wide range of people have an interest in the BMP design, the BMP must operate under a wide range of conditions. Just as the BMP designer may fail to recognize the full range of interests, he or she often fails to consider all of the real-world conditions that the BMP will be subject to by focusing solely on those design conditions necessary for official program approval. This is unfortunate, because the design conditions that received all of the designer's attentions will, in reality, only occur during a small fraction of the BMP's existence. However, its performance during the remainder of its existence, while ignored by the designer, will largely determine the community's opinion of its value.

Therefore, it is important that the BMP designer be aware of all of the weather and other site conditions to which the BMP will be subjected.

Design Conditions

These are obviously the designer's first concern and, as noted above, are normally established by the community's stormwater management program. In the case of runoff quantity control, these conditions usually include either a single event or a range of relatively extreme storm events, the runoff from which must be stored and released at a predetermined rate. New Jersey's Stormwater Management Regulations, for example, require that the runoff from a proposed land development site for the 2-, 10-, and 100-year storm events be controlled so that the peak rate of site runoff after development for each storm does not exceed the peak rate that existed before development. The Somerset County, New Jersey, standards are stricter, requiring a peak rate after development that is actually less than existing to account for development-induced changes in runoff volume and overall hydrograph shape as well.

In the case of stormwater quality control, typical design conditions may include the temporary storage and slow release of the runoff from a much smaller, more frequent storm event to promote pollutant removal through sedimentation. For example, the New Jersey Stormwater Management Regulations require the temporary storage of runoff from a 1-year storm event, with release occurring over 18 to 36 hours depending on the character and intensity of the proposed development. The state of Delaware requires extended storage of the first inch of runoff from a proposed site, with release occurring over 24 hours.

Whatever exact design conditions the stormwater management program may specify, it is vital that the structural BMP function properly under them or the goals of the program cannot be met.

Extreme Conditions

In addition to the program's design conditions, which have been selected with the goal of runoff quantity and/or quality in mind, the responsible BMP designer must also recognize that more extreme storms may also occur. Therefore, due to the inherent dangers of storing runoff and the exceptionally large quantities of runoff that can be produced by these extreme events, it is vital that the BMP designer also address the goal of safety by ensuring that the BMP will also function properly under such extreme conditions. This will typically include the provision of an emergency spillway or other auxiliary outflow device that will safely convey the extreme event runoff that exceeds the capacity of the BMP's normal outflow structure. It will also include protection of critical portions of any embankment, dam, or discharge points that may be subject to scour or erosion from the high flow velocities generated by the storm event.

Dry Weather Conditions

While design and even extreme storm conditions can be expected to occur periodically, the most common operating condition at a structural BMP will be dry weather with various seasonal temperatures, winds, humidities, and periods of daylight. While dry weather may be the most prevalent operating condition, it is also the one that is most frequently overlooked by the BMP designer. As a result, how the BMP will look, smell, and even sound during the majority of its operating life is then left to chance. This can be particularly unfortunate for the BMP maintainer and, more critically, the resident, worker, or commuter who will interact most often with the BMP during dry weather conditions. Therefore, the responsible BMP designer will not only address extreme storm events but will also make sure that the BMP performs satisfactorily when it isn't raining at all.

Design Methodologies

Before starting the actual design process, the responsible designer will have an adequate understanding of the selected design methodologies. These methodologies can cover such aspects as rainfall-runoff computations, hydrograph routings, infiltration and ground-water movement, structural design, and geotechnical issues. In doing so, the designer's understanding should include the methodology's theoretical basis, assumptions, limitations, and applicability. In addition, the responsible designer will also have an understanding of both the accuracy needed to perform the design and the accuracy of the method he or she has selected to do it. From this, the responsible designer will neither waste time producing unneeded accuracy nor attempt to achieve a level of accuracy beyond the limits of the method. Finally, the responsible designer will understand the sensitivity of each of the method's input variables and will appropriately allocate his or her time and resources in developing each one.

Facility Type

The final point for the BMP designer to ponder before beginning the actual design process is the type of structural BMP to be used. Presently, a wide range of facilities are available for use, ranging from relatively simple vegetated filter strips and swales to large ponds and constructed wetlands. Selection of the appropriate BMP depends on several factors, including program requirements, BMP location, site conditions, maintenance needs, safety, cost, and performance characteristics.

Similar to BMP operating conditions, the BMP designer may often consider only a few of these factors, most notably program requirements (keep the regulator happy) and cost (keep the client happy, too), in making his or her selection. The responsible designer, however, will recognize the performance, needs, uncertainties, and risks inherent in each type of BMP and will then select (or help influence the selection of) the most appropriate type of BMP for the site. This process typically begins with the identification of the fundamental characteristics of each type of BMP, along with the project's physical, economic, social, and regulatory constraints. The process then becomes one of comparison and analysis, with the best match found by eliminating the worst.

For example, a site with porous soils, low ground-water table, and close proximity to residences may not be best suited for a wet pond or constructed wetland, while the active recreational needs of the residents may benefit from a dry, extended detention basin that can also serve as an athletic field. Although perfect matches rarely occur, comparisons and analyses such as this will help reduce the number of potential BMPs, improve the thoroughness and objectivity of the overall selection process, and ideally produce the optimal facility type. This process can even help identify inherent weaknesses in or problems with the selected type, which will enable the responsible BMP designer to devote additional time and effort towards correcting them during the design phase.

To undertake such a selection process obviously requires a designer who understands the fundamental characteristics and needs of each BMP and who can objectively assess all of the pertinent site constraints. Such a designer must also be willing and able to confront the differing opinions of other, less objective or informed parties (including the regulator and client) to ensure that the best BMP is selected. As noted throughout this paper, achieving an optimal BMP design is a complex and demanding process that must incorporate numerous interests and requirements. Starting the process with the wrong facility type, however, transforms a complex and demanding process into an impossible one.

BMP Design Considerations: A Checklist

Having completed the BMP selection process with honor, idealism, and design contract still intact, and armed with both the necessary technical and regulatory knowledge and economic and social sensitivity, the responsible BMP designer is ready to begin the actual design process. Presented below is a checklist of six key design considerations to help guide this effort. Ideally, these six items have or will become an integral part of the designer's thought process and will automatically be included in each design effort. These items can also serve as guidelines for those responsible for the review and approval of specific BMP designs as well as goals for those developing new stormwater management programs.

Safety

For several reasons, the safety of the structural BMP must be the primary concern of the designer. Due to its "structural" nature and, in many instances, the fact that it will impound water either permanently or temporarily, the structural BMP will inherently pose some degree of safety threat.

Those at risk include people living, working, or traveling downstream of the BMP whose safety and/or property will be jeopardized if the BMP were to fail and release stored runoff. Because this is a risk that has been created solely by the BMP, the designer must ensure that the probability of such a failure is acceptably small.

Also at risk at a structural BMP are maintenance personnel, inspectors, mosquito control personnel, and equipment operators, who must work in and around the facility. Typical hazards include deep water, excessively steep slopes, slippery or unstable footing, limited or unsafe access, and threats posed by insects and animals. As noted above, the responsible BMP designer understands the importance of facilitating BMP maintenance. Providing a safe working environment for the BMP maintainer is one important way to do it.

Finally, those living, working, attending school, or playing in the vicinity of a structural BMP may also be at risk, particularly if the BMP serves both as a stormwater management and recreational facility. Once again, such things as standing water, steep slopes, unstable footings, and insect and animal bites must be addressed by the designer to avoid creating a facility that is a detriment to the community it is intended to serve. Failure to do so will only alienate those members of the community who will be asked to play a vital role in future stormwater management efforts.

Performance

Having made a strong commitment to safety, the BMP designer must then consider facility performance. This normally includes achieving the necessary stormwater detention times, flow velocities, settling rates, peak flow attenuation, and/or ground-water recharge for the range of storm events to be managed. Again with a commitment to safety, the designer must also ensure that the BMP performs adequately under emergency conditions, most notably when the peak rate and/or volume of runoff flowing into the basin exceeds the discharge capacity of the BMP's principal outlet. This will require the inclusion of emergency or auxiliary outlets in the BMP to safely convey this excessive inflow through the BMP without jeopardizing its structural integrity.

In most instances, the performance standards that the BMP design must meet will be specified in the stormwater management program's regulations. Experience has shown, however, that these performance standards may, at times, be vague, contradictory, or even impossible to meet. For example, many BMP designers have been confronted with a requirement to reduce both the peak rate and total runoff volume from a developed (or developing) watershed to predeveloped levels. This has often lead to much head scratching, for the solution normally requires the use of an infiltration or recharge basin which, due to site constraints, may either be impractical or impossible. Faced with such circumstances, the responsible designer looks beyond the written regulations and investigates their origins and true intent with regulatory personnel. Direct inclusion of these individuals in the design process will also help ensure more positive overall results.

Constructability

Up until now, the designer's efforts to achieve adequate BMP safety and performance levels have been achieved only on paper or computer disk. Because the ultimate goal of the design process is to actually create a BMP, the BMP designer must also give careful consideration to how it is to be constructed. Achieving exceptional safety and performance characteristics in a BMP that cannot actually be built solves nothing and wastes much. Achieving required levels of safety and performance in a BMP that can be reconstructed with relative ease using readily available materials, equipment, and skills is commendable and not only solves a specific stormwater management problem, but also helps to advance the community's overall program. "Constructability" can be defined as a measure of the effort required to construct a structural BMP. A BMP that is highly "constructable" utilizes materials that are readily available, relatively inexpensive, and do not require special shipping or handling measures. They will be both durable and easily modified in the field to meet specific site conditions. Similarly, the construction techniques and equipment required to construct the BMP will also be relative simple, straightforward, and familiar to the people who will be performing and operating them.

It is important to note that the above description is not intended to discourage the use of new or innovative materials or construction techniques, nor to inhibit creativity in the BMP design process. In fact, innovation in design and construction is vital to the future growth of stormwater management. Instead, the above description of "constructability" is intended to remind designers that they must consider the construction aspects of the BMP in the design process and strike a balance between performance and safety requirements, constructability, and innovation for each design they undertake.

Maintenance

The same reminder stated above for constructability must also be said for BMP maintenance. Similar to construction, the degree of effort and expense required to adequately maintain a structural BMP will help determine the overall success of its design. A BMP with manageable maintenance needs can be expected to remain in reasonably good condition and has a stronger chance of becoming an asset to the surrounding community. On the other hand, a BMP with excessive maintenance needs is likely to be neglected and will quickly become a community liability. As such, BMP maintenance can directly effect the overall success of the community's stormwater management program.

The BMP designer can help determine a BMP's maintenance needs by considering several aspects of that maintenance in the design process. First, the BMP design should include the use of durable materials that are able to withstand the many and varied physical conditions that the BMP will experience over its lifetime. Secondly, suitable access to key BMP components and areas is vital if required maintenance levels are to be achieved. This will include provisions for walkways, staging and disposal areas, access hatches and gates, and safe, stable working areas. The frequency of maintenance has a large impact on both maintenance cost and quality, and it is the designer's responsibility to achieve an appropriate level. Finally, the BMP designer should always strive to minimize the overall amount of maintenance at the BMP and to make that amount as easy as practicable to perform.

Cost

Inclusion of a BMP's cost in a list of design considerations is not surprising. Once again, however, a review of the full costs associated with a structural BMP may yield a few surprises that may increase designers' understanding and encourage them to give BMP costs the full consideration they deserve.

The most obvious BMP cost is its construction. This can be estimated with reasonable accuracy and is the cost most directly borne by the designer's client. As such, designers most often focus on this cost during the design process to the exclusion of all others.

What other costs may be overlooked? One may be the designer's own fee, which is part of the overall BMP cost but which has probably been excluded from consideration because it has already been determined. The designer's fee, however, has a direct impact on the BMP design because it determines the effort and resources the designer uses to produce it. The level of effort expended during the BMP design can have a similarly direct effect on the effort and cost of both construction and maintenance. The greater cost of a more thorough BMP design can ultimately result in cost savings to the client during subsequent project stages. Therefore, while this is not a signal to BMP designers to raise their fees, it is meant to remind designers that their fee is part of the overall BMP cost and that it is their responsibility to determine what level of design effort and cost represents the best investment for both the client and the community.

Another portion of total BMP cost that is frequently overlooked is the cost associated with its maintenance. While this cost on an annual basis is usually a small percentage of the construction and even the design cost, it must be remembered that, unlike construction or design, maintenance costs are recurring and must be paid throughout the life of the BMP. Therefore, while a maintenance cost savings may appear to be insignificant on a per-operation basis and not worth the extra investment in design or construction required to achieve it, its value may be viewed quite differently when multiplied by the numerous times it will be realized. As such, an added investment in design to produce a trash rack that will require less frequent cleaning or an added investment during construction to reduce the frequency of repairs may quickly yield a positive return in the form of reduced maintenance costs. Similar conclusions can be reached for many other design and construction efforts, such as providing better access, using more durable materials, and selecting a BMP that best suits site conditions.

Community Acceptance

The final recommended design consideration once again involves those people who may have the greatest interest in the structural BMP. Not coincidentally, these are the same people who will have the greatest role in the various nonstructural programs intended to augment and even replace structural BMPs in the future. To protect those interests and encourage assumption of that role, it is up to the designer to help achieve a structural BMP that will be reviewed as a community asset rather than a liability.

As discussed above, this can be achieved by considering the aesthetic value of the BMP, preventing the creation of nuisances and safety threats, as well as achieving required performance levels. Through all three, stormwater management gains the understanding and credibility it requires within the community.

Suggested Design Review Techniques

Throughout this paper, the BMP designer has been encouraged to consider a wide range of interests, operating conditions, costs, and other responsibilities

R0015899

throughout the design process. Presented below are two recommended techniques to help accomplish it. They can either be used as review techniques following completion of a preliminary BMP design or, ideally, be incorporated into the overall design process and used continually throughout it.

Spend a Mental Year With the BMP

To use this technique, the BMP designer simply imagines conditions at the constructed BMP throughout a full year. This should not only include rainy and sunny weather, but also light rain showers (with little or no runoff), light and heavy snowfalls, and frozen ground conditions. Other site conditions may include late autumn, when trees have lost their leaves and the BMP has found them, and hot, dry weather or even drought, when the turf or other vegetation is stressed or even killed. Finally, the designer may wish to imagine what the BMP will be like at night.

As these conditions are visualized, the designer should also imagine how those conditions may effect not only the operation of the BMP itself but also the people that will interact with it. Can blowing snow completely fill the BMP, leading the unsuspecting pedestrian to think that the grade is level? Will the outlet structure's trash rack be particularly prone to clogging by fallen leaves, particularly from the trees the designer just specified for the BMP's bottom?

What about the ice that will form on the surface of a pond or constructed wetland? Can someone fall through? Could that someone be a child taking a shortcut home? How will people be warned not to? How will they be rescued if they do anyway? What about night conditions? Will the constructed wetland next to the office parking lot that is so attractive during summer lunch hours become a safety hazard to workers walking to their cars in the winter darkness? Or will that same summer sun and a lack of rainfall produce some of the wonderful aromas of anaerobic decomposition?

At first, it may be exasperating to realize that the possible site conditions and circumstances can be as numerous and varied as the number of possible BMP uses But then again, that is the point of the exercise. It is intended to help the designer consider and design for all conditions at the BMP, not just the 1- or 100-year storm event required by the regulations. In doing so, the BMP designer will not only meet the letter of the regulations but will raise the spirit of the entire stormwater management program.

Who, What, When, Where, and How?

The second recommended review technique a BMP designer may employ is to simply focus on one or more characteristics or functions of the BMP and then ask (and attempt to answer) the above questions. For example, let's consider BMP maintenance and then ask:

- Who will perform it? Does the BMP design require specialists, or will someone with general maintenance equipment and training be able to do the job?
- What needs to be maintained? Preparing a list of all the BMP components included in a design that will need attention sooner or later may prompt a revised design with a shorter list.
- When will maintenance need to be performed? Once a day? A week? A year? Remember, the recurring costs of BMP maintenance can be substantial. In addition, can maintenance only be performed during dry weather? If so, what happens during 2 or 3 weeks of wet, rainy weather? What happens when repairs need to be made or debris removed during a major storm event? In terms of effort and possible consequences, it is easier for the designer to find answers to these questions now than for maintenance or emergency personnel to scramble for them later.
- Where will maintenance need to be performed? Will the maintainer be able to get there? Once there, will he or she have a firm, safe place to stand and work? In addition, where will such material as sediment, debris, and trash removed from the BMP be disposed of? Before answering that question, do you know what is in it? Are there toxics or hazardous materials in the sediment or debris? If so, is the place you originally intended to use still suitable? Once again, it is easier to address these questions now then when the dump truck is loaded and the engine's running.
- How will maintenance be performed? The simple instruction to remove the sediment or harvest the vegetation can become rather complicated if no provisions have been made to allow equipment to get to the bottom or even into the site. "Mowing the grass" can become "risking your limbs" on long, steep slopes. How will you explain to your client why the BMP in which he or she has invested has become a liability to themselves and their community?

Similar exercises can be performed with constructors, inspectors, and residents as the object of inquiry. For example, where will the nearest residence be? How will the constructor build the emergency spillway? When will the inspector need to visit to check for mosquitos?

Similar to the "mental year" review technique, the questions raised in this technique are intended to make the designer more aware of all the possible impacts the BMP may have and, further, to encourage the designer to address those impacts now, during the design phase, rather than leave them for others to cope with later. Even if the designer cannot completely answer all of the questions, he or she will be able to advise the others of any unavoidable needs or problems that will be inherent in the BMP and allow them to adequately prepare.

Summary

Stormwater management must still be considered a relatively new endeavor, particularly on a nationwide basis. Despite its nascent state, it has been charged with the responsibility of addressing some very complex environmental problems. For stormwater management to grow to the level demanded by this charge, the designers of structural BMPs must be willing to assume a degree of responsibility for that growth. BMP designers can fulfill that responsibility by producing BMP designs that do not merely meet official regulations and standards, but help inspire new, better, and more comprehensive ones. BMP designers must also incorporate a wide range of interests into the BMP design, including those held by stormwater program regulators, BMP constructors and maintainers, and all those members of the community who will interact with the BMP over its lifetime. During the design process, BMP designers must not only consider the BMP's performance but also its cost, durability, ease of construction, and maintenance needs. Finally, BMP designers must always recognize the BMP's impacts both on the community around it and on the stormwater management program with which the community has entrusted them.

Targeting and Selection Methodology for Urban Best Management Practices

Peter Mangarella, Eric Strecker, and Gail Boyd
Woodward-Clyde Consultants,
Oakland, California, and Portland, Oregon

Abstract

Selecting best management practices (BMPs) to implement as part of a stormwater management plan is quite difficult and controversial because of a variety of technical, regulatory, institutional, and financial factors and constraints. Specifically, the nature and sources of stormwater-borne pollutants and the water quality and ecological problems these pollutants cause are not well understood. The cost, effectiveness, and applicability of many BMPs are also not well understood, although several BMP manuals summarize existing information. The federal National Pollutant Discharge Elimination System (NPDES) stormwater regulations provide flexibility in selecting BMPs to control urban pollutants. EPA gives only general guidance on the types of BMP programs that are desirable and does not require the implementation of specific BMPs. Several other factors contribute to difficulties in selecting and implementing BMPs. In many cases, institutional jurisdictions do not correspond to watershed boundaries, and water management institutions' roles and responsibilities are fragmented for effectively dealing with the myriad nonpoint sources of pollution associated with stormwater drainage systems. Finally, the availability of funds, which are currently very limited, significantly determines BMP implementation.

This paper provides guidance on the selection of BMPs given this current environment and based on experience in developing stormwater management plans for areawide programs, individual municipalities, industries, developments, and government facilities. The paper describes the current tools available for BMP selection, a 10-step "model" selection process, and case studies for a large areawide municipal program and for an industrial facility.

Introduction

In October 1990, the U.S. Environmental Protection Agency (EPA) issued regulations requiring certain municipalities and industries to select and implement best management practices (BMPs) to control pollution associated with stormwater runoff and dry weather discharges into storm drain systems. Such BMPs would be selected and described in stormwater management plans and implemented in compliance with an NPDES permit. The specific regulatory language in Section 402(p) of the Clean Water Act is "Permits for discharges from municipal storm sewers shall require controls to reduce the discharge of pollutants to the maximum extent practicable . . . ." The maximum extent practicable (MEP) standard has a legal definition; however, considerable uncertainty exists in the regulated community about what constitutes technical compliance with the MEP standard.

Other existing and proposed regulations require BMP selection. Section 303 of the Clean Water Act requires that delegated states and EPA establish total maximum daily loads (TMDLs) for designated "water quality limited" water bodies. The TMDL process considers both point and nonpoint sources. For nonpoint sources, water quality management plans must be developed to meet load allocations for urban and other land uses. The 1990 Coastal Zone Act Reauthorization Amendments (CZARA) require the development of state nonpoint source control plans for the coastal zone using BMP guidance recently released by EPA and the National Oceanic and Atmospheric Administration (NOAA).

Finally, watershed planning is gaining favor as a way of meeting water quality goals for the nation's waters. The watershed planning approach requires examination of all land uses and activities in a watershed and development of BMPs to protect water quality. EPA is considering the watershed approach for the phase II portion of the NPDES program.

This paper describes our experience in selecting BMPs for clients complying with the NPDES stormwater regulations; the process would also be applicable to TMDL, coastal zone, and watershed planning. We discuss types of BMPs and sources of information on BMPs available for developing management plans. Based on our experience, we also describe the attributes of a good selection process and describe the steps involved in a "model" selection process. Because of numerous site-specific conditions that enter into any selection process, the actual process chosen must be adapted to each situation. To illustrate how such a process might be adapted to different circumstances, we describe two case studies, one for a large areawide municipal program and one for multiple federal facilities regulated as industrial dischargers.

Best Management Practices

Although BMPs may be organized in many ways, it is useful in the selection process to distinguish controls based on how they function. BMPs based on function are often considered as source controls, treatment controls, and hydraulic controls.

- *Source controls* are intended to prevent pollution in the first place (i.e., pollution prevention) or to intercept the pollutants before they enter the storm drainage system. Preventing pollution in the first place often involves behavior modification, which requires public information and education, an important source control BMP. Street sweeping and catch basin cleaning are examples of source controls that intercept pollutants before stormwater carries them into receiving waters.
- *Treatment-based controls* are controls that remove pollutants from stormwater, usually through some structural means such as a detention basin or grassy swale.
- *Hydraulic controls* are structural controls that reduce the volume of runoff (or otherwise alter the runoff hydrograph) or divert flows away from source areas. Examples of hydraulic controls are infiltration systems.

In general, the effectiveness of these types of controls are not well understood. The effectiveness of treatment and hydraulic controls generally can be measured through monitoring, and there is an increasing body of literature regarding the effectiveness of treatment and hydraulic controls under limited conditions. Federal, state, and local agencies have developed numerous BMP guidance manuals to help identify, select, and design BMPs. The following is a partial list of manuals, starting with design manuals that contain detailed control selection and design information.

- U.S. EPA. 1993. Handbook: Urban runoff pollution prevention and control planning. EPA/625/R-93/004.
- City of Austin Environmental Resource Management Division. 1991. Environmental criteria manual. Environmental and Conservation Services Department (February 19).
- Metropolitan Washington Council of Governments (MWCOG). 1987. Controlling urban runoff: A practical manual for planning and designing urban BMPs. Prepared for Washington Metropolitan Water Resources Board (July).
- State of Florida Department of Environmental Regulation. 1988. The Florida development manual: A guide to sound land and water management (June).
- State of Washington Department of Ecology. 1992. Stormwater management manual for the Puget Sound Basin (the technical manual) (February).
- Urban Drainage and Flood Control District. 1992. Urban storm drainage criteria manual. Denver, CO (September).
- Metropolitan Washington Council of Governments (MWCOG). 1992. Design of stormwater wetland systems. Prepared for the Nonpoint Source Subcommittee of the Regional Water Committee (October).

The following documents primarily discuss control effectiveness and do not contain control selection and design information:

- City of Austin Environmental Resource Management Division. 1990. Removal efficiencies of stormwater control structures. Environmental and Conservation Services Department (May).
- Metropolitan Washington Council of Governments (MWCOG). 1992. A current assessment of urban best management practices. Prepared for the U.S. Environmental Protection Agency (March).
- U.S. EPA. 1990. Urban targeting and BMP selection: An information and guidance manual for state nonpoint source program staff engineers and managers. Region 5, Water Division, Chicago, IL 60604 (November).
- Metropolitan Washington Council of Governments (MWCOG). 1992. Analysis of urban BMP performance and longevity.
- U.S. EPA. 1993. Guidance specifying management measures for sources of nonpoint pollution in coastal waters. EPA/840/B-92/002. Washington, DC (January). (Includes costs.)
- California State Stormwater Task Force. 1993. California BMP handbooks for municipal, construction, and industrial/commercial (April).

Finally, the following document addresses BMP costs:

- Southeastern Wisconsin Regional Planning Commission. 1991. Costs of urban nonpoint source water pollution control measures. June.

These manuals describe BMP function, requisite site conditions, existing performance information, and cost ranges. In general, these manuals are well written and provide a good starting point for developing an understanding of the advantages and disadvantages of many treatment-based controls. For some BMPs, there is limited information on effectiveness and cost; for these, pilot testing may be helpful under site-specific conditions.

Treatment-based controls are especially applicable in construction and new developments, where structural measures may be incorporated into the construction process and site design. The cost of constructing and maintaining treatment-based controls is a major concern to municipal and industrial dischargers.

In contrast to treatment-based controls, source control effectiveness in terms of water quality improvement cannot easily be measured, if at all. For example, the effect of a public education program on improving water quality cannot be determined, although some public education activities obviously are more effective than others. The effectiveness of street sweeping and catch basin cleaning on water quality requires careful and expensive paired catchment types of studies. Source controls are generally considered the most cost-effective long-term solution because they address the cause of the problem; thus, we see many programs focusing on source control measures.

Attributes of a Good Selection Process

The following sections describe some attributes of a good selection process.

Keep It Simple and Straightforward

BMP selection for nonpoint source controls is in its infancy compared with point source controls, for which treatment technologies and associated costs are well understood. Instead of traditional cost benefit analysis, nonpoint source BMP selection is more of an art and requires experience, sound judgement, and common sense. Though the process of selection may involve several steps, the process itself must be easily understandable and accepted by the various interest groups involved, including public agency staff and decision-makers, environmental groups, and regulatory personnel.

Document the Process

It is essential to carefully document the process by which BMPs were selected and the various assumptions and considerations made during the selection process. In other words, the process, even though it may be subjective in part, should not be "arbitrary and capricious." The selection process must be clear to reviewers in evaluating the adequacy of the process in meeting the intent of the regulations. Also if the process is clear, it can be improved or modified in the future as more information becomes available or policies change.

Be Comprehensive

The federal regulations require a comprehensive approach such that a broad range of controls are evaluated for various land uses and activities. The selection process must evaluate a comprehensive list of BMPs to address pollutants of concern and their sources.

Plan for Implementation

Human nature being what it is, effectively implementing many BMPs at once is difficult. The solution to this dilemma is to minimize the number of BMPs chosen, prioritize or phase their implementation, and/or group related BMPs into a few categories, sometimes called program elements.

Involve Affected Parties in the Process

A second element of human nature is adverseness to implementing someone else's plan. Therefore, BMPs are selected ideally by those who have to implement them (with guidance, of course). A second alternative is that the process heavily involves those who will implement the BMPs in a review and approval role. If neither of these approaches are followed, the plan is not likely to be well implemented.

Indeed, involvement of the affected parties in the selection process is probably more important to the success of the program than the exact nature of the process itself. Through this process, the parties become educated regarding problems, possible solutions, and the need for teamwork in implementing solutions.

Model of a Good Selection Process

There is no one correct selection process as the process must be tailored to local institutional, political, and regulatory conditions. Figure 1 is a schematic showing six steps in a BMP evaluation, selection, and planning process that are generally applicable. The following is a somewhat expanded discussion of BMP selection steps appropriate for most areawide municipal programs.

Step 1: Establish Program Goals and Objectives

The clients must agree on a compliance strategy from which will stem goals and objectives for the program. The strategy should address such issues as organization and administration, decision-making, coordination with other interest groups, and degree of proactiveness.

Step 2: Identify Receiving Waters, Problems, Pollutants, and Resources

The ultimate intent of the regulations is to protect and improve the water quality and ecology of receiving waters, and this goal should drive the BMP selection proc-

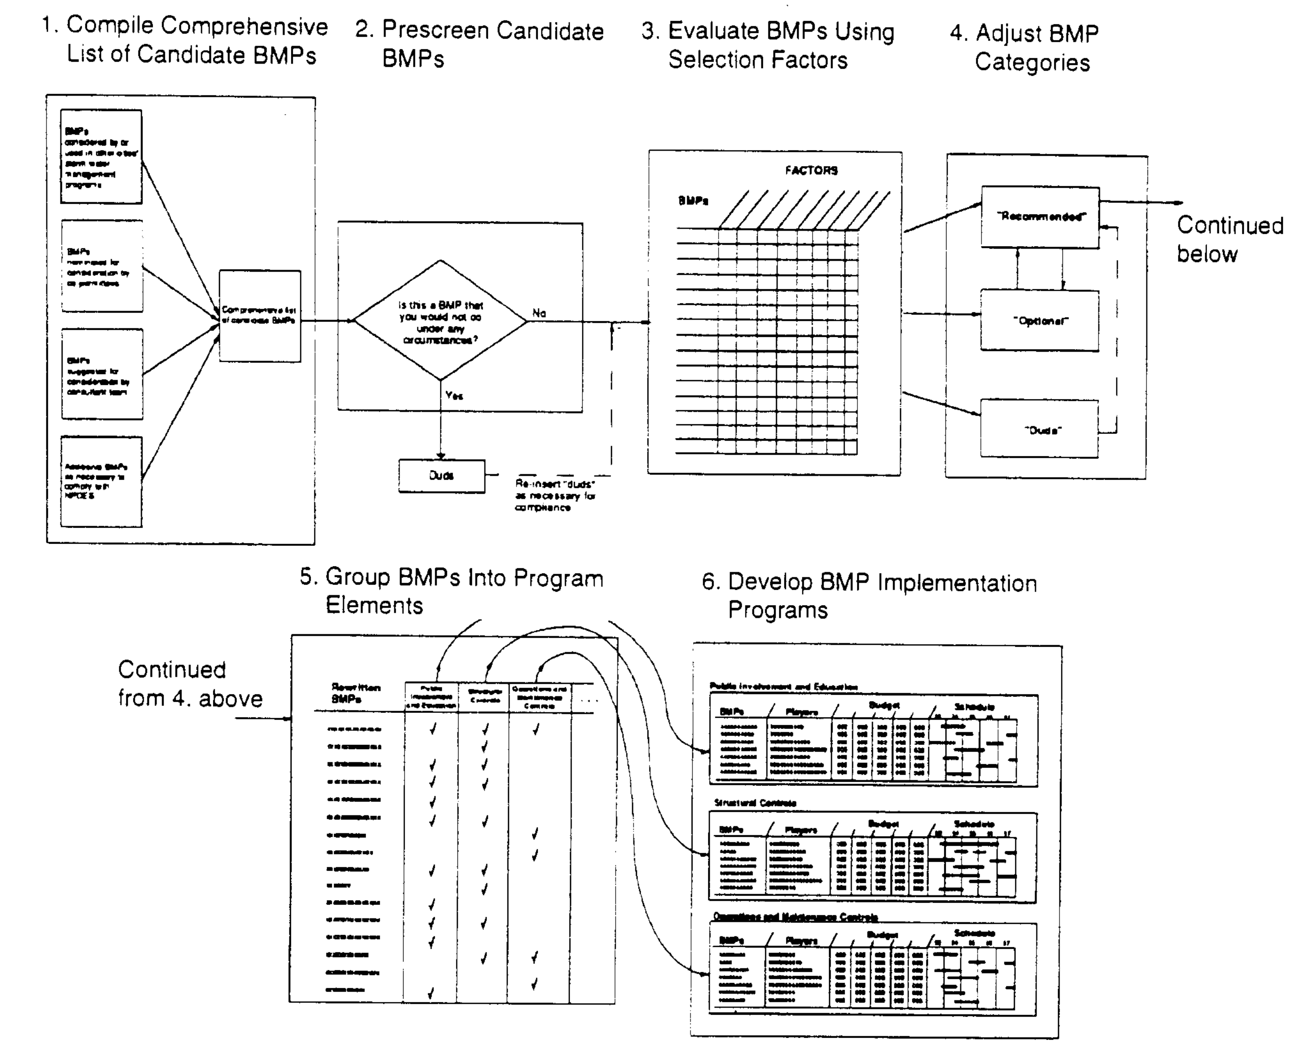

Figure 1. BMP evaluation, selection, and planning process.

ess to the extent possible. Ideally this step identifies water resources of particular value that are especially critical to protect, as well as impaired water bodies (e.g., 304(L) segments) that are currently not meeting water quality objectives appropriate for the beneficial uses. Where data are available, pollutants to be controlled should be identified. Without this step, much work and resources may be focused on activities that do not necessarily translate into an improved aquatic environment. Many programs find that a nontechnical one- or two-page "fact sheet" on receiving water problems, pollutants, sources, and management implications helps to develop support from taxpayers and decision-makers.

Step 3: Identify Sources and Pathways

Given the problems, the next step is to try to identify the important point and nonpoint sources of pollutants that are causing the problems. This is an essential step, because control of nonpoint sources only makes sense to the extent that it is a major source of the problem pollutant. For nonpoint sources, try to describe the pathway from source to receiving water, because this helps identify the BMPs that can most effectively intercept the pollutant along the pathway. For example, dumping waste oil into catchbasins can be mitigated by labeling storm drain inlets and/or requiring a monetary deposit at the point of purchase. It should also be pointed out that some sources may be quite difficult to control (e.g., natural erosion).

Step 4: Prioritize Sources (Areas) for Control

Targeting sources for BMP application is the next step. Focusing resources on selected areas is important, otherwise resources tend to be spread too thin to be effective. This is particularly important in municipal programs, where some early "successes" encourage the participation and financial support of local citizens.

A systematic targeting scheme using a ranking process based on stream size, beneficial uses, pollutant loads, and ease of implementation of the BMP is provided in U.S. EPA (1) and U.S. EPA (2). Use of these manuals might be appropriate after an areawide plan is developed; for example, a BMP might be to begin basin planning for selected basins within a city. The targeting manual (1) could be used to identify the basin and subbasins for BMP selection.

Step 5: Identify and Evaluate Existing BMPs

Compile a list of existing BMPs that are currently being conducted and organize them according the sources identified in Step 5. Identifying existing measures is often very difficult. Some municipalities do not know their system very well and are organized into departments in such a way that no one department is aware of what stormwater measures are currently being implemented. Carefully crafted questionnaires work quite well at developing information on existing practices that affect stormwater quality. Evaluate the effectiveness of these measures and improve or discontinue as appropriate.

This step also involves identifying existing environmental programs that are conducting activities that relate to stormwater pollution control and with whom cooperation should be sought. Examples include pretreatment programs, HAZMAT programs, solid waste control and recycling programs, and public information programs.

Step 6: Compile Candidate BMPs

Compile a comprehensive list of candidate BMPs that may be appropriate. This list should contain both source- and treatment-based controls and include such things as regulatory authority. Attach attributes to each BMP, including (if available) pollutant type controlled, cost, and effectiveness. (Recall that such information is generally not available for source controls.) Note dependencies or synergistic relationships between BMPs. For example, some BMPs may be more effective if or may require that another BMP is implemented before or at the same time.

Step 7: Develop Selection Criteria

In addition to the obvious criteria that the BMP address the problems and sources identified in Steps 2 and 5, developing a list of additional criteria that can be used to assist in the selection process is helpful. Such criteria include regulatory requirement compliance, effectiveness, reliability and sustainability, implementation and continuing costs, equitability, public and agency acceptability, risk and liability, environmental implications, and synergy with existing or other BMPs.

Step 8: Apply Criteria for Selection of Baseline Measures

Selection criteria may be applied in numerous ways. For example, applying different criteria in multiple screening "passes" is a common procedure. BMPs may be required to meet "critical criteria" such as obtain co-permittee acceptance, address the problem pollutants and sources, and meet regulatory requirements. Then, in a second "pass," those BMPs that met the critical criteria are further evaluated by applying additional criteria that would help to select preferred BMPs. Such criteria could include effectiveness, cost, and reliability. Often the second pass allows the municipality to help determine what is financially feasible. In the second pass, qualitative (e.g., high, medium, low) or simple quantitative (e.g., 1, 2, 3) scoring might be used to help rank preferred BMPs. Unequal weighting can be assigned to each criteria as appropriate.

BMP selection should also anticipate the evolution of the program. For example, we often recommend that a set of "baseline" BMPs be selected that fully exploits the existing control measures and focuses on additional source control. The selection process can then be used to select the baseline measures and also candidates for a reserve list of BMPs that could be implemented at a later time based on experience with the baseline BMPs.

Step 9: Implement Baseline Measures

Implement the baseline measures with appropriate phasing to allow for planning, pilot testing, etc., prior to full scale implementation. For each BMP, develop measures of effectiveness. As described above, baseline measures tend to be source controls.

Step 10: Monitor Effectiveness and Reevaluate BMPs

Monitor the effectiveness of each BMP and, based on monitoring, annually reevaluate each BMP. As appropriate, delete or select additional BMPs. Annual evaluation should also include any new information obtained through monitoring receiving waters and/or source identification studies.

Case Study 1: Areawide Municipal Program

The following describes a case study of the BMP selection process that multiple agencies who were part of an areawide stormwater program conducted.

County X is 200 square miles in area and contains 20 co-permittees consisting of municipalities, the county, and a special district. The county population is 1 million people. The municipalities cover a wide range of sizes and land uses, from one city of 100,000 population with major industrial facilities down to small residential cities

R0015906

of 10,000 population. At the behest of the state environmental agency, the co-permittees elected to form a countywide stormwater pollution control program to comply with the federal NPDES stormwater regulations. During the Part I application, the co-permittees compiled a list of existing BMPs.

The co-permittees were very concerned that their management plans reflected local conditions and resources and insisted that they each conduct the BMP selection process themselves. We refer to this approach as the "bottom up" approach, in contrast to the "top down" approach in which BMP selection is conducted by the program and then distributed to the co-permittees for their review and approval. Woodward-Clyde Consultants (WCC) acted as facilitators by designing a process for BMP selection that included development of guidance documents, workshops for all co-permittees, and meetings with individual cities. Program representatives and WCC met with the individual jurisdictions three times throughout the process to provide assistance or clarification. The process from start to finish took about 9 months.

The following guidance documents were developed:

1. Description of Management Plan Development Process
2. Selecting the "Right People" To Participate in the Process
3. Source Identification
4. BMPs for Industrial Facilities
5. BMPs for Agency Activities
6. Transportation BMPs
7. Illicit Discharge Elimination BMPs
8. Commercial Area BMPs
9. Construction and New Development BMPs
10. Public Education and Industrial Outreach BMPs
11. How To Complete Your Stormwater Management Plan

The guidance documents included tables that each co-permittee was asked to complete based on guidance provided. The tables formed the basis of each entity's plan. A key element in the process was a problem and source identification step (Guidance Document 3), in which each entity identified receiving water problems, water resources of special interest, and pollutant sources. Based on this problem identification, cities selected BMPs to address source areas in their jurisdictions.

Guidance Documents 4 through 9 described a menu of individual BMPs from which the cities could select. In addition, WCC recommended a basic list of BMPs applicable for most jurisdictions. The co-permittees chose to participate in a countywide public education program involving various BMPs described in Guidance Document 10. Guidance Document 11 explained how to "put it all together."

An example of a BMP description is given in Table 1. The information provided consisted of a BMP name and identifier, description, steps for implementation, methods to assess effectiveness, and remarks. For those BMPs selected, co-permittees were asked to show when tasks would be completed, and the budget for each BMP over the 5-year permit period.

The BMP information was intended for guidance only, and some jurisdictions revised or created new BMPs that better addressed their circumstances. Some jurisdictions showed real creativity and enthusiasm in developing BMPs. This participatory process results in a much more implementable, practical, and effective stormwater management plan.

Case Study 2: Industrial Facility

Selection of BMPs for industrial facilities is more site specific and tends to be guided by the types of activities being conducted at the facility. The process of BMP selection then involves identifying industrial activities that could potentially generate sources, identifying the types of pollutant releases associated with

Table 1. Best Management Practices for Agency Activities and Facilities

Number	AA-11
Best Management Practice	Reduce agency use of herbicides and pesticides.
Description	Reduce the use of herbicides and pesticides on city streets, landscaping in parks, flood control channels, municipal golf courses, etc.
Steps for Implementation	1) Assess current herbicide and pesticides uses (e.g., types, amounts, areas used). 2) Research areas where less toxic substances could be substituted or usage could be eliminated altogether (e.g., use of mosquitofish rather than pesticides). 3) Develop implementation programs for various areas.
Methods To Assess Effectiveness	Compare amounts and types of herbicides and pesticides currently used with amounts and types used after implementation of the program(s) to demonstrate overall reduction and/or transition to less toxic substances.
Remarks	Coordinate with public education and industrial outreach component for public education in the area of residential herbicide and pesticide use.

each source, identifying optional BMPs that would prevent or eliminate that source, and selecting the preferred option. The following describes a pared-down process of BMP selection that we have used on several industrial projects.

Step 1: Identify Drainage System and Receiving Water

Define the drainage system and receiving waters, including water quality and other concerns in receiving waters. Ensure plant personnel (particularly nonenvironmental personnel) understand the receiving water and regulatory issues when they are involved in the BMP selection process.

Step 2: Identify Industrial Activities and Associated Pollutant Sources

Discuss what industrial activities are conducted at the facility and how these activities might lead to discharges into storm drain systems. This can best be accomplished through a combination of a site investigation and a sit-down brainstorming session with plant personnel. Table 2 shows the result of this step for a steam plant. Indicated in the table are the source activities, drainage areas within the facility where these sources are located, potential pollutants associated with the source, and a relative measure of the importance of the source for creating receiving water problems.

Contamination potential:

1 = high

2 = medium

3 = low

Step 3: Develop Candidate Control Measures

Develop candidate control measures for consideration that address each of the potential and known sources of pollutants. The last column in Table 2 shows these measures.

Table 2. Example of Source and Pollutant Identification and BMP Selection for Industrial Facility

Source Areas	Drainage Areas	Potential Pollutant	Contamination Potential	Recommended Control Measure
Parking lots	1, 2, 4	Oil and grease TSS	2 2	• Inspect and clean catchbasins • Conduct good housekeeping practices
Loading docks	1, 2	Oil and grease Toxics	3 3	• Provide mats to cover catchbasins if spill occurs while raining
Construction equipment parking	1, 2	Oil and grease TSS	2 2	• Inspect and clean catchbasins • Conduct good housekeeping practices
Materials storage	1	TSS Metals Toxics	2 2 3	• Sweep after loading and unloading materials from concrete vaults • Place materials with greatest contamination potential under Ferry St. overpass
Curing oil storage	1	Oil and grease	2	• Move drums inside or to a bermed area that is covered
Vehicle fueling	2	Fuel Oil and grease	3 3	• None
Aboveground fuel storage	2, 3	Fuel	3	• None
Utility pole storage	2	PCP1 Creosol Metals Oil and grease	1 1 1 1	• Determine feasibility of moving poles under Ferry St. overpass
Vehicle rinse area	2	TSS Oil and grease	2 1	• Clean sediment trap more often • Consider adding oil/water separator
Steam cleaner	2	TSS Oil and grease Detergents Toxics	3 3 3 3	• Enlarge pad area • Post signs providing employees with proper instructions • Rinse pad after cleaning • Clean oil/water separator more often

Table 2. Example of Source and Pollutant Identification and BMP Selection for Industrial Facility *(Continued)*

Source Areas	Drainage Areas	Potential Pollutant	Contamination Potential	Recommended Control Measure
Transformer cleaner	2	Mineral oil	3	• None
		PCBs	3	
Sodium hypochlorite storage	2	NaOCl	2	• Relocate drums inside or to a bermed area that is covered
Hogged fuel pipe	3	Tannin and lignin	3	• Sweep street after heavy winds
		BOD	2	• Clean catchbasin more often
		COD	3	
Sulfuric acid storage	3	H_2SO_4	3	• None
Oil drum storage		Oil and grease	3	• None
Ash handling area	4	TSS	2	• Enlarge the loading area
		pH	2	• Improve the loading procedure
		Toxics	2	• Clean the catchbasins in the immediate area more often

Step 4: Conduct BMP Evaluation and Selection

Conduct a BMP evaluation and selection session with plant personnel. Just as in a municipality, involving the right plant personnel in the process is very beneficial. Such involvement allows the plan to reflect their extensive knowledge of the site and industrial activities, and encourages the plant staff to take ownership of the management plan. Often, we have found that personnel have been trying to implement some of the BMPs, and the NPDES permit requirements now give them the impetus to get them more fully implemented. In these sessions, we have sometimes used a formal decision process, while at other times a less formal, but still documentable, discussion of the potential BMPs was used to select BMPs. The focus of BMPs at industrial sites where we have worked has been source control. Compared with municipalities, however, industries tend to be more willing to consider installing or retrofitting structural controls.

Step 5: Prioritize BMPs and Develop Monitoring Program

Prioritize BMPs and develop and implement "monitoring" programs for assessment of effectiveness.

A Catalog of Stormwater Quality Best Management Practices for Heavily Urbanized Watersheds

Warren Bell
City of Alexandria, Alexandria, Virginia

Abstract

Various federal and state environmental programs require the use of onsite structural best management practices (BMPs) to control the quality of stormwater discharges from development sites. Space constraints, extremely high property values, soil conditions, and the proximity of other building foundations often preclude the use of conventional stormwater BMPs for infill construction or redevelopment in the intensely builtup centers of major cities, where pollutant loads are usually the greatest. Unconventional solutions must be applied in these heavily urbanized environments.

Alexandria, Virginia, has adopted and published design criteria for several nonconventional BMPs, many of which employ intermittent sand filter technology; some of these BMPs were developed by pioneering jurisdictions throughout the United States; the city's engineering staff devised others:

- Stormwater sand filter basins in widespread use in Austin, Texas, are readily adaptable for large development projects.
- Underground vault sand filters employed in the District of Columbia (DC) allow full economic use of surface areas.
- Double-trench sand filters adopted by the state of Delaware can be placed either in or adjacent to paved areas.
- Simple trench and modular sand filters developed by the city of Alexandria are suitable for small or medium-size sites.
- A peat-sand filter adapted from a Metropolitan Washington Council of Governments design is applicable to situations where high pollutant removal is required.
- Water quality volume detention tanks for use in Alexandria's combined sewer areas capture the most polluted stormwater for later treatment in the wastewater treatment plant.

The Heavily Urbanized Environment

The U.S. Environmental Protection Agency (EPA) program for National Pollutant Discharge Elimination System (NPDES) permits for stormwater discharges envisions the use of onsite structural best management practices (BMPs) to control the quality of runoff from development sites. Many state programs already impose the requirement for onsite BMPs on developers. Under the Virginia Chesapeake Bay Preservation Act (VCBPA), no net increase in pollutants in stormwater runoff is allowable from previously undeveloped sites in Chesapeake Bay Preservation Areas (CBPAs). Runoff from redevelopment sites in CBPAs must contain 10 percent fewer pollutants than existed before redevelopment. In devising a local program to meet these pollutant removal performance requirements, Alexandria confronted the dilemma of which structural BMPs to employ. The entire city is designated as a CBPA. Most of the land is already developed, and large areas are heavily built up, in many cases with lot-line to lot-line structures. Property values are also extremely high. Such conditions exist in the central business districts of most metropolitan areas.

Use of conventional structural BMPs is often impractical in the heavily urbanized environment. Space and cost constraints severely inhibit the use of dry detention ponds and wet ponds. Soil conditions and high water tables in the river valleys where most older cities are located frequently preclude the use of infiltration devices because of the prevalence of marine clays. Unconventional solutions had to be found to remove the pollutants from stormwater runoff created by development activity. Research by the engineering staff of Alexandria's Transportation and Environmental Services Department revealed that very little information is available on how to remove pollutants from runoff in heavily urbanized environments.

BMP Design Criteria for Heavily Urbanized Areas

The Alexandria engineering staff consulted with jurisdictions throughout the United States where BMPs addressing heavy urbanization are being investigated, then synthesized the information obtained into comprehensive design criteria for local developers. The staff also developed several additional BMPs for use in the city. Design criteria for these BMPs for heavily urbanized areas were published in the *Alexandria Supplement to the Northern Virginia BMP Handbook* in February 1992 (1). The publication is being used by the Virginia Chesapeake Bay Local Assistance Department as a guide for other urban stormwater programs within the commonwealth.

The Concept of BMPs for Heavily Urbanized Areas

Stormwater quality management in the heavily urbanized environment involves the following activities for the most polluted runoff:

- Collection
- Pretreatment to remove sediments
- Storage
- Treatment to remove pollutants of a specific quantity

In Virginia, the minimum quantity of stormwater to be treated is the first 1/2 in. of runoff from the impervious areas on the site—the water quality volume (WQV). The WQV for each impervious acre is just over 1,800 ft^3.

Capturing the WQV

A typical approach for achieving isolation of the WQV is to construct an isolation/diversion weir in the stormwater channel or pipe such that the height of the weir equals the height of the water in the BMP when the entire WQV is being held. When additional runoff greater than the WQV enters the stormwater channel or pipe, it will spill over the isolation/diversion weir, and the extent of mixing with water stored in the BMP will be minimal. The overflow runoff then enters a peak flow rate reducer or exits directly into the stormwater collection system. Figure 1 illustrates this approach.

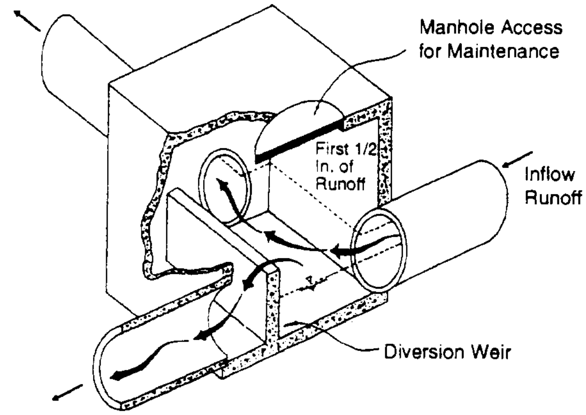

Figure 1. Typical isolation/diversion structure.

Pretreatment Requirements

Several conventional BMPs, such as buried infiltration devices, and most unconventional BMPs require some type of pretreatment system to remove excessive sediments, which would result in premature failure of the BMP. Pretreatment mechanisms may be installed either at the point of collection or after separation of the WQV. These mechanisms may be either separate devices or an integral part of the BMP itself.

Water quality inlets (WQIs), or oil-grit separators (OGSs), have been employed for several years for the removal of grit and oil, which are found in large quantities in parking lots and other areas where vehicular traffic is significant. Recent studies by the Metropolitan Washington Council of Governments (MWCOG), however, have established that WQIs provide little or no pollutant and questionable hydrocarbon removal (3).

Sedimentation basins have traditionally been the first step in water or wastewater treatment. Where site conditions allow, presettling basins may provide a low cost approach to removal of sediments, which can clog infiltration devices or filter systems. In situations where space is not a problem, presettling basins may be built directly into the ground. In the heavily urbanized environment, where space utilization is an important economic consideration, underground presettling chambers in vaults or pipe galleries may provide a more feasible solution. Alexandria sizes sedimentation basins using a methodology based on the Camp-Hazen equation, published by the State of Washington Department of Ecology (4).

Grassed filter strips are a common method employed in northern Virginia for removing sediments from stormwater to be treated in infiltration systems. To be effective, the strip must be at least 20 ft wide, have a slope of 5 percent or less (5), and be stabilized.

Storage of the WQV

Following isolation of the WQV and pretreatment to remove sediments and other pollutants, water must be stored until it can be processed in the primary treatment device (up to 40 hours in Alexandria). Creating over 1,800 ft^3 of water storage per impervious acre on the site is often the most costly item in the overall BMP system. In some cases, as with sedimentation basins, storage may be combined with pretreatment. In others, separate storage galleries of round or arched-section pipe may be required. Some BMPs for heavily urbanized areas combine pretreatment, storage, and primary treatment in a single underground vault.

Treatment of the WQV

Most of the BMPs described in this paper employ intermittent sand filters. Originally developed during the 1800s for treating both water supplies and wastewater, intermittent sand filters have regained popularity for use in the treatment of small wastewater flows (6).

Austin, Texas, and the state of Florida pioneered the use of sand filters in the treatment of stormwater runoff. Alexandria uses the Austin sand filter equation derived from Darcy's Law by the Austin Environmental and Conservation Services Department to size sand filters (2):

$$A_f = I_a H d_f / k(h+d_f) t_f$$

where

A_f = surface area of sand bed (acres or square feet)
I_a = impervious drainage area contributing runoff to the basin (acres or square feet)
H = runoff depth to be treated (feet)
d_f = sand bed depth (feet)
k = coefficient of permeability for sand filter (feet per hour)
h = average depth (feet) of water above surface of sand media between full and empty basin conditions (half maximum depth)
t_f = time required for runoff volume to pass through filter media (hours)

Based on long-term observation of existing sand filter basins, Austin uses k values of 3.5 ft/day for systems with full sedimentation pretreatment and 2.0 ft/day for systems with only partial sedimentation pretreatment. Alexandria has also adopted these values. Both Austin and Alexandria use a BMP drawdown time (t_f) of 40 hours. With these constants, the equation for sand filter systems with full sedimentation protection reduces to

$$A_{f(FS)} = 310 I_a d_f/(h+d_f),$$

where A_f is in cubic feet and I_a is in acres.

For sand filter systems with partial sedimentation protection, the equation reduces to

$$A_{f(PS)} = 545 I a d_f/(h+d_f),$$

where A_f is in cubic feet and I_a is in acres.

Descriptions of BMPs for Heavily Urbanized Areas

The BMPs discussed below should not be thought of merely as drainage structures. They are low technology treatment works that use water and sewage treatment technology from the late 19th century. Treatment works cannot always be made to function by gravity flow, although it is usually desirable from a cost-effectiveness standpoint.

Surface Sand Filter Basin Systems

Austin, Texas, was a pioneer in the use of intermittent sand filtration systems for treating stormwater runoff. The Austin program is managed by the Environmental and Conservation Services Department, which has published design criteria in their *Environmental Criteria Manual* (2).

Typical intermittent sand filters employ an 18- to 24-in. layer of sand as the filter media underlain by a collector pipe system in a bed of gravel. A layer of geotechnical cloth separates the sand and gravel to keep the sand from washing into voids in the gravel. Austin pretreats the stormwater runoff in a sediment trapping structure to protect the filter media from excessive sediment loading.

Figure 2 is a centerline cutaway of one Austin sand filter configuration. In this system, the sedimentation structure is a basin designed to hold the entire WQV, then release it to the filtration basin over an extended drawdown period. An alternate design allows use of a smaller sedimentation chamber but requires increasing the filter size to compensate for increased clogging of the filter media. While the system shown uses concrete basins, a sediment pond and a geomembrane-lined filter built directly into the ground may be used where terrain and soil conditions allow. The Austin sand filter systems are most appropriate for large developments covering several acres.

Austin has monitored the performance of their sand filters for several years and currently recognizes up to 60 percent phosphorus removal efficiency based on these studies (7). Alexandria is currently recognizing a 40 percent phosphorus removal rate pending further sand filter monitoring results by Austin and the District of Columbia. (Phosphorus is the "keystone pollutant" used to measure compliance with the VCBPA.)

Underground Vault Sand Filter Systems

Truong developed a stormwater quality sand filtration system in an underground vault (8). Over 70 of the structures have been installed since 1987. Figure 3 is a centerline cutaway of the original concrete vault DC sand filter. DC sand filters may be placed underneath parking lots, alleys, or driveways, taking up no usable space on the surface. This is an important advantage in the heavily urbanized environment. Truong believes that

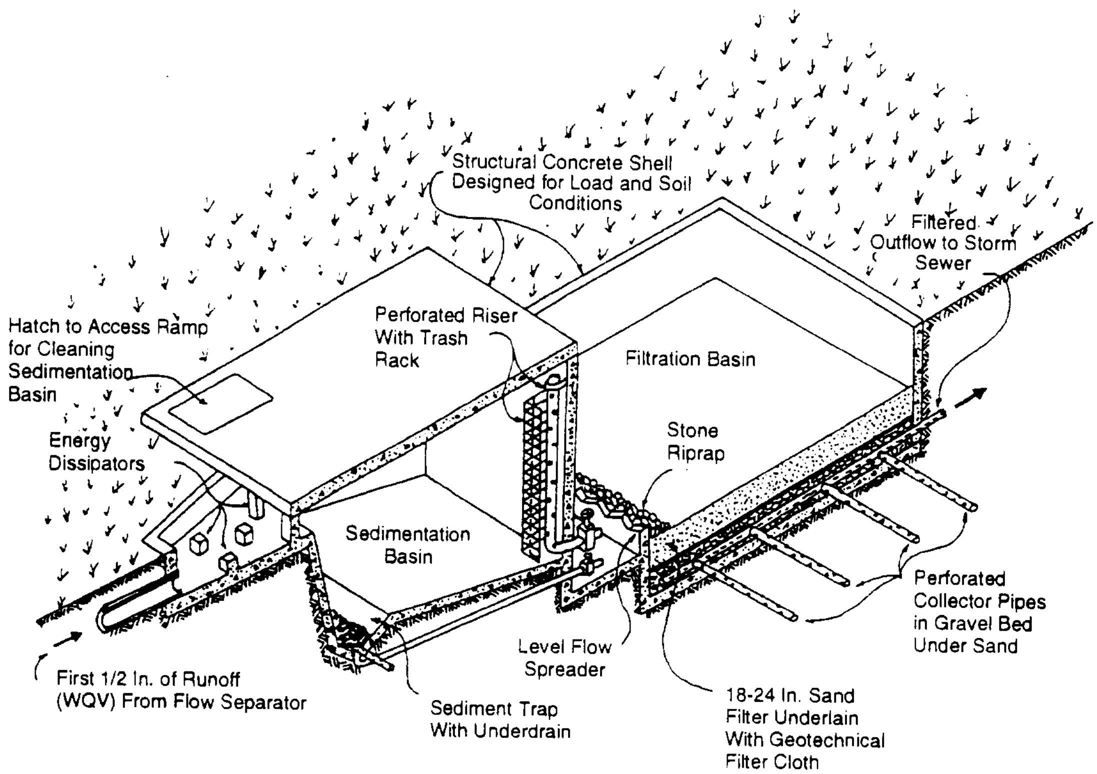

Figure 2. Austin basin sand filter system.

this system works best on watersheds with 1 acre or less of impervious cover.

The DC sand filter is a three-chamber gravity-flow system. The first chamber and the throat of the second chamber contain a permanent pool that traps grit and floating organic material, such as oil, grease, and tree leaves. A submerged rectangular opening at the bottom of the first dividing wall connects the two parts of the pool. The second chamber also contains a 24-in. deep sand filter underlain by a layer of geotechnical fabric and collector pipes in gravel. A top layer of plastic-reinforced geotechnical filter cloth held in place by a 1-in. layer of gravel is provided above the sand to compensate for the smallness of the sedimentation chamber.

New runoff entering the structure causes the pool to rise and overflow onto the filter. After percolating through the sand, the treated water enters the underdrains and flows out into the third chamber, or clearwell. The clearwell conveys the treated water to the storm sewer or drainage system. If possible, this BMP should be configured to allow gravity outflow; however, in instances where filters must be placed below the storm drainage system elevation, such as under the entrance driveway to a parking garage, a sump pump must be used.

The trash and hydrocarbon water trap in the first chamber must be pumped out and refilled with clean water every 6 months for proper functioning. Every 3 to 5 years, the top filter cloth layer and gravel must be removed and replaced because of fine sediment clogging. Placement of the second chamber manhole directly above the center of the filter allows the corners of the cloth to be peeled up and bound together to form a bag that can be lifted out as a unit.

The District of Columbia Environmental Regulation Administration is conducting a program of monitoring to establish the actual removal rates of this system. As of this writing, no data are available.

The Austin partial sedimentation sand filter may also be placed in underground vaults. Figure 4 shows a modified vault design developed by Alexandria from both Austin and District of Columbia methodologies. The Austin approach uses a gabion wall to separate the partial sedimentation chamber from the filter area. The gabion absorbs energy and provides initial filtration. Heavy sediments are deposited in this first chamber to dry out between storms. The filter is exactly like that used in the DC sand filter system.

Double Trench Sand Filter Systems

Shaver developed a surface sand filter system for use in Delaware (9). The Delaware sand filter is intended to be an in-line facility processing all stormwater exiting the site until it overflows.

R0015913

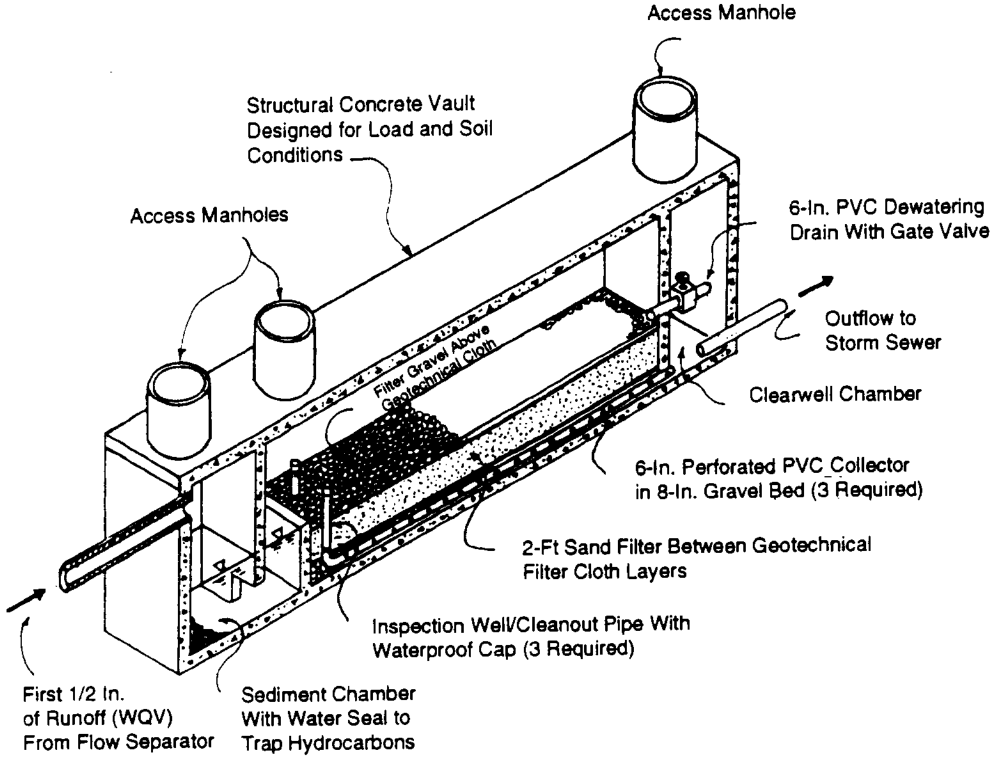

Figure 3. DC underground vault sand filter.

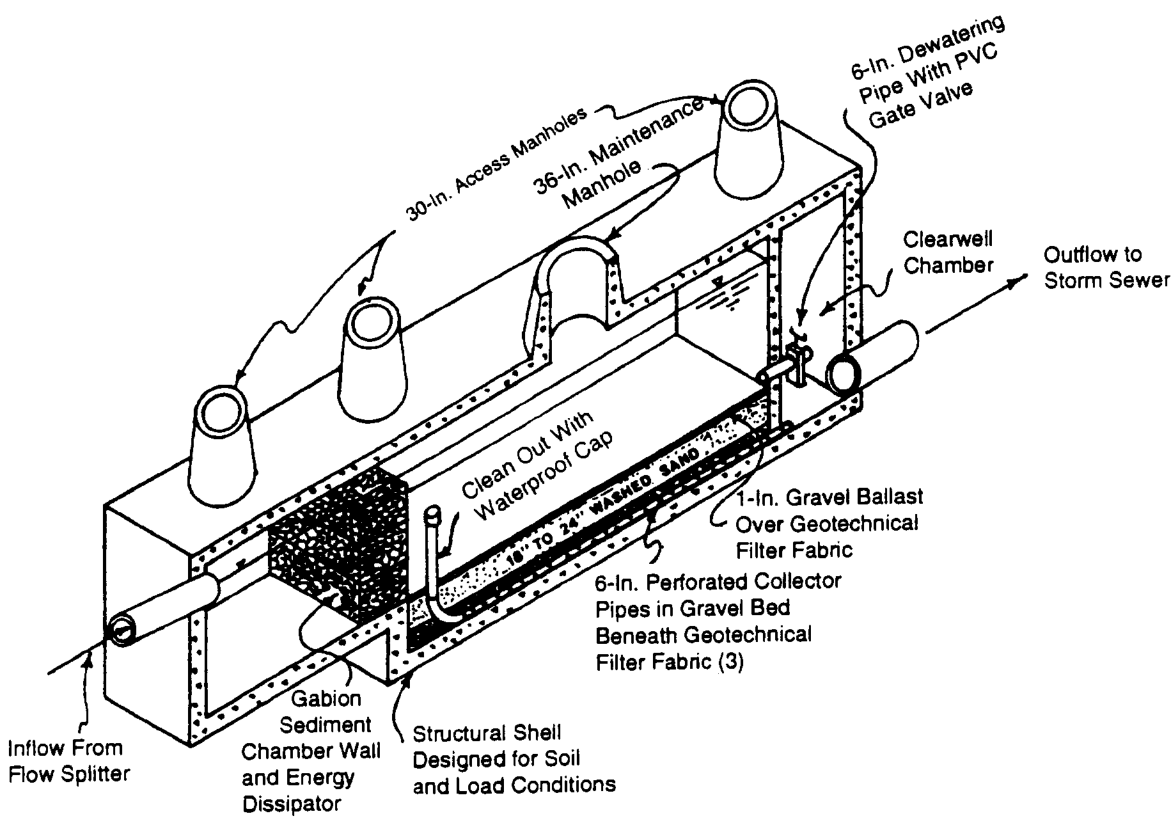

Figure 4. Dry vault stormwater sand filter.

Figure 5 is a schematic drawing of the Delaware sand filter system. The concept uses two parallel waterproof trenches connected by close-spaced wide notches in the top of the wall between them. The trench adjacent to the site being served is the sedimentation chamber. Polluted stormwater must be conveyed to the chamber in enclosed storm-drain pipes. The permanent pool in the sedimentation chamber inhibits resuspension of particles that were deposited in earlier storms and prevents the heavier sediments from being washed into the filter chamber. As new stormwater enters the system, the permanent pool overflows through the weir notches and onto the filter as sheet flow to prevent scouring out the sand.

The second chamber contains an 18-in. sand filter that is always fitted with a solid cover. No underdrain piping is provided. Water percolates through the sand and escapes from the filter through a geotechnical cloth-covered grate at the downhill end of the filter chamber.

Four Delaware sand filters were constructed in Alexandria during 1992. The first two systems served small parking lots and were built according to the original Delaware design. The third application, involving two separate filters, was used to treat runoff from a large (1.7 acre) parking lot. The high cost of steel grates and covers led the developer's consultant to propose moving the filter off the lot and providing slotted curb ingress and precast concrete lids. Premature failure of one of the filters led the owner to install a collector pipe in gravel below the sand layer. This design is shown in Figure 6.

Although the filters illustrated are contained in reinforced concrete shells, these systems may be installed in any waterproof container that will bear the wheel loads or soil pressures involved with the particular application; molded fiberglass or other plastic materials would work well. Delaware sand filters made of timber lined with rubberized roofing material have been proposed for use on temporary parking lots for development sales offices.

Delaware does not rate these systems for nutrient removal efficiency. Delaware has made a determination, however, that when treating the first 1 in. of runoff, this sand filter provides 80-percent suspended solids removal, as required by state environmental regulations (9).

Stone Reservoir Trench Sand Filter Systems

The filter system concepts embodied in the Austin and District of Columbia designs may be readily adapted for small and less complex applications. Alexandria's engineering staff has developed a simple trench sand filter for use on such projects as townhouses or small commercial developments in areas where infiltration devices are not practicable.

Figure 7 is a schematic drawing of a stone reservoir trench sand filter. The system is constructed in an excavation lined with impervious geomembrane (such as EPDM roofing material) sandwiched between protective layers of filter cloth. The bottom of the trench contains a simple sand filter that is connected to the storm sewer. The upper part of the system is built the same as an infiltration trench designed to treat the first 1/2 in. of runoff. Placement of perforated pipes in the stone reservoir greatly increases the voids available for storage.

Dispersed overland sheet flow is treated in a grassed filter strip before entering the system. The reservoir is further protected from sediment clogging by a layer of geotechnical filter cloth 6 in. beneath the top surface of

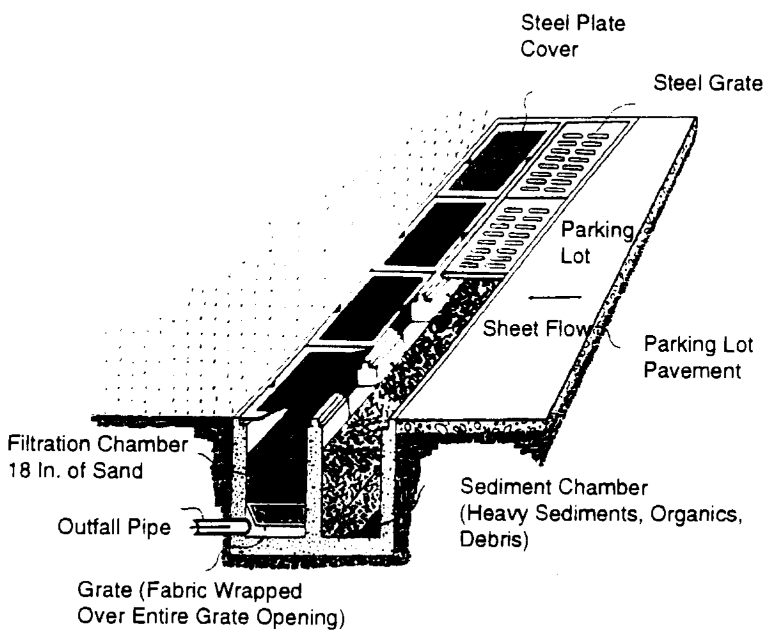

Figure 5. Delaware sand filter with grated inlets.

R0015915

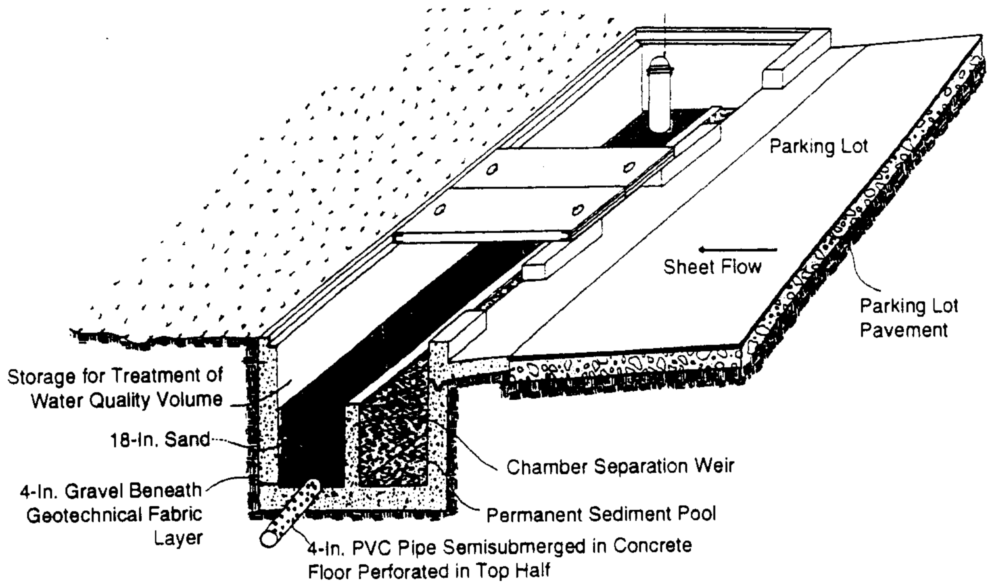

Figure 6. Slotted curb Delaware sand filter.

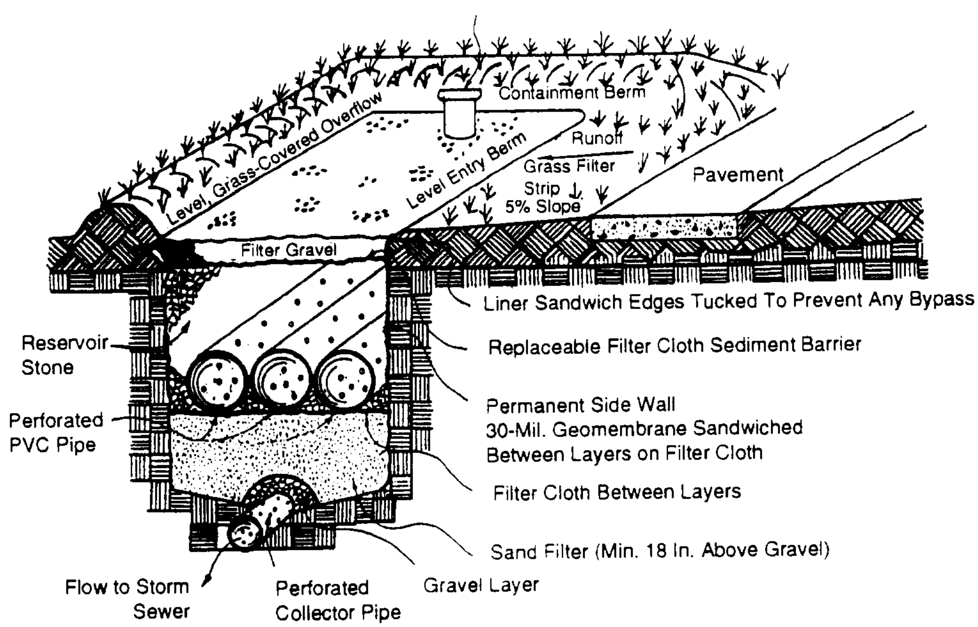

Figure 7. Stone reservoir trench sand filter.

the aggregate. The WQV flows into the reservoir until the voids in the rock and perforated pipes are completely full. Any overflow is directed to the storm sewer. Runoff collected in the reservoir filters down through the sand to the collector pipe, from which it is conveyed to the storm sewer.

Trench sand filter systems should have the same removal efficiency as an Austin sand filter.

Peat-Sand Filter Systems

Because of their high pollutant removal capabilities, simple design, low-maintenance, and affordability, peat-sand filters (PSFs) are potentially effective in heavily urbanized areas. A stormwater "end-of-pipe" PSF system was scheduled to be constructed in Montgomery County, Maryland, in the summer of 1993. MWCOG staff participated heavily in the development of this project.

R0015916

Figure 8 is a centerline cutaway of a stormwater PSF system concept developed by the Alexandria engineering staff. It combines features of the Austin sand filtration system with the PSF design proposed by John Galli of MWCOG for use in the Montgomery County application (10). The Alexandria concept is intended to operate as an off-line system treating the WQV from each storm. Any additional detention required for stormwater quantity restrictions should be provided separately downstream of the PSF system. PSFs would be appropriate for commercial developments for which a high pollutant removal is required or for end-of-pipe treatment of entire storm sewer watersheds.

The sedimentation basin design is essentially the same as that of the Austin sand filter. Because PSF systems cannot normally operate during the more severe winter months of the mid-Atlantic region, however, a gate-valve equipped bypass is provided to divert flow from the basin directly to the storm sewer. The invert of this pipe is placed at an elevation that will detain a permanent pool in the basin averaging at least 4 ft deep. In effect, this configuration converts the sedimentation basin to a small extended detention/wet pond during the winter months. As with the Austin sand filter, the basins may be either walled with concrete, as shown, or, if soil conditions permit, be constructed as soil structures.

The filtration basin is basically the Austin design with the sand filter enhanced by adding a 12- to 18-in. thick surface layer of hemic or fibric peat, a layer of calcitic limestone (for greater phosphorus removal), and a 4-in., 50:50 well-mixed layer of peat and fine-medium grain sand atop the normal filter sand and collector underdrains. A nutrient-removing grass-cover crop must be planted and maintained in the top of the peat layer. (PSFs will not function in underground applications because anaerobic conditions would develop.)

The system shown is designed for gravity flow. In situations where the terrain does not provide sufficient relief, pumps must be added to move the stormwater between basins.

Based on information provided by MWCOG (10), the Alexandria engineering staff estimates that their PSF design should have a phosphorus-removal efficiency approaching 90 percent during the months in which the filter is in operation. Assuming that the filter would be bypassed from mid-December to mid-March in the mid-Atlantic region, the annual phosphorus removal efficiency of the overall system, including the small extended detention/wet pond, is estimated at 70 percent.

Water Quality Volume Storage Tanks

This concept involves the collection and storage for later treatment in the wastewater treatment plant of the WQV from each storm. WQV storage tanks are used on all developments or redevelopments that require a BMP within Alexandria's combined sewer watersheds. Figure 9 shows a centerline cutaway of a WQV storage tank. The stored water is released into the combined or sanitary sewer system by telemetry-controlled pumps or automatic valves that ensure that none of the WQV escapes while combined sewer overflows into streams

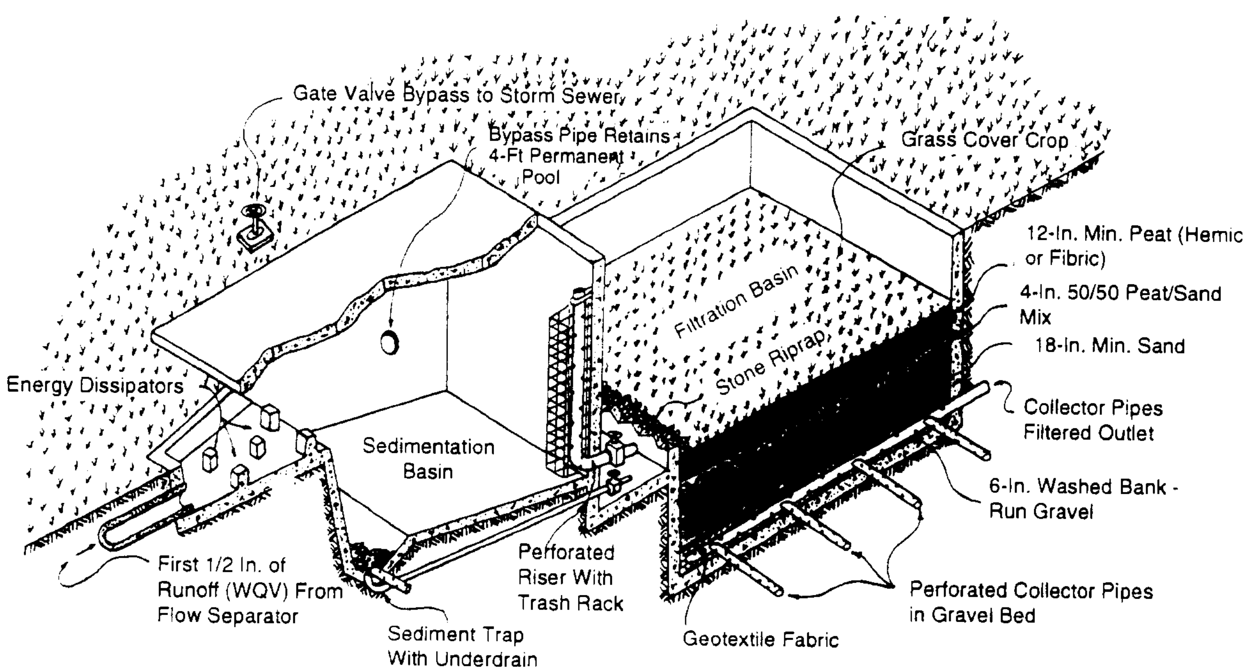

Figure 8. Stormwater peat-sand filter system.

R0015917

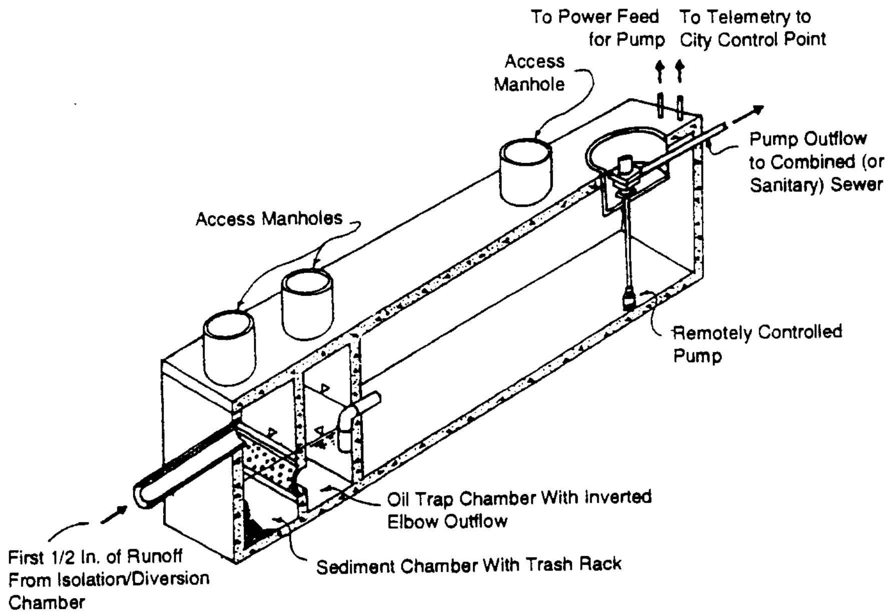

Figure 9. Water quality volume storage tank.

are occurring or in periods when inflow and infiltration are taxing the capacity of the wastewater treatment plant. This approach conforms to EPA's August 19, 1989, National Combined Sewer Overflow Strategy, which requires establishment of a high-flow management plan that maximizes the capacity of the combined sewage system for storage and treatment.

The tank shown in Figure 9 has a water quality inlet to provide sediment and petroleum hydrocarbon removal before the runoff is allowed to enter the storage tank. The inlet must be pumped out and refilled with clean water every 6 months for proper functioning.

WQV storage reservoirs may be either prefabricated tanks or vaults fabricated on site from such materials as Portland cement. Either single or multiple tanks may be employed. Although originally developed for use in combined sewer watersheds, WQV storage tanks may be applied in other situations where WQV runoff will not be routed into the storm sewer (e.g., landscaping irrigation systems or "gray water" toilet flushing systems).

When WQV water is discharged directly into a combined or sanitary sewer or used in gray-water flushing systems, the pollutant removal efficiency of the system becomes that of the receiving wastewater treatment plant. The phosphorus removal capacity of such plants is typically in the 95- to 100-percent range. When the WQV water is reused and retained on site for landscape irrigation, pollutant removal may approach 100 percent if the water is not allowed to escape from the site.

Challenges in Development and Use of BMPs for Heavily Urbanized Areas

The field of BMPs for heavily urbanized areas is in its infancy. The next few years must bring much wider use of this technology if the pollutant removal objectives of the NPDES stormwater program and other federal and state clean water initiatives are to be met. Several significant challenges need to be addressed.

Reduce Construction Effort and Costs

The construction cost for Austin sand filters serving projects with approximately 1 acre of impervious cover ranged from $13,000 to $19,000 in 1990 (1). The cost of DC sand filters was approximately $35,000 per impervious acre when the filters were first introduced but has since fallen to approximately $12,000 to $16,000 through the introduction of precasting and the maturity of the design (11). The large, slotted-curb Delaware sand filters recently constructed in Alexandria cost approximately $40,000 to serve 1.7 acres of impervious cover. This was, in essence, a prototype facility, and costs are expected to fall in a manner similar to the DC sand filter costs as contractors and engineers become familiar with the technology.

Applying prefabrication and modular concepts, especially for smaller projects, should further reduce construction effort and costs. Alexandria and the District of Columbia are exploring the rationalization of sand filter vaults in circular sections with manufacturers of aluminized corrugated pipe and fiberglass underground tanks. The pipe manufacturer has indicated that filters that would serve up to 1 acre of impervious cover could be prefabricated in a shop and delivered as a unit to a job site. The District of Columbia has also developed a sand filter in a standard precast sewer manhole. By introducing the runoff through a large catch basin with a hooded outlet, the addition of a 6-ft manhole with a sand filter in the bottom makes a BMP suitable for treating the runoff from approximately 5,200 ft^2 of impervious cover; 8-ft manhole filters can serve approximately 10,000 ft^2. Alexandria is examining the feasibility of adapting standard large highway precast curb inlets as the shells of both Delaware sand filters and underground vault sand filters. Storage of runoff awaiting filtration in arched corrugated-pipe galleries appears to be a promising approach in areas where storm sewers are too shallow to employ vault filters without pumping. Much more innovation is still needed for heavily urbanized areas.

One of the major costs of BMPs for heavily urbanized areas is creating a container to store the runoff before it undergoes treatment. More studies need to be performed characterizing different types of runoff to determine whether all sites need similar treatment. For instance, pollutants in runoff strictly from roofs may be concentrated in a smaller amount of "first flush." Pollution concentration versus time studies of roof water might well establish that treatment of a smaller amount of runoff would meet pollutant removal performance requirements. This development would likely have a significant impact on costs.

Reduce Maintenance Requirements and Costs

All BMPs for heavily urbanized areas require significant maintenance. Permanent pools require pumping out on a periodic basis (currently twice per year in Alexandria) to remove accumulated sediments and trapped hydrocarbons. As discussed above, sand filters require the replacement of the top few inches of sand or overlying layers of geotechnical cloth every 3 to 5 years. Trash must be removed from all BMPs as it accumulates to prevent premature clogging. Special care must be taken to ensure that sand filter systems are not placed in service before all open areas are stabilized with vegetation. Otherwise, the filters might quickly clog with topsoil, as occurred with one of Alexandria's Delaware sand filters. Trash screens need to be included in all designs to preclude the intrusion of materials into filter chambers that can cause premature failures. The provision of ready maintenance access is an absolute necessity. The initial cost/maintenance cost tradeoff must be carefully examined during the BMP design process.

Enhance Removal of Pollutants

The 1990 Austin report on removal of pollutants by that city's sand filters is the only scientific data available at present on long-term monitoring of such systems (7). The reported results are encouraging, but more monitoring data is needed to assess the impact of such factors as acid rain and variations in chemical content of the filter media on performance before the Austin experience can be generalized for application to other regions of the country.

While Austin reports very promising phosphorus removal values, enhancing the nitrogen and perhaps the heavy-metal removal efficiencies of BMPs may develop as a more pressing need as NPDES runoff monitoring data become available. One avenue that appears promising is the employment of a wet gravel filter component to introduce biological activity in the treatment process, an approach that is already being used to treat individual home sewage in Anne Arundel County, Maryland (12). The District of Columbia is considering adding a layer of activated carbon to a sand filter to assess the benefits through monitoring. BMPs for heavily urbanized areas represent a field that is ripe for additional innovation. Universities should take a more active role in developing BMP technologies for these areas.

Spread the Technology

Currently, the use of BMPs for heavily urbanized areas is limited to a relatively small area in the mid-Atlantic states, the Austin area in Texas, and the state of Florida. The technology is applicable to all areas of the country where pollution in stormwater runoff must be controlled under the NPDES permit program. Information on these BMPs needs to be disseminated throughout the country by EPA and other environmental agencies so that the technology is available to all parties who are wrestling with the problems of attaining NPDES compliance. This paper was written to facilitate that process.

Postconstruction Responsibilities for Effective Performance of Best Management Practices

Joseph J. Skupien
Somerset County Engineering Department, Somerville, New Jersey

Abstract

Effective performance of best management practices (BMPs) is vital to achieving the high goals and justifying the equally high estimated costs of urban runoff management. This paper identifies inspection, maintenance, and performance monitoring as three key postconstruction activities for ensuring correct and continued performance of BMPs. These activities are equal in importance to planning, design, and construction BMPs.

The paper demonstrates how failure to meet inspection and maintenance BMP responsibilities not only leads to diminished BMP performance but may also create new health and safety threats that exceed those the BMPs were intended to prevent. It further demonstrates how such a result represents both a failure to realize a gain on the resources already invested in BMPs and the cause of significant additional expenditures.

The paper also describes the key components of a successful postconstruction inspection and maintenance program, including the need for self-evaluation and feedback components to inform planners, designers, construction contractors, and maintenance personnel about ways to reduce or facilitate future maintenance. Additionally, the paper emphasizes the importance of a stable source of program funding and discusses various methods for achieving it.

Finally, the paper emphasizes the need for accurate, scientific monitoring and reporting of BMP performance to achieve optimal BMP designs and expand the ability to address urban runoff impacts on a regional or watershed basis.

Introduction

One of the top priorities of any stormwater management program is the effective performance of structural best management practices (BMPs). Effective BMP performance not only helps ensure that the program's goals are accomplished but also represents a positive return on the time, effort, and materials invested in the structural BMP's planning, design, and construction. To achieve such performance, however, everyone involved with the stormwater management program must fulfill several key responsibilities before, during, and after construction.

Before construction, these responsibilities include the development by program managers of design standards and practices that are both accurate and practical. Designers must use these standards and practices to produce construction drawings that accurately convert their ideas into a tangible structure. Using these drawings, construction contractors must create a durable structure that meets the designers' requirements and is true to the regulators' intentions.

While stormwater management remains a relatively new field, the results to date of these relatively short-term preconstruction activities have been greatly improved by several factors, including the maturation of older flood control programs; the continued growth of hydrologic and hydraulic databases, design methods, and training programs; and the implementation of formal construction inspection programs. Other factors that have assisted in the improvement of regulatory, design, and construction activities include the continued development and greater availability of computer software and hardware and the greater level of construction experience and capability. As a result, the ability of program managers, designers, and construction contractors to meet their responsibilities for effective BMP performance has increased significantly in recent years. Furthermore, these improvements have helped to kindle further interest and involvement in stormwater management.

In addition to planning, design, and construction responsibilities, however, three key areas of responsibility must be met once construction has been completed and the structural BMP has been put into operation. These responsibilities consist of the inspection, maintenance, and monitoring of the structural BMP. For the purposes of this paper, these three activities are defined briefly as follows:

- *Inspection:* Periodic observation and evaluation of a structural BMP and its individual components by qualified personnel to determine maintenance needs.
- *Maintenance:* Periodic preventative and corrective measures taken by qualified personnel to ensure safe, effective, and reliable BMP performance.
- *Monitoring:* Extended observation and evaluation of BMP performance by qualified personnel to determine effectiveness and improvement needs.

Of the three activities, inspection and maintenance are the most well established in terms of BMPs, while monitoring represents a somewhat more recent aspect of stormwater management. More complete descriptions of each activity and their growing importance is presented in later sections of this paper. For now, it is important to note that each activity represents a long-term, ongoing responsibility carried out after the shorter term planning, design, and construction efforts have been completed. It is also important to note that BMPs for inspection, maintenance, and monitoring have not received the same level of attention typically devoted to planning, design, and construction. While lack of adequate funding may be a cause, the reasons for this imbalance are generally unclear. This is unfortunate, because such an imbalance may critically affect the long-term success of stormwater management programs and regulations. Possible reasons include the ongoing, long-term, and somewhat routine nature of inspection and maintenance in particular, which may not offer either the intellectual and creative challenge of planning and design or the immediacy of construction. Additional reasons may be an unacknowledged reluctance to confront the reality of current planning, design, and regulatory efforts (particularly the negative aspects of that reality), or the failure to fully appreciate the importance of BMPs in regard to inspection, maintenance, and monitoring and the serious consequences of their prolonged neglect.

Regardless of the reasons, it is apparent that BMPs for inspection, maintenance, and monitoring have suffered the neglect typical of long-term, ongoing activities. As noted above, this neglect has critical implications for the long-term success of efforts to manage stormwater, particularly through the use of structural BMPs. In an effort to correct this problem, this paper presents information emphasizing the importance of and need for BMPs in inspection and maintenance and describes the key components of a comprehensive inspection and maintenance program. Additionally, the paper highlights the increasing need for monitoring as a means to improve BMP performance and effectiveness and to reduce required inspection and maintenance efforts.

The Importance of BMP Inspection and Maintenance

A common requirement of virtually all stormwater structures, particularly those that encounter various weather conditions, is their need for periodic inspection and maintenance. While these needs may be obvious in a general sense, the particular importance of inspection and maintenance for structural BMPs needs to be stressed.

Perhaps the most recognizable reason is the need to reliably and consistently achieve the performance levels required by the stormwater management program and designed into the BMP. For example, a BMP that relies on the temporary storage of stormwater runoff to achieve required peak outflow or pollutant removal rates must be periodically cleaned of accumulated sediment and debris to maintain required storage capacity and prevent re-suspension of captured pollutants. The outlet structures at these facilities must also be periodically cleared of accumulated debris to maintain discharge rates at required levels. Maintenance of vegetation is also important, particularly for those BMPs that use the vegetation for pollutant filtration and/or uptake. This maintenance can range from mowing, seeding, and fertilizing turf grass areas to ensure stability and prevent erosion to harvesting wetland vegetation to promote and manage growth.

The maintenance described can also be viewed as an effective means of ensuring a positive return on the time, effort, and materials invested in the planning, design, and construction of a BMP. The total amount of this investment for a single BMP can be considerable, with total construction costs exceeding $50,000 and total project costs exceeding $100,000. Failure to adequately inspect and/or maintain such a facility can lead to ineffective performance, structural failure, and, consequently, a failure to realize a return on the investment. It is generally recognized that the cost of providing comprehensive water quality protection may be considerably greater than our present ability to pay for it. In such cases, we must strive to achieve the greatest possible return on the resources we do invest in such protection.

Perhaps the most important need for BMP inspection and maintenance is the need to avoid the health and safety threats inherent in their neglect. The foremost of these threats is the potential for structural failure, which can rapidly release stored waters and flood downstream areas, causing property damage, injury, and even death. The fact that this flooding threat would not exist if the BMP had not been constructed further highlights the need for proper inspection and maintenance to prevent it from ever occurring. Another health and safety threat from maintenance neglect is mosquito breeding, which can threaten a broad area in the general vicinity of the BMP. Other undesirable insects, animals, and odors can also result from maintenance neglect, adversely affecting those who must live or work nearby. In all such cases, the BMP can actually have worse environmental impacts than those it was originally constructed to prevent.

A final reason for effective BMP inspection and maintenance lies in preserving and nurturing the community and political support that stormwater management efforts have gained to date. Such continued support is vital to the success of our stormwater management efforts, particularly because much of the solution to stormwater pollution lies in source controls and lifestyle changes that the public will be asked to adopt. We cannot count on even passive public support, however, let alone active public involvement in nonstructural programs, if we are unable to create and maintain structural BMPs that are community assets rather than liabilities. Any support that we now have or hope to generate in the future will quickly be lost if we allow structural BMPs to become aesthetic nuisances or safety hazards due to a lack of adequate inspection and maintenance.

Comprehensive Inspection and Maintenance: An Overview

The key components of a comprehensive inspection and maintenance program for structural BMPs are described below. The exact character of each component and the manner in which it is implemented depends on the specific economic, political, environmental, and social characteristics of the community in which the program functions.

Official Inclusion of Inspection and Maintenance in Overall Stormwater Management Program

BMP inspection and maintenance should not be an afterthought but should be included from the beginning in the community's overall stormwater management program. As the overall program develops, determining how (and how often) inspections and maintenance efforts are performed is as important as determining allowable peak outflow rates and extended detention times. To ignore this fact is to invite eventual program failure through diminishing BMP performance and increasing health and safety threats. To ensure a secure role for inspection and maintenance in the overall stormwater management program, both the importance of inspection and maintenance and the ways in which they are achieved should be officially included in any implementing ordinances, resolutions, or laws establishing the overall program.

Sufficient and Stable Funding

Because BMP inspection and maintenance requires specific actions by qualified personnel, the availability of sufficient and stable funding may be the single most important component of a comprehensive program. The best intentions, talent, and equipment cannot overcome a paucity of funds, nor can regular, consistent inspections and maintenance be achieved if funding levels are erratic and/or uncertain.

Therefore, during the development of the overall stormwater management program, a stable source of funding for inspection and maintenance must be identified and formalized. This may include the use of general or specialized tax revenues, dedicated contributions from land developers or owners, and/or permit fees from those creating the need for the structural BMP. Funding may also be secured through the creation of a stormwater utility, which would provide BMP inspection and maintenance services funded by fees paid by those within the utility's service area. While the creation of a stormwater utility requires a significant amount of effort to organize and operate, several successful stormwater utilities have been created throughout the country in recent years.

Adequate Equipment and Materials

Having sufficient equipment and materials is particularly important for BMP maintenance efforts, which involve the regular performance of preventative maintenance activities such as grass mowing and debris removal and the prompt execution of emergency repairs and restorations. The long-term, repetitive nature of the preventative activities, in particular, demonstrates how a positive return can be quickly achieved from investments in equipment that expedite maintenance efforts and in materials that prolong the life of BMP components.

Fortunately, due in part to the basic nature of stormwater and its management, the character of the equipment necessary to conduct most maintenance efforts is not particularly complex or specialized. Instead, standard and relatively simple equipment such as lawn mowers, shovels, rakes, compressors, and trimmers can be used to perform the majority of maintenance tasks. This helps simplify the selection and acquisition process and keeps costs at more manageable levels.

Trained and Motivated Staff

Similar to equipment needs, many BMP maintenance tasks are not particularly complex or specialized. This means that, under most circumstances, program staff can be assembled from a relatively large labor pool, either directly by a public agency performing maintenance in house or by a contractor hired to provide such services. These factors, however, should not diminish the need for thorough training of maintenance staff. This has become increasingly true in recent years as the role of structural BMPs expands to provide higher levels of stormwater treatment and more comprehensive control of runoff rates. This has led to increasingly sophisticated facilities containing specialized vegetation and diverse habitats that require management as well as maintenance. This trend is expected to continue, further emphasizing the need for thoroughly trained staff.

The importance of motivation and enthusiasm must also be emphasized. Unfortunately, the repetitive and relatively simple nature of many BMP maintenance tasks can lead to indifferent staff performance. In addition to poor overall results, this indifferent attitude can also be dangerous, particularly for those staff members operating mowing or cutting equipment that, however simple, demands concentration and care. Indifference and a lack of enthusiasm can also stifle creativity, which is essential if improved and/or less costly maintenance techniques are to be honed from existing ones. Finally, experience has shown that the vegetated, "living" character of most structural BMPs requires a certain interest and concern on the part of maintenance staff (qualities that are evident in most successful gardeners) if proper maintenance, performance, and aesthetic levels are to be achieved.

Therefore, it is essential for maintenance staff to have an interest in the overall success of the BMP. One way that this may be accomplished is by having the long-term maintenance of a given BMP performed by the same maintenance crew, which then becomes the sole group responsible for its success or failure. Such "ownership" of the BMP helps promote more direct interest in its condition and a greater effort to maintain it.

In addition, competent BMP inspection, particularly of larger, more complex structures and dams, requires a high degree of skill, experience, and knowledge. Often, such levels require that some of the inspections be conducted by a licensed professional engineer who has a background in geotechnical and structural engineering. Other necessary skills may include biology or plant sciences, particularly if the BMP includes diverse vegetation and habitats. Obviously, the training required for such inspection personnel is more rigorous and the number of qualified personnel available to the program will be less. Finally, the training provided to maintenance workers should, in part, be directed at making them informal inspectors as well. When maintenance workers are trained and motivated to spot and report such problems as sloughing or settling of embankments, surface erosion, animal burrows, and structural cracks, repairs can be performed more promptly and with less expense and effort.

Regular Performance of Routine Maintenance Tasks

The essence or core of any facility maintenance program is the regular, consistent performance of the actual maintenance tasks that the remainder of the program has identified, planned, and scheduled, and for which staff, equipment, and funding have been provided. The competent and consistent performance of these routine tasks is the single greatest factor in determining the success of the overall BMP inspection and maintenance program. These routine tasks normally include grass mowing and trimming, trash and debris removal, soil fertilization, and sediment removal. Experience has shown that the regular, frequent (e.g., monthly or less) performance of these tasks often requires less overall time and effort on an annual basis than if the tasks are performed only a few times a year.

In addition, a flexible and informed definition of "regular" should be adopted when scheduling routine maintenance tasks. For example, while it will be easier to schedule maintenance at a given BMP for the first week of every month, the actual performance of the work should instead be based on weather conditions and maintenance need. This is particularly true of turf grass, which may be damaged by a regularly scheduled mowing during dry or drought conditions. During wet conditions, attempts to perform maintenance tasks may result in rutting and other ground disturbances, causing more facility damage. The ability to perform "regular" maintenance tasks on a somewhat "irregular" basis is one of the greatest challenges of a comprehensive inspection and maintenance program.

Timely Performance of Emergency Maintenance Tasks

Despite the best efforts of any inspection and maintenance program, emergency maintenance measures may be necessary at a structural BMP from time to time for a variety of causes, ranging from excessive rainfall to vandalism. As a result, the successful inspection and maintenance program must be ready to respond to this need in a timely and comprehensive manner. To do so, it is best to plan ahead for emergencies by developing an emergency response plan that identifies potential emergency problems and ways to address them. This may include the preparation of a list of typical repair materials, which then can be either stockpiled in house or quickly acquired through designated suppliers. The plan may also identify individuals and organizations that can provide technical input or services on short notice to assist in the emergency repair effort. Finally, a designated number of staff personnel should be available on a 24-hour basis to respond to maintenance emergencies.

Regular, Competent Inspections

One of the keys to program efficiency and overall BMP safety is the performance of competent BMP inspection on a regular basis. In view of the increasingly complex nature of structural BMPs and the wide range of technical aspects inherent in each, the need for competent inspectors should be obvious. In fact, a team of inspectors may be necessary to adequately review the geotechnical, environmental performance, structural, hydraulic, and biological aspects of many BMPs. Inspections must be performed on a regular basis to identify problems and special maintenance needs quickly and efficiently. This allows repairs to be performed promptly without the need for major remedial or emergency action.

The frequency of inspections varies with the size and complexity of a given BMP. Regular inspections by qualified personnel may range from once a year for large facilities with high damage potential to every 2 to 5 years for smaller, less complex sites. Additional inspections should also be performed as appropriate following major rain storms and other extreme climatological events such as droughts, extreme snowfalls, or high winds. It should also be noted that the growing complexity and technical range of structural BMPs is expected to require more frequent inspections covering a wider range of BMP features.

Finally, the formal inspections described above should be supplemented by informal inspections conducted by maintenance personnel during each of their site visits. This further enhances the program's ability to quickly identify and respond to special maintenance needs before they can become costly emergencies. As noted above, such informal inspections require further training of maintenance personnel.

Performance Guarantees and Defaults

In many BMP inspection and maintenance programs, the owners of the property on which the BMP is located are responsible for performing maintenance tasks. Such properties may range from single-family residences to major industrial or commercial complexes. Under such conditions, the governmental agency responsible for the overall success of the program must obtain some form of guarantee that the maintenance will in fact be performed. This guarantee is acquired through several steps. First, the property owner's responsibilities should be specified in a written agreement between the owner and the agency. This agreement should also grant the agency the right to enter the property and inspect the BMP to ensure that the stipulated maintenance is, in fact, being performed satisfactorily. In addition, the agreement should also provide a method by which the agency can perform both emergency and regular maintenance tasks in the event of default by the owner, including a provision to charge the owner for the cost. Finally, such an agreement should be binding on all future owners of the property to ensure continuity.

Accurate Recordkeeping

In view of the large number of tasks, equipment, and materials that may be involved in a comprehensive BMP inspection and maintenance program, accurate records of the maintenance effort should be kept. This includes logs of time and manpower, records of material quantities and costs, and the type and frequency of the various maintenance tasks performed. In addition, accurate records should also be kept of any complaints received from community residents regarding the adequacy and/or frequency of the various maintenance tasks as well as all reports of potentially hazardous conditions. The time and expense of such recordkeeping, including the need for staff training in the proper procedures, can be quickly offset if the recorded information is used to improve scheduling, task performance, and purchasing practices. Additional details of such use is described below.

Productive Self-Evaluation and Interaction

To achieve improved levels of efficiency, a BMP inspection and maintenance program should conduct regular reviews and self-evaluations. The availability of thorough program records is of great assistance in this effort. The program review should include input from all program personnel and should address such aspects as maintenance frequency, the sequence of facility visits, equipment suitability, staffing levels, and training needs. In addition, establishing a positive dialogue with stormwater regulators, designers, and contractors is highly desirable because all of these people are responsible for creating the structural BMPs that the inspection and maintenance program must ultimately (and forever) maintain. Studies and experience have shown that many of the problems encountered during BMP maintenance are actually the result of poor or misinformed regulations, designs, or construction efforts. Therefore, maintenance personnel need to identify such problems and be given a means to inform those responsible. Such interaction can be achieved through conferences and meetings with professional societies, industry groups, and governmental agencies and departments. Public input should also be sought through individual contacts (using the complaint records noted above) and community meetings.

The Growing Need for BMP Performance Monitoring

More than just grass mowing, BMP inspection and maintenance represent a broad range of integrated technical activities. In fact, this can also be said for the entire field of modern stormwater management, which requires technical interaction between regulators, designers, contractors, maintenance personnel, and the public to truly achieve the goal of comprehensive runoff management. Unfortunately, due to the random and, at times, unpredictable behavior of storm events and the inherent complexity of the rainfall-runoff process, it is often difficult to determine how well our runoff goals are being met, regardless of the proficiency of design, construction, and maintenance efforts. For this reason, BMP performance monitoring should also be included in any stormwater management program.

By closely and accurately monitoring BMP performance through field monitoring, sampling, and laboratory analysis, BMP monitoring can enable us to better define the "problem" of runoff pollution and allow regulators and designers to gain a better understanding of both BMP function and performance. This information can be used more conclusively to identify those runoff goals and management functions that either can or cannot be realistically achieved by structural BMPs. This will further allow regulators and designers to improve those functions that are viable and to develop alternatives to those that are not, both through enhanced design standards and techniques and updated regulations. BMP performance monitoring can also provide information regarding construction and maintenance practices that may have an effect on facility performance, which can in turn lead to improved or new practices or equipment.

In overview, BMP performance monitoring can be seen as a means of achieving greater return on the time, materials, and property invested now and in the future in our stormwater management programs. And because these amounts are expected to grow considerably as we expand our programs to address more complex stormwater problems, the importance of such improved returns will certainly increase.

In addition, BMP performance monitoring can also be seen as a way to help ensure overall program credibility and achieve stronger community acceptance. In recent years, much attention has focused on the need to expand traditional stormwater management programs beyond structural measures to also include nonstructural measures in order to achieve more comprehensive results. To do so, we must achieve greater community involvement in our stormwater management efforts, both through lifestyle changes (involving a wide scope of activities, from pet care to car washing to home landscaping) and through participation in various nonstructural stormwater programs (ranging from household waste disposal to carpooling to resource preservation). With the real data obtained through BMP performance monitoring, it will be easier to convince the community of both the need for and the promise of stormwater management.

Such data will also lend greater credibility to our concerns over runoff pollution and will enable us to credibly demonstrate the value of both structural and nonstructural measures. Such credibility is vital if we are to expect the public to make the changes and sacrifices demanded by both the structural and nonstructural BMPs we now have or hope to implement in their communities (and even their backyards) in the future. Finally, BMP performance monitoring will help us to more closely monitor our progress and more quickly identify program problems and shortcomings. This will help us to develop and implement program modifications and improvements in a manner that will not threaten community acceptance. As noted earlier, we will not be able to rely on public support for nor participation in vital nonstructural stormwater programs if we are unable to create and maintain aesthetically pleasing structural BMPs. We can also expect similar results if we discover that those same BMPs simply do not work.

Summary

- To achieve comprehensive success in our stormwater management efforts, it is vital that inspection, maintenance, and monitoring be considered as equal in importance to structural BMP planning, design, and maintenance.
- The neglect of BMP inspection and maintenance can actually result in worse environmental impacts to a community than the ones that the BMP was intended to prevent. This result can threaten the viability of the entire stormwater management program.
- BMP inspection and maintenance must be an official component of a comprehensive stormwater management program, with adequate staffing, equipment, and funds.
- Self-evaluation and interaction with regulators, designers, constructors, and members of the community are vital to reducing overall maintenance needs, efforts, and costs.
- BMP performance monitoring is increasingly important to the continued effectiveness and growth of stormwater management programs.

Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters

Rod Frederick
Office of Water, U.S. Environmental Protection Agency, Washington, DC

Abstract

This paper describes the technology-based management measures developed under Section 6217(g) of the Coastal Zone Act Reauthorization Amendments to control sources of nonpoint pollution in the coastal zone. The implementation of state coastal nonpoint source control programs, including the development of enforceable policies and mechanisms, is the subject of other papers. The management measures, and the various practices that can be implemented cost-effectively to achieve conformity with the management measures, are the subjects of this paper. The U.S. Environmental Protection Agency document *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters* (1) contains most technical information available on the effectiveness of practices to control nonpoint source pollutants and the costs of these practices. Nonpoint sources addressed in the document include agriculture, forestry, urban areas, marinas, and hydromodification (dams, shorelines, and channels). Practices include nonstructural methods such as planning, pollution prevention, and source reduction alternatives in addition to structural methods such as detention ponds and composting facilities. A separate chapter of the document contains information on the protection and restoration of wetlands with nonpoint source pollution abatement functions and the use of vegetated treatment systems in nonpoint source control programs.

Introduction

Section 6217 of the Coastal Zone Reauthorization Amendments of 1990 (CZARA) requires the development of coastal nonpoint source (NPS) control programs to protect and restore coastal waters. States with coastal zone management plans that the National Oceanic and Atmospheric Administration (NOAA) has already approved will develop the new NPS control programs by implementing management measures found in the U.S. Environmental Protection Agency (EPA) document *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters* (1). The development process, including determination of program content, use of alternative management measures, and development of additional management measures to meet water quality standards, is described in a separate document (2) and is the subject of other papers. This paper focuses on the development of the management measures and their basis—the structural and nonstructural practices that can be used to cost-effectively control NPS pollution and achieve conformity with the management measures. The value of the management measures guidance as a comprehensive technical reference should not be underestimated because it was developed as guidance for coastal state programs; the management measures guidance contains detailed information on the cost and effectiveness of a wide variety of methodologies and technologies that have proven effective in controlling nonpoint sources of pollution in both coastal and noncoastal areas.

Legislative Background

Congress enacted CZARA on November 5, 1990. A major focus of this law is the control of NPS pollution to avoid impacts on coastal waters. Congress showed concern in section 6202(a) that growing populations in the coastal zone are endangering wetlands and marine resources. Section 6217 addresses this concern by requiring that each state with an approved coastal zone management program develop a coastal NPS control program and submit it to NOAA and EPA for approval. The purpose of the coastal NPS control program is to develop and implement management measures for NPS pollution to restore and protect coastal waters, working closely with other state and local agencies. Simply stated, EPA develops the management measures and publishes them as guidance, and the states develop and implement programs in conformity with the management measures and program guidance.

Section 6217(g) of CZARA defines management measures as the best available controls that can be economically achieved to reduce pollutants from existing and new categories and classes of NPS pollution. The charge is clearly to develop technology-based controls to reduce pollution from nonpoint sources. In addition, Section 6217(b) of CZARA requires the implementation of additional water-quality-based management measures to protect impaired and critical coastal areas if implementation of the measures developed under Section 6217(g) is not effective at improving water quality.

Guidance Development

To develop the guidance, EPA formed work groups composed of more than 250 people recognized as knowledgeable in the control of NPS pollution. The work groups corresponded to the six technical chapters of the management measures guidance and were cochaired by EPA staff and a combination of staff from NOAA, the U.S. Department of Agriculture (USDA) and the U.S. Forest Service. Other work group members included staff from state agencies, interstate agencies, research agencies, universities, and other federal agencies including the Bureau of Land Management, Fish and Wildlife Service, Army Corps of Engineers, Federal Highway Administration, National Park Service, and Geological Survey.

Work group members provided references, literature reviews, and advice as EPA worked with its own contractors and experts to pull together, analyze, and summarize information on management practices and their effectiveness. EPA released the proposed management measures guidance in May 1991. EPA and NOAA also published a proposed program implementation guidance in October 1991.

Input on the proposed management measures guidance was solicited from the public during a 7-month comment period. The major problems identified in the public comments on the technical chapters were a lack of cost information and a perceived "East Coast bias" in the practices identified. There were, however, many positive comments on the usefulness of the guidance as a compendium of structural and nonstructural control alternatives for NPS pollution in all areas of the country.

The final management measures guidance was released in January 1993. That document incorporated most suggested improvements and additional information received from the public comments, as well as 1) a more thorough literature review; 2) additional focus on regional differences in climate, weather, and geomorphology; 3) additional cost information; and 4) information on economic achievability. The final management measures guidance is more than twice the size of the May 1991 proposed guidance and, hopefully, twice as useful. There are more alternative practices, better descriptions, additional source reduction and pollution prevention programs, and examples of successful implementation of cost-effective practices under a variety of site conditions. Based on the favorable response to date on the final management measures guidance, the guidance is a valuable technical reference for identifying NPS problems and cost-effective solutions.

Description of the Final Management Measures Guidance

Problem Identification

Each chapter contains a discussion of NPS pollutants and problems as a rationale for the management measures and controls to be implemented as part of state coastal NPS control programs.

Agricultural Runoff

Coastal waters are affected by NPS pollution resulting from the erosion of crop land; from the manure and other wastes produced in confined animal facilities; from the application of nutrients, pesticides, and irrigation water to crop land; and from physical disturbances caused by livestock and equipment, particularly in and along streambanks.

Urban Runoff

Urbanization in the form of new development changes the natural hydrology of an area and increases runoff volumes, erosion, sediment loadings to surface waters, and loadings of sediment, nutrients, oxygen-demanding substances, pathogens, metals, hydrocarbons, and other pollutants. These changes and increases can impair water quality, alter habitats, close and destroy fisheries and shellfish beds, and close recreational areas such as beaches. Decreases in base flows caused by impervious areas can also adversely alter habitat and impair water quality. Existing urban activities such as the use of onsite disposal systems, improper disposal of household wastes, turf and lawn management, pets wastes, and road maintenance can also cause water quality problems.

Silvicultural (Forestry) Operations

Forestry operations can degrade water quality in water bodies receiving drainage from forest lands. Sediment concentrations can increase because of accelerated erosion; water temperatures can increase because of removal of the overstory riparian shade; slash and other debris can deplete dissolved oxygen; and organic and inorganic chemical concentrations can increase due to harvesting and the use of fertilizers and pesticides. Increased stream flow can also result from the removal of trees and vegetation.

Marinas and Recreational Boating

Because marinas are located at the water's edge, a variety of nonpoint effects are associated with poor flushing of boat basins, spills from refueling areas, bilge pumping, and wastes produced by the cleaning and repair of boats.

Hydromodification

Hydromodification activities have been separated into three categories:

- *Channelization and channel modification* frequently diminish the suitability of instream and streamside habitat for fish and wildlife, and alter instream patterns of water temperature and sediment transport. Hardening of banks, in particular, can increase the speed of movement of NPS pollutants from the upper reaches of watersheds into coastal waters.
- *Dams* can affect the hydraulic regime, the quality of surface waters, and the suitability of instream and streamside habitat for fish and wildlife.
- *Shoreline and streambank erosion* is a natural process that can have either beneficial or adverse impacts on surface water quality and on the creation and maintenance of coastal habitat. Eroded shoreline sediments help maintain beaches and replenish the substrate in tidal flats and wetlands. Excessively high sediment loads, however, can smother submerged aquatic vegetation, cover shellfish beds, fill in riffle pools, and contribute to increased levels of turbidity and nutrients.

Wetlands and Vegetated Treatment Systems

Wetlands and riparian areas reduce NPS pollution by filtering pollutants—especially sediment, nitrogen, and phosphorus—from surface waters. Wetlands and riparian areas can also attenuate flows from higher-than-average storm events, thereby protecting receiving waters from peak flow hydraulic impacts such as channel scour, streambank erosion, and fluctuations in temperature. Degraded wetlands lose this important set of NPS control functions. Also, degradation of wetlands and riparian areas can cause these areas to become sources of nonpoint pollution because they will then deliver increased amounts of sediment, nutrients, and other pollutants to adjoining water bodies.

Management Measures and Practices

The management measures are major subheadings within each chapter. The coastal NPS control programs that states are to develop must be in conformity with these measures. An applicability section for each measure contains information on the activities and locations to which each measure applies. A description section is included for each measure to illustrate goals and objectives and provide more detail on what the measures mean. The selection section provides the rationale used in selecting the management measure. Usually, selection is based on widespread use of a management practice or combination of practices that can be used to achieve the management measure. The economic achievability of the management measures was evaluated separately (3). If this evaluation affected the selection of a measure, the effect is described in the selection section.

Management practices are described in a separate section under each management measure for illustrative purposes. State programs do not have to specify or require the implementation of any of these management practices. EPA does expect, however, that one or a combination of these practices appropriate to local conditions can be used to achieve conformity with the management measures. For example, the management measure for runoff from new development calls for 80 percent reduction in the average annual total suspended solid (TSS) loadings. Several management practices such as sand filters or extended detention wet ponds can be used to achieve the required TSS removal. If local conditions are not appropriate for one of those practices, however, a combination of vegetated filter strips, grass swales, wet ponds, or constructed wetlands could also be used to achieve the measure. The costs and effectiveness of the management practices are usually included within the description of each practice or in a separate summary section at the end of each management measure chapter. An economic impacts study (3) was prepared based on representative practices and combinations of practices and their costs.

Management Measures by Chapter

Presented below are brief synopses of the major management measures presented in each of the technical chapters. The discussion below is not comprehensive, and the management measures guidance should be consulted to establish the exact requirements and applicability of the management measures.

Agriculture

- *Sediment and erosion control:* Rely on USDA's conservation management system to promote practices such as conservation tillage and strip-cropping.
- *Animal facilities (large units):* Contain runoff and animal waste in storage structures.
- *Animal facilities (small units):* Use less-stringent requirements for economic reasons.
- *Nutrient management:* Develop and implement comprehensive nutrient management plans that involve fertilizer application rates, timing, and use efficiency.

- *Pesticide management:* Evaluate the problem and site, use integrated pest management (IPM) where possible, and apply pesticides properly and safely.
- *Livestock grazing:* Protect sensitive areas through appropriate grazing management techniques (e.g., providing alternative water, salt, and shade sources away from sensitive areas and providing livestock crossing areas).
- *Irrigation:* Optimize water use and use chemigation safely.

Forestry

- *Preharvest planning:* Consider the timing, location, and design of harvest activities.
- *Streamside management areas (SMAs):* Establish SMAs to protect against soil disturbance and delivery of sediment and nutrients from upslope activities; retain canopy species to moderate water temperature.
- *Road construction/reconstruction and road management:* Reduce the generation and delivery of sediment.
- *Timber harvesting:* Protect waters during harvesting, yarding, and hauling.
- *Site preparation and forest regeneration:* Confine onsite potential NPS pollution and erosion resulting from these activities.
- *Management of fire, chemicals, and forested wetland areas:* Reduce NPS pollution of surface waters.
- *Revegetation of disturbed areas:* Prevent sedimentation from harvest units or road systems.

Urban

- *Runoff control for new development:* Reduce runoff levels of TSS by 80 percent, and maintain natural hydrology.
- *Watershed protection/site development:* Use comprehensive planning to protect areas that are ecologically sensitive, provide water quality benefits, or are prone to erosion.
- *Construction erosion/sediment and chemical control:* Reduce construction-related erosion, retain sediment onsite, and properly manage chemical use.
- *Runoff management for existing development:* Identify and implement runoff quality controls as appropriate and feasible.
- *New and operating onsite disposal systems (OSDSs):* Select, site, and operate OSDSs to reduce OSDS impacts on coastal waters.
- *Pollution prevention for urban areas:* Target and implement NPS reduction and public education programs.
- *Roads, highways, and bridges:* Site, construct, operate, and maintain roads, highways, and bridges properly.

Marinas

- *Marina siting and design:*
  - Allow for maximum flushing of the marina basin.
  - Perform water quality and habitat assessments to protect against adverse impacts on shellfish resources, wetlands, and submerged aquatic vegetation.
  - Control stormwater runoff (additional controls exist for hull maintenance areas).
- *Fueling station design:* Design to allow for ease of cleanup, and develop spill contingency plans.
- *Sewage facilities:* Ensure availability of pumpouts and pump stations, and develop maintenance procedures.
- *Operation and maintenance:* Establish marina operation and maintenance programs to control and to provide for proper disposal of solid waste, fish waste, liquid materials, petroleum products, and boat cleaning byproducts.
- *Public education:* Develop public education programs for marina users.

Hydromodification

- *Channelization and channel modification:* Evaluate effects of new projects on physical and chemical characteristics of surface waters and on instream and riparian habitats
- *Dams:* Control erosion/sediment and chemicals during and after construction; develop and implement an operation and maintenance plan to protect surface water quality and instream and riparian habitat.
- *Eroding shorelines and streambanks:* Stabilize streambanks and shorelines where erosion is a nonpoint problem; vegetative methods are strongly preferred over engineering structures where vegetation will be cost-effective. Protect streambanks and shorelines from erosion from the use of the shore and adjacent waters.

Wetlands, Riparian Areas, and Vegetated Treatment Systems

- *Protection:* Protect wetlands and riparian areas serving a NPS pollution abatement function to maintain water quality benefits and ensure that they do not become a source of nonpoint pollution.
- *Restoration:* Promote the restoration of damaged and destroyed wetlands and riparian systems where they will have a significant NPS pollution abatement function.

- *Vegetated treatment systems:* Promote the use of constructed wetlands and filter strips where they will serve a significant NPS pollution abatement function.

Next Steps

1993

NOAA and EPA began meeting with states and other interested parties to assist in program development and determine their needs for future technical assistance. Activities included:

- Regional workshops with state coastal zone management and NPS control agencies.
- Briefings of other federal agencies and interest groups (e.g., trade associations and environmental groups).
- Presentations at meetings of other interested parties (e.g., International Marina Institute, National Association of Conservation Districts, Water Environment Federation, and Coastal State Organization).

1994

NOAA and EPA formulated and implemented a technical assistance program using information on needs obtained from state and local government, industry, trade organizations, and others. Elements of this program include:

- Publishing several guidance documents, including *State and Local Government Guide to Environmental Program Funding Alternatives* and *Developing Successful Runoff Control Programs for Urbanized Areas* (4, 5).
- Providing funds to help produce additional technical guidance, including *Urbanization and Water Quality, Watershed Protection Techniques,* and *Fundamentals of Urban Runoff Management* (6-8).
- Conducting workshops on such topics as stream restoration, NPS monitoring, and marina NPS controls.
- Developing educational curricula and sponsoring train-the-teacher programs on runoff NPS pollution.
- Developing an expert system for identifying and selecting agricultural NPS controls.

Biotechnical Streambank Protection

Don Roseboom, Jon Rodsater, Long Duong, Tom Hill, Rich Offenback, Rick Johnson, John Beardsley, and Rob Hilsabeck
Illinois State Water Survey, Peoria, Illinois

Abstract

Streams in areas of intense residential and commercial development have high rates of surface water runoff, so bank erosion and downstream flooding become more common and severe. Throughout the greater Chicago area, this has resulted in destabilized streams lacking habitat for fish, wildlife, and people. The Illinois Environmental Protection Agency and the U.S. Environmental Protection Agency funded the urban stream restoration projects on Glen Crest Stream and the Waukegan River. During the spring and summer of 1992, stabilization sites were completed on Glen Crest Stream, in Glen Ellyn, and in Washington Park of the Waukegan Park District. The lunker technique was chosen for its low cost of installation and ability to resist the high-velocity runoff while increasing instream habitat for gamefish and the stream side habitat for the urban population. At Glen Ellyn, lunkers were constructed of recycled plastic lumber for increased longevity. Low-cost vegetative stabilization incorporated an initial matrix of grasses and willows, plus rooted stock of redosier dogwood near the water's edge, followed by appropriate riparian trees on the upper bank that the landowner chose. Both projects trained senior members and staff personnel of the park district and the city in the application of lunkers and vegetative stabilization.

Introduction

This paper describes methods of biotechnical stabilization and instream habitat enhancement that have been field trialed in Illinois. These practices have been authorized and funded by the U.S. Fish and Wildlife Service, the Soil Conservation Service, the U.S. Environmental Protection Agency, and all Illinois state agencies responsible for stream modification permits. The following methods are described: willow post bank stabilization, lunker instream habitat enhancement with vegetative bank stabilization, and A-jack structural and vegetative bank stabilization (Figures 1, 2, and 3).

In rural Illinois areas, bank erosion is not addressed because of limited financial resources. In agricultural states, U.S. Army Corp of Engineers district offices receive many requests for assistance on bank erosion protection. Within recent years, the need for bank erosion control has been coupled with the need for environmental protection of the stream habitat and riparian areas for wildlife and fisheries. Keeping costs low while considering various environmental issues has made bank erosion control a difficult challenge for the Corps.

In Illinois, stream channel erosion increased when prairies were converted to rowcrop agriculture and residential development, thereby increasing surface water runoff rates. Man has become a dominant geomorphic factor in the watershed hydrology of both rural and urban watersheds. In most urban and agricultural areas, streams were channelized to move floodwaters away from valued lands, to maximize the size and uniformity of land holdings, even to decrease channel erosion (1). One result of increased water runoff rates and poorly designed channelization efforts has been massive bank erosion in the floodplains of Illinois streams.

Watershed studies by the Illinois State Water Survey have documented the channel erosion damages to floodplain fields and the consequent increased sediment yield. Channel erosion contributed 40 to 60 percent of the sediment yield in two monitored Illinois watersheds (2). Within these watersheds, increased runoff rates and stream channelizations caused the streambed to be downcut at first and then erode laterally to regain a meander shape (Figure 4). This process was hastened by channel incision into extremely unstable glacials and gravel deposits below an 8- to 20-ft layer of loess clays. The Crow Creek watershed study demonstrates both the bridge damages from channel incision and the field damages from bank erosion (3).

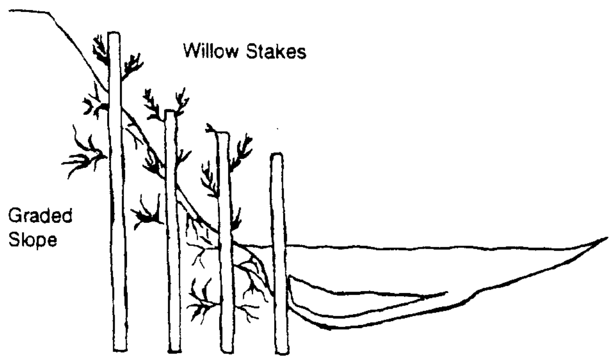

Figure 1. Willow posts installed below depth of streambed scour.

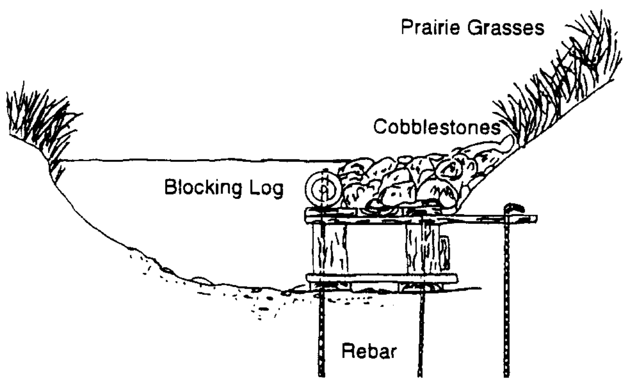

Figure 2. Lunker with riprap below baseflow stage. Rebar is driven below bed scour depth.

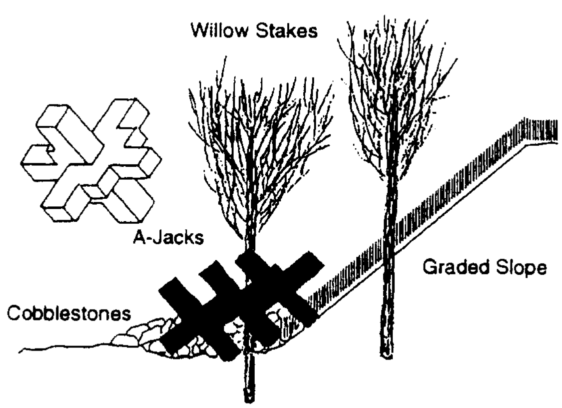

Figure 3. A-jack bank structures.

Willow Post Bank Stabilization

The willow post method differs from most European bioengineering techniques (4, 5) in that individual willows are positioned vertically below the depth of channel scour. Most biotechnical bank stabilization techniques have used vegetation with a riprap mentality. Layers of horizontally bundled woody vegetation are entrenched in the bed and bank. This type of earth

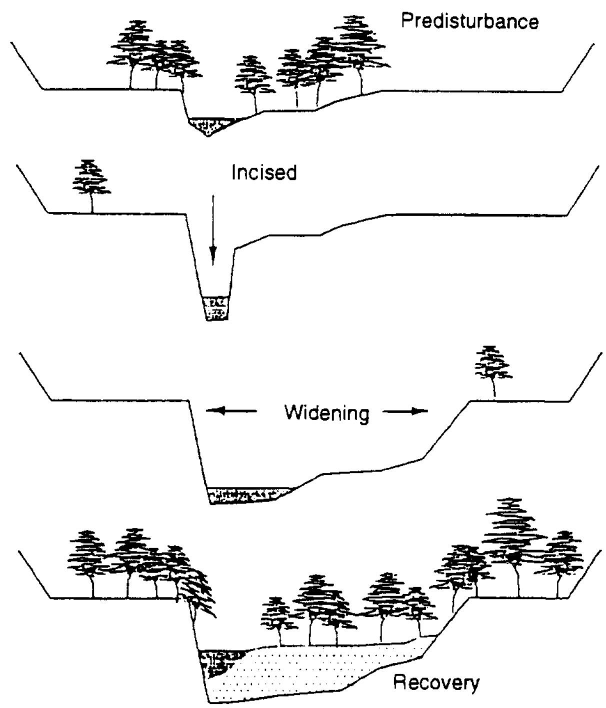

Figure 4. Incision and recovery process. Vegetative bank stabilization can be applied during the widening phase.

moving and hand labor often doubles installation costs and installation times.

Willows and most woody riparian vegetation do not naturally extend root systems very deeply below the water table. The posts are implanted much deeper than native seedlings would grow. Lateral root growth rapidly binds adjacent posts together in the bank soil. Lateral branch growth also interlocks adjacent posts to slow flow velocity near the bank.

The willow post method was mentioned by Scheichtl (4) as a method of ravine stabilization in Germany during the 1800s. Both the Corps of Engineers and the Soil Conservation Service used large willow poles in the 1930s (6, 7). In most cases, the posts or poles were laid as a layer along the sloped bank. York (8) placed willow posts in vertical holes to protect the base of levees in Arizona.

Willows are cut into 10- to 14-ft posts when the leaves have fallen and the tree is dormant. At this time, growth hormones and carbohydrates are stored in the root system and lower trunk. Dense stands of 4- to 6-year-old willows make the best harvesting areas. These stands are commonly found on the stream deltas in lakes or in old stream channel cutoffs. The willow posts are 4 to 6 in. in diameter and may be stored up to 1 month if kept wet.

The eroding streambank is shaped to a 1:1 slope with the spoil placed in a 6-in. deep layer along the top of the bank. In major erosion sites, post holes are formed in the bed and bank so that the end of the post is 2 ft below maximum streambed scour. The posts are placed 4 ft apart in rows up the streambank. The posts in one row are offset from the posts in adjacent rows.

While the steel ram and excavator is more efficient at depths of 6 ft in clay soils, a hydraulic auger and excavator unit forms deeper and longer lasting holes in stony or sand streambeds. Large stone layers of streambed material cause damage to the excavator when the steel ram is used. In fine sand layers, ram holes collapse before the post reaches the bottom of the holes. In highly fluid sands, even auger holes fill but the post can be pushed deeper with the bucket or boom. In streams with sand or gravel beds, the hydraulic auger places posts 9 to 11 ft deep in the bed. Almost all contractors in Illinois currently use an excavator and hydraulic auger unit.

In larger streams with noncohesive sand banks, large cedar trees are cabled to the willow posts along the toe of the bank. The cedars not only reduce bank scour while root systems are growing but also retain moisture during drought periods. In larger streams, such as Illinois's only designated scenic river, the Middle Fork, large rounded boulders were used as additional bank protection with the willow posts.

In Illinois, the contractor slopes 15-ft banks on a 1:1 grade for 80 cents per linear foot. Each post hole is augered 10 ft deep for $2.90. Each willow post costs $1 to $2. With a five-man crew at $10.00 per hour per man, bank sites are estimated to cost between $5 and $8 per linear foot.

Bank Erosion Site Assessment

The following questions should be asked when determining the applicability of willow bank post stabilization:

1. Does sunlight fall directly on the eroding bank? (Willows must have sun.)
2. Is bedrock close to the surface? (Streambed material should be 4 ft deep; check with a tile probe.)
3. Are lenses of fine sand exposed in the eroding bank?
4. Is the stream channel stable upstream of the erosion site? (If the stream cuts behind the upper end of willow posts, the entire bank will erode.)
5. How deep is the stream along the eroding bank? (Willow posts must be 2 ft deeper than the deepest water or the posts will be undercut below the root zone. The length of the willow posts depends on the water depth. In sand or cobble streams, a hydraulic auger forms a deeper and more stable hole.)
6. How wide is the stream channel at the erosion sites compared with stable channels upstream and downstream? (If the channel is wider at the erosion site, vegetation will not choke the stream channel and cause other erosion problems.)
7. Do you have a source of large willows close to the site? (Your costs are small when the willows are close.)
8. Will the site be wet during dry summers? (Willow posts require a lot of water while the roots are regrowing; willow posts should only extend 1 to 2 ft aboveground in dry sites.)
9. Can you keep cattle away from the posts during the first summer? (Willows must be able to produce leaves for photosynthesis and regrowth.)
10. Have debris jams forced floodwater into the eroding bank? (Large debris jams must be removed according to guidelines established by the American Fisheries Society (9).)

The willow post method of bank stabilization is the lowest cost bank stabilization method that provides both wildlife and fisheries benefits. This method has received widespread support by both the agricultural and environmental communities: Farm Bureau, soil and water conservation districts, American Fisheries Society, and Nature Conservancy. The willows serve only as a pioneer plant on the disturbed soils. Succession to wooded or grass banks is speeded by additional trees or grass plantings with active site management if the landowner desires.

Lunker Instream Habitat Structures

Lunkers are constructed of 2-in. oak planks (10). The planks form upper and bottom layers so that the interior is open to water flow at both ends and on the stream side of the structure (Figure 2). A series of lunkers are placed along the base of the eroding bank. When necessary, the lunkers are placed into an excavated trench, especially on the upper and lower ends of the sites. Each lunker is held with nine lengths of rebar, which are driven 5 ft into the streambed. In the Illinois adaptation, riprap was placed only on lunkers behind the blocking log.

In rural areas and in state parks, the bank above the lunkers was stabilized with willow posts. The bank was steeply sloped to keep the lunkers scoured (11) and to prevent silt deposition in the lunkers. In Court Creek, the upper bank was seeded with prairie grasses. During the second year, the posts were cut down so that only a narrow fringe of willow grew along the water's edge. By the third year, with active burn management, the prairie grasses had become established.

At Franklin Creek State Park, the banks were seeded with cool season grasses because the erosion site was located beside the equestrian corral. Once again, the willow posts were to be cut during the second year. A large population of protected beavers sped up the postcutting schedule. A spray of Ropel, an unpleasant-tasting liquid, mixed with a tackifer (to decrease water solubility) gave protection until the grasses became established. When Ropel applications were discontinued, the large posts were quickly cut down. Even with heavy browsing, however, the willow stubs regrew branches because the root systems were not damaged.

While the cool season grasses became established more quickly than the prairie grasses, the root systems of cool season grasses are shallow and therefore more susceptible to scour during high velocity flows. While damages have been minor after 4 years, two 9 ft^2 areas were seeded with grasses and 18-in. willow cuttings in April 1993. Adult smallmouth bass populations increased over 50 percent. Of more importance to stream bass populations, the yearling bass survival increased 300 percent at the lunker site (12).

Costs of lunker installation were $25 to $35 per linear foot, with prairie grass seeding and maintenance accounting for higher costs at the Court Creek site. Labor was 45 percent of costs, contractual equipment was 30 percent, and materials were 25 percent. A 300-ft site is estimated to cost $8,000 to $10,000.

Urban Lunkers

In northeastern Illinois near Chicago, urban streams respond quickly to rainfall events so that floods are extremely erosive. Damage to homes and the higher cost of lands allow more intensive stream management. Often this has led to concrete or heavily riprapped stream channels with acute environmental damages. While necessary in some urban settings, the value of residential homes and parks can be increased if stream channel stabilization can be made more environmentally sensitive. In the smaller stream, the lunkers were constructed from recycled plastic lumber so that lunkers would not dry rot during lowflow drought periods. In larger stream segments, deeper pools allowed the use of wooden lunkers.

In urban streams, the higher cost of materials, the higher cost of contractual equipment as excavators, and the very high cost of landscape repairs to private lawns substantially increase the cost of lunker installation. The lunker installations are $45 to $55 per linear foot of bank.

Summer scheduling of stream restoration required the use of rooted and therefore smaller willow saplings. Additional rooted stock as redosier dogwood played a greater role in riparian revegetation of urban sites. Tree corridors were preserved as sound barriers to traffic noises and visual privacy barriers between homes. The resulting shade, however, denied the use of willows in some areas. In these shaded areas, redosier dogwood were planted with very good survival.

These urban sites were only 1 year old at the time this paper was presented, but the Chicago area had just undergone an extremely wet fall and spring. Two fall floods and three spring floods did not damage the urban lunkers sites.

A-Jack Structures With Willow and Dogwood Bank Revegetation

A-jacks look like small versions of the World War II tank traps (see Figure 3). The A-jacks can be placed so that each A-jack will interlock within each row and with A-jacks in adjacent rows. The lowest rows of A-jacks are trenched along the base of the eroding bank, with the excavated sediment placed along the top of the bank. In the Glen Crest Stream and the Waukegan River, 2-ft diameter A-jacks were used.

Fibredam, a geotechnical fabric that locks the curled wood fibers in excelsior blankets, was placed between the rows of A-jacks and the bank soils to reduce soil movement through the A-jacks. Fibredam is easily torn apart and molded into crevices between A-jacks.

Willow cuttings were driven into the streambed between A-jacks and behind the last interior rows of A-jacks. The fluid sediment was placed on the rows and allowed to fill the interior spaces. The vertical streambank was then sloped over the A-jacks.

This structure ran $45 to $50 per linear foot of bank when composed of two base rows and one upper row. The cost of materials was $25 per foot. Ease of handling and suitability for transport by small marsh vehicles are advantages of this system. Each A-jack is composed of two halves that lie flat on pallets during transport. A-jacks are assembled at the bank site.

When the willows and dogwood are fully grown, root systems lock the entire structure together while giving a natural appearance to the streambank. Small stone is added to A-jack rows near the waterline to give a more natural appearance.

The Use of Wetlands for Stormwater Pollution Control

Eric W. Strecker
Woodward-Clyde Consultants, Portland, Oregon

Abstract

This paper presents the results of a literature review that summarizes the current state of knowledge regarding the use of wetlands for stormwater pollution control. The paper reviews the primary removal mechanisms in wetlands, including sedimentation, adsorption, precipitation and dissolution, filtration, biochemical interactions, volatilization and aerosol formation, and infiltration. The results from 26 wetlands are reviewed and contrasted regarding their ability to remove pollutants from stormwater. The systems range from salt marshes to high-elevation riverine wetlands. The study sites are reviewed in relation to the type of wetlands system, including design features and upstream watershed characteristics. The wetlands receive stormwater from different land uses, including residential, commercial, highway, golf courses, and open. The observed pollutant removal efficiencies are quite variable but generally show good removals of phosphorus (median of 46 percent average removal) and the heavy metals cadmium, copper, lead, and zinc (median of 70, 40, 83, and 42 percent average removal, respectively) from stormwater. Constructed wetlands generally perform better and with greater consistency. In general, larger wetlands perform better than their watershed areas as well. Nevertheless, some carefully planned constructed systems with a small area performed quite well compared with their watershed areas. Because there is little information on noted impacts to biota, these are just briefly reviewed. Finally, the paper suggests collecting additional information in new studies. This would make comparisons among different sites more useful in assessing the factors that affect the abilities of constructed wetlands to remove pollutants from stormwater.

Introduction

Constructed wetlands are receiving increasing attention as attractive systems for removing pollutants from stormwater runoff. Other potential benefits that such systems provide include flood control and habitat. Wetlands have long been used for the treatment of wastewaters from municipal, industrial, and agricultural sources (1). The U.S. Environmental Protection Agency (EPA) encourages the use of constructed wetlands for water pollution control through the innovative and alternative technology provisions of the construction grants program (2).

The purpose of this paper is to assist EPA, state, and local technical personnel in assessing the capabilities and limitations of using wetlands as a control measure to reduce the environmental impacts of stormwater pollution on downstream water bodies. The paper summarizes a report prepared for EPA by Strecker et al. (3) that reviewed published literature and documented reports on aspects of stormwater wetland design, operation, and performance. An appendix that accompanied the published report included a one- to six-page summary of each pertinent study reviewed for the report. The summaries covered influent and effluent water quality, the effectiveness of the system, flows and volumes, wetland and watershed areas, and the biological characteristics of the system.

Table 1 presents a list of selected reports with which researchers have documented the ability of wetland systems to remove pollutants from stormwater. The table includes some general characteristics of the wetland systems. Figure 1 shows the wetlands' geographic locations. The wetlands differed widely in location and wetland type (e.g., Florida's southern swamplands, Minnesota's northern peatlands, California's brackish marshlands, and Puget Sound's palustrine wetlands). Each of these locations differs in climate, vegetation, and soil types.

Wetland Stormwater Pollutant Removal Mechanisms

Wetlands can combine various actions to remove pollutants from stormwater:

- Incorporation into or attachment to wetland sediments or biota.
- Degradation.

Figure 1. Location of wetlands researched for their ability to treat stormwater runoff.

- Export of pollutants to the atmosphere or ground water.

Both physical and chemical pollutant removal mechanisms probably occur in wetlands. These mechanisms include sedimentation, adsorption, precipitation and dissolution, filtration, biochemical interactions, volatilization and aerosol formation, and infiltration. Because of the many interactions between the physical, chemical, and biological processes in wetlands, these mechanisms are generally not independent. Sedimentation is usually the most dominant removal mechanism. The large variation in wetland characteristics (e.g., hydrology, biota) may cause the dominant removal mechanisms to vary from wetland to wetland. Variations in wetland characteristics can also help explain why wetlands differ so widely in their pollutant removal efficiencies. Following is a brief description of the principal removal mechanisms.

Sedimentation

Sedimentation is a solid-liquid separation process using gravitational settling to remove suspended solids. It is considered the predominant mechanism for the removal of many pollutants from the water column in wetland and other flow detention systems. Sedimentation of suspended material, along with pollutants that are highly adsorbed, has been documented as the primary removal mechanism in wetlands by many study authors, including Martin and Smoot (4) and Oberts (23). The most significant factors affecting settling of suspended material pertain to the hydraulic characteristics of the wetland system, including the detention time, inlet-outlet conditions, turbulence, and depth. The opposite of sedimentation is flotation. Floatable pollutants such as oil and grease, litter, and other pollutants can accumulate in the surface microlayer. These pollutants can be removed by adsorption.

Adsorption

Adsorption of pollutants onto the surfaces of suspended particulates, sediments, vegetation, and organic matter is a principal mechanism for removing dissolved or floatable pollutants. The literature suggests that these processes remove pollutants such as phosphorus, dissolved metals, and other adsorbents (including colloidal pollutants) (5, 11, 16). Adsorption occurs through three main processes:

- Electrostatic attractions.
- Physical attractions (e.g., Van der Waals forces and hydrogen bonding).
- Reactions.

R0015939

The rates by which these processes occur are thought to be inversely related to the particle size and directly related to the organic content of the particles in the wetland soils (5). Increasing the contact of stormwater with the underlying soils and organic matter can enhance adsorption processes. In addition, high residence times, shallow water depths, and even distribution of influent enhance the interactions of water with soil and plant substances, thereby increasing the adsorption potential.

Precipitation and Dissolution

Many ionic species (e.g., metals) dissolve or precipitate in response to changes in the solution chemistry of the wetland environment. Metals such as cadmium, copper, lead, mercury, silver, and zinc can form insoluble sulfides under the reduced conditions commonly found in wetlands (24). Decaying organic matter releases fulvic and humic acids that can form complexes with metal ions. In addition, decreased pH can promote the dissolution of metals, thereby making them available for bonding to inorganic and organic molecules (25).

Filtration

Filtration occurs in most wetlands simply because vegetation acts like a sieve to remove pollutants and sediments from the water column. Dense vegetation can be very effective at removing floatables (including oil and grease) and litter from stormwater. Filtration can also take place in the soil matrix when infiltration occurs. Brown (9) and Wotzka and Oberts (10) also noted that increased density of vegetation slows the velocity and wave action, thereby allowing increased settling of suspended material.

Biochemical Interactions

Vegetative systems possess a variety of biochemical interaction processes that can remove nutrients and other material from the water column. In general, these processes are:

- High plant productivity and associated nutrient uptake
- Decomposition of organic matter
- Adsorption
- Bacterially aerobic or anaerobic mediated processes

Through interactions with the soil, water, and air, plants can increase the assimilation of pollutants within a wetland system. Plants provide surfaces for bacterial growth and adsorption, filtration, nutrient assimilation, and the uptake of heavy metals (26).

Volatilization and Aerosol Formation

Volatilization (or evaporation) can remove volatile pollutants from wetlands. Air and water temperature, wind speed, subsurface agitation, and surface films can affect the rate of volatilization. Surface films may act as a barrier for the volatilization of some substances. Alternatively, evaporation may be a key mechanism for exporting substances such as chlorinated hydrocarbons or oils, which are often found in the surface films of water bodies receiving urban stormwater runoff (26). Aerosol formation may play only a minor role in removing pollutants in wetlands and occurs only during strong winds (26).

Infiltration

For wetlands with underlying permeable soils, infiltration can remove pollutants. Stormwater percolates through the soil, eventually reaching ground water. Passage through the soil matrix can provide physical, chemical, and biological treatment depending on the matrix thickness, particle size, degree of saturation, and organic content. Infiltration is also dependent on the ground-water level at a site. In some instances, seasonal fluctuations in ground-water levels may cause some wetlands to discharge ground water during part of the year and recharge to ground water during other times of the year. The potential of pollutants to migrate to ground water depends highly on the type of pollutant, the soil type and properties, the hydrology, and the characteristics of the aquifer. Contamination of unconfined aquifers by stormwater is likely to be more significant from upland infiltration than from recharge through wetlands because of the high filtering action of typical wetland soils (27).

Wetland Stormwater Pollutant Removal Efficiencies

Only a limited number of studies have investigated the effectiveness of wetlands to treat stormwater runoff (Figure 1), and those have primarily focused on a few geographical locations (e.g., Florida, Minnesota, and California). The studies that this paper summarizes represent a wide diversity of wetland types, ranging from southern cypress swamplands and northern peatlands to brackish marshlands and high-elevation meadowlands. This section presents a discussion of wetland stormwater pollutant removal efficiencies found in the literature.

Table 2 summarizes reported removal efficiencies for total suspended solids (TSS) and selected nutrients and metals. The broad ranges of pollutant removal efficiencies were not surprising because wetlands vary in their hydraulic conditions, climate, and vegetation, and because the studies employed various monitoring and reporting procedures. Figure 2 presents histograms of pollutant removal efficiencies reported for TSS, total phosphorus (TP), ammonia (NH_3), and lead (Pb).

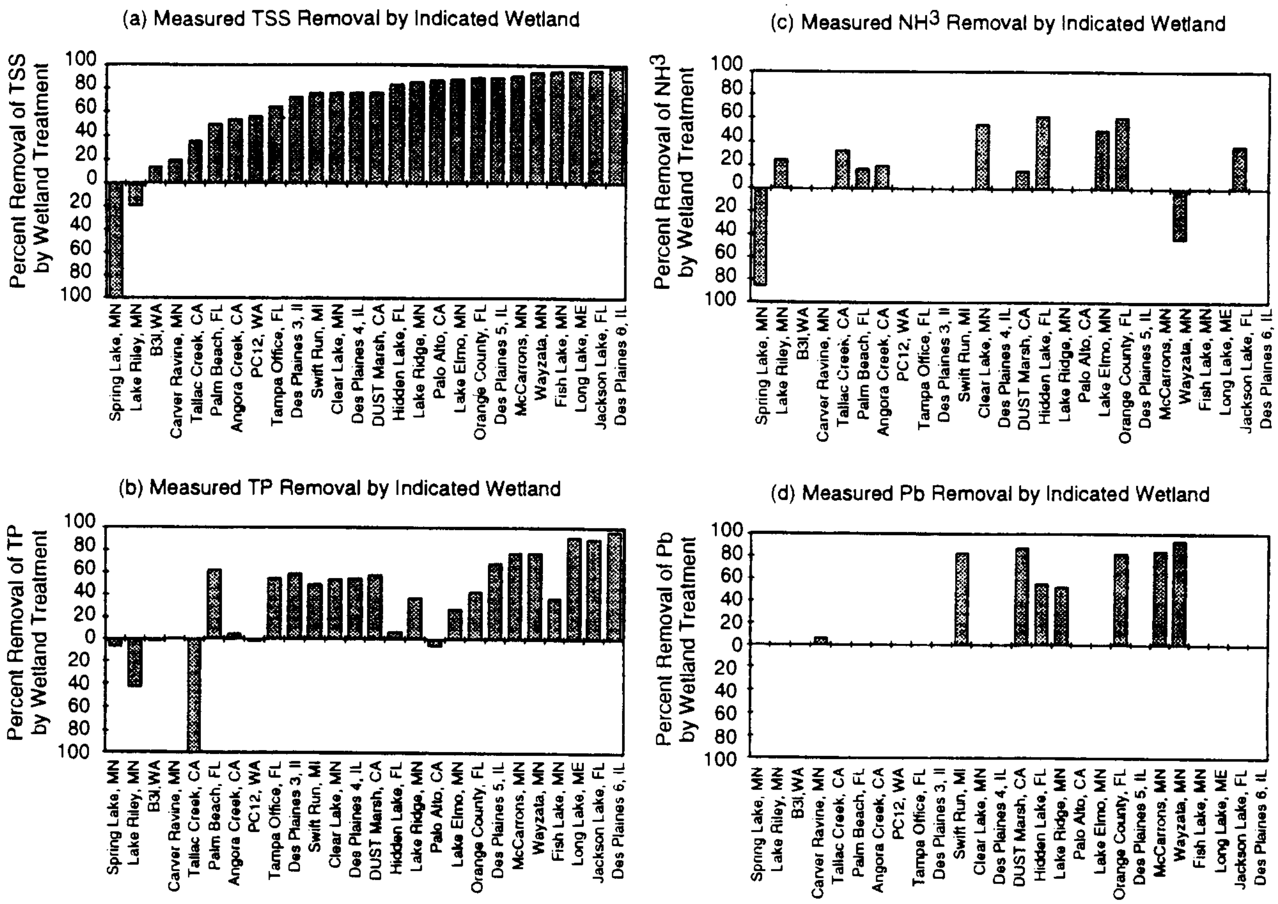
[a]Negative removal efficiencies indicate net export in pollutant loads.

COD = chemical oxygen demand

BOD = biochemical oxygen demand



Note: No bar indicates that the removal estimates were not reported for this parameter at the indicated wetland.

Figure 2. Pollutant removal rates for a) TSS, b) TP, c) NH_3, and d) Pb.

Despite the variability observed in pollutant removal efficiencies, some similarities exist among the wetlands. The following observations can be made:

- Suspended solids and total lead (TPb), followed by total zinc and chromium, show the greatest consistency with pollutant removal efficiencies.
- Suspended solid removal efficiencies tend to be more consistent and larger in constructed wetlands than in natural systems. This is likely due to the design and management of the constructed systems.
- In some cases, concentrations of dissolved Pb, zinc, and copper appear to be reduced significantly.
- Nutrient removal efficiencies vary widely among wetlands. The variations appear to be a function of the season, vegetation type, and wetland systems management methods.
- Total phosphorus and nitrate show the greatest consistency for nutrient removal efficiencies. Total phosphorus removal efficiencies tend to be more variable for the natural wetlands and less variable for detention basins and constructed wetlands.

Probable Causes of Variations and Dissimilarities of Reported Wetland Pollutant Removal Effectiveness

In addition to the efficiencies that the authors tabulated, several reports presented conclusions to help explain the effectiveness of wetland treatment and variations. Hydrology is reportedly the most critical parameter influencing wetland performance. Variations in local hydrology, detention times, rates of runoff, water level fluctuations, and seasonality all reportedly affect the function of wetlands and thus their effectiveness at removing pollutants (25). Table 3 presents geographic, hydrologic, and hydraulic characteristics for each of the wetlands reviewed.

The size and volume of a wetland system can greatly affect both the actual removal efficiencies and the ability to estimate these efficiencies. EPA (26) reported difficulties in estimating pollutant removal efficiencies due to the volume of the wetland basin. The volume of the Demonstration Urban Stormwater Treatment (DUST) marsh is large enough that the treatment cycle spans several storms; therefore, no one storm provided a complete picture of pollutant efficiencies. The DUST marsh accu-

System = summary information

a Short-circuiting was observed during several storms.

b The wetland is not a basin but similar to a grassy swale.

c Design configuration suggests little short-circuiting occurred.

d Generally sheet flow exists within the artificial wetland.

e The major influent to these natural wetlands is discrete channelized flow.

f The schematic suggests large areas of dead storage exist.

g Short-circuiting was not discussed by the author.

h Three discrete inlets help to minimize short-circuiting and dissipate surface water energy.

i Design configuration suggests minimal short-circuiting existed regardless of a single discrete inlet.

j Design configuration suggests little short-circuiting occurred due to long and narrow wetland basins.

k Flow occurs as channelized flow until the storm volume is large enough to force sheet flow through the meadowlands.

l Water level and volume are controlled by the tidal cycle.

m Channelized flow exists until the tide increases, causing the surrounding marsh to become inundated.

n Entire system consists of a sedimentation basin, grass filter strip, constructed wetland, and deep pond.

o Monitoring occurred during a dry period.

p Storm flows reduce detention times.

q Channelization reduced effective area in wetland.

r Overflow from adjacent wetlands occurred during extremely high water; leak and breach problems occurred during study.

s Water is pumped to the system from the river (drainage area of 210 square miles) for 20 hr/wk.

mulates stormwater flows within the system and discharges effluent slowly over days or weeks, depending on the interval between storms. Thus, the water collected at the discharge from the DUST marsh is probably a mixture of water that entered from the previous storms.

The type of inlet structure and the flow patterns through wetland areas also can significantly affect pollutant removal efficiencies. Morris et al. (14) found that sheet flow (as opposed to channelized flow) was the most critical factor in the effectiveness of meadowland treatment. This finding is consistent with the theory that shallow, vegetative overland flow decreases velocities and increases sedimentation. In addition, close contact with the soil matrix was found to increase assimilation of nutrients and bacteria. Brown (9) found that an undefined inflow (multiple input locations) to the wetland, which results in better dispersion of incoming load, was critical in the effectiveness of the wetland. An undefined inflow reduced short-circuiting and increased mixing and contact of the stormwater with the soil and plant substrates.

The change in seasons has been considered another important factor in the effectiveness of wetland treatment of storm runoff. Typical factors of seasonality are evapotranspiration rates and seasonal productivity and decay of plant and animal life. Removal efficiencies in wetlands located in areas with strong seasonal variation may vary significantly between seasons. For example, Meiorin (13) reported that high summer evapotranspiration rates caused a 200- to 300-percent increase in the total dissolved solids concentrations within the DUST marsh. Furthermore, high productivity during warm periods can lead to decreases in nutrients and increases in biochemical oxygen demand (BOD) and suspended solids. Morris et al. (14) reported that flushing and leaching effects of spring snowmelt caused an increase in total Kjeldahl nitrogen and organic carbon in flows leaving the Tahoe Basin meadowland. Harper et al. (5) reported that detention times greater than 2 days caused an increase in the export of orthophosphorus from the Hidden Lake wetland.

Hickok et al. (11) described microbial activity as the most important factor affecting phosphorus removal. Other factors that probably cause variations in the reported pollutant removal effectiveness include maturity of the wetland, the buildup of nutrients and heavy metals in a wetland system, particle-size distribution (which affects the settling of suspended sediments), and maintenance practices performed at a wetland.

Comparison of Factors Affecting Reported Treatment Efficiencies

This study reviewed data on removal efficiencies for 26 different wetland systems. The study evaluated the following factors regarding their effects on wetlands pollutant removal performance:

- Constructed versus natural systems.
- Vegetation types found in the wetland.
- Land-use types draining to the wetland.
- Area of the wetland system compared with the contributing watershed.
- Estimated average storm-flow quantities draining to the wetland.
- Inlet types.

These factors affected only a few meaningful direct relationships. This was because of the limited amount

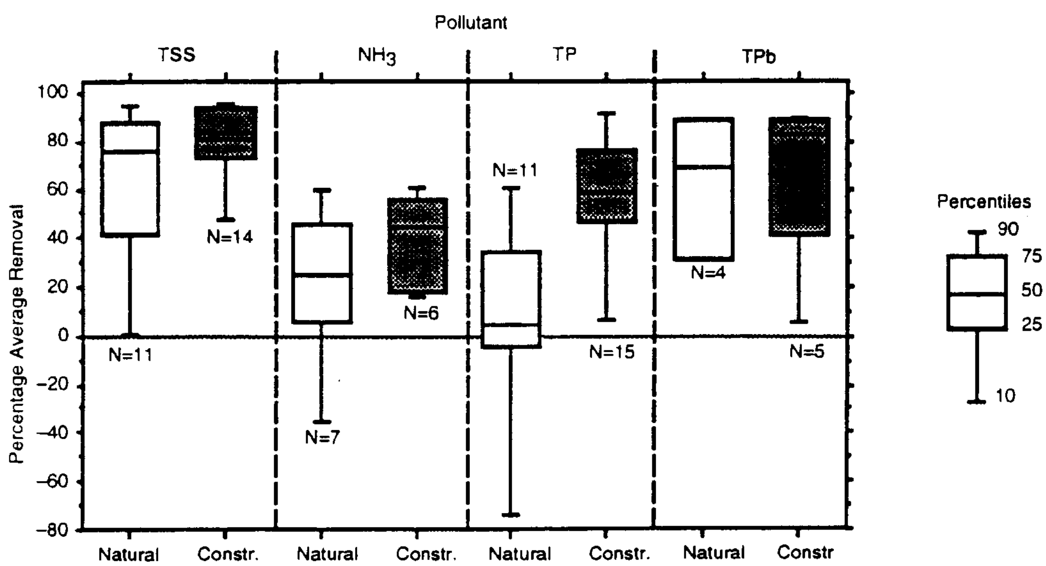

Figure 3. Box plot percentiles comparison of site average pollutant removals for natural and constructed wetland systems: TSS = total suspended solids, NH_3 = ammonia, TP = total phosphorus, TPb = total lead, and N = number of wetland sites.

R0015947

of data available to determine these relationships as well as the multiple factors that affect performance. Without a large database, a meaningful multiple regression analysis was not possible.

Several trends, however, were noted. First, constructed systems generally had a higher average removal performance than natural systems, with less variability. Second, larger wetlands compared with their tributary watershed areas also showed the same trend: a higher average removal performance, with less variability. Figure 3 presents TSS, TP, NH_3, and TPb in a percentile box plot for the constructed and natural systems. Note that, in all cases for the pollutants summarized, constructed systems showed a higher average and median performance level. More significant, however, is the difference in variability between the two types of wetlands. Constructed sites were much less variable. This is not a surprising finding, given that constructed systems have generally been designed to handle expected incoming flows and to minimize short-circuiting. They should generally show a higher performance level with more consistency.

Investigators also looked at the area of the wetland system compared with the size of its contributing watershed. Regression of the wetland to watershed area ratio

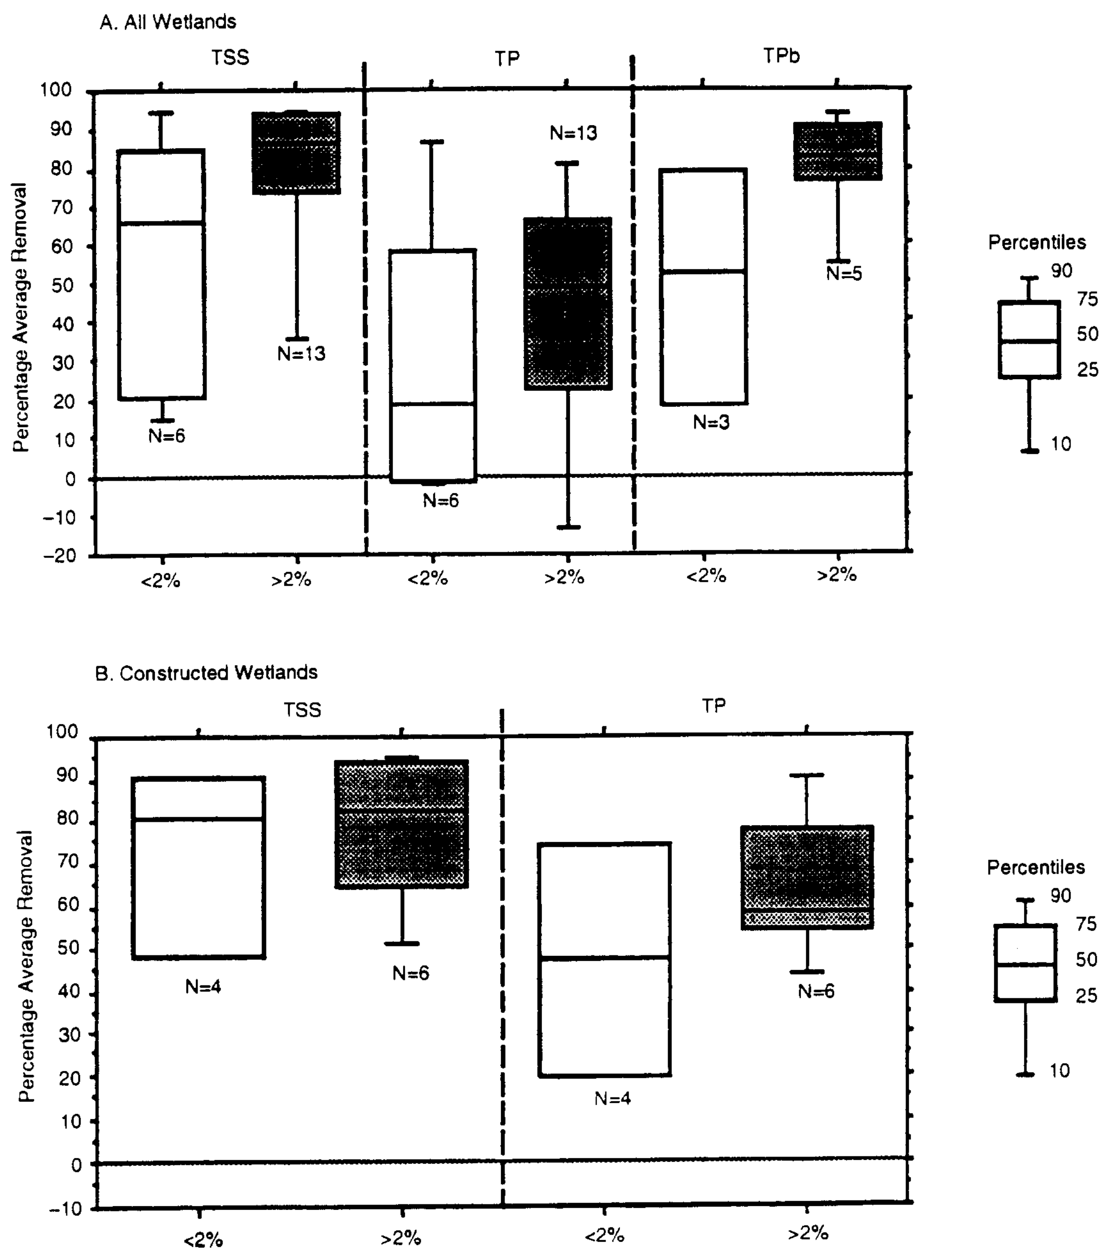

Figure 4. Average site percentile box plots for TSS, TP, and TPb pollutant removals for wetlands with less than 2 percent and greater than 2 percent wetland-to-watershed size ratios (WWAR): N = number of wetland sites, TSS = total suspended solids, TP = total phosphorus, and TPb = total lead.

(DAR) to pollutant removal performance did not reveal good direct relationships. Grouping sites according to a greater than or less than 2 percent DAR, however, did result in some general trends. Figure 4 presents performance results for all wetland systems with reported tributary watershed areas. In general, the larger DAR wetlands had higher performance levels, with less variability. This analysis included all wetland sites, natural and constructed. To separate out the effects of natural versus constructed systems, Figure 4 also presents a similar analysis for constructed sites only. Generally, for constructed sites the trends are the same, although the differences in performance levels and variability in performance are much less. The data indicate that carefully constructed systems can probably mitigate the importance of DAR as a factor in determining performance. Therefore, at this time we are not suggesting that 2 percent minimum DAR is a proper design criteria for constructed wetlands.

The Jackson Lake wetland is an example of a wetland with a small DAR that still achieved excellent performance (85 percent TSS removal). The DUST marsh and the Lake Ridge wetlands also showed high performance levels (76 and 85 percent TSS removals, respectively). One factor that explains the DUST marsh performance is that it is an "off-line" device: it only receives flow volumes up to a certain flow rate, then bypasses high flows. This type of design is particularly appropriate for wetlands receiving stormwater from larger catchments relative to wetland size.

To better measure the capacity of a wetland to treat runoff from a given watershed would entail evaluating average storm runoff volumes of wetland tributary areas with wetland storage volumes and/or contact surface areas. The data from the studies, however, did not consistently include data on rainfall statistics, percent impervious for land uses, specific percentages for land uses in a catchment, flow volumes to the wetland, capacity of the wetland system, and surface areas for contact with stormwater (including soils and plants). Therefore, we were not able to analyze the wetland systems using this approach. The summary of this paper contains some recommendations regarding reporting information for future studies, so that such analyses can be completed.

Finally, no good studies or documentation exists regarding maintenance activities in wetlands that are treating stormwater. In addition, the need for maintenance and level of maintenance are not well understood or documented. These activities could affect performance characteristics of wetlands, particularly over the long term.

Assessment of the Reliability of Wetland Data

There are various difficulties in comparing one wetland study to another. Table 4 presents a list of the selected literature, including information on the sampling characteristics that each study employed. The table shows that the studies identified generally lasted a year or less. There was quite a variation in the number of samples collected (from 3 to about 150), as well as in the sampling methods used (i.e., grab sample or samples versus composite sample for an event). These factors all contribute to the difficulty of comparing results from the different studies. Another complication in comparing the performance of wetlands involves the method of quantifying their effectiveness.

Noted Impacts of Stormwater Runoff on Wetland Biota

Many researchers have expressed concern over the impact of the quantity and quality of stormwater runoff on wetland biota, especially in natural wetlands (27, 28). The quantity of stormwater runoff determines the hydrologic characteristics of a wetland, including the average and extreme water levels and duration and frequency of flooding. Stormwater runoff also contains pollutants that can adversely affect wetland biota if accumulated in high concentrations. The hydrology of a wetland is one of the most important factors in establishing and maintaining specific types of wetlands and wetland processes (29). Hydrology is a key factor in wetland productivity, vegetation composition, nutrient imports, salinity balance, organic accumulation, sedimentation transport, and soil anaerobiosis.

Few of the reports reviewed indicated concern regarding the effects of contaminants in urban stormwater on wetland systems. Many of the reports referenced studies performed in wetlands receiving sewage effluents or industrial discharges of some type. Urban runoff, especially from residential watersheds, frequently has much lower concentrations of pollutants than do sewage effluents or industrial discharges.

Sediments typically constitute the most significant store of toxic substances available to organisms in a wetland (29). Plants can take up metals and toxic organic compounds from the sediments, thus introducing them into the food web (30-32). Both metals and organics tend to be adsorbed to finely divided solids, depending on conditions such as pH, oxidation-reduction potential, and salinity (33). The way a metal is complexed determines its availability to plants (33).

Water resides longer in wetlands compared with more swiftly moving waters because of the flatness of wetlands and the filtering action of the vegetation. This longer residence time allows suspended solids to drop out and be retained (32, 33). Woodward-Clyde Consultants (34) found that the greatest concentration of metals in sediments occurred at the location nearest the stormwater inlet and declined with distance from the inlet. They found the sediment concentration and bioavailabil-

ity of copper, lead, and zinc to be at or near background levels in the downstream marsh area.

Plants take more metals from the sediment than from the water column. Phytoplankton, however, can remove metals directly from the water, releasing them to the sediments or to the water upon death (35). In general, far greater amounts of metals remain in the sediment than are taken up by plants (36-39). Some plants are apparently able to exclude toxic metals selectively. Organic compounds undergo many of the same processes in wetlands as metals, including adsorption to sediments and plant uptake. In addition, they can be biodegraded.

The uptake of toxic materials by plants can introduce these materials into the grazing and detrital food chains, with potentially deleterious effect. Metals from sewage effluents introduced to wetlands tend to accumulate in the food chain (32). Finally, the relative responses of plants and animals to toxic metals and organic compounds indicate that these contaminants are more likely to affect animals negatively.

Comparison of Wetland and Detention Basin Performance

Detention facilities have traditionally been constructed to control stormwater runoff quantities. These facilities temporarily store stormwater runoff and later release the water at a lower flow rate. Design of detention basins and ponds can provide for water quality enhancement by including a permanent pool of water and inlet and outlet structures to maximize detention. Quiescent velocities within the basins allow sediments to settle out of the stormwater and undergo chemical and biological removal processes. Detention basins usually do not have vegetation within the permanent pool, but the banks may be planted with grasses for erosion control.

Detention basin/constructed wetland treatment systems have been recommended for stormwater treatment (4, 10, 40). Typically in these systems, stormwater runoff discharges to the detention basin, which then releases the water to the wetland for additional treatment. The detention basin can provide pretreatment for the wetland, reducing the sediment and pollutant loads to the wetland. In other instances, detention basins and constructed wetlands are competing alternatives under consideration for stormwater treatment. To make a decision, the designer or planner requires knowledge of the relative pollutant removal efficiencies, environmental impacts, maintenance requirements, and costs of the two alternatives.

To further illustrate how those systems compare, the following discussion focuses on the results from a case study of the McCarrons treatment facility system, which compared the performance of wetlands with that of detention basins through simultaneous monitoring of both systems. Wotzka and Oberts (10) presented a paper discussing the combined detention-wetland stormwater treatment facility. The McCarrons treatment facility consisted of a 30-acre detention basin with an average depth of 1.2 ft and a 6.2-acre constructed wetland with an average depth of 2.5 ft. The detention basin received stormwater and then discharged to the wetland. The contributing watershed consisted of 600 acres of primarily urban land use. The predominant vegetation in the wetland consisted of cattails with other emergent plant species.

Overall, the system produced very good results. The detention basin proved to be more effective than the wetland in reducing several pollutants. For example, Table 5 lists removal efficiencies for the detention basin and wetland.

Wotzka and Oberts (10) discussed some of the possible explanations for the good results of the detention basin and for its differences from the wetland. In general, they believed that the treatment efficiencies were lower in the wetland due to pretreatment by the detention basin. They stated that the inflows into the detention basin spread equally around the perimeter of the detention basin, thus dissipating the entry velocities of the storm runoff. Dissipation of inflow energy probably promoted settling and minimized short-circuiting.

Table 5. Removal Efficiencies (%) for Detention Basin and Wetland

Parameter	Detention Basin	Wetland
TSS	91	87
TP	78	36
TN	85	24
TPb	85	68

Wotzka and Oberts (10) suggested that the percentage of phosphorus in the dissolved and particulate phases affected the reduction potential. They found that more than 80 percent of the phosphorus was in the particulate form, resulting in high removal efficiencies due to settling. Apparently, the wetland did not perform as well as the detention basin because of the periodic release of nutrients from decaying vegetation and the fact that significant pretreatment had occurred. The authors also suggested that the high removal of phosphorus was due in part to the newly exposed soils on the bottom of the detention basin. They explained that the newly exposed soils probably had more adsorption capacity available than the soils in the wetland further downstream. They also suggested that saturated soil conditions could lead to a reduction in phosphorus removal.

In conclusion, this study indicated that the detention basin performed better than the wetland system. This may be misleading, however, because the wetland received pretreated waters from the detention basin. The detention basin removed the fraction of pollutants that were more readily settled and treated, leaving the wetland with the more difficult-to-treat, finer particulates and dissolved pollutants.

Summary

Wetlands have a good capability for removing pollutants from stormwater runoff. Several factors contribute to and influence removal efficiencies, including sedimentation, adsorption, precipitation and dissolution, filtration, biochemical interactions, volatilization and aerosol formation, and infiltration. The reported removal efficiencies are, as expected, quite variable. For the wetlands systems reviewed, removal efficiencies for TSS had a median of 76 percent. TSS removal is a good indicator of pollutant removal potential for heavy metals and phosphorus, as well as other pollutants associated with fine particulate matter. Constructed wetlands tended to be more consistent than natural wetlands in their removal of TSS and the other analyzed parameters. Wetlands have also shown the ability to remove dissolved metals. Nutrient removal in wetlands is variable, depending on both wetlands characteristics and seasonal effects.

Because many dissimilarities exist between the wetlands studied, wetlands stormwater pollutant removal efficiencies vary widely. Properly designed, constructed, and maintained wetlands, however, can be effective pollution control measures. Examining additional wetlands in a variety of geographical areas, as well as long-term pollutant removal efficiencies, is definitely necessary.

A significant issue, however, involves whether stormwater control measures should include natural wetland systems. In general, natural wetlands have been found to be somewhat less predictable than constructed wetlands in terms of pollutant removal efficiency. This difference may be due to the fact that constructed wetlands have generally been engineered specifically to provide favorable flow capacity and routing patterns. As a result, they tend to detain inflows for longer periods and have less short-circuiting than many natural systems.

People often question the appropriateness of using a natural, healthy wetland for such purposes. Their concern is whether the modified flow regime and the accumulation of pollutants will result in undesirable environmental effects. There are many situations where natural wetlands have been receiving urban runoff for years. Some of these wetlands reflect significant degradation because of many factors, including urban runoff, whereas others have been less affected. A general consensus from the literature is to discourage the use of a healthy natural wetland for stormwater pollution control. In the case of rehabilitating a natural but degraded wetland, modifications should ensure that the applied runoff receives sufficient pretreatment. One pretreatment technique would be to use pond areas to provide an opportunity for suspended materials to settle out before the flows enter the wetland. Other possible options include routing inflows to the wetlands through upstream grass swales, oil/water separators, heavily vegetated areas (e.g., thick, shallow cattail areas), and overland flow areas.

These techniques would not only act on solids but also on floatables such as oil and water. Although little evidence exists of problems in wetlands that have been receiving stormwater runoff, the available data are quite limited, and developing additional information on impacts is critical. Additional studies on the impacts to biota should be undertaken.

In addition, the maintenance needs of wetland systems that treat stormwater merit further study. Such maintenance activities could include sediment removal and plant harvesting. Further studies should address the need for and the frequency and appropriateness of maintenance.

Gathering more information on wetland effectiveness would benefit design development procedures for sizing wetland treatment facilities. There is currently not enough information in the existing literature to develop design guidelines for constructed wetland treatment systems. Additional studies are needed to broaden the type of wetland systems reviewed, develop information on long-term performance, and evaluate seasonal characteristics of wetland performance.

A review of the data available on wetland stormwater treatment effectiveness revealed that most studies did not contain enough information on study and wetland characteristics to analyze in detail the factors affecting treatment performance among different wetlands. Table 6 presents a summary of the information that would hopefully provide a better means to compare wetland

Table 6. Suggested Reporting Information for Studies That Assess the Ability of Wetlands To Treat Stormwater Pollution

Wetland classification

Constructed or natural or combination wetland?

Vegetation species

Vegetation density (percentage open and vegetated)

Vegetation types (submerged, emergent, floating)

Wetland size

Wetland aspect (length-to-width ratio)

Side slopes

Soil type and depths

Watershed size (acres)

Watershed land use (percent residential, industrial, agricultural, undeveloped, etc.)

Watershed percent impervious (percent impervious area)

Rainfall data/statistics

Average rainfall during study (in./year)

Average number of storms per year

Average storm intensity (in./hr)

Average storm duration (hr)

Average time between storms (days)

Low flow inflow rate(s)

Ground-water interaction?

Total flow from average storm

Wetland volume (maximum storage volume)

Average detention time for average storm (hours)

Water depth (minimum, maximum, average)

Inflow condition (discrete or diffuse inlets)

Pretreatment of inflow (settling forebays, overland flow, detention basin, grassed swales, etc.)

Maintenance practices (including frequency)

Plant harvesting?

Flushing?

Sediment removal?

Chemical treatment?

Other maintenance?

Provide hydrology and water quality data for all storms monitored

Type of samples (grab or composite)

Number of storms monitored

Method used to compute pollutant removal efficiencies

Dominant removal mechanisms (sedimentation, adsorption, filtration, biochemical, etc.)

designs and treatment effectiveness from different wetland systems. This type of information could be useful when comparing watershed to wetland characteristics regarding performance.

This paper compared watershed to wetland size ratios. A comparison of average storm volume to wetland volume would have made a better analysis of the effect of wetland "sizes" on treatment abilities. The currently available data, which predominantly present areas of wetlands and watersheds, did not allow for this kind of comparison. Percent impervious factors and therefore runoff volumes could be very different in different watersheds. Data such as percent imperviousness, land use information, and rainfall statistics, along with wetland volume information, would have allowed us to compare average runoff volumes, wetland volumes, and resulting performance characteristics.

Acknowledgments

The author would like to thank EPA and specifically Thomas Davenport, the project officer, for his support and guidance on the original project. The author gratefully acknowledges the coauthors of the study report on which this paper is based, Joan Kersnar, Eugene Driscoll, and Richard Horner.

Constructed Wetlands for Urban Runoff Water Quality Control

Richard Horner
University of Washington, Seattle, Washington

Abstract

Like all options for urban runoff water quality control, constructed wetlands have their advantages, disadvantages, and limitations. To realize their advantages, avoid problems, and use them appropriately requires recognition and adherence to certain principles. A hallmark of true constructed wetlands is their structural diversity, which yields the substantial advantages of breadth in treatment capabilities and potential for ancillary benefits as well as the disadvantage of larger land requirements for equivalent service than alternative measures. Prerequisites for success are functional objectives for the project to achieve and a corresponding design concept based on the structural characteristics of natural wetlands that are responsible for effective performance of the identified functions. Critical implementation considerations are proper siting, sizing, configuring of design features, construction, and various aspects of operations. Careful site-specific hydrologic analysis must be performed to ensure a sufficient water supply to sustain a wetland. The basis for sizing is limited at present, but application of climatological statistics and existing knowledge of needed hydraulic residence times for given treatment objectives provide some foundation. Equal in importance to planning, siting, and sizing are shaping, contouring, vegetating, and following up with short- and long-term maintenance, for which specific guidance is offered.

Background

Scope

Wetlands specifically constructed to capture pollutants from stormwater runoff draining urban and agricultural areas are gaining attention as versatile treatment options. Several recent major pieces of work have covered constructed wetland treatment, including those by Hammer (1), Strecker et al. (2), Olson (3), and Schueler (4). This paper draws on these resources and is intended to offer a concise summary of the current state of stormwater treatment using constructed wetlands and the methods for developing projects. The paper was derived from a 1-day continuing education course on the subject at the University of Washington, for which a course manual is available (5). In particular, this paper emphasizes the fundamental concepts on which successful application is based.

More than 150 wetlands have been constructed in the United States to treat municipal and industrial, especially mining, wastewaters (2). No complete accounting of stormwater constructed wetlands exists, but their number is certainly fewer.

The two basic types of municipal and industrial systems are both forms of attached growth biological reactors: free water surface (FWS) and subsurface flow (SF), or vegetated submerged bed (VSB) (6). The first type is similar to natural wetlands, with a soil base, emergent vegetation, and water exposed to air. The second type has a soil base overlain by media, emergent vegetation, and a water level below the media surface. The majority of municipal and industrial applications, most of small scale, are of this type. The advantages of a submerged system in these applications are reduced odor, insect problems, and land requirements because of the greater surface area for biological growth offered by the media. The FWS type is generally more appropriate for stormwater applications, where usually no odor problem exists, flows vary widely, and often there is a desire to integrate the treatment system with the landscape and to provide ancillary benefits. This paper covers only the FWS type of system.

Legal and Regulatory Considerations

From a legal and regulatory standpoint, "constructed wetlands" are designed, built, and continually maintained for the purpose of waste treatment. In this status, they are not regarded under the Clean Water Act as "waters of the United States." Accordingly, no regulations apply to water quality within, but the discharge is regulated in the same way as any treatment system.

This designation is in contrast to wetlands built for such purposes as mitigation of wetland losses under Clean Water Act Section 404 or to develop waterfowl habitat, known as "created wetlands." These systems have the same legal protections as natural wetlands, including prohibition on using them for the conveyance or treatment of waste. They usually have multiple functions, with any water quality improvement benefit being only incidental; entering water must be managed to prevent damage to any intended function. A constructed wetland also differs in purpose and legal status from a wetland "restoration," the purpose of which is to return a degraded system with reduced acreage or functional ability to the condition preceding degradation. If the wetland is not completely restored but one or more functions are increased, it is termed an "enhanced wetland." Restored and enhanced wetlands also have the same legal protections as natural wetlands.

A somewhat fuzzy issue with respect to constructed wetlands is their regulatory status if the principal purpose is waste treatment but ancillary benefits (e.g., wildlife habitat) are gained by design or incidentally. This situation is subject to interpretation by state and federal agencies. Such benefits are often among the objectives of project developers and are certainly possible to attain along with stormwater treatment in many circumstances; this paper provides advice on pursuing these objectives in a judicious way.

Constructed Wetlands in Relation to Alternative Methods

Alternatives to constructed wetlands for general-purpose stormwater treatment include wet ponds, extended-detention dry ponds, infiltration basins and other devices that drain into ground water, filtration, and "biofiltration" through terrestrial or hydrophytic plants in swales or on broad surface areas. Constructed wetlands have both advantages and disadvantages relative to these other options. Principal advantages are:

- More diversity in structure than any alternative, which offers the potential for relatively effective control of most types of pollutants.
- Wider range of potential side benefits than any alternative.
- Relatively low maintenance costs.
- Wider applicability and more reliable service than infiltration.

Disadvantages of constructed wetlands include:

- Larger land requirements for equivalent service than wet ponds and other systems, especially if intended to serve quantity as well as quality control purposes.
- Relatively high construction costs.
- Delayed efficiency until plants are well established.
- Uncertainty in design, construction, and operating criteria, a drawback also hampering competitive methods.
- Public concern about nuisances that can develop with stormwater constructed wetlands without care in siting, design, construction, and operation.

Functioning of Constructed Wetlands

Pollutant Removal Mechanisms

Numerous physical, chemical, and biological mechanisms can potentially operate in constructed wetlands to trap and transform entering pollutants. Understanding these mechanisms is the basis for determining effective treatment systems. That understanding can inform the entire process, from conception of the project, through preliminary planning and all phases of implementation, and, finally, to the long-term operation of the system. Table 1 summarizes the various mechanisms, the pollutants that they affect, and features that can promote their operation.

Some beneficial features are controllable through choices made during the project development process, while others are largely outside of the designer's influence, especially in a stormwater application. As can be seen in Table 1, some features are helpful in achieving multiple treatment objectives, but others are more specialized. Features that are largely under the project developer's control and help achieve any objective are 1) increasing hydraulic residence time (HRT); 2) providing an environment that creates flow at a low level of turbulence; 3) propagating fine, dense, herbaceous plants; and 4) establishing the wetland on a medium-fine textured soil, or amending soils to attain that condition.

Somewhat more specialized features, still mostly controllable, include 1) circumneutral Ph, which advances microbially mediated processes such as decomposition and nitrification-denitrification and avoids the mobility of certain pollutants at extreme pH; 2) a relatively low level of toxic substances in the site soils and entering flow, also needed for microbes; and (3) high soil organic content, which advances adsorption and decomposition and can be attained by site selection or soil amendment. Even more specialized are measures that can aid phosphorus capture, one of the most difficult treatment objectives to achieve. High soil exchangeable aluminum and iron contents have been found to enhance phosphorus reduction (7) but would require special soil amendments where naturally lacking, which thus far is an undemonstrated option in a full-scale wetland system. Addition of precipitating agents is an active treatment measure that is difficult to apply in passive

Table 1. Constructed Wetland Pollutant Removal Mechanisms

Mechanism	Pollutants Affected	Promoted By
Physical		
Sedimentation	Solids, BOD, pathogens; particulate COD, P, N, metals, synthetic organics	Low turbulence
Filtration	Solids, BOD, pathogens; particulate COD, P, N, metals, synthetic organics	Fine, dense herbaceous plants
Soil incorporation	All	Medium-fine textured soil
Chemical		
Precipitation	Dissolved P, metals	High alkalinity
Adsorption	Dissolved P, metals, synthetic organics	High soil Al, Fe (P); high soil organics (met.); circumneutral pH
Ion exchange	Dissolved metals	High soil cation exchange capacity
Oxidation	COD, petroleum hydrocarbons, synthetic organics	Aerobic conditions
Photolysis	COD, petroleum hydrocarbons, synthetic organics	High light
Volatilization	Volatile petroleum hydrocarbons and synthetic organics	High temperature and air movement
Biological		
Microbial decomposition	BOD, COD, petroleum hydrocarbons, synthetic organics	High plant surface area and soil organics
Plant uptake	P, N, metals	High plant activity and metabolism and surface area
Natural die-off	Pathogens	Plant excretions
Nitrification	NH_3-N	Dissolved oxygen >2 mg/L, low toxics temperature >5-7°C circumneutral pH
Denitrification	NO_3 + NO_2-N	Anaerobic, low toxics, temperature >15°C

Al = aluminum, BOD = biochemical oxygen demand, COD = chemical oxygen demand, Fe = iron, N = nitrogen, NH_3 = ammonia, NO_2 = nitrite, NO_3 = nitrate, P = phosphorus.

stormwater treatment systems subject to unpredictable and variable flow conditions.

Also outside the control of the designer and operator in a stormwater wetland is exploitation of the nitrification-denitrification processes to achieve nitrogen removal ultimately through evolution of nitrogen gas to the atmosphere. Full operation of the several steps in the bacterially driven processes requires alternating aerobic and anaerobic conditions at favorable temperatures, the first condition to permit oxidation to nitrate and the second to allow nitrate reduction to free N_2 gas. While these processes can be brought under some control in municipal and industrial treatment applications through timing of flow introduction, that degree of management is usually not possible in stormwater cases.

Expected Performance of Constructed Wetlands

Strecker et al. (2) conducted a full literature review of the use of both natural and constructed wetlands for controlling stormwater pollution. This review considered more than 140 papers and reports and assembled detailed information on 18 locations throughout the United States. Median pollutant removals in constructed wetlands were 80.5 percent for total suspended solids (TSS), 44.5 percent for NH_3-N, 58.0 percent for total phosphorus (TP), 83.0 percent for lead (Pb), and 42.0 percent for zinc (Zn). Coefficients of variation (standard deviation/mean) for these contaminants ranged from 27.7 to 56.1 percent, pointing out that both substantially higher and lower performances than median levels were reported. Pollutant reductions in constructed wetlands were overall higher than in natural wetlands, which was attributed to the specific design features and more intensive management of the constructed systems.

Schueler (4) estimated the performance potential of wetlands designed as he recommended based on the overall literature (Table 2). He considered these efficiencies to be provisional pending monitoring of the new systems.

Table 2. Projected Long-Term Pollutant Removal Rates for Wetlands Constructed as Recommended by Schueler (4)

Pollutant	Removal Rate (percent)[a]
TSS	75
TP	45[b]
Total nitrogen (TN)	25[c]
BOC, COD, total organic carbon	15
Pb	75
Zn	50
FC	Two orders of magnitude

[a] Lower by an unknown amount for pocket wetlands (see below for description of wetland types).
[b] 65 percent in pond/marsh system.
[c] 40 percent in pond/marsh system.

The Constructed Wetland Design and Implementation Process

Developing a constructed wetland treatment system should proceed carefully through a number of steps, as follows:

1. Planning the project.

R0015957

2. Selecting the site.
3. Sizing the facility.
4. Configuring the facility, and incorporating design features that promote pollution control.
5. Designing for ancillary benefits.
6. Selecting vegetation and developing a planting plan.
7. Constructing the facility and establishing vegetation.
8. Developing and implementing an operation and maintenance plan.

The remainder of this paper explains these steps.

Project development for a constructed wetland must be a team effort, with a number of skills and specialties represented, including:

- Hydrology
- Water quality
- Soils
- Botany
- Wildlife ecology
- Landscape architecture
- Design engineering
- Construction engineering
- Stormwater facility maintenance

It bears emphasizing that a high level of hydrologic expertise should be employed to ensure that the most essential need—water supply—is met.

Planning and Site Selection

Preliminary Planning Considerations

Constructed wetland projects should be planned systematically and on a watershed scale as much as possible. This comprehensive analysis should start with consideration of management and source control practices that can prevent pollutant release. Another general consideration that should receive attention is the overall place of constructed wetlands and how they can best be used in conjunction with other treatment practices.

If the constructed wetland option is pursued, project objectives should be stated in functional terms, for example:

- The type of protection to be provided to the receiving water, pollutants to be controlled, and levels of control to be achieved (if possible).
- Benefits to be provided in the areas of, for example, open space, aesthetics, and recreation.
- Animals and life stages for which habitat is to be provided.

The potential for constructed wetlands to play a key role in stormwater management has developed from the understanding of natural wetland functioning gained during the past 20 years. Natural wetlands serve their recognized functions, which include providing flood flow control, water quality improvement, and ecological benefits, as a consequence of their structure and the interactions among their component parts. Mimicking these functions in an engineered system can best be done with reference to natural models. Therefore, using nearby natural wetlands as reference models for the configuration and planting of the wetland to be designed is strongly recommended. The reference system(s) should be characterized through formal observations and measurements of its hydrology, water quality, soils, vegetation, and, if appropriate, animal habitat and species. It is not necessary to mimic the reference plant community entirely, but studying it provides an idea of how the constructed system is likely to evolve.

With the natural model(s) in mind, a design concept can be developed. Schueler (4) proposed four basic stormwater wetland designs:

- *Shallow marsh:* A system with a relatively large land requirement that generally is used in larger drainage basins.
- *Pond/Marsh:* A two (or more) cell arrangement with a land requirement that is reduced by a relatively large deep pool.
- *Extended-detention wetland:* A more highly fluctuating hydrologic system in which the land requirement is reduced by adding high marsh to the shallow marsh zone.
- *Pocket wetland:* A design for smaller drainage basins (0.4 to 4 hectares) that may provide insufficient baseflow for permanent pool maintenance and cause greater water level fluctuations.

Figure 1 illustrates the pond/marsh type design. For diagrams of the other designs, see Schueler (4). Table 3 summarizes some of the principal selection criteria for the respective wetland types.

To complete preliminary planning, the design process and its aftermath should be organized. The following list of general principles for project design and implementation, derived from the various comprehensive references cited earlier, provides guidance for these steps:

- Design and implement with designated objectives constantly and clearly in mind.
- Design more for function than for form. Many forms can probably meet the objectives, and the form to which the system evolves may not be the planned one.

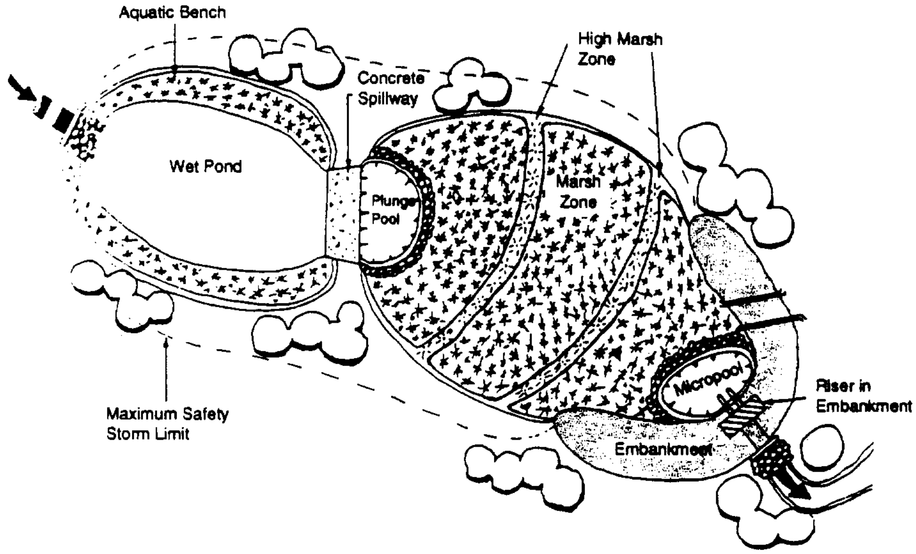

Figure 1. Two-cell pond/marsh design concept (4).

Table 3. Design Concept Selection Criteria (adapted from Schueler [4])

Attribute	Shallow Marsh	Pond/ Marsh	Extended-Detention Wetland	Pocket Wetland
Minimum wetland-to-watershed area ratio	0.02	0.01	0.01	0.01
Minimum watershed area (hectares)	10	10	4	0.4
Dry weather baseflow	Yes	Yes	Not necessarily	Not necessarily
Relative potential for ecological benefits	High	High	Moderate	Low to moderate

- Design relative to the natural reference system(s), and do not over-engineer.
- Design with the landscape, not against it (e.g., take advantage of natural topography, drainage patterns).
- Design the wetland as an ecotone. Incorporate as much "edge" as possible, and design in conjunction with a buffer and the surrounding land and aquatic systems.
- Design in structural complexity for beneficial distribution of water (e.g., its contact with vegetation and soils) and for biological advantages, as appropriate to objectives.
- Design to protect the wetland from potential high flows and sediment loads.
- Design to avoid secondary environmental and community impacts.
- Plan on sufficient time for the system to develop before it must satisfy objectives. Attempts to short-circuit ecological processes by overmanagement usually fail.
- Design for self-sustainability and to minimize maintenance.

Constructed Wetland Site Selection

Prospective constructed wetland sites should be evaluated carefully and a selection made after analyzing a number of conditions. Brodie (8) presented a generalized site screening procedure, which is reproduced in Figure 2. Table 4 summarizes the major considerations that should enter into this analysis. Application of these recommendations implies a significant data-gathering effort, which is essential at this sensitive stage in project development.

The need for a sufficient water supply to sustain a wetland is an especially important consideration; neglect of this consideration has led to constructed and created wetlands that are not viable. Thus, a water balance should be carefully established using the following formula to ensure that water availability and inputs at least balance outputs at all periods throughout the year:

$$I + P + D + S > O + E + R$$

where
I = surface inflow
P = precipitation
D = ground-water discharge

R0015959

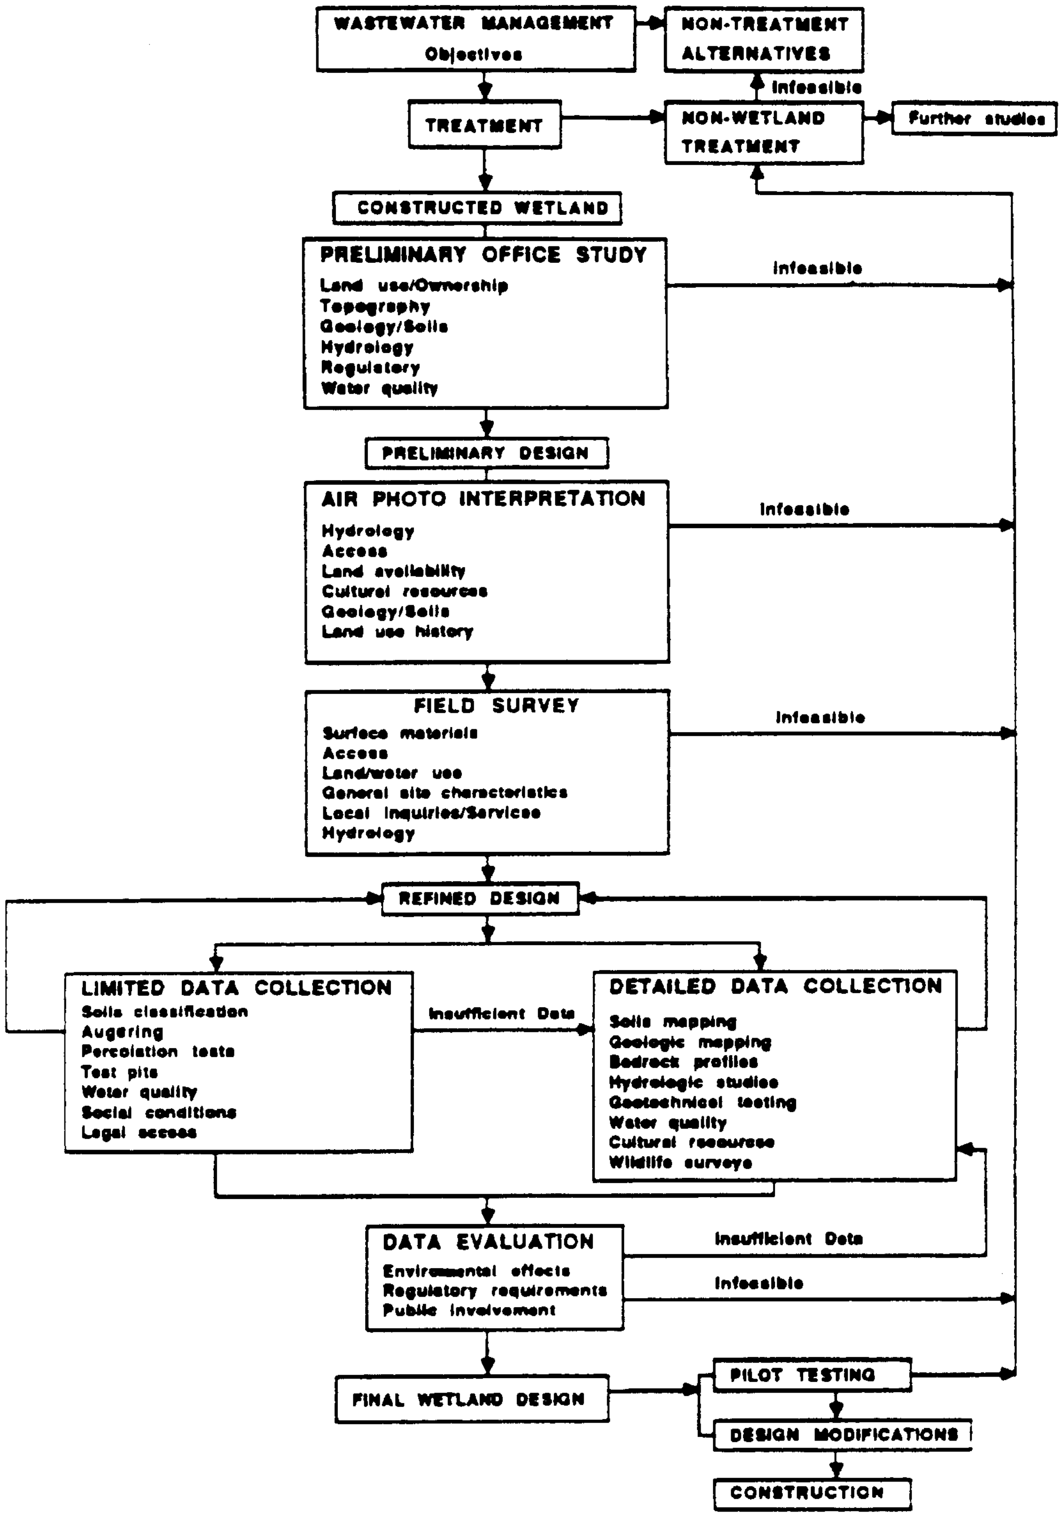

Figure 2. A generalized methodology for screening sites for constructed wetlands (8).

Table 4. Considerations in Constructed Wetland Site Selection

Category	Considerations
Land-use and general factors	Land availability Existing site use and value Site problems (e.g., previous dumping, utility lines) Adjacent land use and value Connection to wildlife corridors and potential for adjacent areas to be biological donors Public opinion Accessibility for construction and maintenance Ability to control public access according to project objectives
Environmental and regulatory factors	Federal, state, and local laws and regulations Avoidance of archaeological and cultural resources Avoidance of critical wildlife habitat areas
Hydrology and water quality factors	Water supply reliability Low potential for disruptive flooding Water supply of adequate quality to sustain biota Low potential for the project to adversely affect downstream water bodies and adjacent properties and their water supplies Need for lining to retain water or avoid ground-water contamination
Geology factors	Preferably flat or gently sloped topography Adequate soil development Sufficient depth to bedrock Soil characteristics consistent with pollution control objectives Suitability of site materials for use in construction

S = wetland storage at beginning of calculation period
O = surface outflow
E = evapotranspiration
R = ground-water recharge

All units are expressed in terms of volume or water depth over the wetland surface.

The water balance should be estimated during site selection and checked after preliminary design. In areas with pronounced seasonal drought (e.g., most of the western United States), the calculation should definitely be performed for this period. Ground-water terms are difficult to establish with assurance, but they should at least be estimated as closely as possible by a hydrogeologist familiar with the location. As demonstrated by the fact that natural wetlands often dry below the soil surface, permanent standing water is not required for a wetland to be viable. Research on natural wetlands in Washington State has found that plant community richness declines substantially when drying extends longer than 2 months, compared to wetlands with shorter dry periods (9). Hence, the water balance should at least demonstrate that drying will never extend longer than 2 months.

Brodie (8) and Mitsch (10) have discussed positioning constructed wetlands in watersheds. Brodie (8) listed advantages and disadvantages of locating wetlands in upper reaches, on slopes, and in lowlands. No single setting is clearly optimal; thus, location from this standpoint depends on project objectives and the relative importance of the advantages and disadvantages at the specific site under consideration. Some possibilities for locating constructed wetlands in the overall landscape include:

- Just off stream channels, for baseflow supply by diversion.
- In stream floodplains, separated from the low-flow channel by a natural levee, with periodic water supplied to the wetland when the levee is topped.
- Several small wetlands in upper reaches of the watershed.
- One large wetland in lower reaches.
- Several small wetlands in lower reaches.
- Terracing into the landscape in steep terrain.

Constructing several small wetlands in the upper watershed provides some advantages relative to locating one large wetland in the lower reaches, such as better survival of extreme events, closer proximity to pollutant sources, and local flood protection. In contrast, the single large lowland wetland can provide overall greater flood reduction capability, if that is an objective. An alternative is the multiple lowland wetland plan, under which each can take a portion of high flows with less vulnerability to any one.

Sizing Constructed Wetlands

Establishing Volume

Possible arrangements of a constructed wetland in relation to runoff quantity and quality control requirements are:

- Place a runoff quantity control device "on line" and a constructed wetland "off line" to treat all runoff up to a certain volume.
- Construct a wetland with a permanent pool ("dead storage") zone for treatment and a "live storage" zone and discharge control sized for peak runoff rate control.
- Construct a wetland only for treatment (for situations where quantity control is not required).

The first arrangement takes advantage of the fact that most of the pollutant mass loading over time is transported by runoff from the more frequent, smaller storms and the "first flush" from the less frequent, larger storms. This is the recommended arrangement where runoff quantity control is required because 1) the relatively shallow depths needed to maintain wetlands are somewhat inconsistent with the large storage volume needed for quantity control and 2) large surges of water can damage the wetland.

Basic sizing decisions involve the dead storage volume, surface area, depth contouring, and live storage volume, if runoff quantity control will be provided. There are three fundamental ways to calculate the treatment volume of a constructed wetland:

- Compute the volume needed to provide the required HRT for achieving a desired effluent concentration of the limiting pollutant (the hardest to remove), given a certain influent concentration, by using a mechanistic equation.
- Compute according to maximum allowable loading rates of water or specific pollutants established empirically from measurements on operating systems.
- Compute on the basis of a hydrologic criterion.

The first two approaches are employed in municipal and mining industry wastewater applications, where parameterized mechanistic equations or allowable loading rates exist for BOD and nitrogen in sewage and iron and manganese in mining effluents (6). Similar relationships do not exist for stormwater and will be difficult to develop, given the variability of flows and pollutant concentrations.

Therefore, stormwater wetland sizing must be determined using some form of the third approach. One version calls for choosing a volume sufficient to hold all runoff from a set percentage of the annual storms (e.g., 90 percent) or to hold a set depth of runoff generated by the contributing catchment (e.g., the first 2.5 cm = 1 in.). Schueler (4) presents several sizing rules of this type. Equivalent to this version is an approach for using a "water quality design storm" of a selected recurrence frequency and duration. The Washington State Department of Ecology (11) has taken this approach, selecting the 6-month, 24-hour rainfall event, which in Seattle is approximately equivalent to the first 3 cm of runoff, for stormwater treatment design in the Puget Sound basin.

A third version of the hydrologic basis is the method developed from wet pond performance data collected during the Nationwide Urban Runoff Program by the U.S. Environmental Protection Agency (EPA) (12). Using this method implicitly assumes that constructed wetlands will perform at least as well as wet ponds of equivalent treatment volume, which seems to be a safe assumption given the treatment advantages offered by a more structurally complex, vegetated system. The data exhibited an association between treatment efficiency and the ratio of permanent pool volume to runoff volume associated with the mean storm, termed the "volume ratio." The mean storm is the average rainfall quantity over all storms in a long-term record at a gaging station. TSS loading reduction is typically around 75 percent at a volume ratio of 2.5, which is a common design basis. Obtaining increasingly better performance levels requires exponentially increasing basin size because the contaminants hardest to capture are those still in suspension or solution.

With this means of sizing constructed wetlands, the task almost entirely involves hydrologic analysis. This is another point at which hydrologic expertise is important to the design effort. Unless actual data are available from gaging the catchment that will contribute to the constructed wetland, the hydrologic analysis must be performed using a model. Modeling options include, in order of preference, a well-calibrated continuous simulation computer model, such as EPA's SWMM and HSPF, an event-based model such as the Soil Conservation Service's curve number method, and, where adequate data exist, a locally derived empirical model of the rational method type.

Once the hydrologic analysis is complete, the permanent pool volume (VP) calculation can be made very simply by using the equation:

$$VP = C * VR * AC$$

where

C = unit conversion factor
VR = runoff volume from hydrologic analysis
AC = contributing catchment area

Schueler (4) recommended a minimum VP of 1.6 cm/ha of contributing catchment area, which will increase the wetland size over that calculated by the equation in small catchments.

This procedure is used for general runoff pollution control purposes. Knowledge is inadequate at present to perform detailed sizing calculations for such specific purposes as control of metals and nutrients. These special objectives can be advanced in part by installing appropriate design features (addressed later in this paper). It is known that the maximum potential to remove dissolved pollutants, which include certain nitrogen and phosphorus forms and some metals, is reached with a long HRT in the dead storage (2 to 3 weeks) (13, 14). The average residence time can be checked as follows: 1) perform the hydrologic analysis to determine the rate of flow to the wetland associated with the mean storm (Q), and 2) calculate HRT = VP/Q. If HRT is less than 2 to 3 weeks and dissolved pollutant removal is an objective, increase VP to obtain HRT in that range.

If the wetland has live storage for peak runoff rate control, the volume of that zone and the discharge orifice size will also have to be calculated. These calculations require hydrograph simulation and routing analysis and are beyond the scope of this paper. They should be performed by a qualified hydrologist.

Permanent Pool Surface Area and Depth Contouring

A larger surface area for the same volume provides better treatment by allowing more light penetration for photosynthetic activity by plants and algae, more aeration for aerobic chemical and biological processes, and a shorter settling distance for particles. A straightforward way of establishing the wetland surface area (AW) is to start by selecting a trial mean depth (D) from the following approximate ranges (after Schueler [4]):

Shallow marsh:	0.30 to 0.45 m
Pond/marsh:	0.60 to 0.85 m
Extended-detention wetland:	0.25 to 0.30 m (permanent pool) 1.0 m (extended-detention zone)
Pocket wetland:	0.15 to 0.40 m

Using the trial mean depth, calculate surface area by AW = VP/D. Determine the wetland to contributing catchment area ratio (AW/AC), and compare it with the guidelines in Table 3.

Once satisfactory basic dimensions are determined, allocate depths to the different wetland zones according to the design concept. Schueler (4) recommended the following zones to obtain diversity in structure and treatment capabilities:

- Deep areas (30 to 180 cm deep, no emergent vegetation)—forebay, micropools, deep water pools, and channels.
- Low marsh (15 to 30 cm below normal pool).
- High marsh (0 to 15 cm below normal pool).
- Irregularly inundated zone (above normal pool).

Schueler went on to supply approximate depth allocations for the various zones and design concepts, and the reader is referred to his guidelines for these details. For example, he recommended allocating 40 percent of the surface area to the high marsh and 40 percent to the low marsh in the shallow marsh design, with 5 percent each given to the forebay, micropools, deep water, and irregularly inundated zones.

Recommended Constructed Wetland Design Features

Adequate size is a necessary but not sufficient condition for good treatment performance. The theoretical HRT provided by the volume will not be achieved in practice if the layout permits water to traverse the wetland faster. Many of the features presented in this section are recommended to reduce the tendency of flow to short-circuit the wetland and fail to achieve an actual HRT as long as the theoretical HRT. Given that natural wetlands generally exhibit the recommended features, the selected reference system(s) should be employed as a model for designing these features. The recommendations are presented here in an abbreviated list format; consult the comprehensive sources referenced earlier for more detail.

Shaping the Wetland

Create a complex microtopography to lengthen the edge and flow path by using high marsh peninsulas and islands. Create at least two distinct cells by restricting the flow to a narrow passageway using the following features:

- Make the wetland relatively wide at the inlet to facilitate distribution of the flow well.
- Maximize the distance between the inlet and outlet.

The effective length to width ratio should be 5:1, preferably, and at least 3:1.

Slopes

The longitudinal slope (parallel to the flow path) should be less than 1 percent.

The wetland should be carefully constructed to have no lateral slope (perpendicular to the flow path) to avoid concentration of the flow in preferred channels, which reduces actual HRT and risks erosion.

Side slopes should be gradual (e.g., 5:1 to 12:1 horizontal to vertical), as in natural wetlands. Nowhere should the side slope be greater than 3:1.

Forebay

A forebay is a relatively deep zone placed where influent water discharges. It traps coarse sediments, reduces incoming velocity, and helps to distribute runoff evenly over the marsh.

Install a forebay in shallow marsh and extended-detention wetlands. In the case of a pond/marsh system, the pond serves this purpose. The restricted size of pocket wetlands generally does not allow for a forebay. Make the forebay 1.2 to 1.8 m deep. The forebay should be a separate cell set aside by high marsh features.

Provide maintenance access for heavy equipment (4.5 m wide and a maximum 5:1 slope) directly to the forebay. The forebay bed should be hardened to prevent disturbance during cleanout.

Flow Channeling

Create sheet flow to the maximum extent possible. Where flow must be channeled, use multiple, meandering channels rather than a single straight one. Intersperse open water areas with marsh, rather than connecting along the flow path. Minimize velocity in channels to prevent erosion and expand habitat opportunities.

Outlet Design

Place a micropool 1.2 to 1.8 m deep at the outlet. Install a reverse-sloped pipe 30 cm below the permanent pool elevation. This outlet design has been found to avoid clogging, to which constructed wetland outlets are prone (4).

Install a drain capable of dewatering the wetland in 24 hours to allow for maintenance. Control the drain with a lockable, adjustable gate valve. Place an upward-facing, inverted elbow on the end of the drain to extend above the bottom sediments.

Soils

Medium-fine textures, such as loams and silt loams, are optimal for establishing plants, capturing pollutants, retaining surface water, and permitting ground-water discharge. Circumneutral pH (approximately 6 to 8) is best for supporting microorganisms, insects, and other aquatic animals.

A relatively high content of highly decomposed organics ("muck") is favorable for plant and microorganism growth and the adsorption of metals and organic pollutants. Muck soils are preferred to peats (less decomposed organics), which tend to produce somewhat acidic conditions, to be low in plant nutrients, and to offer relatively poor anchoring support to plants.

Vegetation becomes established more quickly and effectively in constructed wetlands when soils contain seed banks or rhizomes of obligate and facultative wetland plants. Attempt to obtain any available soils that offer these resources.

Soil characteristics recommended for specific pollution control objectives are:

- High cation exchange capacity—for control of metals.
- High exchangeable aluminum and/or iron—for control of phosphorus.

Liner

An impermeable liner is required when infiltration is too rapid to sustain permanent soil saturation, when there is a substantial potential of ground water being contaminated by percolating stormwater, or both. Infiltration losses are insignificant at most sites with Soil Conservation Service Class B, C, and D soils. Also, sediment deposition is likely to seal the bottoms of constructed wetlands. Generally, therefore, a liner is likely to be needed only in Class A soils.

Emergency Spillway

An emergency spillway is required when the wetland will be used for runoff quantity control (and any other situation in which it would be possible for runoff to enter from a larger storm than the largest storm the facility is sized to handle).

Buffer

A buffer should be provided around the wetland both to separate the treatment area from the human community and, if development habitat is an objective, to reduce the exposure of animals to light, humans, and pets. The buffer requirement can be waived for pocket wetlands without wildlife habitat objectives and adjacent structures. The minimum buffer width should be 8 m, measured from the maximum water surface elevation, plus 5 m to the nearest structure. The buffer should be increased to at least 16 m when developing wildlife habitat is an objective. It should be sloped no more than 5:1 (horizontal to vertical).

Preserve existing forest in the buffer area if at all possible. At least 75 percent of the buffer should be forested to avoid attracting geese and to provide better protection and habitat for other wildlife.

Pretreatment

The constructed wetland is expected to serve as the primary treatment device. Nevertheless, some pretreatment can prevent problems in the wetland, produce a more self-sustaining system, and increase the potential for ancillary benefits. Pretreatment mechanisms that should be considered include:

- Catch basins, for trapping the largest solids.
- A presettling basin or biofilter, when the watershed produces relatively high solids loadings.
- Oil-water separators.

Designing for Ancillary Benefits and Avoidance of Problems

Ancillary Benefits

Potential ancillary benefits of constructed wetlands include:

- Wildlife habitat.
- Aquaculture for harvest.
- Primary production for food-chain support.

- Biological diversity.
- Open space for recreational, educational, and other human uses.

This paper focuses on creating wildlife habitat, which also helps achieve the latter three benefits. The preceding recommendations on configuring the wetland were also designed in part to contribute to these benefits.

An issue, of course, is the attraction of wildlife to a wastewater treatment area that might be contaminated. It is thought, but not proven, that levels of contamination hazardous to wildlife are a relatively rare problem restricted to watersheds with very high vehicle traffic, proportions of impervious surface, and/or population densities. It is also thought that such problems can be addressed at least partially by reversing the recommendations to attract wildlife; that is, install features that discourage wildlife colonization. In either case, a qualified wildlife biologist is needed to design the features. For now, the best course seems to be using and studying constructed wetlands for many applications, but avoiding their use in areas with a high potential for toxic contamination.

The main factor in designing for wildlife habitat is complex structure that provides a variety of possible niches to support feeding, nesting, breeding, and refuge requirements of desired species. Fortunately, many features that promote pollution control also enhance wildlife habitat. Figure 3 illustrates several suggested features for habitat development, and the comprehensive references provide other illustrations.

Following is a summary of features that enhance wildlife habitat drawn from Figure 3 and the references:

- Irregular shorelines.
- A wide range of depth zones—deep zones provide habitat for invertebrates, amphibians, and possibly fish; higher marsh areas offer feeding grounds to birds; and various nesting opportunities are provided in the different zones.
- Perimeter forest buffer at least 16 m wide.
- Connect wetland to corridors (e.g., streams and passages to forests and other wetlands) that allow wildlife movement.
- Increase wetland size if very small—research has shown that wildlife use is not strongly correlated to the size of natural wetlands of 0.5 to several hectares in area (15), but is low in very small natural and constructed wetlands (less than 0.1 hectares).
- Select plants that offer refuge, nesting, feeding, and breeding habitat.
- Install other features providing for nesting and refuge, such as:
  - Islands (protection for ground-nesters) (minimum 3 m^2 for a waterfowl pair, above maximum water surface elevation, densely vegetated, positively drained).

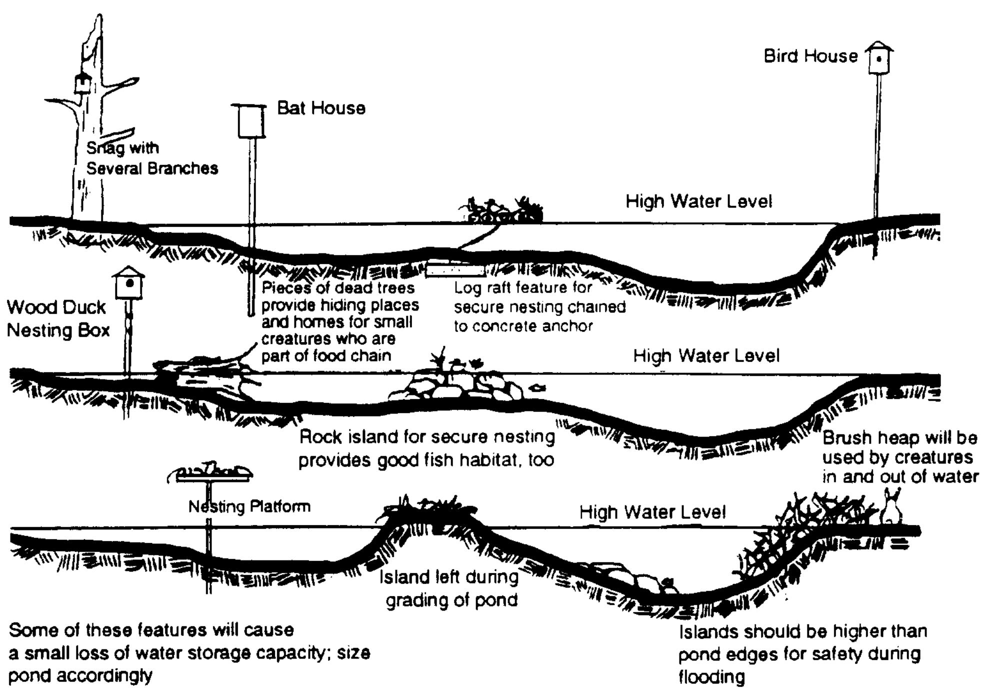

Figure 3. Suggested constructed wetland habitat features (11).

- Snags (dead tree trunks installed for cavity-nesters).
- Nest boxes and platforms (unique designs for cavity-nesters).
- Buffer trees (for foliage-nesters).
- Logs, stumps, and brush (for bird perches and small-mammal refuge).

• Avoiding significant water level fluctuations—this is an inherent disadvantage of stormwater wetlands relative to wildlife. The best remedy is to precede the wetland with runoff quantity control. Otherwise, the configuring recommendations stated earlier provide the best situation obtainable in stormwater applications.

Avoidance of Problems

Potential problems associated with constructed wetlands include:

- Mosquito breeding.
- Aesthetic drawbacks.
- Safety concerns.
- Attraction of geese and ducks, which can constitute a nuisance.
- Development of a monoculture of undesirable vegetation.
- Accumulation of toxicants.

The extent of actual occurrence of these problems and managing to avoid or minimize them is addressed briefly in this paper.

Mosquitoes are actually rarely a problem in well-designed and operated constructed wetlands; thus, education of the concerned public is part of the solution. A problem with mosquitoes can best be prevented by providing diverse habitats that support predatory insects. Mosquito fish *(Gambusia)* have been used successfully to control mosquitoes in permanent ponds, but the introduction of the fish in areas to which they are not native must be carefully assessed.

Aesthetic problems can be avoided with careful attention to construction and vegetation establishment. The buffer and tall emergent vegetation can be used to conceal such wetland characteristics as water level fluctuation and films on the water.

Constructed wetlands are inherently safer than deeper ponds, but some degree of potential hazard to children is associated with deep zones. Hazards can be avoided by establishing gradual side slopes and a shallow marsh safety bench (5 m wide) where the toe of the side slope meets any deep pool, by concealing outlet piping, and by providing lockable access. In general, fencing should only be needed on the embankment above large outfalls, where they exist.

Nuisance waterfowl can be discouraged in several ways. Maintain the buffer largely with forestland (at least 75 percent), and avoid the growth of turf grass around the wetland. Also, maintain a variety of depths, especially high marsh not favored by geese and mallards. Another important measure is to educate citizens and place signs to discourage feeding.

The tendency for wetlands to develop undesirable plant monocultures can be limited by maintaining structural diversity and a range of depths, especially shallower areas. A diverse selection of native flora should be planted shortly after the wetland is constructed.

Regarding toxicant accumulations, evidence suggests that metals and organics are tightly bound in sediments and do not tend to become mobilized over long periods. When maintenance is performed, disposal of spoils becomes an issue. Current knowledge indicates that spoils pass hazardous waste tests and can be safely land applied or landfilled (4). Plan an onsite application area if possible to save costs of disposal.

Vegetation Selection and Establishment

As experience with wetland creation, restoration, and construction projects accumulates, it is becoming increasingly clear that the plant community develops best when the soils harbor substantial vegetative roots, rhizomes, and seed banks. Its development is also enhanced by the opportunity for volunteer species to enter from nearby donor sites; however, volunteers cannot be relied on for vegetation establishment. Transplants may be supplanted by more vigorous resident and volunteer stock under these circumstances and may actually constitute a minor component of the eventual community. Nevertheless, transplanting is generally a wise strategy, and most of the specific guidance available for establishing wetlands concerns this source; thus, it is fully covered below.

Hydric soils containing vegetative plant material collected for establishing new wetlands are becoming known as "wetland mulch." It appears that ample use of this mulch enhances diversity and the speed of vegetation establishment, but the mulch content is somewhat unpredictable and donor sites are limited. Also, guidelines for extracting, handling, and storing the material are limited. A danger with the use of mulch is the possible presence of exotic, opportunistic species that will out-compete more desirable natives. Therefore, at least the donor sites that obviously support such plant species should be avoided in obtaining material. Preferred donor material includes wetland soils removed during maintenance of highway ditches, swales, sedimentation ponds, retention/detention ponds, and clogged infiltration basins and during dredging, or from natural wetlands that are going to be filled under permit (although these soils are best used for mitigating the loss). It is recommended that the upper 15 cm of donor soils be obtained at the end of the growing season, if possible. The best way to hold soils until installation is somewhat uncertain but must include keeping soils moist in conditions that will maintain vital dormancy. Efforts are under way to establish repositories for mulch reclaimed in maintenance operations.

The reliability of transplanting and the instant partial cover it provides make it necessary regardless of the potentials offered by wetland mulch and volunteer species recruitment. Commercial wetland plant nurseries now operate in many places in the nation to provide material. The following list of general vegetation selection principles was compiled from Garbisch's (16) recommendations for creating wetlands and from the comprehensive constructed wetland works:

- Base selections more on the prospects for successful establishment than on specific pollutant uptake capabilities (plant uptake is a highly important mechanism only for nutrients, much of which are released upon the plant's death; nutrient removal is more the result of chemical and microbial processes than of plant uptake).
- Select native species, and generally avoid natives that invade vigorously.
- Use a minimum of species adaptable to the various elevation zones; diversification will occur naturally.
- Select mostly perennial species, and give priority to those that establish rapidly.
- Select species that are adaptable to the broadest ranges of depth, frequency, and duration of inundation (hydroperiod).
- Match the environmental requirements of plant selections to the conditions to be offered by the site. Consider especially hydroperiod and light requirements.
- Give priority to species that have been used successfully in constructed wetlands in the past and to commercially available species.
- Avoid specifying only species that are foraged by wildlife expected to utilize the site.
- Phase the establishment of woody species to follow herbaceous ones.
- Consider planting needs to achieve designated objectives other than pollution control.

Although excessive emphasis on vegetation selection based on pollution control capabilities should be avoided, considerable information on that subject has been compiled. Kulzer (17) prepared a summary of the demonstrated capabilities of plants for the various common classes of pollutants. The most versatile genera that have species representatives in most parts of the nation are *Carex, Scirpus, Juncus, Lemna,* and *Typha.*

Schueler (4) and Garbisch (16) have assembled a considerable amount of specific guidance on the construction and vegetation establishment process for constructed wetlands and created wetlands, respectively. The course manual by Horner (5) also incorporates this guidance. Given the available literature, these topics are not addressed in this paper.

Operating Constructed Wetlands

Relative to retention/detention ponds, constructed wetlands pose a relatively significant routine operating burden. Operated properly, however, they should not require periodic expensive sediment cleanouts. From the outset, the project should include a formal operation and maintenance plan that covers the following elements: 1) inspection, 2) sediment management, 3) water management, and 4) vegetation management.

There are two levels of inspection: routine and comprehensive. Rapid, routine inspections should be made by a qualified observer to identify and take action on any problems that would damage the wetland's function. Recommended scheduling for these inspections is monthly and after each storm totaling more than 1.25 cm (0.5 in.) of precipitation. Comprehensive inspections should take place twice yearly the first 3 years, once in the growing season and again in the nongrowing season. Conditions that should be noted during these inspections include:

- Dominant plants and their distributions in each zone.
- Relative presence of intentionally planted and volunteer invasive and noninvasive species.
- Plant condition—look for signs of disease (yellowing, browning, wilting), pest infestations, and stunted growth.
- Depth zones and microtopographic features compared with the original plan.
- Normal pool elevation compared with the original plan.
- Sediment accumulations (locations and approximate quantities).
- Outlet clogging.
- Buffer condition.

The objective of sediment management is to trap—and when necessary remove—sediments before they reach the shallow zones. Forebays will probably have to be drained and dredged every 2 to 5 years. The pond in a pond/marsh system is, in part, a large forebay and should not need dredging as frequently.

If water levels do no conform to plans, or there is another reason to change them, regulation can be accomplished by installing a flash board at the desired height at the outlet weir or by adjusting the gate valves (if provided). Remove clogging debris from around the outlet as necessary.

In vegetation management, provide extra care during the first 3 years to plantings, especially trees, including watering, supporting, mulching, and removing weeds. Reinforcement plantings will probably be required after 1 or 2 years and should be added as necessary. Manually remove undesirable species with a high potential to invade and dominate, if they will subvert achievement of the designated objectives. Cut or dig out woody, unwanted species in marsh zones before they cause damage and become too difficult to remove.

Harvesting the wetland for nutrient control can be performed but has many drawbacks, including cost, disposal, and damage to the system. It is generally only possible to cut aboveground biomass, which will not adequately control the release of nutrients.

Stormwater Pond and Wetland Options for Stormwater Quality Control

Thomas R. Schueler
Metropolitan Washington Council of Governments, Washington, DC

Abstract

In this paper, 10 designs for stormwater wetland and pond systems used for effective urban runoff quality control are surveyed. Each design is based on a different allocation of deep-pool, marsh, and extended detention storage. The comparative pollutant removal capability of the 10 designs are reviewed based on a national survey of 58 performance monitoring studies. In addition, the reported longevity, maintenance requirements, and environmental constraints of each design is assessed.

A team approach for selecting the most appropriate design at the individual development site is strongly recommended. Key selection factors, such as space, drainage area, and permitability, are discussed. A seven-stage design/construction process is outlined to ensure the team selects and builds the most appropriate and effective design.

The paper points out that the uncertain regulatory status of pond/wetland systems should be resolved so that this effective runoff control technology can be appropriately used.

Introduction

The use of stormwater ponds to control the quality of urban stormwater runoff has become more widespread in recent years. At the same time, designs have become more sophisticated to meet many environmental objectives at the development site. Today, the term stormwater pond can refer to any design alternatives in a continuum that allocates different portions of runoff treatment volume to deep pools, shallow wetland areas, and temporary extended detention storage. This paper provides a broad review of the comparative capabilities of pond and wetland systems.

In an operational sense, these systems can be classified into one of ten categories:

1. Conventional dry ponds (quantity control only)
2. Dry extended detention (ED) ponds
3. Micropool dry ED ponds
4. Wet ponds
5. Wet ED ponds
6. Shallow marsh systems
7. ED wetlands
8. Pocket wetlands
9. Pocket ponds
10. Pond/marsh systems

Table 1. Comparative Storage Allocations for the 10 Stormwater Pond/Wetland Options (% of Total Treatment Volume)

Pond/Wetland Alternative	Deep Pool	Marsh	ED
1. Conventional dry ponds (quantity control only)	0	0	0
2. Dry ED ponds	0	10 (ls)	90
3. Micropool dry ED ponds	30 (f, m)	0	70
4. Wet ponds	80	20 (b)	0
5. Wet ED ponds	50	10 (b)	40
6. Shallow marsh systems	40 (f, m, c)	60	0
7. ED wetlands	20 (f, m)	30	50
8. Pocket wetlands	20 (f)	80	0
9. Pocket ponds	80	20 (b)	0
10. Pond/marsh systems	70	30 (b, m)	0

Note: The storage allocations shown are approximate targets only.
ls = lower stage of ED pond often assumes marsh characteristics
f = forebay
m = micropool
c = channels
b = aquatic bench

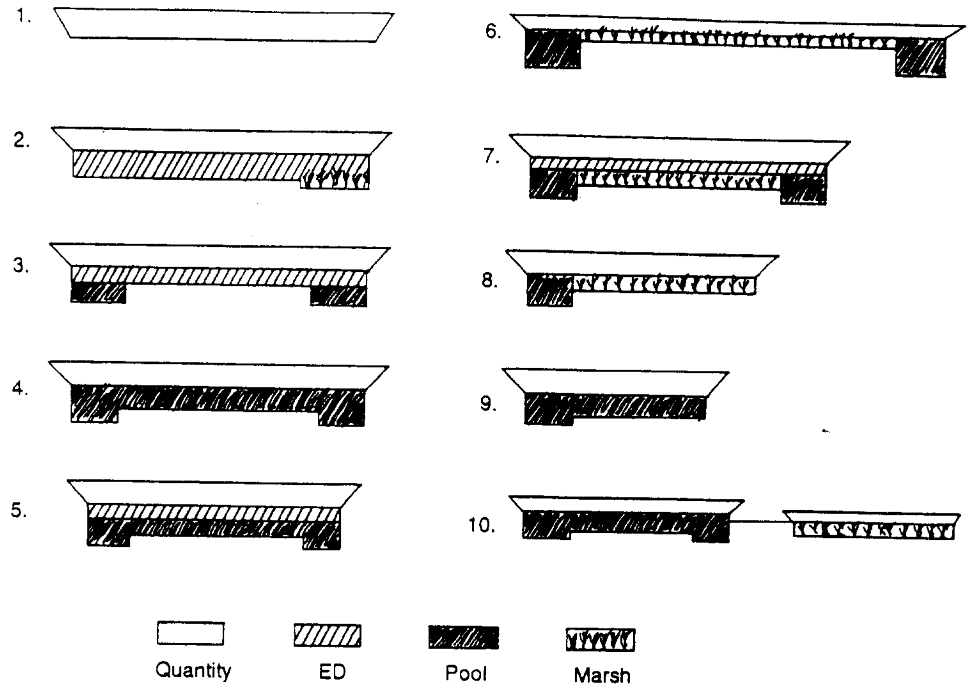

Figure 1. Stormwater pond options.

Each of these designs (shown in cross-sectional view in Figure 1) can be distinguished by how it allocates the total treatment volume to deep pools, shallow wetlands, and temporary extended detention storage. As can be seen, most designs incorporate two and sometimes three runoff treatment pathways. Comparative storage allocations are shown in quantitative terms in Table 1. It is important to note that these allocation targets are approximate and relative, and individual systems may not always conform to the target.

Stormwater pond systems can also be configured in many different ways, as shown in Figure 2. Ponds can be located "on-line" or "off-line" and can be arranged in multiple cells. On-line ponds are located directly on streams or drainage channels. Off-line ponds are constructed away from the stream corridor. Runoff flow is split from the stream and diverted into off-line ponds by a flow splitter or smart box.

The total treatment volume need not be provided within only one cell. Stormwater ponds can contain multiple storage cells, and these often enhance the performance, longevity, and redundancy of the entire system.

All pond designs provide additional storage to control the increased quantity of stormwater produced as a consequence of urban development. This "quantity control" storage is usually defined as the storage needed to keep postdevelopment peak discharge rates equivalent to predevelopment levels for the 2-year storm. The quantity control storage is in addition to, and literally on top of, the quality control runoff storage.

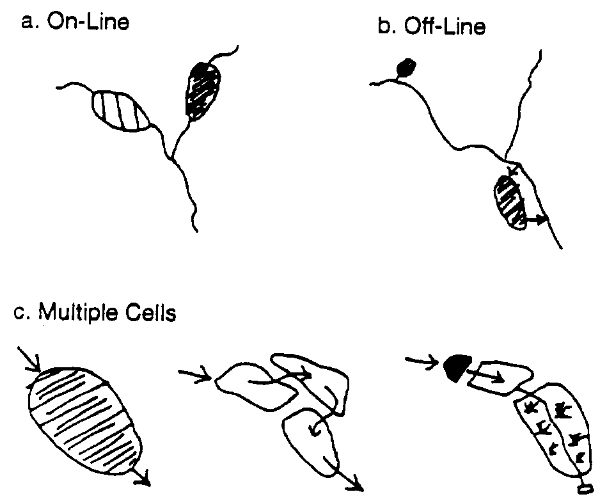

Figure 2. Stormwater pond configurations.

Comparative Pollutant Removal of Stormwater Pond Designs

Each of the three basic treatment volume allocations (pool, marsh, and ED) use different pollutant removal pathways. Therefore, it is not surprising to find considerable variability in the projected removal rates for each of the 10 stormwater pond designs (Table 2). The table is based

R0015970

Table 2. Comparative Pollutant Removal Capability of Stormwater Pond/Wetland Alternatives

	Pollutant Removal Rate			
Pond/Wetland Alternative	**TSS**	**TP**	**TN**	**Reliability**
1. Conventional dry ponds	10	0	0	Moderate
2. Dry ED ponds	30	10	10	Low
3. Micropool dry ED ponds	70	30	15	Moderate (projected)
4. Wet ponds	70	60	40	High
5. Wet ED ponds	75	65	40	High
6. Shallow marsh systems	75	45	25	High
7. ED wetlands	70	40	20	Moderate
8. Pocket wetlands	60	25	15	Moderate (projected)
9. Pocket ponds	60	30	20	Moderate (projected)
10. Pond/marsh systems	80	70	45	High

TSS = total suspended solids
TP = total phosphorus
TN = total nitrogen

on a review of 58 pond and wetland performance studies conducted across the United States and Canada (1).

While seven of the ten pond designs have been monitored in the field, the performance of three designs (pocket ponds, pocket wetlands, and micropool dry ED ponds) can only be projected based on design inferences and field experience.

Two of the pond designs possess limited capability to remove pollutants—the conventional dry pond and the dry ED pond. These pond systems seldom have been observed to reliably remove sediment and have shown virtually no capability to remove nutrients. The performance of dry ED ponds is expected to improve if micropools are added at the inlet and the outlet. Micropools help to pretreat incoming runoff, prevent resuspension, and reduce clogging.

When properly sized and designed, wet ponds can reliably remove sediments and nutrients at relatively high rates. The deep pool of the wet pond allows for gravitational settling. Removal rates for wet ponds can be incrementally improved if the deep pool is combined with extended detention, as in the wet ED pond system.

The removal capability of wetland systems (designs 6, 7, and 8) is generally comparable to that of wet ponds of similar size. Sediment removal often is slightly higher in wetland systems, but nutrient removal appears to be somewhat lower and less reliable. Shallow marsh systems exhibit slightly higher removal rates than either the ED wetland or the pocket wetland systems, which may be explained by the greater surface area and complexity of shallow marsh systems (2).

Ponds and wetlands that do not have a reliable source of base flow, and that have a water level that frequently fluctuates, are termed pocket ponds and wetlands. These systems typically serve very small drainage areas and are excavated to the local water table. Consequently, pocket facilities are often less than a quarter acre in size and possess few of the design features of their larger counterparts. Therefore, pocket wetlands are thought to have lower pollutant removal capability, especially for nutrients.

Pond-marsh systems appear to possess the greatest overall pollutant removal capability of all the designs monitored. The permanent pool and the shallow wetland provide complementary and redundant removal pathways, and reduce remobilization of pollutants.

It should be noted that while differences in removal capability do exist among the 10 designs, other key design factors also must be present if these rates are to be achieved. First, the system must be capable of capturing at least 90 percent of the annual runoff volume delivered. Second, incoming runoff must be pretreated in a forebay or deep pool. Third, the system must meet minimum criteria for internal geometry (flow path, microtopography, surface-area-to-volume ratio). Clearly, a poorly conceived or designed pond system will not achieve the rates shown in Table 2.

Comparative Ability To Protect Downstream Channels

Pond systems that combine ED storage with stormwater quantity storage appear to provide the best measure of protection for downstream channels exposed to the erosive potential of bankfull and subbankfull floods. Recent field research has demonstrated that control of the 2-year storm quantity exacerbates, rather than reduces, downstream channel erosion problems. Modeling studies suggest that extended detention (e.g., 6 to 24 hours) of relatively small treatment volumes may have some potential to alleviate downstream channel erosion problems. Additional field research is needed to confirm the value of ED in protecting channels.

Comparative Physical, Environmental, and Maintenance Constraints

Each of the 10 pond systems are subject to many different constraints that may limit their use at a particular site. Some of the more common constraints are outlined in Table 3.

Physical constraints include available space, climate, dry weather base flow, and contributing drainage area. Maintenance constraints may involve susceptibility to clogging and the frequency and difficulty of sediment cleanout.

Table 3. Comparative Capability of 10 Pond/Wetland Alternatives—Physical, Environmental, and Maintenance Constraints

Pond/Wetland Alternative	Minimum Drainage Area[a]	Space Index[b]	Water Balance	Clogging Risk	Sediment Cleanout	Waters of U.S. (404)	Stream Warming	Safety Risk
1. Conventional dry ponds	5	0.5	No restrictions	Moderate	Basin (10-20 yr)	?	Low	Low
2. Dry ED ponds	10	1.0	No restrictions	High	Basin (10-20 yr)	Yes	Moderate	Low
3. Micropool dry ED ponds	15	1.0	May require base flow	Low	Forebay (2-5 yr)	Yes	Moderate	Low
4. Wet ponds	25+	1.0	Climate	Low	Forebay (2-5 yr)	Yes	High	High
5. Wet ED ponds	25+	1.0	Climate	Low	Forebay (2-5 yr)	Yes	High	High
6. Shallow marsh systems	25+	2.5	Climate, base flow	Low	Forebay (2-5 yr)	Yes	High	Moderate
7. ED wetlands	10+	1.5	Climate, base flow	Low	Forebay (2-5 yr)	?	High	Moderate
8. Pocket wetlands	1-5	2.0	Climate, ground water	Moderate	Basin (5-10 yr)	No	Moderate	Moderate
9. Pocket ponds	1-5	1.0	Climate, ground water	Moderate	Basin (5-10 yr)	No	Moderate	Moderate
10. Pond/marsh systems	25+	1.5	Climate, base flow	Low	Pool (10-15 yr)	Yes	High	High

[a]Maximum of 400 acres in most cases.
[b]Space consumption index (1 = space required for wet pond).

Perhaps the most restrictive constraints, however, are of an environmental nature. Recent research has indicated that on-line pond and wetland systems can have serious impacts on the local and downstream environment, if they are not properly located and designed (2). The most serious include the modification or destruction of high-quality forests and wetlands as a consequence of construction, and downstream warming. Consequently, the siting of ponds and wetlands in the mid-Atlantic region has become a major focus of federal and state regulatory agencies. Presently, both a Section 404 (wetlands) and a Section 401 water quality certification permit must be obtained for the construction of any on-line stormwater pond or wetland.

A Team Approach for Selecting the Most Appropriate System

Selecting and designing a pond system has become a complex and lengthy process. An effective approach is to assemble a design team consisting of a stormwater engineer, landscape architect, environmental consultant, and the construction contractor. The combined expertise of the design team, along with early and frequent coordination with local plan reviewers, is an essential ingredient for implementing the most appropriate system for the development site and the downstream community.

The design team works together throughout the planning, design, approval, and construction process, which can take as long as 2 years. Building an effective and appropriate pond system consists of seven general steps, as outlined below:

1. Evaluation of the Feasibility of the Site

The design team has two major tasks. The first task is to define, in consultation with local planning and resource protection agencies, the primary watershed protection objectives for the particular site and stream. The objectives may include specific targets for pollutant reduction, flood control, channel protection, wetland creation, habitat protection, protection of indicator species (e.g., trout), or preservation of stream corridors. Careful identification of realistic and achievable objectives early in the process is critical for allowing the design team to incorporate them into the design and construction process.

The second task is to analyze the physical and environmental features of the development site to determine if a pond system is feasible, appropriate, and can meet the primary watershed protection objectives. This typically involves a thorough delineation of the wetlands, forests, and catchments within the development, as well as the collection of geotechnical data to define soil properties and water balances. The design team also

R0015972

should assess both the site and downstream aquatic conditions during a site visit.

2. Development of the Initial Concept Plan

The task for the design team in this stage is threefold: 1) select the most appropriate pond design option, 2) identify the most environmentally suitable location for it, and 3) compute the size and geometry of the facility. The design team assembles a concept plan and then submits it to the local stormwater review agency and other regulatory agencies for preliminary review and approval. Early input from the permitting agencies is essential, and a joint field visit is often a useful means of securing it.

3. Development of the Final Design

In final design stage, the team adds engineering details to the concept plan and responds to the comments made by the local permitting authorities. The team works together to ensure that all standard pond design features are incorporated into the final design plans (e.g., benches, forebays, buffers, gate valves). (See Schueler [2] for a full list.) In addition, the plan should be thoroughly analyzed to reduce safety risks, allow for easy maintenance access, provide safe and environmentally sensitive conveyance to the pond, and reduce the future maintenance burden. The final plan is then submitted for review and approval by the appropriate local and state regulatory agencies.

4. Preparation of a Pondscaping Plan

This stage of the design process is critical but frequently overlooked. The design team jointly prepares an aquatic and terrestrial landscaping plan for the pond or wetland, known as a pondscape. It specifies the trees, shrubs, ground cover, and wetland plants that will be established to meet specific functional objectives within different moisture zones in and around the pond.

The pondscaping plan is more than a landscaping materials list, it also specifies necessary soil amendments, planting techniques, maintenance schedules, reinforcement plantings, and wildlife habitat elements needed to establish a dense and diverse pondscape over several growing seasons. Although landscape architects take the lead in the development of the pondscape, other members of the team can provide important contributions. For example, the engineer projects soil moisture zones, the contractor provides practical guidance on tree protection during construction and temporary stabilization, and the environmental consultant provides input on native wetland plants and propagation techniques.

5. Construction of the Pond

Appropriate designs only work when they are constructed properly. Therefore, it is essential to conduct a field meeting with the entire construction crew prior to construction. The design team outlines the purpose of the project, the sequence of construction activities, and walks through the no-disturbance limits. Short but regular meetings to inspect progress are helpful during the construction process, especially to modify decisions in the field. After construction is complete and the pond site is stabilized, the engineer performs an as-built survey for submission to local government authorities that verifies that the pond was constructed in accordance with the approved plans.

6. Establishment of the Pondscape

Establishing a functional pondscape requires frequent adjustment of the original pondscaping plan. Initially, the design team modifies the plan to account for actual moisture conditions and water elevations that exist after construction. The design team then reexamines the pondscape after the first growing season to determine if reinforcement plantings are needed.

7. Inspection and Operation of the Pond

The final stage of the process involves the final inspection of the facility, development of the maintenance practices and schedules, and the transfer of maintenance responsibilities to the responsible party.

Resolving the Regulatory Status of Stormwater Ponds

Although pond and wetland systems are attractive options for urban nonpoint source control, their regulatory status has recently become very confused. This is due to the fact the these systems fall under the scope of three often conflicting sections of the Clean Water Act—Section 401 (water quality certification permits), Section 402 (stormwater National Pollutant Discharge Elimination System [NPDES] permits), and Section 404 (wetland permits). Confusion about these systems also stems from a number of particular factors:

First, pond systems often acquire wetland characteristics over time, whether by design or simply with age. At some point, they may become delineated wetlands, subject to the same protection and restrictions as natural wetlands. If a stormwater pond system does evolve into wetland status, then Section 404 wetland permits may be required and all future maintenance activities conducted on the stormwater pond system would likely require a permit. Conversely, it also is possible that a well-designed stormwater wetland would be eligible for a partial mitigation "credit" when it "evolves" into wetland status.

Second, most pond systems are located on waters of the United States (i.e., intermittent or perennial streams or drainage channels) and are thus subject to the Section 404 permit process, even when the system is not located within a delineated wetland. Some regulators have advocated that the prohibition against "instream treatment" should apply to stormwater pond systems, while others have required that an extensive alternatives analysis be undertaken before a permit is issued. In the former interpretation, the use of stormwater pond systems would be limited to off-line or pocket applications. Under the latter interpretation, the design team might have to demonstrate that all upland best management practice (BMP) alternatives are exhausted before a pond system can be constructed. While upland BMPs are an alternative, they do not possess the performance or longevity of pond and wetland systems and may not be adequate to protect streams or meet pollutant reduction targets.

Third, construction of stormwater ponds and wetlands within or adjacent to delineated natural wetlands can radically alter the characteristics of that wetland, either through excavation, fill, pooling, or inundation. In most cases, construction of stormwater ponds in natural wetland areas is strongly discouraged. In other cases, however, it may actually be desirable to convert degraded natural wetlands into stormwater wetlands. The conditions, if any, where these conversions might take place are the subject of considerable controversy. The influence of stormwater ponds on wetlands need not always be negative, however. In many cases, stormwater ponds can help protect downstream wetlands from degradation caused by uncontrolled stormwater flows and construction-stage sediment deposition.

Fourth, stormwater ponds have a dual nature: They can help to meet water quality standards in receiving waters, while at the same time contributing to possible violations of other standards. For example, ponds can help meet sediment, turbidity, nutrient, and toxics limits. At the same time, they may amplify the stream warming associated with urban development and thus lead to violations of temperature standards in some sensitive streams. This creates a great dilemma for regulators that must perform water quality certification on stormwater ponds.

The resolution of the uncertain and confusing regulatory issues relating to stormwater ponds is critical if application of this effective technology is to continue on a widespread basis. The challenge for designers will be to acknowledge and avoid the potential for negative environmental impact, whereas the challenge for the regulatory community will be to recognize the benefits of stormwater ponds and craft a regulatory policy that is practical rather than merely legal. Otherwise, the fifth member of the pond design team may have to be a lawyer. Hopefully, a workable policy can be developed in the near future that sets guidelines on the appropriate use of this effective nonpoint source control technology.

Practical Aspects of Stormwater Pond Design in Sensitive Areas

Richard A. Claytor, Jr.
Loiederman Associates, Inc., Frederick, Maryland

Abstract

This paper's purpose is to provoke thought in establishing some considerations and techniques for the design of stormwater management ponds in sensitive areas, not to describe a step-by-step process for designing stormwater management ponds. The reader should have a basic understanding of the principles of small pond design, urban hydrology, water quality control, and best management practices.

First, practical design requires an inventory of the sensitive resources that need protection and an estimate of the project goals and potential environmental benefits. The next step is to develop a concept plan, which initiates the design process and ensures agency and public involvement in early stages of the project. Several techniques can be used to avoid or minimize negative impacts on sensitive areas, which this paper groups into techniques for either warm water or cool water environments. In addition, the paper covers three new theoretical techniques that combine warm water design practices with cool water mitigation approaches. Maintenance and monitoring issues are also discussed. Coupling a common sense approach with the need for innovative thinking should be a primary goal, and designers must factor into this challenge the goal of reaching a consensus with different interest groups.

Goals and Expectations

Stormwater management ponds are often installed or constructed to fulfill regulations for the control of urban runoff. Controlling urban runoff usually means providing some kind of detention facility that controls the increased runoff frequency and volume in developing areas.

Good, practical stormwater management requires an assessment of what the pond needs to protect and an estimate of how well pond is likely to work. This involves conducting an inventory of existing natural and constructed features, which then becomes a basis for design considerations. For example, stormwater ponds often need to be located in the lower portion of a site to maximize the area and runoff draining toward them. This can create a conflict with existing, sensitive natural features, such as wetlands, seeps, springs, or even intermittent or perennial streams.

A natural resources inventory, which is essential for design, should at a minimum incorporate the following features:

- Topography
- Wetlands (including springs and seeps)
- Soils
- Floodplains
- Forest lands (vegetation)
- Watercourses
- Specimen trees
- Steep slopes, rock outcroppings, etc.
- Historical or archeological features
- Habitat

After a reasonably detailed natural resources inventory has been conducted, design should continue with an analysis of the receiving stream or ground-water aquifers. This may be very detailed and use various habitat analyses or biological indicators, or it can be a general overview. To pursue a sensitive design approach, however, establishing the type of aquatic resource fisheries (cold water versus warm water) is important.

After establishing the natural resources inventory and assessing what level of aquatic resource protection is warranted, a concept plan should be developed.

Concept Plan Development

One of the most important elements in implementing a successful stormwater management plan is the development of a good concept plan. A concept plan allows various agencies and interest groups the opportunity to offer input at a time when change is reasonably inexpensive. Later in a program, change becomes much more difficult. Many resource protection agencies and special interest groups have conflicting goals, which should be resolved as much as possible in the early stages of the concept plan process so that meaningful projects ultimately become a reality.

One of the key elements of working in an environmentally sensitive area is compromise, but ingenuity is equally important. To advance technology and find different and possibly more successful methods of stormwater management pond design, new techniques should be proposed and implemented, even if unproven.

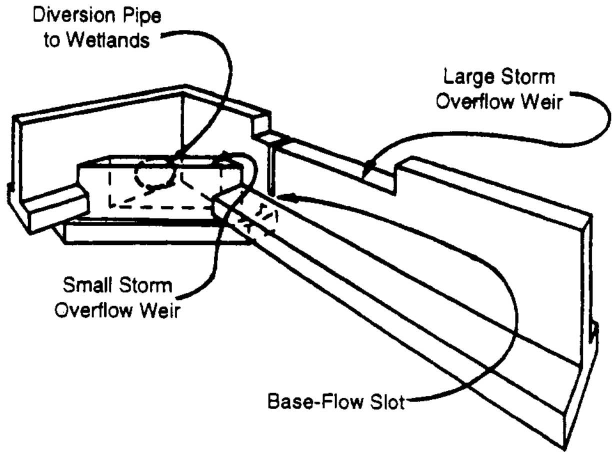

Figure 1. Diversion structure or "flow splitter."

Techniques for Avoiding or Minimizing Impacts to Sensitive Areas

Warm Water Environments

For warm water fisheries, where thermal impacts are not a major consideration, wet ponds (permanent pools of water) represent the most reliable and maintenance-free option for stormwater runoff quality control (1). Several techniques can enhance the pollutant removal efficiency of wet ponds and simultaneously minimize the impact that a large body of water has on surrounding sensitive areas. Some of these techniques are:

- Location of a pond "off-line" from active flowing streams reduces the impact to existing aquatic environment and does not necessarily inhibit fish migration.
- Diversion structures or "flow splitters" provide a technique for conveying both base flow and storm flow away from sensitive areas (see Figure 1).
- Pond grading techniques that provide storage volumes direct impacts away from sensitive areas.
- Pond grading techniques that give curvilinear geometry to the pond can increase flow lengths and decrease ineffective storage areas.
- Pond grading techniques that use shallow aquatic zones, peninsulas and/or islands, and low-lying areas for riparian vegetation provide varied water regimes.
- Incorporating vegetative practices into the design, such as shallow marsh emergent wetlands, submerged aquatic vegetation, and riparian fringe plantings, can create additional wildlife habitats.

Figure 2 depicts a wet pond concept for a warm water environment.

Cool Water Environments

For cool water fisheries, where thermal impacts are a major consideration, a design must attempt to maximize pollutant removal efficiencies but also to reduce and/or offset thermal impacts.

The following are some of the techniques that incorporate these goals:

- The facility should avoid open bodies of water where solar radiation would heat up the water column. Examples in descending order of preference would be infiltration facilities, filtration facilities, dry extended detention ponds, and shallow stormwater wetland ponds (2).
- The location and orientation of the facility should account for the hours of potential solar radiation, such as a north/south dominant orientation.
- Shading of the pool area by maximizing tree canopy can minimize solar penetration.
- Incorporating underdrain and toe drain groundwater collection systems can provide an additional source of cool water release, where available, while implementing an earthen embankment safety consideration.
- Shading and covering a pond's outlet channel helps prevent thermal impacts associated with water running over heated rocks.
- Watershedwide landscaping, including shading of impervious asphalt surfaces, helps reduce thermal loading at the source.

Figure 3 depicts a dry pond concept for a cool water environment.

New Theorized Techniques

New approaches may afford the opportunity to combine the pollutant removal efficiencies of wet ponds with temperature mitigation measures. Three approaches are to:

R0015976

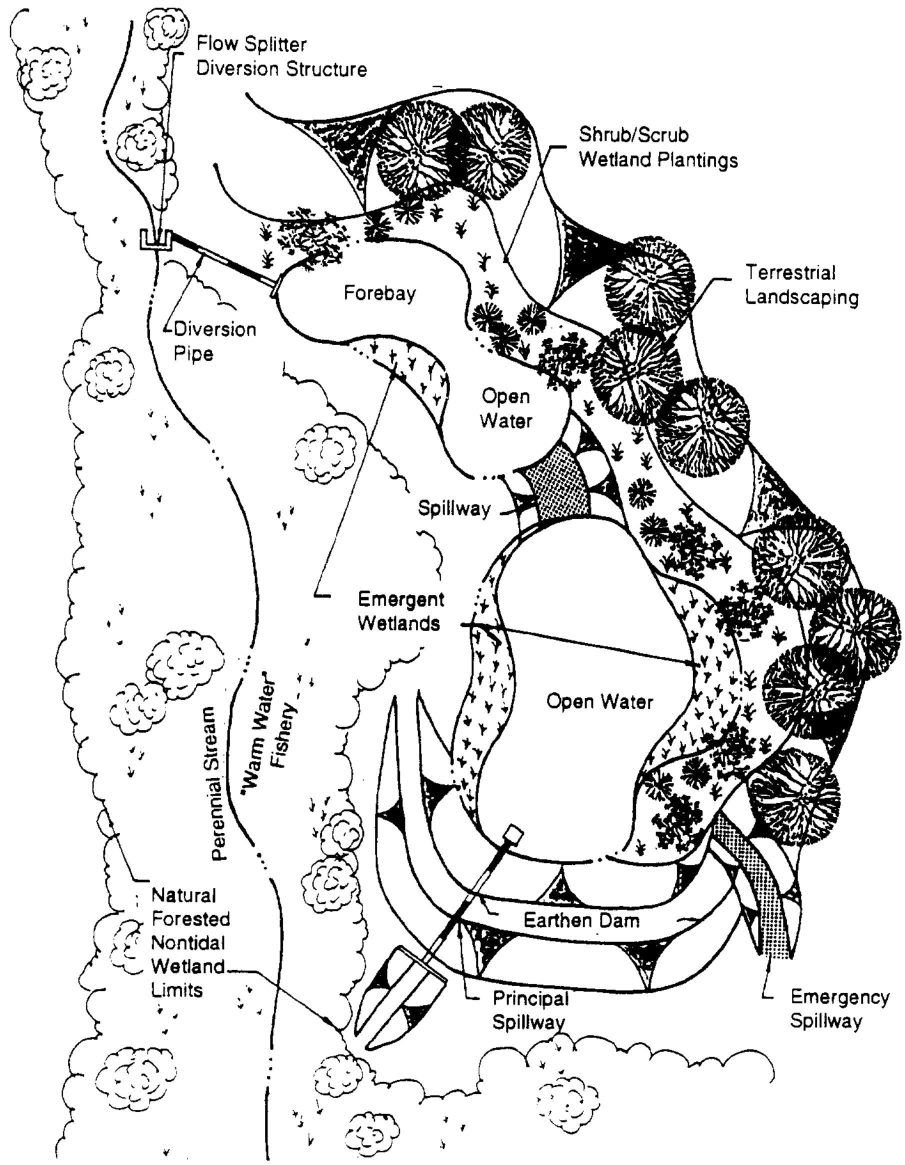

Figure 2. Wet pond concept with diversion structure for warm water environment.

- Incorporate "cooling tower" design practices into the outlet structure of the spillway system (Figure 4) (3).
- Investigate vegetative practices that cover the open water surface of ponds to minimize solar radiation of the water column (4).
- Incorporate a ground-water siphon system into the design of the release structures to siphon ground water as the low flow release (Figure 5) (5).

Maintenance and Monitoring

An effective design cannot become a practical application without a good implementation program, an effective monitoring program, and a maintenance program that keeps a facility functioning at its best. Many of the techniques and considerations previously discussed are new and may not meet expectations. These techniques require short- and long-term monitoring to ensure that they are meeting the expectations of the designer and agency.

In addition, many of the more innovative design approaches require periodic maintenance. It is not practical to assume that these approaches will function without the necessary observations and periodic maintenance. Some of the approaches (e.g., flow splitters) require only periodic trash removal to keep them functioning as designed, while others (e.g., filters and infiltration basins) require a more intensive maintenance program.

Conclusion

In sensitive areas, design approaches need to combine innovative alternatives, common sense, and compromise. Everyone agrees that our sensitive resources

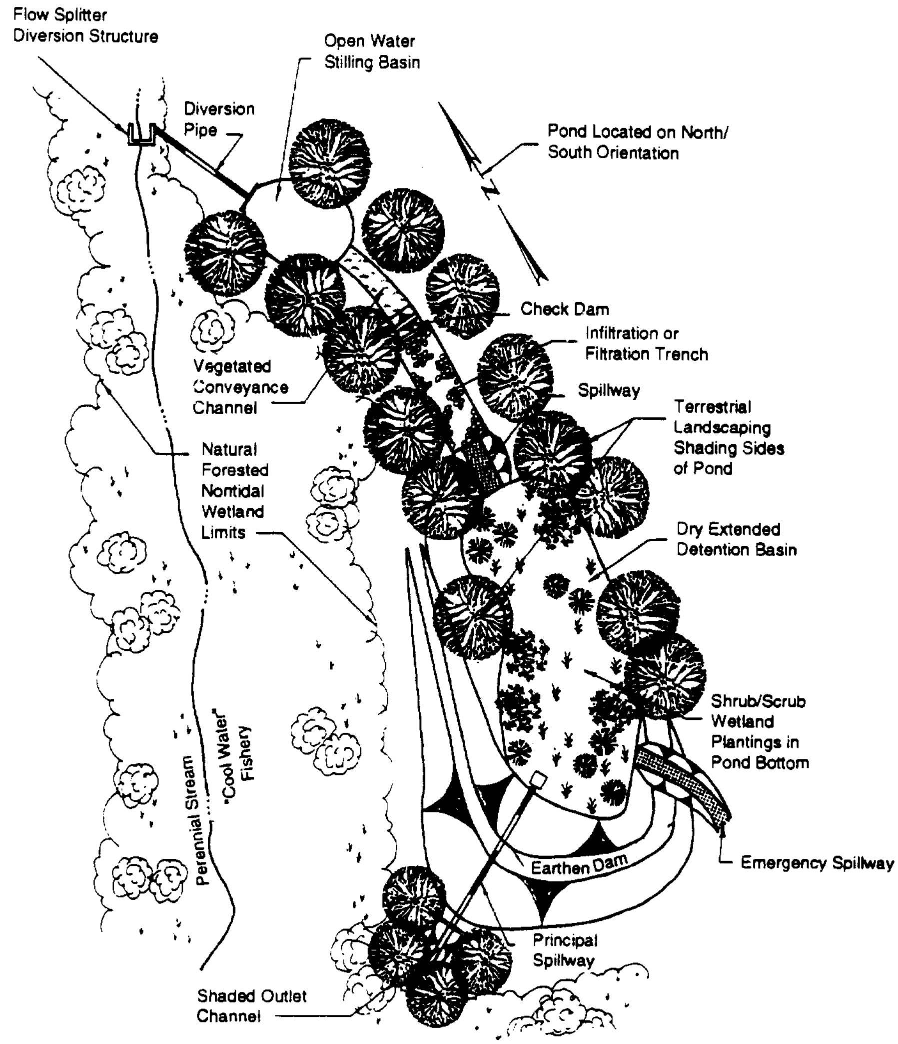

Figure 3. Dry pond concept with diversion structure for cool water environment.

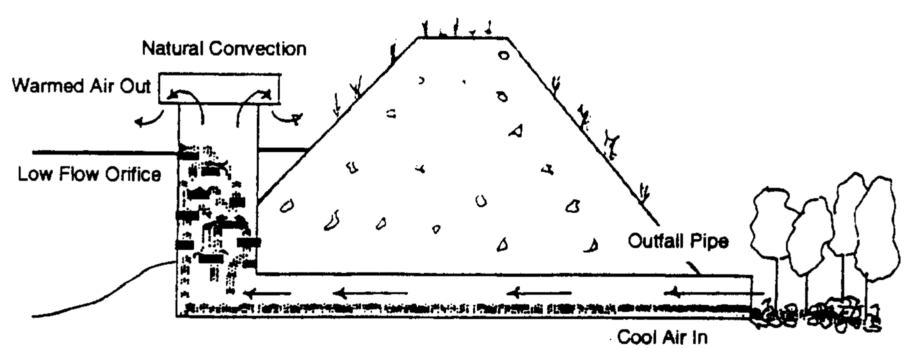

Figure 4. Combination atmospheric and natural draft cooling tower to cool water discharged from a wet pond system (3).

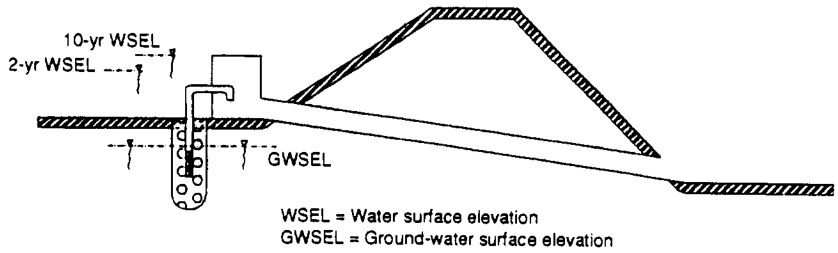

Figure 5. Siphon thermal cooler concept for stormwater management ponds (5).

need special protection and require the utmost care if a disturbance occurs. There is not agreement, however, on the best approaches and on what resources are the most important. Therefore, it is vital to document the existing conditions carefully, prepare flexible concepts and designs, and be prepared to revise plans and design approaches as new information and monitoring results emerge. Practical aspects of stormwater pond design will not remain static but will continue to change as new technologies and techniques advance and older considerations become obsolete.

Infiltration Practices: The Good, the Bad, and the Ugly

Eric H. Livingston
Florida Department of Environmental Regulation,
Tallahassee, Florida

Abstract

Of all the best management practices (BMPs) in the stormwater treatment tool box, infiltration practices are the most effective in removing stormwater pollutants and, equally important, in reducing both stormwater volume and peak discharge rate. This paper explains the concept of on-line and off-line systems, and discusses factors that influence their treatment effectiveness. Design guidelines for infiltration systems, including the importance of the BMP treatment train approach, will be reviewed, focusing on soil types, water table elevation, geology, vegetation, and determination of infiltration rates. Construction considerations will be reviewed. Because of their likelihood for clogging, the importance of regular inspection and maintenance programs is stressed.

Infiltration practices that the paper covers include roadside swales, retention basins, landscape retention, exfiltration systems, infiltration trenches, and porous pavement. For each type of system, information on treatment effectiveness, design criteria, advantages, and disadvantages is presented, along with discussion of the good, the bad, and the ugly. The paper reviews the effect of infiltration practices on ground-water quality and presents recommendations to limit adverse impacts. Special design guidelines for infiltration practices in areas with karst geology, which is characterized by sinkholes, will also be reviewed.

Introduction

To achieve the desired objectives of flood and water quality protection, erosion control, improved aesthetics, and recreation, a stormwater management system must be an integral part of the site planning for every site. Although the basic principles of stormwater management remain the same, each individual site and each specific project presents unique challenges, obstacles, and opportunities. The many variations in climate, soils, geology, ground water, topography, vegetation, and planned land use require site-specific design. Each site contains natural attributes that will influence the type and configuration of the stormwater system.

The variety of features contained on a site suggest which particular combination of best management practices (BMPs) can be successfully integrated into an effective system. Whenever site conditions allow, the stormwater management system should be designed to achieve maximum onsite storage (and even reuse) of stormwater by incorporating infiltration practices throughout the remaining natural and landscaped areas of a site. A stormwater management system should be viewed as a "treatment train" in which the BMPs are the individual cars. Generally, the more BMPs that are incorporated into the system, the better the performance of the treatment train. Inclusion of infiltrative practices as one of the cars should be a primary goal of stormwater system designers.

Infiltration practices are one of the few BMPs that can help to ensure that all four stormwater characteristics (the volume, rate, timing, and pollutant load) after development closely approximate the conditions that occurred before development. This is because infiltration practices help to maintain predevelopment site perviousness and vegetative cover, thereby reducing stormwater volume and discharge rate, which further promotes infiltration and filtering of the runoff.

The benefits of infiltration include:

- Reducing stormwater volume and peak runoff rate.
- Recharging ground water, which helps to replenish wetlands, creeks, rivers, lakes, and estuaries.
- Augmenting base flow in streams, especially during low flow times.
- Aiding in the settling of pollutants.
- Lowering the probability of downstream flooding, stream erosion, and sedimentation.
- Providing water for other beneficial uses.

Another benefit of infiltration practices is their ability to serve multiple uses because they are temporary storage basins. Recreational areas (e.g., ballfields, tennis courts, volleyball courts), greenbelt areas, neighborhood parks, and even parking facilities provide excellent settings for the temporary storage of stormwater. Such areas are not usually in use during periods of precipitation, and the ponding of stormwater for short durations does not seriously impede their primary functions.

Determining Treatment Effectiveness

To design a BMP for water quality enhancement, a pollutant reduction goal must first be established. Stormwater treatment regulatory programs in Florida and Delaware are based on a performance standard of reducing the annual average total suspended solids (pollutant) load by 80 percent for stormwater systems discharging to waters classified as fishable and swimmable. In Florida, stormwater systems discharging to potable supply waters, pristine waters, or highly polluted waters may be required to remove up to 95 percent of the average annual pollutant load. Technology-based performance standards such as these provide water quality goals for nonpoint sources that create equity with the minimum treatment requirements for domestic wastewater point sources (1). Design criteria for various types of stormwater management systems that achieve the desired performance standard (treatment efficiency) are then adopted, thereby providing guidance to the design community and making it relatively easy to obtain a stormwater permit.

The average annual pollutant removal efficiency is calculated by considering the annual mass of pollutants available for discharge and the annual mass removed. The primary removal mechanism for infiltration practices is the volume of stormwater that is infiltrated, because this eliminates the discharge of stormwater and its associated pollutants. As with any type of stormwater management practice, its actual field efficiency depends on many factors. For infiltration practices, these factors include:

- Long-term precipitation characteristics such as mean number of storms per year along with their intensity and volume; average interevent time.
- The occurrence of first flush, which is related to the amount of directly connected impervious area, type of stormwater conveyance system, and the pollutant of interest.
- "On-line" or "off-line" design.

Cumulatively, the above three factors determine the minimum treatment volume and maximum storage recovery time.

The National Weather Service (within the National Oceanic and Atmospheric Administration) has measured weather statistics at many locations around the country. Long-term precipitation records, including information such as day and duration of event, intensity, and volume, are available from either the federal government or private vendors. Statistical analysis of these records can develop probability frequencies for storm characteristics such as the mean storm volume and the mean interevent period between storms.

"First flush" describes the washing action that stormwater has on accumulated pollutants in the watershed. In the early stages of runoff, the land surfaces, especially impervious ones such as streets and parking areas, are flushed clean by the stormwater. This flushing creates a shock loading of pollutants. The occurrence and prevalence of first flush, however, depends largely on precipitation patterns. Studies in Florida have determined that for urban land uses there is a first flush for many pollutants, especially particulates (2, 3). In areas such as Oregon and Washington, however, where rainfall consists of low intensity, long-duration "events," the first flush is not very prevalent. Where it exists, the first-flush effect generally diminishes as the size of the drainage basin increases and the amount of impervious area decreases.

On-line stormwater practices store runoff temporarily before most of the volume is discharged to surface waters. These systems capture all of the runoff from a design storm. This mixes all stormwater within the system, thereby masking first flush and reducing pollutant removal. They primarily provide flood control benefits, with water quality benefits usually secondary, although on-line wet detention systems do provide both benefits.

Off-line practices are designed to divert the more polluted stormwater first flush for water quality treatment, isolating it from the remaining stormwater that is managed for flood control. The diverted first flush is not discharged to surface waters but is stored until it is gradually removed by infiltration, evaporation, and evapotranspiration. Vegetation, such as grass in the bottom and sides of infiltration areas, helps to trap stormwater pollutants and reduce the potential for transfer of these pollutants to ground waters. Off-line retention practices are the most effective for water quality enhancement of stormwater.

Because an off-line retention area primarily provides for stormwater treatment, it must be combined with other BMPs for flood protection to form a comprehensive stormwater management system. Figure 1 is a schematic of an off-line system, commonly referred to as a "dual pond system," in which a smart weir directs the first flush stormwater into the infiltration area until it is filled, with the remaining runoff routed to the detention facility for flood control.

Using the three factors above, design criteria have been developed and implemented in Florida to achieve the

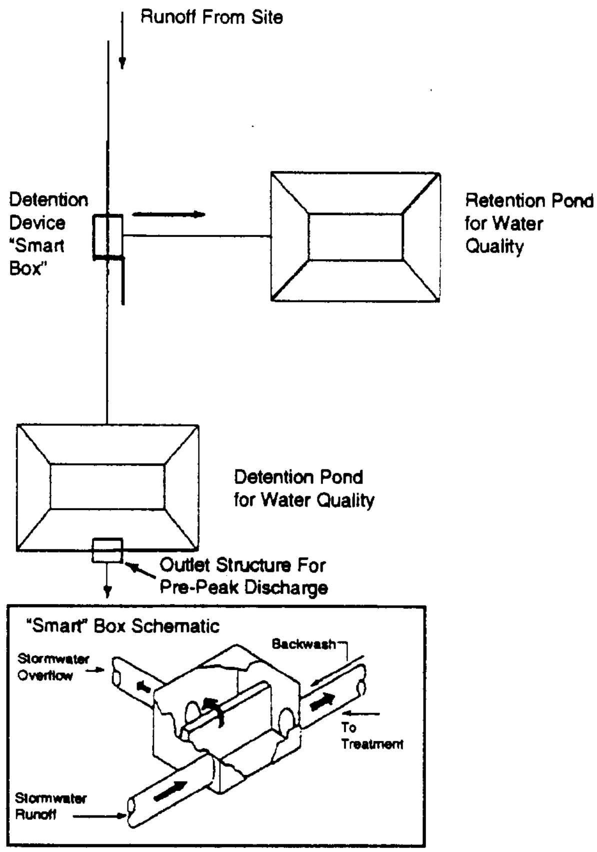

Figure 1. Schematic of an off-line system (4).

desired 80 or 95 percent treatment performance standard (5). The pollutant removal efficiency of an off-line system depends on the annual volume of stormwater that is diverted and infiltrated. For each storm, pollutant removal efficiencies will vary from 100 percent for storms producing less runoff than the diversion design volume to lower efficiencies for much larger storms. If the time between storms is less than the design interevent period, then the design treatment volume will not be available, and more runoff will not be captured and treated. Wanielista (6) developed cumulative frequency distributions for storm-related efficiencies using a simulation model dependent on 20 years of rainfall data and 16 measured storm event runoff quantities and qualities. The results shown in Table 1 are based on Florida rainfall characteristics (90 percent of all annual rainfall events are less than 2.54 cm) and a distinct first flush (up to 90 percent of the pollution load carried in the first 2.54 cm of runoff). An off-line retention system designed to accept at least the first 1.25 cm of runoff (or the volume calculated by 1.25 times the percent imperviousness of the site) will remove more than 80 percent of the average annual pollutant load.

A more recent investigation of the influence of long-term rainfall characteristics on the efficiency of retention practices led to the development of diversion volume curves for interevent dry periods of varying length (7). Figure 2 shows an example diversion volume curve for the Orlando area. It is important to note that first flush is not considered in these curves. If a first-flush effect does exist, the design curves would be conservative in that the percent treatment efficiency of the infiltration system would increase. Furthermore, these curves are based on precipitation interevent frequency (PIF) curves, which also include consideration of the probability that a storm greater than the design storm will occur. The PIF analysis looked at exceedance probabilities for storms with a return period of 2, 3, 4, or 6 months, representing a chance that the storm will exceed the design volume six, four, three, or two times a year.

Table 1. Cumulative Frequency Distributions on Efficiencies per Storm Event as a Function of Storage Volume (Area = 4.6 Ac, 85 percent Impervious, Tc = 20 min)

Average[a] Efficiency	Volume of Storage, centimeters (inches) 0.25 (0.1)	0.64 (0.25)	1.27 (0.50)	2.54 (1.0)
100	35.4	66.4	92.9	99.0
>96	42.5	74.3	97.3	100.0
>92	46.0	77.9	97.4	
>88	47.8	81.4	98.2	
>84	50.4	90.3	100.0

R0015982

Design of Infiltration (Retention) Practices

Infiltration practices also are commonly called retention practices because they retain the runoff on site. They are designed to infiltrate a design volume (treatment volume) of stormwater, and the tool box includes on-line and off-line percolation ponds and trenches, infiltration areas, exfiltration systems, and vegetated swales. Design factors that influence the treatment effectiveness and feasibility of infiltration practices include choice of on-line or off-line system, use of the BMP treatment train concept, and soil type, geology, water table elevation, topography, and vegetation.

Infiltration areas, especially off-line ones, can be incorporated easily into landscaping or open space areas of a site. These can include natural or excavated grassed depressions, recreational areas, and even parking lot landscape islands. If site conditions prevent the exclusive use of infiltration, then off-line retention areas should be used as pretreatment practices in a stormwater treatment train. This is especially true if detention lakes are the primary component of the stormwater system and the lakes are intended to serve as a focal point of the development. Parking lots with their landscape islands offer an excellent opportunity for the use of this concept because even the infiltration of a quarter inch of runoff will greatly reduce sediments, metals, and oils and greases. Placing storm sewer inlets within recessed parking lot landscape areas, raising the inlet a few inches above the bottom, and using curb cuts to allow runoff to enter this area represent a highly effective treatment train.

Siting, Design, and Planning Considerations for Infiltration Practices

The suitability of a site for certain infiltration practices depends on a careful evaluation of the site's natural attributes. Proposed infiltration areas should be evaluated for feasibility on any particular site or project by examining the following.

Soils

Soils must have permeability rates that allow the diverted volume to infiltrate within 72 hours, or within 24 to 36 hours for infiltration areas that are planted with grasses. Soil textures with minimum infiltration rates of 0.43 cm/hr or less are not suitable for infiltration practices (8). These unsuitable soils include soil textures that have at least 30 percent clay content.

Infiltration Rates

One of the most difficult aspects of designing infiltration practices is obtaining reliable information about the actual infiltration rate of the soil where the practice will be constructed. Unfortunately, such information is not easily obtainable. Avellaneda (9) conducted 20 hydrologic studies of vegetated swales constructed on sandy soils with a water table at least 1 ft below the bottom during dry conditions. Infiltration rates were measured using laboratory permeability tests, double-ring infiltrometers, and field mass balance experiments. The field mass balance method measured a minimum infiltration rate of 5 to 7.5 cm/hr. This measured rate was much less than lab permeabilities, rates measured by double-ring infiltrometer tests (12.5 to 51 cm/hr), or rates published in the detailed soil survey. Recommendations for determining the infiltration rate for retention practices include the following:

- Because the infiltration rate is the key to designing any retention practices, conservative estimates should be used and safety factors incorporated into the design to ensure that the design volume will actually be percolated into the soil and not discharged downstream.
- Onsite infiltration measurements must be taken at the locations where retention practices will be located. More importantly, because soil characteristics and infiltration rate change with depth, it is crucial that the measurements be made at the depth of the design elevation of the bottom of the retention practice.
- Infiltration rates should be determined by mass balance field tests if possible. These provide the most realistic estimate of the percolation rate. If field tests are not possible, then infiltrometer tests should be used, with lab permeability tests a third option. In either of these two tests, the design infiltration rate should be half of the lowest measured rate. As a last resort, information from detailed soil surveys can be used to estimated the infiltration rate. The lowest rate should be used, however, as should a safety factor of two.

Water Table

The seasonal high water table should be at least 1 m beneath the bottom of the infiltration area to ensure that stormwater pollutants are removed by the vegetation, soil, and microbes before contacting the ground water. When considering the ground-water elevation, it is important to remember that the retention area can cause a mounding effect on the water table, thereby raising it above the predevelopment level.

Geology

Bedrock should be at least 1 m beneath the bottom of the infiltration area. In those parts of the country where limestone is at or near the land surface, special precautions must be taken when using infiltration practices. The potential for ground-water contamination in such areas is quite high, especially in "karst sensitive areas" (KSAs), where sinkhole formation is common. In KSAs, solution pipe sinkholes may form in the bottom of infiltration areas, creating a direct conduit for stormwater pollutants to enter the ground water. Solution pipes often open in the bottom of retention areas because the natural soil plug capping the solution pipe is thinned by partial excavation to create the retention area and because the stormwater creates hydraulic pressure that can wash out the plug.

In KSAs, a site-specific hydrogeologic investigation should be undertaken that includes geologic borings wherever infiltration areas are proposed and mapping limerock outcroppings and sinkholes on site. Infiltration systems in KSAs should:

- Include several small offsite areas.
- Use swale conveyances for pretreatment.
- Be as shallow as possible.
- Be vegetated with a permanent cover such as sodded grasses.
- Have flat bottoms to keep the stormwater spread out across the entire area.

Topography

Infiltration practices should not be located on areas with slopes over 20 percent to minimize the chance of downstream water seepage from the subgrade. Sloping sites often require extensive cut and fill operations. Infiltration practices should not be sited on fill material because fill areas are very susceptible to slope failure, especially when the interface of the fill/natural soil becomes saturated.

Vegetation

To reduce the potential for stormwater pollutants to enter ground waters and to help maintain the soil's capacity to absorb water, infiltration practices should be vegetated with appropriate native vegetation, especially grasses. This type of vegetation cannot tolerate long-term inundation, however, so the retention area must be capable of infiltrating all of its runoff within a relatively short period (i.e., 24 to 36 hours).

Set Backs

Infiltration areas should be located at least 33 m from any water supply well and at least 3.5 m downgradient from any building foundations. Additionally, they should be set back at least 15 m from onsite wastewater systems, especially drain fields.

Land-Use Restrictions

Certain infiltration practices can only be applied to particular land uses. Some sites are so small or intensively developed that space is insufficient for practices that require a large area (e.g., retention basin). Other practices (e.g., porous pavement) can only be used on sites with parking lots and limited truck traffic.

Sediment Input

Infiltration practices must be protected from large loads of sediment to prevent clogging and subsequent failure. Although sediment loads drop sharply after construction is complete, gradual clogging of infiltration practices can still occur. Pretreatment practices such as swale conveyances or vegetated buffer strips can help to filter out sediments and extend the life of retention practices.

Construction Considerations

To prevent clogging of infiltration areas, special precautions must be taken during the entire construction phase of a project. These are needed to prevent sedimentation during construction, compaction of the soil, and subsequent reduction in its infiltration capacity. Areas with suitable characteristics that are selected for infiltration use should be well marked during site surveying and protected during construction. Heavy equipment, vehicles, and sediment laden runoff should be kept out of infiltration areas to prevent compaction and loss of infiltration capacity.

- Before the development site is graded, the area planned for use as infiltration areas should be well marked during site surveying. Then, the area should be roped off to prevent heavy equipment from compacting the underlying soils.
- Diversion berms should be placed around the perimeter of the infiltration area during all phases of construction. Sediment and erosion control plans for the site should be oriented to keep sediment and runoff completely away from the area. Actual construction of the infiltration practice should not begin until after the site has been stabilized completely.
- Infiltration areas should never be used as a temporary sediment basin during the construction phase. It is somewhat common for infiltration areas, especially basins, to be used as a sediment trap, with initial excavation to within 2 ft of the final design elevation of the basin floor. Sediment that accumulates during the construction phase can then be removed when the basin undergoes final excavation after the development has been completed. Recent experience, however, indicates that even with this type of construction practice infiltration areas used as sediment traps tend to fail.
- Infiltration areas/basins should be excavated using light earth-moving equipment with tracks or oversized tires. Normal rubber tires should be avoided because they compact the subsoil and reduce its infiltration capabilities. For the same reason, the use of bulldozers or front-end loaders should be avoided. Because some

compaction of the underlying soils is still likely to occur during excavation, the floor of the basin should be deeply tilled with a rotary tiller or disc harrow.

- The basin should be stabilized with vegetation within a week after construction. Use of low maintenance, rapid-germinating grasses such as fescues are recommended. The condition of the newly established vegetation should be checked several times over the first 2 months and any necessary remedial actions taken (e.g., reseeding, fertilization, and irrigation).

Maintenance

All infiltration practices require regular and nonroutine maintenance to maintain their ability to infiltrate stormwater. The frequency and need for maintenance depends primarily on the loading of particulates and the use of pretreatment practices. Inspections should be conducted on a regular basis after storm events, and maintenance activities should be conducted whenever stormwater remains in the practice beyond the designed time. Specific maintenance needs are discussed for each of the different types of infiltration practices in the next section.

Discussion of Various Infiltration Practices

Infiltration Basins

An infiltration basin is made by constructing an embankment or by excavating in or down to relatively permeable soils. The basin temporarily stores stormwater until it infiltrates through the bottom and sides of the system. The infiltration "basin" can actually be a landscape depression within open spaces, even parking lot islands or a recreational area such as a soccer field. Infiltration areas generally serve drainage areas ranging from 2 to 20 hectares. Infiltration basins should be designed as off-line systems but they can be on-line, especially if predevelopment stormwater volume is being maintained.

Advantages of infiltration basins are that they preserve the natural water balance of a site, can serve larger developments, and can be integrated into a site's landscaping and open spaces. Disadvantages of infiltration basins can include their land area; fairly high rate of failure due to unsuitable soils, poor construction, or lack of maintenance; the need for frequent maintenance; and possible nuisances such as odors, mosquitos, or soggy ground (all signs of a failing system).

The function of infiltration basins can be improved if the following design tips are followed:

- *Basin floor and sides:* The rate and quantity of infiltration are enhanced by increasing the surface area of the bottom. Large, relatively shallow areas are preferable, especially in KSAs, so that the stormwater spreads evenly over the entire surface area. Therefore, it is very important that the bottom be evenly graded with a zero slope. If the bottom is uneven, these low spots will remain underwater for a longer time and may become chronically wet as the floor clogs and infiltration is reduced. Side slopes should be no steeper than 3:1 to allow for vegetative stabilization, easier mowing and access, and better public safety.
- *Vegetation:* The side slopes and bottoms of infiltration areas should be vegetated with a dense turf of water-tolerant grass immediately after construction. Not only does the vegetation stabilize these areas, but it also helps to filter stormwater pollutants, remove dissolved nutrients and metals, enhance aesthetic qualities, reduce maintenance needs, and even maintain or improve infiltration rates.
- *Reducing incoming water velocities:* Inlets to an infiltration area should be stabilized to prevent inflowing runoff velocities from reaching erosive levels and scouring the bottom. Riprapping inlet channels or pipe outfalls and using bubble-up inflow devices or perimeter swale and berms can address this problem. Because the stormwater should spread evenly over the entire infiltration area, riprap inlets should terminate in a broad apron that serves as a crude level spreader.
- *Construction requirements:* Proper construction and routine maintenance as discussed above are essential for successful infiltration basin implementation. In a recent survey, approximately 40 percent of the infiltration basins had partially or totally clogged within their first few years of operation (10). Many of the systems failed almost immediately after construction or never worked properly from the beginning.
- *Routine maintenance requirements:* Infiltration areas should be inspected following major storms, especially in the first few months after construction. If stormwater remains in the system beyond the design drawdown time (typically 24 to 36 hours if grassed, 48 to 72 hours if not grassed), either the infiltration capacity was overestimated or maintenance is needed. Factors responsible for clogging may include upland erosion and sedimentation, low spots, excessive compaction, or poor soils. Cleaning frequently depends on whether the basin is vegetated or nonvegetated and is a function of storage capacity, sediment and debris load, and land use. Litter, leaves, brush, and other debris should be removed regularly, perhaps during the mowing of vegetation. The buffer, side slopes and bottom of the retention area should be mowed as needed, with the grass clippings removed. Eroded or barren areas should be immediately revegetated. Nonvegetated basins can be tilled annually after accumulated sediments are removed. Sediments should be removed only after the basin is thoroughly dry, preferably to the point where the top

layer begins to crack. To reduce soil compaction, only light equipment should be used.

- *Nonroutine maintenance requirements:* Over time, the original infiltration capacity of the bottom will gradually decline. Deep tilling every 5 to 10 years can be used to break up clogged surface layers, followed by regrading, leveling, and revegetation. If the original infiltration rate was overestimated, underdrains may be installed beneath the bottom, or perhaps the system should be converted to a shallow marsh or wet detention system.

Infiltration Trenches

An infiltration trench generally consists of a long, narrow excavation, ranging from 1 to 3 m in depth, that is backfilled with stone aggregate, allowing for the temporary storage of the first-flush stormwater in the voids between the aggregate material. Stored runoff then infiltrates into the surrounding soil. To minimize clogging potential and maximize treatment effectiveness, infiltration trenches should always be designed as off-line systems. Infiltration trenches usually are designed to serve drainage areas of 2 to 4 hectares and are especially appropriate in urban areas where land costs are prohibitive. As with any infiltration practice, the treatment train concept must be employed to capture sediment before it enters the trench to minimize and reduce clogging.

Advantages of infiltration trenches include ground-water recharge, reduced stormwater volume, and the ability to fit into perimeters or other underused areas of a development, even beneath parking areas. Disadvantages include potential clogging, especially if sediment is not kept out during construction, the need for careful design and construction, and maintenance.

Infiltration trenches can be located on the surface or below the ground. Surface trenches receive sheet flow runoff directly from adjacent areas after it has been filtered by a grass buffer. Underground trenches can accept runoff from storm sewers but require use of special pretreatment inlets to prevent coarse sediment, soils, leaves, and greases from clogging the stone reservoir.

Surface trenches typically are used in residential areas where smaller loads of sediment and oil can be trapped by grass filter strips that are at least 6 m wide. While surface trenches may be more susceptible to sediment accumulations, their accessibility makes them easier to maintain. Surface trenches can be used in highway medians, parking lots, and narrow landscape areas.

Underground trenches can be applied in many development situations and are particularly suited to accept concentrated runoff; however, pretreatment is essential. Inlets to underground trenches should include trash racks, catch basins, and baffles to reduce sediment, leaves, debris, and oil and grease. Maintenance of underground trenches can be very difficult and expensive, especially if placed beneath parking areas or pavement.

The most commonly used underground trench is an exfiltration system, in which the stormwater treatment volume is diverted into an oversized perforated pipe placed within an aggregate envelope. The first-flush stormwater is stored in the pipe and exfiltrates out of the holes, through the gravel and filter fabric, and into the surrounding soil. The city of Orlando, Florida, has installed exfiltration systems using perforated corrugated metal pipe and slotted concrete pipe throughout the downtown area to reduce stormwater pollution of its lakes.

Dry wells are used extensively in Maryland to store and infiltrate runoff from rooftops. The downspout from the roof gutter is extended into an underground trench, which is constructed at least 3 m away from the building foundation. Rooftop gutter screens are used to trap particles, leaves, and other debris. Additional design information on dry wells is available from the Maryland Department of the Environment (11).

The following design and construction guidelines are provided for infiltration trenches.

Infiltration Rates

The actual rate at which water leaves the infiltration trench is determined by several factors. Whether infiltration primarily occurs through the trench bottom or sides depends on the elevation of the water table and soil properties. To prevent ground-water contamination, trench bottoms should be at least 4 ft above the seasonal high water table (remember to consider ground-water mounding). This will also ensure infiltration through the bottom. In addition to the infiltration rate of the parent soil, the permeability of the surrounding filter fabric (if used) is crucial and can become a limiting factor. A recent investigation of exfiltration systems (12) provides the following:

- Permeability of the parent soil is not the limiting exfiltration rate.
- The limiting exfiltration rate is set by the geotextile filter fabric, not the soil.
- A maximum rate of 1.27 cm/hr should be used, assuming infiltration through the sides and bottom.
- A maximum rate of 2.54 cm/hr should be used if the geotextile filter fabric is matched correctly to the soil type and only the trench side areas are assumed to exfiltrate.

Construction of Infiltration Trenches

Successful use of infiltration trenches requires thorough site planning and evaluation and proper construction. In addition to the construction recommendations for all infiltration practices discussed above, the construction of infiltration trenches should also include the following:

- Excellent erosion and sediment control should be maintained during construction to keep sediments away from the trench. Allowing even an inch or two of soil to get into the trench between the aggregate and the fabric will almost ensure clogging. If constructed before the drainage area is entirely stabilized, then the trench should be covered with heavy plastic to prevent any inflow until stabilization is completed.
- The trench should be excavated using a backhoe or trencher equipped with tracks or oversized tires. Normal rubber tires should be avoided because they compact the subsoil and may reduce infiltration capability. For the same reason, the use of bulldozers or front-end loaders should be avoided. Excavated material should be stored at least 3 m from the trench to avoid backsliding and cave-ins.
- Once the trench is excavated, the bottom and sides should be lined with a geotextile filter fabric to prevent upward piping of underlying soils. The fabric should be placed flush with the sides and bottom, with a generous overlap at the seams. Care should be taken in selecting the proper kind of filter fabric, as available brands differ significantly in their permeability and strength. The geotextile fabric must be handled carefully to prevent holes and tears that allow soil to get into the trench. As an alternative, a 15-cm deep filter of clean, washed sand may be substituted for filter fabric on the bottom of the trench.
- Clean, washed 2.5- to 7.5-cm stone aggregate should be placed in the excavated reservoir in lifts and lightly compacted with plate compactors to form the coarse base. Unwashed stone has enough associated sediment to pose a risk of clogging at the soil/filter cloth interface. Where possible, the use of limestone or bluestone aggregate should be avoided.
- A simple observation well should be installed in every trench. Wells can be made of secure foot plate, perforated polyvinyl chloride pipe, and locking cover. The observation well is needed to monitor the performance of the trench and is also useful in marking its location. The drain time for a trench can be measured by placing a graduated dipstick down the well immediately after a storm and again 24, 48, and 72 hours later.
- Postconstruction sediment control is critical. It is therefore important that 1) sediment and erosion controls be inspected to make sure they still work, 2) vegetated buffer strips are established immediately, preferably by sodding, and 3) if hydroseeding is used, reinforced silt fences are placed between the buffer and trench to prevent sediment entry before the buffer becomes fully established.

Maintenance of Infiltration Trenches

If properly constructed with pretreatment practices to prevent heavy sediment loading, infiltration trenches can provide stormwater benefits without tremendous maintenance needs. Because trenches are "out of sight, out of mind," getting property owners to maintain them can be difficult. Accordingly, a public commitment for regular inspection of privately owned trenches is essential, as is a legally binding maintenance agreement and education of owners about the function and maintenance needs of trenches.

Trenches should be inspected frequently within the first few months of operation and regularly thereafter. Inspections should be done after large storms to check for water ponding, with water levels in the observation well recorded over several days to check drawdown. Grass buffer strips should maintain a dense, vigorous growth of grass and receive regular mowing (with bagging of grass clippings) as needed. Pretreatment devices should be checked periodically and sediment removed when the sediment reduces available capacity by more than 10 percent.

Swales

Swales, or grassed waterways, are one of the oldest stormwater BMPs, having been used along streets and highways and by the farmer for many years. By definition, a swale is a shallow trench that:

- Has side slopes flatter than 3 ft horizontal to 1 ft vertical.
- Contains contiguous areas of standing or flowing water only following a rainfall.
- Is planted with or has stabilized vegetation suitable for soil stabilization, stormwater treatment, and nutrient uptake.
- Is designed to take into account the soil erodability, soil percolation, slope, slope length, and drainage areas so as to prevent erosion and reduce stormwater pollutants.

Traditionally, swales have been and are used primarily for stormwater conveyance; as such, they are considered an on-line practice. The removal of stormwater pollutants by swales can occur by either infiltration or vegetative filtration and uptake. Investigations in Florida (13, 14) have concluded that swale treatment efficiency largely depends on the volume of stormwater that can be infiltrated through the filtering vegetation and into the soil. To achieve Florida's performance standards, swales must be designed to infiltrate the runoff from a 3-yr/1-hr storm (about 7.5 cm) within 72 hours. Investigations in Washington state (15, 16), however, indicate that swales can also act as a biofilter, with removal of particulate pollutants without infiltration of stormwater.

Avellaneda (9) developed the following equation for a triangular shaped swale to estimate the length of swale necessary to infiltrate the design runoff volume:

$$L = \frac{KQ^{5/8} S^{3/16}}{n^{3/8} i} \qquad (1\text{–}1)$$

where:

L = swale length (m)
n = Mannings roughness coefficient
Q = average runoff flow rate (m^3/sec)
i = infiltration rate (cm/hr)
S = longitudinal slope (m/m)
K = constant that is a function of side slope (see Table 2)

For most residential, commercial, and highway projects, the length of swales necessary to percolate the stormwater needed to achieve the 80 percent performance standard was found to be excessive or at least twice the distance available. Thus, some type of swale block (berm) or on-line detention/retention may be more helpful. Swales make excellent pretreatment practices by providing for the infiltration of some stormwater and for some vegetative filtration. By using a raised stormsewer inlet, swales can provide water quality enhancement via retention and still serve as effective conveyances for flood protection. Swales can incorporate retention by using swale blocks, small check dams, or elevated driveway culverts to create storage, thereby reducing runoff velocity, reducing erosion, and promoting infiltration.

Using the runoff from 7.5 cm of rainfall as a design treatment volume, equations have been developed for swale block designs to store and infiltrate the runoff (17).

Table 2. Constant (K) for Design Equation for Triangular Shape

Z (Side Slope) $\left(\frac{\text{1 Vertical}}{\text{Z Horizontal}}\right)$	K (U.S. Units)	K (SI Units)
1	10,516	75,552
2	9,600	68,971
3	8,446	60,680
4	7,514	53,984
5	6,784	48,740
6	6,203	44,565
7	5,730	41,167
8	5,337	38,344
9	5,006	35,966
10	4,722	33,925

The swale block volume can be calculated for a fixed length of swale using:

Volume of runoff – volume infiltrated = swale block volume

$$Q(\Delta t) - Q_i(\Delta t) = \text{swale block volume}$$

$$Q(\Delta t) - \left[\frac{L n^{3/8} i}{K S^{3/16}}\right]^{8/5} (\Delta t) = \text{swale block volume} \qquad (1\text{–}2)$$

where

Q_i = average infiltration rate (m^3/sec)
Δt = runoff hydrograph time (sec)

Wanielista and Yousef (18) present the following example problem using Equations 1 and 2 for designing a swale with cross blocks to satisfy a specific water quality goal:

Given

n = 0.05
i = 7.5 cm/hr
S = 0.0279
z = 7
Q_i = 0.0023m^3/sec for Δt = 100 min

what swale length would be necessary to percolate all the runoff?

Using Equation 1,

$$L = \frac{41{,}167\,(0.0023)^{5/8}\,(0.0279)^{3/16}}{(0.05)^{3/8}\,7.5} = 193 \text{ meters.}$$

If only 76 m is available, how much storage volume is necessary?

Using Equation 2,

$$(0.0023)(60)(100) - \left[\frac{(76)(0.05)^{3/8}(7.5)}{41{,}167(0.0279)^{3/16}}\right]^{8/5} 60(100) = \text{volume,}$$

and the volume of storage is equal to 10.7 m^3.

In highway designs for high-speed situations, safety must be considered; thus, a maximum depth of water equal to 0.5 m (about 1.5 ft) and flow line slopes on the berms of 1 vertical/20 horizontal are recommended. Along lower speed highways or in some residential/commercial urban settings, steeper flow line berm slopes (1/6) are acceptable.

The studies of swales in Washington state resulted in the following recommendations to improve water quality benefits (15):

- Maximum design velocity should not exceed 27 cm/sec.
- A hydraulic residence time of at least 9 min is recommended for removal of about 80 percent of the total suspended solids. Longer residence times will provide higher removal effectiveness.
- Swale width should be limited to 2 to 2.5 m unless special measures are provided to ensure a level swale bottom, uniform flow spreading, and management of flows to prevent formation of low-flow channels.
- Swale slopes should be between 2 and 4 percent.
- Water depth should be limited to no greater than one half the height of the grass, up to a maximum of 7.5 cm.
- Swale length will be a function of the hydraulic residence time, swale width, and stormwater volume and velocity.

Porous Pavement

Local land development codes typically specify the type of material for a parking lot (i.e., paved, grass, gravel) and determine the number and size of parking spaces within a parking lot. These requirements should be reviewed carefully to ensure that they are necessary (Is paving really required in every case?) and that the number of spaces is related to actual traffic demands. After these requirements have been reviewed and verified, the use of porous pavement within a parking lot should be examined. Porous pavement materials include porous asphalt, porous concrete, turf blocks, and even Geoweb covered with sod.

Overall, experiences with porous pavements have not been very good. Porous pavements have been prone to clogging. Causes include poor erosion and sediment control during construction, unstabilized drainage areas after construction, improper mixing and finishing of the pavement, and poor maintenance. Field investigations of porous concrete that has been in use for up to 15 years in Florida, however, indicate that these parking lots can continue to infiltrate rainfall and runoff if they were installed and maintained properly (19). Recommendations to improve the utility of porous pavements include the following:

- Be sure that the installer is properly trained in the design, mixing, installation, and finishing of the porous pavement material. Both porous asphalt and concrete must be mixed and installed much differently than regular asphalt or concrete.
- Exemplary erosion and sediment control during construction and complete site stabilization after construction are essential to prevent clogging of the void spaces within the porous pavement.
- The porous pavement must receive regular, routine vacuuming to remove accumulating solids. At times, nonroutine maintenance may involve cleaning with high-pressure water.
- The entrance to any porous pavement area should have a large sign warning those about to enter that porous pavement is in use. Precautions should include prohibiting vehicles with large amounts of soil on their tires.

Problems Associated With Infiltration Practices

There have been several concerns regarding the use of infiltration practices, including their propensity to fail, their potential effects on ground-water quality, and their need for maintenance.

Infiltration systems seem to have a very high rate of failure. The author believes, however, that this high failure rate is a reflection of improperly estimated infiltration rates and improper erosion and sediment control during the construction process. A 1990 field survey of stormwater infiltration facilities constructed in Maryland replicated a 1986 field survey, thereby providing data on the performance of infiltration practices after they have been in operation for several years (20). Table 3 summarizes the information from this project.

From Table 3 it can be seen that the overall condition and functioning of infiltration systems declined over time. In 1986, about two-thirds of all facilities were functioning as designed, while in 1990 only about half were. Only 42 percent of the facilities were functioning as designed in both 1986 and 1990, while about 27 percent were not functioning as designed in both years. About 24 percent of the systems were functioning in 1986 but not in 1990, while only 7 percent of those not working in 1986 were working in 1990. Maintenance was needed at more facilities in 1990 (66 percent) than in 1986 (45 percent). Additionally, many facilities (38 percent) that needed maintenance in 1986 still needed maintenance in 1990, while 32 percent of the facilities that did not need maintenance in 1986 did need it in 1990. Only 10 percent of the systems that needed maintenance in 1986 did not need maintenance in 1990. These data indicate that little effort is expended on maintaining the operational capabilities of stormwater management systems.

A second concern about infiltration practices is whether they simply are transferring the stormwater pollution problem from surface waters to ground waters. Harper (14) has shown that stormwater pollutants, especially heavy metals, quickly bind to soil particles, while vegetation is effective in filtering pollutants, thereby minimizing the risk of ground-water contamination. Ground water beneath swales and retention areas located in

Table 3. Comparison of the Operation of Maryland Infiltration Practices

Type of BMP	1986 Number of Sites	1986 Number of Sites Working	1990 Number of Sites	1990 Number of Sites Working
Basins	63	30 (48%)	48	18 (38%)
Trenches	94	75 (80%)	88	47 (53%)
Dry wells	30	23 (77%)	25	18 (72%)
Porous pavement	14	7 (50%)	13	2 (15%)
Swales	6	3 (50%)	3	2 (67%)
Totals	207	138 (67%)	177	87 (49%)

highly sandy soils with low organic content and sparse vegetative cover, however, did show elevated levels of heavy metals down to depths of 20 ft (21).

Stormwater Reuse: An Alternative Method of Infiltration

Marty Wanielista
University of Central Florida, Orlando, Florida

Abstract

Runoff water stored in a wet detention pond can be an asset if it is used to recharge surficial aquifer levels. The recharge can occur directly from the pond by infiltrating the detained water, or the detained water can be irrigated over the watershed. Reuse in the watershed or infiltration at the pond lessens the quantity of water discharged, thus reducing the pollutant mass discharged to surface waters. A benefit of irrigation is a reduction in the use of potable water otherwise used for irrigation.

A mass balance on pond storage volume using rainfall data for select areas in the southeastern United States was completed to determine the percentage of stormwater runoff that can potentially be irrigated or infiltrated for each area as a function of contributing area, runoff coefficient, volume of temporary storage, and irrigation rate. Design curves were developed that relate the efficiency (E), or the percentage of runoff that is irrigated on a yearly basis, to the volume of temporary storage (V) in a reuse pond and the rate of irrigation (R). The design curves, called REV curves, permit the selection of a temporary storage volume and irrigation rate for a given efficiency, runoff coefficient, and geographic area. This paper contains example REV curves and presents simplified uses of the results.

Introduction

The pollutants associated with stormwater and the volume of stormwater discharges can result in significant impacts to the natural and manufactured environments of any watershed. As watersheds are made more impervious due to paving and other construction activities, the volume of runoff and pollutant mass discharged to surface waters increases relative to predeveloped conditions.

Potential impacts from uncontrolled runoff are loss of freshwater from an area where the rainfall occurred, additional freshwater discharges to estuaries, increased pollutant mass loadings, decreased river base flows, reduced wetland areas, and an economic loss associated with the need to replace discharged freshwater with potable or other waters.

Water policy in the state of Florida requires a performance standard for all stormwater management methods. A stormwater pollutant annual average load reduction of 80 percent for discharges to most waters and of 95 percent for those discharging into outstanding Florida waters (1) are required. Of the currently used stormwater management methods, off-line retention and chemical treatment can achieve the stated pollutant removal efficiencies. Wet detention ponds that discharge to adjacent surface waters, however, do not. If some of the detained water can be used within the watershed and not discharged to surface waters, the wet detention ponds may also meet the standards.

A Stormwater Reuse Pond

A stormwater reuse pond is proposed to retain runoff water within a watershed and to reduce the mass of pollutants in the discharges to surface water bodies. The difference between a wet detention pond and a reuse pond is the operation of the temporary storage volume. A wet detention pond is designed to discharge the runoff water and possibly some ground water to adjacent surface waters, while a reuse pond is designed to reuse a specific fraction of the runoff volume and not discharge that fraction. In this paper, mathematical relationships are developed between the reuse volume (temporary storage volume), the rate at which stormwater is reused, and the percentage of annual surface runoff that is reused.

The traditional design of pond temporary storage volume for a wet detention pond has been based on the consideration of water quality and uses a design storm. The design storm, however, usually ignores the preceding rainfall record and assumes that there is an antecedent dry period long enough to ensure that the pond is at some control elevation. The usual assumption is a zero temporary storage.

To address the sensitivity of the temporary storage volume to interevent dry periods, long-term rainfall records were used from 25 Florida and seven other southern states' rainfall stations in a model that simulates the behavior of a reuse pond over time. A spreadsheet was used to build a 15-year mass balance for a pond. After each rainfall event, surface runoff and reuse volumes were respectively added to and subtracted from the previous pond storage volume. If the temporary storage volume exceeded the available storage volume, discharge occurred. If the temporary storage volume was less than zero (the permanent pool volume was used for reuse water), supplemental water was used to replenish the pond and maintain the permanent pool. Both the rate of reuse from the pond and the reuse volume were varied. The reuse efficiency, defined as one minus the total volume of surface discharge divided by the total volume of runoff times 100, was calculated for each combination.

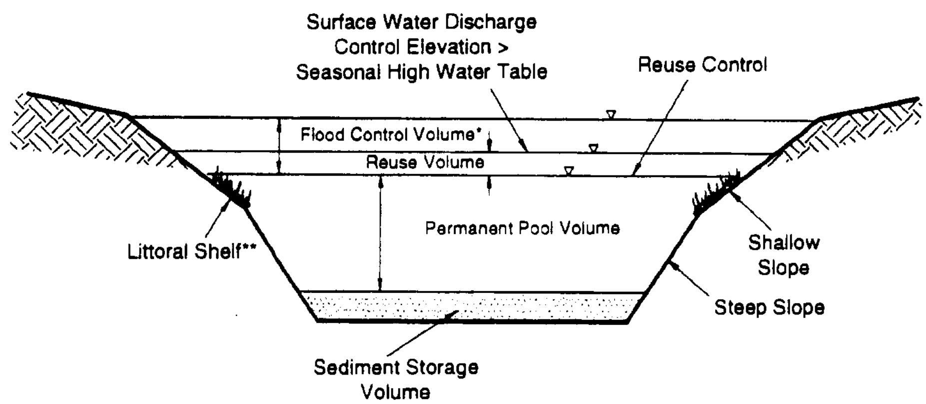
Simulation of a Reuse Pond

To establish a relationship between the efficiency, the reuse rate, and the reuse volume of a pond, a continuous time model was used to simulate the dynamics of a reuse pond. Continuous models are reported to be most representative (2). The efficiency of the pond, or the percentage of runoff that is reused, was calculated for different reuse volumes and reuse rates. Charts for different regions were produced using the local rainfall records of these regions. The term "model" is used to refer to the basic unchanged equation of the mass balance in which different rainfall records were inserted and reuse volumes and reuse rates were varied. "Simulation" is used to refer to the complete calculations of the model in which volume and rate were defined. There is only one model, while many simulations were done.

Figure 1 depicts a cross section of a typical reuse pond. The sediment storage volume lies at the bottom to receive settled matter. Above this is the permanent pool volume, which provides a minimum residence time for stormwater. The reuse volume (temporary storage volume) is the volume above the permanent pool and below the flood control structure. The flood control volume would typically be above the reuse volume.

The reuse pond differs from a typical detention pond in that instead of the temporary storage volume being depleted by a surface water discharge device (such as a bleed-down orifice in an outlet pipe), it is drawn down by a reuse system and is thus called the reuse volume. A reuse pond may deplete the pond volume below the permanent pool boundary requiring a supplemental volume to maintain this volume. A discharge structure is still necessary for flood control. Common practice should be used for the design of sediment storage, permanent pool, and flood control volumes, and their elevations and side slopes. This paper provides methodology and design criteria for the reuse volume only.

The water level of a typical reuse pond fluctuates during a year. During and following a rainfall event, there is runoff into the pond, and the water level rises to some depth above the permanent pool. If this new water level exceeds the level of the surface discharge control, discharge will occur at some rate until the water level drops back to the elevation of the control structure. The reuse pond volume is incremented daily, removing an amount of water for reuse. If the reuse volume is expended, supplemental water, such as ground water, may be used to maintain the permanent pool volume. This could occur as seepage through the sides of the pond or by mechanical pumping. This scenario was simulated by creating a mass balance for pond operation.



* Can be measured above permanent pool; however, some regulatory agencies measure above the reuse volume.
** The reader should consult local water management districts and other regulatory agencies to determine specific geometric and littoral zone design requirements.

R0015992

The Model

The model is based on the continuity equation

$$\text{INPUTS} - \text{OUTPUTS} = \Delta S. \qquad \text{(Eq. 1)}$$

If all potential water movements are considered, a complete hydrologic balance may be expressed in volume units as

$$R_E + G + P \pm F - R - D - ET = \Delta S, \qquad \text{(Eq. 2)}$$

where

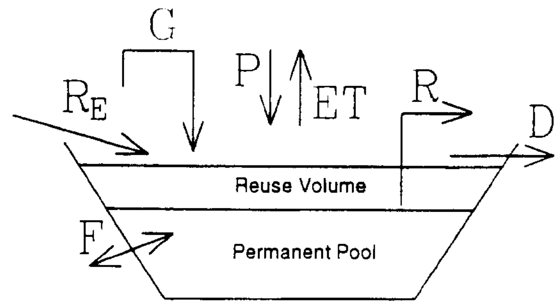
R_E = rainfall excess or runoff volume
G = supplemental water (ground water)
P = precipitation directly on the pond
F = water movement through the sides of the pond
R = reuse (infiltration)
D = discharge
ET = evapotranspiration
S = storage in pond

In Florida, the average evapotranspiration rate for a pond is generally equal to the average precipitation on the pond in a 1-year period (approximately 50 in.). Additionally, evaporation data are only available in mean monthly rates compared with the daily time step of the model, making the estimate of evaporation potentially inaccurate. These parameters were dropped from the mass balance. Also, because of its complexity, the flow of ground water through the sides of the pond was assumed to equal zero, and Equation 2 was further simplified to

$$R_E + G - R - D = \Delta S. \qquad \text{(Eq. 3)}$$

For Florida modeling purposes, there were two inputs, runoff and supplement, and two outputs, reuse and discharge (Figure 2). Runoff was established from known precipitation and watershed data. The reuse rate was a controlled variable. Both supplemental water and discharge were functions of the water level of the pond, or the storage volume. Because ground-water movement was assumed to equal zero, supplemental water is considered as that which is pumped into the pond mechanically. Supplement occurs at a rate necessary to maintain the permanent pool; the maximum required rate would equal that of reuse. Because potential storage capacity is being constantly eliminated by supplement, this may be considered as being conservative. With the previous simplifications, the actual pond may be simulated by the model.

The calculations for each simulation were done using Quattro Pro, an electronic spreadsheet. The top and bottom calculations and input data for one simulation can be seen in Figure 3. The columns of the upper portion of the simulation are the incremental registers of



$$R_E + G + \not{P} \pm \not{F} - R - D - \not{E}\not{T} = \Delta S$$

$$R_E + G - R - D = \Delta S$$

Figure 2. Summary of mass balance of reuse pond, simplified for Florida conditions.

the various parameters, which are labeled along the top. Each of these variables is defined as follows:

EVENT	A distinct rainfall occurrence; for computational purposes, each day of a multiday rainstorm is considered a separate event.
DATE	The date on which an event occurs.
DRY	The dry period separating rainfall events (days); if events occur on consecutive days there are no dry days. This value is not used in the basic model but is needed for the sensitivity analysis of the discharge potential.
RAIN	The amount of rainfall recorded during each event (inches). This information was taken directly from National Oceanic and Atmospheric Administration (NOAA) rainfall data.
RUNOFF	The amount of runoff that enters the pond during an event (inches).
REUSE	The amount of water reused during the day of an event and the dry days following the previous event (inches); the rate of reuse remains constant during a single simulation.
DISCHARGE	
Potential:	The potential amount of discharge for an event (inches); the amount that could, if necessary, physically discharge during the time since the previous event. This was established as 2 in./day over the equivalent impervious area (EIA).

Figure 3. Example of computer model using rainfall data from Orlando, Florida.

Actual:	The amount that does discharge during an event (inches); depends on the water level of the pond but is restricted to the potential discharge.
SUPLMNT	The amount of water needed between events to maintain the permanent pool volume (inches).
NET	The amount of water above the permanent pool recorded at the end of each event (inches).

Every day in which a rainfall event takes place represents one line in the simulation. This is the fundamental time step of the model. All inputs and outputs occur during this 24-hour period. At the end of the period, the net storage value of the pond is calculated. From this value, decisions are made concerning discharge and supplement. The process then repeats itself.

The 15-year totals for rain, runoff, reuse, actual discharge, and supplement are calculated as shown in Figure 3. From these values, the efficiency, or the percentage of runoff reused, can be determined for a particular simulation. The efficiency is equal to one minus the volume of water that is discharged divided by the volume of runoff times 100. The percent discharged, the volume of water discharged divided by the volume of runoff, is also calculated. The percent reused plus the percent discharged equals 100.

At the bottom of Figure 3 is a summary of the mass balance for the entire record. Both the inputs and outputs are listed and totaled. The difference between the inputs and outputs, labeled "Storage," is compared with the final value for NET. The values should be identical. This is used primarily to check the calculations.

This single model was used to predict the behavior of a reuse pond subjected to the rainfall record of 32 different locations in the southeastern United States. Previously, one location in Florida was reported (4). To simulate a pond in a particular region, the rainfall record of that region was inserted into the DATE and RAIN columns of the model. The model was then lengthened or shortened to match the span of the rainfall record. Otherwise, no changes were made to the model. By using one model and varying only the rainfall record, the consistency of the simulations was assured.

Length of Rainfall Record

An investigative question that arises when examining the random behavior of rainfall is how large a record must be to accurately represent the meteorological characteristics of a region. In other words, how many years of rainfall data must be used to estimate the ultimate dynamics of the pond? Obviously, the greatest accuracy can be obtained by using the most data. But the incremental benefit of each additional unit of data diminishes so that there is a point beyond which using more is no longer reasonable. This is the limit for investigation.

Twenty-four individual simulations were run for the Moore Haven and Tallahassee stations using, first, 1 year of rainfall data (1988) and then incrementally adding the next previous year to the rainfall record. The yearly efficiencies for several combinations of reuse volumes and reuse rates were recorded. As expected with only a few years of data, the average yearly efficiencies fluctuated widely but then leveled out as more years of data were added. As the size of the database increased, each additional year had less impact. Beyond 15 years, there was very little change in the average annual estimate.

Volume Units

Runoff, discharge, reuse, supplement, and net storage are volumes of water that are expressed in units of inches. Volumes are commonly expressed as inches over a defined area and, likewise, the parameters of this model are based on a variable unit area that the user defines. Rates are merely volumes delivered over a period and thus can be expressed in the same manner. This unit area is the EIA of the watershed or the product of the runoff coefficient and the contributing watershed area. The volumetric unit of inches on the EIA is a way in which the results are generalized for any runoff coefficient and contributing area. Once the EIA is known, the values can be converted to more practical units using simple conversions.

Model Output

The basic function of the model is to determine a relationship between the reuse rate, the reuse volume, and the efficiency. This was done by varying the reuse rate and the reuse volume, then calculating the efficiency. Thus, a simulation was done for each combination of reuse rate and reuse volume. The reuse volumes considered varied between 0.25 and 7.0 in. on the EIA. The reuse rates varied between 0.04 and 0.30 in./day on an area equivalent to the EIA. The respective efficiencies are shown as fractions. The results are presented in chart form as shown in Figure 4. The ultimate functional product of the reuse pond model is the rate-efficiency-volume (REV) chart. Wanielista et al. (5) presents the REV charts for all of the 25 locations in Florida for which accurate and long-term rainfall data were available. Individual REV charts are specific to geographical regions with similar meteorological characteristics.

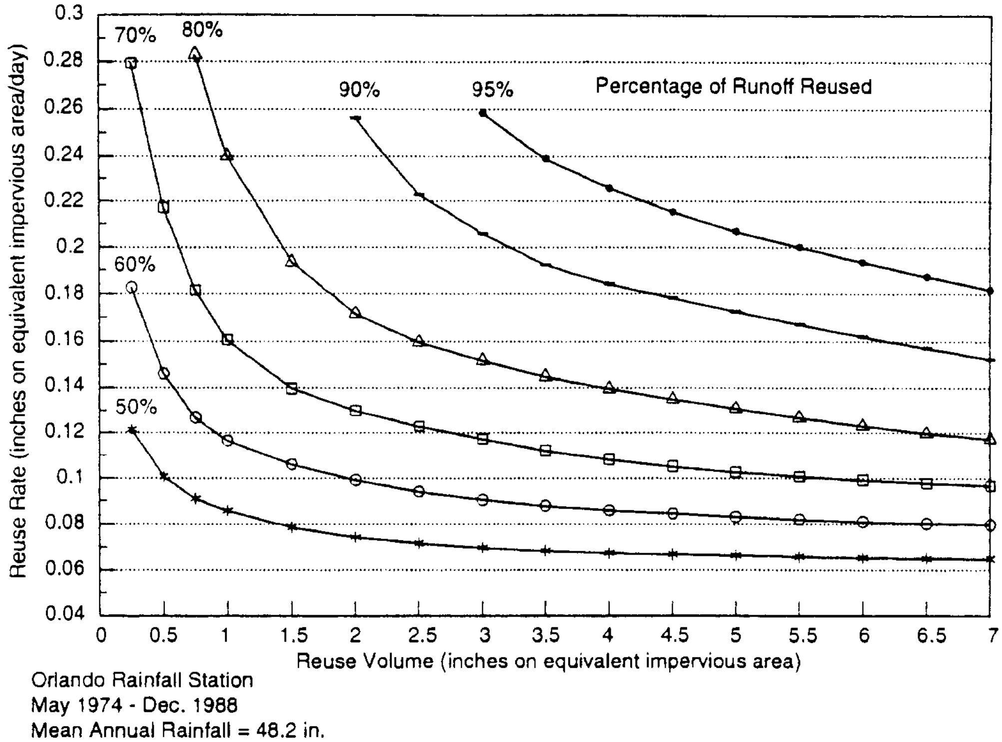

Figure 4. REV chart for Orlando, Florida.

Use of the REV Charts

REV charts relate the reuse rate, the efficiency, and the reuse volume of a pond. Recommended irrigation rates for Florida are between 0.38 in./week in the winter to 2.25 in./week in the summer (6). Information concerning any two of these three variables is necessary for the determination of the third. The use of a REV chart requires an understanding of the concept of the EIA. The units of both the reuse rate and the reuse volume are based on this area. A REV chart is specific for an area, and the accuracy of the predictions are related to the accuracy of the input data. The REV charts of this paper have been placed in a computer program that reduces the possibility of calculation errors (7).

The efficiency is defined as the average percentage of runoff that is reused over a period, specifically 15 years. A pond that discharges to surface waters 10 percent of the runoff that flows into it must reuse the remaining and so is 90 percent efficient. It may sometimes be desirable to determine the efficiency of an existing pond. More often it will be necessary to achieve a required efficiency established by local regulations, thus making the efficiency one of the known values. On every REV chart, there is a curve for each of the following efficiency levels (in percentage): 50, 60, 70, 80, 90, and 95.

Examples of Direct Use

Example 1

A watershed in Orlando must reuse 80 percent of the annual runoff from a 10-acre impervious area. The pond area is included in the impervious area. The maximum reuse storage volume available for the pond is equal to the runoff from a 3-in. rainfall event. At what rate must the runoff be reused?

Because the entire watershed is impervious, the EIA is equal to 10 acres. Because runoff equals rainfall on impervious areas, the storage volume is equal to 3 in. on the EIA. The reuse rate is a function of the efficiency and the reuse volume:

$$R = f(E,V)$$
$$= f(80\%, 3 \text{ in.})$$
$$= 0.152 \text{ in./day}$$

By referring to the Orlando REV chart (Figure 4), the necessary reuse rate is estimated at 0.152 in./day on the EIA. The rate and volume can be expressed in other units:

$$V = 3 \text{ in.} \times \text{EIA} \times \frac{10 \text{ ac}}{\text{EIA}}$$

$$= 30 \text{ ac–in.} \times \frac{43{,}560 \text{ ft}^2}{\text{ac}} \times \frac{\text{ft}}{12 \text{ in.}}$$

$$= 109{,}000 \text{ ft}^3$$

and

$$R = 0.152 \frac{\text{in.}}{\text{day}} \times \text{EIA} \times \frac{10 \text{ ac}}{\text{EIA}}$$

$$= 1.52 \frac{\text{ac–in.}}{\text{day}} \times \frac{43{,}560 \text{ ft}^2}{\text{ac}} \times \frac{\text{ft}}{12 \text{ in.}}$$

$$= 5{,}520 \frac{\text{ft}^3}{\text{day.}}$$

Example 2

An apartment complex located in Tallahassee needs to reuse 90 percent of the runoff from its parking lots. The EIA is equal to the directly connected impervious area and is 4 acres. The complex wants to use 0.26 in. of water per day over the EIA. What must the reuse volume be to maintain these conditions?

From the REV chart for Tallahassee (Figure 5), the required reuse volume is determined to be 3.5 in. on the EIA:

$$V = f\,(E,R)$$
$$= f\,(90\%,\ 0.26 \text{ in./day})$$
$$= 3.5 \text{ in.}$$

Again, the volume and rate can be expressed in other units:

$$V = 3.5 \text{ in.} \times \text{EIA} \times \frac{4 \text{ ac}}{\text{EIA}}$$

$$= 14 \text{ ac–in.} \times \frac{43{,}560 \text{ ft}^2}{\text{ac}} \times \frac{\text{ft}}{12 \text{ in.}}$$

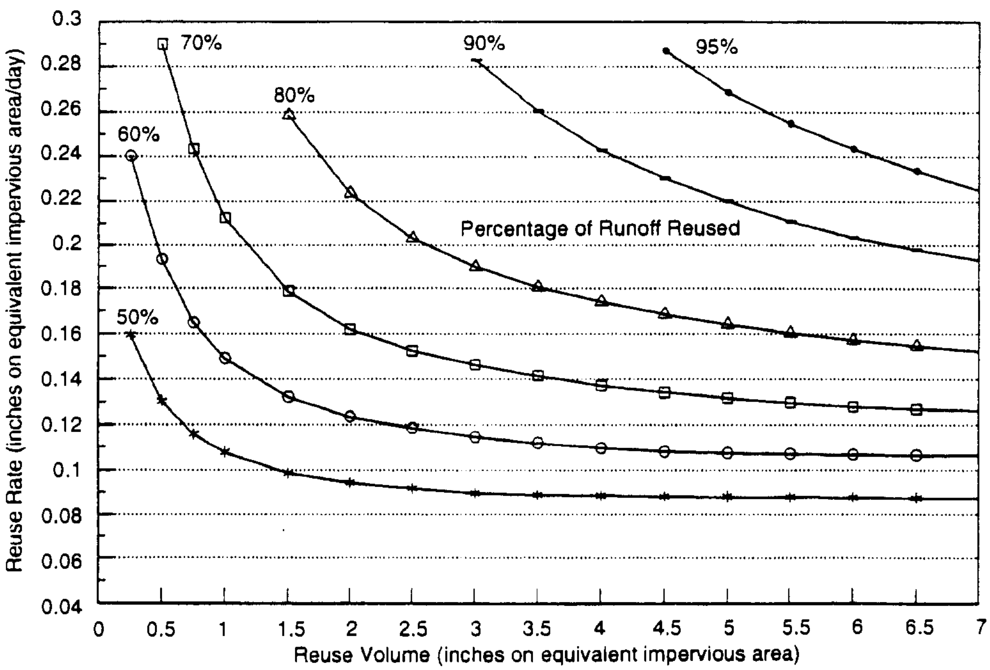
$$= 50{,}800 \text{ ft}^3$$

and

$$R = 0.260 \frac{\text{in.}}{\text{day}} \times \text{EIA} \times \frac{4 \text{ ac}}{\text{EIA}}$$

$$= 1.04 \frac{\text{ac–in.}}{\text{day}} \times \frac{43{,}560 \text{ ft}^2}{\text{ac}} \times \frac{\text{ft}}{12 \text{ in.}}$$

$$= 3{,}780 \frac{\text{ft}^3}{\text{day.}}$$



Tallahassee Rainfall Section
Jan. 1974 - Dec. 1988
Mean Annual Rainfall = 64.3 in.

Figure 5. REV chart for Tallahassee, Florida.

The previous examples illustrate the most simple application: the watershed being impervious and the volume and rate given in terms of the EIA. Much more complex design problems, however, can be solved using the same technique. The following steps can be used in any design situation:

1. Select the appropriate chart.
2. Compute the EIA of the watershed (EIA = contributing area x effective C).
3. Determine known variables in terms of the EIA.
4. Reference the chart to obtain a solution.
5. Convert the answer to desired units.

Evaporation and Rainfall on Pond

One of the initial simplifications of the pond mass balance was the assumption that the mean annual evaporation from the pond is equal to the mean annual rainfall on the pond. The evaporation totals in the Southeast may range from 30 to over 60 in./yr. Precipitation rates range from 37 in./yr in Key West to 64.5 in./yr in Tallahassee.

While evaporation and direct rainfall rates are based on the size of the pond, all other model parameters were based on the EIA. Therefore, a ratio was established between the size of the pond and the EIA. Because detention ponds usually require no more than 5 percent of the total area of the watershed, depending on the impervious area, a conservative estimate of pond area to a completely impervious area was chosen as 1:10. As an example, a 1-in. rainfall event, through direct precipitation, would add 1 in. of rainfall to the pond or 0.10 in. over the EIA.

Evaporation data were obtained from NOAA Climatological Data publications for the years 1985 through 1989. Because the locations of climatological stations match those of precipitation stations in only a few instances, evaporation data from nearby stations were used with selected model locations. Evaporation data from Lisbon and Lake Alfred were introduced into the models of Orlando and Parrish, respectively. The evaporation data were available in monthly pan evaporation totals. Fifteen years of records were used and converted to surface water evaporation rates by multiplying by a pan coefficient. The mean annual total evaporation for the two locations is 56.46 in. for Lake Alfred and 41.07 in. for Lisbon.

The evaporation function was added to the models by distributing evaporation depths in inches for each time interval. The amount of evaporation for each interval is the product of the number of days in that interval and mean daily evaporation rates for the month. To ensure the assumed distribution did not affect the total evaporation volume, the mean annual evaporation volumes for the 15-year simulations were compared with the mean volumes obtained from NOAA. The totals were almost identical.

To use the REV charts, rainfall on the pond must be included in the calculation of the EIA. When the area of the pond (approximated at 15 percent of the EIA) was added to the EIA, the pond reuse volume increased, and for a fixed reuse rate the average annual efficiency increased by at least 2.5 percent. Because rainfall on the pond reflects an impervious condition (all rainfall yields rainfall excess), it must be added to the EIA while maintaining consistent units (depth on an impervious area).

Recommendations

A mathematical mass balance model can be developed to simulate the operation of a stormwater reuse pond. This can be done for areas that have daily rainfall data available for a significant period, about 15 years.

The reuse of stormwater within a watershed from which it came should be encouraged and in some areas required. Reuse ponds can be designed to conserve water within a watershed and to reduce the mass of pollutants entering the surface waters.

The effective impervious area for a watershed should include the area of the pond when using the REV curves. The effective impervious area calculation is necessary for the use of the REV curves. More than one REV curve for a location is expressed in a figure called a REV chart.

For an average annual pollutant mass removal of 80 percent in a wet detention pond, at least 50 percent of the runoff volume should be reused when the REV charts are used for design. For a 95 percent annual pollutant mass removal, at least 90 percent of the runoff volume should be reused. The reuse percentages assume a wet detention pond will remove an average 60 percent of the incoming runoff pollution mass annually before surface discharge, which may overestimate the actual efficiency.

The reuse of stormwater is both an environmentally and economically sound management practice. The current common practice is to release stormwater to adjacent surface waters from detention ponds using weirs and orifices. Frequently, if not all the time, this detained volume of water is greater than the volume of water released from the land in its natural condition. Some fraction of this detained water can be reused within the watershed to 1) irrigate open areas, 2) recharge ground water, 3) supplement water used for certain industrial purposes, 4) enhance and create wetlands, and 5) supply water for agricultural users.

Currently, the most popular reuse method has been the irrigation of relatively open spaces, for example, golf courses, cemeteries, recreation areas, citrus groves, and common areas of apartment complexes. The primary reason for these reuse systems is economics. Many irrigation systems use treated ground water. An alternative to the use of ground water is detained stormwater. Treated ground water cost about $1.00/thousand gallons. A golf course of 100 acres using treated ground water at a cost of $1.00/thousand gallons and irrigating at 2 in./wk would pay almost $300,000/yr for the irrigation. Using detained stormwater, the irrigation system yearly cost could be less than $40,000.

In this paper, continuous modeling for reuse ponds was completed and was based on a mass balance using area-specific rainfall data to develop design criteria for stormwater reuse ponds. The design procedure relates pond temporary storage (reuse volume) to reuse rate and a percent reuse of the runoff water and is expressed as a REV curve. Also, mathematical equations for the curves have been computer coded.

The REV curves can be used for various watershed sizes or runoff coefficients. They may be used to determine the reuse rate, the reuse volume, or the efficiency of a pond. Supplemental water needs in a hydrologic balance also can be estimated. The REV charts presented in this paper could facilitate the rational planning of stormwater reuse systems.

Acknowledgments

The outcomes of this paper resulted from a research project funded by the Florida Department of Environmental Regulation in Tallahassee, Florida. The authors also appreciate the technical assistance given to them by Eric Livingston and John Cox of that department.

Use of Sand Filters as an Urban Stormwater Management Practice

Earl Shaver
State of Delaware, Department of Natural Resources and Environmental Control, Dover, Delaware

Background

As our recognition of the need for stormwater control, from both quantity and quality perspectives, has increased, efforts to develop strategies and practices to address stormwater runoff have emerged all over the country. Many of these efforts have been developed on a state or local level depending on the specific issues that motivated program development.

The concerns over stormwater control and strategies for dealing with stormwater are now international in scope. Society as a whole needs to learn about what individuals have already accomplished to allow for evolution of control strategies and individual practices. Efforts under way at the state level (in Delaware, Florida, Maryland, South Carolina, and Washington) and at the municipal level (in Austin, Texas; Washington, DC; and Alexandria, Virginia) provide some hands-on knowledge regarding the programs and types of stormwater control practices that have been used successfully.

The intent of this paper is to discuss stormwater control practices, in particular, filtration systems. Experience with stormwater control ponds and infiltration systems has led to considerable knowledge about these methods, but interest is increasing in the use of sand filters in several locations around the country for stormwater treatment. Use of these systems will expand as national efforts addressing stormwater control are implemented.

Existing Efforts in the Use of Sand Filter Systems

The first interesting point is the way that sand filter systems have been used historically around the country. These systems are being used for onsite and regional control, as well as for water quality control only and for both water quality and water quantity control.

Austin, Texas

The city of Austin has pioneered the use of sand filters for stormwater treatment. Other areas have experimented over the years with sand filters, but Austin has made a long-term commitment to their use and evolution. The design standards for sand filters have evolved based on performance and maintenance considerations.

Sand filters are used on site and on a regional basis (usually less that 50 acres of drainage), and the filters are sized to accept and treat the first half-inch of stormwater runoff from the contributing drainage area (1). They are frequently used in conjunction with a stormwater detention basin, which provides for control of larger storms from a water quantity perspective. Good water quality data for the performance of these systems have resulted, which indicates that sand filters can be very effective at pollutant removal.

Washington, DC

Sand filter use is based on a design standard developed by the Stormwater Management Branch of the Department of Consumer and Regulatory Affairs. The sand filter system design is based on whether water quantity is a concern in addition to water quality on a specific site. Washington, DC, has a combined sewer system, and sites that discharge into a combined sewer system must design their sand filters to provide for peak control of the 15-year storm. If only water quality is an issue, a design procedure is established based on the degree of site imperviousness. For water quality control alone, storage requirements are between 0.3 and 0.5 in. of runoff per acre (2). The Stormwater Management Branch is initiating a monitoring program to determine the performance of the sand filters.

State of Delaware

Delaware has developed a sand filter design system based on the Austin design but that serves for water quality control only. It is intended for sites where stormwater runoff, only from impervious areas, may drain to the sand filter. The sand filter is designed to accept and treat the first inch of stormwater runoff and is used as either a "stand alone" practice or in conjunction with another practice, such as an infiltration practice (3). Where infiltration practices are used, the sand filter provides pretreatment of the runoff to reduce premature clogging of the infiltration practice. At this time, design performance is not being monitored, but achieving an 80-percent reduction in suspended solids is considered an acceptable practice as required under the statewide stormwater management law.

Alexandria, Virginia

The city of Alexandria has developed a design manual that supplements the northern Virginia BMP handbook (4). The Alexandria supplement details the design requirements of "no net increase" in pollutant loading for new development and a 10-percent reduction in pollutant loading at site redevelopment locations. To achieve these goals, phosphorus was accepted as a "keystone" pollutant for design purposes. The Alexandria supplement provides information on a number of different sand filter design procedures and is probably the single best compilation of information relating to design procedures developed in areas such as Austin, Delaware, and Washington.

Other Areas and Efforts

The only other procedure that is more experimental (although, in reality, they all still are) is the peat-sand filter developed by the Washington Council of Governments. This procedure is a variation of the traditional sand filter design that uses peat as a medium for enhanced nutrient reduction. The State of Washington has recently completed a stormwater design manual that presents a sand filter design based on the Austin system.

Discussion

Sand filters represent an emerging technology with significant potential for evolution in coming years. The procedure developed for the State of Delaware was intended for use on small sites where overall site imperviousness was maximized. Examples of these sites would be fast food restaurants, gas stations, or industrial sites, where space for retrofitting is not readily available. Another emphasized use for sand filters is as a pretreatment system for stormwater infiltration practices. Infiltration practices are very susceptible to clogging by particulates, and sand filters could provide an effective means to reduce particulate loading and to block oil and grease from entry into infiltration systems.

Sand filters are especially appropriate for highway systems where site conditions and right-of-ways limit the types of feasible stormwater treatment practices. Sand filter systems generally have lower maintenance needs than infiltration practices have, so their use appeals to highway officials if the costs can be made reasonable.

If the sand filter is moved to the edge of the parking lot or roadway, where structural strength is not as important, the system can be installed at significantly lower cost. The City of Alexandria has developed a variation of the Delaware approach where the sand filter is behind curb openings. In addition, increasing the head over the filter can increase the time between required maintenance of the filter, thus lowering the system's operation and maintenance costs. Consideration should be given to placing stone over the sand to prevent scour of the sand as water drops on the filter, in addition to increasing the overall depth of the sand to improve performance.

The design procedure developed for use in Delaware is meant as guidance and can be modified or enhanced as needed depending on specific site conditions. The practice as presented may be used in the middle of a parking lot, where concrete and grate strength are established, so that automobiles or trucks could travel over the system. Consultants have taken that design standard literally, which has made construction costs extremely high.

Any one of these systems could be modified or improved with proper engineering. Conversations have started with different manufacturers to see if sand filter units could be prefabricated which would reduce the overall cost of installation. The use of sand filters will dramatically increase if construction costs are reduced.

Conclusion

Sand filters have a strong potential for becoming an effective tool for stormwater treatment, but engineering expertise is necessary to improve performance and cost. With proper maintenance and in conjunction with other practices, sand filters can assist in water quality protection. They also have potential in arid regions, where more conventional practices such as wet ponds are not feasible.

We live in an era where our desires and mandates for clean water exceed our abilities to actually protect our aquatic resources when structural controls are considered as the only method of stormwater control. The term "treatment train" is certainly a concept that must be expanded if resource protection is to be realized. Sand filters are one car of the "treatment train," but the overall train must include many different considerations. Ultimately, land use must be a consideration in overall site stormwater planning, and considerations of roadway widths, curbing, and site compaction and utilization must be flexible depending on individual site needs. Why does a residential street have to be wide enough for a fire engine to turn around in? We need to question basic planning assumptions with respect to resource protection, and to evaluate whether a specific design requirement is necessary in light of that requirement's impact on our natural resources. Otherwise, we need to recognize and accept the fact that a decline in quality and productivity of our resources will occur.

Application of the Washington, DC, Sand Filter for Urban Runoff Control

Hung V. Truong
DC Environmental Regulation Administration, Washington, DC
Mee S. Phua
University of DC, Washington, DC

Abstract

Conventional infiltration systems are frequently used for water quality control of urban runoff. These types of urban best management practices (BMPs), however, may adversely affect ground-water quality through the migration of pollutants into ground-water aquifers. Additionally, these BMPs may not be feasible in high-density urban areas because of the large land areas required for their installation.

To address these problems, this paper presents an alternative solution: to replace conventional infiltration BMPs with the confined, underground sand filter water quality (SFWQ) control structure. Over 70 of these structures have been installed in Washington, DC, since 1988.

The Washington, DC, underground sand filter is a gravity flow system consisting of a concrete structure with three chambers. It is designed to provide quality control for the first ½ in. of runoff. The first chamber performs pretreatment of stormwater runoff by removing floating organic material such as oil, grease, and tree leaves. The second chamber is the filter chamber (process chamber) and optimally contains a 3-ft filter layer. The filter layer consists of gravel, clean sand, and geotextile filter fabric. At the bottom of the filter is a subsurface drainage system of polyvinyl chloride perforated pipes in a gravel bed. The third chamber is a discharge chamber that collects flow from the underdrain pipes.

The SFWQ structure may vary in size and shape. The depth can range from 8 to 10 ft depending on the final grading of the site.

Introduction

Urbanization resulting in surface- and ground-water contamination is a serious and constant threat to water quality. In turn, poor water quality is an undesirable economic burden on taxpayers. Because of the extremely high cost involved in restoring contaminated surface and ground water, prevention seems to be the only economical course of action to protect natural water systems.

To regulate and provide protection for surface- and ground-water systems, the federal government passed the Clean Water Act. As part of this effort, the District of Columbia enacted stormwater management regulations (DC Law 5-188, section 509-519) in January 1988. These regulations require new developments and redevelopments to control nonpoint source pollution transported from construction sites by urban runoff, using best management practices (BMPs) or best available technologies (BATs).

Infiltration devices are the most frequently used BMPs for controlling stormwater runoff in urban areas. These conventional BMPs have limitations, however, due to soil and site-specific constraints. These BMPs may also adversely affect ground water through the migration of pollutants into ground-water aquifers. Additionally, conventional infiltration systems may not be feasible in an urban environment because of the large land areas required for their installation. In an effort to mitigate these problems, an alternative design is outlined in this paper to replace the conventional infiltration BMPs, where applicable. This alternative system is called the confined sand filter water quality (SFWQ) structure and is illustrated in Figure 1. The system uses multiple filter layers combined with a moderate detention time to filter the suspended pollutant particles and hydrocarbons from urban runoff. A multiple-layer filter was chosen because it has proven to be more effective than a single-layer filter design.

Background

Infiltration practices have been widely used to improve the quality of urban stormwater runoff. Several limitations, however, are associated with the use of conventional

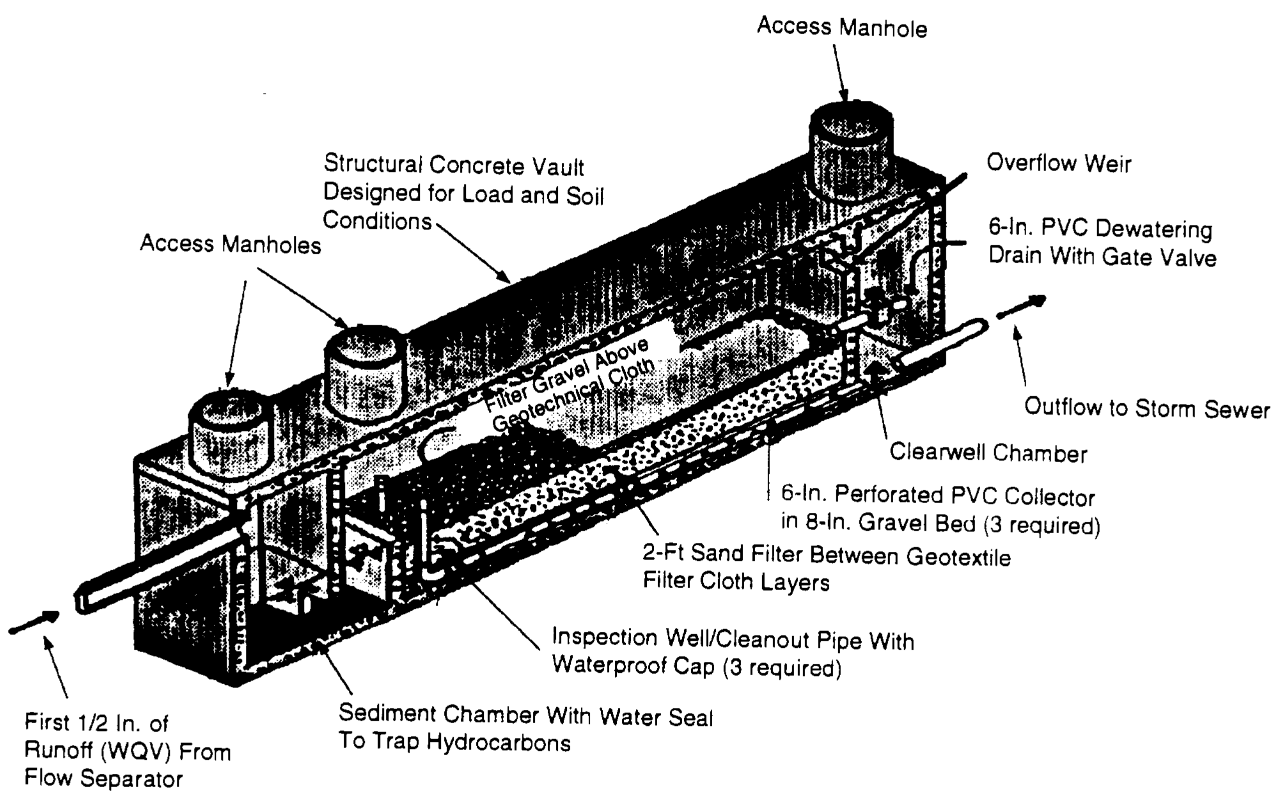

Figure 1. DC three-dimensional sandfilter centerline cutaway (source: District of Columbia).

infiltration systems. According to several studies (1-3), the practice of infiltration may have a negative impact on ground-water quality. In addition, infiltration practices are only recommended for sites with soil infiltration rates higher than 0.27 in./hr and with a clay content of less than 30 percent. Recently, a study by the Metropolitan Washington Council of Government (MWCOG) shows that over 50 percent of the infiltration trenches installed in the Metropolitan Washington region either partially or totally failed within the first 5 years of construction (4). Research has also found that clogging may occur in infiltration trenches and is also very common in other infiltration systems. In surface systems, clogging is most likely to occur near the top of the structure, between the upper layer of stone and the protective layer of filter fabric. For underground infiltration systems, clogging is likely to occur at the bottom of the structure, at the filter fabric, and at the soil interface.

Restoration of both surface and underground infiltration systems is tedious and very costly, requiring the removal of the vegetation layer, top soil, protective plastic layer, stone aggregate, and filter fabrics. If the surface layer is pavement or concrete, the rehabilitation effort becomes even more difficult and expensive. Conventional infiltration systems also require relatively large areas of land for their installation; therefore, this family of BMPs is not feasible due to the high cost of land in an urban environment.

Design Rationale

Whenever a liquid containing solids in suspension is placed in a relatively quiescent state, solids having a higher specific gravity than the liquid settle, while those having a lower specific gravity rise. The design of the SFWQ structure uses the one-dimensional "falling head test" in Darcy's Law for calculating the head loss of fluid flow through a multiple-layer filter medium to treat stormwater runoff. The design uses various media layers with different permeabilities to intercept pollutant particles as fluid flows vertically through the filter layers. This principle can be used to accelerate the removal of pollutants by increasing the residence times of stormwater runoff, and to facilitate the filtering process in the filter chamber. The SFWQ structure also utilizes Stoke's Law for terminal falling velocities of individual particles in allowing time for particles to settle out of stormwater runoff. The average detention time of this system ranges from 6 to 8 hr for an optimal design consideration.

Functional and Physical Description

The SFWQ structure is a gravity flow system consisting of three chambers. The facility may be precast or cast-in-place. The first chamber (same as water quality inlet) is a pretreatment facility removing any floating organic material such as oil, grease, and tree leaves. The chamber has a submerged weir leading to the second chamber (filter chamber) and may be designed with a flow splitter or with a bypass weir if the system is for off-line storage, as illustrated in Figure 2.

The second chamber contains 3 ft of filter material consisting of gravel, geotextile fabric, and sand, and is situated behind a 3-ft weir. At the bottom is a subsurface drainage system consisting of a parallel polyvinyl chloride (PVC) pipe system in a gravel bed. A dewatering valve is at the top of the filter layer for maintenance purposes and for safety release in case of emergency. It also has an overflow weir at the top to protect the system from backing up when the storage volume is exceeded, if the system is designed for on-line storage (Figure 3).

Water enters the first chamber of the system by gravity or by pumping. This chamber removes most of the heavy solid particles, floatable trash, leaves, and hydrocarbon material. A submerged weir (designed to minimize the energy of incoming stormwater) conveys the effluent to the second chamber. The effluent enters the filter layer by overflowing the weir typically 3 ft above the bottom of the structure. The water is filtered through various filtering layers to remove suspended pollutant particles. The filtered stormwater is then picked up by the subsurface drainage system that empties it into the third chamber. The third chamber also receives any overflow from the second chamber for an on-line system and overflow from the first chamber flow splitter for an off-line system.

Applicability

The SFWQ structure is specifically designed for highly urbanized areas where open space is not available. The

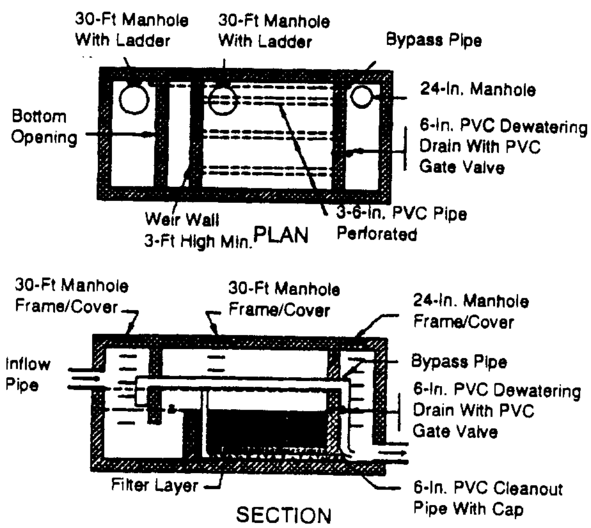

Figure 2. DC off-line underground sand filter (source: District of Columbia).

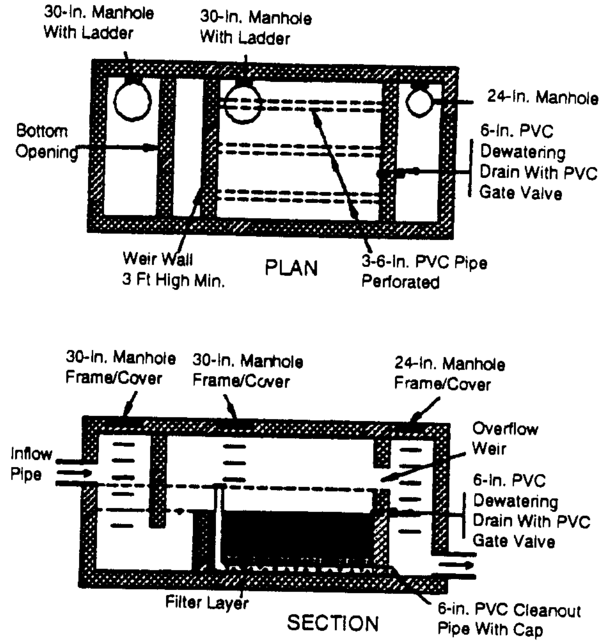

Figure 3. DC on-line underground sand filter (source: District of Columbia).

structure works best for impervious catchment areas of 1 acre or less. Multiple systems are recommended for catchment areas greater than 1 acre.

Over 70 underground and surface sand filter structures have been installed in Washington, DC, since 1988. In fact, the structure has been adopted and incorporated in the stormwater management programs of several states and neighboring jurisdictions.

The structure may also be designed to provide detention, especially for on-line application when discharge rates must be modified in accordance with local and municipal regulations. Recommended areas where this device may be used include:

- Surface parking lots.
- Underground parking lots or multilevel garages.
- Parking apron, taxiway, and runway shoulders at airports.
- Emergency stopping and parking lanes and sidewalks.
- Vehicle maintenance areas.
- On-street parking aprons in residential areas.
- Recreational vehicle camping area parking pads.
- Private roads, easement service roads, and fire lanes.
- Industrial storage yards and loading zones.
- Driveways for residential and light commercial use.
- Office complexes.

Planning Considerations

Location

The SFWQ structure must be located in areas where it is accessible for inspection and maintenance, as well as to the vacuum trucks that are usually required to provide maintenance.

Ground Water and Bedrock

The seasonally high ground-water table and bedrock should be at least 2 to 4 ft below the footing of the structure.

Size

The SFWQ structure may vary in size from a small-site single installation to large or multiple facility installations. Site topography and the presence of underground utilities, however, may limit the size and depth of the system. Use of other practices in combination with the SFWQ structure may solve this problem.

Hydraulic Head

Because the SFWQ structure is a gravity flow system, sufficient vertical clearance between the inverts of the inflow and outflow pipes must be provided. When elevation is insufficient, a well pump may be used to discharge the effluent from the third chamber into the receiving drainage system.

Water Trap

In combined sewer areas, a water trap must be provided in the third chamber to prevent the backflow of odorous gas.

Design Criteria

In designing the SFWQ structure, the nature of the area, such as imperviousness, determines the control volume of the sand filter chamber. Other recommended steps to consider when designing a SFWQ structure are the following:

- Examine the site topographical conditions and select possible outfalls from the existing drainage or sewer map.
- Review the final grading plans and determine the maximum head available between the proposed inflow and outflow pipes.
- Determine the total connected impervious area.
- Select the design (first flush) runoff based on land use characteristics. (Washington, DC, uses 0.5 in. for surface parking lots, 0.3 in. for rooftops, and 0.4 in. for other impervious surfaces.)
- Estimate the storage volume and the release rate. The storage volume and release rate depends on local stormwater management regulations.
- Select design storm(s). This should be based on the storm frequencies selected by the stormwater management authorities.
- Determine the size of the inflow, outflow, and emergency release pipes. These should be sized to pass the lowest selected storm frequency permitted by local stormwater regulations. (Washington, DC, uses 15-yr, 5-min storms for postdevelopment runoff.)
- Determine detention time. All SFWQ structures should be designed to drain the design (first flush) runoff from the filter chamber 5 to 24 hr after each rainfall event.
- Determine structural requirements. A licensed structural engineer should design the structure in accordance with local building codes.
- Provide sufficient headroom for maintenance. A minimum head space of 5 ft above the filter is recommended for maintenance of the structure. If 5 ft of headroom is not available, a removable top should be installed.

Design Procedures

Determine Design Invert Elevations

Determine the final surface elevation, invert in, invert out, and bottom invert elevation of the structure (see Figure 4):

$$D_t = (\text{Inv. in} - \text{Inv. out}) + H_w + 1, \qquad \text{(Eq. 1)}$$

where

D_t = total depth of structure (ft)
Inv. in = final invert elevation of inflow pipe (ft)
Inv. out = final invert elevation of outflow pipe (ft)
H_w = vertical height of overflow weir (ft)
1 = freeboard constant (ft)

Peak Discharge Calculation for Bypass Flow

Using the Rational Method:

$$Q_{pk} = CIA, \qquad \text{(Eq. 2)}$$

where

Q_{pk} = bypass peak flow (ft_3/sec)
C = runoff coefficiency (dimensionless)
I = rainfall intensity (in./hr)
A = drainage area (ac)

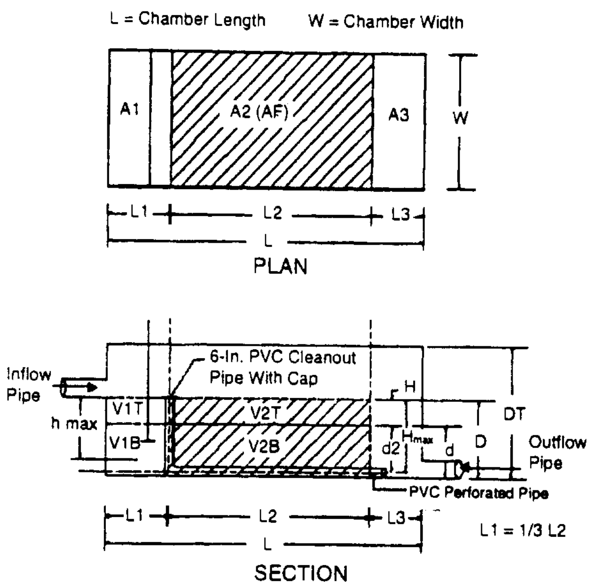

Figure 4. Design guide for DC sandfilter (source: District of Columbia).

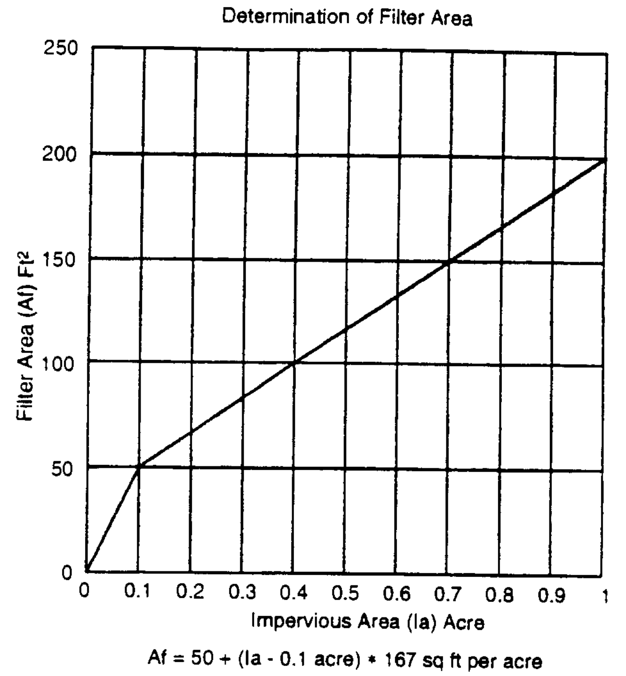

Figure 5. Filter area versus watershed imperviousness (source: District of Columbia).

Determine Area of Sand Filter

Use Figure 5 or the following equation:

$$A_f = 50 + [Ia - 0.1 \text{ acres}] \times 167 \text{ ft}^3/\text{ac}, \qquad \text{(Eq.3)}$$

where

A_f = sand filter area (ft2)
I_a = impervious area (ac)

Determine Storage Volume

Use the equation

$$V_w = (Q_i \times I_a) - (F \times T \times A_f), \qquad \text{(Eq. 4)}$$

where

V_w = volume storage needed (ft3)
Q_i = first flush runoff (in)
I_a = impervious area (ft^2)
F = final infiltration rate for filter (ft/hr)
T = filling time (1 hr, based on empirical data)
A_f = sand filter area (ft^2)

Calculate Bottom Storage Volume in Second Chamber

Use the equation

$$V_{2b} = Af \times d \times V_v, \qquad \text{(Eq. 5)}$$

where

V_{2b} = bottom volume of filter chamber (ft3)
A_f = surface area of filter layer (ft2)
d = depth of filter layer (ft)
V_v = sum of void ratio for filter media

Calculate Bottom Storage Volume in First Chamber

Use the equation

$$V_{1b} = A_1 \times d, \qquad \text{(Eq. 6)}$$

where

V_{1b} = bottom volume of first chamber (ft^3)
A_1 = surface area of first chamber (ft^2)
d = depth of filter layer (ft)

Note: $A_f/3 < A1 < A_f/2$ for optimum design condition.

Calculate Storage Volume in First and Second Chambers

Use the equation

$$(V_{1t} + V_{2t}) = V_w - (V_{2b} + V_{1b}), \qquad \text{(Eq. 7)}$$

where

$V_{1t} + V_{2t}$ = sum of top volume of first and second chambers

R0016007

V_w = volume of water from Equation 4
$V_{2b} + V_{1b}$ = sum of bottom volume of first and second chambers

Determine Maximum Storage Depth for On-Line System

Use the equation

$$D = [(V_{1t} + V_{2t})/(A_1 + A_2)] + d, \quad \text{(Eq. 8)}$$

where

D = maximum storage depth (ft)
$V_{1t} + V_{2t}$ = sum of top volume of first and second chambers
$A_1 + A_2$ = sum of surface area of first and second chambers
d = depth of filter layer (ft)

Note: D must be equal to or smaller than the difference between the invert in and invert out from Equation 1.

Determine Size of Submerged and Overflow Weirs

Submerged weir opening in first chamber:

$$A(h \times l) = Q_{pk}/C \times (2 \times g \times h_{max})^{0.5}, \quad \text{(Eq. 9)}$$

where

$A(h \times l)$ = area of weir opening (ft^2)
Q_{pk} = bypass flow from Equation 2 (ft3/sec)
C = 0.6, weir coefficient
g = 32.2 ft^2/sec
h_{max} = hydraulic head above the center line of weir (ft)
h = weir height, minimum 1 ft

Overflow weir opening in second chamber:

$$H^{1.5} = Q_{pk}/CL, \quad \text{(Eq. 9a)}$$

where

H = height of weir opening (ft)
Q_{pk} = bypass flow (ft^3/sec)
C = 3.33, weir coefficient
L = length of weir opening (ft)

Determine Flow Through Filter and Detention Time After Storage Volume Fills Up

Average flow through the filter:

$$q_f = k \times A_f \times i, \quad \text{(Eq. 10)}$$

where

q_f = flow through the filter (ft^3/hr)
k = sand permeability (ft/hr)
A_f = filter area
i = hydraulic gradient ($H_{max}/2$ x filter depth)

Estimate the detention time:

$$T_s = V_w/q, \quad \text{(Eq. 11)}$$

where

T_s = average dewatering time for SFWQ structures (hr)
V_w = volume of first flush storage from Equation 3 (ft^3)
q = average flow from Equation 10 (ft^3/hr)

Develop Inflow and Outflow Hydrographs

Figure 6 is a typical illustration of inflow/outflow hydrographs for the SFWQ structure.

For inflow hydrograph, use Modified Rational Method Hydrograph with:

$T = T_c$
$T_R = 1.67\ T_c$,

where

T = time to peak
T_c = time of concentration
T_R = recession period

For outflow hydrographs, use the following equations to determine when flow occurs:

when

$$T_c \times Q_{pk} < 2V_w, + \quad \text{(Eq. 12)}$$
$$T = [2*T_c2 - (2T_c2 - 2V_w*T_c/Q_{pk})^{0.5}].$$

when

$$T_c \times Q_{pk} = 2V_w, + \quad \text{(Eq. 13)}$$
$$T = (0.5T_c) + (V_w/Q_{pk})$$

when

$$T_c \times Q_{pk} > 2V_w, + \quad \text{(Eq. 14)}$$
$$T = [(2V_w*T_c)/Q_{pk}]^{0.5}.$$

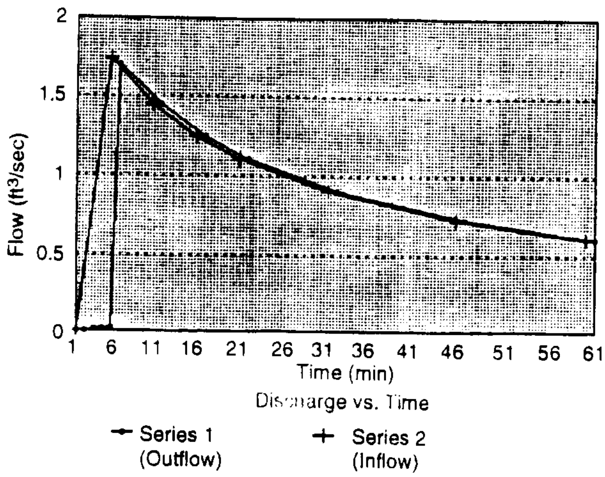

Figure 6. Typical inflow-outflow hydrograph (source: District of Columbia).

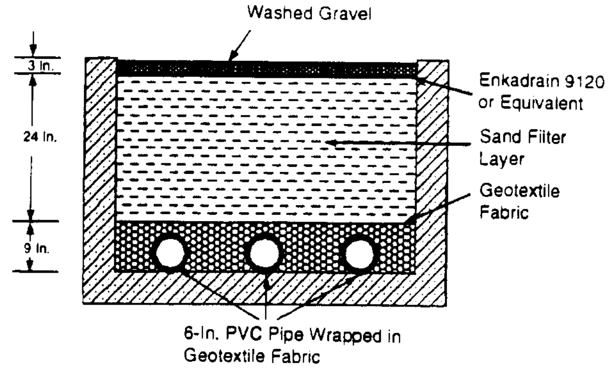

Figure 7. Cross section of filter compartment (source: District of Columbia).

Filter Layer Details

Figure 7 is a typical cross section of the filter chamber.

Upper Gravel Layer

The washed gravel or aggregate layer at the top of the filter may be 1 to 3 in. thick and meet American Society for Testing Materials (ASTM) standard specifications for 1-in. maximum diameter or DC #57 gravel.

Geotextile Fabrics

The filter fabric (geotextile fabric) beneath the top gravel layer should be Enkadrain 9120 or equivalent with the specifications shown in Table 1.

The filter cloth beneath the sand should meet the specifications shown in Table 2.

The fabric roll should be cut with sufficient dimensions to cover the entire wetted perimeter of the filter area with a 6-in. minimum overlap.Sand Filter Layer

Sand Filter Layer

The sand filter layer should be 18 to 24 in. deep. ASTM C33 Concrete Sand is recommended, but sand with similar specifications may be used.

Table 1. Geotextile Fabric Specifications

Property	Test Method	Unit	Specification
Material	Nonwoven geotextile fabric		
Unit weight	ASTM D-1777	oz/yd^2	4.3 (min)
Flow rate	"Falling head test" ASTMD-751	gpm/ft^2 lb	120 (min) 60 (min)
Puncture thickness		in.	0.8 (min)

Bottom Gravel Layer

The bottom gravel layer surrounding the collector (perforated) pipes should be 1/2- to 2-in. diameter gravel and provide at least 3 in. of cover over the tops of the drainage pipes. No gravel is required under the pipes. The gravel and the sand layer above must be separated by a layer of geotextile fabric that meets the specifications listed above.

Underdrain Piping

The underdrain piping consists of three 6-in. pipes with 3/8-in. perforations and should be reinforced to withstand the load of the overburden. All piping should be to schedule 40 polyvinyl chloride (PVC) or greater strength.

The minimum grade of piping shall be 1/8 in./ft or 1 percent slope. Access for cleaning all underdrain piping is needed. Cleanouts for each pipe should extend to the invert of overflow weir or maximum surface elevation of the storage water.

Each pipe should be carefully wrapped with geotextile fabric that meets the above specifications before placement in the filter.

Table 2. Filter Cloth Specifications

Property	Test Method	Unit	Specification
Material	Nonwoven geotextile fabric		
Unit weight		oz/yd^2	8.00 (min)
Filtration rate		in./sec	0.08 (min)
Puncture strength	ASTM D-751 (Modified)	lb	125 (min)
Mullen burst strength	ASTM D-751	psi	400 (min)
Tensile strength	ASTM D-1682	lb	300 (min)
Equivalent opening size	U.S. Standard Sieve	no.	80 (min)

Construction Specifications

The SFWQ structure may be either cast-in-place or precast. In Washington, DC, precast structures require advanced approval. The approved erosion and sediment control plans should include the specific measures to provide the protection of the filter system before the final stabilization of the site.

Excavation and Installation

Excavation for SFWQ structure and connecting pipes should include removal of all materials and objects encountered in excavation; disposal of excavated material as specified in the approved erosion and sediment control plans; maintenance and subsequent removal of any sheeting, shoring and bracing; dewatering and precautions; and work necessary to prevent damage to adjacent properties resulting from this excavation. Access manholes and steps to the filtration system should conform to local standards.

Leak Test

After completion of the SFWQ structure shell, a leak test may be performed to verify watertightness before the filter layers are installed.

Filter Materials

All filter materials in the second chamber should be placed according to construction and materials standards and specifications, as specified on an approved construction plan.

Completion and Site Stabilization

No runoff should be allowed to enter the sand filter system before completion of all construction activities, including revegetation and final site stabilization. Construction runoff should be treated in separate sedimentation basins and routed to bypass the filter system. Should construction runoff enter the filter system prior to final site stabilization, all contaminated materials must be removed and replaced with new, clean filter materials before a regulatory inspector approves its completion.

System Calibration and Verification

The water level in the filter chamber should be monitored by the design engineer after the first storm event before the project is certified as completed. If the dewatering time of the filter chamber takes longer than 24 hr, the top gravel layer and filter fabric underneath must be replaced with a more rapid draining fabric and clean gravel. The structure should then be checked again to ensure a detention time that is less than 24 hr.

Maintenance Requirements

The SFWQ structure is designed to minimize maintenance. It is subject to clogging, however, by sediment, oil, grease, grit, and other debris. Actual performance and service life of the structure is not available at this time. Nevertheless, it is still very important to provide general standard maintenance guidelines to maintain adequate structure operation. The maintenance of the system includes the following steps:

- The water level in the filter chamber should be monitored by the owner on a quarterly basis and after every large storm for the first year after completion of construction. A log of the results should be maintained, indicating the rate of dewatering after each storm and the water depth for each observation. Once the regulatory stormwater inspector indicates that satisfactory performance of the structure has been demonstrated, the monitoring schedule may be reduced to an annual basis.
- As with other pretreatment structures, the first chamber must be pumped out semiannually. If the chamber contains an oil skim, it should be removed by a firm specializing in oil recovery and recycling. The remaining material may then be removed by a vacuum pump truck and disposed of in an approved landfill. After each cleaning, refill the first chamber to a depth of 3 ft with clean water to reestablish the water seal.
- After approximately 3 to 5 yr, the upper layer of the filter can be expected to become clogged with fine silt. When the drawdown time for the filter exceeds 72 hr, the upper layer of gravel and geotextile fabric must be removed and replaced with new, clean materials conforming to the original specifications.

Conclusion and Discussion

At the present time, the environmental and economic impacts of the SFWQ structure have not been fully evaluated. A long-term monitoring program is being implemented in Washington, DC, to determine water quality benefits and address long-term maintenance concerns. The results from this monitoring effort will provide important information on the removal efficiency of common urban pollutants. In addition, the monitoring data will provide information on actual headloss in the system, which will indicate the need for filter replacement.

Based on the results of the Austin, Texas, monitoring program on its sand filter systems and on several years of success in the application of the SFWQ structure in Washington, DC, the feasibility of the SFWQ structure has been demonstrated for use in an urban environment. The authors believe that the SFWQ structure may be used as an alternative urban BMP for highly developed areas where other options are not available.

In conclusion, the design presented here is an attempt to provide an alternative solution to control nonpoint source pollution from urban stormwater runoff. The application of this system should be viewed with some caution, as the structure has not been monitored for optimal effectiveness.

When the SFWQ structure is used strictly as a gravity flow system, one of its limitations is that it requires a hydraulic head of at least 4 ft relative to the outflow pipe. To minimize this problem, further study is needed to evaluate the different thicknesses of the sand layers (with thicknesses such as 18, 12, and 6 in.) to determine the relationship between the depth of sand layer and pollutant removal efficiency.

Acknowledgments

Computer-aided design was performed by Renette Dallas, DC Environmental Regulation Administration, Washington, DC. The authors would also like to thank Renette Dallas and Collin R. Burrell, also of the DC Environmental Regulation Administration, for technical assistance.

Stormwater Measures for Bridges: Coastal Nonpoint Source Management in South Carolina

H. Stephen Snyder
South Carolina Coastal Council,
Charleston, South Carolina

Abstract

Although stormwater runoff from bridges has a direct pathway to estuaries, rivers, and lakes, little research has been undertaken to directly measure the concentration of pollutants flushed from the bridge surface or the impact of those pollutants on the receiving water body. A general correlation can be made, however, from the body of research available concerning runoff from roads and streets in general and from the wider body of information regarding urban runoff characteristics. The general assumption is that runoff from highways (and bridges) can negatively affect the water quality of receiving waters through the shock of acute loadings during rainfall events and through long-term exposure and/or accumulations of pollutants in sediments or marine organisms. Research does indicate a relationship between the average daily traffic volume and potential water quality impacts. Concern is heightened where the runoff has a direct, unobstructed pathway to the receiving waters and, even more so, where the receiving waters are extremely sensitive, such as shellfish habitat.

This paper provides a brief overview of potential water quality pollutants from highway and bridge runoff, then focuses on management and control measures for runoff from bridges. These include requirements of Section 6217 of the Coastal Zone Act Reauthorization Amendments and stormwater management requirements for bridges in the coastal zone of South Carolina. Included is a case study of retrofitting a major bridge already designed and under construction, which transverses significant shellfish resources in coastal South Carolina.

Introduction

South Carolina's 187-mile coastline is only the facade for some 3,000 shoreline miles of estuaries, bays, rivers, and creeks that intertwine among some 500,000 acres of coastal marshes and wetlands. This immense coastal system supports approximately 279,000 acres of estuarine shellfish-growing waters and thousands of acres of other sensitive habitats. For people to live and work in this environment, all of these coastal resources, rivers, bays, marshes, and sensitive habitats must be transversed in one form or another, most often by roadways and bridges. These roadways and bridges and their associated uses can provide a direct source of contaminants to our coastal waters and, as such, must be managed to reduce or alleviate the potential impacts.

For coastal states, addressing pollution from bridges may no longer be a choice. Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990 requires states with coastal zone programs to develop coastal nonpoint source pollution programs. Such programs must address pollution in the following areas: agriculture, silviculture, hydrologic modifications, marinas, and urban settings, the latter of which include roads and, even more specifically, bridges.

A basic assumption contained herein is that the results of studies on highways and their associated pollution potential from runoff are also applicable to highway bridges.

Contaminants

A series of studies sponsored by the U.S. Department of Transportation in the 1980s (1-3) confirms the presence and possible sources of a wide variety of contaminants that may be associated with roadways and bridges. A basic listing is presented in Table 1. These contaminants accumulate on roadway surfaces between major removal events, such as rainfalls and street sweeping (which may be rare or nonexistent in nonurban areas). The severity and order of magnitude of these contaminants are site specific and variable, and can depend on such factors as traffic characteristics, highway or bridge design, maintenance activities, accidental spills, surrounding land use, and climate.

Table 1. Common Highway Runoff Constituents and Their Primary Sources (1)

Constituent	Primary Sources
Particulates	Pavement wear, vehicles, atmosphere, highway maintenance
Nitrogen, phosphorus	Atmosphere, roadside fertilizer application
Lead	Leaded gasoline (auto exhaust), tire wear (lead oxide filler material), lubricating oil and grease, bearing wear
Zinc	Tire wear (filler material), motor oil (stabilizing additive), grease
Iron	Auto body rust, steel highway structures (guardrails, bridges, etc.), moving engine parts
Copper	Metal plating, bearing and bushing wear; moving engine parts; brake lining wear; fungicides and insecticides (roadside maintenance operations)
Cadmium	Tire wear (filler material), insecticides
Chromium	Metal plating, moving engine parts, brake lining wear
Nickel	Diesel fuel gasoline (exhaust) and lubricating oil, metal plating, bushing wear, brake lining wear, asphalt paving
Manganese	Moving engine parts
Bromide	Auto exhaust
Cyanide	Anticake compound (ferric ferrocyanide, etc.) used to keep deicing salt granular
Chloride	Deicing salts
Sulphate	Roadway beds, fuel, deicing salts
Petroleum	Spills, leaks, or blow-by of motor lubricants; antifreeze, and hydraulic fluids, asphalt surface leachate
Polychlorinated biphenyls (PCBs), synthetic pesticides	Spraying of highway right-of-ways, background atmospheric deposition, PCB catalyst in tires
Pathogenic bacteria (indicators)	Soil, litter, bird droppings, trucks hauling livestock and stockyard waste
Rubber	Tire wear
Asbestos	Clutch and brake lining wear

The studies have revealed some interesting results that may influence management decisions. To elaborate on one pollutant, tests (1) indicated that the pathogenic bacteria indicators fecal coliform and fecal *Streptococcus* were not consistently present on roadway systems at any given time or place; their presence is most often associated with nonspecific events, i.e., animal and bird droppings, soil spills, and road kills. When present, however, the bacteria can remain viable for relatively long periods in highway sweepings (up to 7 weeks) and up to 13 days in stagnant storm sewer systems. As one would expect, the tests showed that the coliform bacteria were consistently lower when runoff was conveyed through a grassy area, although none of the standard nonpoint source management measures effectively kills coliforms and their associated microbes (2).

According to the U.S. Department of Transportation (1), the major portion of priority pollution load in highway runoff was attributed to metals (e.g., lead, zinc, and copper), although a significant number of organic pollutants were present in the highway environment.

Studies (4, 5) indicate that the magnitude of pollutants associated with highway runoff is related to traffic volume. Research (2) tends to indicate that 30,000 average daily traffic (ADT) is a general threshold for the potential of impacts from highway runoff; however, several variables must be factored into this conclusion, including sensitivity of receiving waters, distance to receiving waters, type of traffic, road or bridge design, and others.

The U.S. Department of Transportation (2) has drawn the following conclusions from these studies and other literature concerning highway runoff pollution potential:

- Highway runoff does have the potential to adversely affect the water quality and aquatic biota of receiving waters.
- The significance of these adverse effects is variable by highway type and design, receiving water, and runoff event.
- Runoff from urban highways with high ADT volumes may have a relatively high potential to cause adverse effects.
- Runoff from rural highways with low ADT volumes has a relatively low potential to cause adverse effects.

Basic Management Practices and Processes

Of the variety of best management practices available for nonpoint source pollution control, four basic management measures are generally considered cost effective for treatment of highway runoff based on effectiveness for specific pollutants, relative capital costs, land requirements, and operation and maintenance costs (2):

- Vegetative controls
- Wet detention basins
- Infiltration basins
- Wetlands

Pollution measures that were not considered effective when used as a sole management tool were street cleaning, catch basins, filtration devices for sediment control, dry detention ponds, and porous pavements (2). The first three methods were not effective in capturing the fine sediments to which many pollutants attach themselves, while the dry detention pond tended to reflush the settled particles after each rainfall event. Porous pavement is limited to low-volume traffic areas, such as parking lots, because of current highway construction standards.

All of the measures have in common several physical or biochemical processes that occur to provide the necessary control of pollutants: settling, filtering, adsorption, bioassimilation, biodegradation, and volatilization or evaporation. Table 2 lists the process associated with each management measure as related to the general type of pollutant control.

Management Measures for Bridges

Although bridges can be assumed to cause the same types of water quality impacts as highways, and although the techniques to manage those impacts are fairly straightforward and generally well accepted, the unique location of bridges presents some problems. First, the runoff from the bridge must be intercepted from seeking its natural pathway and routed back to high land or another area suitable for treatment; secondly, land areas for treatment are usually limited.

Collection and transportation are most easily solved in the design of the bridge, although in coastal areas runoff may have to be transported long distances with little grade. The physical land requirements for the appropriate treatment method, however, tend to be the most limiting factors. Solutions are very site specific and must be included in the earliest planning stages of the bridge. Topography at the bridge/land junction is often the single most important factor in considering the design of an appropriate treatment method, although other factors, such as high water tables, soil types, and adjacent land use, also can be important in the design consideration process. The design of the stormwater system should not drive the design of the bridge, but neither should the design of the bridge preclude the design of an effective stormwater treatment system.

All of the traditional stormwater management methods can be considered for treatment of runoff from bridges: wet detention ponds, infiltration systems, grassed waterways, and wetlands. These can be used even in combination with less favorable methods, such as frequent sweeping or catch basins, if the lack of good alternatives so dictates. Other opportunities that may be present in the area should also be considered, such as nearby spoil disposal containment areas, preexisting treatment systems for nearby development, or discharge routing to less sensitive areas.

The U.S. Environmental Protection Agency (EPA) (6) lists several general guidelines and management practices for illustrative purposes, specifically for bridges, in the Section 6217 management measure guidance document:

Table 2. Principal Pollutant Fate Processes by Major Management Measures

	Management Measures			
Pollutant	**Vegetative Control**	**Detention Basins**	**Infiltration Systems**	**Wetlands**
Heavy metals	Filtering	Adsorption, settling	Adsorption, filtration	Adsorption, settling
Toxic organics	Adsorption	Adsorption, settling, volatilization	Adsorption, biodegradation	Adsorption, settling, biodegradation, volatilization
Nutrients	Bioassimilation	Bioassimilation	Absorption	Bioassimilation
Solids	Filtering	Settling	Adsorption, settling	Adsorption
Oil and grease	Adsorption	Adsorption, settling	Adsorption	Adsorption, settling
Biochemical oxygen demand	Biodegradation	Biodegradation	Biodegradation	Biodegradation
Pathogens	NA	Settling	Filtration	NA

NA = information not available

- Coordinate design with the Federal Highway Administration (FHWA), U.S. Coast Guard, U.S. Army Corps of Engineers, and other state and federal agencies as appropriate.
- Review National Environmental Policy Act requirements to ensure that environmental concerns are met.
- Avoid highway locations requiring numerous river crossings.
- Direct pollutant loadings away from bridge decks by diverting runoff waters to land for treatment.
- Restrict the use of scupper drains on bridges less than 400 ft in length and on bridges crossing very sensitive ecosystems.
- Site and design new bridges to avoid sensitive ecosystems.
- On bridges with scupper drains, provide equivalent urban runoff treatment in terms of pollutant load reduction elsewhere on the project to compensate for the loading discharged off the bridge.

Regardless of the "illustrative" nature of the above practices, EPA and the National Oceanic and Atmospheric Administration (NOAA) expect the states to address nonpoint pollution from bridges and to adopt enforceable policies by 1995 to manage the runoff or to document why such runoff is not a problem.

South Carolina's Approach

In 1988, the South Carolina Coastal Council was faced with the permitting of a new 2-mile bridge connecting the mainland with a major developed barrier island (see below) and crossing a major shellfish-producing area. As an outcome of the permitting of this project, the Coastal Council developed a set of guidelines to use in conjunction with the South Carolina Department of Highways and Public Transportation to allow all parties to anticipate the design of stormwater controls in new bridges. It is not unusual for bridges to be designed well in advance of the permitting process, and the inclusion of new design criteria can cause both new expenses and a politically unpleasant situation. The guidelines have been in use since 1989 and have been introduced as regulations to the 1993 South Carolina General Assembly. The regulations appear to meet the basic intent of the EPA/NOAA Section 6217 guidance, although this has yet to be determined. The basic regulations are as follows.

Stormwater Management Requirements for Bridge Runoff

The following are the criteria used to address stormwater management for bridges traversing saltwater and critical areas.

- No treatment is necessary for runoff from bridge surfaces spanning Class SA and Class SB tidal saltwaters. (SA and SB waters are suitable for primary and secondary contact recreation, crabbing, and fishing. The two classes differ in their dissolved oxygen [DO] limitations: SA waters must maintain daily averages of not less than 5.0 mg/L, and SB waters must maintain DO levels not less than 4.0 mg/L.) This runoff can be discharged through scupper drains directly into surface waters. The use of scupper drains, however, should be limited as much as possible.
- If the receiving water is classified as either outstanding resource waters (ORW) or shellfish harvesting waters (SFH), then the stormwater management requirements shall be based on projected traffic volumes and the presence of any nearby shellfish beds. Table 3 lists the necessary treatment practices over the different classes of receiving waters.
- The ADT volume is based on the design carrying capacity of the bridge.

Table 3. Requirements for Stormwater Management on Bridges in the Coastal Zone, South Carolina

	ADT Volume	
Water Quality Classification	**0-30,000**	**30,000**
ORW (within 1,000 ft of shellfish beds)	A	A
ORW (not within 1,000 ft of shellfish beds)	B	B
SFH (within 1,000 ft of shellfish beds)	B	A
SFH (not within 1,000 ft of shellfish beds)	B	B
SFH (not within 1,000 ft of shellfish beds)	B	B
SA (exceptional)	C	C
SB (high quality)	C	C

A = The first 1-in. of runoff from the bridge surface must be collected and routed to an appropriate stormwater management system or routed so that maximum overland flow occurs, encouraging exfiltration before reaching the receiving water body. Periodic vacuuming of the bridge surface should be considered.
B = A stormwater management plan must be implemented that may require the overtreatment of runoff from associated roadways to compensate for the lack of direct treatment of runoff from the bridge surface itself. Periodic vacuuming should be considered. The use of scupper drains should be limited as much as possible.

The Isle of Palms Connector: A Case Study in Retrofitting

The incorporation of a stormwater management system into a bridge design usually can be done without any great difficulty. Trying to incorporate a system into a bridge already designed and ready for permitting, however, can be much more difficult. Such was the case with the Isle of Palms Connector, an 11,500-ft, $30 million bridge that was to provide alternate access to the Isle of Palms, a barrier island town just outside of Charleston, South Carolina. The bridge route called for the crossing of some 9,000 ft of marsh, two major marsh creeks, and the Intracoastal Waterway. Location and environmental studies and basic bridge design were completed in 1979, the same year the state's coastal zone management program was authorized. Funding limitations slowed the process until 1987, when federal funds became available.

The proposed route for the Isle of Palms Connector crossed over some of the state's most productive commercial and recreational shellfish grounds. The live oyster volume in Hamlin Creek and Swinton Creek alone was surveyed by the South Carolina Wildlife and Marine Resources Department at 32,000 bushels. Annual clam production potential in the immediate area of the bridge is estimated to be between 140,000 and 250,000 clams.

The bridge was originally designed with traditional methods of handling stormwater; water was drained directly from the bridge through scuppers except at one previously identified sensitive area, where discharge was eliminated. Because there were no objections to the stormwater design in the original environmental impact assessment, approved by the FHWA in 1986, the South Carolina Department of Highways and Public Transportation was reluctant to make any changes. Relocation of the bridge was not an option, nor, as it turned out, was redesign of the bridge. The bridge was designed with approximately 9,000 ft at 0.0 percent grade, with elevated spans over the Intracoastal Waterway and one of the creeks (Figure 1). The State Highway Department estimated redesign to accommodate positive flows to both ends of the bridge at $10 million, a one-third increase in bridge cost (7).

The South Carolina Coastal Council, however, as primary permitting agency for the bridge, was sensitive to public demand that the bridge must incorporate a stormwater management system that met basic coastal stormwater guidelines (8). After several meetings, which included public input, the South Carolina Department of Highways and Transportation agreed to work with the Coastal Council in addressing stormwater within the limits of two constraints: the bridge location could not be changed, and the stormwater system must be adaptable to the existing bridge design. Once this decision was reached, both agencies began a serious and cooperative effort in resolving the problem. It was immediately apparent that the traditional methods of stormwater treatment usually employed on high land must be ruled out; other than pumping, which was explored and rejected due to cost, there was no way to get the runoff back to high ground for treatment. Therefore, the study team threw

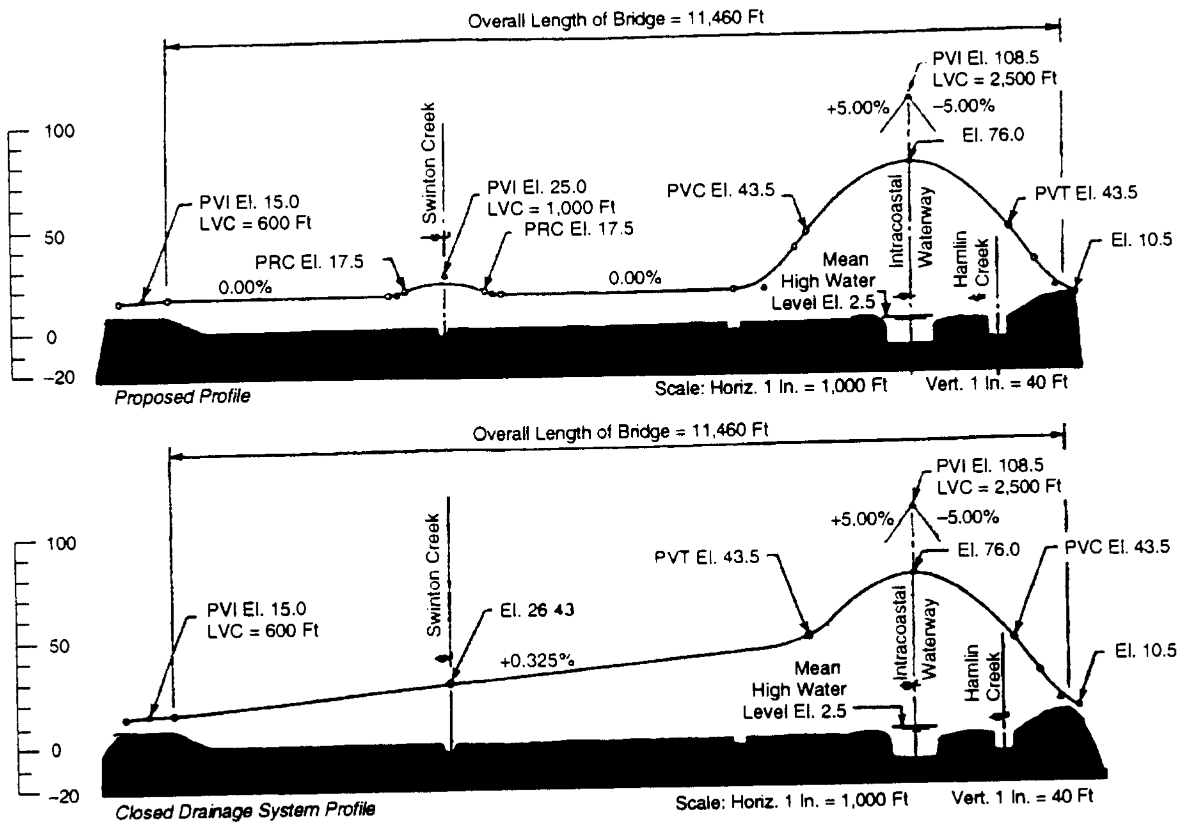

Figure 1. Proposed and closed drainage system profiles for Isle of Palms Connector.

out the preconceived traditional approaches and focused on the basic tenents of stormwater management: retention, settling, and pollutant removal. A variety of alternatives were identified, evaluated, and rejected for various reasons. Among these alternatives were storage and retention in gutters of several configurations along the shoulder of the bridge roadway and the design of an "in the marsh" sand filtering system constructed in large cylinders.

What emerged from this process was the design of an open-faced "runoff pan," 15 ft long by 32 in. wide, to be bolted in place to catch the discharge from each scupper drain (Figure 2). The pan, constructed of fiberglass, was 1 ft deep with a baffle overflow to prevent the discharge of oil and grease. In addition to containing the first 3/4 in. of runoff, the pans were to be managed with a vigorous maintenance program that would include dry/wet vacuuming on a to-be-determined basis and disposal of the residue in accordance with state hazardous waste regulations. The estimated cost for the stormwater management system, to include piping of runoff from the vertical expansions of the bridge to high ground and an adjacent spoil disposal area, was about 3.5 percent of the total bridge cost.

Accompanying this alternative was the commitment of the State Highway Department and the Coastal Council to develop a monitoring program to test the effectiveness of this technique. The monitoring program was to be implemented on completion of the bridge, estimated for the fall of 1993. Background data was collected in the summer and fall of 1993.

Both agencies, along with the concerned public, eagerly await the results of the monitoring. If successful, the runoff pan may provide one alternative for addressing stormwater management on existing bridges crossing sensitive waters.

Conclusion

Roadways and bridges are certainly not unique in their potential contribution to lessened water quality. Virtually all human activities on the land, on the water, and in the air contribute to the problem. No one solution to correct the problem exists; rather, the solution lies with the incremental "micromanagement" of each specific activity that contributes to the problem.

Controlling Pollutants in Runoff From Industrial Facilities

Kevin Weiss
Storm Water Section, NPDES Permits Division, U.S. Environmental Protection Agency, Washington, DC

Abstract

Industrial facilities can be significant contributors of pollutants to urban runoff. On November 16, 1990, the U.S. Environmental Protection Agency (EPA) published National Pollutant Discharge Elimination System (NPDES) permit application requirements for "stormwater discharges associated with industrial activities." These regulations provide a framework for reducing pollutants in runoff from the industrial facilities addressed. EPA subsequently developed a long-term strategy for issuing NPDES permits for these discharges. As the initial step in this strategy, the Agency issued general permits on September 9, 1992, and September 25, 1992, for the majority of stormwater discharges in states where EPA issues NPDES permits. This paper provides an overview of major categories of sources that contribute pollutants to runoff at industrial sites and describes pollution prevention measures in EPA's NPDES general permits.

Introduction

Pollutants in urban runoff depend in part on the nature of land use. Several studies indicate that runoff from industrial land uses is of relatively poorer water quality than runoff from other general land uses (1-5). In addition, industrial sites can be significant sources of polluted, uncontrolled nonstormwater to separate storm sewers (6, 7).

Source of Pollutants to Industrial Runoff

The volume and quality of stormwater discharges associated with industrial facilities depend on several factors, including the industrial activities occurring at the facility, the nature of precipitation, and surface imperviousness. The sources of pollutants that can affect the quality of stormwater from industrial facilities differ with the type of operations and specific facility features. For example, air emissions may be a significant source of pollutants at some facilities, material storage operations at others, and still other facilities may discharge stormwater associated with industrial activity with relatively low levels of pollutants.

Six classes of activities can be identified as major potential sources of pollutants in stormwater discharges associated with industrial activity (7-11):

- Loading or unloading of dry bulk materials or liquids.
- Outdoor storage of raw materials or products.
- Outdoor process activities.
- Dust or particulate generating processes.
- Illicit connections or inappropriate management practices.
- Waste disposal practices.

The potential for pollution from many of these activities may be influenced by the presence and use of toxic chemicals.

Loading and unloading operations typically are performed along facility access roads and railways and at loading/unloading docks and terminals. These operations include pumping of liquids or gases from trucks or rail cars to a storage facility or vice versa; pneumatic transfer of dry chemicals to or from the loading or unloading vehicle; transfer by mechanical conveyor systems; and transfer of bags, boxes, drums, or other containers from vehicles by forklift trucks or other materials handling equipment. Material spills or losses may discharge directly to the storm drainage systems or may accumulate in soils or on surfaces, to be washed away during a storm or facility washdown.

Outdoor storage includes the storage of fuels, raw materials, byproducts, deicing chemicals, intermediates, final products, and process residuals and wastes. Methods of material storage include use of storage containers (e.g., drums or tanks), platforms or pads, bins, silos, boxes, and piles. Materials, containers, and material storage areas exposed to rainfall or runoff may contribute pollutants to stormwater when solid materials wash off or materials dissolve into solution.

Other outdoor activities include certain types of manufacturing and commercial operations and land-disturbing operations. Although many manufacturing activities are performed indoors, some activities (e.g., equipment and vehicle maintenance and cleaning, timber processing, rock crushing, vehicle maintenance and cleaning, and concrete mixing) typically occur outdoors. Processing operations may result in liquid spillage and losses of material solids to the drainage system or surrounding surfaces, or creation of dusts or mists that can be deposited locally. Some outdoor industrial activities cause substantial physical disturbance of land surfaces that result in soil erosion by stormwater. For example, disturbed land occurs in construction and mining. Disturbed land may result in soil losses and other pollutant loadings associated with increased runoff rates. Facilities whose major process activities are conducted indoors may still apply chemicals such as herbicides, pesticides, and fertilizer outdoors for a variety of purposes.

Dust or particulate generating processes include industrial activities with stack emissions or process dusts that settle on plant surfaces. Localized atmospheric deposition can be a particular concern with heavy manufacturing industries. For example, monitoring of areas surrounding smelting industries has shown much higher levels of metals at sites nearest the smelter. Other industrial sites, such as mines, cement manufacturing plants, and refractories, generate significant levels of dusts.

Illicit connections or inappropriate management practices result in improper nonstormwater discharges to storm sewer systems. Pollutants from nonstormwater discharges to the storm sewer systems are caused typically by a combination of improper connections, spills, improper dumping, and improperly disposed of rinse waters, cooling waters, or other process and sanitary wastewater. Often dischargers believe that the absence of visible solids in a discharge is equivalent to the absence of pollution. Illicit connections are often associated with floor drains that are connected to separate storm sewers. Rinse waters used to clean or cool objects discharge to floor drains connected to separate storm sewers. Large amounts of rinse waters that discharge to floor drains may originate from industries using regular washdown procedures; for example, bottling plants use rinse waters for removing waste products, debris, and labels. Rinse waters can be used to cool materials by dipping, washing, or spraying objects with cool water; for example, rinse water is sometimes sprayed over the final products of a metal plating facility for cooling purposes. Condensate return lines of heat exchangers often discharge to floor drains. Heat exchangers, particularly those used under stressed conditions (e.g., exposure to corrosive fluids), such as in the metal finishing and electroplating industry, may develop pinhole leaks that result in contamination of condensate by process wastes. These and other nonstormwater discharges to storm sewers may be intentional, based on the belief that the discharge does not contain pollutants, or they may be inadvertent, if the operator is unaware that a floor drain is connected to the storm sewer.

Waste management practices include temporary storage of waste materials and operations at landfills, waste piles, and land application sites that involve land disposal. Outdoor waste treatment operations also include wastewater and solid waste treatment and disposal processes, such as waste pumping, additions of treatment chemicals, mixing, aeration, clarification, and solids dewatering.

Options for Control

Options for controlling pollutants in stormwater discharges associated with industrial activity are discussed below in terms of two major pollutant sources: 1) materials discharged to separate storm sewers via illicit connections, improper dumping, and spills; and 2) pollutants associated with runoff.

Nonstormwater Sources

As discussed above, nonstormwater discharges to separate storm sewers come from a wide variety of sources, including illicit connections, improper dumping, spills, or leakage from storage tanks and transfer areas. Measures to control spills and visible leakage can be incorporated into the best management practices discussed below.

In many cases, operators of industrial facilities may be unaware of illicit discharges or other nonvisible sources of nonstormwater to a storm sewer. In such cases, the key to controlling these discharges is to identify them. Several methods for identifying the presence of nonstormwater discharges are discussed below. (A more complete discussion of methods to identify illicit connections can be found in U.S. EPA [6, 12]). A comprehensive evaluation of the storm sewers at a facility often should incorporate several of the following methods:

- *Evaluation of drainage map and inspections:* Drainage maps should identify the key features of the drainage system (i.e., each of the inlet and discharge structures, the drainage area of each inlet structure, storage and disposal units, and materials loading areas) that may be the source of an illicit discharge or improper dumping. In addition, floor drains and other water disposal inlets thought to be connected to the sanitary sewer should be identified. A site inspection can be used to augment and verify map development. These inspections, along with the use of the drainage map, can be coordinated with other identification methods discussed below.

- *End-of-pipe screening:* Discharge points or other access points such as manhole covers can be inspected for the presence of dry weather discharges and other signs of nonstormwater discharges. Dry weather flows, material deposits, and stains are often indicators of illicit connections. Dry weather flows can be screened by a variety of methods. Inexpensive onsite tests include measuring pH; observing for oil sheens, scums, and discoloration of pipes and other structures; and colorimetric detection for chlorine, detergents, metals, and other parameters. In some cases, it may be appropriate to collect samples for more expensive analysis in a laboratory for fecal coliform, fecal *Streptococcus,* volatile organic carbon, or other appropriate parameters.

- *Manhole and internal TV inspection:* Inspection of manholes and storm sewers, either physically or by television, can be used to identify a potential entry point for illicit connections. TV inspections are relatively expensive and generally should be used only after a storm sewer has been identified as having illicit connections.

- *Dry weather testing:* Where storm sewers do not normally discharge during dry weather conditions, water can be introduced into floor drains, toilets, and other points where nonstormwater discharges are collected. Storm drain outlets are then observed for possible discharges.

- *Dye testing:* Dry weather discharges from storm sewers can occur for several legitimate reasons, including ground-water infiltration or the presence of a continuous discharge subject to a National Pollutant Discharge Elimination System (NPDES) permit. Where storm sewers do have a discharge during dry weather conditions, dye testing for illicit connections can be used. Dye testing involves introducing fluorometric or other types of dyes into floor drains, toilets, and other points where nonstormwater discharges are collected. Storm drain outlets and manholes are then observed for possible discharges. Dye testing can also be used to identify unknown submerged outfalls to nearby receiving waters.

- *Water balance:* Many sewage treatment plants require that industrial discharges measure the volume of effluent discharged to the sanitary sewer system. Similarly, the volume of water supplied to a facility is generally measured. A significantly higher volume of water supplied to the facility relative to that discharged to the sanitary sewer and other consumptive uses may be an indication of illicit connections. This method is limited by the accuracy of the flow meters used.

- *Schematics:* Where they exist, accurate piping schematics can be inspected as a first step in evaluating the integrity of the separate storm sewer system. The use of schematics is limited because schematics usually reflect the design of the piping system and may not reflect the actual configuration constructed. Schematics should be updated or corrected based on additional information found during inspections.

Smoke tests are sometimes listed in the literature as a method for detecting illicit connections to separate storm sewers. While smoke tests can be used to identify inflow of stormwater to sanitary sewers, they can be much less effective for identifying discharges of nonstormwater to storm drains. This is because many nonstormwater drainage locations have a sewer gas trap that blocks smoke used in a test. Smoke tests can identify nonstormwater discharges to storm drains if the piping for the nonstormwater discharge has a vent or does not have a sewer gas trap.

Options for Preventing Pollutants in Stormwater

The following five categories describe options for reducing pollutants in stormwater discharges from industrial plants:

- Providing end-of-pipe treatment.
- Implementing best management practices (BMPs) to prevent pollution.
- Diverting stormwater discharge to treatment plants.
- Using traditional stormwater management practices.
- Eliminating pollution sources/water reuse.

A comprehensive stormwater management program for a given plant often includes controls from each of these categories. Development of comprehensive control strategies should be based on a consideration of plant characteristics.

End-of-Pipe Treatment

At many types of industrial facilities, it may be appropriate to collect and treat the runoff from targeted areas of the facility. This approach was taken with the 10 industrial categories with national effluent guideline limitations for stormwater discharges: cement manufacturing (40 CFR 411), feedlots (40 CFR 412), fertilizer manufacturing (40 CFR 418), petroleum refining (40 CFR 419), phosphate manufacturing (40 CFR 422), steam electric (40 CFR 423), coal mining (40 CFR 434), mineral mining and processing (40 CFR 436), ore mining and dressing (40 CFR 440), and asphalt emulsion (40 CFR 443).

Best Management Practices

BMPs encompass a wide range of management procedures, schedules of activities, prohibitions on practices, and other management practices to prevent or reduce the pollution of waters of the United States. BMPs also include operating procedures, treatment requirements and practices to control plant site runoff, and drainage from raw materials storage, spills, or leaks. Requirements for BMP-based pollution prevention plans generally applicable to all industries are discussed in more detail in the paper in the context of the U.S. Environmental Protection Agency's (EPA's) general permits for stormwater discharges associated with industrial activity.

In addition to generic BMPs or pollution prevention plans, industry- or activity-specific BMPs can be used. Table 1 provides a listing of industry-specific BMPs that the Washington State Department of Ecology has developed.[1]

Diversion of Discharge to Treatment Plant

Where stormwater discharges contain significant amounts of pollutants that can be removed by a wastewater or sewage treatment plant, the stormwater discharge can be diverted to a wastewater treatment plant or sanitary sewage system. Such diversions must be coordinated with the operators of the sewage treatment plant and the collection system to avoid problems with either combined sewer overflows (CSOs), basement flooding, or wet weather operation of the treatment plant. Where CSO discharges, flooding or plant operation problems can result, and onsite storage followed by a controlled release during dry weather conditions may be considered.

Traditional Stormwater Management Practices

In some situations, traditional stormwater management practices such as grass swales, catch basin design and maintenance, infiltration devices, unlined onsite retention and detention basins, regional controls (offsite retention or detention basins), and oil and grit separators can be applied to an industrial setting. Care must be taken, however, to evaluate the potential of many of these traditional devices for ground-water contamination. Other types of controls, such as secondary containment systems, can be used to prevent catastrophic events that can lead to surface or ground-water contamination via traditional stormwater measures. In some cases, it is appropriate to limit traditional stormwater management practices to those areas of the drainage system that generate stormwater with relatively low levels of pollutants (e.g., many rooftops, parking lots, etc.). At facilities located in northern areas of the country, snow removal activities may play an important role in a stormwater management program.

Elimination of Pollution Sources/Water Reuse

In some cases, the elimination of a pollution source or water reuse may be the most cost-effective way to control pollutants in stormwater discharges associated with industrial activity. Options for eliminating pollution sources include reducing onsite air emissions affecting runoff quality, changing chemicals used at the facility, and modifying materials management practices such as moving storage areas into buildings. Water reuse involves collecting runoff and using it in a process or in some manner that does not release the pollutants in the stormwater to the environment. For example, many inorganic wood preserving facilities use drip pad runoff to dilute wood preserving fluids used in their processes. In some cases, it may be less expensive to store and treat stormwater for subpotable, industrial water supply purposes than purchasing municipal potable water.

Clean Water Act Requirements

In 1972, the Clean Water Act (CWA) was amended to provide that the discharge of any pollutants to waters of the United States from a point source is unlawful, except where the discharge is authorized by an NPDES permit. The term "point source" is broadly defined to include "any discernible, confined and discrete conveyance, including but not limited to any pipe, ditch, [or] channel, . . . from which pollutants are or may be discharged." Congress has specifically exempted agricultural stormwater discharges and return flows from irrigated agriculture from the definition of point source.

Most court cases have supported a broad interpretation of the term "point source" under the CWA. For example, the holding in *Sierra Club v. Abston Construction Co., Inc.*, 620 F 2d. 41 (5th Cir., 1980) indicates that changing the surface of land or establishing grading patterns on land where the runoff from the site ultimately is discharged to waters of the United States will result in a point source:

> A point source of pollution may be present where [dischargers] design spoil piles from discarded overburden such that, during periods of precipitation, erosion of spoil pile walls results in discharges into a navigable body of water by means of ditches, gullies and similar conveyances, even if the [dischargers] have done nothing beyond the mere collection of rock and other materials. . . . Nothing in the Act relieves [dischargers] from liability simply because the operators did not actually construct

[1] The document *Best Management Practices for the Use and Storage of Hazardous Materials* (14) also provides examples of industry-specific BMPs. The guidance addresses small mechanical repair facilities, large mechanical repair facilities, dry cleaning facilities, junkyards, photo processing facilities, print shops and silk screen shops, machine shops and airport maintenance facilities, boat manufacturing and repair facilities, concrete plants and mining facilities, agricultural facilities, paint manufacturers and distributors, and plastics manufacturers.

Table 1. **Categories of Targeted Stormwater Controls Addressed in Puget Sound Guidance (13)**

Category	Targeted Stormwater Controls
Manufacturing facilities	Cement Chemical Concrete products Electrical products Food products Glass products Industrial machinery and equipment, trucks and trailers, aircraft, parts and aerospace, railroad equipment Log storage and sorting yards, debarking Metal products Petroleum products Printing and publishing Rubber and plastic products Ship and boat building and repair yards Wood products Wood treatment Other manufacturing businesses
Transportation and communication	Airfields and aircraft maintenance Fleet vehicle yards Railroads Private utility corridors Warehouses and miniwarehouses Other transportation and communication businesses
Wholesale and retail businesses	Gas stations Recyclers and scrap yards Restaurants/fast food Retail general merchandise Retail/Wholesale vehicle and equipment dealers Retail/Wholesale nurseries and building materials Retail/Wholesale chemicals and petroleum Retail/Wholesale foods and beverages Other retail/wholesale businesses
Service businesses	Animal care services Commercial car and truck washes Equipment repair Laundries and other cleaning Marinas and boat clubs Golf and country clubs, golf courses, and parks Miscellaneous services Professional services Vehicle maintenance and repair Multifamily residences Construction businesses
Pubic agencies	Public buildings and streets Vehicle and equipment maintenance shops Maintenance of open space areas Maintenance of public stormwater facilities Maintenance of roadside vegetation and ditches Maintenance of public utility corridors Water and sewer districts and departments Port districts
Source controls	Fueling stations Vehicle/Equipment washing and steam cleaning Loading and unloading liquid materials Liquid storage in aboveground tanks Container storage of liquids, food wastes, and dangerous wastes Outside storage of raw materials, byproducts, and finished products Outside manufacturing activities Emergency spill cleanup plans Vegetation management/integrated pest management Maintenance of storm drainage facilities Locating illicit connections to storm drains

those conveyances. . . . Conveyances of pollution formed either as a result of natural erosion or by material means, and which constitute a component of a drainage system may fit the statutory definition and thereby subject the operators to liability under the Act.

Although the definition of point source is very broad, before 1987 efforts under the NPDES program to control water pollution focused on controlling pollutants in discharges from publicly owned treatment works (POTWs) and industrial process wastewaters. The major exceptions to this are the 10 effluent limitation guidelines that EPA has issued for stormwater discharges: cement manufacturing (40 CFR 411), feedlots (40 CFR 412), fertilizer manufacturing (40 CFR 418), petroleum refining (40 CFR 419), phosphate manufacturing (40 CFR 422), steam electric (40 CFR 423), coal mining (40 CFR 434), mineral mining and processing (40 CFR 436), ore mining and dressing (40 CFR 440), and asphalt emulsion (40 CFR 443).

As part of the Water Quality Act of 1987, Congress added Section 402(p) to the CWA to require EPA to develop a comprehensive, phased program for regulated stormwater discharges under the NPDES program. One of the first priorities under the stormwater program was to develop NPDES requirements for stormwater discharges associated with industrial activity.

On November 16, 1990, EPA published the initial NPDES regulations under Section 402(p) of the CWA (see 55 FR 47990). The November 16, 1990, regulations:

- Defined the initial scope of the program by defining the terms "stormwater discharge associated with industrial activity" and large and medium "municipal separate storm sewer systems."
- Established permit application requirements.

The regulatory definition of the term "stormwater discharge associated with industrial activity" is provided at 40 CFR 122.26(b)(14) and addresses point source discharges of stormwater from eleven major categories of facilities. Table 2 summarizes these 11 major categories.

The NPDES regulations provided three options for submitting permit applications for stormwater discharges associated with industrial activity: 1) individual applications, 2) group applications for groups of similar industrial discharges, and 3) where an appropriate general permit has been issued, submittal of a notice of intent (NOI) to be covered by a general permit. The group application option is no longer available; EPA received over 1,100 group applications covering over 45,000 facilities. The Agency has organized these applications into the 32 industrial sectors shown in Table 3 and intends to develop guidance on issuing permits for the 32 industrial sectors.

Table 2. Summary of Classes of Industrial Facilities Addressed by Regulatory Definition of "Stormwater Discharge Associated With Industrial Activity"

Class	Description
(i)	Facilities subject to stormwater effluent limitations guideline, new source performance standards, or toxic pollutant effluent standards (see 40 CFR Subpart N)
(ii)	Manufacturing facilities classified as Standard Industrial Classification (SIC) 24 (except 2434), 26 (except 265 and 267), 28 (except 283), 29, 311, 32 (except 323), 33, 3441, and 373
(iii)	Active and inactive mining operations classified as SIC 10-14
(iv)	Hazardous waste treatment, storage, or disposal facilities that are operating under interim status or a permit under Subtitle C of RCRA
(v)	Landfills, land application sites, and open dumps that receive industrial wastes
(vi)	Recycling facilities, including metal scrapyards, battery reclaimers, salvage yards, and automobile junkyards
(vii)	Steam electric power generating facilities
(viii)	Transportation facilities classified as SIC 40, 41, 42 (except 4221-25), 43, 44, 45, and 5171, which have vehicle maintenance shops, equipment cleaning operations, or airport deicing operations
(ix)	Sewage treatment plants with a design flow of 1.0 million gal/day or more or required to have an approved pretreatment program
(x)	Construction activities except operations that result in the disturbance of less than 5 acres of total land area and that are not part of a larger common plan of development or sale
(xi)	Facilities under SIC 20, 21, 22, 23, 2434, 25, 265, 267, 27, 283, 285, 30, 31 (except 311), 323, 34 (except 3441), 35, 36, 37 (except 373), 38, 39, and 4221-25 (and which are not otherwise included within categories (i)-(x))

Table 3. Industrial Sectors Identified in NPDES Group Application Process

Sector	SIC Codes/Activities Represented	Number of Facilities
1	SIC 24—Lumber and Wood Products	2,640
2	SIC 26—Paper and Allied Products	1,023
3	SIC 28—Chemicals and Allied Products	1,498
4	SIC 29—Petroleum Refining and Related Industries	2,245
5	SIC 32—Stone, Clay, Glass, and Concrete Products	4,786
6	SIC 33—Primary Metal Industries	730
7	SIC 10—Metal Mining	188
8	SIC 12—Coal Mining	495
9	SIC 13—Oil and Gas Extraction	457
10	SIC 14—Mining and Quarrying of Nonmetallic Minerals	2,437
11	Hazardous Waste Treatment Storage or Disposal Facilities	77

Table 3. **Industrial Sectors Identified in NPDES Group Application Process (continued)**

Sector	SIC Codes/Activities Represented	Number of Facilities
12	Industrial Landfills, Land Application Sites, and Open Dumps	1,430
13	SIC 5015—Used Motor Vehicle Parts	2,009
14	SIC 5093—Scrap and Waste Materials	1,688
15	Steam Electric Power Generating Facilities	162
16	SIC 40—Railroad Transportation	1,024
17	SIC 41—Local and Suburban Transit and Interurban Highway Passenger Transportation SIC 42—Motor Freight Transportation SIC 43—United States Postal Service	13,089
18	SIC 44—Water Transportation	368
19	SIC 3731—Ship Building and Repairing SIC 3732—Boat Building and Repairing	498
20	SIC 45—Air Transportation	1,581
21	SIC 5171—Petroleum Bulk Stations and Terminals	131
22	Domestic Wastewater Treatment Plants	1,249
23	SIC 20—Food and Kindred Products SIC 21—Tobacco Products	2,608
24	SIC 22—Textile Mill Products SIC 23—Apparel and Other Finished Products Made From Fabrics and Similar Materials	872
25	SIC 25—Furniture and Fixtures	339
26	SIC 27—Printing, Publishing, and Allied Industries	65
27	SIC 30—Rubber and Miscellaneous Plastic Products	190
28	SIC 31—Leather and Leather Products	61
29	SIC 34—Fabricated Metal Products SIC 391—Jewelry, Silverware, and Plated Ware	965
30	SIC 35—Industrial and Commercial Machinery SIC 37—Transportation Equipment	935
31	SIC 36—Electronic Components SIC 357—Computer and Office Equipment SIC 38—Measuring, Analyzing, and Control Instruments; Photographic and Optical Goods, Watches, and Clocks	14
32	SIC—Miscellaneous Manufacturing Industries	769

Long-Term Strategy

Many of the initial concerns regarding the NPDES stormwater program focused on adapting the NPDES permit program to effectively address the large number of stormwater discharges associated with industrial activity. In response to these concerns, EPA developed a strategy for permitting stormwater discharges associated with industrial activity that will serve as a foundation for future program development and technology transfer. The strategy consists of two major components: a tiered framework for developing permitting priorities and a framework for the development of state stormwater management plans.

Permitting Priorities

Under the strategy, most stormwater permitting activities are described in terms of the following four classes of activities:

- *Tier I—Baseline permitting:* One or more general permits will be developed initially to cover the majority of stormwater discharges associated with industrial activity.
- *Tier II—Watershed permitting:* Facilities within watersheds shown to be adversely affected by stormwater discharges associated with industrial activity will be targeted for individual or watershed-specific general permits.
- *Tier III—Industry-specific permitting:* Specific industry categories will be targeted for individual or industry-specific general permits.
- *Tier IV—Facility-specific permitting:* A variety of factors will be used to target specific facilities for individual permits.

These four classes of activities will be implemented over time and will reflect priorities within given states. In most states, Tier I activities will be the starting point. Initially, the coverage of the baseline permits will be broad. As priorities and risks within the state are evaluated, however, classes of stormwater discharges or individual stormwater discharges will be identified for Tier II, III, or IV permitting activities.

State Stormwater Management Programs

State stormwater management programs are to provide, among other things, a description of NPDES permit issuing activities for stormwater discharges associated with industrial activity, including categories of industrial activity that are being considered for industry-specific general permits. These plans will assist EPA in developing technology transfer activities with other states, evaluating states' progress in implementing stormwater permitting activities, and identifying both successes and difficulties with ongoing program implementation.

EPA's Baseline General Permits

Consistent with the long-term permit issuance strategy, EPA published Tier I general permits, which potentially could apply to the majority of stormwater discharges associated with industrial activity located in 12 states on

September 9, 1992, and September 25, 1992 (see 57 FR 41236 and 57 FR 44438). The 12 states where the EPA general permits apply are Alaska, Arizona, Florida, Idaho, Louisiana, Maine, Massachusetts, New Hampshire, New Mexico, Oklahoma, South Dakota, and Texas. Other states have authorized NPDES state programs, and the state issues NPDES permits instead of EPA.

Consolidating many sources under a general permit greatly reduces the administrative burden of issuing permits for stormwater discharges associated with industrial activity. Several advantages to this approach are:

- Pollution prevention measures and/or BMPs are established for discharges covered by the permit.
- Facilities whose discharges are covered by the permit are certain of their legal responsibilities and have an opportunity to comply with the CWA.
- EPA and authorized NPDES states will begin to collect and review data on stormwater discharges from priority industries, thereby supporting subsequent permitting activities.
- The public, including municipal operators of municipal separate storm sewers, will have the opportunity to review data and reports developed by industrial permittees pursuant to NPDES requirements.
- The baseline permits will provide a basis for coordinating 1) requirements for stormwater discharges associated with industrial activity with 2) requirements of municipal stormwater management programs in permits for discharges from municipal separate storm sewer systems.
- The baseline permits will provide a basis for bringing selected enforcement actions.
- The baseline permit, along with state stormwater permitting plans, will provide a focus for public comment on draft permits and subsequent phases of the permitting strategy for stormwater discharges.

The Agency believes that Tier I permits can establish the appropriate balance between monitoring requirements and implementable controls that will initiate facility-specific controls and provide sufficient data for compliance monitoring and future program development.

Permit Requirements

The major requirements of EPA's Tier I stormwater general permits are notification requirements, requirements for stormwater pollution prevention plans, and special requirements for selected facilities.

Notification Requirements

The general permits require the submittal of an NOI by the discharger before the authorization of discharges. In addition, operators of stormwater discharges that discharge through a large or medium municipal separate storm sewer system must, in addition to submitting an NOI to the Director, submit a copy of the NOI to the municipal operator of the system receiving the discharge.

Tailored Pollution Prevention Plan Requirements

All facilities covered by EPA's general permits must prepare and implement a stormwater pollution prevention plan. These tailored requirements allow the implementation of site-specific measures that address features, activities, or priorities for control associated with the identified stormwater discharges. The approach taken allows the flexibility to establish controls that can appropriately address different sources of pollutants at different facilities.

The pollution prevention approach adopted in the general permits focuses on two major objectives: 1) to identify sources of pollution potentially affecting the quality of stormwater discharges from the facility, and 2) to describe and ensure implementation of practices to minimize and control pollutants in stormwater discharges.

The stormwater pollution prevention plan requirements in the general permits are intended to facilitate a process whereby the operator of the industrial facility thoroughly evaluates potential pollution sources at the site and selects and implements appropriate measures to prevent or control the discharge of pollutants in stormwater runoff. The process involves the following four steps:

- Formation of a team of qualified plant personnel responsible for preparing the plan and assisting the plant manager in its implementation.
- Assessment of potential stormwater pollution sources.
- Selection and implementation of appropriate management practices and controls.
- Periodic evaluation of the ability of the plan to prevent stormwater pollution and comply with the terms and conditions of this permit.

This process is shown in Figure 1. A complete description of this process can be found in U.S. EPA (15).

Pollution Prevention Team

As a first step in the process of developing and implementing a stormwater pollution prevention plan, permittees must identify a qualified individual or team of individuals to be responsible for developing the plan and assisting the facility or plant manager in its implementation. When

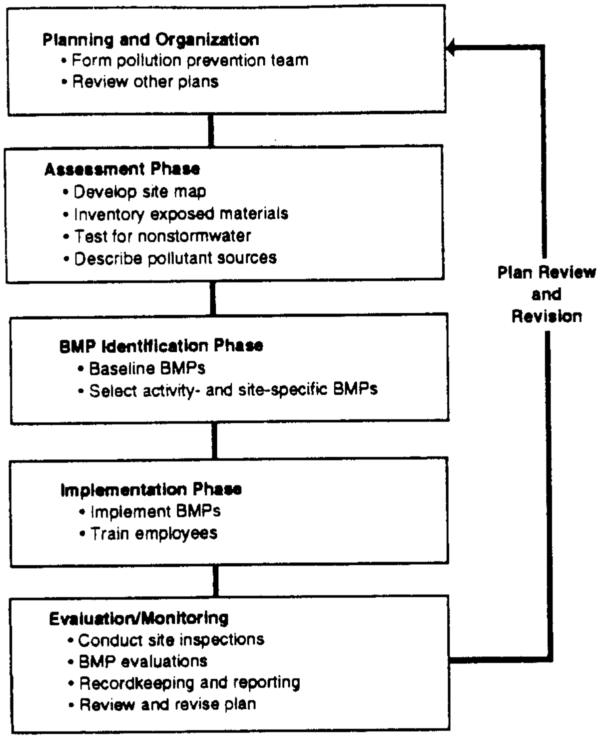

Figure 1. Pollution prevention plan process.

selecting members of the team, the plant manager should draw on the expertise of all relevant departments within the plant to ensure that all aspects of plant operation are considered. The plan must clearly describe the responsibilities of each team member as they relate to specific components of the plan. In addition to enhancing the quality of communication between team members and other personnel, clear delineation of responsibilities will ensure that a specified individual or group of individuals addresses every aspect of the plan.

Description of Potential Pollution Sources

Each stormwater pollution prevention plan must describe activities, materials, and physical features of the facility that may contribute significant amounts of pollutants to stormwater runoff or, during periods of dry weather, result in pollutant discharges through the separate storm sewers or stormwater drainage systems. This assessment of stormwater pollution risk will support subsequent efforts to identify and set priorities for necessary changes in materials, materials management practices, or site features, as well as aid in the selection of appropriate structural and nonstructural control techniques. Plans must describe the site drainage, provide an inventory of exposed materials, describe significant spills and leaks that have occurred at the facility, and include existing sampling data.

Each pollution prevention plan must include a certification that discharges from the site have been tested or evaluated for the presence of nonstormwater discharges. The certification must describe possible significant sources of nonstormwater, the results of any test and/or evaluation conducted to detect such discharges, the test method or evaluation criteria used, the dates on which tests or evaluations were performed, and the onsite drainage points directly observed during the test or evaluation. Acceptable test or evaluation techniques are discussed earlier in this paper.

The description of potential pollution sources culminates in a narrative assessment of the risk potential that sources of pollution pose to stormwater quality. This assessment should clearly point to activities, materials, and physical features of the facility that have a reasonable potential to contribute significant amounts of pollutants to stormwater. Any such activities, materials, or features must be addressed by the measures and controls subsequently described in the plan. In conducting the assessment, the facility operator must consider loading and unloading operations, outdoor storage activities, outdoor manufacturing or processing activities, significant dust or particulate generating processes, and onsite waste disposal practices. The assessment must list any significant pollution sources at the site and identify the pollutant parameter or parameters (i.e., biochemical oxygen demand, suspended solids, etc.) associated with each source.

Measures and Controls

Following completion of the source identification and assessment phase, the permittee must evaluate, select, and describe the pollution prevention measures, BMPs, and other controls that the facility will implement. BMPs include processes, procedures, schedules of activities, prohibitions on practices, and other management practices that prevent or reduce the discharge of pollutants in stormwater runoff.

The plan requirements emphasize the implementation of pollution prevention measures that reduce possible pollutant discharges at the source. Source reduction measures include, among others, preventive maintenance, chemical substitution, spill prevention, good housekeeping, training, proper materials management, material segregation or covering, water diversion, and dust control. The remaining classes of BMPs, which involve recycling or treatment of stormwater, allow the reuse of stormwater or attempt to lower pollutant concentrations before discharge.

The pollution prevention plan must include a schedule specifying the time or times during which each control or practice will be implemented. In addition, the plan should discuss ways in which the controls and practices relate to one another and, when taken as a whole, produce an integrated and consistent approach for preventing or controlling potential stormwater contamination problems. The portion of the plan that describes the measures and controls must address the following minimum components:

- *Good housekeeping:* Good housekeeping involves using common sense to identify ways to maintain a clean and orderly facility and keep contaminants out of separate storm sewers. It includes establishing protocols to reduce the possibility of mishandling chemicals or equipment, and training employees in good housekeeping techniques.
- *Preventive maintenance:* Permittees must develop a preventive maintenance program that involves regular inspection and maintenance of stormwater management devices and other equipment and systems. The program description should identify the devices, equipment, and systems that will be inspected; provide a schedule for inspections and tests; and address appropriate adjustment, cleaning, repair, or replacement of devices, equipment, and systems. For stormwater management devices such as catch basins and oil/water separators, the preventive maintenance program should provide for periodic removal of debris to ensure that the devices are operating efficiently.
- *Spill prevention and response procedures:* Based on an assessment of possible spill scenarios, permittees must specify appropriate material handling procedures, storage requirements, containment or diversion equipment, and spill cleanup procedures that will minimize the potential for spills and in the event of a spill enable proper and timely response. Areas and activities that typically pose a high risk for spills include loading and unloading areas, storage areas, process activities, and waste disposal activities. These activities and areas, and their accompanying drainage points, must be described in the plan. For a spill prevention and response program to be effective, employees should clearly understand the proper procedures and requirements and have the equipment necessary to respond to spills.
- *Inspections:* Qualified facility personnel must be identified to inspect designated equipment and areas of the facility at appropriate intervals specified in the plan. A set of tracking or followup procedures must be used to ensure that appropriate actions are taken in response to the inspections.
- *Employee training:* The pollution prevention plan must describe a program for informing personnel at all levels of responsibility of the components and goals of the stormwater pollution prevention plan. Where appropriate, contractor personnel also must be trained in relevant aspects of stormwater pollution prevention.
- *Recordkeeping and internal reporting procedures:* The pollution prevention plan must describe procedures for developing and retaining records on the status and effectiveness of plan implementation. At a minimum, records must address spills, monitoring, and inspection and maintenance activities. The plan also must describe a system that enables timely reporting of stormwater management-related information to appropriate plant personnel.
- *Sediment and erosion control:* The pollution prevention plan must identify areas that, due to topography, activities, soils, cover materials, or other factors, have a high potential for significant soil erosion. The plan must identify measures that will be implemented to limit erosion in these areas.
- *Management of runoff:* The plan must contain a narrative evaluation of the appropriateness of traditional stormwater management practices (i.e., practices other than those that control pollutant sources) that divert, infiltrate, reuse, or otherwise manage stormwater runoff to reduce the discharge of pollutants. Appropriate measures may include, among others, vegetative swales, collection and reuse of stormwater, inlet controls, snow management, infiltration devices, and wet detention/retention basins.

Based on the results of the evaluation, the plan must identify practices that the permittee determines to be reasonable and appropriate for the facility. The plan also should describe the particular pollutant source area or activity to be controlled by each stormwater management practice. Reasonable and appropriate practices must be implemented and maintained according to the provisions prescribed in the plan.

In selecting stormwater management measures, it is important to consider the potential effects of each method on other water resources, such as ground water. Although stormwater pollution prevention plans primarily focus on stormwater management, facilities must also consider potential ground-water pollution problems and take appropriate steps to avoid adversely affecting ground-water quality. For example, if the water table is unusually high in an area, an infiltration pond may contaminate a ground-water source unless special preventive measures are taken. Under EPA's July 1991 Ground Water Protection Strategy, states are encouraged to develop comprehensive state ground-water protection programs (CSGWPP). Efforts to control stormwater should be compatible with state ground-water objectives as reflected in CSGWPPs.

Comprehensive Site Compliance Evaluation

The stormwater pollution prevention plan must describe the scope and content of comprehensive site inspections that qualified personnel will conduct to 1) confirm the accuracy of the description of potential pollution sources contained in the plan, 2) determine the effectiveness of the plan, and 3) assess compliance with the terms and conditions of the permit. The plan must indicate the frequency of such evaluations, which in certain cases must be at least once a year.

Material handling and storage areas and other potential sources of pollution must be visually inspected for evidence of actual or potential pollutant discharges to the drainage system. Inspectors also must observe erosion controls and structural stormwater management devices to ensure that each is operating correctly. Equipment needed to implement the pollution prevention plan, such as that used during spill response activities, must be inspected to confirm that it is in proper working order. The results of each site inspection must be documented in a report signed by an authorized company official.

Based on the results of each inspection, the description of potential pollution sources and the measures and controls in the plan must be revised as appropriate within 2 weeks after each inspection.

Special Requirements for Selected Facilities

EPA's general permits also establish special requirements for selected classes of facilities. These include:

- *Sampling requirements:* Targeted classes of facilities are required to monitor their stormwater discharges for specified parameters. Facilities that are a member of a targeted class but that can certify that they do not have materials or equipment exposed to precipitation are not required to monitor. This is intended to provide facilities with an incentive to eliminate exposure to precipitation.
- *EPCRA facilities:* Certain facilities that are subject to reporting requirements under Section 313 of the Emergency Planning and Community Right-to-Know Act (EPCRA) because they manufacture or use large amounts of toxic chemicals are subject to special requirements under the NPDES general permits. These special requirements include provisions that are similar to spill prevention, countermeasure, and control (SPCC) plan requirements, and include provisions for secondary containment or equivalent controls for liquid storage areas. In addition, a professional engineer (PE) must inspect the site, review the plan, and certify that the stormwater pollution prevention plan has been prepared in accordance with good engineering practices.
- *Salt piles:* Salt piles must be enclosed or covered to prevent exposure to precipitation.
- *Coal pile runoff:* The permit establishes numeric effluent limitations for coal pile runoff.

Municipal Role in Implementation

The NPDES stormwater program establishes a permit approach that envisions complementary, cooperative efforts by the permit-issuing agency and municipal operators of large and medium municipal separate storm sewer systems to develop programs that result in controls on pollutants in stormwater discharges associated with industrial activity that discharge through municipal systems.

Under the complementary permit approach, stormwater discharges associated with industrial activity that discharge through large and medium municipal separate storm sewer systems are required to obtain permit coverage. Permits for these discharges will establish requirements (such as pollution prevention requirements or monitoring) for industrial operators. Any records, reports, or information obtained by the NPDES permit-issuing authority as part of the permit implementation process, including site-specific stormwater pollution prevention programs that are developed pursuant to the draft general permit, are available to municipalities. This will assist municipalities in reviewing the adequacy of such requirements and developing priorities among industrial stormwater sources. In addition, these permits provide a basis for enforcement actions directly against the owner or operator of stormwater discharges associated with industrial activity.

A second permit, issued to the operator of the large or medium municipal separate storm sewer, establishes the responsibilities of the municipal operators in controlling pollutants from stormwater associated with industrial activity that discharges through their systems. Municipal programs to reduce pollutants in industrial site runoff specifically will address municipal responsibilities in controlling pollutants from industrial facilities. In addition, programs to identify and control nonstormwater discharges to municipal separate storm sewer systems will in many cases focus on industrial areas because these areas often have a significant potential for illicit connections, spills, and improper dumping.

Municipal operators of these systems can assist NPDES permit issuing authorities:

- By identifying priority stormwater discharges associated with industrial activity to their systems.
- In inspecting facilities and reviewing and evaluating stormwater pollution prevention plans that industrial facilities are required to develop under the draft general permit.
- In compliance efforts regarding stormwater discharges associated with industrial activity to their municipal systems.

A pilot program conducted by municipalities in the Santa Clara Valley illustrates how a municipality can work with an NPDES authority to control pollutants in stormwater discharges associated with industrial activities. (A more complete description of the pilot program and its findings is provided in the Santa Clara Valley Nonpoint Source Pollution Control Program [3]). One of the major goals of the program was to reduce discharges to storm drains of dry- and wet-weather heavy metals that result from activities such as processing, storage, and maintenance activities conducted at industrial sites. Components of the program included the following:

- Municipalities developed industrial inspection and illegal dumping/illicit connection programs to ensure that activities focus on priority industries.
- Monitoring requirements were established in the California NPDES general permit for industries. Municipalities evaluated monitoring data collected by priority industries.
- The California NPDES general permit allowed for exemption for industries from monitoring where the municipality provides certification that the industry pollution prevention plan is adequate.
- Municipalities developed industry specific guidance.[2]
- Municipalities implemented a "Clean Bay Business" award program.
- Market-based incentives were considered, such as trading reductions from car pooling and telecommunication programs for pretreatment requirements.

Key findings of the pilot programs identified the following components needed for a successful program:

- Hands-on field training conducted by an experienced industrial inspector.
- Classroom training on industrial stormwater requirements and on methods of communicating with facility managers.
- Classroom training on other related industrial regulatory programs (e.g., HAZMAT, pretreatment).
- A reference manual on the regulations and local legal authority.
- Adequate legal authority to allow site access and take progressive enforcement actions.

[2]See *California Storm Water Best Management Practice Handbook: Industrial/Commercial* (16), which addresses how to prepare a stormwater pollution prevention plan and how to select BMPs. The guidance also addresses source controls for nonstormwater discharges; vehicle and equipment fueling; vehicle and equipment washing and steam cleaning; vehicle and equipment maintenance and repair; outdoor loading/unloading of materials; outdoor container storage of liquids; outdoor process equipment operations and maintenance; outdoor storage of raw materials, products, and byproducts; waste handling and disposal; contaminated or erodible surface areas; building and grounds maintenance; building repair; remodeling and construction; and overwater activities. In addition, the guidance covers treatment control BMPs and measuring BMP performance.

- Prioritizing facilities based on existing information before conducting inspections.
- Advance communications, in the form of a letter, to industries before conducting the inspections.
- A plan for followup actions, including enforcement, where necessary.

The Role of Education and Training in the Development of the Delaware Sediment and Stormwater Management Program

Frank M. Piorko and H. Earl Shaver
Delaware Department of Natural Resources and Environmental Control, Dover, Delaware

On May 31, 1990, the General Assembly of the State of Delaware enacted new legislation on stormwater management and placed it within the revised framework of the state's sediment control law to emphasize the integral relationship between the two programs. Governor Castle signed the legislation into law at a public ceremony on June 15, 1990. The effective date of the regulations was January 23, 1991. Program implementation was initiated on July 1, 1991.

The role of education and training in the development and implementation of Delaware's sediment and stormwater program was recognized at the legislative onset. The educational effort continued through the evolution, development, and promulgation of the regulations and remains an essential component of program strategy. The sediment and stormwater regulations are specific as to the training requirements and opportunities for education that are to be provided for contractors, construction review/inspection personnel, and plan design professionals.

This paper discusses the education and training accomplishments to date, their value to successful program inauguration, and specific training objectives being developed to meet the requirements of the new law and regulations in Delaware.

Background

The State of Delaware has had an erosion and sediment control program since 1978. That program was only marginally successful due to budget and personnel limitations. Environmentally oriented initiatives in other states and within the federal government have since provided an impetus for the Department of Natural Resources and Environmental Control (DNREC) to attempt program improvements with respect to sediment control and stormwater management.

In 1989, DNREC representatives conducted onsite reviews of the existing sediment control program to document program effectiveness. It was readily apparent that too few resources were devoted to a program that lacked legislative and regulatory authority. The site problems were recorded through slide documentation so that a public education program could be developed that clearly showed the need for program improvements.

At the same time, DNREC, in association with local conservation districts, was considering the need for a statewide stormwater management program that considered water quantity and water quality requirements. Fortunately (or unfortunately, depending on the perspective), during the summer of 1989, Delaware had several severe flooding events that reinforced the concept that the state needed a stormwater management program that would prevent existing problems from getting worse.

Delaware does not have a strong environmental lobby group to advocate the passage of new environmental programs, so DNREC has developed a consensus-style approach to get legislation and subsequent regulations accepted by the legislative bodies and the regulated community.

Legislative Process

As the legislation was developed, DNREC sponsored two workshops at which the concept behind the proposed legislation was discussed in a public forum accompanied by slide presentations. The slide presentation focused on problem identification, the proposed state program to address the problems, and the degree to which, in the opinion of DNREC, the sediment and stormwater program was going to evolve. Individual meetings were held with contractors' associations, engineering consultants, land developers, and the general public.

In addition to those workshops and meetings, presentations were made to legislative committees in an informal setting so that individual committee members would have a basic understanding of the need for legislation.

The proposed legislation passed through a state senate committee and the full senate in only 2 days, with not one negative vote. The passage of the legislation through two committees in the state house of representatives and the full house took approximately 1½ months and again received no negative votes. The educational process prior to submission of the legislation and during the legislative process was so successful that not one affected group submitted comments that were in opposition to the legislation. The legislation passed through three committees and two houses unanimously. The legislation was signed into law by Governor Castle in a public ceremony on June 15, 1990.

Regulatory Process

The legislation has several components that specifically address education and training, but one component critical to the process of regulation adoption was the requirement in the law that the regulations were to be developed with the assistance of a regulatory advisory committee. Recognizing the need for program consensus, DNREC placed the regulatory advisory committee requirement within the legislation so that the affected entities would participate in the regulatory process.

The regulatory advisory committee was composed of representatives of 20 organizations representing such groups as contractors, developers, consulting engineers, utility companies, local governments, and conservation districts. DNREC prepared drafts of the regulations prior to meetings. Each section, subsection, paragraph, sentence, and word that was proposed for the regulations was subject to the scrutiny of the regulatory review committee. Each member of the committee did not have to approve all aspects of the regulations, but rather the committee needed to substantially concur. Eight full committee meetings were held, and through the meeting process committee members could understand the rationale behind the various regulatory requirements. As a result, the committee members substantially concurred on all aspects of the regulations. In fact, committee members tended to become advocates of the regulations when they were published for public input.

In addition to the regulatory review committee process, meetings were also held with any interested individual or entity. Once the regulations were in a rough state of completion, three public workshops were held around the state to solicit input from a broader range of interests than just those represented by the regulatory review committee. The input received during this public review process was limited, but the informal public process prepared people for what was intended in the regulations so that any significant opposition to any of the requirements could be addressed before the formal regulation adoption process.

On the basis of the input received from the workshops, DNREC initiated formal regulation adoption procedures with no major changes to the body of the regulations. Announcements were placed in newspapers regarding DNREC's intentions, and a formal public hearing was held on January 16, 1991. Due to the consensus-building process, in which the regulated community participated in developing the regulations, not one adverse comment was received during the public hearing process. The entire public hearing took less than 15 minutes, as there were no questions or comments due to public awareness of the regulations' contents.

The entire process of legislative and regulatory development and approval clearly demonstrates that a consensus-building approach to environmental requirements may be an effective means of obtaining the programmatic infrastructure needed to implement an effective program. In large part due to the strong involvement of the regulated community, there is a significant effort in the law and regulations regarding education and training of contractors, inspectors, consultants, and the general public. It is the position of the authors that environmental programs can only be effective if the regulated community is involved in program development and evolution, recognizes the program need, and understands and accepts their obligations under the regulatory requirements. The individual educational and training obligations under the law and regulations are discussed as they affect the overall sediment and stormwater program.

Delaware Sediment and Stormwater Contractor Certification Program

During the development of the Delaware Sediment and Stormwater Regulations, a provision was made to provide for mandatory training and certification of individuals performing sediment and stormwater related construction. Section 13 of the regulations states that "After July 1, 1991, any applicant seeking sediment and stormwater plan approval shall certify to the appropriate plan approval agency that all responsible personnel involved in the construction project will have a certificate of attendance at a Departmental sponsored or approved training course for the control of sediment and stormwater, before initiation of land-disturbing activity."

"Responsible personnel" means any foreman or superintendent who is in charge of onsite clearing and land-disturbing activities for sediment and stormwater control associated with a construction project.

"Land-disturbing activity" means a land change or construction activity for residential, commercial, silvicultural, industrial, and institutional land uses that may result in soil erosion from water or wind or movement of sediments or pollutants into state waters or onto lands in the state,

R0016032

or which may result in accelerated stormwater runoff including, but not limited to, clearing, grading, excavating, transporting, and filling of land.

Contractor Certification Program Development

The development of the Contractor Certification Program was part of a general sediment and stormwater educational package funded by a Section 205 (G) grant under the Clean Water Act from the U.S. Environmental Protection Agency. Other tasks included a review of similar programs throughout the mid-Atlantic region, contracting for aerial photography of sites under construction, preparation of a portable soils exhibit, and identifying future training and educational needs. The grant tasks were carried out jointly through a memorandum of understanding between DNREC's Division of Water Resources and the New Castle Conservation District. A steering committee was formed in April 1990 and met seven times over the course of the following 9 months. The purpose of the committee was to provide input for the development and implementation of the grant tasks.

It was determined that the certification program was to use a slide presentation format since excellent documentation was already available and additional field slides were easily obtained. In addition to the field slides of sediment and stormwater construction practices, text and technical slides needed preparation. A local company was contracted to produce this material.

The certification program was developed with a 3½- to 4-hour time frame in mind. This would allow for morning or afternoon sessions, even occasional evenings, as necessary. Maryland has enjoyed success for many years in their sediment control training program using a similar format and time frame.

A 55-page narrative describing the slide presentation was developed and made available to the audience upon request. This was done to encourage attention to the slide presentation rather than preoccupation with taking notes. Finally, it was decided that participants should receive a durable plastic laminate card with the state logo and the individual's name and certification number imprinted on it. This would give the participants a tangible item to associate with the completion of the program.

Contractor Certification Program Implementation

By the end of January 1991, the program was ready to be presented. Certain restrictions were placed upon class size in order to communicate most effectively. Optimal class size was 30 to 40 members. Limiting the class size meant that the program would have to be presented many times; therefore, by July 1, 1991, not all of the contractors needing to complete the certification program would have the opportunity to do so. The Sediment and Stormwater Regulations provide for interim certification if individuals notify DNREC of their intent to register for the next available course.

The certification program was designed for presentation in two ways. First, the conservation districts, counties, and other agencies given the responsibility of certain program elements would set up the programs in their own jurisdictions, giving them a chance to meet with the regulated community and explain local program requirements. Second, DNREC would present the program to any regulated company, business or organization if they could provide a suitable location and a minimum of 15 individuals to be trained. DNREC also provided training for DNREC staff and several hundred Delaware Department of Transportation inspectors, technical staff, and engineers.

Throughout the first 6 months of presentations, we were surprised and pleased not only with the response from the contractors but also from the engineers, consultants, and developers who wanted to attend the certification program. All told, from February 1991 until July 1991, DNREC presented the program on 37 occasions, certifying over 1,100 individuals from 300 companies and organizations.

As stated earlier, this was possible only with the assistance from the three state conservation districts, county governments, the Department of Transportation, and organizations such as the Associated Builders and Contractors and the Delaware Contractors Association. As of January 1, 1993, almost 2,000 individuals have completed this training.

Initially, a program quiz was developed not so much to grade the participants but to obtain feedback on the retention of the material being provided. A program evaluation was later substituted for the quiz so that we could determine if any changes or improvements should be made to the training program. A representative sample of 100 evaluations was compiled, the results of which appear in Figure 1. Most notable is that 96 percent of respondents would recommend this training (Question 7), and 86 percent wished to continue in this training (Question 8).

By continuing the Contractor Certification Program, not only are the requirements of the Delaware Sediment and Stormwater Regulations being met, but the knowledge gained by the participants in this program is being transferred to the field through proper construction practices.

Delaware Certified Construction Reviewer Course

The Delaware Sediment and Stormwater Regulations also provide for special site inspection or review requirements under certain site conditions. Section 12 of the

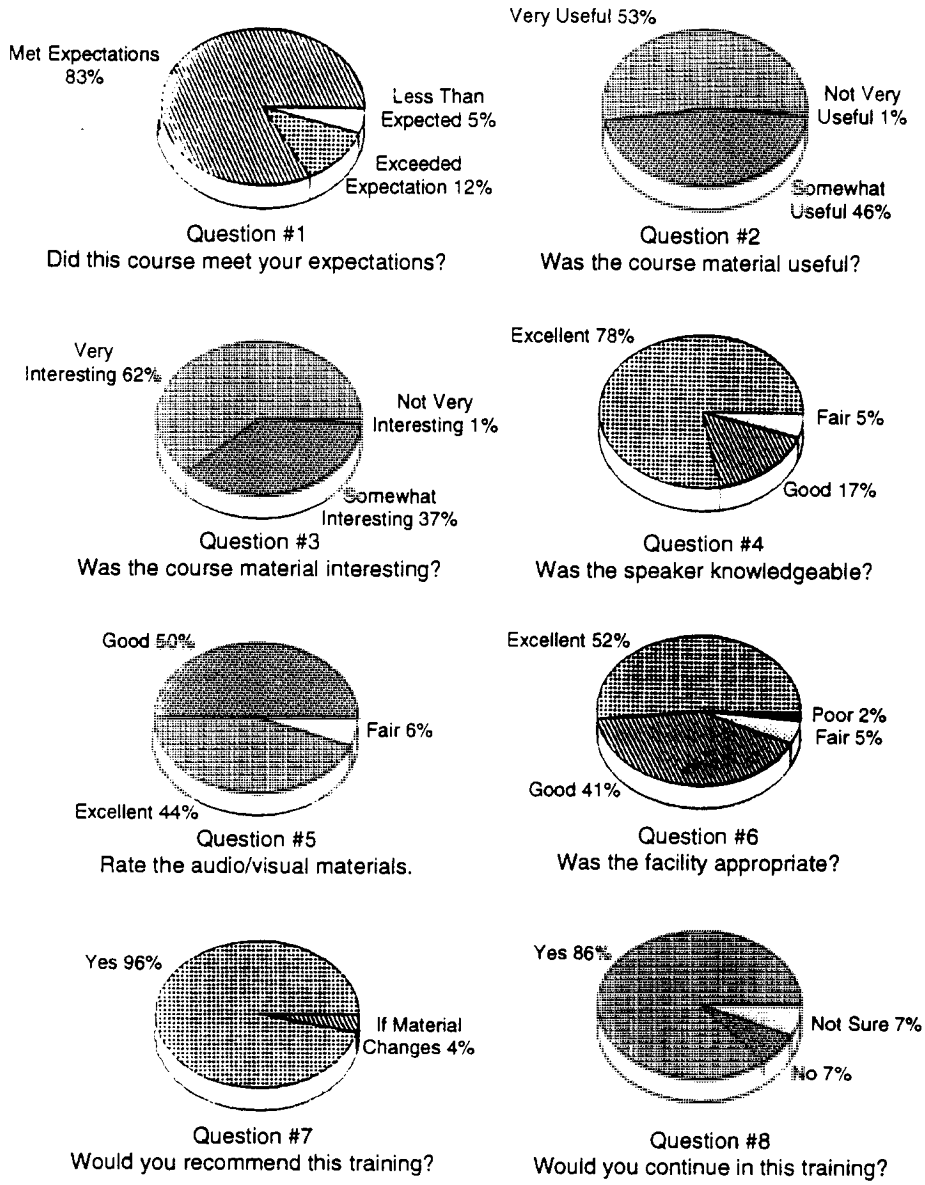

Figure 1. Sediment and stormwater contractor certification program course evaluation.

regulations identifies these site conditions that allow DNREC or the appropriate plan approval agency to require that a certified construction reviewer be present on site. Examples of site conditions that would warrant this requirement would be a site in excess of 50 acres of disturbed area or any site experiencing significant sediment and stormwater problems. The owner or developer of the site in these cases would be responsible for providing a certified construction reviewer for any or all parts of the construction phase as deemed necessary by the plan approval agency. The main responsibility of these individuals is to ensure the adequacy of construction pursuant to the approved sediment and stormwater management plan.

As with the Contractor Certification Program, DNREC has the responsibility to provide training to certify these construction reviewers. A formal Sediment and Stormwater Management Certified Construction Reviewer Course was developed in cooperation with Delaware Technical and Community College. Course material was developed to instruct participants in basic hydrology and hydraulics, soils, vegetative establishment, construction practices, plan preparation and implementation, inspection, enforcement, and maintenance. To instruct this course, over 20 professionals in the area of sediment and stormwater management were recruited, representing government agencies, private industry, and the consulting and engineering community.

The course format was developed to be presented in eight $3\frac{1}{2}$-hour weekly sessions. An examination was developed and arrangements made with Delaware Technical and Community College for Continuing Education Credits to be issued.

We anticipated a lot of interest in this course offering, so registration was limited to one individual per company or organization. In addition to the private community, an attempt was made to include at least one individual that works for each agency responsible for delegation of sediment and stormwater program elements. In all, 85 seats were quickly filled for this course. The second time this course was offered, the class sessions were reduced to four all-day sessions. This seemed to suit the class participants' schedule better.

One important measure of success is the evaluation question that asked class participants to indicate whether the course did not meet, met, or exceeded expectations. The breakdown is as follows:

- 41 responses, or 74 percent of the class, stated that the course met their expectations.
- 12 responses, or 22 percent of the class, stated that the course exceeded their expectations.
- 2 responses, or 3.5 percent of the class, stated that the course did not meet their expectations.

The success of this program is directly attributable to the preparation of the speakers, the attentiveness of the class, and the hard work of the Delaware Sediment and Stormwater Program staff.

Stormwater Management Technical Sessions

The engineering and design community in Delaware has also indicated the need for DNREC to present more design-oriented training in sediment and stormwater management. To date, there have been several workshops in U.S. Department of Agriculture Soil Conservation Service TR-55 and TR-20 hydrologic analyses sponsored by local conservation districts and enlisting the assistance of the Soil Conservation Service. DNREC recognizes the need to expand this basic training and make available more design-oriented training for the consultant community.

Coinciding with the development and release of the *Delaware Stormwater Management Design Manual* in the summer of 1993, training classes were scheduled to present this material in modules, as the manual was developed. This training will help ensure that stormwater management practices are designed to meet established minimum criteria.

Summary

The education and training component of the Delaware Sediment and Stormwater Management Program is one of several areas of program development that will continue to respond to the needs of the regulated community. One obvious benefit in a small state like Delaware is that the efforts of a regulatory agency in providing education and training to the regulated community are recognized and appreciated. As previously discussed, the Sediment and Stormwater Management Program depends highly on interagency cooperation and communication with the businesses and industry involved. By maintaining education and training objectives as a high priority, DNREC will increase chances for program success.

Development and Implementation of an Urban Nonpoint Pollution Educational and Informational Program

Richard Badics
Washtenaw County Environmental Services Department,
Ann Arbor, Michigan

Abstract

Sampling, Abatement, Follow-up, Education, and Response (SAFER) was formed by the Washtenaw County's Environmental Interest Group on January 1, 1992. SAFER includes the county departments of Environmental Coordination, Environmental Services, Drain Commissioner, Planning, and Cooperative Extension, as well as the Soil Conservation District, Huron River Watershed Council, Ecology Center of Ann Arbor, and the Southeast Regional Groundwater Education Center. The purpose of SAFER is to "provide for coordination of water protection programs through inter- and intracounty agencies and group cooperation."

Education is a key element of SAFER. Four groups are targeted for education by SAFER: government, business and industry, community groups, and schools. SAFER members develop their own specific educational programs and materials. Through SAFER, these are coordinated to provide uniform and accurate information to targeted segments of the community. This avoids costly duplication of services.

To effectively deliver an educational program, the target audience must first be determined, then an analysis of existing educational programs must be made to build on past successes. Through this process, an approach is determined that is most likely to be successful. Prior to beginning the educational program, the establishment of an evaluation process is critical.

Overview of Washtenaw County's SAFER Group

Sampling, Abatement, Follow-up, Education, and Response (SAFER) was formed by Washtenaw County's Environmental Issues Group on January 1, 1992. The Environmental Issues Group consists of departments within Washtenaw County government that indirectly or directly manage the environment of Washtenaw County. This provides the county with a coordinated approach to addressing environmental issues. The Environmental Issues Group is chaired by the Environmental Coordination Office. Other member groups within the Environmental Interest Group are the Sheriff's Department, Environmental Services, Emergency Management, Planning, Public Works, Drain Commissioner, and Cooperative Extension, as well as the county's Health Officer. This group meets monthly to discuss the status of county programming, pending state and federal legislation, "hot" environmental topics or issues, and strategic planning.

SAFER was formed as a work group of the Environmental Issues Group "to provide for coordinative water protection programs through inter- and intracounty agencies and group cooperation." SAFER consists of groups internal and external to Washtenaw County government that are involved in dealing with the county's ground and surface water. SAFER includes the county departments of Environmental Coordination, Environmental Services, Drain Commissioner, Planning, Cooperative Extension, Soil Conservation District, Huron River Watershed Council, and Ecology Center of Ann Arbor, as well as the Southeast Regional Groundwater Education Center (SER-GEM). During its first year of operation in 1992, the group focused on categorizing and compiling all current water quality programs and their products. The 1992 SAFER Directory compiled over 100 products addressing water quality issues within the county.

Education is a key element of SAFER. Four target groups for educational programs in SAFER are government, business and industry, community groups, and schools. The SAFER Educational Subcommittee in 1993 is compiling all educational programs and materials on water quality related issues, similar to the 1992 SAFER Directory. Through SAFER, educational materials are coordinated to provide current and accurate information to the community while avoiding costly duplication of services.

Urban Nonpoint Pollution Education

The development and implementation of a nonpoint pollution educational and informational program is critical to a successful urban project. Public awareness of urban nonpoint pollution is relatively low, and the media tends to focus on health or environmental risks that are easy to define, such as AIDS or hazardous waste issues. Due to its nature, nonpoint pollution is harder to pinpoint. Urban nonpoint pollution prevention requires a long-term commitment to changing attitudes.

Urban nonpoint pollution can be directly attributed to people. We all contribute to it. People are accustomed to focusing on easier issues, where the blame can be attributed to activities outside their control. An example is auto safety. People are very concerned about vehicle safety when a manufacturing error is the cause, such as exploding gas tanks. These same people, however, are not as focused on actions that they control, such as wearing seat belts.

An environmental example is oil spills. A study by the Michigan Department of Natural Resources (MDNR) in 1989 found that more oil is illegally released into the environment in Michigan annually than was released in the Valdez tanker incident. Getting people to buy into the idea that they are a major part of the problem is a critical step in gathering their support and cooperation.

Target Audience

Before an education information program can be developed, the target audience must be identified. A general educational approach will not change the habits of a wide range of target groups. Each targeted group must be analyzed independently to understand its particular needs and to develop specific actions it can take. Next, the various media options must be explored.

A multimedia approach enhances the opportunities of reaching larger segments within the target audience. For example, handing out flyers at a garden show will not reach several socioeconomic classes; a spot on a local radio station may be more appropriate. Some common public outreach materials are fact sheets, pamphlets, radio, television, newspapers, magazines, displays, models, posters, group presentations, and one-on-one or community events.

Using existing resources in your educational program is important. An educational program workshop for composting in the community could also be a forum for supplying information to the public on preventing urban nonpoint pollution through the proper application of fertilizers and use of environmentally friendly alternatives to pesticides. By networking with existing programs in the community, nonprofit programs will not compete for and confuse the audience.

Educational Gaps

After analyzing current educational resources within the community, identify audiences and approaches not currently used. All targeted groups need to receive your message. Target groups in the community must "buy into" their contribution to nonpoint pollution and their ability to prevent or minimize it. Urban educational programs must be innovative, well conceived, multimedia, and coordinated with other educational programs in the community.

A large number of ongoing urban nonpoint education programs exist in communities throughout the country. These programs have been developed for various types of audiences. Prior to implementing a program "from scratch," review all ongoing programs. These can be found in EPA "News Notes," as well as through professional groups, conferences, and environmental publications. Regional EPA offices are also a valuable resource for finding suitable ongoing programs. Using existing programs saves time and money.

Program Evaluation

An integral part of all educational programs is evaluation. Valuable time and resources can be wasted if information supplied to an audience is not effective. When developing the evaluation mechanism for the educational process, make sure the educational program focus enhances the overall water quality objectives. One way to evaluate the educational process is to apply Bennett's Hierarchy of Evidence for Program Evaluation. Bennett uses seven steps of evaluation. In an inverted scale, these steps are:

1. Inputs of program resources that are used to make the program work.
2. Activities which can include internal events, such as planning, or external events involving an audience.
3. Involvement of the target audience in activities, focusing on hands-on type activities.
4. The target audience's view of the program.
5. KASA change, or the change in knowledge, attitudes, skills, or aspirations of the audience.
6. Changes in behavior that result from the educational program.
7. End results that reflect the program's goals and objectives.

Many techniques can be used to measure the seven Bennett attributes. The basic who, what, where, and when questions are useful when establishing the specific evaluation technique.

Many books and guides can help in developing program evaluation. Studying these before finalizing an evaluation process is highly recommended. If there are time constraints or expertise is not available for evaluation, this component can be done by an outside party. The key is to establish the evaluation mechanism before implementing the educational program.

Huron River Pollution Abatement Program

Overview

The Huron River Pollution Abatement Project (HRPAP), which encompassed the urbanized area of Washtenaw County, was formed and implemented in 1986 by the county's Drain Commissioner's Office in conjunction with the Environmental Services Department. Public education was a major objective of the project. The educational program used by the HRPAP was designed after reviewing earlier area pilot water quality programs and their targeted community groups. The HRPAP focused on business, industry, community, and school groups.

Business/Industry

The HRPAP conducted surveys and dye tests of facilities located in the urbanized areas of Washtenaw County. Staff interviewed facility owners and managers on their particular businesses and gained critical information about their operations. When a common need was found—for example, an owner unable to dispose of a certain type of waste—the project staff worked with the owner to resolve the problem. For example, many facility operators with oil separators were not familiar with separators and were unable to find a licensed waste hauler to service them. The HRPAP developed a maintenance guideline for the operators, contacted all local waste haulers, and developed a list of haulers that would service oil separators. This information was then distributed to all facilities with oil separators.

Community and Civic Group Education

Over 200 educational presentations were made to the community during the HRPAP's 6 years. The HRPAP used various media to educate the community. One of the most effective was the local press. Articles concerning the HRPAP were published on an ongoing basis. Press releases noted significant events and common problems found within the community.

A second approach to outreach was through community events. Examples are the Ann Arbor City Art Fair and the Ypsilanti City Heritage Festival. These events attract hundreds of thousands of people. Display booths and pamphlets were developed for participating in these events. This became a forum for discussing water quality related issues one-on-one with the public.

School Education

The HRPAP made its first school educational presentation to a third-grade class in 1988. Word of mouth led to over 25 presentations per year in six local school districts. HRPAP student interns with an educational background formulated lesson plans for different grade levels on nonpoint pollution and related topics, such as the water cycle and household hazardous waste.

In classrooms, educational programs concentrated on hands-on activities. Two water quality models were built. One electronic model, entitled "Pathways to Pollution," lights up various pollution pathways when the appropriate button is pushed. A second model is a transparent representation of a town showing the sanitary and storm sewer systems. The students place a dye into catch basins, floor drains, and toilets to observe the route the water takes directly to the stream or the wastewater treatment plant. This model has examples of both proper and improper connections.

Conclusions

The majority of urban nonpoint pollution can be directly attributed to the activities of people. Most people are not aware of the impacts their routine activities at home and at work have on water quality. Education is a key component to improving urban water quality problems. Key target audiences in the community need to be identified, existing educational resources studied, educational program gaps identified, and an evaluation process included to measure a program's effectiveness.

The key to an educational program is to focus on practical activities that the target group can do to eliminate water pollution. A long-term, sustained educational effort leads to an increased awareness and respect for the interdependence of all elements in the ecosystem and for how individual activities affect them. This ultimately leads to a sense of mutual responsibility and a long-term commitment to continued environmentally sound actions.

Leon Moore; Jeffry Krcmarik; and David Wilson, as well as other members of SAFER.

Training for Use of New York's Guidelines for Urban Erosion and Sediment Control

Donald W. Lake, Jr.
U.S. Department of Agriculture,
Soil Conservation Service, Syracuse, New York

Introduction

New York State still does not have a statewide erosion and sediment control law. Unlike many of its neighboring states, New York continues to leave the initiation of such control to local units of government. Historically, counties, towns, and villages have enacted ordinances once a significant environmental accident has occurred. Jurisdiction occurs at the local level, with planning boards having approval authority to issue permits to develop. Because each board is dealing with its local area, the regulations and processes for gaining approval vary from locale to locale.

Technical standards for controlling erosion and sediment were developed by the Soil Conservation Service in March 1988 and issued as *New York Guidelines for Urban Erosion and Sediment Control.* This document provides design details and specifications for both temporary and permanent management practices, as well as resource-planning concepts. Known as the "Blue Book," the document provides consistency in the technical approach to erosion and sediment control plans for construction sites. It has been adopted by the New York State Department of Environmental Conservation and the U.S. Army Corps of Engineers, Buffalo District, as criteria for erosion and sediment control plans. The New York State Department of Transportation has incorporated many of its details into its highway design manual.

In April 1992, the New York State Department of Environmental Conservation (NYS-DEC), Division of Water, published *Reducing the Impacts of Stormwater Runoff From New Development.* This document establishes performance standards for stormwater management control in New York for projects requiring NYS-DEC review. Standards were set for both water quantity and water quality. Water quantity is addressed by requiring no greater discharges from the site after development than present before development for the 2-, 10-, and 100-year frequency storm events. Water quality is addressed by retaining the "first flush," which is defined as the greater of one-half inch of runoff or runoff resulting from a 1-year, 24-hour storm, from the land area for which the infiltration rate has been changed.

These two documents finally provide guidance for erosion and sediment control and stormwater management for local units of governments as well as regulatory agency staffs. Their use and application depends on what the site's size and resource constraints are and whether a local ordinance is in place. The local approval process, in communities with such a regulation, generally requires a formal review of the plan with its erosion and sediment control and stormwater management component by either the town or village engineer and a local soil and water conservation district staff person or health department official. Unfortunately, many of these individuals are unable to identify problems or lack the knowledge of design details to control sediment from the site.

Once a developer begins operations in the field, the building inspector, code enforcement officer, or health department official is responsible for inspecting the site for compliance to the approved plan as well as to ensure that the contractor maintains the installed practices. These field inspectors require training in the concepts of erosion and sediment control installation and maintenance.

Clean Water Act Mandates

On October 1, 1992, stormwater regulations went into effect under the Clean Water Act that require individuals, agencies, and municipalities to apply for a National Pollutant Discharge Elimination System (NPDES) permit for stormwater discharges from a variety of activities. New York State is a NPDES-delegated state, and the

Department of Environmental Conservation is administering this program through their State Pollutant Discharge Elimination System (SPDES) permit. One of the 11 categories covered in the regulations is construction activity. Under this activity, any site where 5 or more acres are disturbed must have an erosion and sediment control plan and a stormwater management plan. The 5-acre size limit has been challenged as arbitrary, and the size limit could be changed to 1 acre of disturbed area. A developer needs to file a Notice of Intent at least 48 hours before beginning operations to have "coverage." This notice is filed with the U.S. Environmental Protection Agency in Newington, Virginia. Under the regulations, copies of the erosion and sediment control plan and stormwater management plan are to be kept on site. Copies of each are also sent to the municipality that has jurisdiction. NYS-DEC does not want the notices or plans sent to its offices; they will not be reviewing or approving these plans. Who will? What will be the local impacts?

As a result of this mandate, many New York counties, towns, and villages will be receiving many erosion and sediment control and stormwater management plans. The majority of these units of government are still unaware of the requirements of the national program and of what their role is or should be. There is a great need for administrators, planners, and legislators to become aware of the program and the process. Technical staff need to learn the principles of planning, design, construction, and inspection for erosion and sediment control and stormwater management systems.

Positive aspects of the NYS-DEC approach to the program include the opportunity for local policy development, provisions for local ordinances, and the formation of interagency partnerships. Because NYS-DEC recognizes that authority should rest at the local level, communities have control over the quality of the natural resources in their backyards. Of course this may require additional staff or cooperation with other agencies to assist with implementation.

Training Programs

Early efforts in erosion and sediment control began with awareness seminars at the local level. The seminars usually lasted 2 hours an evening for local officials involved in the site review and approval process. Recognizing problems, learning the planning steps, and becoming familiar with practices and guidelines were the limit of these seminars.

The complexity of requirements and the technical needs have increased dramatically due to recent mandates. The Soil Conservation Service, in cooperation with NYS-DEC and Syracuse University, has developed a tiered educational program in erosion and sediment control and stormwater management.

A 1-day seminar has been developed for planning board members, environmental management council members, legislators, and town boards, and has included legal advisors, consulting engineers, and other agency personnel responsible for environmental analysis. This agenda is included as Figure 1. This seminar stresses site planning through a slide presentation that demonstrates problems without control and shows practices necessary to maintain resources on the site. Stormwater management performance standards are reviewed in accordance with NYS-DEC criteria. This seminar is reinforced with two specific site examples. Attendees are asked to work in small design teams to design an erosion and sediment control plan for the first site. These same design teams are asked to critique the second site, which already has an erosion and sediment control plan. Thus, attendees go from designers to reviewers in applying their knowledge of these principles.

A 2-day workshop has been developed for the technical staffs of resource agencies, consulting engineers, local governments, and others with technical review or design responsibility (see Figure 2). This session begins with a quick overview of the principles of erosion and sediment control, then continues with a class exercise to design an erosion and sediment control plan for a development site while working in design teams of approximately four individuals. The afternoon of the first day is spent at a field site gathering specific resource information and data to design a detailed erosion and sediment control plan for the site. The design teams also compute and compare peak discharges for the site for predevelopment and postdevelopment conditions using Soil Conservation Service Technical Release 55, Urban Hydrology for Small Watersheds (TR-55). The session concludes with group presentations.

A 3-day short course with Syracuse University has been developed to address the specific technical needs of consulting engineers working with stormwater and erosion control systems. This tuition-based course provides for more indepth design of erosion and sediment control practices using a field site. Sizing stormwater detention basins is also required. In addition to the increased technical emphasis, additional speakers from state and local agencies provide a component on rules and regulations. Syracuse University awards two continuing education units for this course, which 57 people have completed to date. The agenda is included as Figure 3.

Urban Erosion Control and Stormwater Design (CIE 600) stands as a fully accredited 3-hour graduate level course in the Civil and Environmental Engineering Department at Syracuse University. It was taught for the first time in the 1992 fall semester and will be taught again this September. It was developed as a hands-on course that requires detailed designs for two projects, using field trips and six additional site review projects.

EROSION AND SEDIMENT CONTROL SEMINAR
AGENDA

8:30 AM	Registration
9:00 AM	Introduction and Course Overview
9:15 AM	Developing an Erosion and Sediment Control Plan — Planning Considerations — Factors That Influence Erosion — Elements for a Sound Plan — Vegetative and Structural Components — Standards and Specifications
11:00 AM	Site Example — Develop Conceptual Erosion and Sediment Control Plans
12:00 PM	**LUNCH (ON YOUR OWN)**
1:00 PM	Site Review — Critique an Erosion and Sediment Plan for a Specific Site
3:30 PM	Wrap Up/Summary
4:30 PM	Adjournment

Figure 1. Erosion and Sediment Control Seminar agenda.

EROSION AND SEDIMENT CONTROL WORKSHOP

AGENDA

First Day

8:30 AM	Registration
9:00 AM	Introduction and Course Overview
9:15 AM	Developing an Erosion and Sediment Control Plan —Planning Considerations —Factors That Influence Erosion —Elements for a Sound Plan —Vegetative and Structural Components —Standards and Specifications
11:00 AM	Site Example —Develop Conceptual Erosion and Sediment Control Plans
12:00 PM	**LUNCH (ON YOUR OWN)**
1:00 PM	Design Session—Site-Specific Practices —Temporary Swale —Sediment Trap —Urban Runoff
2:30 PM	Field Problem—Design Teams —Gather Data —Develop Concepts in Field
4:30 PM	Adjournment

Second Day

8:30 AM	Complete Group Designs
10:00 AM	Design Critiques
12:00 PM	**LUNCH (ON YOUR OWN)**
1:00 PM	Design Session —TR-55 Analysis for Structures —Rock Outlet Protection —Class Discussion
3:00 PM	Wrap Up and Summary

SYRACUSE UNIVERSITY
UNIVERSITY COLLEGE
EROSION AND SEDIMENT CONTROL

SHORT COURSE AGENDA
April 28-30, 1992

First Day

9:00 AM	Registration and Coffee	Dr. Stephan Nix
	Introduction and Course Overview	
10:00 AM	Legislation, Ordinances, and Regulatory Review Process	Mr. Robin Warrender Mr. William Morton Mr. Russell Nemecek
11:00 AM	Developing Your Stormwater Management Plan and Practices	Mr. William Morton
12:00 PM	Lunch	
1:00 PM	Urban Hydrology and Flow Routing	Mr. Donald W. Lake, Jr.
2:15 PM	Break	
2:30 PM	Urban Hydrology and Flow Routing (continued)	
4:30 PM	Adjourn	

Second Day

8:00 AM	Developing Your Erosion Control Plan	Mr. Donald W. Lake, Jr.
9:30 AM	Break	
9:45 AM	Erosion and Sediment Control Practice Standards	Mr. Donald W. Lake, Jr.
11:30 AM	Lunch (En Route to Field Site)	
12:00 PM	Field Tour/Site Problems	Mr. Donald W. Lake, Jr.
3:00 PM	Group Design Session	
5:00 PM	Adjourn	

Third Day

8:00 AM	Group Presentations and Critiques	
10:00 AM	Break	
10:15 AM	Group Presentations (continued)	
11:45 AM	Wrap Up—Adjourn Short Course	Dr. Stephan Nix
1:00 PM	Certified Professional Erosion Specialist Exam Part II (Optional)	Mr. Donald W. Lake, Jr.

Figure 3. Erosion and Sediment Control short course agenda.

In addition, the class participates in a town planning board meeting. Syllabus topics (see Figure 4) include manual and computer analyses of stormwater discharges and lectures by a plant materials specialist, a code enforcement officer, and governmental representatives dealing with rules and regulations. Twelve students enrolled in the first class, which was extremely well received by both students and the people who provided the example sites.

Summary

Over 2,600 people have received training through 76 different seminars, workshops, short courses, and the graduate course since the training effort began in the fall of 1988. These tiered training sessions have evolved one after another based on needs at the local level. Leaders in the NYS-DEC recognized that benefits are local so training efforts should be local. This has led to interagency cooperative agreements between the U.S. Department of Agriculture, Soil Conservation Service, and NYS-DEC to bring training directly to the communities.

There is no sign of these training requests letting up. An average of 10 requests for the seminar sessions are made at the local level during the year. In addition, the proposed cooperative agreement for Fiscal Year 1994 between the Soil Conservation Service and NYS-DEC calls for five 1-day seminars, four 2-day workshops, four 2-day TR-55 hydrology workshops, and two short courses. The Syracuse University graduate course will be taught again this fall. Future projects also include workshops for New York State code enforcement officers, development of a field notebook for job superintendents, and field application courses for equipment operators. After all, equipment operators have the last word in installation.

We have come a long way, but we can see that challenges are still ahead of us to educate public planners, legislators, consultants, technical staff, and contractors in the use of sound erosion and sediment control and stormwater management practices to protect and enhance water quality and the environment.

DEPARTMENT OF CIVIL AND ENVIRONMENTAL ENGINEERING
SYRACUSE UNIVERSITY

CIE 600

URBAN STORMWATER AND EROSION CONTROL DESIGN
FALL 1992

SCHEDULE:	Monday/Wednesday 6:15-7:45 PM Peck Hall, University College
INSTRUCTOR:	Donald W. Lake, Jr., PE State Conservation Engineer, USDA-SCS
TEXT:	SWCS, Empire Chapter, **New York Guidelines for Urban Erosion and Sediment Control**, October 1991; Soil Conservation Service, Technical Release 55, **Urban Hydrology for Small Watersheds**, June 1986; New York State Department of Environmental Conservation, **Reducing the Impacts of Stormwater Runoff From New Development**, April 1992.
GRADING:	Assignments: 40% Mid-Term Exam: 30% Final Exam: 30%

Course Content:

Week:	**Topics:**	**Reading**	**Instructor**
8/31	Introduction to Urban Stormwater and Erosion Control Design (1)*		Lake
9/7	Resource Planning and Stormwater Impacts (2)	Ch. 1, NY Guide and DEC Manual	Lake
9/14	Computing and Controlling Sediment and Runoff (2)	Ch. 8, Appendix B, NY Guide	Lake
9/21	Stabilizing Soil, Vegetative and Biotech (2)	Chs. 4 and 5, NY Guide	Dickerson Lake
9/28	No lecture—E&S Field Exercise (10/3, 8:30-11:30 AM) (turn in 10/7)	NY Guide	Lake
10/5	Urban Hydrology (2)	SCS-TR-55	Lake
10/12	Urban Hydrology (1) and Site Exercise Critique (1)		Lake
10/19	NO CLASS—HYDROLOGY PROJECT		Lake
10/26	Urban Hydrology Computer Program (1) and MIDTERM	Tr-55	Chapman Lake

Field Office Technical Guide:
Urban Standards and Specifications

Gary N. Parker
U.S. Department of Agriculture, Soil Conservation Service
Champaign, Illinois

Abstract

The *Field Office Technical Guide* is the primary technical reference for the Soil Conservation Service (SCS). It presently contains general resource references and soil and site information, and describes conservation management systems, practice standards and specifications, and conservation effects. Although SCS maintains offices and provides assistance in all Illinois counties, the technical guide does not contain any information specific to natural resource use and management in urban areas. Therefore, in June 1992 the SCS in Illinois entered into an agreement with the Illinois Environmental Protection Agency to develop technical information describing best management practices (BMPs) for controlling urban nonpoint source water pollution.

Currently in development, this information will include 40 BMP standards and accompanying construction specifications, material specifications, and standard drawings. It will also include estimates of pollutant removal effectiveness and stormwater pollutant export, as well as planning and design criteria. When complete, this material will become part of the *Field Office Technical Guide.* The Illinois Environmental Protection Agency will also use the information in a separate, stand-alone technical manual. This material will be useful to planners, engineers, architects, and construction contractors, as well as to local government staff.

Background

The Soil Conservation Service (SCS), an agency of the U.S. Department of Agriculture, is the major federal agency providing natural resource management assistance on nonfederal land. Its primary responsibility is to provide leadership and expertise in managing natural resources in nonurban areas. Currently, SCS maintains a network of field offices in nearly every county in the country, providing local citizens with direct access to a wide range of technical specialists. These specialists include engineers, soil scientists, biologists, agronomists, and natural resource planners.

The technical material and expertise that has been developed to support SCS activities largely pertains to agricultural or rural settings. For example, the seed mixtures that most SCS specifications call for are those appropriate for agricultural areas and not necessarily for parks, recreation sites, or lawns. In addition, design criteria for waterways and diversions assume an agricultural land use context.

Despite this rural, nonurban emphasis within the agency, SCS maintains a field staff in urban and urbanizing areas. In Illinois, this urban staff serves over one-half the state's population. This urban presence has enabled SCS to develop some urban expertise. For instance, SCS TR-55 hydrology modeling techniques are widely used to estimate runoff from urban areas. Moreover, the PL-566 watershed projects constructed in the Chicago suburbs have given the agency some expertise in urban construction site issues. The SCS, however, has not provided any systematic technical support to its field staff on natural resource management issues in an urban setting. It has instead relied on the ability of its staff to adapt the provided information from a rural to an urban environment.

To become more effective in addressing key natural resource issues in urbanizing areas, the SCS in Illinois has initiated several activities:

- It is actively participating in a coalition of state and federal agencies to prepare a strategy for coordinating agency activities in northeastern Illinois.
- It is reviewing and clarifying its policy relative to providing assistance in nonagricultural areas.

- It is expanding the technical information its staff uses when providing assistance to decision-makers in urban areas.

The third initiative listed is the subject of this paper. In June 1992, SCS entered into an agreement with the Illinois Environmental Protection Agency to prepare a set of standards and specifications describing BMPs for controlling urban nonpoint source water pollution. In addition, the SCS will provide estimates on the range of pollutant removal effectiveness and criteria for planning runoff management. The agency will incorporate all this material into its *Field Office Technical Guide.*

Field Office Technical Guide

The *Field Office Technical Guide* is the primary technical reference for the SCS. It contains technical information about conservation of soil, water, air, plant, and animal resources. The guide is designed for use by technically trained people who are assisting landowners and users, land managers, government officials, and other decision-makers to plan, apply, and maintain appropriate conservation practices. The technical guide also is a major reference for those addressing top-priority resource goals identified by the National Program for Soil and Water Conservation. These goals are to reduce the damage caused by excessive erosion and to protect water from nonpoint source pollutants. The technical guide identifies sediment, nutrients, animal waste, pesticides, and salinity as nonpoint source pollutants.

The *Field Office Technical Guide* contains five sections:

- The "General Resource References" section lists references, cost data, maps, climate data, cultural resources information, threatened and endangered species, and pertinent state/local laws, ordinances, and regulations.
- The "Soil and Site Information" section describes the soil survey of the local area. It contains soil descriptions and interpretations that can be used to make decisions about land use and management. This section identifies soil characteristics that limit or affect land use and management, and rates soils according to limitations, capability, or potential.
- The section on "Conservation Management Systems" provides information for developing resource management systems to prevent or treat problems associated with soil, water, air, and related plant and animal resources. This section includes quality criteria that describe the level of resource protection that decision-makers should try to achieve to meet resource quality goals.
- The "Practice Standards and Specifications" section alphabetically lists conservation practices used by the field office, followed by practice standards and specifications. It may also include references and documentation requirements for the individual practices. Practice standards establish the minimum level of acceptable quality for planning, designing, installing, operating, and maintaining conservation practices. Practice specifications describe the technical details and workmanship required to install the practice, as well as the quality and extent of materials used in the practice.
- The last section, "Conservation Effects," contains information describing the economic and environmental effects of implementing particular practices and systems. The purpose of this section is to provide decision-makers with a way to evaluate the extent to which various alternatives can meet their goals.

As stated previously, this guide is the primary technical reference for SCS staff, particularly those at the field level. The guide is also useful to Soil and Water Conservation District staff, and to consultants and staff of state, county, and municipal governments. To expand its usefulness, however, the SCS urban field staff in Illinois have recommended that the guide include information that is directly relevant to natural resource management in an urban environment and is user friendly to urban clients. The material now being developed will attempt to meet that need.

New Material for the *Field Office Technical Guide*

The new material will supplement and expand the existing material in the guide's fourth section, *Practice Standards and Specifications.* The SCS will modify or develop 40 BMPs that deal specifically with urban natural resource management.

Each BMP standard will follow a uniform format:

- "Definition": describes what the practice is.
- "Purpose": explains what the intended effect of the practice is, that is, why this practice is used.
- "Conditions Where the Practice Applies": describes the types of sites where the practice would be appropriate; this section also describes limiting factors such as slope percent, maximum drainage areas, and maximum flow velocities.
- "Criteria": describes, in general terms, material and construction requirements and usually provides references to specific material and/or construction specifications.
- "Considerations": offers general information regarding factors to consider when deciding on the appropriateness of a particular practice; in some cases, this section is a brief, narrative, nontechnical summary of the "Conditions" section.

- "Plan and Specification Requirements": describes the nature and extent of the information the contractor needs to build the practice; it lists the requirements of the plans and specifications needed to install a practice.
- "Operation and Maintenance Requirements": describes the needed operation and maintenance actions and suggests the frequency with which they should be performed.

The revised fourth section of the technical guide will also include all the material specifications and constructions referenced in the practice standards, as well as a series of standard drawings for the practices. The standards and specifications will be available on computer disk. The standard drawings, which will be developed using a CAD system, also will be available on disk. This will allow engineers and consultants to access the material in preparing construction plans and specifications.

In addition to the SCS incorporating the new material into the Illinois *Field Office Technical Guide*, the Illinois Environmental Protection Agency plans to issue a stand-alone technical manual of those standards for use by consultants, state agencies, and local governments. The project is scheduled for completion in December 1994.

Stormwater Outreach at the Federal Level: Challenges and Successes

Kimberly O. Hankins
Office of Wastewater Enforcement and Compliance,
Office of Water, U.S. Environmental Protection Agency, Washington, DC

Background

Stormwater regulations brought a distinctly different community into the realm of U.S. Environmental Protection Agency (EPA) regulation. Many members of this community have never before been regulated by an environmental program. The regulated community now includes all major cities and unincorporated areas with populations of 100,000 or more, as well as a very large, diverse group of industries. The most important factor influencing success with the stormwater regulations is education. By educating all parties concerned with the program, the community can begin to practice all that EPA is learning about how to provide a cleaner, safer environment.

The principal elements of an outreach program are communication and education, with a focus on influencing how people and organizations act. Given this, the National Pollutant Discharge Elimination System (NPDES) stormwater outreach program at the national level should, among other things:

- Disseminate information and educate people about the effects of receiving water pollution from diffuse sources, such as the loss of recreational activities.
- Promote positive environmental results, including the reduction of pollutant loadings into receiving waters.

Theoretically, accomplishing these goals should elicit a successful outreach program at any level. In fact, success is much more elusive. Of course, many outreach programs implement this theory very effectively. At the federal level, however, EPA has 16 different customers reflecting 10 EPA regions, 50 states, thousands of municipalities, and hundreds of thousands of facilities, trade associations, and professional groups. Moreover, when factoring in to this multitude Congress, EPA's own management, and scarce resources, a successful outreach program becomes a tremendously complex and costly endeavor.

At the federal level, it is crucial to provide as much information as possible to as many people as possible. Therein lies the biggest challenge in outreach at the federal level. This paper presents some of the challenges in developing an outreach strategy for the stormwater program at the federal level. It also describes some of the projects EPA's Office of Water has under way, some of which have worked very well and some of which have not. In addition, the paper discusses what the future holds for the stormwater outreach program.

Challenges of Developing a Stormwater Outreach Strategy

For its first year or so, the strategy of the stormwater outreach program consisted of a hotline, which addressed most needs, and speaking engagements, which filled in the gaps.

Almost immediately after the NPDES stormwater program was born, several years ago, the stormwater hotline was established. Since its inception, the hotline has received over 90,000 calls. The hotline staff answers questions, distributes documents, and handles registration for EPA workshops and seminars.

The other important element of the early stages of the stormwater program was speaking engagements and workshops. These continue to be one of the best ways to get "the word out" correctly. Regulated communities need to know exactly how the stormwater program affects them. For example, the program held 12 workshops between 1990 and 1991 to explain the November 10, 1990, regulations.

As the stormwater program matured, it became apparent that the community needed a more substantial outreach strategy. The hotline staff quickly found it difficult to refer all policy interpretation calls to EPA stormwater staff. At that time, the staff at Headquarters was very small and the regions were overburdened.

Consequently, the Headquarters stormwater staff expanded, and one of its first tasks was to develop an outreach plan. The first step was to identify the plan's customers, which turned out to be just about everyone. Primary customers are the regions and states. Of course, there are 11 categories of regulated industries and over 200 municipalities in Phase I alone. The list of customers continues to grow when the general public, elected officials, professional associations, trade groups, and consultants all are factored in. These groups require a different level of understanding of stormwater regulations. This presented a major challenge because the staff needed to examine each document and ensure that it satisfied the needs of more than one group of customers.

This early outreach strategy assumed knowledge of what the customers wanted. The assumption, however, was wrong. There was one crucial step in strategy development that the stormwater staff neglected to complete: ask the customers. Because of their enormous number, however, asking them all was impossible. Some customers, of course, in addition to the regulated community, are the states and regions, who are trying desperately to run their own stormwater programs. These customers were finally asked about the outreach plan at the 1992 Stormwater Coordinator's Conference in Atlanta, Georgia. The stormwater staff reviewed what they had been doing to date, and customers offered helpful suggestions on what to do next. Customers also participated in a session specifically targeted at designing the stormwater workshops held in April 1993 in Annapolis, Maryland, so as to ensure customer input.

During this meeting, it became apparent that many states and regions were duplicating work unnecessarily, that is, developing something that another state had already developed. This was very frustrating for all those involved. Some kind of clearinghouse or electronic communications system was desperately needed. Research, however, had already shown that it could cost from $750,000 to $1 million to set up such a system. This cost prevented Headquarters from accomplishing this effort on its own. Therefore, it asked the states to help by directing their 104(b)(3) grant funds to this effort. This seemed the only way to accomplish the goal quickly and effectively. Although this sounded like it would work, it has not. There is quite a bit of reluctance to use that money for this task. Therefore, stormwater personnel have begun to look for other avenues.

The challenges multiply when budget constraints are considered. One of the biggest problems involves printing a developed document. The printing budget at Headquarters has taken some very serious cuts. Despite attempts to solve this problem, difficulties continue. For instance, Headquarters has tried to distribute items electronically, but this can cause more problems than it solves. Budget cutbacks have seriously hampered plans to develop more public education materials than are currently available.

Of course, nearly everyone has been hit very hard by budget problems. Some states and counties have offered very creative ideas about getting the "most bang for your buck!" This issue has shed new light on the problem of getting out as much information as possible.

These are just some of the challenges stormwater staff have faced in putting together an outreach strategy. The next section describes some current outreach projects.

Current and Developing Outreach Activities

Research

A primary task has been to research existing outreach activities. Much information on these activities exists, and both researchers and audiences find this an ongoing educational process. Research efforts include:

- Research on outreach activities
  Audience: Headquarters management, regions
- Research on videos
  Audience: Headquarters management
- Research on clearinghouses
  Audience: Headquarters management, regions

Current research on existing outreach activities examines their successes and failures. Hopefully, this effort will help target materials and practices that can be expanded to a national level. While outreach videos have had difficulty with funding, the staff is researching what is out there, again, in case it finds something that works well and can be expanded to a national level. Finally, research on clearinghouses began before stormwater staff heard from the regions and states. The staff tried to learn of available clearinghouses to examine the possibility of their use or adaptation.

Outreach Strategy

The strategy is expected to be presented in a dynamic document. Its audience is Headquarters management and the regions. Hopefully, the document will provide an adaptable framework for designing and completing outreach projects within an assigned time frame.

Fact Sheet Development

Because the stormwater program involves so many issues and firestorms, staff often produce fact sheets to clear up confusion. Past fact sheets have focused on:

R0016051

- The Transportation Act's effect on the stormwater program.
- The Ninth Circuit Court decision that affected municipalities.
- The Municipal Part II guidance document.
- Phase II progress and results of public meetings.

Question and Answer Document

The audience for this document is the regions and industries via trade associations. The first volume was developed based on questions from the hotline. The staff compiled over 50 commonly asked questions and answers into one document, which has been distributed through the hotline.

The second volume covers more complex interpretations of the regulations, including questions on sampling, group applications, and the Ninth Circuit Court decisions. Again, distribution will probably proceed through the hotline.

Stormwater Workshops

In fiscal year (FY) 1991, the stormwater staff at Headquarters conducted 12 workshops on the basics of the stormwater program. The workshop audience consisted of regions, states, and the regulated community. The objective was to inform as many people as possible about the requirements of the November 16, 1990, rule. Attendance was in the thousands. The effort was successful.

In FY 1992, the stormwater staff presented workshops and spoke to over 4,000 people. These workshops focused on the requirements of the general permit and the development of pollution prevention plans. In addition, workshops for municipalities covered the requirements of the Part 2 municipal application. All these workshops were well received and also considered successful.

The FY 1993 workshops presented by Headquarters focused on developing pollution prevention plans. The staff developed a workshop series with the first day targeted to reach state and EPA regional representatives. This day is a train-the-trainer session to teach the audience how to lead a workshop on pollution prevention for industry. The second day is designed for the industrial regulated community and focuses on industrial and construction pollution prevention plan development. This day should include case studies and interactive exercises.

These workshops mark the first effort by the stormwater program to conduct workshops of this kind. The hope was to meet the objectives identified by the regions and states at the 1992 Stormwater Coordinator's Conference in Atlanta. Due to budget problems, Headquarters was limited to the number of workshops it could conduct in each region. The goal was, however, for state and regional staff to be able to present the workshops on their own. Each state was to receive a set of slides and speaking materials for its own use.

Municipal Support Division/Permits Division Pamphlet on Stormwater

The audience for this publication is Headquarters, the regions, and the general public. This project has experienced difficulties getting started due to contractual problems. It is, however, now moving ahead toward completion. The pamphlet is predominantly aimed at members of the general public who have little or no knowledge of the stormwater program.

Updated Stormwater Overview

This document addresses general information needs. Its audience consists of Headquarters, the regions, and the general public. The Overview reviews who the stormwater program covers, what their application options are, and what the deadlines are associated with those applications. As the program grows and changes, the Overview is updated. Distribution is currently through the stormwater hotline.

Raindrop Report (Status of the Stormwater Program)

This document is targeted to Headquarters, the regions, and the general public. It supplies a brief update on current activities in the stormwater program and features relevant information from recent *Federal Registers.* In addition, it describes outreach activities and provides specifics on applications submitted and general permits.

Articles for Newsletters

Stormwater staff are developing articles by request for publication in various journals and newsletters. They are trying to establish a regular submittal effort to some publications, such as the *Nonpoint Source News Notes*, which is published by the Headquarters nonpoint source program to supplement the bulletin board.

General Permit Effectiveness Study

The purpose of this effort is to determine the effectiveness of the general permit approach in implementing Phase I. The evaluation assesses, among other things, the rate of compliance, the level of awareness, and the quality of pollution prevention plans being developed. This effort also is identifying obstacles that prohibit the general permit from being as effective as possible.

Monthly Conference Calls

As of March 1993, Headquarters had completed 15 regularly scheduled conference calls with stormwater regional coordinators. These meetings have proven very successful, and they should continue.

Stormwater Awards

These awards recognize municipalities and industries that demonstrate a commitment to protecting and improving the quality of the nation's waters through outstanding implementation of innovative and cost-effective stormwater control programs and projects. In 1991, the winner for a stormwater control program or project by a municipality was Murray City, Utah. In 1992, the city of Orlando, Florida, won, and Prince George's County, Maryland, took second place. Nominations are sought from the 10 EPA regions.

National Stormwater Coordinator's Conference

This annual event is indispensable for planning and feedback from the states and regions. The meeting is designed for regional and state stormwater coordinators, as well as for Headquarters staff.

Continuous Speaking Engagements

Stormwater staff receive requests to speak to groups twice a week on average. While they are not always able to fill some requests because of a limited travel budget, the staff respond to as many as possible. In FY 1992, staff participated in about two dozen talks or seminars, not including the workshops.

Phase II Outreach Meetings

The Phase II Outreach Meetings are a series of meetings designed to include individuals that may be affected by the Phase II regulations in the development of those regulations. As of this writing, four meetings have been held (two in Washington, one in Dallas, and one in Chicago) to involve as many people as possible.

Information and Education Catalog

Another important project is the management and periodic update of the Information and Education Catalog, which was distributed at the National Urban Runoff Management Conference. The author and Tom Davenport manage this project. Everyone concerned should have a copy of this excellent document. Management plans to expand the manual to include stormwater information. In addition to putting out several calls for information, the conference registration packet included a form to fill out if individuals wanted this catalog to include a particular document. Management believes this document will help in the tremendous demand for technology transfer in the stormwater and nonpoint source programs. This, of course, is a top priority that customers have requested.

Electronic Sources

Linking to other clearinghouses and bulletin boards should improve communications. The nonpoint source program at Headquarters has been extremely helpful by placing information and announcements on its electronic bulletin board and in the *Nonpoint Source News Notes* publication. This has proven to be a good way to meet customer needs.

Further Considerations

Education is becoming one of the most important aspects of the stormwater program as people learn about the regulation and how it affects their day-to-day lives. Industries as part of their pollution prevention plans are developing training and education programs for their own employees. Cities are training their employees in sampling techniques and safety procedures as well as developing excellent public education programs. Tremendous efforts involving stormwater education are being undertaken. Stormwater Headquarters needs to know about the successful programs to help the lesser programs learn.

As this program moves forward, each success in educating those affected by the stormwater program, including the general public, leads to greater accomplishments. As these successes continue to build, more people will understand the intent and effects of protecting and cleaning up the waters of our nation. It is a cycle in which we all play a major role.

Training for Construction Site Erosion Control and Stormwater Facility Inspection

Richard Horner
University of Washington, Seattle, Washington

Abstract

Probably the leading reason that stormwater management programs fail in effectively protecting water resources is the lack of followup to ensure that permit conditions are met, approved designs are properly installed, and temporary and permanent management practices and facilities are maintained. Avoiding this downfall requires obtaining the legal authority for and then instituting a coordinated program extending from the first submission of permit applications through construction and all phases of site operation. This program should have components covering the construction phase as well as permanent practices and facilities. While somewhat different elements are appropriate for the two components, they share the common precepts of sound underlying planning; competent plan review; and effective inspection, maintenance, and enforcement. The University of Washington's Center for Urban Water Resources Management and Office of Engineering Continuing Education have developed and are offering courses to train personnel responsible for various aspects of the suggested program. This paper emphasizes the training for site inspectors. For construction-site inspectors, it covers the role of the erosion and sediment control (ESC) plan, the applicability of many ESC practices, key points to check when inspecting them, and how to deal with various circumstances that can arise during inspections. For permanent drainage system inspectors, the paper covers both the initial construction and continuing operation of facilities and offers guidance on key inspection points and such issues as safety, tracking maintenance, and waste handling.

Introduction

Effective stormwater management requires successful execution of steps at all phases of a project. These phases and the accompanying management steps include analysis of potential problems in the planning stage, quality design of programs and practices to protect aquatic resources as the project takes shape, competent review of plans at the permit application point, proper implementation of approved plans during construction, and correct operation and practices at facilities after their installation. All phases of the process need improvement through a better basis in knowledge and greater skills in application. Probably the weakest areas and the leading causes of program failures and environmental damage are implementation during construction and long-term operations.

Redressing this weakness will require widespread development of comprehensive and aggressive programs of inspection during the construction of developments and their stormwater management systems, followed by ongoing inspection of operating systems to ensure sufficient maintenance for continuing adequate performance. The diffusion of development and tradition of local land-use control prevalent in most of the United States will necessitate local acquisition of the legal authority, where it does not now exist, to institute these programs. As is already occurring in some places, it is likely that larger units of government will become involved in setting standards for these programs. The U.S. Environmental Protection Agency's National Pollutant Discharge Elimination System (NPDES) program is presently extending authority over programs in the largest cities and counties and at sites of construction larger than 5 acres and involving industrial activity. Still, the details and the responsibility for conducting the programs will very likely rest with local governments.

The concern of this discussion is the development and execution of local programs to upgrade significantly the quality of followup to increase the probability that approved stormwater management plans are effective. The scope of the programs envisioned would extend from the point of permit issuance through construction and all the years of site operation to follow project completion. The programs might be considered to have distinct components, covering, for example, erosion and sediment control (ESC) inspection at construction sites, inspection of the construction of storm runoff quantity and quality control facilities, and the periodic inspection and maintenance of operating facilities. However they are structured, these programs should embrace some common principles. They should be the logical extension of and ultimate implementation vehicle for the foregoing phases of planning, design, and plan review. Further, they should be conceived and conducted as essential elements of a successful program, deserving of the needed funding, staffing, support by administrators and public officials, training of personnel, and enforcement authority.

This discussion covers aspects of program development and especially emphasizes training for site inspectors. For these purposes it divides the overall program into two components. One covers construction site ESC programs. The second covers permanent drainage practices and facilities, both their inspection at construction and followup inspection and maintenance. In both cases, the paper recommends program structures and discusses some key program elements. It then offers specific examples of inspection checks to perform in the field. The goal of the paper is to give the reader a basis for beginning program design and undertaking the key element of training the staff who will be charged with its performance.

The discussion was derived from two courses developed and offered by the University of Washington's Center for Urban Water Resources Management and Office of Engineering Continuing Education. The course coverage is organized in the same manner as this presentation, and course manuals are available for ESC inspector training (1) and permanent drainage system inspector training (2). Important contributions to the material presented in these courses and in this discussion have been made by local governments and state agencies in the Puget Sound area of Washington state that have been working actively to improve stormwater management through good followup.

Construction Site ESC Inspection Programs

Program Development

Program Elements

The following elements are recommended for a comprehensive construction site ESC program:

- ESC planning
- A plan review process
- Contractor education
- An inspection and enforcement process

The subsections to follow cover two of these program elements in detail, ESC planning and inspection and enforcement. The latter discussion is then extended in the following section to examples of inspection guidelines for common practices.

ESC Planning

ESC planning is an absolute prerequisite for an effective program. A careful site analysis should produce a standalone plan (i.e., a plan devoted exclusively to this aspect of the project) developed with the same thoroughness and care as any other plan in the overall construction set. It is intended for use by the plan reviewer, the construction superintendent and other contractor personnel, and the construction site inspector. This subsection outlines the ESC planning process from beginning to end and concludes with an example of a complete plan.

In approaching an ESC plan, the planner must:

- Understand the erosion process, so that it can be controlled.
- Know the site and the construction plan, so that both potential problems and solutions will be apparent.
- Understand the various ways that erosion can be prevented or that eroded sediments can be caught.

The erosion process is first reviewed for the lessons it can offer ESC planning. Erosion has been understood for thousands of years, as is attested by the extensive evidence of terraced farming—some continuing today—in steep terrain in ancient cultures. Figure 1 illustrates the types of erosion and its nature. Soils can be loosened and set in motion initially by the impact of falling raindrops. Erosion progresses, although gradually, as runoff flows in a sheet over a bare surface and exerts shear stress, which is a function of velocity, on soil particles. The rate of erosion increases when flow concentrates and increases in velocity. Channels formed by these flows are known as rills. When rills join and form highly concentrated, rapidly flowing channels, the rate increases still further, a stage termed gully erosion. Erosion can progress still further to mass wasting when a whole area loses stability.

Several factors involving site soils, vegetation, and topography influence the erosion process. Soil erodability is greater in the case of silts and fine sands than clays or soils with a substantial gravel content. Relatively high organic content also offers cohesiveness that resists erosion. Clays tend to produce a larger volume of runoff, however, because of their relatively poor permeability, which exerts more erosive stress on soil. Vegetative cover offers a number of important advantages, including reducing raindrop impact, slowing runoff velocity, helping to absorb water, and holding soil in place. In regard to topography, both slope gradient and length tend to increase velocity and the resulting frictional

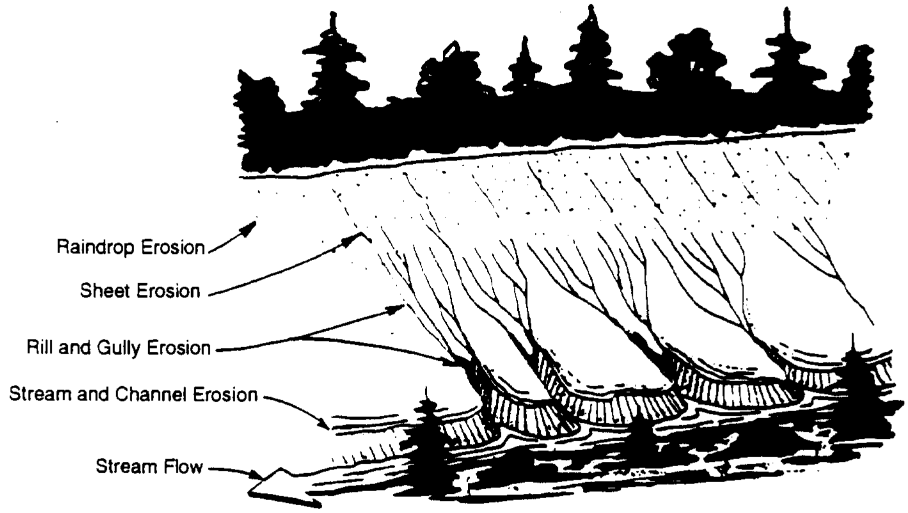

Figure 1. Soil erosion processes (3).

shear stress. Erosion hazards relative to slope gradient and length are listed in Table 1.

Acquiring the familiarity with the site and proposed construction necessary to proceed with the ESC plan involves data collection and analysis. Site data should be collected in regard to:

- Soils
- Vegetation
- Topography
- Ground-water table
- Neighboring water bodies
- Adjacent properties
- Drainage routes and patterns (define subbasins)
- Potential areas of serious erosion problems
- Existing development, utilities, and dump sites

The following construction plan information should be cataloged at the outset of planning:

- Grading (location, amount)
- Topographic changes
- Clearing and grading limits
- Drainage changes

Table 1. Soil Erodability Relative to Slope Gradient and Length

Erosion Hazard	Slope Gradient	Maximum Length
Low	0-7%	300 ft
Moderate	7-15%	150 ft
High	>15%	75 ft

- Materials to be used and locations of use and storage
- Access points

ESC planning should proceed with reference to certain basic principles, as follows:

- First consider all means of preventing erosion; only consider trapping sediments from unavoidable erosion. Prevention has the potential to be more effective in resource protection than later treatment and less costly.
- Phase construction and post clearing limits to maintain as much natural vegetation as possible and for as long as possible.
- Plan construction to fit the site; use terrain advantageously and avoid critical areas.
- Cluster buildings and other developed features, and minimize their impact on impervious area.
- Plan for control of erosion subbasin by subbasin.
- Minimize extent and duration of vegetation removal (especially during wet season) and soil disturbance.
- Stabilize and protect disturbed areas as soon as possible.
- Use natural drainage features, existing vegetation, and materials found on the site.
- Minimize slope length and gradient to control runoff velocities.
- Divert offsite runoff away from disturbed areas.
- Retain any released sediment within the construction area and reduce tracking off site.
- Have a thorough maintenance and followup program.
- Take measures to control potential pollution from construction materials (e.g., paving materials, petroleum

products, other vehicle fluids, fertilizers, pesticides, grinding and sanding debris, wastes).

An ESC plan consists of a narrative and site plans. Points that should be covered by the narrative include 1) a project description, 2) a description of existing and modified site conditions, 3) descriptions of ESC best management practices (BMPs), 4) descriptions of BMPs for pollutants other than sediments, 5) plans for permanent stabilization, 6) calculations, and 7) provisions for inspection and maintenance. Site plans are maps and engineering plans illustrating and specifying the project's location, existing and modified site conditions, and BMPs. The set of site plans should include 1) a data collection worksheet (principally showing topography, soils, and vegetation), 2) a data analysis worksheet (mainly indicating drainage subbasins and primary drainage courses), 3) a site plan development worksheet (showing existing and finished contours, roadways, and permanent stormwater facilities), 4) the ESC plan (showing BMP locations), and 5) diagrams of representative BMPs, as appropriate. The ESC plan (item 4 in the set) is the key element for implementing the plan. BMPs are usually specified on this plan using a system of symbols, which are defined in a legend.

Inspection and Enforcement

The most important general needs of an inspection and enforcement program are a staff dedicated to the function, specific staff training, and administrative support. These needs are best provided for by a dedicated revenue source, such as a stormwater utility assessment. The staff should not have unrelated and distracting duties such as inspection of other facets of construction. Initial training should offer needed background in, for instance, legal and regulatory requirements, water quality, hydrology, soils, and vegetation. Subsequent training should provide detailed coverage of BMP requirements, such as discussed in the following section. Strong support from administrators is essential for a staff undertaking a relatively new function that might be unpopular in terms of economic interests.

Beyond these basic needs are some specific issues to clarify during program development for incorporation as formal program elements. Recommendations on the issues presented in this paper are drawn from experience in the Puget Sound region, especially in King County and the cities of Bellevue and Redmond. One of these issues is the response to a situation in which measures in an approved ESC plan proved inadequate. Strong permit review should normally limit these instances, but unforeseen circumstances can still arise. Inflexible adherence to an ESC plan can be self-defeating when measures prove to be inadequate for whatever reason; thus, the jurisdiction should retain the authority to require additional measures if needed. This option should be noted in a statement on each ESC plan.

A second issue is how field change orders will be handled. The policy should call for careful but expeditious consideration of requests for plan changes, generally after consultation with plan review personnel. Finally at issue is the granting of variances from code requirements. Conditions on granting variances should be strict and specific, such as:

- The expected result should be at least comparable to the outcome expected to be achieved with the approved method.
- Sufficient background information and justification should be presented for adequate assessment of the alternative.
- The ability should be retained with the variance to meet objectives of safety, function, appearance, environmental protection, and maintainability based on sound engineering judgment.
- The variance should be in the public interest.

Enforcement authority must be obtained and the system of enforcement defined and made clear to the regulated parties. A system successfully used by the city of Bellevue has a sequence of three steps, as follows:

- A verbal warning, with a deadline for correction.
- A correction notice (with specifications of corrections), a deadline, and a warning about the consequences of noncompliance.
- A stop-work order, with a warning about the consequences of noncompliance.

ESC Practices and Their Inspection

Categories of Practices

The numerous ESC practices in use can be categorized in various ways. The most basic division is between erosion control practices, which prevent or minimize erosion, and sediment control practices, which attempt to capture soil released through erosion. Within each of these broad groupings are several categories that represent general strategies for achieving either erosion control or sediment control. In addition to sediments, construction sites can generate many other pollutants, such as petroleum products, solvents, paints, sanding dusts, pesticides, and fertilizers. It is most efficient to manage those materials along with sediments and to inspect the management practices for them simultaneously with ESC inspection. Therefore, these practices represent another basic division.

Following is the breakdown of ESC practices used by Reinelt (1), with the number of individual practices in each category. The 29 practices represented are by no means the only ones, but they are the most widely recognized and used. Twenty-two of the 29 (all but the sediment trapping techniques) are preventive and are thus generally the most cost-effective options; however, the straw bale and filter fabric fences and sedimentation ponds among the trapping techniques are most commonly used practices.

1. Erosion control
   - 1.1. Natural vegetative cover—two practices
   - 1.2. Temporary cover—three practices
   - 1.3. Permanent vegetation establishment—two practices
   - 1.4. Stabilized construction entrance and roads—three practices
   - 1.5. Runoff control—eight practices
2. Sediment trapping techniques—seven practices
3. Management of other construction site pollutants—four practices

The following passages provide inspection checklists for example practices, generally the most common, in each category and subcategory. The checklists are divided into checks to be made when the practice is implemented and checks to be made on each followup visit to determine the need for maintenance or replacement of the ESC materials. Many of the points are illustrated in diagrams that accompany the checklists.

While much of an inspector's work is performed in the field, it is often advisable or even absolutely necessary to do some background work in the office before going out to inspect an installation. This work mainly consists of consulting the ESC plan to determine the specifications. The plan should be retained on the construction site should the inspector or construction personnel need to refer to it.

1. Erosion control

1.1. Natural vegetative cover

1.1.1. Phasing construction

Phasing construction is a practice in which clearing operations are performed in stages to take advantage of cover that exists on site before construction.

Installation checks:

1. Are areas that will not be cleared set off with plainly visible clearing-limit fencing?
2. Is plainly visible flagging placed at the drip line of trees to be protected (see Figure 2)?
3. Are fills and cuts near protected trees treated as shown in Figure 2?
4. Is final vegetation established as soon as portions of the site can be made ready?

Maintenance checks:

1. Do fencing and flagging need repair or replacement for personnel to see it clearly?
2. Do exposed or injured roots of protected trees need covering or dressing?

1.2. Temporary cover

Temporary cover practices recognize that portions of most construction sites remain unworked for months, during which time very large amounts of erosion can occur unless these areas are stabilized. Stabilization can be achieved with temporary seeding or various kinds of slope coverings, or both. Slope coverings include both mulches and commercial mats and blankets. It is often necessary to apply temporary cover to different areas several times during construction.

Mulches, mats, and blankets can serve several purposes in erosion control: covering the slope temporarily to prevent erosion by raindrop impact and the friction of runoff, holding water to encourage grass growth, protecting grass seedlings from heat, and enriching the soil. Straw, hay, wood fiber, wood chips, and other natural organic materials can serve as mulches. Inspection guidelines for straw and wood fiber are given below as examples. Mats and blankets are manufactured from both natural and synthetic materials. Guidelines are given for several varieties.

1.2.1. Temporary seeding

Installation checks:

1. Is the soil stabilized within the period specified by regulation? (This period varies from place to place, depending on climate patterns. In the Puget Sound area of Washington, which receives most of its rainfall in the winter, the specified periods are within 2

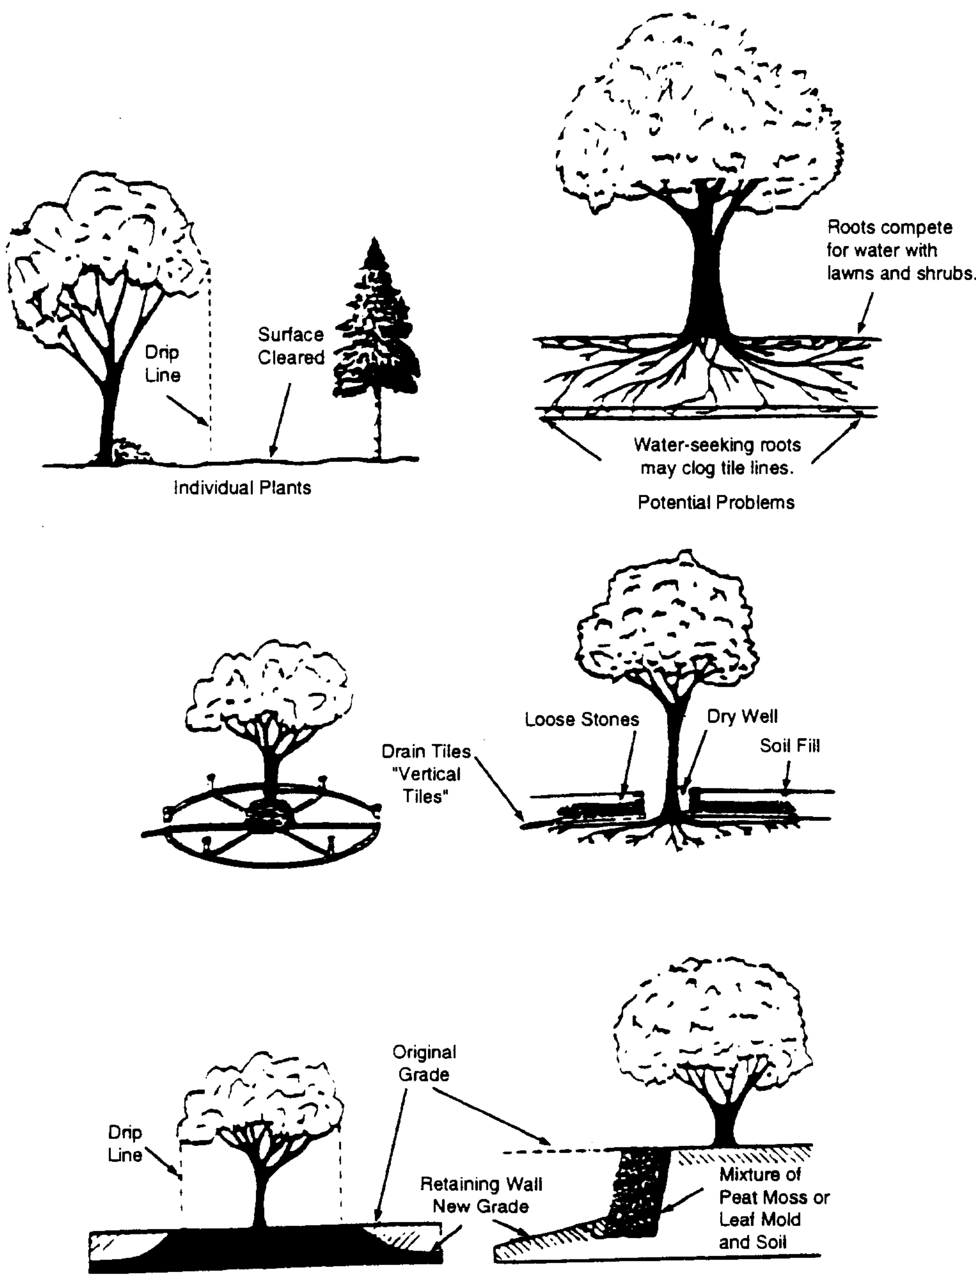

Figure 2. Guidelines for preserving natural vegetation (3).

days during the months October to April and within 7 days during the months May to September.)

2. If used without slope covering practices, is temporary seeding limited to slopes of less than 10 percent and 100 ft in length? If the slope exceeds either limit, is a mulch or mat slope covering used?

3. Has the seedbed been prepared with at least 2 to 4 in. of tilled topsoil?

4. Is fertilizer use limited as much as possible; if used, is it applied in amounts no greater than the needs of the grass for the prevailing soil conditions?

5. Is mulch applied for protection if seeding occurs when temperatures can be high or runoff is likely to occur before the grass is well established?

6. Is irrigation provided if planted when rainfall might be insufficient for good establishment?

Maintenance checks:

1. Is it necessary to irrigate and/or reseed?

2. Is maintenance fertilizer needed?

1.2.2. Straw mulch

Straw mulch can be used without seeding or, for better erosion control, with seeding.

Installation checks:

1. Is the straw spread generally a minimum of 2 in. deep (corresponds to 2 to 3 tons per acre) and greater on very steep slopes, adjacent to sensitive areas, and where concentrated flow passes over the slope?

2. Is the mulch anchored as needed by crimping, disking, rolling, or punching into soil or by moistening, tackifying, or netting?

Maintenance checks:

1. Is replacement needed as a result of blowing away or decomposition over time?

2. Is there any fire hazard requiring moistening?

1.2.3. Wood fiber mulch

Wood fiber mulch should only be used with seeding and generally should be used with a soil bonding agent.

Installation checks:

1. Is the mulch used with seeding and a soil bonding agent? Were the bonding agent distributor's application guidelines followed?

2. Has the wood fiber been applied to cover the soil completely, allowing no bare soil to show through (corresponds to about 1 ton per acre and is adequate for most circumstances)? Are there any special circumstances, such as seeding during hot weather, when the amount should be increased by about 50 percent?

Maintenance checks:

1. Is replacement needed as a result of loss over time?

1.2.4. Excelsior

Excelsior is a product made of fine wood shavings that assume a more-or-less helical form. As a consequence of this form, excelsior does not lie in close contact with the soil and allows runoff to drain beneath it and cause erosion. Therefore, it should be used only with seeding, where it is very useful in holding moisture and providing protection from direct sun in hot periods. Suppliers generally market several grades for sheet and channelized flow and different velocities.

Installation checks:

1. Is the excelsior used only with seeding?

2. Was an appropriate material selected according to manufacturer's recommendations and then placed and stapled as recommended by the manufacturer?

3. On slopes, was it placed 3 ft over the crest or in an anchor ditch?

4. In ditches, was it placed in the direction of water flow with any seams offset 6 in. from the ditch centerline?

Maintenance checks:

1. Is replacement needed as a result of damage or loss over time?

1.2.5. Mats and blankets

Examples of materials produced in a mat or blanket form for erosion control are jute, woven straw, and synthetics. Mats can be used without seeding, or with seeding for better erosion control. As with excelsior, suppliers generally market several grades for sheet and channelized flow and different velocities.

Installation checks:

1. Was an appropriate material selected according to manufacturer's recommendations and then placed and stapled as recommended by the manufacturer?
2. Was it placed in the direction of water flow, in full contact with the soil but not tightly stretched?

Maintenance checks:

1. Is replacement needed as a result of damage or loss over time?

1.3. Permanent vegetation establishment

Permanent vegetation should be established as soon as possible after all construction is completed in each segment of the site. Grass can be established by seeding or sodding. Seeding is generally preferred because of the lower cost and greater flexibility in selecting grass species. Sod is often available only in limited varieties, which may not be the most suitable for erosion control and other purposes unless grown to order. In some cases, overseeding with preferred species is recommended in the spring, when grass must be established with sod in the winter. Species should be selected based on local climatological and soil conditions, with reference to regional guidance documents, and, when necessary, in consultation with regional experts.

1.3.1. Permanent seeding

Installation checks:

1. Has the seedbed been prepared by loosening with a plow if subsoils are highly compacted. spreading 2 to 6 in. of topsoil, and lightly rolling?
2. Is fertilizer use limited as much as possible; if used, is it applied in amounts no greater than the needs of the grass for the prevailing soil conditions?
3. Is mulch applied for protection if seeding occurs when temperatures can be high or runoff is likely to occur before the grass is well established?
4. Is irrigation provided if planted when rainfall might be insufficient for good establishment?

Maintenance checks:

1. Is it nencessary to water, reseed, or add fertilizer?

1.3.2. Sodding

Installation checks:

1. Is the sod placed from the lowest area and perpendicular to water flow?
2. Are sod strips wedged tightly together and joints staggered at least 12 in.?
3. Is the sod stapled if on a steep slope?

Maintenance checks:

1. Is overseeding needed, either to repair damage or to install a preferred grass species?

1.4. Stabilized construction entrance and roads

The entrance is the most important access route to stabilize, since it is the last point at which tracking sediment off site can be stopped. If equipment travels extensively on unstabilized roads on the site, a tire and vehicle undercarriage wash near the entrance will be needed. Perform washing on crushed rock. Wash water will require treatment in a sediment pond or trap.

1.4.1. Stabilized construction entrance (see Figure 3)

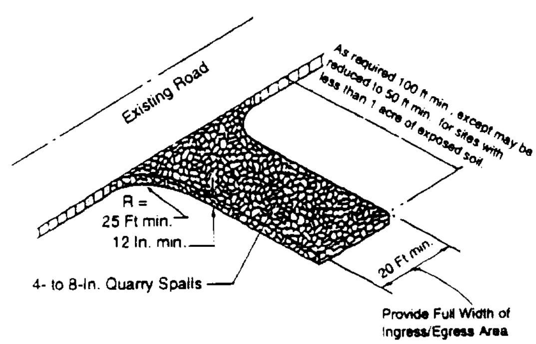

Figure 3. Stabilized construction entrance (from Washington Department of Ecology, 1992).

Installation checks:

1. Is the entrance constructed with quarry spalls 4 to 8 in. in size and at least 12 in. thick?
2. Is the stabilized entrance sized correctly for the site?
3. If the entrance sits on a slope, is a filter fabric fence in place downgradient?

Maintenance checks:

1. Is the entrance clogged with sediments, requiring top dressing the pad with clean 2-in. rock?
2. Is it necessary to clean up any sediments carried from the site onto the street?

1.5. Runoff control

Runoff control represents various practices designed to keep water from coming in contact with bare soil or controlling its velocity if it does. Included are drains for surface and subsurface water, dikes and swales placed across slopes to interrupt runoff, and roughness created on the surface to reduce velocity. Example guidelines presented below are for a pipe slope drain and surface roughening.

1.5.1. Pipe slope drain (see Figure 4)

A temporary pipe slope drain is an effective technique for preventing erosion on a slope caused by runoff from a higher elevation. Upslope runoff needs to be collected and directed into the drain effectively and then discharged in a controlled way to prevent erosion at the bottom of the slope.

Installation checks:

1. Are no more than 10 acres drained into a single pipe slope drain?
2. Was a minimum 6-in. metal toe plate placed at the entrance to prevent undercutting?
3. Is runoff directed into the pipe with interceptor dikes at least 1 ft higher at all points than the top of the pipe?
4. Is there a slope toward the pipe on a grade of at least 3 percent at the inlet?
5. If the pipe is 12 in. in diameter or larger, was a flared entrance section installed and connected securely to the drain with water-tight connecting bands?

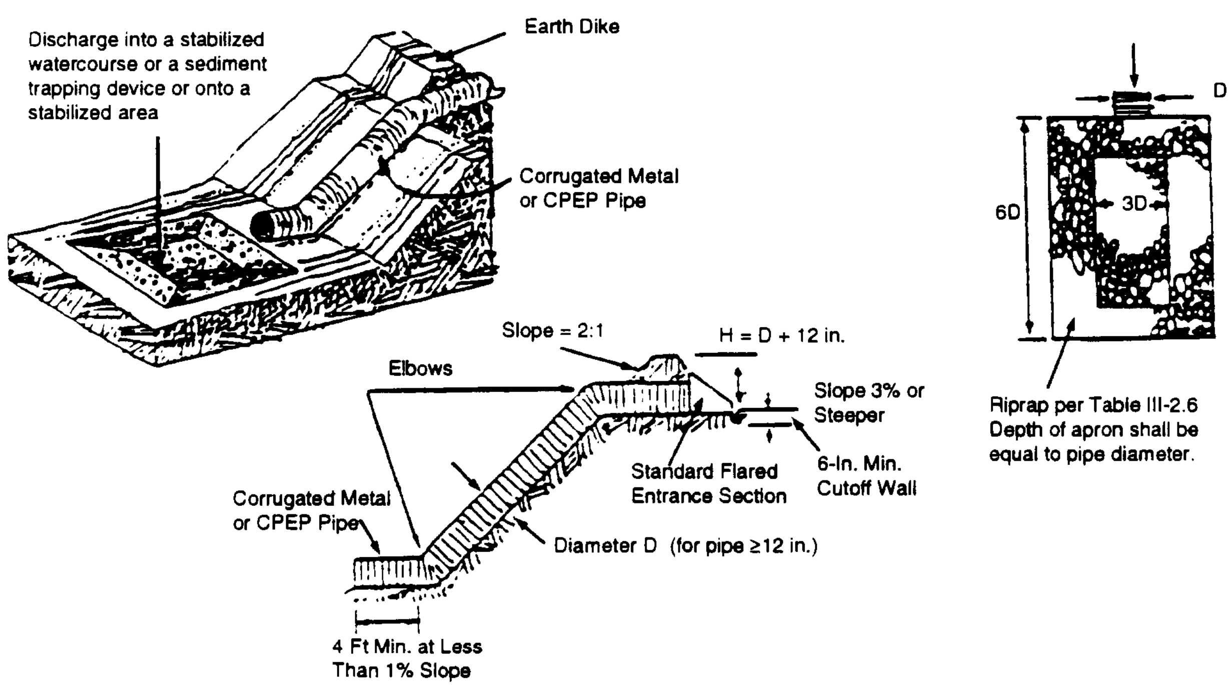

Figure 4. Pipe slope drain details (3).

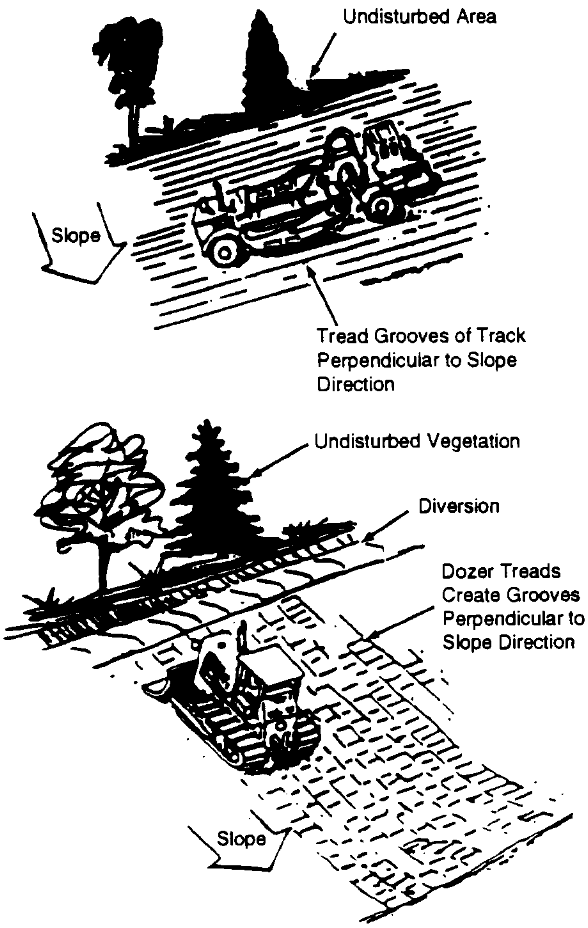

Figure 5. Examples of surface roughening using heavy equipment (3).

6. Was the soil thoroughly compacted at the entrance and underneath the pipe?

7. Were gasketed, water-tight fittings placed between pipe sections, were the sections securely fastened, and was the drain anchored to the soil?

8. Was the area below the outlet stabilized with a riprap apron?

9. If the drainage can carry sediment, is it treated in a sediment pond or trap?

Maintenance checks:

1. Is undercutting or bypassing occurring at the inlet, requiring reinforcing of the headwall with compacted earth or sandbags?

2. Is erosion occurring at the outlet, necessitating rebuilding the apron?

1.5.2. Surface roughening (see Figure 5)

A roughened surface is an easy and inexpensive way to reduce runoff velocity, encourage the growth of vegetation, increase runoff infiltration, and trap some sediment. It is not effective enough to use alone but can reduce the load on sediment trapping installations downstream. Roughening is best used on slopes steeper than 3 horizontal to 1 vertical that do not require mowing. There are several methods of roughening a surface, all of which involve forming horizontal depressions with equipment. Methods include tracking perpendicular to the slope direction, driving treaded equipment along the slope direction to get grooves perpendicular to the slope, or tilling (preferred because it avoids compaction). On steeper slopes (steeper than 2 horizontal to 1 vertical) a stair-step pattern should be formed.

Installation checks:

1. Have all exposed slopes steeper than 3 horizontal to 1 vertical been roughened, with 40- to 50-in. stair-step patterns formed on slopes steeper than 2 horizontal to 1 vertical?

2. Was the soil scarified if it was heavily compacted by the roughening?

3. Was the area seeded as quickly as possible?

Maintenance checks:

1. Have rills appeared that should be regraded and reseeded?

2. Sediment trapping techniques

Trapping sediments once they are released requires slowing the transport velocity sufficiently for soil particles to settle (i.e., reducing the velocity below the settling velocity of the particles). Soil particles range over several orders of magnitude in size, from the small clays to the large sands. Settling velocity is approximately related to the square of the particle diameter; thus, halving the diameter approximately quadruples the time needed for settlement. Therefore, as particles decrease in size, they become increasingly difficult to remove from a runoff stream. This fact is largely why preventive techniques are more cost effective than sediment trapping practices and are strongly preferred.

The two basic types of sediment trapping techniques in use are sediment barriers and settling ponds. Sediment barriers include the commonly used filter fabric and straw bale fences as well as brush fences and barriers constructed of gravel. Both types trap sediments in the same way, by ponding water. Although that mechanism is more obvious in the case of ponds than of barriers, practices of the latter type actually provide only a minimum of filtering capability and primarily slow the flow of water long enough for some particles to settle. Thus, they can only trap relatively large particles, generally the larger silts and sands. The trapping ability of settling ponds depends on their size. While they can theoretically be made large enough to trap any size particle, practical sizes generally limit efficient removal to the medium silts and larger.

2.1. Sediment barriers

Several principles apply to the various types of sediment barriers. Maximizing a sediment barrier's ponding volume maximizes the amount of sediment trapped. Therefore, the barriers should be placed away from the immediate toe of slopes in order to increase the area for ponding. It is very important that sediment barriers be aligned on the contour, not up and down slopes. This alignment places them at a right angle to flow paths and also increases ponding volume. Slopes draining to sediment barriers generally should not be more than 100 ft long. Sediment barriers must be trenched in and staked to hold up under the pressure of the wall of water they will dam. Finally, sediment barriers do not provide effective sediment removal from concentrated flows. While straw bales are sometimes used in ditches, rock check dams are really a better alternative for decreasing velocity in channels.

2.1.1. Filter fabric fence (see Figure 6)

Installation checks:

1. Are filter fabric fences used only in the following applications:

   Maximum of 1 acre served by a single fence?

   Maximum 1:1 slope gradient and 100-ft slope length?

   Sheet flow situation (never in concentrated flow)?

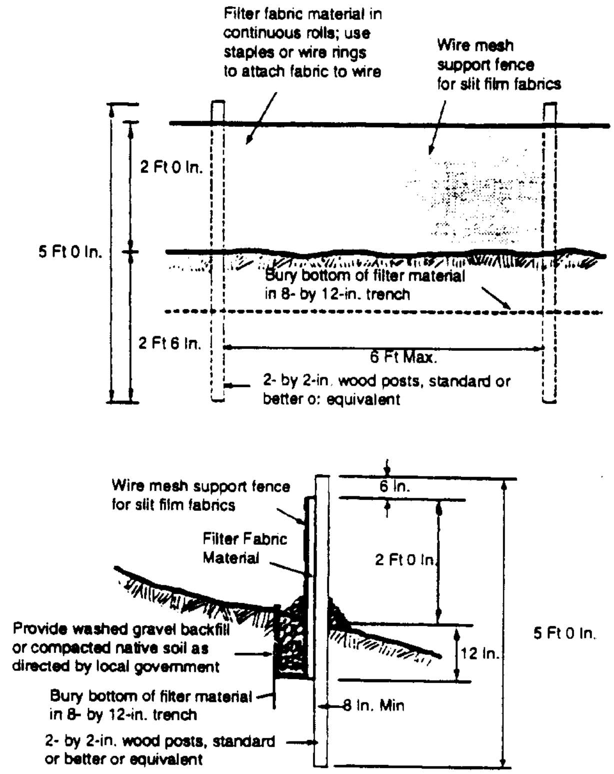

Figure 6. Filter fabric fence detail (3).

2. Is the fence aligned to slope contours as well as possible?

3. Is the fence installed so that its height above the soil is no more than 3 ft?

4. Are posts 2 x 4 in. wood or 1.33 lb/ft steel, or the equivalent?

5. Are posts buried 2.5 ft deep whenever possible and spaced no more than 6 ft apart?

6. Is fabric attached on the upslope side with staples (at least 1 in.), tie wires, or hog rings?

7. Is the end of the fabric buried in a trench sized as shown in Figure 6 and backfilled on both the upslope and downslope sides (as shown)?

8. Is splicing avoided if possible? If impossible, is splicing done only at posts and overlapped at least 6 in.?

9. Nonwoven and woven monofilament materials have the best properties for silt fencing. If a woven slit-film fabric is used, is wire mesh reinforcing (14-gauge rein-

forcing wire mesh with openings no larger than 6 in.) placed on the upslope side and fastened the same as the fabric?

Maintenance checks:

1. Is it necessary to restake, reattach, or replace the fence to maintain all of the above conditions?

2. Is sediment removal needed (before it reaches 1/3 the height of the fence)?

2.1.2. Straw bale fence (see Figure 7)

Straw bale fences tend to swell when they get wet and require frequent maintenance. They are not highly recommended but could be more effective if used according to the following guidelines.

Installation checks:

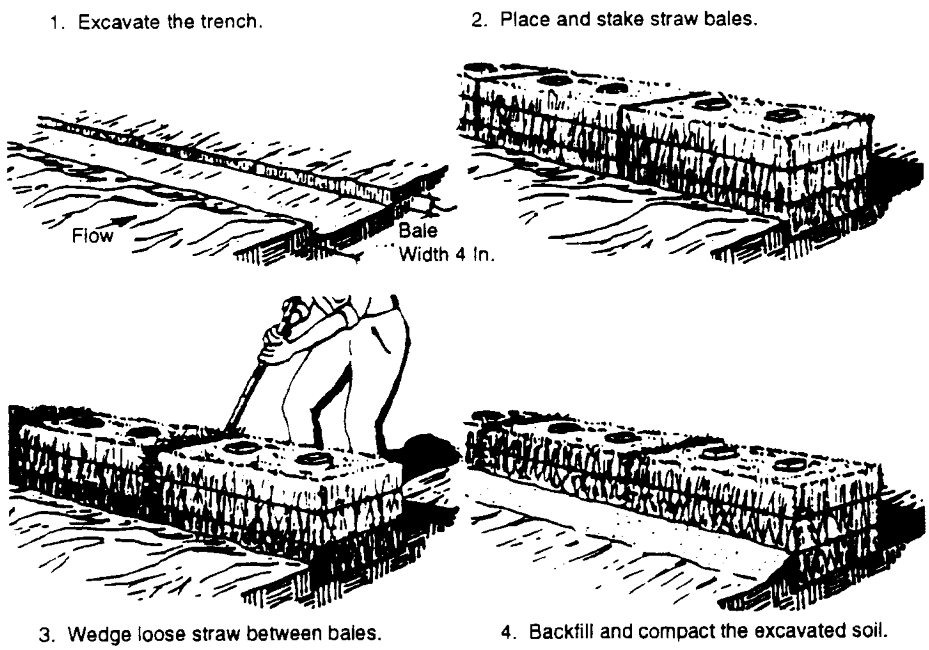
1. Are straw bale fences used only in the following applications:

   Maximum of 1/4 acre served per 100 ft of fence length?

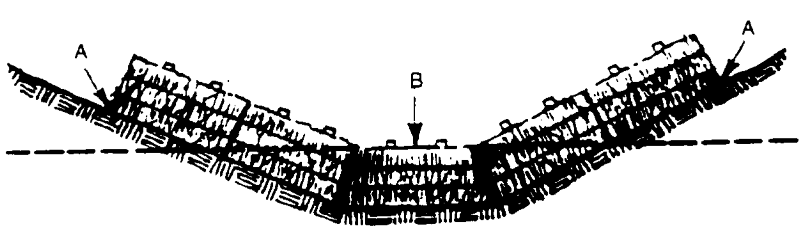
   Maximum 2:1 slope gradient and 100-ft slope length?

2. Is the fence aligned to slope contours as well as possible?

3. Are the bales bound with wire, preferably, or string placed around the sides of the bale, parallel to the ground?



CONSTRUCTION OF A STRAW BALE BARRIER



Points A should be higher than point B.

PROPER PLACEMENT OF STRAW BALE BARRIER IN DRAINAGE WAY

Figure 7. Proper installation of straw bale fences (3).

R0016065

4. Are the bales installed in a 4-in. trench, as shown in Figure 7, and backfilled with 4 in. of soil on the upslope side?

5. Are the bales forced together as tightly as possible and anchored with at least two stakes or pieces of rebar per bale driven toward the previous bale and flush with the top of the bale?

6. Are gaps wedged with straw, and is straw spread on the upslope side?

7. Are straw bale fences used in channels with concentrated flow only when velocities are low and placed as shown in Figure 7 (perpendicular to flow and extending at least one bale length above the mid-channel bale)?

Maintenance checks:

1. Is it necessary to replace the fence to maintain all of the above conditions?

2. Is sediment removal needed (before it reaches 1/2 the height of the fence)?

2.2. Settling ponds

Settling ponds have several advantages. They can function through all construction phases and have relatively low maintenance requirements. They can also be located to intercept runoff both before and after the onsite drainage system is developed.

The three types of settling ponds in use differ only in their outlet structure. The term sediment basin is used to describe a settling pond with a pipe outlet that generally serves a drainage area of 3 to 10 acres. A sediment trap is a settling pond with a stable spillway outlet and a smaller service area. The third type is a permanent water quantity control pond put in temporary service during construction; such a pond is designed to drain completely between storms in permanent service. This operating mode is not appropriate for ESC application, however, because the residence time is too short for good particle trapping and settled material becomes resuspended during draining. Therefore, a temporary riser outlet needs to be installed for use during construction.

A key point in the design and construction of a settling pond is to avoid short-circuiting by the water. Short-circuiting can cut the actual residence time far below the theoretical value and harm performance. Ways of avoiding it are to divide the pond into two or more cells, locate the inlet and outlet far apart, and install baffling to increase the flow path.

2.2.1. Sediment basin (see Figure 8)

Installation checks:

1. Is the bottom graded to be as level as possible?

2. Is the pond no deeper than 7 ft with 1 ft of freeboard?

3. Are side slopes no steeper than 3 horizontal to 1 vertical?

4. Does the pond have an emergency spillway that is 1 ft deep, with a width two to three times the number of acres served by the pond, and lined with 2 to 4 in. of rocks?

5. Does the pond discharge through a riser pipe having at least two 1-in. diameter orifices at the top of the sediment storage zone?

6. Are inlet and outlet areas protected from erosion with riprap?

7. Is baffling installed if the length-to-width ratio is less than 6 or if the entrance velocity is high?

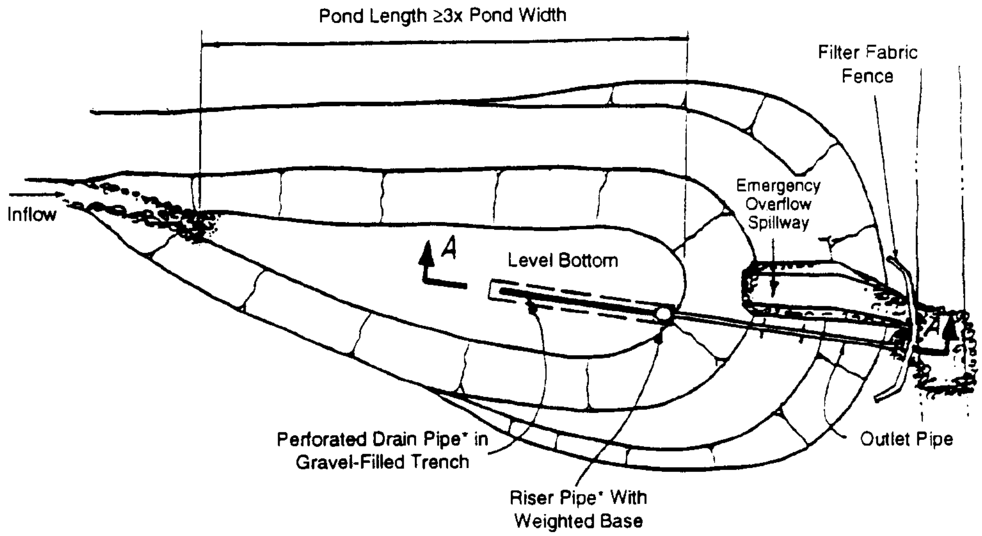
8. A good feature to prevent short-circuiting of flow is a two-celled pond, preferably with cells divided by sandbags or a rock berm and connected by a riser pipe similar to that used for the outlet. A less preferred arrangement is dividing the pond with a filter fabric fence. Is this feature installed if specified in the design?

9. Is the pond fenced if it presents any safety hazard to children?

Maintenance checks:

1. Is sediment removal needed (before 1.5 ft accumulates)?

2. Are any outlet orifices clogged and in need of cleaning?



*Sediment dewatering may be accomplished with perforated pipe in trench as shown or with a perforated riser pipe covered with filter fabric and a gravel "cone." A control structure may also be required; see Conditions Where Practice Applies.

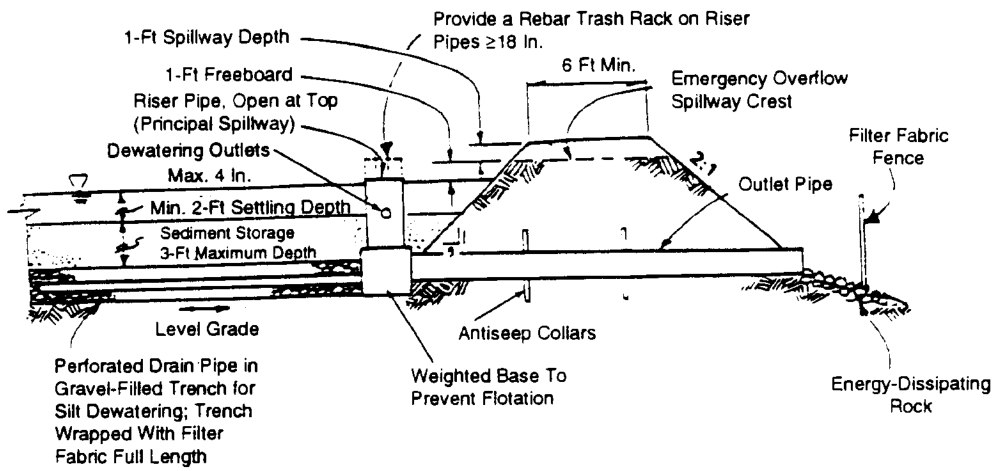


Figure 8. Typical sediment basin (3).

3. Are any embankments damaged and in need of compaction or rebuilding?
4. Has riprap or spillway lining material been lost and need to be replaced?
5. Are there signs of excessive drainage to the pond, requiring rerouting or pond enlargement?
6. Are there signs of excessive sediment loading to the pond, requiring stabilization of the drainage area?

3. Management of other construction site pollutants

Construction sites can create pollution problems over and above erosion and sediments through paving operations, handling and storage of various materials, spills, and waste handling. Inspectors should also be aware of the potential for runoff contamination from these sources and inspect the site according to the following guidelines.

3.1. Handling cement and concrete

Inspection checks:

1. Do concrete trucks have a designated washout area with a sediment trap?

2. Is exposed-aggregate driveway wash water drained toward a collection point at the side or into a sediment trap, where it cannot get into a street drainage system?

3.2. Material storage and handling

Inspection checks:

1. Are weather-resistant enclosures used for the storage and handling of materials, such as paints, coatings, wood preservatives, pesticides, fuels, lubricants, and solvents, and for potentially polluting wastes?

2. Are there designated and clearly communicated procedures for handling materials and wastes and washing containers?

3. Is a chemical inventory maintained, including Material Safety Data Sheets?

4. Are containers and enclosures inspected periodically for leakage, indicating the need for maintenance?

3.3. Spill containment

Inspection checks:

1. Has a spill control plan been developed, and have supplies been obtained to implement it? Does the plan include:

   Who to notify if a spill occurs?

   Specific instructions for different products?

   Who is in charge?

   Spill containment procedures?

   Easy to find and use spill cleanup kits?

   How a spill will be prevented from getting into a drainage system (e.g., valving, diversion, absorption)?

   A disposal plan?

   A worker education program?

3.4. Waste management

Inspection checks:

1. Have waste reduction practices been instituted (e.g., reusing solvents, substituting for toxic products, minimizing quantities of materials used)?

2. Have recycling practices been instituted (e.g., waste separation for recycling, purchasing recycled materials)?

3. Are hazardous and nonhazardous wastes separated and each disposed of properly and promptly?

4. Has an employee education program on waste management been established?

Inspection Programs for Permanent Drainage Practices and Facilities

Program Development

Program Elements

The following elements are recommended for a comprehensive inspection program for permanent drainage practices and facilities:

- Stormwater management planning
- Plan review process
- Construction inspection and enforcement process
- Followup inspection and long-term maintenance process

The stormwater management planning step ensures that each site considered for a permit receives comprehensive analysis. The extensive considerations in this portion of the recommended program are beyond the scope of this discussion. The third element refers to inspection of the stormwater management facilities themselves when they are built to determine whether installation has been consistent with the approved plans. The final element seeks to ensure that facilities continue to operate properly. The next subsection covers programmatic aspects of the followup inspection and long-term maintenance process. The discussion is then extended in the following section to examples of inspection guidelines for common practices and facilities.

Followup Inspection and Long-Term Maintenance Process

Recommended features for a followup inspection and maintenance program are:

- An ordinance designating public authority and public and private responsibilities.
- A tracking system.
- An inspection schedule.
- A maintenance schedule.
- A safety program.
- A citizen response program.
- A detailing of proper waste disposal practices.
- A maintenance contractor education program.

The discussion below elaborates on several of these features, drawing principally on experience in King County, Bellevue, Olympia, and elsewhere in the Puget Sound region of Washington. The examples in the section that follows this discussion present guidance on establishing schedules for common facilities and the specific checks to be made during inspection visits.

Public Versus Private Responsibilities. Whereas inspection is usually a public function, the question of responsibility often arises with respect to the upkeep of privately owned facilities. One model involves establishing a multiyear bonding period, during which the developer has all responsibility. Often after this period and a demonstration of effective operation, the government agency responsible for stormwater management then takes over operation and maintenance. A second model calls for leaving maintenance as a private function (performed by a commercial property owner or homeowners' association), with inspection by the public agency. In this approach, the government assumes the responsibility and assesses costs if the private party does not meet its responsibility. Effective application of this strategy requires that private maintenance contractors competently perform the needed work. The frequent lack of qualified contractors requires government agencies to consider training and certifying them.

Tracking System. King County, Washington, offers a useful model for a tracking system to organize long-term inspections and maintenance. The King County approach uses a computerized information system. Each inspector is assigned an inventory of facilities to inspect and specify maintenance and is given a laptop computer to use in the field. The information system contains an identification number for each facility, its type (e.g., wet pond, infiltration basin), location, any special needs, and data on previous experiences. At the conclusion of each visit, the inspector enters a maintenance needs assessment in the computer database. The computer then generates a maintenance work order.

Safety. Safety is a major consideration because of potentially harmful air quality in below-ground spaces, corroded supports, traffic, falling objects, sharp edges, poisonous plants and insects, and lifting. The safety portion of an inspection and maintenance program should include:

- Testing instruments for harmful atmospheres (explosive, containing hydrogen sulfide, lacking in oxygen); a tester should be capable of checking all potential conditions of concern, and all enclosed spaces should be tested before an inspector enters.
- Ventilating equipment.
- Checking for structural soundness before entering a manhole.
- Traffic warning devices.
- Ladders, safety harnesses, and hard hats.
- Removing poisonous plants and threatening insect nests.
- Adequate personnel.
- Safety training.

Waste Handling. Major maintenance on large facilities should be scheduled when the least runoff is expected. It is often a good idea to use ESC-type installations such as filter fabric fences, sandbags, grassed drainage areas, and revegetation to prevent escape of sediments during maintenance.

Although the vactor truck is the maintenance workhorse, a problem concerns mixing waste that may be relatively clean with very dirty waste. A solution, but an expensive one, is to have "clean" and "dirty" trucks. Another issue concerns disposal of both solids and separated "decant" water picked up by vactor trucks. The best solution for decant water is to discharge it to a special decant station that has sediment and oil separation equipment, before the water is discharged to a sanitary sewer. Few facilities currently operate this way, and most vactor waste is discharged directly to a sanitary sewer. This practice can result in pollutants entering surface waters because of inadequate treatment at the municipal wastewater plant. It can also deliver toxic materials that can upset biological processes at the treatment plant. Guidelines are needed but generally do not exist for disposing of solids. The best programs now send them to a lined municipal landfill, unless they fail a "looks bad and smells bad" test, in which case they are treated as hazardous waste.

Permanent Drainage Practices and Facilities and Their Inspection

Categories of Practices and Facilities

Following is the breakdown of practices used by Reinelt (2), with the number of individual practices in each category:

1. Stormwater devices—three practices
2. Detention facilities—eight practices
3. Infiltration facilities—five practices
4. Biofilters—three practices

The 19 practices represented include some variations on common devices, depending on their intended function, as specified by the Stormwater Management Manual for the Puget Sound Basin (3). For example, detention facilities include "wet ponds," which have a quantity control function, and "water quality wet ponds," which are treatment devices.

The following passages provide inspection checklists for example practices and facilities, generally the most common, in each category. The practices and facilities themselves are described only very briefly in this section. For detailed descriptions, consult a stormwater management manual or textbook. The checklists are divided into checks to make when the practice or facility is first installed and checks to be made on each followup visit to determine the need for maintenance. Many of the points are illustrated in diagrams that accompany the checklists. Also presented for a number of practices are tables of maintenance standards. These tables have been developed over time in the Puget Sound area, and several jurisdictions have contributed to them.

While much of an inspector's work is performed in the field, it is often advisable or even absolutely necessary to do some background work in the office before going out to inspect an installation. This work mainly consists of consulting the design plans to determine the specifications.

Too infrequent inspection and maintenance is one of the main reasons for poor performance by stormwater facilities. The frequency of followup inspections should be determined based on the type of device and the circumstances where it is installed. An inspection and maintenance plan should be developed before an installation goes into service. As a general rule, surface facilities should undergo a drive-by inspection at least monthly and after any rain totaling 0.5 in. or more in 24 hr.

1. Stormwater devices

This group includes devices used for collection and conveyance of stormwater, as well as special-purpose facilities. Within the category are catch basins, pipes and culverts, and oil/water separators. Inspection guidelines are given for oil/water separators as a complete example. Tables of maintenance standards are included for the other types of facilities.

1.1. Oil-Water separators

Figure 9 illustrates the three basic types of oil-water separators. The spill control unit's purpose is to catch small spills; it is not capable of separating dispersed oil. The American Petroleum Institute (API) separator is a baffled tank that can separate "free" (unemulsified) oil but requires a relatively large volume for effectiveness. The coalescing plate (CP) separator can separate free oil in a much smaller volume because of the large surface area provided for oil collection by the corrugated plate pack. The following guidelines generally apply to all types, except as noted.

Installation checks

1. Is the type appropriate for the service?
2. Is the unit sized and installed as specified in the plans?
3. Are adequate removable covers provided for observation and maintenance?
4. Is runoff excluded from roofs and other areas unlikely to contain oil?
5. Is any pump in use placed downstream to prevent mechanical emulsification?
6. Is detergent use avoided upstream to prevent chemical emulsification?
7. For API and CP separators, is a forebay provided sized at 20 ft^2 of surface area per 10,000 ft^2 of drainage area?
8. For API and CP separators, is an afterbay provided for placement of absorbents?
9. For the CP separator, are the plates no more than 3/4 in. apart and at 45 to 60 degrees from horizontal?

Maintenance checks:

1. Is weekly inspection performed by the owner?
2. Are oil and any solids removed frequently enough (at least just before the main runoff period and then after the first major runoff event)?
3. Are absorbents replaced as needed, but at least at the beginning and end of the main runoff season?
4. Is the effluent shutoff valve operational for closure during cleaning?
5. Are waste oil and solids disposed of as specified by regulations?
6. Is any standing water that is removed discharged to the sanitary sewer and then replaced with clean water?

1.2. Pipes and culverts

Refer to Table 2 for a summary of maintenance standards for conveyance facilities.

1.3. Catch basins

Catch basins are routinely placed between the drain inlets in streets and parking lots and the conveyances that transport water away to settle large solids. Refer to Table 3 for a summary of maintenance standards.

2. Detention facilities

Detention facilities include ponds that are designed and operated either to drain within hours after a

Table 2. Maintenance Standards for Pipes and Culverts

Defect	Conditions When Maintenance Needed	Maintenance Results
Sediment and debris	Accumulated sediment that exceeds 20% of the diameter of the pipe.	Pipe cleaned of all sediment and debris.
Vegetation	Vegetation that reduces free movement of water through pipes.	All vegetation removed so water flows freely through pipes.
Damage	Protective coating is damaged; rust is causing more than 50% of deterioration to any part of pipe.	Pipe repaired or replaced.
	Any dent that decreases the end area of pipe by more than 20%.	Pipe repaired or replaced.
Debris barriers	Trash or debris that is plugging more than 20% of the openings in the barrier.	Barrier clear to receive capacity flow.
Damaged/ Missing bars	Bars are bent out of shape more than 3 in.	Bars in place with no bend >3/4 in.
	Bars are missing or entire barrier is missing.	Bars in place according to design.
	Bars are loose and rust is causing 50% deterioration to any part of barrier.	Repair or replace barrier to design standards.

storm (dry ponds), to drain within a day or two (extended-detention dry ponds), or to retain a permanent or semipermanent pool (wet ponds). These ponds can have water quantity control objectives, or water quality control objectives, or both, although dry ponds offer few water quality benefits. Detention facilities also include below-ground concrete vaults and storage pipes, the latter sometimes referred to as tanks. These devices serve primarily quantity control purposes, although if they have relatively long water residence times they can collect some solids. Other facilities sometimes included in this category are parking lot and rooftop storage. Constructed wetlands can be placed in either this group or with biofilters. Inspection guidelines are given for wet ponds as a complete example. A table of maintenance standards is included for vaults and tanks as well.

2.1. Wet ponds

Figure 10 illustrates a typical wet pond. A wet pond has a "dead storage" permanent or semipermanent pool and a "live storage" zone that fills during runoff events and then drains fairly quickly. Its design basis differs depending on its purpose (quantity control or quality control, or both), but the checks made when it is installed and later while it is operating are

Table 3. Maintenance Standards for Catch Basins

Defect	Conditions When Maintenance Needed	Maintenance Results
Trash and debris (including sediment)	Trash or debris of more than 1/2 ft^3 located in front of the catch basin opening or is blocking capacity of basin by >10%.	No trash or debris located immediately in front of catch basin opening.
	Trash or debris in the basin that exceeds 1/3 to 1/2 the depth from the bottom of the basin to the invert of the lowest pipe into or out of the basin.	No trash or debris in catch basin.
	Trash or debris in any inlet or outlet pipe blocking more than 1/3 of the height.	Inlet and outlet pipes free of trash or debris.
	Dead animals or debris that could generate odors that would cause complaints or dangerous gases.	No dead animals or vegetation present.
	Deposits of garbage exceeding 1 ft^3 in volume.	No garbage in catch basin.
Structural damage to frame or top slab	Corner of frame extends more than 3/4 in. past curb face into the street (if applicable).	Frame is even with curb.
	Top slab has holes larger than 2 $in.^2$ or cracks wider than 1/4 in. (intent is to make sure all material runs in to basin).	Top slab is free of holes and cracks.
	Frame not sitting flush on top slab (i.e., separation of >3/4 in. of the frame from top of slab).	Frame is sitting flush on top of slab.
Cracks in basin walls or bottom	Cracks wider than 1/2 in. and longer than 3 ft, any evidence of soil particles entering catch basin through cracks, or structure is unsound.	Basin replaced or repaired to design standards.
	Cracks wider than 1/2 in. and longer than 1 ft at the joint of any inlet/outlet pipe or any evidence of soil particles entering catch basin through crack.	No cracks more than 1/4 in. wide at joint of inlet/outlet pipe.
Settlement/ Misalignment	Basin has settled more than 1 in. or has rotated more than 2 in. out of alignment.	Basin replaced or repaired to design standard.
Fire hazard	Presence of chemicals such as natural gas, oil, and gasoline.	No flammable chemicals present.
Vegetation	Vegetation growing across and blocking >10% of basin.	No vegetation blocking opening to basin.
	Vegetation (or roots) growing in inlet/outlet pipe joints that is >6 in. tall and <6 in. apart.	No vegetation or root growth present.
Pollution	Nonflammable chemicals of >1/2 ft^3 per 3 ft of basin length.	No pollution present other than surface film.

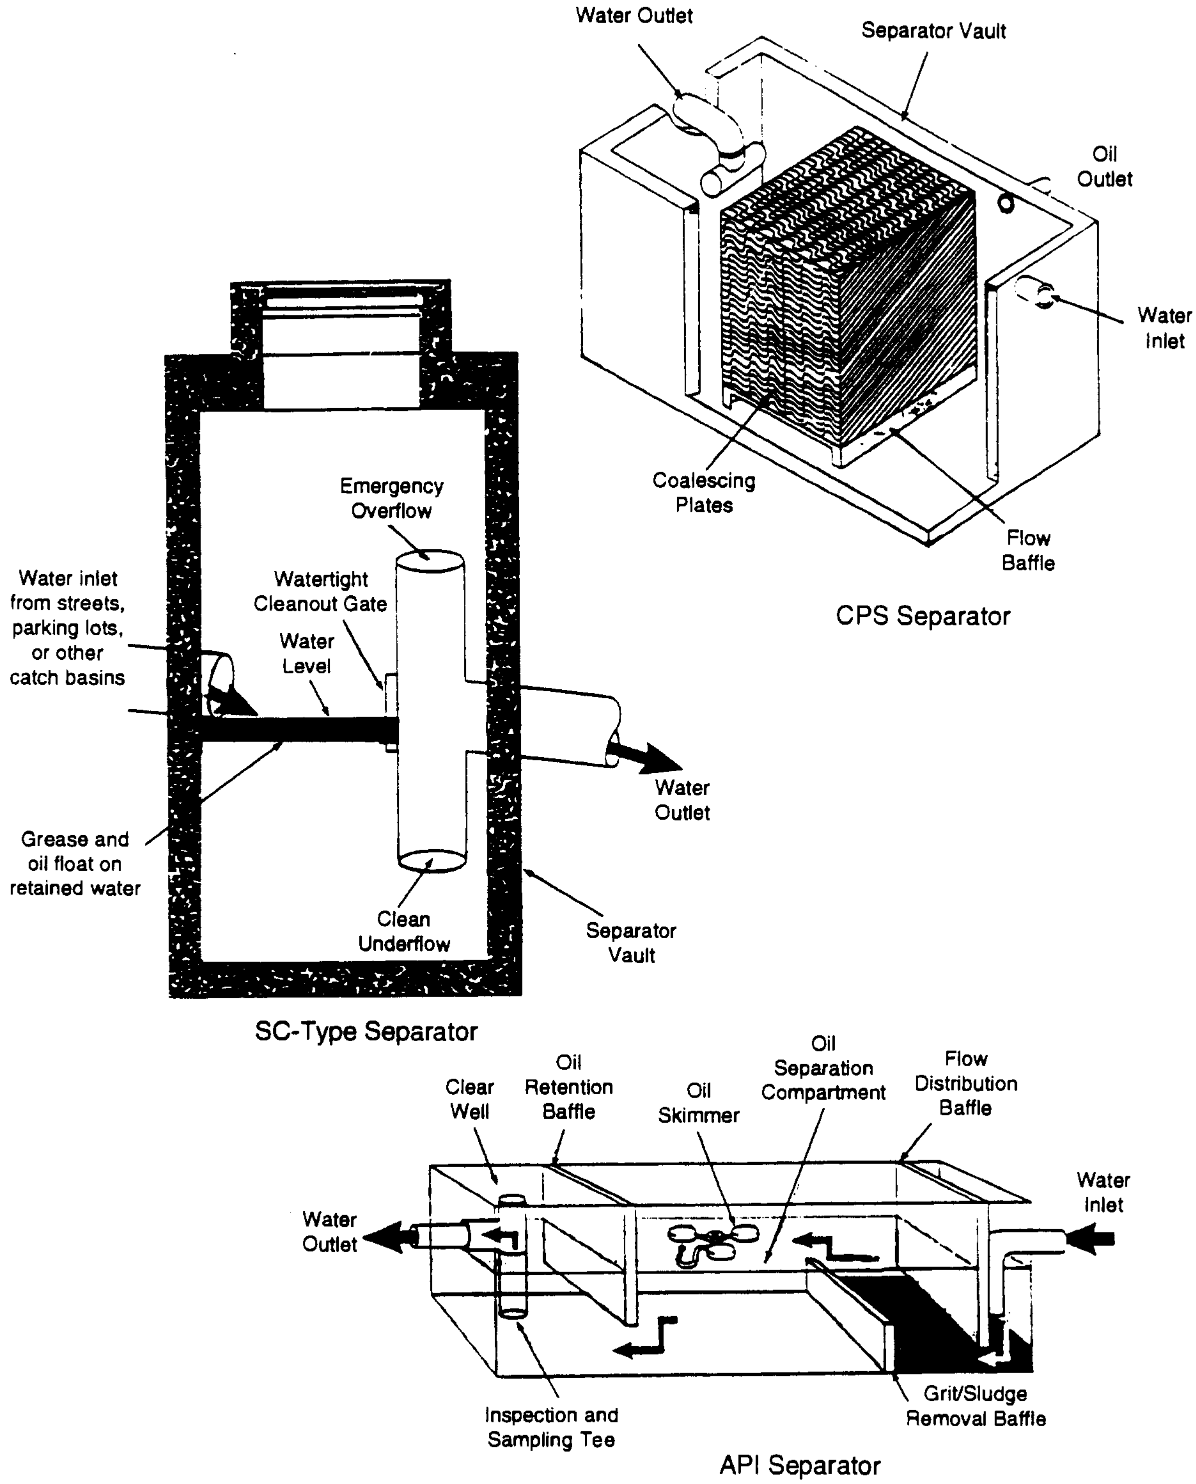

Figure 9. Types of oil/water separators (3).

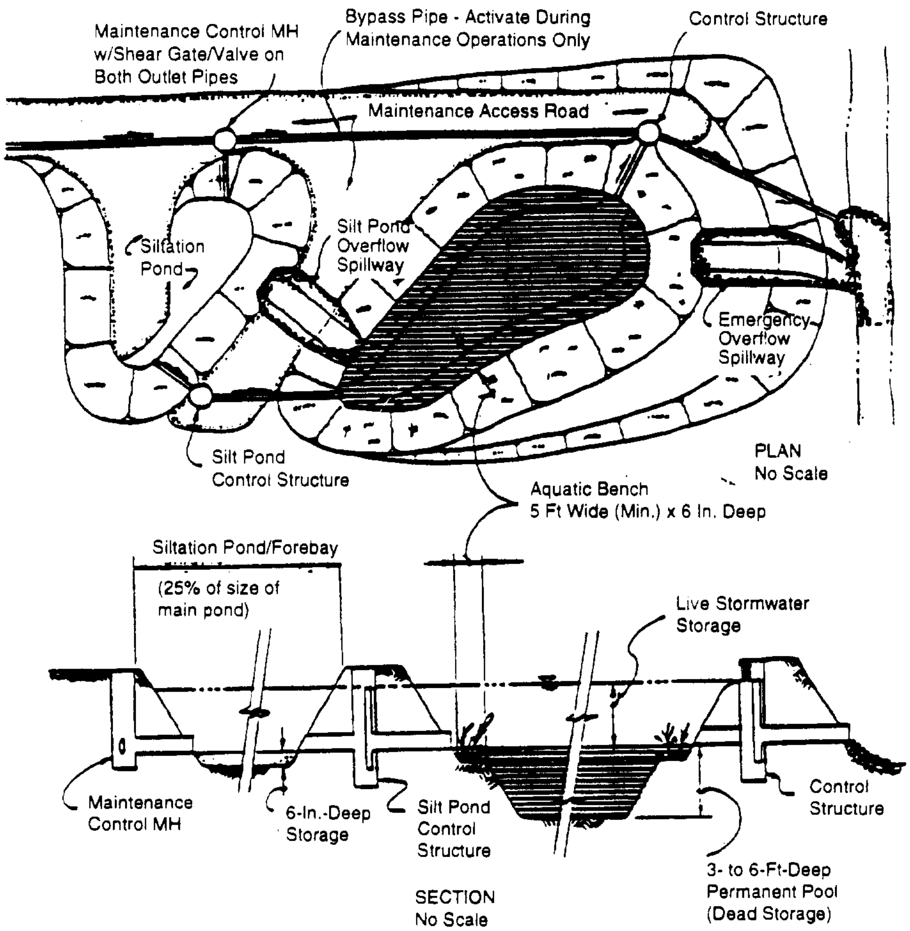

Figure 10. Typical wet pond (3).

generally the same, with the few exceptions noted.

Installation checks:

1. Does construction comply with local requirements for earthwork, concrete, other masonry, reinforcing steel, pipe, water gates, metalwork, and woodwork?
2. Are all dimensions as specified in the approved plan?
3. Are interior side slopes no steeper than 3 horizontal to 1 vertical and exterior side slopes no steeper than 2:1?
4. Is the bottom level?
5. Are the spillways (between cells, if any, and the emergency outlet spillway) sized and reinforced as specified in the approved plan?
6. Is a drain provided that can drain the dead storage zone within 4 hr if necessary?
7. Are inlet and outlet areas stabilized as necessary to avoid erosion?
8. Are safety concerns addressed, for example, with such features as a shallow bench completely around the edge of the pond, barrier plantings to discourage approach by children, and/or fencing (should not be necessary if sloped as recommended and other safety features are provided)?
9. For a water quality pond, is the effective length-to-width ratio at least 3:1 minimum, 5:1 preferably; are the inlet and outlet separated to the greatest width possible?

Maintenance checks:

1. Has a maintenance plan and schedule been developed?
2. Refer to Table 4 for specific checks and maintenance standards (these standards apply to other types of ponds as well).

R0016073

Table 4. Maintenance Standards for Detention Facilities

Defect	Conditions When Maintenance Needed	Maintenance Results
Trash and debris	Any trash or debris that exceeds 1 ft^3/ 1,000 ft^2. There should be no evidence of dumping.	Trash and debris cleared from site.
Poisonous vegetation	Presence of any poisonous vegetation that constitutes a hazard to maintenance personnel or to the public (e.g., poison oak, stinging nettles, devil's club).	No evidence of poisonous vegetation. Coordinate with health department.
Pollution	One gallon or more of oil, gas, or contaminants, or any amount that could 1) cause damage to plant, animal, or aquatic life, 2) constitute a fire hazard, 3) be flushed downstream during storms, or 4) contaminate ground water.	No contaminents present other than surface film. Coordinate with local health department.
Unmowed grass/ ground cover	In residential areas, mowing is needed when the cover exceeds 18 in. in height. Otherwise match facility cover with adjacent ground cover and terrain as long as there is no decrease in facility function.	Grass/ground cover should be mowed to 2 in. Maintain dense cover on slopes and in bottom of dry ponds.
Rodent holes	Any evidence of rodent holes if facility is acting as a dam or berm, or any evidence of water piping through dam or berm via rodent holes.	Rodents destroyed and dam or berm repaired. Coordinate with local health department.
Insects	When insects such as wasps or hornets interfere with maintenance activities.	Insects destroyed or removed from site. Coordinate with people who remove wasps for antivenom protection.
Tree growth	Tree growth does not allow maintenance access or interfere with maintenance activity. If trees are not interfering with access, leave trees alone.	Trees do not hinder maintenance activities.
Erosion of pond side slopes	Eroded damage >2 in. deep where cause of damage is still present or where there is potential for continued erosion.	Slopes stabilized with appropriate erosion control BMPs (e.g., seeding, mats, riprap).
Sediment accumulation in forebay/pond	Accumulated sediment 10% of the design forebay/pond depth, or every 3 yr.	Sediment cleaned out to design depth. Reseed if necessary for erosion control.
Dike settling	Any part of dike that has settled >4 in.	Dike is rebuilt to design elevation.
Rocks missing from overflow spillway	Only one layer of rock above native soil in an area of 5 ft^2 or greater, or any exposed soil.	Rock replaced to design standard.
Inadequate spillway size	Emergency overflow or spillway not large enough to handle flows from large storm events.	Increase capacity of spillway to current design standards.
Missing, broken, or damaged fencing	Any defect in fencing that permits easy entrance to the pond.	Fencing repaired to prevent entrance.
	Damaged fencing including posts out of plumb by >6 in., top rails bent >6 in., missing or loose tension wire, missing or sagging barbed wire, missing or bent extension arms.	Repair fencing and barbed wire to design standards
	Fencing parts that have a rusting or scaling condition that is affecting structural adequacy.	Structurally adequate posts or parts with protective coating.
	Opening in fencing that allows passage of an 8-in. diameter ball.	No opening in fence.
Erosion under fencing	Erosion >4 in. deep and 12 to 18 in. wide, permitting an opening under fence.	No opening under fence >4 in.
Missing or damaged gates	Missing or damaged gate, locking device, or hinges.	Gates, locking devices, and hinges repaired.
	Gate is out of plumb >6 in. and out of design alignment >1 ft.	Gate is aligned and vertical.
	Missing stretcher bar, bands, or ties.	Stretcher bar, bands, and ties in place.
Blocked or damaged access roads	Debris that could damage vehicle tires.	Roadway free of debris.
	Obstructions that reduce clearance above road surface to <14 ft (e.g., tree branches, wires).	Roadway clear overhead to 14 ft.
	Any obstructions restricting access to a 10- to 12-ft width for a distance of >12 ft, or any point restricting access to a width of <10 ft.	Obstructions moved to allow at least a 12-ft access route.
	Any road settlement, potholes, mushy spots, or ruts that prevent or hinder maintenance access.	Road surface repaired and smooth.
	Weeds or brush on or near road surface that hinder access, or are >6 in. tall and <6 in. apart within a 400 ft^2 area.	Weeds and brush on or near road surface cut to 2 in.
	Erosion within 1 ft of the roadway >8 in. wide and 6 in. deep.	Shoulder and road free of erosion.

2.2. Vaults and tanks

Refer to Table 5 for a summary of maintenance standards for closed detention systems.

3. Infiltration facilities

Infiltration facilities discharge most of the entering water to the ground. They include surface basins and trenches, below-ground perforated pipes, roof drain systems, and porous pavements. Inspection guidelines are given for infiltration basins as a complete example. A table of maintenance standards is included for infiltration trenches as well.

3.1. Infiltration basins (see Figure 11 for a typical basin)

Installation checks:

1. Does construction comply with local requirements for earthwork, concrete, other masonry, reinforcing steel, pipe, water gates, metalwork, and woodwork?

2. Are all dimensions as specified in the approved plan?

3. Does the timing of basin construction avoid the entrance of any runoff containing sediment from elsewhere on the site?

4. Is the basin preceded by a pretreatment device (e.g., presettling basin or biofilter) to prevent failure caused by siltation?

5. Is the basin at least 50 ft from any slope greater than 15 percent and at least 100 ft upslope and 20 ft downslope of any building?

6. Is the outlet orifice design consistent with the infiltration capacity on which the facility is based (e.g., to avoid the collection of more water than can infiltrate in 48 hr)?

7. Are the spillways (between cells, if any, and the emergency outlet spillway) sized and reinforced as specified in the approved plan?

8. Are all disturbed areas stabilized to prevent erosion?

9. After final grading, has the bed been deeply tilled to provide a well-aerated, highly porous surface texture?

Maintenance checks:

1. Has a maintenance plan and schedule been developed?

2. Refer to Table 6 for specific checks and maintenance standards.

Table 5. Maintenance Standards for Closed Detention Systems

Defect	Conditions When Maintenance Needed	Maintenance Results
Plugged air vents	Half of the end area of a vent is blocked at any point with debris and sediment.	Vents free of debris and sediment.
Debris and sediment in storage area.	Accumulated sediment depth is >10% of the diameter of the storage area for 1/2 the length of storage vault or any point exceeds 15% of the diameter. Example: 72-in. storage tank would require cleaning when sediment reaches a depth of 7 in. for more than 1/2 the tank length.	All sediment and debris removed from storage area.
Cracks in joints between tank/pipe sections	Any crack allowing material to be transported into the facility.	All joints between tanks or pipe sections are sealed.
Problems with manhole cover	Cover is missing or only partially in place. Any open manhole requires maintenance.	Manhole is closed and secured.
	Locking mechanism cannot be opened by one maintenance person with proper tools. Bolts into frame have <1/2 in. of thread (may not apply to self-locking lids).	Mechanism is repaired or replaced so it functions properly.
	Cover difficult to remove by one maintenance person applying 80 lb of lift.	Cover can be removed and reinstalled by one maintenance person.
Ladder rungs of manhole unsafe	Local government safety officer or maintenance person judges that ladder is unsafe due to missing rungs, misalignment, rust, or cracks.	Ladder meets design standards and allows for maintenance access.
Catch basins	See Table 3.	See Table 3.

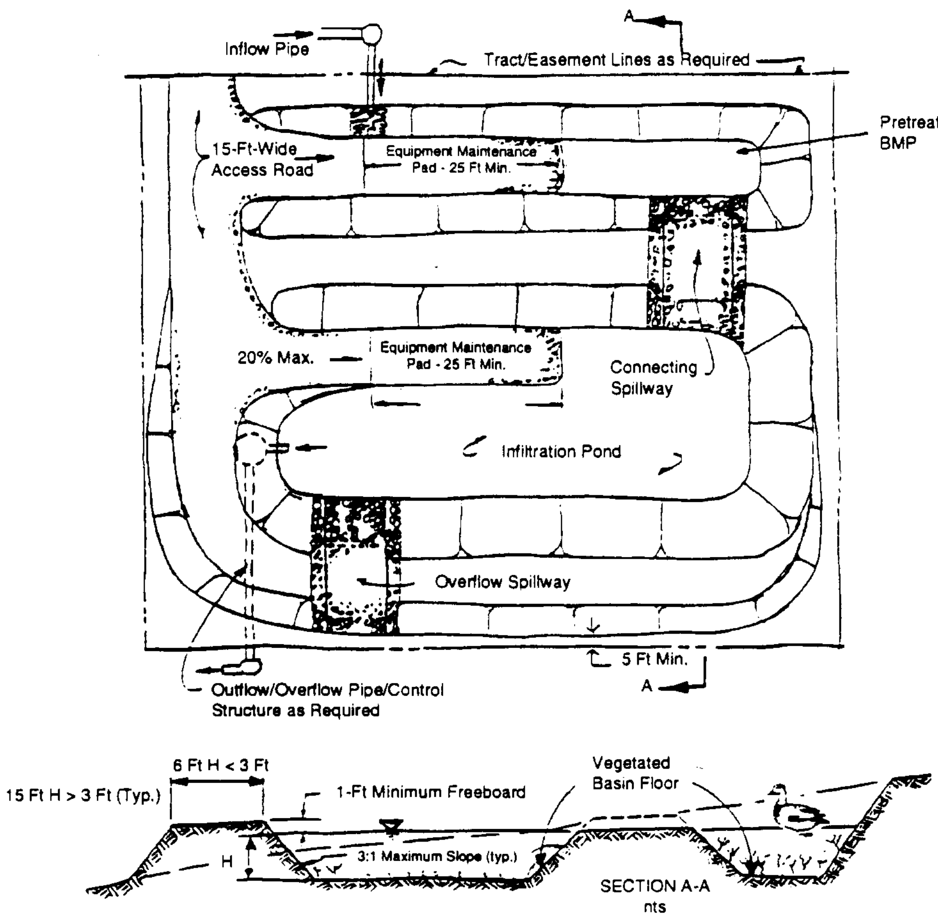

Figure 11. Typical infiltration basin (3).

3. In addition, is tilling necessary to restore infiltration capacity (regular annual tilling is recommended)?

3.2. Infiltration trenches

Refer to Table 7 for a summary of maintenance standards for infiltration trenches.

4. Biofilters

The term "biofilter" applies to vegetated land treatment systems. Biofilters can be in the form of vegetated swales, in which water flows at some measurable depth or in a thin sheet across broad surface areas, sometimes called "filter strips." Constructed wetlands are also sometimes put in this category. The guidelines given below generally pertain to swales and filter strips, although some exceptions are noted. Inspection of constructed wetlands should be conducted with reference to both these guidelines and those given above for wet ponds.

4.1. Biofiltration swales and filter strips

Installation checks:

1. Are the dimensions and plantings as specified in the approved plan?
2. Is the vegetation cover dense and uniform?
3. If the biofilter is a swale, is it parabolic or trapezoidal in shape, with side slopes no steeper than 3 horizontal to 1 vertical?
4. Is the biofilter placed relative to buildings and trees in such a way that no portion will

Table 6. Maintenance Standards for Infiltration Basins

Defect	Condition When Maintenance Needed	Maintenance Results
Sediment buildup in system	Soil texture test indicates facility is not functioning as designed.	Sediment is removed and/or facility is cleaned so that system works according to design. A forebay or presettling basin is installed to reduce sediment transport to facility.
Poor facility drainage (more than 48 hr)	Soil texture test indicates facility is not functioning as designed.	Additional volume added through excavation to provide needed storage. Soil aerated and rototilled to improve drainage.
Sediment trapping area	Sediment and debris fill >10% of sediment mapping facility or sump.	Sediment trapping facility or sump cleaned of accumulated sediment.
No sediment trapping facility	Stormwater enters infiltration area without pretreatment.	Trapping facility (presettling basin, detention pond, biofilter) is added before infiltration facility.

Table 7. Maintenance Standards for Infiltration Trenches

Defect	Condition When Maintenance Needed	Maintenance Results
Sediment and debris buildup in trench	By visual inspection, little or no water flows through the trench during large storms.	Debris blocking infiltration trench is removed. Gravel in infiltration trench is replaced or cleaned.
Observation well	Observation well buried, covered, or inaccessible.	The observation well/cap is accessible to the inspector for opening and inspection.
Water percolates up from trench	Trench water or water with dye percolating to surface.	Gravel and filter fabric in infiltration trench is replaced or cleaned. Trench functions according to design standards.
Filter fabric exposed	Filter fabric is exposed or damaged.	Filter fabric is replaced or repaired and covered with proper backfill material.

be shaded throughout the day and possibly experience poor plant growth?

5. If the longitudinal slope is less than 2 percent or if the water table can reach the root zone of vegetation, is water-resistant vegetation planted to survive a standing water condition or is an underdrain system installed to assist drainage (note: underdrains may not be practical with a large filter strip)?

6. If the longitudinal slope is in the range of 4 to 6 percent, are check dams provided approximately every 50 to 100 ft to reduce velocity (note: check dams may not be practical on a larger filter strip)?

7. If the slope on which a swale is installed exceeds 6 percent, does it traverse the slope in such a way that no reach slopes more than 4 percent, or 6 percent with check dams?

8. Is the lateral slope entirely uniform to avoid any tendency for the flow to channelize?

9. Is flow introduced in such a way that entrance velocity is dissipated quickly, flow is distributed uniformly, and erosion is avoided (e.g., by using a riprap pad or some means of level spreading)?

10. Was construction-phase runoff excluded or was the biofilter reestablished after construction, and are upslope areas stabilized to avoid erosion into the biofilter?

11. Is a bypass in place for flows larger than the flow rate for which the biofilter is designed to provide runoff treatment, or is the facility sufficiently large to pass at least the 100-yr, 24-hr storm without eroding (a bypass is preferred to maintain the treatment function and prevent resuspension of settled material)?

Maintenance checks:

1. Has a maintenance plan and schedule been developed?

2. Refer to Table 8 for specific checks and maintenance standards.

Table 8. Maintenance Standards for Biofilters

Defect	Conditions When Maintenance Needed	Maintenance Results
Trash and debris	Dumping of yard wastes. Accumulation of nondegradable materials.	Remove degradable wastes and compost. Recycle other waste when possible.
Sediment buildup	Accumulation >20% of design depth.	Cleaned or flushed to match design. Vegetation restored as necessary.
Poor vegetation cover	Vegetation sparse and/or weedy. Overgrown with woody vegetation.	Aerate soil and plant. Remove woody growth and replace.
Erosion damage to slopes	Erosion >2 in. deep where cause still present or potential exists for continued erosion.	Find cause and eliminate. Stabilize with appropriate erosion controls (e.g., seeding, mat, mulch).
Conversion to use incompatible with water quality control	Filled, planted appropriately, or blocked.	Discuss with nearby property owners and specify corrections to be made.
Poor drainage	Water stands in swale.	Determine cause. If water table is high, consider rebuilding with liner or underdrain. If slope <1%, use underdrain.

Final National Pollutant Discharge Elimination System Storm Water Multi-Sector General Permit for Industrial Activities

AGENCY: Environmental Protection Agency.

SUMMARY: The following provides notice for a final NPDES general permit, accompanying response to comments, and fact sheets for storm water discharges associated with industrial activity in the following Regions:

Region I—the States of Maine, Massachusetts, and New Hampshire; Federal Indian Reservations located in Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont; and Federal facilities located in Vermont.

Region II—the Commonwealth of Puerto Rico and Federal facilities located in Puerto Rico.

Region III—the District of Columbia and Federal facilities located in Delaware and the District of Columbia.

Region IV—the State of Florida.

Region V—no areas.

Region VI—the States of Louisiana, New Mexico, Oklahoma, and Texas, and Federal Indian Reservations located in Louisiana, New Mexico (except Navajo Reservation lands, which are handled by Region IX, and Ute Mountain Reservation lands, which are handled by Region VIII and are not being covered by this permit), Oklahoma, and Texas.

Region VII—no areas.

Region VIII—no areas.

Region IX—the State of Arizona; the Territories of Johnston Atoll, and Midway and Wake Islands; all Federal Indian Reservations located in Arizona, California, and Nevada; those portions of the Duck Valley, Fort McDermitt, and Goshute Reservations located outside Nevada; those portions of the Navajo Reservation located outside Arizona; and Federal facilities located in Arizona, Johnston Atoll, and Midway and Wake Islands.

Region X—the State of Idaho; Federal Indian Reservations located in Alaska, Idaho (except Duck Valley Reservation lands, which are handled by Region IX), Oregon (except Fort McDermitt Reservation lands, which are handled by Region IX), and Washington: and Federal facilities located in Idaho, and Washington.

The permit covers storm water discharges associated with industrial activity to waters of the United States, including discharges through large and medium municipal separate storm sewer systems, and through other municipal separate storm sewer systems. The permit is intended to cover discharges from the following types of industrial activities: lumber and wood products facilities; paper and allied products manufacturing facilities; chemical and allied products manufacturing facilities; asphalt paving and roofing materials manufacturers and lubricants; stone, clay, glass and concrete products facilities; primary metals facilities; metal mines (ore mining and dressing); coal mines; oil and gas extraction facilities; nonmetallic mines and quarries; hazardous waste treatment, storage or disposal facilities; landfills, land application sites and open dumps; automobile salvage yards; scrap and waste material processing and recycling facilities; steam electric power generating facilities; railroad transportation facilities, local and suburban transit and interurban highway passenger transportation facilities, petroleum bulk oil stations and terminals, motor freight transportation facilities and U.S. Postal Service facilities; water transportation facilities; ship or boat building/repair facilities; airports; wastewater treatment plants; food and kindred products facilities; textile mills, apparel and other fabric manufacturing facilities; furniture and fixture manufacturing facilities; printing and publishing facilities; rubber and miscellaneous plastic product and miscellaneous manufacturing facilities; leather tanning and finishing facilities; facilities that manufacture fabricated metal products, jewelry, silverware, and plated ware; facilities that manufacture transportation equipment, industrial, or commercial machinery; and facilities that manufacture electronic equipment and components, photographic and optical goods. Military installations must comply with the permit and monitoring requirements for all sectors that describe industrial activities that such installations perform. Publication of this final general permit, fact sheets, and response to comments complies with the requirements of 40 Code of Federal Regulations (CFR) 124.10.

The language of the permit is provided as an appendix to the preamble of this notice. Most conditions of the general permit are intended to apply to all permittees, unless stated otherwise. Where conditions vary by State, these differences are indicated in the appendix.

ADDRESSES: Notices of Intent (NOIs) to be covered under this permit and Notices of Termination (NOT) to terminate coverage under this permit must be sent to Storm Water Notice of Intent (4203), 401 M Street, SW., Washington, DC 20460. The complete administrative record is available through the Water Docket MC-4101, Environmental Protection Agency, 401 M Street SW, Washington DC 20460. A reasonable fee may be charged for copying. Each Regional office (see addresses listed in Part VI.G. of this fact sheet) has an index of the complete administrative record.

DATES: This general permit shall be effective on September 29, 1995. Deadlines for submittal of Notices of Intent (NOIs) are provided in Section II.A. of the general permit. Today's general permit also provides additional dates for compliance with the terms of the permits and for submitting monitoring data where required.

FOR FURTHER INFORMATION: For further information on the NPDES storm water general permit, contact the appropriate EPA Regional Office. The name, address and phone number of the EPA Regional Storm Water Coordinators are provided in Part VI.G. of the fact sheet.

Organization of Today's Permit

Today's permit covers storm water discharges from a wide variety of industrial activities. Because the conditions which affect the presence of pollutants in storm water discharges vary among industries, today's permit contains industry-specific sections that describe the storm water pollution prevention plan requirements, the numeric effluent limitation requirements and the monitoring requirements for that industry. These industry-specific sections are contained in Part XI of today's permit and are described in Part VIII of this fact sheet. There are also a number of permit requirements that apply to all industries. These requirements may be found in Parts I through X. They include the general coverage discussion, the Notice of Intent requirements and standard permit conditions. Specifically, Parts I through VII of this fact sheet describe these common requirements. The following is an outline of this fact sheet.

XII. Unfunded Mandates Reform Act

I. Background

In 1972, the Federal Water Pollution Control Act (also referred to as the Clean Water Act (CWA)) was amended to provide that the discharge of any pollutant to waters of the United States from any point source is unlawful, except if the discharge is in compliance with a National Pollutant Discharge Elimination System (NPDES) permit.

For a number of reasons, EPA and authorized NPDES States have failed to issue NPDES permits for the majority of point source discharges of storm water. Recognizing this, Congress added section 402(p) to the CWA in 1987 to establish a comprehensive framework for addressing storm water discharges under the NPDES program. Section 402(p)(4) of the CWA clarifies the requirements for EPA to issue NPDES permits for storm water discharges associated with industrial activity. On November 16, 1990 (55 FR 47990 as amended at 56 FR 12100, Mar. 21, 1991; 56 FR 56554, Nov. 5, 1991; 57 FR 11412, Apr. 2, 1992; 57 FR 60447, Dec. 18, 1992), EPA published final regulations which defined the term "storm water discharge associated with industrial activity." These regulations also set forth NPDES permit application requirements for storm water discharges associated with industrial activity and storm water discharges from certain municipal separate storm sewer systems. The regulations presented three permit application options for storm water discharges associated with industrial activity. The first option was to submit an individual application consisting of Forms 1 and 2F. The second option was to become a participant in a group application. The third option was coverage under a general permit in accordance with the requirements of an issued general permit.

The promulgation of today's general permit is in response to the second of these three options. Group applications were submitted in two parts. Part 1 of the application was due by September 30, 1991, and part 2 of the application was due by October 1, 1992. In part 1 of the application, all participants were identified and information on each facility was included, such as industrial activities, significant materials exposed to storm water, and material management activities. For part 1 of the application, groups also identified sampling subgroups to submit sampling data for part 2. Over 1,200 groups with over 60,000 member facilities submitted part 1 applications. Upon review of the part 1 application, if the EPA determined that the application was an appropriate grouping of facilities with complete information provided on each participant, and a suitable sampling subgroup was proposed, the application was approved.

Part 2 of the application consisted of sampling data from each member of the sampling subgroup identified in part 1 of the application. In drafting today's general permit, EPA reviewed both parts of the applications and formulated the permit language noticed today. NPDES authorized States were provided the data from the group applications. Authorized NPDES States may propose and finalize either individual permits for each facility included in the application located in the State, or general permits, if the State has general permit authority.[1] If the State feels additional information is needed from the applicants, the State may ask each or any of the applicants for more information on their facility and/or discharge.

EPA estimates that about 100,000 facilities nationwide discharge storm water associated with industrial activity (not including oil and gas exploration and production operations) as described under phase I of the storm water program. The large number of facilities addressed by the regulatory definition of "storm water discharge associated with industrial activity" has placed a tremendous administrative burden on EPA and States with authorized NPDES programs to issue and administer permits for these discharges.

To provide a reasonable and rational approach to addressing this permitting task, the Agency has developed a strategy for issuing permits for storm water discharges associated with industrial activity. In developing this strategy, the Agency recognized that the CWA provides flexibility in the manner in which NPDES permits are issued,[2] and has used this flexibility to design workable permitting system. In accordance with these considerations, the permitting strategy (described in more detail in 57 FR 11394) describes four-tier set of priorities for issuing permits for these discharges:

Tier I—Baseline Permitting—One or more general permits will be develope to initially cover the majority of storm water discharges associated with industrial activity.

Tier II—Watershed Permitting—Facilities within watersheds shown to be adversely impacted by storm water discharges associated with industrial activity will be targeted for individual or watershed-specific general permits.

Tier III—Industry-Specific Permitting—Specific industry categori will be targeted for individual or industry-specific general permits.

Tier IV—Facility-Specific Permitting—A variety of factors will be used to target specific facilities for individual permits.

The general permit accompanying th fact sheet will continue Phase 1 permitting activities for storm water discharges associated with industrial activity by providing industry-specific coverage to group applicants in the following areas: the States of Arizona, Florida, Idaho, Louisiana, Maine, Massachusetts, New Hampshire, New Mexico, Oklahoma, and Texas; the District of Columbia; Johnston Atoll, and Midway and Wake Islands; the Commonwealth of Puerto Rico; Federal Indian Reservations in Alaska, Arizona California, Connecticut, Idaho, Louisiana, Maine, Massachusetts, Nevada, New Hampshire, New Mexico Oklahoma, Oregon, Rhode Island, Texas, Utah (only the Navajo and Goshute Reservations), Vermont, and Washington; and Federal facilities located in Arizona, the Commonwealth of Puerto Rico, the District of Columbia Delaware, Idaho, Johnston Atoll, Midway and Wake Islands, Vermont, and Washington.[3] EPA will provide today's permit to the NPDES authorized States and encourages such States to consider this permit for their permittin needs.

II. Types of Discharges Covered

On November 16, 1990 (55 FR 47990 EPA promulgated the regulatory

[1] As of December 1993, 39 of the 40 NPDES authorized State permitting programs had the authority to issue general permits.

[2] The court in *NRDC* v. *Train*, 396 F.Supp. 1393 (D.D.C. 1975) *aff'd*, *NRDC* v. *Costle*, 568 F.2d 1369 (D.C.Cir. 1977), has acknowledged the administrative burden placed on the Agency by requiring permits for a large number of storm water discharges. The courts have recognized EPA's discretion to use certain administrative devices, such as area permits or general permits, to help manage its workload. In addition, the courts have recognized flexibility in the type of permit conditions that can be established, including the use of requirements for best management practices.

[3] In 5 of the 40 States that are authorized to issue NPDES permits for municipal and industrial sources, EPA issues permits for discharges from Federal facilities. EPA also retains authority to issu permits on Federal Indian Reservations. However, this fact sheet only addresses general permits as indicated above. Where EPA is the permit issuing authority for other storm water discharges, either individual permits or a different general permit wi be issued.

definition of "storm water discharge associated with industrial activity" which addresses point source discharges of storm water from eleven major categories of industrial activities. Industrial activities from all of these categories with the exception of construction activities participated in the group application process. The information contained in the group applications indicates that type and amount of pollutants discharged in storm water varies from industrial activity to industrial activity because of the variety of potential pollutant sources present in different industrial activities, as well as the variety of pollution prevention measures commonly practiced by each of the regulated industries. To facilitate the process of developing permit conditions for each of the 1200 group applications submitted, EPA classified groups into 29 industrial sectors where the nature of industrial activity, type of materials handled and material management practices employed were sufficiently similar for the purposes of developing permit conditions. Each of the industrial sectors were represented by one or more groups which participated in the group application process. Table 1 lists each of the industrial activities covered by today's permit, and the corresponding sections of today's fact sheet and permit which discuss the specific requirements for that industry. EPA has further divided some of the 29 sectors into subsectors in order to establish more specific and appropriate permit conditions, including best management practices and monitoring requirements.

Coverage under today's general permit is available to storm water discharges from industrial activities represented by the group application process. However, coverage under this permit is not restricted to participants in the group application process. To limit coverage under this general permit only to those who participated in the Group application process would not be appropriate for administrative, environmental, and national consistency reasons. The administrative burden for EPA to develop separate general permits for non-group members would be excessive, unnecessary, and wasteful of tax dollars. EPA would also need to use the same information in the development of such permits. The permits would be essentially the same. The time spent in this process would leave many facilities unregulated for some number of additional months. This would not address the environmental concerns of the Clean Water Act. Likewise, group members are not precluded from seeking coverage under other available storm water permits such as EPA's "baseline" general permits for Storm Water Discharges Associated with Industrial Activity, (57 FR 41175 and 57 FR 44412). Group members must consider, however, that the deadlines for preparing and implementing the pollution prevention plan required under the baseline permit have already expired for existing facilities. Therefore, group members that seek coverage under the baseline general permit must have a pollution prevention plan developed and implemented prior to NOI submittal.

Unlike the baseline general permits, today's permit does not exclude all storm water discharges subject to effluent limitation guidelines. Four types of storm water discharges subject to effluent limitation guidelines may be covered under today's permit if they are not already subject to an existing or expired NPDES permit. These discharges include contaminated storm water runoff from phosphate fertilizer manufacturing facilities, runoff associated with asphalt paving or roofing emulsion production, runoff from material storage piles at cement manufacturing facilities and coal pile runoff at steam electric generating facilities. The permit does not, however, authorize all storm water discharges subject to effluent guidelines. Storm water discharges subject to effluent guidelines under 40 CFR part 436 or for mine drainage under 40 CFR part 440 are not covered under today's permit nor are discharges subject to effluent guidelines for acid or alkaline mine drainage under 40 CFR part 434.

TABLE 1.—INDUSTRIAL ACTIVITIES COVERED BY TODAY'S GENERAL PERMIT

Industrial activity	Fact sheet section describing discharges covered	Permit section describing discharges covered
Timber Products Facilities	VIII.A	XI.A.
Paper and Allied Products Manufacturing Facilities	VIII.B	XI.B.
Chemical and Allied Products Manufacturing Facilities	VIII.C	XI.C.
Asphalt Paving and Roofing Materials Manufacturers and Lubricant Manufacturers	VIII.D	XI.D.
Glass, Clay, Cement, Concrete, and Gypsum Product Manufacturing Facilities	VIII.E	XI.E.
Primary Metals Facilities	VIII.F	XI.F.
Metal Mining (Ore Mining and Dressing) Facilities	VIII.G	XI.G.
Coal Mines and Coal Mining-Related Facilities	VIII.H	XI.H.
Oil and Gas Extraction Facilities	VIII.I	XI.I.
Mineral Mining and Processing Facilities	VIII.J	XI.J.
Hazardous Waste Treatment, Storage, or Disposal Facilities	VIII.K	XI.K.
Landfills and Land Application Sites	VIII.L	XI.L.

Scrap and Waste Recycling Facilities	VIII.N	XI.N.
Steam Electric Power Generating Facilities, Including Coal Handling Areas	VIII.O	XI.O.
Vehicle Maintenance or Equipment Cleaning Areas at Motor Freight Transportation Facilities, Passenger Transportation Facilities, Petroleum Bulk Oil Stations and Terminals, Rail Transportation Facilities, and the United States Postal Service.	VIII.P	XI.P.
Vehicle Maintenance Areas and/or Equipment Cleaning Operations at Water Transportation Facilities.	VIII.Q	XI.Q.
Ship and Boat Building or Repairing Yards	VIII.R	XI.R.
Vehicle Maintenance Areas, Equipment Cleaning Areas, or Deicing Area located at Air Transportation Facilities.	VIII.S	XI.S.
Treatment Works	VIII.T	XI.T.
Food and Kindred Products Facilities	VIII.U	XI.U.
Textile Mills, Apparel, and Other Fabric Product Manufacturing Facilities	VIII.V	XI.V.
Wood and Metal Furniture and Fixture Manufacturing Facilities	VIII.W	XI.W.

TABLE 1.—INDUSTRIAL ACTIVITIES COVERED BY TODAY'S GENERAL PERMIT—Continued

Industrial activity	Fact sheet section describing discharges covered	Permit section describing discharges covered
Printing and Publishing Facilities	VIII.X	XI.X.
Rubber, Miscellaneous Plastic Products, and Miscellaneous Manufacturing Industries	VIII.Y	XI.Y.
Leather Tanning and Finishing Facilities	VIII.Z	XI.Z.
Fabricated Metal Products Industry	VIII.AA	XI.AA.
Facilities That Manufacture Transportation Equipment, Industrial, or Commercial Machinery.	VIII.AB	XI.AB.
Facilities That Manufacture Electronic and Electrical Equipment and Components, Photographic and Optical Goods.	VIII.AC	XI.AC.

A. Limitations on Coverage

Because of the broad scope of today's permit, most industrial activities currently regulated under the storm water program could be covered by the permit. There are, however, several types of storm water discharges which are not covered under today's permit. Storm water discharges subject to an existing NPDES permit are not covered under today's permit, except facilities which are currently subject to the baseline general permit. EPA believes that in most cases these discharges are more appropriately covered under terms and conditions of their existing permit. These discharges may be covered under today's permit only when the existing permit has expired and only when the expired permit did not contain numeric effluent limitations more stringent than those in today's permit. Owners/operators of facilities currently covered under the baseline general permit who wish to obtain coverage under today's general permit must submit a Notice of Termination (NOT) to terminate coverage under the baseline general permit with a Notice of Intent (NOI) to be covered under today's permit. Storm water discharges that were subject to an NPDES permit that was terminated by the permitting authority are not eligible for coverage under today's permit. Construction activities are not eligible for coverage under this permit. Storm water discharges that were subject to a permit that was terminated as a result of the permittee's request are eligible for coverage under today's permit. Storm water discharges from industrial activities that are not addressed in the appropriate section of Part XI. (see Table 1) of the permit are not eligible for coverage under this permit. These types of industrial activities were not represented in the group application process. Therefore, EPA has no additional information with which to develop permit requirements beyond those developed for the baseline general permit.

(1) Storm Water Discharges Subject to New Source Performance Standards. Section 306 of the Clean Water Act requires EPA to develop performance standards for all new sources described in that section. These standards apply to all facilities which go into operation after the date the standards are promulgated. Section 511(c) of the Clean Water Act requires the Agency to comply with the National Environmental Policy Act prior to issuance of a permit under the authority of Section 402 of the CWA to facilities defined as a new source under Section 306.

Facilities which are subject to the performance standards for new sources as described in this section of the fact sheet must provide EPA with an Environmental Information Document pursuant to 40 CFR 6.101 prior to seeking coverage under this permit. This information shall be used by the Agency to evaluate the facility under the requirements of the National Environmental Policy Act (NEPA) in an Environmental Review. The Agency will make a final decision regarding the direct or indirect impact of the discharge. The Agency will follow all administrative procedures required in this process. The permittee must obtain a copy of the Agency's final finding prior to the submittal of a Notice of Intent to be covered by this general permit. In order to maintain eligibility, the permittee must implement any mitigation required of the facility as a result of the NEPA review process. Failure to implement mitigation measures upon which the Agency's NEPA finding is based is grounds for termination of permit coverage. In this way, EPA has established a procedure which allows for the appropriate review procedures to be completed by this Agency prior to the issuance of a permit under Section 402 of the CWA to an operator of a facility subject to the new source performance standards of Section 306 of the CWA. EPA believes that it has fulfilled its requirements under NEPA for this federal action under Section 40: of the CWA.

(2) Historic Preservation. The Nation: Historic Preservation Act (NHPA) prohibits Federal actions that would affect a property that either is listed on, or is eligible for listing, on the Nationa: Historic Register. EPA therefore cannot issue NPDES permits to discharges that will affect historic properties unless measures will be taken such as under a written agreement between the applicant and the State Historic Preservation Officer (SHPO) that outlines all measures to be undertaken by the applicant to mitigate or prevent adverse effects to the historic property. Therefore, under today's permit a storm water discharge may be covered only if the discharge will not affect a historic property that is listed or is eligible to be listed in the National Historic Register, or the operator has obtained and is in compliance with a written agreement signed by the State Historic Preservation Officer (SHPO) that outlines measures to be taken to mitigate or prevent adverse affects to the historic site.

(3) Endangered Species. The Endangered Species Act (ESA) of 1973 requires Federal Agencies such as EPA to ensure, in consultation with the U.S. Fish and Wildlife Service and the National Marine Fisheries Service (the Services) that any actions authorized, funded, or carried out by the Agency (e.g., EPA issued NPDES permits authorizing discharges to waters of the United States) are not likely to jeopardize the continued existence of any federally-listed endangered or threatened species or adversely modify or destroy critical habitat of such species (see 16 U.S.C. 1536(a)(2), 50 CFR 402 and 40 CFR 122.49(c)). EPA completed a formal consultation with the Services on the action of issuing this permit on April 5, 1995. The terms and conditions of this permit reflect the results of that consultation.

Accordingly, storm water discharges that are likely to adversely affect species identified in Addendum H of the permit are not authorized permit coverage under this storm water multi-sector industrial general permit. Permittees are also not authorized permit coverage if the BMPs they plan to construct and operate as a part of the required storm water pollution prevention plan are likely to adversely affect a species identified in Addendum H.

To be eligible for coverage under the multi-sector storm water permit, applicants are required to review the list of species and their locations which are contained in Addendum H of this permit and which are described in the instructions for completing the application requirements under this permit. If an applicant determines that none of the species identified in the addendum are found in the county in which the facility is located, then there is no likelihood of an adverse affect and they are eligible for permit coverage. Applicants must then certify that their discharges, and the construction of storm water BMPs, are not likely to adversely affect species and will be granted multi-sector storm water permit coverage 48 hours after the date of the postmark on the envelope used to mail in the NOI form.

If species identified in Addendum H are found to be located in the same county as the facility seeking storm water permit coverage, then the applicant next must determine whether the species are in proximity to the storm water discharges at the facility, or any BMPs to be constructed to control storm water runoff. A species is in proximity to a storm water discharge when the species is located in the path or down gradient area through which or over which point source storm water flows from industrial activities to the point of discharge into the receiving water, and once discharged into the receiving water, in the immediate vicinity of, or nearby, the discharge point. A species is also in proximity if a species is located in the area of a site where storm water BMPs are planned to be constructed. If an applicant determines there are no species in proximity to the storm water discharge, or the BMPs to be constructed, then there is no likelihood of adversely affecting the species and the applicant is eligible for permit coverage.

If species are in proximity to the storm water discharges or areas of BMP construction, as long as they have been considered as part of a previous ESA authorization of the applicant's activity, and the environmental baseline established in that authorization is unchanged, the applicant may be covered under the permit. For example, an applicant's activity may have been authorized as part of a section 7 consultation under ESA, covered under a section 10 permit, or have received a clearance letter. The environmentai baseline generally includes the past and present impacts of all federal, state and private actions that were contemporaneous to an ESA authorization. Therefore, if a permit applicant has received previous authorization and nothing has changed or been added to the environmental baseline established in the previous authorization, then coverage under this permit will be provided.

In the absence of such previous authorization, if species identified in Addendum H are in proximity to the discharges, or the construction areas for the BMPs, then the applicant must determine whether there is any likely adverse effect upon the species. This is done by the applicant conducting a further examination or investigation, or an alternative procedure, described in the instructions in Addendum H of the permit. If the applicant determines there is no likely adverse effect upon the species, then the applicant is eligible for permit coverage. If the applicant determines that there likely is, or will likely be an adverse effect, then the applicant is not eligible for multi-sector storm water permit coverage.

All dischargers applying for coverage under this permit must provide in the application information on the Notice of Intent form: (1) a determination as to whether there are any species identified in Addendum H in proximity to the storm water discharges and BMPs construction areas, and (2) a certification that their storm water discharges and the construction of BMPs to control storm water are not likely to adversely affect species identified in Addendum H, or are otherwise eligible for coverage due to a previous authorization under the ESA. Coverage is contingent upon the applicant's providing truthful information concerning certification and abiding by any conditions imposed by the permit.

Dischargers who are not able to determine that there will be no likely adverse affect to species or habitats and cannot sign the certification to gain coverage under this multi-sector storm water general permit, must apply to EPA for an individual NPDES storm water permit. As appropriate, EPA will conduct ESA § 7 consultation when issuing such individual permits.

Regardless of the above conditions, EPA may require that a permittee apply for an individual NPDES permit on the basis of possible adverse effects on species or critical habitats. Where there are concerns that coverage for a particular discharger is not sufficiently protective of listed species, the Services (as well as any other interested parties) may petition EPA to require that the discharger obtain an individual NPDES permit and conduct an individual section 7 consultation as appropriate.

In addition, the Assistant Administrator for Fisheries for the National Oceanic and Atmospheric Administration, or his/her authorized representative, or the U.S. Fisheries and Wildlife Service (as well as any other interested parties) may petition EPA to require that a permittee obtain an individual NPDES permit. The permittee is also required to make the storm water pollution prevention plan, annual site compliance inspection report, or other information available upon request to the Assistant Administrator for Fisheries for the National Oceanic and Atmospheric Administration, or his/her authorized representative, or the U.S. Fisheries and Wildlife Service Regional Director, or his/her authorized representative.

These mechanisms allow for the broadest and most efficient coverage for the permittee while still providing for the most efficient protection of endangered species. It significantly reduces the number of dischargers that must be considered individually and therefore allows the Agency and the Services to focus their resources on those discharges that are indeed likely to adversely affect water-dependent listed species. Straightforward mechanisms such as these allow applicants with expedient permit coverage, and eliminates "permit limbo" for the greatest number of permitted discharges. At the same time it is more protective of endangered species because it allows both agencies to focus on the real problems, and thus, provide endangered species protection in a more expeditious manner.

(4) Storm Water Discharges Associated with Inactive Mines, Landfills, Oil and Gas Operations that Are Located on Federal Lands. The permit does not cover storm water discharges associated with industrial activity from inactive mines, inactive landfills, and inactive oil and gas operations that are located on Federal lands, unless an operator of the industrial activity can be identified. These discharges are not eligible for coverage under this permit because they would more appropriately be covered by the permit currently under development by EPA intended specifically to cover these types of discharges.

III. Pollutants in Storm Water Discharges Associated with Industrial Activities in General

The volume and quality of storm water discharges associated with industrial activity will depend on a number of factors, including the industrial activities occurring at the facility, the nature of precipitation, and the degree of surface imperviousness. A discussion of these factors is provided in the proposed general permit (see FR 58 61146 Nov. 19, 1993).

IV. Summary of Options for Controlling Pollutants

Pollutants in storm water discharges from industrial plants may be reduced using the following methods: eliminating pollution sources, implementing Best Management Practices to prevent pollution, using traditional storm water management practices, and providing end-of-pipe treatment. Each of these is discussed in the proposed general permit (see 58 FR 61146, Nov. 19, 1993).

V. The Federal/Municipal Partnership: The Role of Municipal Operators of Large and Medium Municipal Separate Storm Sewer Systems

A key issue in developing a workable regulatory program for controlling pollutants in storm water discharges associated with industrial activity is the proper use and coordination of limited regulatory resources. This is especially important when addressing the appropriate role of municipal operators of large and medium municipal separate storm sewer systems in the control of pollutants in storm water associated with industrial activity which discharge through municipal separate storm sewer systems. The proposed general permit discussed several key policy factors (see 58 FR 61146).

VI. Summary of Common Permit Conditions

The following section describes the permit conditions common to discharges from all the industrial activities covered by today's permit. These conditions were proposed on November 19, 1993 (58 FR 61146), and reflect the baseline permit requirements established for most regulated industries in EPA's General Permits for Storm Water Discharges Associated with Industrial Activity [57 FR 41344–41356 September 9, 1992, and 57 FR 44438–44470 September 25, 1992]. Permit requirements which vary from industry to industry are discussed in Part VIII of this fact sheet.

A. Notification Requirements

General permits for storm water discharges associated with industrial activity require the submittal of an NOI prior to the authorization of such discharges (see 40 CFR 122.28(b)(2)(i), April 2, 1992 [57 FR 11394]). Consistent with these regulatory requirements, today's general permit establishes NOI requirements that operate in addition to the part 1 and part 2 group application requirements. To be covered under this permit, facilities, including members of an approved group, must submit an NOI and other required information within 90 days of the effective date of this permit. The NOI form is found in Addendum B.

1. Contents of NOIs

a. The operator's name, address, telephone number, and status as Federal, State, private, public, or other entity.

b. Street address of the facility for which the notification is submitted. Where a street address for the site is not available, the location can be described in terms of the latitude and longitude of the facility to the nearest 15 seconds, or the quarter, section, township, and range (to the nearest quarter section) of the approximate center of the site.

c. An indication of whether the facility is located on Federal Indian Reservations.

d. Up to four 4-digit Standard Industrial Classification (SIC) codes that best represent the principal products or activities provided by the facility. For hazardous waste treatment, storage, or disposal facilities, land disposal facilities that receive or have received any industrial waste, steam electric power generating facilities, or treatment works treating domestic sewage, a 2-character code must be provided.

e. The permit number of any NPDES permit for any discharge (including non-storm water discharges) from the site that is currently authorized by an NPDES permit.

f. The name of the receiving water(s), or if the discharge is through a municipal separate storm sewer, the name of the municipal operator of the storm sewer and the receiving water(s) for the discharge through the municipal separate storm sewer.

g. The analytical monitoring status of the facility (monitoring or not).

h. For a co-permittee, if a storm water general permit number has been issued, it should be included.

i. A certification that the operator of the facility has read and understands the eligibility requirements for the permit and that the operator believes the facility to be in compliance with those requirements.

j. Identify type of permit requested (either baseline general, multi-sector, construction); longitude and latitude; indication of presence of endangered species; indication of historic preservation agreement; signed certification stating compliance with the National Historic Preservation Act, Endangered Species Act, and the new source performance standard requirements.

k. For any facility that begins to discharge storm water associated with industrial activity after [insert date 270 days after permit finalization], a certification that a storm water pollution prevention plan has been prepared for the facility in accordance with Part IV of this permit. (A copy of the plan should not be included with the NOI submission.)

An NOI form is provided in Addendum B. The NOI must be signed in accordance with the signatory requirements of 40 CFR 122.22. A complete description of these signatory requirements is provided in the instructions accompanying the NOI. Completed NOI forms must be submitted to the Storm Water Notice of Intent (4203), 401 M Street SW., Washington, DC 20460.

2. Deadlines

Except for the special circumstances discussed below, dischargers who intend to obtain coverage under this permit for a storm water discharge from an industrial activity that is in existence prior to the date 90 days after permit issuance must submit an NOI on or before the date 90 days after permit issuance, and facilities that begin industrial activities after the date 90 days after permit issuance are required to submit an NOI at least 2 days prior to the commencement of the new industrial activity.

A discharger is not precluded from submitting an NOI at a later date. However, in such instances, EPA may bring appropriate enforcement actions.

The storm water regulations (40 CFR 122.27) require that facilities that discharge storm water associated with an industrial activity submit an application for permit coverage on or before October 1, 1992, except industrial activities owned or operated by a medium municipality, which had until May 17, 1993. Today's permit does not extend that application deadline. EPA intends that most of the facilities that will seek coverage under the final version of today's permit are: members of groups with approved applications; facilities that submitted a Notice of

Intent to be covered by EPA's baseline general permit and now wish to switch to coverage under today's permit; or have submitted a complete individual application but have not yet received an individual permit.

EPA may deny coverage under this permit and require submittal of an individual NPDES permit application based on a review of the completeness and/or content of the NOI or other information (e.g., Endangered Species Act compliance, National Historic Preservation Act Compliance, water quality information, compliance history, history of spills, etc.). Where EPA requires a discharger authorized under this general permit to apply for an individual NPDES permit (or an alternative general permit), EPA will notify the discharger in writing that a permit application (or different NOI) is required by an established deadline. Coverage under this industry general permit will automatically terminate if the discharger fails to submit the required permit application in a timely manner. Where the discharger does submit a requested permit application, coverage under this general permit will automatically terminate on the effective date of the issuance or denial of the individual NPDES permit or the alternative general permit as it applies to the individual permittee. Compliance deadlines are discussed in Part VI.H. of this fact sheet.

Municipal Separate Storm Sewer System Operator Notification

Operators of storm water discharges associated with industrial activity that discharge through a large or medium municipal separate storm sewer system or a municipal system designated by the Director,[4] must notify the municipal operator of the system receiving the discharge and submit a copy of their NOI to the municipal operator.

4. Notice of Termination

Where a discharger is able to eliminate the storm water discharges associated with industrial activity from a facility, the discharger may submit a Notice of Termination (NOT) form (or photocopy thereof) provided by the Director.

A copy of the NOT and instructions for completing the NOT are included in Addendum C. The NOT form requires the following information:

a. Name, mailing address, and location of the facility for which the notification is submitted. Where a street address for the site is not available, the location of the approximate center of the site must be described in terms of the latitude and longitude to the nearest 15 seconds, or the section, township and range to the nearest quarter;

b. The name, address and telephone number of the operator addressed by the Notice of Termination;

c. The NPDES permit number for the storm water discharge associated with industrial activity identified by the NOT;

d. An indication of whether the storm water discharges associated with industrial activity have been eliminated or the operator of the discharges has changed; and

e. The following certification:

I certify under penalty of law that all storm water discharges associated with industrial activity from the identified facility that are authorized by an NPDES general permit have been eliminated or that I am no longer the operator of the industrial activity. I understand that by submitting this Notice of Termination I am no longer authorized to discharge storm water associated with industrial activity under this general permit, and that discharging pollutants in storm water associated with industrial activity to waters of the United States is unlawful under the Clean Water Act where the discharge is not authorized by an NPDES permit. I also understand that the submittal of this notice of termination does not release an operator from liability for any violations of this permit or the Clean Water Act.

NOTs are to be sent to the Storm Water Notice of Termination (4203), 401 M Street, SW., Washington, DC 20460.

The NOT must be signed in accordance with the signatory requirements of 40 CFR 122.22. A complete description of these signatory requirements is provided in the instructions accompanying the NOT.

B. Special Conditions

The conditions of this permit have been designed to comply with the technology-based standards of the CWA (BAT/BCT). Based on a consideration of the appropriate factors for BAT and BCT requirements, and a consideration of the factors and options discussed in this fact sheet for controlling pollutants in storm water discharges associated with industrial activity, the general permit lists a set of tailored requirements for developing and implementing storm water pollution prevention plans, and for selected discharges, effluent limitations.[5]

Part VIII. of this fact sheet summarizes the options for controlling pollutants in storm water discharges associated with industrial activity. The permit includes numeric effluent limitations for coal pile runoff, contaminated runoff from fertilizer manufacturing facilities, runoff from asphalt emulsion manufacturing facilities, and material storage pile runoff located at cement manufacturing facilities or cement kilns.

For other discharges covered by the permit, the permit conditions reflect EPA's decision to identify a number of best management practices and traditional storm water management practices which prevent pollution in storm water discharges as the BAT/BCT level of control for the majority of storm water discharges covered by this permit. The permit conditions applicable to these discharges are not numeric effluent limitations, but rather are flexible requirements for developing and implementing site specific plans to minimize and control pollutants in storm water discharges associated with industrial activity. This approach is consistent with the approach used in the baseline general permits finalized on September 9, 1992 (57 FR 41236) and September 25, 1992 (57 FR 44438). In addition, today's general permit reflects information received through the group application process.

EPA is authorized under 40 CFR 122.44(k)(2) to impose BMPs in lieu of numeric effluent limitations in NPDES permits when the Agency finds numeric effluent limitations to be infeasible. EPA may also impose BMPs which are "reasonably necessary * * * to carry out the purposes of the Act" under 40 CFR 122.44(k)(3). Both of these standards for imposing BMPs were recognized in *NRDC* v. *Costle*, 568 F.2d 1369, 1380 (D.C. Cir. 1977). The conditions in the permit are issued under the authority of both of these regulatory provisions. The pollution prevention or BMP requirements in this permit operate as limitations on effluent discharges that reflect the application of BAT/BCT. This is because the BMPs identified require the use of source

[4] The terms large and medium municipal separate storm sewer systems (systems serving a population of 100,000 or more) are defined at 40 CFR 122.26(b)(4) and (7). Some of the cities and counties in which these systems are found are listed in Appendices F, G, H, and I to 40 CFR Part 122. Other municipal systems have been designated by EPA on a case-by-case basis or have brought into the program based upon the 1990 Census.

[5] Part I.C.2 of the general permit provides that facilities with storm water discharges associated with industrial activity which, based on an evaluation of site specific conditions, believe that the appropriate conditions of this permit do not adequately represent BAT and BCT requirements for the facility may submit to the Director an individual application (Form 1 and Form 2F). A detailed explanation of the reasons why the conditions of the available general permits do not adequately represent BAT and BCT requirements for the facility as well as any supporting documentation must be included.

control technologies which, in the context of this general permit, are the best available of the technologies economically achievable (or the equivalent BCT finding). See *NRDC* v. *EPA*, 822 F.2d 104, 122–23 (D.C. Cir. 1987) (EPA has substantial discretion to impose nonquantitative permit requirements pursuant to Section 402(a)(1)).

1. Prohibition of Non-storm Water Discharges

Today's general permit does not authorize non-storm water discharges that are mixed with storm water except as provided below. The only non-storm water discharges that are intended to be authorized under today's permit include discharges from fire fighting activities; fire hydrant flushings; potable water sources, including waterline flushings; irrigation drainage; lawn watering; routine external building washdown without detergents; pavement washwaters where spills or leaks of toxic or hazardous materials have not occurred (unless all spilled material has been removed) and where detergents are not used; air conditioning condensate; compressor condensate; springs; uncontaminated ground water; and foundation or footing drains where flows are not contaminated with process materials such as solvents that are combined with storm water discharges associated with industrial activity.

To be authorized under the general permit, these sources of non-storm water (except flows from fire fighting activities) must be identified in the storm water pollution prevention plan prepared for the facility. (Plans and other plan requirements are discussed in more detail below). Where such discharges occur, the plan must also identify and ensure the implementation of appropriate pollution prevention measures for the non-storm water component(s) of the discharge.

Today's permit does not require pollution prevention measures to be identified and implemented for non-storm water flows from fire-fighting activities because these flows will generally be unplanned emergency situations where it is necessary to take immediate action to protect the public.

The prohibition of unpermitted non-storm water discharges in this permit ensures that non-storm water discharges (except for those classes of non-storm water discharges that are conditionally authorized in Part III.A.2.b.) are not inadvertently authorized by this permit. Where a storm water discharge is mixed with non-storm water that is not authorized by today's general permit or another NPDES permit, the discharger should submit the appropriate application forms (Forms 1, 2C, and/or 2E) to gain permit coverage of the non-storm water portion of the discharge.

2. Releases of Reportable Quantities of Hazardous Substances and Oil

a. This general permit provides that the discharge of hazardous substances or oil from a facility must be eliminated or minimized in accordance with the storm water pollution plan developed for the facility. Where a permitted storm water discharge contains a hazardous substance or oil in an amount equal to or in excess of a reporting quantity established under 40 CFR Part 117, or 40 CFR Part 302 during a 24-hour period, the following actions must be taken:

(1) Any person in charge of the facility that discharges hazardous substances or oil is required to notify the National Response Center (NRC) (800–424–8802; in the Washington, DC, metropolitan area, 202–426–2675) in accordance with the requirements of 40 CFR Part 117, and 40 CFR Part 302 as soon as they have knowledge of the discharge.

(2) The storm water pollution prevention plan for the facility must be modified within 14 calendar days of knowledge of the release to provide a description of the release, an account of the circumstances leading to the release, and the date of the release. In addition, the plan must be reviewed to identify measures to prevent the reoccurrence of such releases and to respond to such releases, and it must be modified where appropriate.

(3) The permittee must also submit to EPA within 14 calendar days of knowledge of the release a written description of the release (including the type and estimate of the amount of material released), the date that such release occurred, the circumstances leading to the release, and steps to be taken to modify the pollution prevention plan for the facility.

b. Anticipated discharges containing a hazardous substance in an amount equal to or in excess of reporting quantities are those caused by events occurring within the scope of the relevant operating system. Facilities that have more than 1 anticipated discharge per year containing a hazardous substance in an amount equal to or in excess of a reportable quantity are required to:

(1) Submit notifications of the first release that occurs during a calendar year (or for the first year of this permit, after submittal of an NOI); and

(2) Provide a written description in the storm water pollution prevention plan of the dates on which such releases occurred, the type and estimate of the amount of material released, and the circumstances leading to the releases. In addition, the pollution prevention plan must address measures to minimize such releases.

c. Where a discharge of a hazardous substance or oil in excess of reporting quantities is caused by a non-storm water discharge (e.g., a spill of oil into a separate storm sewer), that discharge is not authorized by this permit and the discharger must report the discharge as required under 40 CFR Part 110, 40 CFR Part 117, or 40 CFR Part 302. In the event of a spill, the requirements of Section 311 of the CWA and other applicable provisions of Sections 301 and 402 of the CWA continue to apply. This approach is consistent with the requirements for reporting releases of hazardous substances and oil that make a clear distinction between hazardous substances typically found in storm water discharges and those associated with spills that are not considered part of a normal storm water discharge (see 40 CFR 117.12(d)(2)(i)).

3. Co-located Industrial Facilities

Today's general permit addresses storm water discharges from industrial activities co-located at an industrial facility described in the coverage section of the permit. Co-located industrial activities occur when activities being conducted onsite meet more than one of the descriptions in the coverage sections of Part XI. of this permit (e.g., a landfill at a wood treatment facility or a vehicle maintenance garage at an asphalt batching plant). Co-located industrial activities are authorized under today's general permit provided that the industrial facility complies with the pollution prevention plan and monitoring requirements for each co-located activity.

Authorizing co-located discharges allows industrial facilities to develop pollution prevention plans that fully address all industrial activities at the site. For example, if a wood treatment facility has a landfill, the pollution prevention plan requirements for the wood treatment facility will differ greatly from those needed for a landfill. Therefore, by authorizing co-located industrial activities, the wood treatment facility will develop a pollution prevention plan to meet the requirements addressing the storm water discharges from the wood treatment facility and the landfill. The facility is also subject to applicable monitoring requirements for each type of industrial activity as described in the applicable sections of the permit. By monitoring the discharges from the different industrial activities, the facility can better determine the effectiveness of the pollution prevention plan requirements for controlling storm water discharges from all activities.

C. Common Pollution Prevention Plan Requirements

All facilities intended to be covered by today's general permit for storm water discharges associated with industrial activity must prepare and implement a storm water pollution prevention plan. The storm water permit addresses pollution prevention plan requirements for a number of categories of industries. The following is a discussion of the common permit requirements for all industries; special requirements for storm water discharges associated with industrial activity through large and medium municipal separate storm sewer systems; special requirements for facilities subject to EPCRA Section 313 reporting requirements; and special requirements for facilities with outdoor salt storage piles. These are the permit requirements which apply to discharges associated with any of the industrial activities covered by today's permit. These common requirements may be amended or further clarified in the industry-specific pollution prevention plan requirements. Table 2 indicates the location of the industry-specific pollution prevention plans. These industry-specific requirements are additive for facilities where co-located industrial activities occur. For example, if a facility has both a sand and gravel mining operation and a ready mix concrete manufacturing operation, then that facility is subject to the pollution prevention plan requirements in both Part XI.E.3. and Part XI.J.3. of the permit.

TABLE 2.—STORM WATER POLLUTION PREVENTION PLAN REQUIREMENTS

Industrial activity	Fact sheet section describing PPP requirements	Permit section describing PPP requirements
Timber Products Facilities	VIII.A.7	XI.A.3.
Paper and Allied Products Manufacturing Facilities	VIII.B.5	XI.B.3.
Chemical and Allied Products Manufacturing Facilities	VIII.C.6	XI.C.4.
Asphalt Paving and Roofing Materials Manufacturers and Lubricant Manufacturers	VIII.D.4	XI.D.3.
Glass, Clay, Cement, Concrete, and Gypsum Product Manufacturing Facilities	VIII.E.5	XI.E.3.
Primary Metals Facilities	VIII.F.6	XI.F.3.
Metal Mining (Ore Mining and Dressing) Facilities	VIII.G.5	XI.G.3.
Coal Mines and Coal Mining-Related Facilities	VIII.H.4	XI.H.3.
Oil and Gas Extraction Facilities	VIII.I.5	XI.I.3.
Mineral Mining and Processing Facilities	VIII.J.4	XI.J.3.
Hazardous Waste Treatment, Storage, or Disposal Facilities	VIII.K.5	XI.K.3.
Landfills and Land Application Sites	VIII.L.5	XI.L.3.
Automobile Salvage Yards	VIII.M.5	XI.M.2.
Scrap and Waste Recycling Facilities	VIII.N.5	XI.N.3.
Steam Electric Power Generating Facilities, Including Coal Handling Areas	VIII.O.5	XI.O.3.
Vehicle Maintenance or Equipment Cleaning Areas at Motor Freight Transportation Facilities, Passenger Transportation Facilities, Petroleum Bulk Oil Stations and Terminals, Rail Transportation Facilities, and the United States Postal Service Transportation Facilities.	VIII.P.5	XI.P.3.
Vehicle Maintenance Areas and/or Equipment Cleaning Operations at Water Transportation Facilities.	VIII.Q.5	XI.Q.3.
Ship and Boat Building or Repairing Yards	VIII.R.6	XI.R.3.
Vehicle Maintenance Areas, Equipment Cleaning Areas, or Deicing Areas Located at Air Transportation Facilities.	VIII.S.4	XI.S.3.
Treatment Works	VIII.T.5	XI.T.3.
Food and Kindred Products Facilities	VIII.U.4	XI.U.3.
Textile Mills, Apparel, and Other Fabric Product Manufacturing Facilities	VIII.V.5	XI.V.3.
Wood and Metal Furniture and Fixture Manufacturing Facilities	VIII.W.4	XI.W.3.
Printing and Publishing Facilities	VIII.X.5	XI.X.3.
Rubber, Miscellaneous Plastic Products, and Miscellaneous Manufacturing Industries	VIII.Y.4	XI.Y.3.
Leather Tanning and Finishing Facilities	VIII.Z.5	XI.Z.3.
Fabricated Metal Products Industry	VIII.AA.3	XI.AA.3.
Facilities That Manufacture Transportation Equipment, Industrial, or Commercial Machinery.	VIII.AB.5	XI.AB.3.
Facilities That Manufacture Electronic and Electrical Equipment and Components, Photographic and Optical Goods.	VIII.AC.5	XI.AC.3.

The pollution prevention approach in today's general permit focuses on two major objectives: (1) to identify sources of pollution potentially affecting the quality of storm water discharges associated with industrial activity from the facility; and (2) to describe and ensure implementation of practices to minimize and control pollutants in storm water discharges associated with industrial activity from the facility and to ensure compliance with the terms and conditions of this permit.

The storm water pollution prevention plan requirements in the general permit are intended to facilitate a process whereby the operator of the industrial facility thoroughly evaluates potential pollution sources at the site and selects and implements appropriate measures designed to prevent or control the discharge of pollutants in storm water runoff. The process involves the following four steps: (1) Formation of a team of qualified plant personnel who will be responsible for preparing the plan and assisting the plant manager in its implementation; (2) assessment of potential storm water pollution sources; (3) selection and implementation of appropriate management practices and controls; and (4) periodic evaluation of the effectiveness of the plan to prevent storm water contamination and comply with the terms and conditions of this permit. The authorization to include best management practices in the permit to control or abate the discharge of pollutants is derived from 40 CFR 144.45(k).

EPA believes the pollution prevention approach is the most environmentally sound and cost-effective way to control the discharge of pollutants in storm water runoff from industrial facilities. This position is supported by the results of a comprehensive technical survey EPA completed in 1979.[6] The survey found that two classes of management practices are generally employed at industries to control the nonroutine discharge of pollutants from sources such as storm water runoff, drainage from raw material storage and waste disposal areas, and discharges from places where spills or leaks have occurred. The first class of management practices includes those that are low in cost, applicable to a broad class of industries and substances, and widely considered essential to a good pollution control program. Some examples of practices in this class are good housekeeping, employee training, and spill response and prevention procedures. The second class includes management practices that provide a second line of defense against the release of pollutants. This class addresses containment, mitigation, and cleanup. Since publication of the 1979 survey, EPA has imposed management practices and controls in NPDES permits on a case-by-case basis. The Agency also has continued to review the appropriateness and effectiveness of such practices,[7] as well as the techniques used to prevent and contain oil spills.[8] Experience with these practices and controls has shown that they can be used in permits to reduce pollutants in storm water discharges in a cost-effective manner. In keeping with both the present and previous administration's objective to attain environmental goals through pollution prevention, pollution prevention has been and continues to be the cornerstone of the NPDES Permitting program for storm water. EPA has developed guidance entitled "Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices," September 1992, to assist permittees in developing and implementing pollution prevention measures.

1. Pollution Prevention Team

As a first step in the process of developing and implementing a storm water pollution prevention plan, permittees are required to identify a qualified individual or team of individuals to be responsible for developing the plan and assisting the facility or plant manager in its implementation. When selecting members of the team, the plant manager should draw on the expertise of all relevant departments within the plant to ensure that all aspects of plant operations are considered when the plan is developed. The plan must clearly describe the responsibilities of each team member as they relate to specific components of the plan. In addition to enhancing the quality of communication between team members and other personnel, clear delineation of responsibilities will ensure that every aspect of the plan is addressed by a specified individual or group of individuals. Pollution Prevention Teams may consist of one individual where appropriate (e.g., in certain small businesses with limited storm water pollution potential).

2. Description of Potential Pollution Sources

Each storm water pollution prevention plan must describe activities, materials, and physical features of the facility that may contribute significant amounts of pollutants to storm water runoff or, during periods of dry weather, result in pollutant discharges through the separate storm sewers or storm water drainage systems that drain the facility. This assessment of storm water pollution risk will support subsequent efforts to identify and set priorities for necessary changes in materials, materials management practices, or site features, as well as aid in the selection of appropriate structural and nonstructural control techniques. Some operators may find that significant amounts of pollutants are running or the facility property. Such operators should identify and address the contaminated runon in the storm wa pollution prevention plan. If the runc cannot be addressed or diverted by th permittee, the permitting authority should be notified. If necessary, the permitting authority may require the operator of the adjacent facility to obt a permit.

Part XI of the permit includes speci requirements for the various industry sectors covered by today's permit. Th storm water pollution prevention plar generally must describe the following elements:

a. Drainage. The plan must contain map of the site that shows the locatio of outfalls covered by the permit (or b other NPDES permits), the pattern of storm water drainage, an indication o the types of discharges contained in t drainage areas of the outfalls, structur features that control pollutants in runoff,[9] surface water bodies (includin wetlands), places where significant materials [10] are exposed to rainfall and runoff, and locations of major spills ar leaks that occurred in the 3 years prior to the date of the submission of a Noti of Intent (NOI) to be covered under thi permit. The map also must show areas where the following activities take place: fueling, vehicle and equipment maintenance and/or cleaning, loading and unloading, material storage (including tanks or other vessels used for liquid or waste storage), material processing, and waste disposal. For areas of the facility that generate storm water discharges with a reasonable potential to contain significant amoun of pollutants, the map must indicate t probable direction of storm water flow and the pollutants likely to be in the discharge. Flows with a significant potential to cause soil erosion also mu be identified. In order to increase the readability of the map, the inventory c the types of discharges contained in each outfall may be kept as an attachment to the site map.

b. Inventory of Exposed Materials. Facility operators are required to

[6] See "Storm Water Management for Industrial Activities," EPA, September 1992, EPA-832-R-92-006.

[7] For example, see "Best Management Practices: Useful Tools for Cleaning Up," Thron, H. Rogoshewski, P., 1982, Proceedings of the 1982 Hazardous Material Spills Conference: "The Chemical Industries' Approach to Spill Prevention," Thompson, C., Goodier, J. 1980, Proceedings of the 1980 National Conference of Control of Hazardous Materials Spills; a series of EPA memorandum entitled "Best Management Practices in NPDES Permits—Information Memorandum," 1983, 1985, 1986, 1987, 1988; Review of Emergency Systems: Report to Congress," EPA, 1988; and "Analysis of Implementing Permitting Activities for Storm Water Discharges Associated with Industrial Activity," EPA, 1991.

[8] See for example, "The Oil Spill Prevention, Control and Countermeasures Program Task Force Report," EPA, 1988; and "Guidance Manual for the Development of an Accidental Spill Prevention Program," prepared by SAIC for EPA, 1986.

[9] Nonstructural features such as grass swales ar vegetative buffer strips also should be shown.

[10] Significant materials include, but are not limited to the following: raw materials; fuels; solvents, detergents, and plastic pellets; finished materials, such as metallic products; raw materia used in food processing or production; hazardous substances designated under Section 101(14) of tr Comprehensive Environmental Response, Compensation and Liability Act (CERCLA); any chemical the facility is required to report pursuan to EPCRA Section 313; fertilizers; pesticides; and waste products, such as ashes, slag, and sludge th have the potential to be released with storm water discharges. (See 40 CFR 122.26(b)(8)).

carefully conduct an inspection of the site and related records to identify significant materials that are or may be exposed to storm water. The inventory must address materials that within 3 years prior to the date of the submission of a Notice of Intent (NOI) to be covered under this permit have been handled, stored, processed, treated, or disposed of in a manner to allow exposure to storm water. Findings of the inventory must be documented in detail in the pollution prevention plan. At a minimum, the plan must describe the method and location of onsite storage or disposal; practices used to minimize contact of materials with rainfall and runoff; existing structural and nonstructural controls that reduce pollutants in runoff; and any treatment the runoff receives before it is discharged to surface waters or a separate storm sewer system. The description must be updated whenever there is a significant change in the types or amounts of materials, or material management practices, that may affect the exposure of materials to storm water.

c. Significant Spills and Leaks. The plan must include a list of any significant spills and leaks of toxic or hazardous pollutants that occurred in the 3 years prior to the date of the submission of a Notice of Intent (NOI) to be covered under this permit. Significant spills include, but are not limited to, releases of oil or hazardous substances in excess of quantities that are reportable under Section 311 of CWA (see 40 CFR 110.10 and 40 CFR 117.21) or Section 102 of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) (see 40 CFR 302.4). Significant spills may also include releases of oil or hazardous substances that are not in excess of reporting requirements and releases of materials that are not classified as oil or a hazardous substance.

The listing should include a description of the causes of each spill or leak, the actions taken to respond to each release, and the actions taken to prevent similar such spills or leaks in the future. This effort will aid the facility operator as she or he examines existing spill prevention and response procedures and develops any additional procedures necessary to fulfill the requirements of Part XI. of this permit.

d. Non-storm Water Discharges. Each pollution prevention plan must include a certification, signed by an authorized individual, that discharges from the site have been tested or evaluated for the presence of non-storm water discharges. The certification must describe possible significant sources of non-storm water, the results of any test and/or evaluation conducted to detect such discharges, the test method or evaluation criteria used, the dates on which tests or evaluations were performed, and the onsite drainage points directly observed during the test or evaluation. Acceptable test or evaluation techniques include dye tests, television surveillance, observation of outfalls or other appropriate locations during dry weather, water balance calculations, and analysis of piping and drainage schematics.[11]

Except for flows that originate from fire fighting activities, sources of non-storm water that are specifically identified in the permit as being eligible for authorization under the general permit must be identified in the plan. Pollution prevention plans must identify and ensure the implementation of appropriate pollution prevention measures for the non-storm water discharge.

EPA recognizes that certification may not be feasible where facility personnel do not have access to an outfall, manhole, or other point of access to the conduit that ultimately receives the discharge. In such cases, the plan must describe why certification was not feasible. Permittees who are not able to certify that discharges have been tested or evaluated must notify the Director in accordance with Part XI. of the permit.

e. Sampling Data. Any existing data on the quality or quantity of storm water discharges from the facility must be described in the plan, including data collected for part 2 of the group application process. These data may be useful for locating areas that have contributed pollutants to storm water. The description should include a discussion of the methods used to collect and analyze the data. Sample collection points should be identified in the plan and shown on the site map.

f. Summary of Potential Pollutant Sources. The description of potential pollution sources culminates in a narrative assessment of the risk potential that sources of pollution pose to storm water quality. This assessment should clearly point to activities, materials, and physical features of the facility that have a reasonable potential to contribute significant amounts of pollutants to storm water. Any such activities, materials, or features must be addressed by the measures and controls subsequently described in the plan. In conducting the assessment, the facility operator must consider the following activities: loading and unloading operations; outdoor storage activities; outdoor manufacturing or processing activities; significant dust or particulate generating processes; and onsite waste disposal practices. The assessment must list any significant pollution sources at the site and identify the pollutant parameter or parameters (i.e., biochemical oxygen demand, suspended solids, etc.) associated with each source.

[11] In general, smoke tests should not be used for evaluating the discharge of non-storm water to a separate storm sewer as many sources of non-storm water typically pass through a trap that would limit the effectiveness of the smoke test.

3. Measures and Controls

Following completion of the source identification and assessment phase, the permit requires the permittee to evaluate, select, and describe the pollution prevention measures, best management practices (BMPs), and other controls that will be implemented at the facility. BMPs include processes, procedures, schedules of activities, prohibitions on practices, and other management practices that prevent or reduce the discharge of pollutants in storm water runoff.

EPA emphasizes the implementation of pollution prevention measures and BMPs that reduce possible pollutant discharges at the source. Source reduction measures include, among others, preventive maintenance, chemical substitution, spill prevention, good housekeeping, training, and proper materials management. Where such practices are not appropriate to a particular source or do not effectively reduce pollutant discharges, EPA supports the use of source control measures and BMPs such as material segregation or covering, water diversion, and dust control. Like source reduction measures, source control measures and BMPs are intended to keep pollutants out of storm water. The remaining classes of BMPs, which involve recycling or treatment of storm water, allow the reuse of storm water or attempt to lower pollutant concentrations prior to discharge.

The pollution prevention plan must discuss the reasons each selected control or practice is appropriate for the facility and how each will address one or more of the potential pollution sources identified in the plan. The plan also must include a schedule specifying the time or times during which each control or practice will be implemented. In addition, the plan should discuss ways in which the controls and practices relate to one another and, when taken as a whole, produce an integrated and consistent approach for preventing or controlling potential storm water contamination problems. The permit requirements included for the various industry sectors in Part XI of today's permit generally require that the portion of the plan that describes the measures and controls address the following minimum components.

When "minimize/reduce" is used relative to pollution prevention plan measures, EPA means to consider and implement best management practices that will result in an improvement over the baseline conditions as it relates to the levels of pollutants identified in storm water discharges with due consideration to economic feasibility and effectiveness.

a. Good Housekeeping. Good housekeeping involves using practical, cost-effective methods to identify ways to maintain a clean and orderly facility and keep contaminants out of separate storm sewers. It includes establishing protocols to reduce the possibility of mishandling chemicals or equipment and training employees in good housekeeping techniques. These protocols must be described in the plan and communicated to appropriate plant personnel.

b. Preventive Maintenance. Permittees must develop a preventive maintenance program that involves regular inspection and maintenance of storm water management devices and other equipment and systems. The program description should identify the devices, equipment, and systems that will be inspected; provide a schedule for inspections and tests; and address appropriate adjustment, cleaning, repair, or replacement of devices, equipment, and systems. For storm water management devices such as catch basins and oil/water separators, the preventive maintenance program should provide for periodic removal of debris to ensure that the devices are operating efficiently. For other equipment and systems, the program should reveal and enable the correction of conditions that could cause breakdowns or failures that may result in the release of pollutants.

c. Spill Prevention and Response Procedures. Based on an assessment of possible spill scenarios, permittees must specify appropriate material handling procedures, storage requirements, containment or diversion equipment, and spill cleanup procedures that will minimize the potential for spills and in the event of a spill enable proper and timely response. Areas and activities that typically pose a high risk for spills include loading and unloading areas, storage areas, process activities, and waste disposal activities. These activities and areas, and their accompanying drainage points, must be described in the plan. For a spill prevention and response program to be effective, employees should clearly understand the proper procedures and requirements and have the equipment necessary to respond to spills.

d. Inspections. In addition to the comprehensive site evaluation, facilities are required to conduct periodic inspections of designated equipment and areas of the facility. Industry-specific requirements for such inspections, if any, are discussed in Section VIII. of this fact sheet. When required, qualified personnel must be identified to conduct inspections at appropriate intervals specified in the plan. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the inspections. Records of inspections must be maintained. These periodic inspections are different from the comprehensive site evaluation, even though the former may be incorporated into the latter. Equipment, area, or other inspections are typically visual and are normally conducted on a regular basis, e.g., daily inspections of loading areas. Requirements for such periodic inspections are specific to each industrial sector in today's permit, whereas the comprehensive site compliance evaluation is required of all industrial sectors. Area inspections help ensure that storm water pollution prevention measures (e.g., BMPs) are operating and properly maintained on a regular basis. The comprehensive site evaluation is intended to provide an overview of the entire facility's pollution prevention activities. Refer to Part VI.C.4. below for more information on the comprehensive site evaluation.

e. Employee Training. The pollution prevention plan must describe a program for informing personnel at all levels of responsibility of the components and goals of the storm water pollution prevention plan. The training program should address topics such as good housekeeping, materials management, and spill response procedures. Where appropriate, contractor personnel also must be trained in relevant aspects of storm water pollution prevention. A schedule for conducting training must be provided in the plan. Several sections in Part XI. of today's permit specify a minimum frequency for training of once per year. Others indicate that training is to be conducted at an appropriate interval. EPA recommends that facilities conduct training annually at a minimum. However, more frequent training may be necessary at facilities with high turnover of employees or where employee participation is essential to the storm water pollution prevention plan.

f. Recordkeeping and Internal Reporting Procedures. The pollution prevention plan must describe procedures for developing and retaining records on the status and effectiveness of plan implementation. At a minimum records must address spills, monitoring and inspection and maintenance activities. The plan also must describe a system that enables timely reporting o storm water management-related information to appropriate plant personnel.

g. Sediment and Erosion Control. The pollution prevention plan must identify areas that, due to topography, activities, soils, cover materials, or other factors have a high potential for significant soil erosion. The plan must identify measures that will be implemented to limit erosion in these areas.

h. Management of Runoff. The plan must contain a narrative evaluation of the appropriateness of traditional storm water management practices (i.e., practices other than those that control pollutant sources) that divert, infiltrate, reuse, or otherwise manage storm water runoff so as to reduce the discharge of pollutants. Appropriate measures may include, among others, vegetative swales, collection and reuse of storm water, inlet controls, snow management infiltration devices, and wet detention/retention basins.

Based on the results of the evaluation, the plan must identify practices that the permittee determines are reasonable and appropriate for the facility. The plan also should describe the particular pollutant source area or activity to be controlled by each storm water management practice. Reasonable and appropriate practices must be implemented and maintained according to the provisions prescribed in the plan.

In selecting storm water management measures, it is important to consider the potential effects of each method on other water resources, such as ground water. Although storm water pollution prevention plans primarily focus on storm water management, facilities mus also consider potential ground water pollution problems and take appropriat steps to avoid adversely impacting ground water quality. For example, if the water table is unusually high in an area, an infiltration pond may contaminate a ground water source unless special preventive measures are taken. Under EPA's July 1991 Ground Water Protection Strategy, States are encouraged to develop Comprehensive State Ground Water Protection Programs (CSGWPP). Efforts to control storm water should be compatible with State ground water objectives as reflected in CSGWPPs.

4. Comprehensive Site Compliance Evaluation

The permit requires that the storm water pollution prevention plan describe the scope and content of the comprehensive site evaluations that qualified personnel will conduct to (1) confirm the accuracy of the description of potential pollution sources contained in the plan, (2) determine the effectiveness of the plan, and (3) assess compliance with the terms and conditions of the permit. Note that the comprehensive site evaluations are not the same as periodic or other inspections described for certain industries under Part VI.C.3.d of this fact sheet. However, in the instances when frequencies of inspections and the comprehensive site compliance evaluation overlap they may be combined allowing for efficiency, as long as the requirements for both types of inspections are met. The plan must indicate the frequency of comprehensive evaluations which must be at least once a year, except where comprehensive site evaluations are shown in the plan to be impractical for inactive mining sites, due to remote location and inaccessibility. [12] The individual or individuals who will conduct the comprehensive site evaluation must be identified in the plan and should be members of the pollution prevention team. Material handling and storage areas and other potential sources of pollution must be visually inspected for evidence of actual or potential pollutant discharges to the drainage system. Inspectors also must observe erosion controls and structural storm water management devices to ensure that each is operating correctly. Equipment needed to implement the pollution prevention plan, such as that used during spill response activities, must be inspected to confirm that it is in proper working order.

The results of each comprehensive site evaluation must be documented in a report signed by an authorized company official. The report must describe the scope of the comprehensive site evaluation, the personnel making the comprehensive site evaluation, the date(s) of the comprehensive site evaluation, and any major observations relating to implementation of the storm water pollution prevention plan. Comprehensive site evaluation reports must be retained for at least 3 years after the date of the evaluation. Based on the results of each comprehensive site evaluation, the description in the plan of potential pollution sources and measures and controls must be revised as appropriate within 2 weeks after each comprehensive site evaluation, unless indicated otherwise in Section XI of the permit. Changes in procedural operations must be implemented on the site in a timely manner for non-structural measures and controls not more than 12 weeks after completion of the comprehensive site evaluation. Procedural changes that require construction of structural measures and controls are allowed up to 3 years for implementation. In both instances, an extension may be requested from the Director.

D. Special Requirements

1. Special Requirements for Storm Water Discharges Associated With Industrial Activity Through Large and Medium Municipal Separate Storm Sewer Systems

Permittees that discharge storm water associated with industrial activity through large or medium municipal separate storm sewer systems [13] are required to submit notification of the discharge to the operator of the municipal separate storm sewer system. A list of these systems is provided in Addendum D of today's notice.

Facilities covered by this permit must comply with applicable requirements in municipal storm water management programs developed under NPDES permits issued for the discharge of the municipal separate storm sewer system that receives the facility's discharge, provided the discharger has been notified of such conditions. In addition, permittees that discharge storm water associated with industrial activity through a large or medium municipal separate storm sewer system must make their pollution prevention plans available to the municipal operator of the system upon request by the municipal operator.

2. Special Requirements for Storm Water Discharges Associated With Industrial Activity From Facilities Subject to EPCRA Section 313 Requirements

Today's permit contains special requirements for certain permittees subject to reporting requirements under Section 313 of the EPCRA (also known as Title III of the Superfund Amendments and Reauthorization Act (SARA)). EPCRA Section 313 requires operators of certain facilities that manufacture (including import), process, or otherwise use listed toxic chemicals to report annually their releases of those chemicals to any environmental media. Listed toxic chemicals include more than 500 chemicals and chemical classes listed at 40 CFR Part 372 (including the recently added chemicals published November 30, 1994).

The criteria for facilities that must report under Section 313 are given at 40 CFR 372.22. A facility is subject to the annual reporting provisions of Section 313 if it meets all three of the following criteria for a calendar year: it is included in SIC codes 20 through 39; it has 10 or more full-time employees; and it manufactures (including imports), processes, or otherwise uses a chemical listed in 40 CFR 372.65 in amounts greater than the "threshold" quantities specified in 40 CFR 372.25.

There are more than 300 individually listed Section 313 chemicals, as well as 20 categories of Toxic Release Inventory (TRI) chemicals for which reporting is required. EPA has the authority to add to and delete from this list. The Agency has identified approximately 175 chemicals that it is classifying for the purposes of this general permit as "Section 313 water priority chemicals." For the purposes of this permit, Section 313 water priority chemicals are defined as chemicals or chemical categories that (1) are listed at 40 CFR 372.65 pursuant to EPCRA Section 313; (2) are manufactured, processed, or otherwise used at or above threshold levels at a facility subject to EPCRA Section 313 reporting requirements; and (3) meet at least one of the following criteria: (i) are listed in Appendix D of 40 CFR Part 122 on either Table II (organic priority pollutants), Table III (certain metals, cyanides, and phenols), or Table V (certain toxic pollutants and hazardous substances); (ii) are listed as a hazardous substance pursuant to Section 311(b)(2)(A) of the CWA at 40 CFR 116.4; or (iii) are pollutants for which EPA has published acute or chronic toxicity criteria. A list of the water priority chemicals is provided in Addendum F to today's notice. In today's permit, EPA is not extending the special requirements to facilities that store liquid chemicals in above-ground tanks or handle liquid chemicals in areas exposed to precipitation if such facilities are not subject to EPCRA Section 313 reporting requirements.

[12] Where annual site inspections are shown in the plan to be impractical for inactive mining sites, due to remote location and inaccessibility, site inspections must be conducted at least once every 3 years.

[13] Large and medium municipal separate storm sewer systems are systems located in an incorporated city with a population of 100,000 or more, or in a county identified as having a large or medium system (see 40 CFR 122.26(b) (4) and (7) and Appendices F through I to Part 122). A list of these municipalities is provided in Addendum D to today's notice.

a. Summary of Special Requirements. The special requirements in today's permit for facilities subject to reporting requirements under EPCRA Section 313 for a water priority chemical, except those that are handled and stored only in gaseous or non-soluble liquids or solids (at atmospheric pressure and temperature) forms (see Part VI.D.2.c below), state that storm water pollution prevention plans, in addition to the baseline requirements for plans, must contain special provisions addressing areas where Section 313 water priority chemicals are stored, processed, or otherwise handled. These requirements reflect the Best Available Technology for controlling discharges of water priority chemicals in storm water. The permit provides that appropriate containment, drainage control, and/or diversionary structures must be provided for such areas. An exemption from the special provisions for Section 313 facilities will be granted if the facility can certify in the pollution prevention plan that all water priority chemicals handled or used are gaseous or non-soluble liquids or solids (at atmospheric pressure and temperature). At a minimum, one of the following preventive systems or its equivalent must be used: curbing, culverting, gutters, sewers, or other forms of drainage control to prevent or minimize the potential for storm water runon to come into contact with significant sources of pollutants; or roofs, covers, or other forms of appropriate protection to prevent storage piles from exposure to storm water and wind.

In addition, the permit establishes requirements for priority areas of the facility. Priority areas of the facility include the following: liquid storage areas where storm water comes into contact with any equipment, tank, container, or other vessel used for Section 313 water priority chemicals; material storage areas for Section 313 water priority chemicals other than liquids; truck and rail car loading and unloading areas for liquid Section 313 water priority chemicals; and areas where Section 313 water priority chemicals are transferred, processed, or otherwise handled.

The permit provides that site runoff from other industrial areas of the facility that may contain Section 313 water priority chemicals or spills of Section 313 water priority chemicals must incorporate the necessary drainage or other control features to prevent the discharge of spilled or improperly disposed material and to ensure the mitigation of pollutants in runoff or leachate. The permit also establishes special requirements for preventive maintenance and good housekeeping, facility security, and employee training.

In the proposed permit, EPA proposed to require facilities subject to EPCRA Section 313 requirements to have a Registered Professional Engineer (PE) certify their pollution prevention plans every 3 years. However, in response to commentors' concerns, EPA has revised the permit to eliminate the PE certification requirement. Instead, the permit now requires facilities subject to the special requirements to satisfy the pollution prevention plan signature requirements in Part IV.B.1. of the permit. EPA agrees with commentors that the operator is the most appropriate person to perform the certification. In addition, instead of certifying the plan every 3 years, facilities subject to EPCRA Section 313 requirements must amend the pollution prevention plan only when significant modifications are made to the facility, such as the addition of material handling areas or chemical storage units.

b. Requirements for Priority Areas. The permit provides that drainage from priority areas should be restrained by valves or other positive means to prevent the discharge of a spill or other excessive leakage of Section 313 water priority chemicals. Where containment units are employed, such units may be emptied by pumps or ejectors; however, these must be manually activated. Flapper-type drain valves must not be used to drain containment areas, as these will not effectively control spills. Valves used for the drainage of containment areas should, as far as is practical, be of manual, open-and-closed design. If facility drainage does not meet these requirements, the final discharge conveyance of all in-facility storm sewers must be equipped to be equivalent with a diversion system that could, in the event of an uncontrolled spill of Section 313 water priority chemicals, return the spilled material or contaminated storm water to the facility. Records must be kept of the frequency and estimated volume (in gallons) of discharges from containment areas.

Additional special requirements are related to the types of industrial activities that occur within the priority area. These requirements are summarized below:

(1) Liquid Storage Areas. Where storm water comes into contact with any equipment, tank, container, or other vessel used for Section 313 water priority chemicals, the material and construction of tanks or containers used for the storage of a Section 313 water priority chemical must be compatible with the material stored and conditions of storage, such as pressure and temperature. Liquid storage areas for Section 313 water priority chemicals must be operated to minimize discharges of Section 313 chemicals. Appropriate measures to minimize discharges of Section 313 chemicals may include secondary containment provided for at least the entire contents of the largest single tank plus sufficient freeboard to allow for precipitation, a strong spill contingency and integrity testing plan, and/or other equivalent measures. A strong spill contingency plan would typically contain, at a minimum, a description of response plans, personnel needs, and methods of mechanical containment (such as use of sorbents, booms, collection devices, etc.), steps to taken for removal of spill chemicals or materials, and procedures to ensure access to and availability of sorbents and other equipment. The testing component of the plan would provide for conducting integrity testing of storage tanks at set intervals such as once every 5 years, and conducting integrity and leak testing of valves and piping at a minimum frequency, such as once per year. In addition, a strong plan would include a written and actual commitment of manpower, equipment and materials required to comply with the permit and to expeditiously control and remove any quantity of spilled or leaked chemicals that may result in a toxic discharge.

(2) Other Material Storage Areas. Material storage areas for Section 313 water priority chemicals other than liquids that are subject to runoff, leaching, or wind must incorporate drainage or other control features to minimize the discharge of Section 313 water priority chemicals by reducing storm water contact with Section 313 water priority chemicals.

(3) Truck and Rail Car Loading and Unloading Areas. Truck and rail car loading and unloading areas for liquid Section 313 water priority chemicals must be operated to minimize discharges of Section 313 water priority chemicals. Appropriate measures to minimize discharges of Section 313 chemicals may include the placement and maintenance of drip pans (including the proper disposal of materials collected in the drip pans) where spillage may occur (such as hose connections, hose reels, and filler nozzles) when making and breaking hose connections; a strong spill contingency and integrity testing plan; and/or other equivalent measures.

(4) Other Transfer, Process, or Handling Areas. Processing equipment and materials handling equipment must be operated to minimize discharges of Section 313 water priority chemicals.

Materials used in piping and equipment must be compatible with the substances handled. Drainage from process and materials handling areas must minimize storm water contact with Section 313 water priority chemicals. Additional protection such as covers or guards to prevent exposure to wind, spraying or releases from pressure relief vents to prevent a discharge of Section 313 water priority chemicals to the drainage system, and overhangs or door skirts to enclose trailer ends at truck loading/unloading docks must be provided as appropriate. Visual inspections or leak tests must be provided for overhead piping conveying Section 313 water priority chemicals without secondary containment.

c. Today's permit allows facilities to provide a certification, signed in accordance with Part VII.G. (signatory requirements) of this permit, that all Section 313 water priority chemicals handled and/or stored onsite are only in gaseous or non-soluble liquid or solid (at atmospheric pressure and temperature) forms in lieu of the additional requirements in Part VI.E.2 of today's permit. By allowing such a certification, EPA hopes to limit the application of the special requirements Part IV.E.2. of the permit to those facilitios with 313 water priority chemicals that truly have the potential to contaminate storm water discharges associated with industrial activity.

3. Special Requirements for Storm Water Discharges Associated With Industrial Activity From Salt Storage Facilities

Today's general permit contains special requirements for storm water discharges associated with industrial activity from salt storage facilities. Storage piles of salt used for deicing or other commercial or industrial purposes must be enclosed or covered to prevent exposure to precipitation, except for exposure resulting from adding or removing materials from the pile. This requirement only applies to runoff from storage piles discharged to waters of the United States. Facilities that collect all of the runoff from their salt piles and reuse it in their processes or discharge it subject to a separate NPDES permit do not need to enclose or cover their piles. Permittees must comply with this requirement as expeditiously as practicable, but in no event later than 3 years from the date of permit issuance.

These special requirements have been included in today's permit based on human health and aquatic effects resulting from storm water runoff from salt storage piles compounded with the prevalence of salt storage piles across the United States.

4. Consistency With Other Plans

Storm water pollution prevention plans may reference the existence of other plans for Spill Prevention Control and Countermeasure (SPCC) plans developed for the facility under Section 311 of the CWA or Best Management Practices (BMP) Programs otherwise required by an NPDES permit for the facility as long as such requirement is incorporated into the storm water pollution prevention plan.

E. Monitoring and Reporting Requirements

The permit contains three general types of monitoring requirements: analytical monitoring or chemical monitoring; compliance monitoring for effluent guidelines compliance, and visual examinations of storm water discharges. This section provides a general description of each of these types of monitoring. Actual monitoring requirements for a given facility under the permit will vary depending upon the industrial activities that occur at a facility and the criteria for determining monitoring used to develop the permit. Table 3 lists the sections of the permit and of this fact sheet that describe the monitoring requirements as they apply to the specific industrial activities eligible for coverage under the permit. These are minimum monitoring requirements and if a permittee so chooses, he may conduct additional sampling to acquire more data to improve the statistical validity of the results. Through increased analytical or visual monitoring the permittee may be able to better ascertain the effectiveness of their pollution prevention plan.

Analytical monitoring requirements involve laboratory chemical analyses of samples collected by the permittee. The results of the analytical monitoring are quantitative concentration values for different pollutants, which can be easily compared to the results from other sampling events, other facilities, or to National benchmarks. Section VI.E.1. describes the analytical monitoring requirements and the process and criteria by which an industry sector or subsector was selected for analytical monitoring. Compliance monitoring requirements are imposed under today's permit to insure that discharges subject to numerical effluent limitations under the storm water effluent limitations guidelines are in compliance with those limitations. The compliance monitoring requirements are explained in Section VI.E.2.

Visual examinations of storm water discharges are the least burdensome type of monitoring requirement under the permit. Almost all of the industrial activities are required to perform visual examinations of their storm water discharges when they are occurring on a quarterly basis. Visual examinations are described in Section VI.E.8.

TABLE 3.—STORM WATER MONITORING REQUIREMENTS

* Denotes a sector that contains analytical monitoring requirements for an entire sector or a subsector.

1. Analytical Monitoring Requirements.

Today's permit requires analytical monitoring for discharges from certain classes of industrial facilities. EPA believes that industries may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of a storm water pollution prevention plan discussed in today's permit. Analytical monitoring is a means by which to measure the concentration of a pollutant in a storm water discharge. Analytical results are quantitative and therefore can be used to compare results from discharge to discharge and to quantify the improvement in storm water quality attributable to the storm water pollution prevention plan, or to identify a pollutant that is not being successfully controlled by the plan. EPA realizes there are greater cost burdens associated with analytical monitoring in comparison to visual examinations. Today's permit only requires analytical monitoring for the industry sectors or subsectors that demonstrated a potential to discharge pollutants at concentrations of concern.

To determine the industry sectors and subsectors that would be subject to analytical monitoring requirements contained in the sections listed in Table 3, EPA reviewed the data submitted in the group application process. First, EPA divided the Part 1 and Part 2 application data by the industry sectors listed in Table 3. Where a sector was found to contain a wide range of industrial activities or potential pollutant sources, it was further subdivided into the industry subsectors listed in Table 4. Next, EPA reviewed the information submitted in Part 1 of the group applications regarding the industrial activities, significant materials exposed to storm water, and the material management measures employed. This information helped identify potential pollutants that may be present in the storm water discharges. Then, EPA entered into a database, the sampling data submitted in Part 2 of the group applications. That data was arrayed according to industrial sector and subsector for the purposes of determining when analytical monitoring would be appropriate. Data received by EPA prior to January 1, 1993 (three months after the application deadline) were entered into EPA's database. Some additional data that was submitted even after January 1, 1993 was also entered into the database to bolster the data set for some sectors or subsectors (e.g., the auto salvage industry). All data submitted even later by group applicants which was not loaded into the database was reviewed by EPA during development of the permit. EPA notes that preliminary copies of the database were distributed to the public upon request in advance of a complete screening of the quality of the data set. These copies of the database contained a variety of errors that were screened and removed prior to EPA statistical analysis and evaluation of the results. The results of the statistical analyses are presented in the appropriate section of the fact sheet referenced in Table 3.

* Denotes subsector with analytical (chemical) monitoring requirements.
NA indicated those industry sectors in which subdivision into subsectors was determined to be not applicable.

To conduct a comparison of the results of the statistical analyses to determine when analytical monitoring would be required, EPA established "benchmark" concentrations for the pollutant parameters on which monitoring results had been received. The "benchmarks" are the pollutant concentrations above which EPA determined represents a level of concern. The level of concern is a concentration at which a storm water discharge could potentially impair, or contribute to impairing water quality or affect human health from ingestion of water or fish. The benchmarks are also viewed by EPA as a level, that if below, a facility represents little potential for water quality concern. As such, the benchmarks also provide an appropriate level to determine whether a facility's storm water pollution prevention measures are successfully implemented. The benchmark concentrations are not effluent limitations and should not be interpreted or adopted as such. These values are merely levels which EPA has used to determine if a storm water discharge from any given facility merits further monitoring to insure that the facility has been successful in implementing a storm water pollution prevention plan. As such these levels represent a target concentration for a facility to achieve through implementation of pollution prevention measures at the facility. Table 5 lists the parameter benchmark values.

As can be seen in Table 5, benchmark concentrations were determined based upon a number of existing standards or other sources to represent a level above which water quality concerns could arise. EPA has also sought to develop values which can realistically be measured and achieved by industrial facilities. Moreover, storm water discharges with pollutant concentrations occurring below these levels would not warrant further analytical monitoring due to their de minimis potential effect on water quality.

The primary source of benchmark concentrations is EPA's National Water Quality Criteria, published in 1986 (often referred to as the "Gold Book"). For the majority of the benchmarks, EPA chose to use the acute aquatic life, fresh water ambient water quality criteria. These criteria represent maximum concentration values for a pollutant, above which, could cause acute effects on aquatic life such as mortality in a short period of time. Where acute criteria values were not available, EPA used the lowest observed effect level (LOEL) acute fresh water value. The LOEL values represent the lowest concentration of a pollutant that results in an adverse effect over a short period of time. These two acute freshwater values were selected as benchmark concentrations if the value was not below the approved method detection limit as listed in 40 CFR Part 136 and the value was not substantially above the concentration which EPA believes a facility can attain through the implementation of a storm water pollution prevention plan. These acute freshwater values best represent, on a national basis, the highest concentrations at which typical fresh water species can survive exposures of pollutants for short durations (i.e., a storm discharge event).

Acute freshwater criteria do not exist for a number of parameters on which EPA received data. For these parameters, EPA selected benchmark values from several other references. The benchmark concentrations for five day biochemical oxygen demand (BOD_5) and for pH are determined based upon the secondary wastewater treatment regulations (40 CFR 133.102). EPA believes that the BOD_5 value of 30 mg/L is a reasonable concentration below which adverse effects in receiving waters under wet weather flow conditions should not occur. EPA also believes, that given group application data on BOD_5, this value should be readily achievable by industrial storm water dischargers. The benchmark value for pH is a range of 6.0–9.0 standard units. EPA believes this level, given the group application data, is reasonably achievable by industrial storm water dischargers and represents and acceptable range within which aquatic life impacts will not occur. The benchmark concentration for chemical oxygen demand (COD) is based upon the State of North Carolina benchmark values for storm water discharges, and is a factor of four times the BOD_5 benchmark concentration. EPA has concluded that COD is generally discharged in domestic wastewater at four times the concentration of BOD_5 without causing adverse impacts on aquatic life. EPA selected the median concentration from the National Urban Runoff Program as the benchmark for total suspended solids (TSS) and for nitrate plus nitrite as nitrogen. EPA believes the median concentration, which is the mid-point concentration (half the samples are above this level and half are below) represents concentration above which water quality concerns may result. For TSS a value of 100mg/L is similar to the storm water benchmark used by North Carolina for storm water permits, and given the group application data, should be readily achievable by industry with implementation of BMPs, many of which are designed for the purpose of controlling TSS. EPA also believes, given the group application data, that there is a relationship between TSS and the amount of exposed industrial activity and that industrial activities even in arid western States should be able to implement BMPs that will accomplish this benchmark. EPA selected the storm water effluent limitation guideline for petroleum refining facilities as the benchmark for oil and grease. Given the lack of an acute criteria, EPA selected the chron[ic] fresh water quality criteria as the benchmark for iron. Water quality criteria for waterbodies in the State of North Carolina were used to determin[e] benchmarks for total phosphorus and for fluoride. The concentration value [for] phosphorus was designed to prevent eutrophication of fresh waterbodies from storm water runoff. The fluoride value was designed by North Carolina [to] be protective of water quality, as was the manganese value developed by Colorado. EPA believes that each of these benchmark values represent a reasonable level below which water quality impacts should not occur and they therefore represent a useful level [to] assess whether a pollution prevention plan is controlling pollution in storm water discharges.

For several other parameters, EPA chose a benchmark value base on a numerical adjustment of the acute fresh water quality criteria. Where the acute water quality criteria was below the method detection level for a pollutant, EPA used the "minimum level" (ML) as the benchmark concentration to ensure that the benchmark levels could be measured by permittees. For a few pollutants minimum levels have been published and these were used. For other pollutants, minimum levels need to be calculated. EPA calculated the minimum levels using the methodology described in the draft "National Guidance for the Permitting, Monitoring, and Enforcement of Water Quality-based Effluent Limitations Set Below Analytical Detection/Quantitation Levels" (Michael Cook, OWEC, March 18, 1994).

Additionally, several organic compounds (ethylbenzene, fluoranthene, toluene, and trichloroethylene) have acute fresh water quality criteria at substantially high concentrations, much higher than criteria developed for the protection of human health when ingesting water or fish. In addition, trichloroethylene is a human carcinogen. Therefore, EPA selected the human health criteria as benchmarks for these parameters. For dimethyl phthalate and total phenols, EPA selected benchmark concentrations based upon existing discharge limitations and compliance data (no industry had median concentrations above the selected benchmark for these parameters and therefore no industry sector is required to monitor for these two pollutants).

EPA conducted statistical analyses of the group Part 2 data for each parameter within every industry sector or subsector listed in Table 5. The pollutants, benchmark values, and source of the benchmark values are indicated below in Table 5.

TABLE 5.—PARAMETER BENCHMARK VALUES

Parameter name	Benchmark level	Source
Biochemical Oxygen Demand(5)	30 mg/L	4
Chemical Oxygen Demand	120 mg/L	5
Total Suspended Solids	100 mg/L	7
Oil and Grease	15 mg/L	8
Nitrate + Nitrite Nitrogen	0.68 mg/L	7
Total Phosphorus	2.0 mg/L	6
pH	6.0–9.0 s.u.	4
Acrylonitrile (c)	7.55 mg/L	2
Aluminum, Total (pH 6.5–9)	0.75 mg/L	1
Ammonia	19 mg/L	1
Antimony, Total	0.636 mg/L	9
Arsenic, Total (c)	0.16854 mg/L	9
Benzene	0.01 mg/L	10
Beryllium, Total (c)	0.13 mg/L	2
Butylbenzyl Phthalate	3 mg/L	3
Cadmium, Total (H)	0.0159 mg/L	9
Chloride	860 mg/L	1
Copper, Total (H)	0.0636 mg/L	9
Dimethyl Phthalate	1.0 mg/L	11
Ethylbenzene	3.1 mg/L	3
Fluoranthene	0.042 mg/L	3
Fluoride	1.8 mg/L	6
Iron, Total	1.0 mg/L	12
Lead, Total (H)	0.0816 mg/L	1
Manganese	1.0 mg/L	13
Mercury, Total	l0.0024 mg/L	1
Nickel, Total (H)	1.417 mg/L	1
PCB–1016 (c)	0.000127 mg/L	9
PCB–1221 (c)	0.10 mg/L	10
PCB–1232 (c)	0.000318 mg/L	9
PCB–1242 (c)	0.00020 mg/L	10
PCB–1248 (c)	0.002544 mg/L	9
PCB–1254 (c)	0.10 mg/L	10
PCB–1260 (c)	0.000477 mg/L	9
Phenols, Total	1.0 mg/L	11
Pyrene (PAH,c)	0.01 mg/L	10
Selenium, Total (*)	0.2385 mg/L	9
Silver, Total (H)	0.0318 mg/L	9
Toluene	10.0 mg/L	3
Trichloroethylene (c)	0.0027 mg/L	3
Zinc, Total (H)	0.117 mg/L	1

Receiving water hardness CaCO3 100 mg/L.
Receiving water salinity 20 g/kg.
Acute to Chronic Ratio (ACR)—10.

EPA prepared a statistical analysis of the sampling data for each pollutant parameter reported within each sector or subsector. (Only where EPA did not subdivide an industry sector into subsectors was an analysis of the entire sector's data performed.) The statistical analysis was performed assuming a delta log normal distribution of the sampling data within each sector/subsector. The analyses calculated median, mean, maximum, minimum, 95th, and 99th percentile concentrations for each parameter. The results of the analyses may be found in the appropriate section of Part VIII of this Fact Sheet. From this analysis, EPA was able to identify pollutants for further evaluation within each sector or subsector.

EPA next compared the median concentration for each pollutant for each sector or subsector to the benchmark concentrations listed in Table 5. EPA also compared the other statistical results to the benchmarks to better ascertain the magnitude and range of the discharge concentrations to help identify the pollutants of concern. EPA did not conduct this analysis if a sector had data for a pollutant from less than three individual facilities. Under these circumstances, the sector or subsector would not have this pollutant identified as a pollutant of concern. This was done to ensure that a reasonable number of facilities represented the industry sector or subsector as a whole and that the analysis did not rely on data from only one facility.

For each industry sector or subsector, parameters with a median concentration higher than the benchmark level were considered pollutants of concern for the industry and identified as potential pollutants for analytical monitoring under today's permit. EPA then analyzed the list of potential pollutants to be monitored against the lists of significant materials exposed and industrial activities which occur within each industry sector or subsector as described in the part I application information. Where EPA could identify a source of a potential pollutant which is directly related to industrial activities of the industry sector or subsector, the permit identifies that parameter for analytical monitoring. If EPA could not identify a source of a potential pollutant which was associated with the sector/subsector's industrial activity, the permit does not require monitoring for the pollutant in that sector/subsector. Industries with no pollutants for which the median concentrations are higher than the benchmark levels are not required to perform analytical monitoring under this permit, with the exceptions explained below.

In addition to the sectors and subsectors identified for analytical monitoring using the methods described above, EPA determined, based upon a review of the degree of exposure, types of materials exposed, special studies and in some cases inadequate sampling data in the group applications, that industries in the following sections of today's fact sheet also warrant analytical monitoring not withstanding the absence of data on the presence or absence of certain pollutants in the group applications: VIII.K.7 (hazardous waste treatment storage and disposal facilities), and VIII.S.6 (airports which use more than 100,000 gallons per year of glycol-based fluids or 100 tons of urea for deicing). These industries are required to perform analytical monitoring under the permit due to the high potential for contamination of storm water discharge, which EPA believes was not adequately characterized by group applicants in the information they provided in the group application process.

All facilities within an industry sector or subsector identified for analytical monitoring must, at a minimum, monitor their storm water discharges during the second year of permit coverage, unless the facility exercises the Alternative Certification described in Section VI.E.3 of this fact sheet. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter for which the facility is required to monitor. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed. Monitoring must be conducted for the same storm water discharge outfall in each sampling period. Where a given storm water discharge is addressed by more than one sector/subsector's monitoring requirements, then the monitoring requirements for the applicable sector's/subsector's activities are cumulative. Therefore, if a particular discharge fits under more than one set of monitoring requirements, the facility must comply with all sets of sampling requirements. Monitoring requirements must be evaluated on an outfall-by-outfall basis.

If the average concentration for a pollutant parameter is less than or equal to the benchmark value, then the permittee is not required to conduct analytical monitoring for that pollutant during the fourth year of the permit. If, however, the average concentration for a pollutant is greater than the benchmark value, then the permittee is required to conduct quarterly monitoring for that pollutant during the fourth year of permit coverage. Analytical monitoring is not required during the first, third, and fifth year of the permit. The exclusion from analytical monitoring in the fourth y of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit.

2. Compliance Monitoring

In addition to the analytical monitoring requirements for certain sectors, today's permit contains monitoring requirements for discharg which are subject to effluent limitatio These discharges must be sampled annually and tested for the parameter which are limited by the permit. Discharges subject to compliance monitoring include: coal pile runoff, contaminated runoff from phosphate fertilizer manufacturing facilities, run from asphalt paving and roofing emulsion production areas, material storage pile runoff from cement manufacturing facilities, and mine dewatering discharges from crushed stone, construction sand and gravel, a industrial sand mines located in Texa Louisiana, Oklahoma, New Mexico, ar Arizona. All samples are to be grabs taken within the first 30 minutes of discharge where practicable, but in no case later than the first hour of discharge. Where practicable, the samples shall be taken from the discharges subject to the numeric effluent limitations prior to mixing wi other discharges.

Monitoring for these discharges is required to determine compliance wit numeric effluent limitations. Furthermore, discharges covered unde today's permit which are subject to numeric effluent limitations are not eligible for the alternative certification in Part VI.E.3. of this fact sheet.

3. Alternate Certification

Throughout today's permit, EPA ha included monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storr water discharges. The alternative certification described below is included in the permit to ensure that monitoring requirements are only imposed on those facilities which do, fact, have storm water discharges containing pollutants at concentration of concern. EPA has determined that i there are no sources of a pollutant exposed to storm water at the site ther the potential for that pollutant to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subjec to the analytical monitoring requirements provided the discharger makes a certification for a given outfall, on a pollutant-by-pollutant basis, that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan, and submitted to EPA in lieu of monitoring reports required under Part XI of the permit. The permittee is required to complete any and all sampling until the exposure is eliminated. If the facility is reporting for a partial year, the permittee must specify the date exposure was eliminated. If the permittee is certifying that a pollutant was present for part of the reporting period, nothing relieves the permittee from the responsibility to sample that parameter up until the exposure was eliminated and it was determined that no significant materials remained. This certification is not to be confused with the low concentration sampling waiver. The test for the application of this certification is whether the pollutant is exposed, or can be expected to be present in the storm water discharge. If the facility does not and has not used a parameter, or if exposure is eliminated and no significant materials remain, then the facility can exercise this certification.

The permit does not allow facilities with discharges subject to numeric effluent limitations to submit alternative certification in lieu of the compliance monitoring requirements in Sections VI.C., XI.C.6., XI.D.5., XI.E.5., and XI.J.5. The permit also does not allow air transportation facilities subject to the analytical monitoring requirements under Section XI.S.5. to exercise an alternative certification.

A facility is not precluded from exercising the alternative certification in lieu of analytical monitoring requirements in the fourth year of permit coverage, even if that facility failed to qualify for a low concentration waiver in year two. EPA encourages facilities to eliminate exposure of industrial activities and significant materials where practicable.

4. Reporting and Retention Requirements

Permittees are required to submit all analytical monitoring results obtained during the second and fourth year of permit coverage within three months of the conclusion of the second and fourth year of coverage of the permit. For each outfall, one Discharge Monitoring Report Form must be submitted per storm event sampled. For facilities conducting monitoring beyond the minimum requirements an additional Discharge Monitoring Report Form must be filed for each analysis. The permittee must include a measurement or estimate of the total precipitation, volume of runoff, and peak flow rate of runoff for each storm event sampled. Permittees subject to compliance monitoring requirements are required to submit all compliance monitoring results annually on the 28th day of the month following the anniversary of the publication of this permit. Compliance monitoring results must be submitted on signed Discharge Monitoring Report Forms. For each outfall, one Discharge Monitoring Report form must be submitted for each storm event sampled.

Permittees are not required to submit records of the visual examinations of storm water discharges unless specifically asked to do so by the Director. Records of the visual examinations must be maintained at the facility. Records of visual examination of storm water discharge need not be lengthy. Permittees may prepare typed or hand written reports using forms or tables which they may develop for their facility. The report need only document: the date and time of the examination; the name of the individual making the examination; and any observations of color, odor, clarity, floating solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution.

The location for submittal of all reports is contained in the permit. Consistent with Office of Management and Budget Circular A–105, facilities located on the following Federal Indian Reservations, which cross EPA Regional boundaries, should note that permitting authority for such lands is consolidated in one single EPA Region.

a. Duck Valley Reservations lands, located in Regions IX and X, are handled by Region IX.

b. Fort McDermitt Reservation lands, located in Regions IX and X, are handled by Region IX.

c. Goshute Reservation lands, located in Regions VIII and IX, are handled by Region IX.

d. Navajo Reservation lands, located in Regions VI, VIII, and IX, are handled by Region IX.

e. Ute Mountain Reservation lands, located in Regions VI and VIII, are handled Region VIII (no areas in Region VIII are receiving coverage under this permit).

Pursuant to the requirements of 40 CFR 122.41(j), today's permit requires permittees to retain all records for a minimum of 3 years from the date of the sampling, examination, or other activity that generated the data.

5. Sample Type

The discussion below is a general description of the sample type required for monitoring under today's permit. Certain industries have different requirements, however, so permittees should check the industry-specific requirements in Part XI. of today's permit to confirm these requirements. Grab samples may be used for all monitoring unless otherwise stated. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval may be waived by the permittee where the preceding measurable storm event did not result in a measurable discharge from the facility. The 72-hour requirement may also be waived by the permittee where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample must be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger must submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable. A minimum of one grab is required. Where the discharge to be sampled contains both storm water and non-storm water, the facility shall sample the storm water component of the discharge at a point upstream of the location where the non-storm water mixes with the storm water, if practicable.

6. Representative Discharge

The permit allows permittees to use the substantially identical outfalls to reduce their monitoring burden. This representative discharge provision provides facilities with multiple storm water outfalls, a means for reducing the number of outfalls that must be sampled and analyzed. This may result in a substantial reduction of the resources required for a facility to comply with analytical monitoring requirements. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfalls provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explaining in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area (e.g., low (under 40 percent), medium (40 to 65 percent) or high (above 65 percent)) shall be provided in the plan. Facilities that select and sample a representative discharge are prohibited from changing the selected discharge in future monitoring periods unless the selected discharge ceases to be representative or is eliminated. Permittees do not need EPA approval to claim discharges are representative, provided they have documented their rationale within the storm water pollution prevention plan. However, the Director may determine the discharges are not representative and require sampling of all non-identical outfalls.

The representative discharge provision in the permit is available to almost all facilities subject to the analytical monitoring requirements (not including compliance monitoring for effluent guideline limit compliance purposes) and to facilities subject to visual examination requirements.

The representative discharge provisions described above are consistent with Section 5.2 of NPDES Storm Water Sampling Guidance Document (EPA 833–B–92–001, July 1992).

7. Sampling Waiver

a. Adverse Weather Conditions. The permit allows for temporary waivers from sampling based on adverse climatic conditions. This temporary sampling waiver is only intended to apply to insurmountable weather conditions such as drought or dangerous conditions such as lightning, flash flooding, or hurricanes. These events tend to be isolated incidents and should not be used as an excuse for not conducting sampling under more favorable conditions associated with other storm events. The sampling waiver is not intended to apply to difficult logistical conditions, such as remote facilities with few employees or discharge locations which are difficult to access. When a discharger is unable to collect samples within a specified sampling period due to adverse climatic conditions, the discharger shall collect a substitute sample from a separate qualifying event in the next sampling period as well as a sample for the routine monitoring required in that period. Both samples should be analyzed separately and the results of that analysis submitted to EPA. Permittees are not required to obtain advance approval for sampling waivers.

b. Unstaffed and Inactive Sites—Chemical Waiver. The permit allows for a waiver from sampling for facilities that are both inactive and unstaffed. This waiver is only intended to apply to these types of facilities when the ability to conduct sampling would be severely hindered and result in the inability to meet the time and representative rainfall sampling specifications. This sampling waiver is not intended to apply to remote facilities that are active and staffed, or typical difficult logistical conditions. When a discharger is unable to collect samples as specified in this permit, the discharger shall certify to the Director in the DMR that the facility is unstaffed and inactive and the ability to conduct samples within the specifications is not possible. Permittees are not required to obtain advance approval for this waiver.

c. Unstaffed and Inactive Sites—Visual Waiver. The permit allows for a waiver from sampling for facilities that are both inactive and unstaffed. This waiver is only intended to apply to these types of facilities when the ability to conduct visual examinations would be severely hindered and result in the inability to meet the time and representative rainfall sampling specifications. This sampling waiver is not intended to apply to remote facilities that are active and staffed, or typical difficult logistical conditions. When a discharger is unable to perform visual examinations as specified in this permit, the discharger shall maintain on site with the pollution prevention plan a certification stating that the facility is unstaffed and inactive and the ability to perform visual examinations within the specifications is not possible. Permittees are not required to obtain advance approval for visual examination waivers.

8. Quarterly Visual Examination of Storm Water Quality

In order to provide a tool for evaluating the effectiveness of the pollution prevention plan, the permit requires the majority of industries covered under today's permit to perform quarterly visual examinations of storm water discharges. EPA believes these visual examinations will assist with the evaluation of the pollution prevention plan. This section provides a general description of the monitoring and reporting requirements under today's permit. The visual examination provides a simple, low cost means of assessing the quality of storm water discharge with immediate feedback. Most facilities covered under today's permit are required to conduct a quarterly visual examination of storm water discharges associated with industrial activity from each outfall, except discharges exempted under the representative discharge provision. The visual examination of storm water outfalls should include any observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, or other obvious indicators of storm water pollution. No analytical tests are required to be performed on these samples.

The examination of the sample must be made in well lit areas. The visual examination is not required if there is insufficient rainfall or snow-melt to runoff or if hazardous conditions prevent sampling. Whenever practicable the same individual should carry out the collection and examination of discharges throughout the life of the permit to ensure the greatest degree of consistency possible in recording observations. Grab samples for the examination shall be collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 1 hour) of when the runoff begins discharging. Reports of the visual examination include: the examination date and time, examination personnel, visual quality of the storm water discharge, and probable sources of any observed storm water contamination. The visual examination reports must be maintained on site with the pollution prevention plan.

When conducting a storm water visual examination, the pollution prevention team, or team member, should attempt to relate the results of the examination to potential sources of storm water contamination on the site. For example, if the visual examination reveals an oil sheen, the facility personnel (preferably members of the pollution prevention team) should conduct an inspection of the area of the site draining to the examined discharge to look for obvious sources of spilled oil, leaks, etc. If a source can be located, then this information allows the facility operator to immediately conduct a clean-up of the pollutant source, and/or to design a change to the pollution prevention plan to eliminate or minimize the contaminant source from occurring in the future.

To be most effective, the personnel conducting the visual examination should be fully knowledgeable about the storm water pollution prevention plan, the sources of contaminants on the site, the industrial activities conducted exposed to storm water and the day to day operations that may cause unexpected pollutant releases.

Other examples include; if the visual examination results in an observation of floating solids, the personnel should carefully examine the solids to see if they are raw materials, waste materials or other known products stored or used at the site. If an unusual color or odor is sensed, the personnel should attempt to compare the color or odor to the colors or odors of known chemicals and other materials used at the facility. If the examination reveals a large amount of settled solids, the personnel may check for unpaved, unstabilized areas or areas of erosion. If the examination results in a cloudy sample that is very slow to settle-out, the personnel should evaluate the site draining to the discharge point for fine particulate material, such as dust, ash, or other pulverized, ground, or powdered chemicals.

If the visual examination results in a clean and clear sample of the storm water discharge, this may indicate that no visible pollutants are present. This would be a indication of a high quality result, however, the visual examination will not provide information about dissolved contamination. If the facility is in a sector or subsector required to conduct analytical (chemical) monitoring, the results of the chemical monitoring, if conducted on the same sample, would help to identify the presence of any dissolved pollutants and the ultimate effectiveness of the pollution prevention plan. If the facility is not required to conduct analytical monitoring, it may do so if it chooses to confirm the cleanliness of the sample.

While conducting the visual examinations, personnel should constantly be attempting to relate any contamination that is observed in the samples to the sources of pollutants on site. When contamination is observed, the personnel should be evaluating whether or not additional BMPs should be implemented in the pollution prevention plan to address the observed contaminant, and if BMPs have already been implemented, evaluating whether or not these are working correctly or need maintenance. Permittees may also conduct more frequent visual examinations than the minimum quarterly requirement, if they so choose. By doing so, they may improve their ability to ascertain the effectiveness of their plan. Using this guidance, and employing a strong knowledge of the facility operations, EPA believes that permittees should be able to maximize the effectiveness of their storm water pollution prevention efforts through conducting visual examinations which give direct, frequent feedback to the facility operator or pollution prevention team on the quality of the storm water discharge.

EPA believes that this quick and simple assessment will help the permittee to determine the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. EPA recommends that the visual examination be conducted at different times than the chemical monitoring, but is not requiring this. In addition, more frequent visual examinations can be conducted if the permittee so chooses. In this way, better assessments of the effectiveness of the pollution prevention plan can be achieved. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examinations. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the site's storm water problems and the effects of the management practices that are included in the plan.

9. SARA Title III, Section 313 Facilities

Today's permit does not contain special monitoring requirements for facilities subject to the Toxic Release Inventory (TRI) reporting requirements under Section 313 of the EPCRA. EPA has reviewed data submitted by facilities in the group application and determined that storm water monitoring requirements are more appropriately based upon the industrial activity or significant material exposed than upon a facility's status as a TRI reporter under Section 313 of EPCRA. This determination is based upon a comparison of the data submitted by TRI facilities included in the group application process to data from group application sampling facilities that were not found on the TRI list. Table 6 summarizes the data comparison. The data indicate that there are no consistent differences in the level of water priority chemicals present in samples from TRI facilities when compared to the samples from facilities not subject to TRI reporting requirements.

EPA has included a revised Appendix A that lists 44 additional water priority chemicals that meet the definition of a section 313 water priority chemical or chemical categories requirements as defined by EPA in the permit under Part X, Definitions.

F. Numeric Effluent Limitations

1. Industry-specific Limitations

Part XI. of today's permit contains numeric effluent limitations for phosphate fertilizer manufacturing facilities, asphalt emulsion manufacturers, cement manufacturers, coal pile runoff from steam electric power generating facilities, and sand, gravel, and crushed stone quarries. These limitations are required under EPA's storm water effluent limitation guidelines in the Code of Federal Regulations at 40 CFR Part 418, Part 443, Part 411, Part 423, and Part 436. Parts VIII.C.6., VIII.D.5., VIII.E.6., and VIII.J.5. of this fact sheet discuss these limitations.

2. Coal Pile Runoff

Today's permit establishes effluent limitations of 50 mg/L total suspended solids and a pH range of 6.0–9.0 for coal pile runoff. Any untreated overflow from facilities designed, constructed, and operated to treat the volume of coal pile runoff associated with a 10-year, 24-hour rainfall event is not subject to the 50 mg/L limitation for total suspended solids. Steam electric generating facilities must comply with these limitations upon submittal of the NOI. EPA has adopted these technology-based pH limitations in today's general permit in accordance with setting limits on a case-by-case basis as allowed under 40 CFR 125.3 and Section 402 of the Clean Water Act. These case-by-case limits are derived by transferring the known achievable technology from an effluent guideline to a similar type of discharge. When developing these technology-based limitations, variables such as rainfall pH, sizes of coal piles, pollutant characteristics, and runoff volume were considered. Therefore, these variables need not be considered again. As discussed above, these pH limitations are technology-based and are not based on water quality. All other types of facilities must comply with this requirement as expeditiously as practicable, but in no event later than 3 years from the date of permit issuance.

The pollutants in coal pile runoff can be classified into specific types according to chemical characteristics. Each type relates to the pH of the coal pile drainage. The pH tends to be of an acidic nature, primarily as a result of the oxidation of iron sulfide in the presence of oxygen and water. The potential influence of pH on the ability of toxic and heavy metals to leach from coal piles is of particular concern. Many of the metals are amphoteric with regard to their solubility behavior. These factors affect acidity, pH, and the subsequent leaching of trace metals: concentration and form of pyritic sulfur in coal; size of the coal pile; method of coal preparation and clearing prior to storage; climatic conditions, including rainfall and temperature; concentrations of calcium carbonate and other neutralizing substances in the coal; concentration and form of trace metals in the coal; and the residence time of water in the coal pile.

Coal piles can generate runoff with low pH values, with the acid values being quite variable. The suspended solids levels can be significant, with levels of 2,500 mg/L not uncommon. Metals present in the greatest concentrations are copper, iron, aluminum, nickel, and zinc. Others present in trace amounts include chromium, cadmium, mercury, arsenic selenium, and beryllium[14].

G. Regional Offices

1. Notice of Intent Address

Notices of Intent to be authorized to discharge under this permit should be sent to: NOI/NOT Processing Center (4203), 401 M Street, S.W., Washington DC 20460.

2. Address for Other Submittals

Other submittals of information required under this permit or individu permit applications should be sent to the appropriate EPA Regional Office:

a. ME, MA, NH, Federal Indian Reservations in CT, MA, NH, ME, RI, and Federal Facilities in VT

EPA, Region I, Water Management Division, (WCP), Storm Water Sta JFK Federal Building, Boston, MA 02203

b. PR and Federal Facilities in PR

[14] A more complete description of pollutants in coal pile runoff is provided in the "Final Development Document for Effluent Limitations Guidelines and Standards and Pretreatment Standards for the Steam Electric Point Source Category," (EPA–440/1–82/029), EPA, November 1982.

R0016109

EPA, Region II, Water Management Division, (2WM-WPC), Storm Water Staff, 290 Broadway, New York, NY 10007–1866

c. DC and Federal Facilities in DC and DE

EPA, Region III, Water Management Division, (3WM55), Storm Water Staff, 841 Chestnut Building, Philadelphia, PA 19107

d. FL

EPA, Region IV, Water Management Division, Permits Section (WPEB-7), 345 Courtland Street, NE, Atlanta, GA 30365

e. LA, NM, OK, and TX and Federal Indian Reservations in LA, NM (Except Navajo and Ute Mountain Reservation Lands), OK, and TX

EPA, Region VI, Enforcement and Compliance Assurance Division, (6EN-WC), EPA SW MSGP, First Interstate Bank Tower at Fountain Place, P.O. Box 50625, Dallas, TX 75205

f. AZ, Johnston Atoll, Midway Island, Wake Island, all Federal Indian Reservations in AZ, CA, and NV; those portions of the Duck Valley, Fort McDermitt, and Goshute Reservations that are outside NV; those portions of the Navajo Reservation that are outside AZ; and Federal facilities in AZ, Johnston Atoll, Midway Island, and Wake Island.

EPA, Region IX, Water Management Division, (W–5–3), Storm Water Staff, 75 Hawthorne Street, San Francisco, CA 94105

g. ID, OR, and WA; Federal Indian Reservations in AK, ID (except the Duck Valley Reservation), OR (except the Fort McDermitt Reservation), and WA; and Federal facilities in ID, and WA

EPA, Region X, Water Division, (WD-134), Storm Water Staff, 1200 Sixth Avenue, Seattle, WA 98101

H. Compliance Deadlines

For most permittees, today's permit imposes a deadline of 270 days following date of publication of this permit for development of pollution prevention plans and for compliance with the terms of the plan.

Today's general permit provides additional time if constructing structural best management practices is called for in the plan. The portions of a plan addressing these BMP construction requirements must provide for compliance with the plan as soon as practicable, but in no case later than 3 years from the effective date of the permit. However, storm water pollution prevention plans for facilities subject to these additional requirements must be prepared within 270 days of the date of publication of this permit and provide for compliance with the baseline terms and conditions of the permit (other than the numeric effluent limitation) as expeditiously as practicable, but in no case later than 270 days after the publication date of this permit.

Facilities are not required to submit the pollution prevention plans for review unless they are requested by EPA or by the operator of a large or medium municipal separate storm sewer system. When a plan is reviewed by EPA, the Director can require the permittee to amend the plan if it does not meet the minimum permit requirements.

VII. Cost Estimates for Common Permit Requirements

The conditions of today's general permit reflects the baseline permit requirements established in EPA's NPDES permits for Storm Water Discharges Associated With Industrial Activity (57 FR 41175 and 57 FR 44412). The requirements found under today's permit are more specific to the conditions found in the industries. EPA does not consider these requirements to be more costly than the pollution prevention plan requirements established in the baseline general permit. The following section contains the estimates of the cost of compliance with the baseline permit requirements.

A. Pollution Prevention Plan Implementation

Storm water pollution prevention plans for the majority of facilities will include relatively low cost baseline controls. EPA's analysis of storm water pollution prevention plans indicates that the cost of developing and implementing these plans is variable and will depend on a number of the following factors: the size of the facility, the type and amount of significant materials stored or used at a facility, the nature of the plant operations, the plant designs (e.g., the processes used and layout of a plan), and the extent to which housekeeping measures are already employed. Table 7 provides estimates of the range of costs for preparing and implementing the common requirements for a storm water pollution prevention plan. It is expected that the low cost estimates provided in Table 7 are appropriate for the majority of smaller facilities. The high cost estimates in Table 7 are more applicable to larger, more complex facilities with more potential sources of pollutants. Please note that the costs in this table exclude special requirements, such as EPCRA 313 requirements. EPA estimated the cost of preparing a storm water pollution prevention plan for a hypothetical small business in the automobile salvage yard industry. Based on experience and best professional judgment, EPA estimates that a typical small automobile salvage yard would face a one-time cost of about $874. This cost is lower than the low end of the cost estimate provided in Table 7 because it is based on a particular (though hypothetical) small business. Table 7 estimates are based on what EPA expects are appropriate for the majority of small facilities. Some facilities are likely to face lower costs, such as the hypothetical small automobile junk yard, and other facilities are likely to face higher costs.

The cost of compliance, monitoring and preparing the PPP for the multi-sector permit are not high when compared to the site-specific requirements to comply with an individual permit. The Clean Water Act does not give EPA the authority to exempt permitted facilities from requirements designed to improve the quality of the nation's waters. The economic ability of small businesses to comply with this permit can be a factor to consider if water quality concerns are not applicable to the surface water body receiving the storm water discharge.

The operators of regulated storm water discharges have to consider the economic effects of coverage under the multi-sector permit, the baseline general permit, or an individual NPDES permit. Coverage under either of the two general permits is not required by EPA. The NPDES regulations give EPA the authority to require coverage under an individual NPDES permit, not general permits. A facility's decision to be covered under a general permit is voluntary. Individual permits can require numerical limits and more frequent monitoring and reporting, along with the development and implementation of SWPPPs. The burden of developing an SWPPP is controlled by the facility's ability to achieve the permits goal: reduce or eliminate the discharge of pollutants to the nation's waters.

TABLE 7.—SUMMARY OF ESTIMATED RANGES OF COSTS FOR COMPLIANCE WITH STORM WATER POLLUTION PREVENTION PLANS WITH BASELINE REQUIREMENTS

	Low costs		High costs	
	First year costs	Annual costs	First year costs	Annual costs
Submittal of NOI	$14		$14	
Notification of Municipality	14		14	
Plan Preparation	1,518		76,153	
Plan Implementation	90	294	35,400	9,371
Comprehensive Site Compliance Evaluation/Plan Revision		267		8,875
Reportable Quantities	(1) No Costs		8,501	
Total	1,636	561	120,082	18,246

This table identifies estimated low and high costs (in 1992 dollars) to develop and implement storm water pollution prevention plans.
Low costs of implementing program components are zero where existing programs or procedures is assumed adequate.
The estimated costs for plan preparation and plan revisions includes costs of preparing/revising plan to address baseline requirements. However, the costs of implementing special requirements, such as those for EPCRA Section 313 facilities coal piles and salt piles are not otherwise addressed in this table.

B. Cost Estimates for EPCRA Section 313

Table 8 provides estimates of the range of costs of preparing and implementing a storm water pollution prevention plan for facilities subject to the special requirements for facilities subject to EPCRA Section 313 reporting requirements for chemicals classified as "Section 313 water priority chemicals." EPA expects the majority of facilities to have existing containment systems that meet the majority of the requirements of this permit. High cost estimates correspond to facilities that are expected to be required to undertake some actions to upgrade existing containment systems to meet the requirements of this permit.

TABLE 8.—SUMMARY OF ESTIMATED ADDITIONAL COSTS FOR COMPLIANCE WITH STORM WATER POLLUTION PREVENTION PLANS FOR FACILITIES SUBJECT TO SECTION 313 OF EPCRA FOR WATER PRIORITY CHEMICALS

	Low costs		High costs	
	Costs during first 3 years	Annual costs	Costs during first 3 years	Annual costs
Plan Preparation	$630		0	
Liquid Storage Areas			$11,200	
Material Storage Areas			560	
Loading Areas			21,000	
Process Areas			11,190	
Drainage/Runoff			7,750	
Housekeeping/Maintenance				
Facility Security				$5,957
Employee Training			3,240	
Toxicity Reduction				1,403
				3,046
Totals	630	$0	54,940	10,406

This table identifies estimated additional low and high costs to develop and implement storm water pollution prevention plans for EPCRA Section 313 facilities subject to special conditions.
Low costs of implementing program components are zero where existing programs, procedures or security is assumed adequate.
The high costs for preparing pollution prevention plans to include EPCRA Section 313 additional requirement were addressed as part of the estimated high costs for preparation of baseline pollution prevention plans (see Table 7).

C. Cost Estimates for Coal Piles

The effluent limitations for coal pile runoff in the permit can be achieved by these two primary methods: limiting exposure to coal by use of covers or tarpaulins and collecting and treating the runoff. In some cases, coal pile runoff may be in compliance with the effluent limitations without covering of the pile or collection or treatment of the runoff. In these cases, the operator of the discharge would not have a control cost.

The use of covers or tarpaulins to prevent or minimize exposure of the coal pile to storm water is generally expected to be practical only for relatively small piles. Coal pile covers or tarpaulins are anticipated to have a fixed cost of $400 and annual cost of $160.

Table 9 provides estimates of the costs of treating coal pile runoff.[15] These costs are based on a consideration of a treatment train requiring equalization, pH adjustment, and settling, including the costs for impoundment (for equalization), a lime feed system and mixing tanks for pH adjustment, and a clarifier for settling. The costs for the

[15] The type and degree of treatment required to meet the effluent limitations of this permit vary depending on factors such as the amount of sulfur in the coal. This section describes a model treatment scheme for estimating costs for compliance with the effluent limitations. Dischargers may implement other less expensive treatment approaches to enable them to discharge in accordance with these limits where appropriate.

impoundment area include diking and containment around each coal pile and associated sumps and pumps and piping from runoff areas to the impoundment area. The costs for land are not included. The lime feed system employed for pH adjustment includes a storage silo, shaker, feeder, and lime slurry storage tank, instrumentation, electrical connections, piping, and controls.

Additional costs may be incurred if a polymer system is needed. In this case, costs would include impoundment for equalization, a lime feed system, mixing tank, and polymer feed system for chemical precipitation, a clarifier for settling, and an acid feeder and mixing tank to readjust the pH within the range of 6 to 9. The equipment and system design, with the exception of the polymer feeder, acid feeder, and final mixing tank, are essentially the same as shown in Table 9. Two tanks are required for a treatment train with a polymer system, one for precipitation and another for final pH adjustment with acid. The cost of mixing is therefore twice that shown in Table 9. The polymer feed system includes storage hoppers, chemical feeder, solution tanks, solution pumps, interconnecting piping, electrical connections, and instrumentation. The costs of clarification are identical to that of Table 9. A treatment train with a polymer system requires the use of an acid addition system to readjust the pH within the range of 6 to 9. The components of this system include a lined acid storage tank, two feed pumps, an acid pH control loop, and associated piping, electrical connections, and instrumentation.

Additional information regarding the cost of these technologies can be found in "Development Document for Effluent Limitations Guidelines and Standards and Pretreatment Standards for the Steam Electric Point Source Category," (EPA-440/182/029), November 1982, EPA.

TABLE 9.—SUMMARY OF ESTIMATED COSTS FOR TREATMENT OF COAL PILE RUNOFF

	30,000 cubic meter coal pile	120,000 cubic meter coal pile
IMPOUNDMENT:		
Installed Capital Cost	6,850	6,850
Operation and Maintenance ($/year)	Negligible	Negligible
LIME FEED SYSTEM:		
Installed Capital Cost ($)	138,800	255,700
Operation and Maintenance ($/year)	5,780	10,655
Energy Requirements (kwh/yr)	3.6x10**4	3.6x10**4
Land Requirements (ft**2)	5,000	5,000
MIXING EQUIPMENT:		
Installed Capital Cost ($)	65,750	91,320
Operation and Maintenance ($/year)	2,280	2,430
Energy Requirements (kwh/yr)	1.3x10**3	3.3x10**3
Land Requirements (ft**2)	2,000	2,000
CLARIFICATION:		
Installed Capital Cost ($)	182,650	237,450
Operation and Maintenance ($/year)	3,200	3,650
Energy Requirements (kwh/yr)	1.3x10**3	3.3x10**3
Land Requirements (acres)	0.1	0.1

Source: "Development Document for Effluent Limitations Guidelines and Standards and Pretreatment Standards for the Steam Electric Point Source Category" (EPA-440/182/029), November 1982, EPA). Costs estimates are in 1992 dollars.

D. Cost Estimates for Salt Piles

Salt pile covers or tarpaulins are anticipated to have a fixed cost of $400 and an annual cost of $160 for medium-sized piles and a fixed cost of $4,000 and an annual cost of $2,000 for very large piles. Structures such as salt domes are generally expected to have a fixed cost of between $30,000 for small piles ($70 to $80 per cubic yard) and $100,000 for larger piles ($18 per cubic yard) with costs depending on size and other construction parameters.

VIII. Special Requirements for Discharges Associated With Specific Industrial Activities

The industry-specific requirements allow the implementation of site-specific measures that address features, activities, or priorities for control associated with the identified storm water discharges. This framework provides the necessary flexibility to address the variable risk for pollutants in storm water discharges associated with the different types of industrial activity addressed by this permit. This approach also assures that facilities have the opportunity to identify procedures to prevent storm water pollution at a particular site that are appropriate, given processes employed, engineering aspects, functions, costs of controls, location, and age of the facility (as contemplated by 40 CFR 125.3). The approach taken also allows the flexibility to establish controls that can appropriately address different sources of pollutants at different facilities.

A. Storm Water Discharges Associated With Industrial Activity From Timber Products Facilities

1. Discharges Covered Under This Sector

Eligibility for coverage under this section is limited to those facilities in the lumber and wood products industry (primary SIC Major Group is 24), except wood kitchen cabinets manufacturers (SIC Code 2434). Permit conditions for facilities in the wood kitchen cabinets manufacturers industry (SIC Code 2434) are discussed in the wood and metal furniture and fixture manufacturing sector (Part XI.W of today's permit). SIC Major group 24 represents those "establishments engaged in cutting timber and pulpwood, merchant sawmills, lath mills, shingle mills, cooperage stock mills, planing mills, and plywood and veneer mills engaged in producing lumber and wood basic materials; and establishments engaged in wood preserving or in manufacturing finished articles made entirely of wood or related materials." [16]

[16] "Handbook of Standard Industrial Classifications," Office of Management and Budget, 1987.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

Wood kitchen cabinet facilities (SIC Code 2434) are excluded from coverage under this section because EPA believes it is more appropriate to cover manufacturers of wood cabinets with furniture manufacturing facilities (SIC Major group 25). As indicated in the November 16, 1990, **Federal Register** (55 FR 48008), "Facilities under SIC Code 2434 and 25 are establishments engaged in furniture making." EPA believes that this grouping is more appropriate due to the typical use by cabinet makers of wood treating solutions such as mineral spirits and propenyl butyl.[17] This practice is common to wood furniture manufacturing, but is atypical of the other industrial operations performed at facilities in the lumber and wood products industry (SIC Major group 24).

Certain silvicultural activities are not required to be covered under National Pollutant Discharge Elimination System (NPDES) storm water permits (40 CFR 122.27). In accordance with 40 CFR 122.27(b), point sources that must be covered by an NPDES permit are "any discernible, confined and discrete conveyance related to rock crushing, gravel washing, log sorting, or log storage facilities, which are operated in connection with silvicultural activities and from which pollutants are discharged into waters of the United States." Discharges from nonpoint source silvicultural activities, including harvesting operations (see 40 CFR 122.27) are not required to be covered.

It is EPA's determination harvesting activities include: the felling, skidding, preparation (e.g., delimbing and trimming), loading and initial transport of forest products from an active harvest site. An active harvest site is considered to be an area where harvesting operations are actually on-going. EPA also interprets the definition of harvesting operations to include incidental stacking and temporary storage of harvested timber on the harvest site prior to its initial transport to either an intermediate storage area or other processing site. EPA considers this activity to be an inherent part of harvesting operations. However, EPA does not intend the definition of active harvesting operations to include sites that are processing, sorting, or storing harvested timber which has been transported there from one or more active harvesting sites. Consequently, EPA considers these site activities a point source under 40 CFR 122.27(b)(1) and operators of these sites must seek an NPDES permit for discharges of storm water.

Effluent guidelines have been promulgated for the Timber Products Processing Point Source Category at 40 CFR Part 429 (46 FR 8260; January 26, 1981). Under these regulations, effluent limitations and standards were set for process wastewaters from any timber products processing operation, and any plant producing insulation board with wood as the major raw material. The definition of process wastewater excluded "noncontact cooling water, material storage yard runoff (either raw material or processed wood storage) and boiler blowdown. For the dry process hardboard, veneer, finishing, particleboard, and sawmills and planing mills subcategories, fire control water is excluded from the definition." Any discharge subject to an effluent limitation guideline is not eligible for coverage under this section. Even though discharges of boiler blowdown and noncontact cooling water are not considered "process water discharges," they do not fall under the definition of storm water discharges. As such, this section does not provide for their coverage. In addition, contact cooling waters and water treatment wastewater discharges from steam operated sawmills will not be covered. Finally, material storage yard runoff, exempted from coverage under the effluent limitation guidelines, is eligible to be covered in accordance with the terms and conditions of this section.

In addition, it should be noted that certain wood preserving wastes have been listed under 40 CFR 261.31 as hazardous wastes from nonspecific sources (55 FR 50450; December 6, 1990). Storm water discharges that come in contact and/or commingle with these wastes will be considered a hazardous waste and will not be authorized for discharge under this section. Despite the listing of these wastes, however, there remains a potential for storm water to become contaminated through incidental activities such as tracking of materials, fugitive emissions, and miscellaneous other activities. These discharges are covered under today's permit. Wastewaters, process residuals, preservative or protectant drippage, and spent formulations from wood preserving processes that use chlorophenolic formulations, creosote formulations, or arsenic and chromium formulations have been listed as hazardous wastes. Wastes from wood surface protection were proposed for listing under this subpart (53 FR 53282; December 30, 1988, and 58 FR 25706; April 27, 1993) but listing the wastes was determined unnecessary in a subsequent rulemaking (59 FR 458; January 4, 1994). Storm water discharges containing these wastes are therefore covered under today's permit.

2. Industry Profile/Description of Industrial Activities

Facilities engaged in activities classified under SIC Major Group 24 use wood as their primary raw material. Although there is diversity among the types of final products that are produced at timber products facilities, there are common industrial activities performed among them. These activities are broadly classified for ease of discussion and include the following: log storage and handling; untreated wood lumber and residue generation activities, and untreated wood materials storage; wood surface protection activities, and chemicals and surface protected materials storage; wood preservation activities, and chemicals and preserved wood material storage; wood assembly/fabrication activities and final fabricated wood product storage; and equipment/vehicle maintenance, repair and storage.

In many cases, more than one of these activities may be conducted at a single facility location.

a. Log Storage and Handling. Log storage and handling activities may occur onsite at many types of facilities covered under this section of today's permit, such as wood collection yards and lumber processing and veneer manufacturing facilities. However, facilities that are primarily engaged in these activities (e.g., wood collection yards) are most appropriately classified under SIC Code 2411.

Typical industrial activities performed include loading and unloading of logs onto trucks or railroad cars for transport to other facilities, log

[17] Part 1 Storm Water Group Permit Applications. Summaries from individual applicant descriptions including Applicant No. 1156 (Westvaco), Applicant No. 92 (Bowater), and Applicant No. 866 (Louisiana-Pacific).

sorting, and storage of logs. In addition, some cutting may be performed such as chopping off tree branches and sectioning of tree trunks for easier handling during transport. Although not typically performed at wood collection facilities, chipping may be performed at facilities serving pulp industries. Residues generated at these sites may include bark, coarse sawdust, and wood chunks.

Significant materials that have the potential to come in contact with storm water discharges at facilities practicing these activities include: uncut logs (hardwood and softwoods), wood bark, wood chips, coarse saw dust, other waste wood material, petroleum and other products for equipment maintenance (fuels, motor oils, hydraulic oils, lubricant fluids, brake fluids, and antifreeze), herbicides, pesticides, and fertilizers, material handling equipment (forklifts, loaders, vehicles, chippers, debarkers, cranes, etc.).

These log storage and handling activities described above have the potential to discharge pollutants including bark and wood debris, total suspended solids (TSS), and leachates.[18] The leachate generated from these operations from the decay of wood products can contain high levels of TSS and biochemical oxygen demand (BOD_5).[19]

b. Untreated Wood Lumber and Residue Generation Activities and Untreated Wood Materials Storage. The primary product from sawmills and other cutting activities is lumber. However, residues such as debarked wood chips; whole tree chips and slab wood; bark; and sawdust constitutes approximately 25 percent of the total wood production.[20] At large saw mills, approximately 2,500 lbs of residue is generated for each 1,000 board feet of lumber derived.[21]

Facilities that produce untreated lumber and residues can be classified under most of the SIC Codes in Major group 24. These facilities include saw mill and planing mill facilities classified in group 242; millwork, veneer, plywood and structural wood member manufacturing facilities classified in group 243; wood container manufacturing facilities in group 244; wood building and mobile home manufacturing facilities in group 245; and miscellaneous wood product manufacturers in group 249.

These facilities may engage in one or more activities such as log washing, bark removal, milling, sawing, resawing edging, trimming, planing, machining, air drying, and kiln drying. In addition, there may be associated boiler operations, loading and unloading activities and storage activates.

Effluent guidelines have been established at 40 CFR Part 429 Subparts A, I, and J for discharges from log washing, debarking and wet storage, respectively. These discharges are considered process waters and are subject to the effluent limitations of each subpart.

Some facilities generate residue as a product, in lieu of lumber or other finished products, while other facilities may generate residues as a waste product. In most cases, there are markets for these residues. For example, chips and sawdust are used in the production of pulp and paper and wood products manufacturing. A summary of the residues generated and their potential uses include: bark (used in landscaping, compost, recreational applications (trails), energy recovery); wood chips (used in pulp and paper mill feed, landscaping, recreational applications, fire logs, energy recovery); planer shavings (used in particle board, livestock bedding, compost, fire logs, domestic pet litter, energy recovery); and sawdust (used in particle board, livestock bedding, compost, fire logs, domestic pet litter, energy recovery.)[22]

Storage activities at these sites include wet and dry storage of logs and storage of residuals. Wet storage, called "wet decking," is a process used when logs are to be stored for an extended period of time. Wet storage retards decaying and infestation by insects. The logs may be stored under water in ponds or may be placed in areas where water is continuously sprayed over them. Residuals are typically stored dry.

Storm water discharges from lumber and residue generation and storage may come in contact with the following types of wastes and/or materials at the facility which can then contribute pollutants to the storm water: uncut logs (hardwood and softwoods), wood bark, wood chips, wood shavings, sawdust, green lumber, rough and finished lumber, other waste wood material, nonhazardous wood ash, above and below ground fuel storage tanks for diesel, gasoline, propane and fuel oil, finishing chemicals (stain, lacquer, varnish, paints, water repellant, sealants), solvents and cleaners, petroleum and other products for equipment maintenance (fuels, motor oils, hydraulic oils, lubricant fluids, brake fluids, and antifreeze), herbicides, pesticides, and fertilizers, sawmill equipment, material handling equipment (Forklifts, loaders, vehicles, chippers, debarkers, cranes, etc.), boiler water treatment chemicals, scrap metals, scrap equipment and plastics, boiler blowdown water, and leachate from decaying organic matter.

Pollutants resulting from lumber and residue generation and storage activities are typically conventional in nature. Low pH levels can result from the leachate of decaying organic materials. TSS and BOD_5 may be elevated in this leachate.[23] In addition to leachate, washed away residue particles contribute to TSS loadings. Equipment and machinery at the facility site may result in the discharge of oil and grease.

c. Wood Surface Protection Activities, Chemicals and Surface Protected Materials Storage. At many hardwood saw mills, wood surface protection is conducted to prevent sap stain. Sap stain is the unsightly discoloration of lumber products caused by fungus.[24] Surface protection is a cosmetic fix only and differs from wood preservation which is a practice designed to enhance the wood's structural integrity.

Surface protection is accomplished by one of three methods: spraying, ranging from manual spraying with a garden hose to more sophisticated on-line high pressure spray boxes; dipping, a batch process where lumber is immersed then removed from the formulation; and green chain operations, a continuous immersion operation where lumber is pulled through the protection tanks by conveyer.[25]

Historically, the primary chemical used in surface protection has been commercial pentachlorophenate. Concentrated chemicals are diluted to 0.5 to 1 percent pentachlorophenol for surface protection. This concentration is lower than the 2 percent to 9 percent pentachlorophenol used in wood

preserving. Producers of chlorophenolic formulations used in surface protection have recently discontinued the product due to the pending hazardous waste regulations and it is expected that stocks will soon be exhausted. Alternatives to pentachlorophenate solutions which have been developed and are currently used include: iodo-prophenyl butyl carbamate, dimethyl sulfoxide, didecyl dimethyl ammonium chloride mixtures; sodium azide mixtures; iodo-prophenyl butyl carbamate, didecyl dimethyl ammonium chloride mixture; 8-quinolinol, copper (II) chelate mixtures; iodo-prophenyl butyl carbamate mixtures; sodium ortho-phenylphenate mixtures; 2-(thiocyanomethylthio)-benzothiozole (TCMTB) and methylene bis (thiocyanate) mixture; and zinc naphthenate mixtures.[26]

Industrial activities at saw mills with the potential to contaminate storm water include spills from surface protection areas, storage and mixing tank areas, treated wood drippage, transport or storage areas, maintenance and shop areas, and areas used for treatment/disposal of wastes. Fugitive emissions from negative pressure spraying activities and hand spraying surface protection formulations may also result in the contamination of storm water.[27]

Significant materials that have the potential to come in contact with storm water discharges at facilities practicing these activities include: all of the materials stated in 3.b. above (under untreated wood lumber and residue generation activities and untreated materials storage) plus treated lumber, treatment chemicals, and treatment equipment (dipping tanks, green chain, material handling equipment, etc.).

Pollutants which result from these types of surface protection operations may include the constituents of those surface protection chemicals listed above, as well as aggregate parameters such as BOD_5, COD, and TSS.

d. Wood Preservation Activities, and Chemicals and Preserved Wood Material Storage. Wood preserving is the application of chemicals to wood and wood products to preserve the structural integrity of the wood. Wood preserving is designed to prevent/delay the deterioration/decay of wood through the addition of flame retardants, water repellents, and chemicals. Wood preserving differs from wood surface protection which is generally performed for aesthetic reasons.[28]

Wood preserving is accomplished by two steps. First, the moisture content of wood is reduced to increase its permeability (this is referred to as conditioning). Conditioning may be accomplished by: (1) allowing wood to dry at ambient temperatures; (2) kiln drying; (3) steaming the wood, then applying a vacuum; (4) dipping the wood in a heated salt bath; or (5) vapor drying, and immersing the wood in a solvent (usually naphtha or Stoddard solvent). After conditioning, wood is impregnated with a preservative for fire retardency, insecticidal resistance, and/or fungicidal resistance. Preservation may be accomplished by either nonpressurized and pressurized methods. The nonpressurized method involves dipping stock in a bath containing the preservatives (either heated or at ambient temperatures), while pressurized methods involve subjecting the wood to the preservative when under pressure. After treatment, the wood stock is often subject to cleaning in order to remove excess preservative prior to stacking treated lumber products outside.[29]

There are a number of different avenues by which wood preserving wastes may contaminate storm water. These may include: drippage of condensate or preservative after pressurized treatment; washing after preservation to remove excess preservative, which usually occurs either in the treatment or storage areas; spills and leaks from process equipment and preservative tanks; fugitive emissions from vapors in the process, as well as blow outs and emergency pressure releases; and kick-back (phenomenon where preservative leaks as it returns to normal pressure) from the lumber.[30]

A wide variety of chemicals are used in the preservation of wood, the most common are creosote, pentachlorophenol and inorganics.

Creosote-based preservatives are mixtures of coal-tar derivatives and creosote solutions (creosotes fortified with insecticide additives such as pentachlorophenol, arsenic trioxide, copper compounds or malathion). Pentachlorophenol preservatives are typically formulations using petroleum solvents and 5 percent total pentachlorophenol. Waxes and resins may also be added.[31] Inorganic preservatives consist of arsenical and chromate salts and fluorides dissolved in water. The most commonly used inorganic preservatives include:[32] chromated copper arsenate (CCA); ammoniacal copper arsenate (ACA); acid copper chromate (ACC); chromated zinc chloride (CZC); and fluor-chrome-arsenate-phenol (FCAP).

Significant materials that have the potential to come in contact with storm water discharges at facilities practicing wood preservation include: all of the materials stated in 3.b. (untreated wood lumber and residue generation activities and untreated wood materials storage) plus treated lumber, treatment chemicals, and treatment equipment (preservative, tanks, preservative contaminated material handling equipment).

Pollutants expected to be discharged from wood preserving facilities typically include conventional pollutants such as BOD_5, TSS and oil and grease, as well as toxics which are dependent upon the preserving formulations used. Organic solvent components such as benzene, toluene, xylene, and ethylbenzene can be found at pentachlorophenol preservation operations. Phenolic compounds such as phenol, chlorophenols, nitrophenols can be found at plants using pentachlorophenol and creosote preservatives. The polynuclear aromatic hydrocarbons of creosote, including anthracene, pyrene, and phenanthrene are often contained in the entrained oils. High phenolic, COD, and oil and grease concentrations have been noted to result from creosote and pentachlorophenol operations. Traces of copper, chromium, arsenic, zinc, and boron often can be found in the wastewaters of plants which use waterborne salt preservatives.[33]

e. Wood Assembly/Fabrication Activities and Final Fabricated Wood Product Storage. The industrial

activities conducted as part of the assembly and fabrication process are very diverse. For the most part, industrial activities that have the potential to come in contact with precipitation are similar to those described under lumber and residue generation (see Section A.3.b). However, there are a number of additional industrial activities that differ. For example, the fabrication of fiberboard, insulation board, and hardboard may involve the use of wax emulsions, paraffin, aluminum sulfate, melamine formaldehyde, and miscellaneous thermosetting resins. These chemicals may be introduced as part of the board formation process or as a coating to maintain the board's integrity. Generally, these additives account for less than 20 percent of the board. In the formation of fiberboard/insulation board/hardboards, the digestion of pulp and fiber by mechanical, thermal, and sometimes chemical means takes place.[34] Another operation which involves resinous agents is the formation of veneer. In this process, veneer is placed in hot ponds or vats to soften the wood. Veneer strips are removed and often bound by glue or a resinous agent. Glues are also used in the assembly of wood components.[35] Other types of activities include the finishing of wood products. Stains, paints, lacquers, varnish, water repellents and sealants, etc. may be applied to some of the wood products. Many of these materials may not have the potential to come in contact with precipitation as most of these processes are performed within a covered area or building.

Pollutants expected to be found in storm water discharges at facilities that perform these types of industrial activities include BOD_5 and TSS. Oil and grease may be present due to material handling equipment and transport vehicles.

f. Equipment/Vehicle Maintenance, Repair and Storage. Many of the facilities included in the SIC Major group 24 employ the use of material handling equipment, vehicles and other machinery. These facilities store the equipment onsite and may also engage in maintenance and repair activities on them. These types of activities are performed in either covered or outdoor areas of the facility. Associated with these activities is the storage of significant materials such as petroleum products and other maintenance fluids such as fuels, motor oil, hydraulic oils, lubricant fluids, brake fluids, solvents, cleaners and antifreeze.

3. Pollutants Contributing to Storm Water Contamination

Based on the wide variety of industrial activities and significant materials at the facilities included in this sector, EPA believes it is appropriate to divide the timber products industry into subsectors to properly analyze sampling data and determine monitoring requirements. As a result, this sector has been divided into the following subsectors: general saw mills and planning mills; wood preserving; log storage and handling; and hardwood dimension and flooring mills, special products saw mills, millwork, veneer, plywood and structural wood, wood containers, wood buildings and mobile homes, reconstituted wood products and wood products not elsewhere classified. Tables A–1 through A–4 below include data for the eight pollutants that all facilities were required to monitor for under Form 2F. The tables also lists those parameters that EPA has determined may merit further monitoring.

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.
[ii] Composite samples.

The descriptions of industrial activities and significant materials exposed submitted by the group applicants in the wood preserving subsector indicated that these facilities has a high potential to discharge wood preservatives in their storm water discharge. These preservatives typically contain copper and arsenic compounds. The monitoring data which was statistically analyzed for the wood treatment indicated the presence of both arsenic and copper in the discharges. However, data from only eight facilities had been submitted in time for EPA to perform a statistical analysis. EPA, therefore reviewed additional data submitted by wood preserving facilities,and found that copper was present in concentrations greater than the benchmark value in 22 out of 34 observations. Arsenic was higher than bench mark in 12 out of 34 observations.

4. Options for Controlling Pollutants

There are three options for controlling pollutants at timber products facilities: source reduction, best management practices (BMPs), and/or end-of-pipe treatment. In evaluating the options for controlling pollutants in discharges of storm water associated with industrial activity, EPA must provide for compliance with the Best Available Technology Economically Achievable (BAT) and Best Conventional Pollutant Control Technology (BCT) requirements of Section 402(p)(3) of the Clean Water Act. The variabilities in both the industrial activities performed on a specific site and the storm water discharges from timber product facilities, coupled with the lack of sufficient characterization data make it infeasible to develop effluent limitations at this point in time. EPA believes that enabling the owner/operator of the facility to develop BMPs based on site-specific factors such as facility size, industrial activities performed, climate, geographic location, hydrogeology and the environmental setting of each facility will provide the flexibility needed to address appropriate controls to meet the BAT/BCT requirements. Development of a storm water pollution prevention plan that addresses exposure minimization BMPs, will be required for all facilities that discharge storm water from timber product facilities. EPA believes that exposure minimization BMPs will provide appropriate levels of control for pollutants in storm water discharges while allowing relatively inexpensive BMPs to be implemented.

In some instances, however, more labor and resource intensive structural controls such as sedimentation ponds may be appropriate. EPA believes that the BMPs discussed below will help provide a sufficient level of control for the types of pollutants found in discharges associated with timber product facilities.

In developing these industry-specific BMPs both the part 1 application data for facilities that sampled were reviewed, as well as industry-specific literature sources. The BMPs provided are separated into those most appropriate for certain areas of a site where pollutants may be released such as: log, lumber, and other wood product storage areas; residue storage areas; loading and unloading and material handling areas: chemical storage areas: and equipment/vehicle maintenance, storage and repair areas. These types of activities can be found at all types of timber product facilities. Table A–5 provides a summary of the effective practices for the control of pollutants for all timber product facilities.

TABLE A–5.—EFFECTIVE POLLUTANT CONTROL OPTIONS FOR ALL TIMBER PRODUCT FACILITIES

Activity	Associated BMPs
Log, Lumber, and Other Wood Product Storage Areas.	Divert storm water around storage areas with ditches, swales and/or berms.
	Locate storage areas on stable, well-drained soils with slopes of 2–5 percent.
	Line storage areas with crushed rock or gravel or porous pavement to promote infiltration, minimize discharge and provide sediment and erosion control.
	Stack materials to minimize surface areas of materials exposed to precipitation.
	Practice good housekeeping measures such as frequent removal of debris.
	Provide collection and treatment of runoff with containment basins, sedimentation ponds and infiltration basins.
	Use ponds for collection, containment and recycle for log spraying operations.
	Use of silt fence and rip rap check dams in drainage ways.
Residue Storage Areas	Locate stored residues away from drainage pathways and surface waters.
	Avoid contamination of residues with oil, solvents, chemically treated wood, trash, etc.
	Limit storage time of residues to prevent degradation and generation of leachates.
	Divert storm water around residue storage areas with ditches, swales and/or berms.
	Assemble piles to minimize surface areas exposed to precipitation.
	Spray surfaces to reduce windblown dust and residue particles.
	Place materials on raised pads of compacted earth, clay, shale, or stone to collect and drain runoff.
	Cover and/or enclose stored residues to prevent contact with precipitation using silos, van trailers, shed, roofs, buildings or tarps.
	Limit slopes of storage areas to minimize velocities of runoff which may transport residues.
	Provide collection and treatment of runoff with containment basins, sedimentation ponds and infiltration basins.
	Use of silt fence and rip rap check dams in drainage ways.
Loading and Unloading and Material Handling Areas.	Provide diversion berms and dikes to limit runon.
	Cover loading and unloading areas.
	Enclose material handling systems for wood wastes.
	Cover materials entering and leaving areas.
	Provide good housekeeping measures to limit debris and to provide dust control.
	Provide paved areas to enable easy collection of spilled materials.
Chemical Storage Areas	Provide secondary containment around chemical storage areas.
	Provide fluid level indicators.
	Inventory of fluids to identify leakage.
	Locate storage areas away from high traffic areas and surface waters.
	Develop spill prevention, containment and countermeasure (SPCC) plans and implement.
	Cover and/or enclose chemical storage areas.
	Provide drip pads to allow for recycling of spills and leaks.

Wood surface protection and preserving facilities should consider additional controls for their storm water discharges because of the types of pollutants which may contaminate the discharges. Therefore, Table A–6 contains a summary of effective practices for the control of pollutants from timber product facilities that treat their wood. These BMPs are to be considered in conjunction with BMPs in Table A–5.

TABLE A–6.—ADDITIONAL EFFECTIVE POLLUTANT CONTROL OPTIONS FOR TIMBER PRODUCT FACILITIES THAT SURFACE PROTECT OR PRESERVE

Activity	Associated BMPs
Wood surface protection and preserving activities.	Extend drip time in process areas before moving to storage areas.
	Pave and berm areas used by equipment that has come in contact with treatment chemicals.
	Dedicate equipment that is used for treatment activities to that specific purpose only to prevent the tracking of treatment chemicals to other areas on the site.
	Locate treatment chemical loading and unloading areas away from high traffic areas where tracking of the chemical may occur.
	Provide drip pads under conveyance equipment from treatment process areas.
	Provide frequent visual inspections of treatment chemical loading and unloading areas during and after activities occur to identify any spills or leaks needing clean-up.
	Cover and/or enclose treatment areas.
	Provide containment in treated wood storage areas.
	Cover storage areas to prevent contact of treated wood products with precipitation.
	Elevate stored, treated wood products to prevent contact with runon/runoff.

Control of sediments leaving the site should also be considered by timber product facilities as sediments contribute to the total suspended solids in the storm water discharges. There are several areas of the site that may be prone to erosion due to intense industrial activities. These areas include, but are not limited to: loading and unloading areas, access roads, material handling areas, storage areas, and any other areas where heavy equipment and vehicle use is prevalent. Specific erosion and sediment controls should be implemented to minimize the discharge of sediments from the site. Measurements that timber facilities may consider include, but are not limited to: stabilization measures such as seeding, mulching, chemical stabilization, sodding, soil retaining measures and dust control and structural measures such as sediment traps, contouring, sediment basins, check dams and silt fences.

5. Special Conditions

a. Prohibition of Non-storm Water Discharges. Today's permit authorizes, in addition to the discharges described in part III.A.2., an additional non-storm water discharge specific to the timber products industry that, when combined with storm water, is authorized to be discharged under this permit. To be authorized under the permit, the sources of non-storm water must be identified in the storm water pollution prevention plan prepared for the facility. Where these discharges occur, the plan must identify and ensure the implementation of appropriate pollution prevention measures for the non-storm water components of the discharge. Authorized discharges include the following: spray down of lumber and wood product storage yards.

Spray down of lumber and wood product in storage yards is intermittently performed for fire control and pest control. Discharges from spray down activities are not storm water discharges; however, resulting discharges created as a result of spray down of raw lumber and wood product storage yards are authorized under this section where no chemical additives are used in the spray down waters and no chemicals are applied to the wood during storage. EPA believes that this practice, when performed in compliance with the terms and conditions of this section, will not pose any additional risks to human health and the environment because it is an industrial activity which is performed intermittently and within the confines of an area that should already contain controls for pollutants in storm water discharges.

It should be noted that the following discharges are not authorized under this section: noncontact cooling wastewater; contact cooling wastewater; boiler blowdown and water treatment wastewater; and storm water from areas of surface protection hand spraying activities.

This prohibition of unpermitted non-storm water discharges ensures that these discharges are not inadvertently covered under this section and requires the permittee to submit the appropriate NPDES permit applications to gain coverage for the non-storm water portion of the discharge.

6. Storm Water Pollution Prevention Plan Requirements

Several storm water pollution prevention plan requirements are added in the section of today's permit for the timber products industry, in addition to the baseline conditions described in part VI.C. of today's fact sheet. These deal with the identification and description of potential pollutant sources, and requirements to meet specific good housekeeping, inspection, and sediment/erosion control measures. EPA is also recommending that several criteria be considered during the development of the storm water pollution prevention plan.

a. Contents of the Plan

(1) Description of Potential Pollutant Sources

(a) Drainage—There are no additional requirements beyond those described in Part VI.C.2.a. of this fact sheet.

(b) Inventory of Exposed Materials—This section will require those facilities that have conducted activities associated with wood preserving and wood surface protection with pentachlorophenol formulations, creosote formulations, or arsenic/

chromium formulations in the past to identify: areas where soils are contaminated, treatment equipment, and/or stored materials which remain as a result of these operations. This section will also require the identification of any management practices being employed to minimize the contact of these materials with storm water runoff.

EPA has added these requirements because it is aware through studies performed for the hazardous waste listing process that sites where wood surface protection and wood preserving chemicals have been used in the past continue to contribute pollutants to the storm water discharges that come in contact with them, even once the industrial activity has ceased.[36] In particular, soils that have been contaminated with formulation chemicals, equipment such as dipping tanks and those used for material handling, and wastes and materials that are still stored on the site may continue to release pollutants. EPA is requiring the facility to identify these pollutant sources so that appropriate controls can be implemented.

During the EPA process to list wastes from wood preservation and surface protection processes, data were gathered that showed that the concentration of constituents (of the treatment chemicals) in storm water runoff, in some instances, were equivalent to those concentrations found in process wastewaters. These studies also found high concentrations of phenolic compounds, pentachlorodifluron and phenanthrenes, and metals in soils contaminated with process residuals at several sites. These concentrations were attributed to treated wood drippage and precipitation washoff of treated woods.[37]

Where facilities have used chlorophenolic, creosote, or chromium-copper-arsenic formulations for wood surface protection or preserving activities onsite in the past, and information is available, EPA is requiring that the facility inventory the following: areas where soils are contaminated, treatment equipment, and treated materials remain. Once these areas are identified, measures to minimize their exposure to storm water or to limit discharge of pollutants into storm water must be implemented. EPA is requiring this evaluation because soils, equipment, and other materials that are contaminated by treatment chemicals may continue to be a source of pollutants and can contribute to the contamination of storm water runoff.

(c) Non-storm Water Discharges—There are no additional requirements beyond those described in Part III.A.2. of this permit.

(d) Risk Identification and Summary of Potential Pollutant Sources—There are not additional requirements beyond those described in Part VI.C.2.f. of this fact sheet.

(2) Measures and Controls. As contained in Part VIII.A.5. of this fact sheet, EPA has set forth a number of options which are effective in controlling releases of pollutants to storm water discharges associated with industrial activity. Due to the success of BMPs as a cost effective method of pollution control, EPA is requiring that all facilities consider the implementation of BMPs in the following areas of the site: log, lumber and other wood product storage areas; residue storage areas, loading and unloading areas; material handling areas; chemical storage areas; and equipment/vehicle maintenance, storage and repair areas. The conditions of this section also require facilities that surface protect and/or preserve wood products to address specific BMPs for wood surface protection and preserving activities.

EPA believes it is appropriate to require that permittees indicate in their storm water pollution prevention plan all potential sources of pollution. Effective pollution control measures are currently being implemented at timber product facilities and/or are identified in literature sources specific to timber products facilities. Additional practices may also be found in the "Storm Water Management for Industrial Activities, Developing Pollution Prevention and Best Management Practices" (EPA 832–R–92–006), EPA, September 1992. The determination of the appropriateness or inappropriateness of a measure must be indicated in the facility's storm water management plan.

(a) Good Housekeeping—In addition to typical good housekeeping measures that require the maintenance of areas which may contribute pollutants to storm water in a clean and orderly manner, the pollution prevention plan must specifically address good housekeeping measures and the specific frequency of performance of these measures which are designed to: (1) limit the discharge of wood debris; (2) minimize the leachate generated from decaying wood materials; and (3) minimize the generation of dust.

EPA has specified that BMPs limit the discharge of solids because storm water discharges containing TSS and BOD_5 are prevalent at timber products facilities and can often be controlled by good housekeeping measures.

(b) Preventive Maintenance—This section requires periodic removal of debris from ditches, swales, diversion, containment basins, and infiltration measures. The discharge of solids at timber product facilities may inhibit the performance of storm water controls if they are not maintained properly.

(c) Spill Prevention and Response Procedures—This section requires the development of schedules for response procedures to limit the tracking of spilled materials to other areas of the site. Specifically, this section requires that leaks or spills of wood surface protection or preservation chemicals be cleaned up immediately.

Requirements have been placed in this section to limit the tracking of significant materials that have been leaked or spilled on the site from containers, facility equipment, or onsite vehicles. Of particular concern is the tracking of leaks or spills of treatment chemicals outside near where storm water controls are in place. This may occur, for example, during the filling of storage tanks. Vehicles or equipment used to transfer materials may come into contact with any materials spilled during the filling or emptying of tanks. As the vehicles move to other locations at the site, such material may be tracked and eventually lead to contamination of storm water discharges.

(d) Inspections—Facility operators must conduct visual inspections of BMPs on a quarterly basis. Inspections must be performed quarterly at processing areas, transport areas, and treated wood storage areas of facilities performing wood surface protection and preservation activities. Quarterly inspections are designed to assess the usefulness of practices in minimizing drippage of treatment chemicals on unprotected soils and in areas that will come in contact with storm water discharges. In addition, all timber products facilities must conduct daily inspections of material handling activities and unloading and loading areas whenever activities are occurring in those areas (if activities are not occurring in those areas, no inspection is required).

[36] "Background Document Supporting the Proposed Listing of Wastes from Surface Protection Processes, Part One Final Engineering Analysis Volume 1," EPA Office of Solid Wastes, February 1993.

[37] "Background Document Supporting the Proposed Listing of Wastes from Surface Protection Processes, Part One Final Engineering Analysis Volume 1," EPA Office of Solid Wastes, February 1993.

Records will be required to be maintained showing that these inspections have been performed at the required frequencies. In addition, a set of tracking or follow-up procedures must be implemented to ensure appropriate actions are taken based on the findings of the inspections. These records should be developed on a case-by-case basis depending upon the facility's needs.

(e) Employee Training—There are no additional requirements beyond those listed in Part VI.C.3.e. of this fact sheet.

(f) Sediment and Erosion Control—This section requires that the following areas of the plant be considered for sediment and erosion controls: loading and unloading areas, access roads, material handling areas, storage areas, and any other areas where heavy equipment and vehicle use is prevalent. Sediment and erosion controls include: stabilization measures such as seeding, mulching, chemical stabilization, sodding, soil retaining measures; and dust control and structural measures such as sediment traps, contouring, sediment basins, check dams, and silt fences. This requirement is added because part 2 storm water group permit application data showed that many of the sites were discharging high TSS concentrations in their storm water discharges. Identifying those areas of the site where erosion occurs will aid the permittee in determining appropriate BMPs that will achieve a reduction in TSS loadings.

(g) Storm Water Management—There are no additional requirements beyond those described in Part VI.C.3.h. of this fact sheet.

(3) Comprehensive Site Compliance Evaluation. There are no additional requirements beyond those described in Part VI.C.4. of this fact sheet.

7. Monitoring and Reporting Requirements

(a) Analytical Monitoring Requirements. Under the revised methodology for determining pollutants of concern for the timber products subsectors, all facilities must monitor their storm water discharges. EPA believes that timber product facilities may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. In order to provide a tool for evaluating the effectiveness of the pollution prevention plan and to characterize the discharge for potential environmental impacts, today's permit requires timber products facilities to collect and analyze grab samples of their storm water discharges for the pollutants listed in the applicable Tables (A–7 through A–10). The pollutants listed in Tables A–7 through A–10 were found to be above benchmark levels for a significant portion of facilities in the subsectors that submitted quantitative data in the group application process. Because these pollutants have been reported at or above benchmark levels, EPA is requiring monitoring after the pollution prevention plan has been implemented to assess the effectiveness of the pollution prevention plan and to help ensure that a reduction of pollutants is realized.

Today's permit requires the wood preserving subsector to monitor for arsenic and copper. These parameters are commonly found in wood preservatives. The discharge data initially analyzed by EPA indicate that these parameters are found in the storm water discharges from wood preserving facilities. Review of additional sampling data revealed that there was a substantial portion of the facilities discharging these parameters in concentrations greater than the bench mark values. Therefore, EPA has determined that monitoring of arsenic and copper is necessary to ensure that the storm water pollution prevention plans developed by wood preserving facilities adequately addresses sources of these parameters.

Under the Storm Water Regulations at 40 CFR 122.26(b)(14), EPA defined "storm water discharge associated with industrial activity". The focus of today's permit is to address the presence of pollutants that are associated with the industrial activities identified in this definition and that might be found in storm water discharges. Under the methodology for determining analytical monitoring requirements, described in section VI.E.1 of this fact sheet, nitrate plus nitrite nitrogen is above the bench mark concentrations for the wood preserving subsector. After a review of the nature of industrial activities and the significant materials exposed to storm water described by facilities in this subsector, EPA has determined that the higher concentrations of nitrate plus nitrite nitrogen are not likely to be caused by the industrial activity, but may be primarily due to non-industrial activities on-site. Today's permit does not require wood preserving facilities to conduct analytical monitoring for this parameter.

At a minimum, storm water discharges from timber products facilities must be monitored quarterly during the second year of permit coverage. Samples must be collected at least once in each of the following periods: January through March; April through June; July through September; and October through December. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in the applicable Tables (A–7 through A–10). If the permittee collects more than four grab samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE A–7.—MONITORING REQUIREMENTS FOR GENERAL SAWMILLS AND PLANING MILLS

Pollutants of concern	Cut-off concentration
Chemical Oxygen Demand (COD)	120 mg/L
Total Suspended Solids (TSS)	100 mg/L
Zinc, Total Recoverable	0.117 mg/L

R0016121

TABLE A–8.—ADDITIONAL MONITORING REQUIREMENTS FOR WOOD PRESERVATION FACILITIES WITH CHLOROPHENOLIC FORMULATIONS

Parameter of concern	Cut-off concentration
Total Recoverable Arsenic	0.16854 mg/L.
Total Recoverable Copper	0.0636 mg/L.

TABLE A–9.—MONITORING REQUIREMENTS FOR LOG STORAGE AND HANDLING FACILITIES

Parameter of concern	Cut-off concentration
Total Suspended Solids (TSS)	100 mg/L.

TABLE A–10.—MONITORING REQUIREMENTS FOR HARDWOOD DIMENSION AND FLOORING MILLS; SPECIAL PRODUCTS SAWMILLS; MILLWORK, VENEER, PLYWOOD AND STRUCTURAL WOOD; WOOD CONTAINERS; WOOD BUILDINGS AND MOBILE HOMES; RECONSTITUTED WOOD PRODUCTS; AND WOOD PRODUCTS FACILITIES NOT ELSEWHERE CLASSIFIED

Parameter of concern	Cut-off concentration
Chemical Oxygen Demand (COD)	120 mg/L.
Total Suspended Solids (TSS)	100 mg/L.

If the average concentration for a parameter is less than or equal to the value listed in the appropriate Tables (A–7 through A–10), then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration listed in Tables (A–7 through A–10), then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit.

TABLE A–11.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Tables A–7 through A–10, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Tables A–7 through A–10, then no further sampling is required for that parameter.
4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Tables A–7 through A–10. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will reassess the effectiveness of the adjusted pollution prevention plan.

The monitoring cut off concentrations listed in Tables A–7 through A–10 are not numerical effluent limitations. These values represent a level of pollutant discharge which facilities may achieve through the implementation of pollution prevention plans. At least half of the facilities that submitted Part 2 data from the applicable subsectors reported concentrations more than or equal to the values listed in Tables A–7 through A–10. Facilities that achieve average discharge concentrations which are less than or equal to the values in Tables A–7 through A–10 are not relieved from the pollution prevention plan requirements or any other requirements of the permit.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

b. Alternative Certification. Throughout today's permit, there are monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall or on a pollutant-by-pollutant basis in lieu of monitoring reports described under paragraph (*c*) below, under penalty of law, signed in accordance with Part VII.G. (Signatory Requirements), that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, and significant materials from past industrial activity that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in accordance with Part VI.C of this permit. In the case of certifying that a pollutant is not present, the permittee must submit the certification along with the monitoring reports required under paragraph (*c*) below. If the permittee cannot certify for an entire period, they must submit the date exposure was eliminated and any monitoring required up until that date. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters such as TSS and BOD.

c. *Reporting Requirements.* Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one signed Discharge Monitoring Report Form must be submitted per storm event sampled. For facilities conducting monitoring beyond the minimum requirements an additional Discharge Monitoring Report Form must be filed for each analysis.

d. *Sample Type.* All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable.

If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

e. *Representative Discharge.* When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

f. *Quarterly Visual Examination of Storm Water Quality.* Timber products facilities shall perform and document a visual examination of a storm water discharge associated with industrial activity from each outfall, except discharges exempted below. The examination(s) must be made at least once in each of the following 3-month periods: January through March, April through June, July through September, and October through December. The examination shall be made during daylight hours unless there is insufficient rainfall or snow melt to produce a runoff event.

(*1*) Examinations shall be made of grab samples collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 1 hour) of when the runoff or snowmelt begins discharging. The examinations shall document observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on the samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. Where practicable, the same individual should carry out the collection and examination of discharges for entire permit term.

(*2*) Visual examination reports must be maintained onsite in the pollution prevention plan. The report shall include the examination date and time, examination personnel, the nature of the discharge (i.e., runoff or snow melt), visual quality of the storm water discharge (including observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution), and probable sources of any observed storm water contamination.

(*3*) When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may collect a sample of effluent of one of such outfalls and report that the examination data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluents. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

(*4*) When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination and retain this documentation onsite with the records of the visual examinations. Adverse weather conditions that may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

(5) EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

B. Storm Water Discharges Associated With Industrial Activity From Paper and Allied Products Manufacturing Facilities

1. Discharges Covered Under This Section

On November 16, 1990 (55 FR 47990), EPA promulgated the regulatory definition of "storm water discharges associated with industrial activity." This definition included point source discharges of storm water from 11 categories of facilities, including paper and allied product manufacturing facilities that are commonly identified by Standard Industrial Classification (SIC) Major Group 26. Today's permit establishes special conditions for the storm water discharges associated with industrial activities at paper and allied product manufacturing facilities. Based on an evaluation of part 1 and part 2 group application data, these facilities were determined to perform similar operations, use similar raw materials, and employ similar material handling and storage practices. In light of the available information, it was determined that the storm water discharge characteristics would be similar for facilities covered by this section.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

2. Industry Profile

SIC Major Group 26, the production of pulp, paper, and paperboard, is a highly diversified industry group which manufactures a variety of products. Products include newsprint, printing and writing papers, bleached and unbleached packaging paper, glassine, tissue papers, vegetable parchment, greaseproof papers, bleached and unbleached paperboard, special industrial papers, and pulp. Pulp, paper, and paperboard is produced from wood and nonwood products such as jute, hemp, rags, cotton linters, bagasse, and esparto. Secondary fibers, or wastepaper, is also used to produce paper and paperboard.

Four standard manufacturing processes are involved in the production of pulp, paper, and paperboard: (1) Raw material preparation, (2) pulping, (3) bleaching, and (4) papermaking.

a. Raw Material Preparation. Wood is the most widely used raw material for manufacturing pulp and paper products. Wood must be prepared for pulping by log washing, bark removal, and chipping/sawing. These activities are usually conducted outdoors and produce large amounts of wood chips, sawdust, and other wood debris. If exposed to storm water, these activities may contribute TSS and BOD_5 to the storm water discharge.

b. Pulping. Pulping involves reducing a cellulosic raw material into a form that may be further processed to produce paper or paperboard, or into a form that may be chemically converted. Two pulping methods are used to reduce the raw material: mechanical pulping and chemical pulping.

Mechanical pulping, also known as groundwood pulping, uses two processes to produce pulp, stone groundwood and refiner groundwood. Stone groundwood uses a grindstone to tear fiber from the side of short logs. Refiner groundwood passes wood chips through a disc refiner. In both processes, wood may be softened with chemicals or heat to reduce the amount of energy required for grinding. Mechanical pulp is very suitable for use in newspapers, catalogs, tissues, and one-time publications.

Chemical pulping, using cooking chemicals under controlled conditions, produces a variety of pulps for multipurposes. This process generally produces high quality paper products. Three types of chemical pulping are used: alkaline, sulfite, and semichemical.

Alkaline pulping, more commonly known as the kraft process, produces a very strong pulp and is adaptable to almost all wood species. The pulp is formed by boiling wood chips in an alkaline solution usually containing sodium sulfate. Alkaline pulping also provides for the successful recovery of chemicals used in the process. This pulping technique is the most highly used pulping process worldwide.

Sulfite pulps are generally prepared from softwoods and produce various types of paper including tissue paper and writing paper. Wood chips are boiled with calcium-based chemicals, magnesium-based chemicals, or ammonia-based chemicals. Calcium was the original sulfite liquor base, however, the spent liquor from this base was difficult and expensive to recover. Many sulfite mills have now been converted to the kraft process or have been shut down because of the problems of chemical recovery and the reduced availability of softwoods.

Semichemical pulping involves the cooking of wood chips from hardwoods with a neutral or slightly alkaline sodium sulfite solution. Both sodium and ammonia-based chemicals are used in this process. Pulps produced from semichemical pulping are used in the manufacture of corrugated paperboard. Semichemical pulping mills practice chemical recovery from the waste liquor by balancing the pH of the waste liquor. Spent liquor is then burned in a furnace.

Some facilities use secondary fibers to produce the paper products. Secondary fibers are wastepapers and may be used with little or no preparation depending on their condition. The wastepaper may be blended directly with the virgin pulps or may have to be screened and filtered to remove dirt before being added to the pulp.

Some secondary fibers must be deinked before use. In order to reclaim a useful pulp, all noncellulosic materials, such as ink, fillers, and coatings, must be removed. This process uses detergents and solvents to remove these materials. The detergents and solvents may be stored in an area exposed to storm water.

c. Bleaching. After pulping, the pulp is brown or deeply colored. The color results from the presence of lignins and resins or residue from spent cooking liquor. The pulp must be bleached to produce a light colored or white product.

A brightness scale ranging up to 100 (the brightest) is used to determine the degree of bleaching needed. For example, newspaper and food containers do not need a high degree of brightness so semibleached pulps are used. For white paper products, fully-bleached pulps are used. A bleaching sequence is followed in which specific chemicals are sequentially added. The following sequence may be used in bleaching: chlorination and washing; alkaline extraction and washing;

R0016124

chlorine dioxide addition and washing; alkaline extraction and washing, and chlorine dioxide addition and washing.

The sequence may be modified to meet specific bleaching requirements. In general, less bleaching is required for mechanical pulps because they contain all of the wood substrate and would require massive amounts of bleaching. Therefore, mechanical pulps are used to produce lower quality paper products, such as telephone directories, newsprint, and disposable products. Chemical pulps may be brightened to a higher degree. Hydrosulfite, hypochlorite, chlorine, oxygen, and peroxides are used in bleaching and may be stored in areas exposed to storm water.

d. Papermaking. After pulps have been bleached, further mixing and blending may be necessary and noncellulosic materials may be added to prepare the pulp for the papermaking stage. Different types of pulp may be blended for desired effects. Softwood pulps are very strong and are used to make high strength, tear resistant paper. These pulps may be blended with hardwood pulps which add porosity, opacity, and printability qualities to the paper. Other materials may be added to the pulp such as clay, talc, or calcium carbonate to improve the texture, brightness, or opacity of the paper. By adding resin or starch, the paper becomes more ink or water resistant. Each of these additives may be a source of contamination for storm water if stored outdoors.

After noncellulosic materials have been blended with the pulp, it is ready for papermaking. The mixture of pulp and additives is called a pulp furnish. In making paper, fiber from a dilute pulp furnish is placed on a fine screen, called a wire. The water is drained through, and the fiber layer is removed, pressed and dried.

Two basic types of processes are used in papermaking: the cylinder machine and the Fourdrinier. The cylinder machine has wire cylinders which rotate in the dilute pulp furnish and collect fibers. The cylinders deposit the collected fibers on a moving felt to form a fibrous sheet. In the Fourdrinier process, the dilute pulp furnish is placed on a continuous wire belt where the fibrous sheet is formed. The cylinder machine is usually associated with the manufacturing of heavy grades of paper and paperboard; the Fourdrinier process is mostly used for producing paper, but may also be used to make paperboard.

The pressing and drying operations are similar for the two processes. After the fibrous sheet is formed, it is transferred to two or more presses to remove water and enhance smoothness and density. The sheet is then dried by being passed through heated hollow iron or steel cylinders. For a smoother finish, the sheet may be passed through a series of rollers (calendaring) used to produce high density paper.

After the sheet is dry, coatings may be applied to increase appearance, printability, water resistance, or texture. Coatings consist of a high density water slurry of pigments and adhesives that are blended together. Mixtures of starches, latices, polyvinylacetate, and recoverable solvents are used depending on the purpose of the coating. The coating is applied using rolls, air knives, blades, or metering rods. High gloss and smoothness is achieved by using high speed rollers with alternating steel and fabric-filled rolls. The coatings, when stored exposed to storm water discharges may be a source of contamination.

e. Wastewater Treatment. Most pulp, paper, and paperboard facilities have onsite wastewater treatment systems for treating process wastewater, although some facilities may discharge to a POTW. To reduce BOD_5 and TSS loads, many facilities use biological treatment. The most common treatment process is aerated stabilization. At nonintegrated facilities (facilities that do not produce pulp) and secondary fibers facilities, however, primary treatment may be the only method used. At these facilities, primary treatment is usually very effective in reducing BOD_5.

f. Activities Contributing to Storm Water Contamination. Although there is diversity among the types of final products produced at pulp, paper, and paperboard facilities, several industrial activities are common to all. These activities are presented in Table B–1 Below.

Table B–1.—Common Industrial Activities at Paper and Allied Product Manufacturing Facilities

Industrial Activities
Bactericide use
Baghouse, cyclone, dust collectors
Coating
Corrugate
Creasing
Cutting
Equipment storage
Vehicle fueling
Gluing
Rail and Truck loading areas
Material handling sites
Printing
Access Railroads
Scoring
Stitching
Storage areas
Taping

Typical activities performed at pulp, paper, and paperboard facilities include log washing, chipping and cutting of logs, log sorting, log storage, and loading and unloading of logs onto trucks or railroad cars for transport to other facilities. These log storage and handling activities may contribute bark and wood debris, TSS, and leachates to a storm water discharge. Leachates from the decay of wood products may contain high levels of TSS and BOD_5.

Many of the facilities in SIC Major group 26 employ the use of material handling equipment (forklifts, loaders, vehicles, chippers, debarkers, cranes, etc.), vehicles, and other machinery. These facilities store the equipment onsite and may also engage in equipment maintenance and repair activities. These types of activities are performed in either covered or outdoor areas of the facility. Associated with these activities is the storage of significant materials such as petroleum products and other maintenance fluids such as fuels, motor oils, hydraulic oils, lubricant fluids, brake fluids, and antifreeze. When exposed to storm water, these materials may cause contamination of a storm water discharge.

The manufacturing processes at paper and allied product manufacturing facilities are not typically exposed to storm water. Because of the lack of industrial activities occurring outdoors, the primary sources of storm water pollutants originate from materials handling, storage of materials, and waste management or disposal activities. Sources of pollutant are most often from spills and leaks of materials at loading and unloading areas, storage areas, and waste disposal areas. Table B–2 lists the materials that may be exposed to storm water at paper and allied product manufacturing facilities.

Dust and particulates from cyclones used in paper trim activities, resins/polymers
Clay slurries.

3. Pollutants in Storm Water Discharges Associated With Industrial Activity From Paper and Allied Product Manufacturing Facilities

Few pollutants are expected in storm water discharges from the manufacturing of paper and allied products, because the majority of industrial activities occur indoors. Pollutants may be present in storm water as a result of outdoor activities associated with the industry such as discharges which come into contact with the following areas of the site: loading or unloading of materials; outdoor storage of raw materials or unpackaged products; outdoor process activities; dust or particulate generating processes; and illicit connections or inappropriate management practices.

The volume and quantity of storm water discharges associated with industrial activity depend upon a number of factors, including the nature of the industrial activities occurring at the facility, the nature of the precipitation, and the degree of surface imperviousness. Storm water may pick up pollutants from structures and other surfaces as it drains from the facility. Even within a group of facilities with similar activities and materials used, handled, stored, or produced, the quality of the storm water can vary greatly.

The regulatory deadline for submission of the part 2 data was October 1, 1992. Many part 2 data submittals remain incomplete and many of those that did submit data did not identify the significant material or industrial activity that may have contributed the pollutants to the storm water discharge. Based on the wide variety of industrial activities and significant materials at the facilities included in this sector, EPA believes it is appropriate to divide the paper and allied products manufacturing industry into subsectors to properly analyze sampling data and determine monitoring requirements. As a result, this sector has been divided into the following subsectors: paper mills; paperboard mills, paperboard containers and boxes; and converted paper and paperboard products, except containers and boxes. Tables B–2, B–3, and B–4 below include data for the eight pollutants that all facilities were required to monitor for under Form 2F. The tables also list those parameters that EPA has determined merit further monitoring. A table has not been included for paper mill facilities because less than 3 facilities submitted data in that subsector.

TABLE B–2.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY PAPERBOARD MILL FACILITIES SUBMITTING PART II SAMPLING DATA (MG/L)

[ii] Composite samples.

4. Options for Controlling Pollutants

There are two options for reducing pollutants in storm water discharge; end-of-pipe treatment, and implementing best management practices (BMPs) to prevent and/or eliminate the contact between significant materials and storm water. A comprehensive storm water management program for a given plant may include controls from each of these categories and should be based on a consideration of site and facility plant characteristics. End-of-pipe treatment is effective for the control of process waters when the types of pollutants and the volume of water to be treated is known. However, storm water discharges from any industry, including the paper and allied product manufacturing industry, can be numerous, intermittent, and of various volumes. Therefore, the channelization of storm water that comes into contact with significant materials into a single treatment facility, or construction of numerous treatment devices for each discharge, may be burdensome and ineffective for treating pollutants contained in storm water from these types of facilities. EPA believes that the most appropriate means of storm water management at paper and allied product manufacturing facilities can be sufficiently determined by the operator of the facility.

EPA believes that the most effective storm water management control for limiting the offsite discharge of pollutants in storm water is a combination of passive and active BMPs.

Examples of BMPs range from simple housekeeping, material handling practices, preventive maintenance, diversions practices, to more advanced structural control such as detention and retention ponds and infiltration devices.

The selection of the most effective BMPs will be based on site-specific considerations such as: facility size, climate, geographic location, hydrogeology and the environmental setting of each facility, volume and type of discharge generated, and number of outfalls. Each facility will be unique in that the source, type and volume of contaminated storm water discharges will differ. In addition, the fate and transport of pollutants in these discharges will vary. EPA believes that the management practices discussed herein are well suited mechanisms to prevent or control the contamination of storm water discharges associated with the paper and allied product manufacturing industry.

As part of the group application review process, a review of the part 1 data was analyzed. The applications indicated that numerous BMPs were already being implemented at many of the representative sites. Table B-5 provides the most common practices presently being employed and the relative percentage of facilities who are implementing them. Table B-6 provides an additional list of BMPs that may be appropriate for the industry. Many of the BMPs identified are examples of practices intended to limit the exposure of significant materials and industrial activities to storm water. Facility operators should review their current operations and consider implementing these BMPs if they are applicable to the site and are expected to reduce the discharge of pollutants from the site in storm water.

TABLE B-5.—BEST MANAGEMENT PRACTICES DISCUSSED IN PART 1 GROUP APPLICATIONS[i]

BMP	Percent of facilities
Catch Basins	22.2
Diversion structures around potential contaminants	43.8
Spill Control Procedures, Contingency Plans (SPCC)	67.4
Swales, ditches, trench or graded surfaces	51.4
Employee training	62.5

[i] Material Management Practices were identified in over 20 percent of the 144 facilities in the sampling subset.

TABLE B-6.—SUGGESTED BEST MANAGEMENT PRACTICES AT PULP AND ALLIED PRODUCTS MANUFACTURING FACILITIES

Activity	Suggested BMPs
Outdoor loading and unloading	• Confine loading/unloading activities to a designated response and control area. • Avoid loading/unloading materials in the rain. • Cover loading/unloading area/or conduct these activities indoors. • Develop and implement spill plans. • Use berms or dikes around area.

TABLE B–6.—SUGGESTED BEST MANAGEMENT PRACTICES AT PULP AND ALLIED PRODUCTS MANUFACTURING FACILITIES—Continued

Activity	Suggested BMPs
Raw and/or waste material storage areas	• Inspect containers for leaks or damage prior to loading. • Use catch buckets, drop cloths, and other spill prevention measures where liquid materials are loaded/unloaded. • Provide paved areas to enable easy collection of spilled materials. • Confine storage to a designated area. • Store materials inside. • Cover storage areas with a roof or tarp. • Use dikes or berms for storage tanks and drum storage. • Cover dumpsters used for waste paper and other materials. • Store materials on concrete pads to allow for recycling and spills of leaks. • Expedite recycling process for exposed scrap paper. • Develop and implement spill plans. • Provide paved areas to enable easy collection of spilled materials. • Provide good housekeeping (i.e., dust and debris collection) where cyclones are utilized.
Log, lumber and other wood product storage areas.	• Divert storm water around storage areas with ditches, swales, and/or berms. • Practice good housekeeping measures such as frequent removal of debris. • Line storage areas with crushed rock or gravel or porous pavement to promote infiltration, minimize discharge and provide sediment and erosion control. • Use ponds for collection, containment and recycle for log spraying operations.

5. Special Conditions

There are no requirements beyond those described in Part VI.B. of this fact sheet.

6. Storm Water Pollution Prevention Plan Requirements

There are no requirements beyond those described in Part VI.C. of this fact sheet.

a. Description of Potential Pollutant Sources. There are no requirements beyond those described in Part VI.C. of this fact sheet.

b. Measures and Controls. There are no requirements beyond those described in Part VI.C. of this fact sheet.

c. Comprehensive Site Compliance Evaluation. There are no requirements beyond those described in Part VI.C. of this fact sheet.

7. Numeric Effluent Limitation.

There are no effluent limits beyond those described in Part VI.B. of this permit.

8. Monitoring and Reporting Requirements

a. Analytical Monitoring Requirements. Under the revised methodology for determining pollutants of concern for the various industrial sectors, only one subsector, paperboard mills, is required to monitor storm water discharges. As discussed previously, the median value for COD of 124.5 mg/L is higher than the benchmark value for COD of 120 mg/L for the paperboard subsector, thus triggering monitoring for COD. The monitoring requirements are presented in Table B–7 for paperboard mills.

At a minimum, storm water discharges from paperboard mills must be monitored quarterly during the second year of permit coverage. Monitoring must be performed during each of the following periods: January through March; April through June; July through September; and October through December. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Table B–7. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE B–7.—PAPERBOARD MILLS MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Chemical Oxygen Demand	120 mg/L.

If the average concentration for a parameter is less than or equal to the cut-off concentration, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit. The schedule for monitoring is presented in Table B–8.

TABLE B–8.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Table B–7, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Table B–7, then no further sampling is required for that parameter.

TABLE B–8.—SCHEDULE OF MONITORING—Continued

4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Table B–7. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will be used to reassess the effectiveness of the adjusted pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

(1) Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable.

If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

(2) Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

(3) Alternative Certification. Throughout today's permit, EPA has included monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative certification described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall on a pollutant-by-pollutant basis in lieu of monitoring described in Table B–8 under penalty of law, signed in accordance with Part VII.G. (Signatory Requirements) of the permit, that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity, and that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in lieu of monitoring reports required under paragraph b. The permittee is required to complete any and all sampling until the exposure is eliminated. If the facility is reporting for a partial year, the permittee must specify the date exposure was eliminated. If the permittee is certifying that a pollutant was present for part of the reporting period, nothing relieves the permittee from the responsibility to sample that parameter up until the exposure was eliminated and it was determined that no significant materials remained. This certification option is not applicable to compliance monitoring requirements associated with effluent guidelines. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

b. Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one Discharge Monitoring Report Form must be submitted per storm event sampled. For facilities conducting monitoring beyond the minimum requirements an additional Discharge Monitoring Report Form must be filed for each analysis. The permittee must include a measurement or estimate of the total precipitation, volume of runoff, and peak flow rate of runoff for each storm event sampled.

c. Quarterly Visual Examination of Storm Water Quality. Quarterly visual examinations of a storm water discharge from each outfall are required at all paper and allied products manufacturing facilities. The examination must be of a grab sample collected from each storm water outfall. The examination of storm water grab samples shall include any observations of color, odor, turbidity, floating solids, foam, oil sheen, or other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on these samples.

The examination must be made at least once in each designated period during daylight hours unless there is insufficient rainfall or snow-melt to runoff. Whenever practicable, the same individual should carry out the collection and examination of discharges throughout the life of the permit to ensure the greatest degree of consistency possible. Examinations shall be conducted in each of the following periods for the purposes of inspecting storm water quality associated with storm water runoff and snow melt: January through March; April through June; July through September; October through December. Grab samples shall be collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 60 minutes) of when the runoff begins discharging. Reports of the visual examination include: the examination date and time, examination personnel, visual quality of the storm water discharge, and probable sources of any observed storm water contamination. The visual examination reports must be maintained onsite with the pollution prevention plan.

EPA believes that this quick and simple assessment will help the permittee to determine the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examinations. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and the effects of the management practices that are included in the plan.

When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may collect a sample of effluent from one such outfall and report that the examination data also apply to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluents. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination. Adverse weather conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

C. Storm Water Discharges Associated With Industrial Activity From Chemical and Allied Products Manufacturing Facilities

1. Discharges Covered Under This Section

EPA regulations define "storm water discharges associated with industrial activity" at 40 CFR 122.26(b)(14) in order to specify those discharges that are required to be permitted under the NPDES program. Category (ii) of this definition includes facilities classified as Standard Industrial Classification (SIC) code 28, Chemical and Allied Products Manufacturing, with the exception of facilities classified as SIC code 285—Paints, Varnishes, Lacquers, Enamels, and Allied Products Manufacturing, which are included in category (xi) of the definition. EPA did not receive any group applications from facilities with primary SIC code 283 (Drugs Manufacturing). Therefore, as EPA had no data on such facilities, they are not eligible for coverage under this section of today's permit. The following section describes facilities covered by Part XI.C. of today's permit and the conditions and requirements of facilities covered by Part XI.C.

For additional information on the subsectors and their industrial activities, please see the following documents:

"Development Document for Effluent Limitations Guidelines and Standards for the Paint Formulating Point Source Category." EPA–440/1–79/049–b. 1979.

"Development Document for Interim Final Effluent Limitations Guidelines for the Pesticide Chemicals Manufacturing Point Source Category." EPA–440/1–75/060d. 1976.

"Development Document for Effluent Limitations Guidelines and New Source Performance Standards for the Major Organic Products Segment of the Organic Chemicals Manufacturing Point Source Category." EPA–440/1–74–009a. 1974.

"Development Document for Effluent Limitations Guidelines, New Source Performance Standards and Pretreatment Standards for Organic Chemicals and the Plastics and Synthetic Fibers Point Source Category." EPA–440/1–87/009. 1987.

"Development Document for Effluent Limitations Guidelines and New Source Performance Standards for the Basic Fertilizer Chemicals Segment of the Fertilizer Manufacturing Point Source Category." 1974.

"Development Document for Final Effluent Limitations Guidelines, New Source Performance Standards and Pretreatment Standards for the Pharmaceutical Manufacturing Point Source Category." EPA–440/1–83/084. 1983.

"Development Document for Effluent Limitations Guidelines, New Source Performance Standards and Pretreatment Standards for the Inorganic Chemicals Manufacturing Point Source Category, Phase 2." EPA–440/1–84/007. 1984.

Part XI.C. of today's permit has been developed for storm water discharges at facilities primarily engaged in the manufacture of chemicals and allied products. This sector of industry includes facilities which manufacture a broad range of products including plastic and synthetic materials, detergents, paints and varnishes, drugs, fertilizers and pesticides, adhesives, inks, explosives, artist's inks and paints, and organic and inorganic chemicals used for industrial purposes. Specifically, Part XI.C. of today's permit applies to establishments primarily engaged in manufacturing:

a. Industrial inorganic chemicals (including SIC 281).

b. Plastic materials and synthetic resins, synthetic rubbers, and cellulosic and other humanmade fibers, except glass (including SIC 282).

c. Soaps and detergents; specialty cleaning, polishing, and sanitation preparations; surface active preparations used as emulsifiers, wetting agents, and finishing agents, including sulfonated oils; perfumes, cosmetics, and other toilet preparations; glycerin made from vegetable and animal fats and oils (including SIC 284).

d. Paints (in paste and ready-mixed form), varnishes, lacquers, enamels, shellac, putties, wood fillers, and sealers, paint and varnish removers, paint brush cleaners, and allied paint products (including SIC 285).

e. Industrial organic chemicals (including SIC 286).

f. Nitrogenous fertilizers; phosphatic fertilizers; fertilizers, mixing only; pesticides; and other agricultural chemicals, not elsewhere classified (including SIC 287).

g. Industrial and household adhesives, glues, caulking compounds, sealants, and linoleum, tile, and rubber cements from vegetable, animal, or synthetic plastics materials (including SIC 2891).

h. Explosives (including SIC 2892).

i. Printing ink, including gravure, screen process, and lithographic ink, and carbon black (including SIC 2893 and 2895); and, due to the nature of manufacturing activities, EPA has included industrial facilities represented by SIC 3952 in this category, but only those primarily engaged in the manufacturing of ink and paints, including china painting enamels, india and drawing ink, platinum paints for burnt wood or leather work, paints for china painting, artists' paints and artists' water colors.

j. Miscellaneous that are not in Sections a. through i. of this part, such as fatty acids, essential oils, nonvegetable gelatin, sizes, bluing, laundry sours, writing and stamp pad ink, industrial compounds, such as boiler and heat insulating compounds, metal, oil, and water treatment compounds, waterproofing compounds, and chemical supplies for foundries (including SIC 2899).

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

2. Pollutants Found in Storm Water Discharges

Water quality impacts caused by storm water discharges associated with an industrial activity from Chemical and Allied Products Manufacturing facilities are expected to vary depending on several factors. Such factors include the geographic location and hydrology of the site, the type of manufacturing and/or industrial activities, the amount and type of operations and material storage occurring outside, imperviousness of surfaces at the site, and the impact of a given precipitation event. In addition, sources of pollutants from non-storm water discharges such as washwaters from industrial areas, illicit connections, and spills may increase the pollutant loading to waters of the United States. Because there is wide variety of products and manufacturing activities in this sector of today's permit, EPA has subdivided the chemicals and allied products manufacturing industry into "subsectors."

Part 1 of the group application required a summary of industrial activities and the significant materials stored exposed to precipitation. This provided useful qualitative information to EPA, but information that is not possible to quantify reliably due to differences in terminology and thoroughness. For the summary of industrial activities, some participants reported their industrial activity as "manufacture of product X," rather than listing the components of that main activity. Other participants listed some or all general industrial actions, e.g., "shredding" or "wastewater treatment." (Products listed represent most of the industrial classifications which are subject to this section of today's permit). Table C.1. lists the general industrial actions occurring at facilities according to part 1 of their group applications.

TABLE C–1.—INDUSTRIAL ACTIVITIES OCCURRING AT CHEMICAL AND ALLIED PRODUCT MANUFACTURERS (AS REPORTED IN PART 1 OF GROUP APPLICATIONS)

1. Storage of materials in tanks, either below or above ground.
2. Wastewater treatment, use of activated sludge process, or land application of wastewaters.
3. Bagging of materials/products.
4. Blending and mixing of chemicals.
5. Packaging of chemicals.
6. Cooling towers.
7. Crushing, Milling, Shredding, Granulation and Grinding of materials.
8. Storage of cylinders used to contain industrial gases.
9. Distribution of products.
10. Storage of empty or full drums.
11. Equipment storage and maintenance, including vehicles.
12. Application of fertilizers or pesticides.
13. Operation of a foundry.
14. Fueling of vehicles.
15. Hazardous waste temporary storage or operation of RCRA treatment, storage, or disposal facility.
16. Hot oil system for cooling/heat exchange.
17. Landfills or temporary refuse site.
18. Application of lime.
19. Loading/Unloading.
20. Use of machinery to process materials.
21. Material handling and warehousing.
22. Plant yard and areas of past industrial activity.
23. Access roads and rail tracks.
24. Steam boilers.

TABLE C–1.—INDUSTRIAL ACTIVITIES OCCURRING AT CHEMICAL AND ALLIED PRODUCT MANUFACTURERS (AS REPORTED IN PART 1 OF GROUP APPLICATIONS)—Continued

25. Thermal oxidation of lead.
26. Washing of drums.
27. Waste dumpster or compactor.

Table C–2 shows the subsectors and their corresponding SIC codes and letters (from discharges covered under this section in this fact sheet).

Part 2 of the storm water group application required that quantitative data be submitted by a representative sampling subgroup. Based on the wide variety of industrial activities and significant materials at the facilities included in this sector, EPA believes it is appropriate to divide the chemical and allied products industry into subsectors to properly analyze sampling data and determine monitoring requirements. As a result, this sector has been divided into the following subsectors: industrial inorganic chemicals; plastics, synthetics, and resins; drugs; soaps, detergents, cosmetics, perfumes; paints, varnishes, lacquers, enamels, and allied products; industrial organic chemicals; agricultural chemicals; and miscellaneous chemical products. Tables C–2, C–3, C–4, C–5, C–6, C–7, and C–8 below include data for the eight pollutants that all facilities were required to monitor for under Form 2F. The tables also list those parameters that EPA has determined merit further monitoring. A table has not been included for industrial organic chemical manufacturing facilities because less than 3 facilities submitted data in that subsector.

TABLE C–2.—SUBSECTOR INDEX

Subsector		SIC Code(s)
1	....	281
2	....	282
3	....	284
4	....	285
5	....	286
6	....	287
7	....	289, 2891, 2892, 2893, 2894, 2899, 3952
8	....	28[i]

[i] Subsector 8 includes those facilities that indicated their SIC code only as 28, without the following 1 or 2 digits.

TABLE C–8.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY MISCELLANEOUS CHEMICAL PRODUCTS MANUFACTURING FACILITIES SUBMITTING PART II SAMPLING DATA[i] (mg/L)—Continued

Pollutant	# of Facilities		# of Samples			Grab	Minimum		Maximum		Median		95th Percentile		99th Percentile	
Sample type	Grab	Comp[ii]	Grab	Comp	Mean	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp
Total Suspended Solids	19	15	28	23	50	47.8	0	0.0	415	350	13	8.0	246	220.5	728	687.3

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.

[ii] Composite samples.

3. Options for Controlling Pollutants

As required in part 1 of the storm water group permit application, participants were required to provide information regarding existing storm water management practices and controls. Table C–9 below identifies the material management practices for the identified sampling facilities.

TABLE C–9.—CURRENT STORM WATER MANAGEMENT PRACTICES USED BY THE CHEMICAL AND ALLIED PRODUCTS MANUFACTURING INDUSTRY (AS REPORTED IN PART 1 OF THE GROUP APPLICATIONS)[i]

Subsector	Current management practices
1	Unloading Boot, Catch Basin, Containment, Covering, Curbing, Dike Diversion, Housekeeping, Inspection of Equipment, Infiltration, Oil/Water Separator, Roof, SPCC, Sump, Storm Water Collector for Water Reuse, Training, Indoor Storage.
2	Catch Basin, Covering, Dike, Indoor Storage, Pond, SPCC, Swale, Vegetation Strip.
3	Caps on Tank Vents, Concrete Pad, Containment, Covering, Curbing, Dike, Diversion, Drain, Hazardous Waste Management, Hazardous Waste Pad, Holding Tank, Indoor Storage, Infiltration, Pond, Roof, Sealed Drums, SPCC, Storm Water Collector, Tarp, Vaulted.
4	Containment, Covering, Dike, Holding Tank, Infiltration, Pond, Roof Drain, Site Inspection, SPCC, Swale, Training, Waste Minimization.
5	Curbing, Dike, Pond, SPCC.
6	Catch Basin, Covering, Dike, Housekeeping, Indoor Storage, Infiltration, Oil/Water Separator, Pond, Roof, Site Inspection, SPCC, Sump, Swale, Sweep, Valves.
7	Absorbent Materials, BMP Plan, Catch Basin, Concrete Pad, Containment, Covering, Curbing, Dike, Drain, Drip Pan, Housekeeping, Indoor Storage, Infiltration, Oil/Water Separator, Pond, Roof, Inspection, Sloped Containment, SPCC, Sump, Swale, Training, Valves.
8	Catch basin, Containment, Covering, Dike, Indoor Storage, Pond, Roof, Site Inspection, SPCC, Swale, Training.

[i] The information presented in this table was received from part 1 group applications for Sector 3.

In order to develop achievable storm water management practices and controls, EPA has evaluated all existing management practices as well as practices developed and implemented under the September 9, 1992, storm water general permit. For a detailed explanation regarding specific storm water controls and management practices, the reader may refer to the pollution prevention plan requirements section below.

4. Special Conditions

a. Prohibition of Non-storm Water Discharges. In addition to the discharges prohibited under Part III.A.2 of today's permit, EPA has specified that the following types of discharges are not authorized by this section:

(1) Inks, paints or substances (hazardous, nonhazardous, etc.) resulting from an onsite spill including materials collected in drip pans.

(2) Washwaters from material handling and processing areas. This includes areas where containers, equipment, industrial machinery, and any significant materials are exposed to storm water.

(3) Washwaters from drum, tank or container rinsing and cleaning.

EPA has included these prohibitions in order to emphasize that spilled materials should be cleaned up and properly disposed, and that washwaters constitute process wastewater and not storm water. These types of discharges contribute excessive amounts of pollutants to water bodies and must be permitted by an NPDES permit for process wastewater, as they are not authorized by this section.

5. Storm Water Pollution Prevention Plan Requirements

a. Contents of the Plan. Today's permit requires that all facilities covered under this section prepare a Drainage and Site Plan. Based on the information contained in the part 1 application, EPA has identified and specified areas where materials are commonly handled. EPA is requiring that the site plan detail the drainage patterns of the runoff and identify the outfall and receiving water body. [Language on site map not included.]

(1) Description of Potential Pollutant Sources. The Inventory of Exposed Materials as well as Risk Identification and Summary of Potential Pollutants Sources requirements were further defined to avoid confusion. In addition, EPA is requiring that the information submitted in the group application regarding pollutant sources and current management practices be evaluated and considered when developing the plan.

Measures and Controls. EPA has divided this section of the permit into two parts. The first part addresses nonstructural pollution prevention controls, while the second part addresses structural controls.

The following requirements were established by EPA under the nonstructural conditions to identify specific practices that must be implemented by all permittees:

(a) Good Housekeeping—In addition to the information provided in the group application process, EPA conducted a series of inspections to identify areas of concern, materials exposed to storm water and current management practices used by the chemicals and allied products manufacturing industry. EPA also reviewed a series of existing pollution prevention plans that were developed under the requirements of the baseline general permit. Based on this information, EPA is requiring that at a minimum, permittees shall consider establishing the following good housekeeping practices:

R0016134

(i) Schedule regular pickup and disposal of garbage and waste materials or other measures to dispose of waste. This schedule may be included in the plan. Individuals responsible for waste management and disposal should be informed of the procedures established under the plan.

(ii) Routinely inspect for leaks and conditions of drums, tanks and containers. Ensure that spill cleanup procedures are understood by employees.

(iii) Keep an up-to-date inventory of all materials present at the facility. While preparing the inventory, all containers should be clearly labeled. Hazardous containers that require special handling, storage, use and disposal considerations should be clearly marked and readily recognizable.

(iv) Maintain clean ground surfaces by using brooms, shovels, vacuum cleaners or cleaning machines.

(b) Employee Training—Training should also address procedures for equipment and containers cleaning and washing. The training should emphasize the human hazards and the potential environmental impacts from the discharges of washwaters. In addition, today's permit requires that the pollution prevention plan for chemical and allied products manufacturing facilities identify periodic dates for such training of at least once per year. EPA recommends that facilities conduct training annually at a minimum. However, more frequent training may be necessary at facilities with high turnover of employees or where employee participation is essential to the storm water pollution prevention plan.

(c) Inspections—Qualified personnel shall conduct quarterly inspections. A wet weather inspection (during a rainfall event) shall be conducted in the second (April to June) and third quarters (July to September) of each year. A dry weather inspection (no precipitation) shall be conducted in the first (January to April) and fourth quarters (October to December).

However, where a seasonal arid period is sustained for more than 3 months, a dry weather inspection will satisfy the wet weather inspection requirement. This requirement will assure that permittees conduct at least one inspection every quarter.

EPA believes that this requirement will satisfy the requirements of this section by measuring the effectiveness of the pollution prevention plan during dry and wet weather conditions. These inspections will increase awareness and responsibility for storm water pollution. Moreover, conducting these dry and wet weather inspections on a quarterly basis will provide permittees with a tool for evaluating best management practices, structural and nonstructural measures, good housekeeping and spill cleaning procedures, among other pollution prevention activities.

(d) Facility Security—Facilities should consider evaluating existing security systems such as fencing, lighting, vehicular traffic control, and securing of equipment and buildings and should include existing and new system into the plan to prevent accidental or intentional entry which could cause a discharge of pollutants to waters of the United States.

(e) Structural Storm Water Management Controls—Under the structural conditions, EPA has identified specific practices that should be considered by all permittees. These structural practices are divided into four activities/areas: material handling and storage; management of runoff; sediment and erosion control; and sampling.

(f) Practices for Material Handling and Storage Areas—Under material handling and storage, EPA is recommending a series of management practices to minimize materials exposed to precipitation. These areas were selected after evaluation of part 1 data and current practices used by the group participants. For areas where liquid or powdered materials are stored, facilities shall consider providing either diking, curbing, or berms. For all other outside storage areas including storage of used containers, machinery, scrap and construction materials, and pallets, facilities shall consider preventing or minimizing storm water runon to the storage area by using curbing, culverting, gutters, sewers or other forms of drainage control. For all storage areas, roofs, covers or other forms of appropriate protection shall be considered to prevent exposure to weather. In areas where liquid or powdered materials are transferred in bulk from truck or rail cars, permittees shall consider appropriate measures to minimize contact of material with precipitation. Permittees shall consider providing for hose connection points at storage containers to be inside containment areas and drip pans to be used in areas which are not in a containment area, where spillage may occur (e.g., hose reels, connection points with rail cars or trucks) or equivalent measures. In areas of transfer of contained or packaged materials and loading/unloading areas, permittees shall consider providing appropriate protection such as overhangs or door skirts to enclose trailer ends at truck loading/unloading docks or an equivalent.

In order to prevent facilities from discharging contaminated storm water from areas where precipitation is contained, contained areas should be restrained by valves or other positive means to prevent the discharge of a spill or leak. Containment units may be emptied by pumps or ejectors; however, these should be manually activated. Flapper-type drain valves should not be used to drain containment areas. Valves used for the drainage of containment areas should, as far as is practical, be of manual, open-or-closed design. If facility drainage is not engineered as above, the final discharge point of all in-facility sewers should be equipped to prevent the discharge in the event of an uncontrolled spill of materials.

(g) Management of Runoff—Under management of runoff conditions, EPA is requiring that the plan contain a description of storm water management practices used and/or to be used to divert, infiltrate, reuse, or otherwise manage storm water runoff in a manner that reduces pollutants in storm water discharges from the site.

(h) Sediment and Erosion Control—For areas with a potential for significant soil erosion, the permittee should describe permanent stabilization practices to be used in order to stabilize disturbed areas. The measures will minimize the amount of sediment materials in the discharge.

(i) Non-storm Water Discharges—There are no additional requirements beyond those described in Part VI.C of this fact sheet.

(j) Comprehensive Site Compliance Evaluation—In accordance with 40 CFR 122.24(i)(4)(i), EPA has established that comprehensive site compliance evaluations be conducted at least once every year. Members of the pollution prevention team or a qualified professional designated by the team must conduct the evaluation. Requirements for the evaluation are listed under Part VI.C.4 of this fact sheet.

6. Numeric Effluent Limitations

a. Phosphate Fertilizer Manufacturing Runoff. Part XI.C.5.a. of today's permit establishes numeric effluent limitations for storm water discharges from facilities identified by SIC 287, the Phosphate Subcategory of the Fertilizer Manufacturing Point Source Category, which are subject to effluent limitations guidelines at 40 CFR Part 418. The term contaminated storm water runoff shall mean precipitation runoff, which during manufacturing or processing, comes into incidental contact with any raw materials, intermediate product, finished product, by-products or waste product. The concentration of pollutants in storm water discharges shall not exceed the following effluent limitations included in Table C–10 below:

TABLE C–10

Effluent characteristics	Effluent limitations (mg/L)	
	Maximum for any 1 day	Average of daily values for 30 consecutive days shall not exceed
Total Phosphorus (as P)	105.0	35.0
Fluoride	75.0	25.0

Facilities with discharges as described above must be in compliance with these effluent limitations upon commencement of coverage and for the entire term of this permit. Discharges that are associated with industrial activities that do not contain runoff from the areas or activities specified above are not subject to the effluent limitation in Table C–10 above.

7. Monitoring and Reporting Requirements

a. Analytical Monitoring Requirements. EPA believes that chemical manufacturing facilities may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. Under the revised methodology for determining pollutants of concern for the various industrial sectors, four subsectors in the chemical and allied products manufacturing sector must monitor their storm water discharges. The monitoring requirements are presented in Tables C–11, C–12, C–13, and C–14 for agricultural chemical manufacturing facilities; industrial inorganic chemical facilities; soaps, detergents, cosmetics, and perfume manufacturing facilities; and plastics, synthetics, and resin manufacturing facilities. The pollutants listed in Tables C–11, C–12, C–13, and C–14 were found to be above benchmark levels. Because these pollutants have been reported at benchmark levels from agricultural chemical facilities; industrial inorganic chemical facilities; soaps, detergents, synthetics, and resin manufacturing facilities, EPA is requiring monitoring after the pollution prevention plan has been implemented to assess the effectiveness of the pollution prevention plan and to help ensure that a reduction of pollutants is realized.

Under the Storm Water Regulations at 40 CFR 122.26(b)(14), EPA defined "storm water discharge associated with industrial activity". The focus of today's permit is to address the presence of pollutants that are associated with the industrial activities identified in this definition and that might be found in storm water discharges. Under the methodology for determining analytical monitoring requirements, described in section VI.E.1 of this fact sheet, nitrate plus nitrite nitrogen is above the bench mark concentrations for the plastics, synthetics, and resins subsector. After a review of the nature of industrial activities and the significant materials exposed to storm water described by facilities in this subsector, EPA has determined that the higher concentrations of nitrate plus nitrite nitrogen are not likely to be caused by the industrial activity, but may be primarily due to non-industrial activities on-site. Today's permit does not require plastics, synthetics, and resins facilities to conduct analytical monitoring for this parameter.

At a minimum, storm water discharges from agricultural chemical facilities; industrial inorganic chemical facilities; soaps, detergents, cosmetics, and perfume manufacturing facilities; and plastics, synthetics, and resin manufacturing facilities must be monitored quarterly during the second year of permit coverage. Samples must be collected at least once in each of the following periods: January through March; April through June; July through September; and October through December. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Tables C–11, C–12, C–13, and C–14. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE C–11.—AGRICULTURAL CHEMICALS MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Nitrate plus Nitrite Nitrogen	0.68 mg/L
Total Recoverable Lead	0.0816 mg/L
Total Recoverable Iron	1.0 mg/L
Total Recoverable Zinc	0.117 mg/L
Phosphorus	2.0 mg/L

TABLE C–12.—INDUSTRIAL INORGANIC CHEMICALS MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Recoverable Aluminum	0.75 mg/L
Total Recoverable Iron	1.0 mg/L
Nitrate plus Nitrite Nitrogen	0.68 mg/L

TABLE C–13.—SOAPS, DETERGENTS, COSMETICS, AND PERFUMES MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Nitrate plus Nitrite Nitrogen	0.68 mg/L
Total Recoverable Zinc	0.117 mg/L

TABLE C–14.—PLASTICS, SYNTHETICS, AND RESIN MANUFACTURING MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Recoverable Zinc	0.117 mg/L

If the average concentration for a parameter is less than or equal to the cut-off concentration, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit. The schedule for monitoring is presented in Table C–15.

TABLE C–15.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Tables C–11, C–12, C–13, and C–14, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Tables C–11, C–12, C–13, and C–14, then no further sampling is required for that parameter.
4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Tables C–11, C–12, C–13, and C–14. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will be used to reassess the effectiveness of the adjusted pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

(b). Alternative Certification. Throughout today's permit, EPA has included monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative certification described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall or on a pollutant-by-pollutant basis in lieu of monitoring described in Tables C–11, C–12, C–13, and C–14, that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity, and that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in lieu of monitoring reports required under paragraph c. below. The permittee is required to complete any and all sampling until the exposure is eliminated. If the facility is reporting for a partial year, the permittee must specify the date exposure was eliminated. If the permittee is certifying that a pollutant was present for part of the reporting period, nothing relieves the permittee from the responsibility to sample that parameter up until the exposure was eliminated and it was determined that no significant materials remained. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

c. Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one signed Discharge Monitoring Report Form must be submitted to the Director per storm event sampled. For facilities conducting monitoring beyond the minimum requirements, an additional signed Discharge Monitoring Report Form must be filed for each analysis. The permittee must include a measurement or estimate of the total precipitation, volume of runoff, and peak flow rate of runoff for each storm event sampled.

d. Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable.

If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable, permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

e. Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

f. Compliance Monitoring Requirements. Today's permit requires permittees with phosphate fertilizer manufacturing facilities with contaminated storm water discharges to monitor for the presence of phosphorus and fluoride. These monitoring requirements are necessary to evaluate compliance with the numeric effluent limitation for these discharges. Monitoring shall be performed upon a minimum of one grab sample. All samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable. Monitoring results shall be submitted on Discharge Monitoring Report Form(s) postmarked no later than the 31st day of the month following collection of the sample. Facilities which discharge through a large or medium municipal separate storm sewer system (systems serving a population of 100,000 or more) must also submit signed copies of discharge monitoring reports to the operator of the municipal separate storm sewer system. Alternative Certification provisions described in Section XI.C.5 of the permit do not apply to facilities subject to compliance monitoring requirements in this section. Compliance monitoring is required at least annually for discharges subject to effluent limitations. Therefore, EPA cannot permit a facility to waive compliance monitoring.

Phosphate fertilizer manufacturing facilities are not required to collect and analyze separate samples for the presence of total phosphorus to satisfy the Compliance Monitoring requirements of Section XI.C.6.c. during a year in which the facilities have collected and analyzed samples for total phosphorus in accordance with the Analytical Monitoring Requirements of Section XI.C.6.a. The results of all Analytical Monitoring analyses may be reported as Compliance Monitoring results in accordance with Section XI.C.5.d.(3) where the monitoring methodologies are consistent.

g. Quarterly Visual Examination of Storm Water Quality. Chemical and allied products manufacturing facilities shall perform and document a visual examination of a storm water discharge associated with industrial activity from each outfall, except discharges exempted below. The examination(s) must be made at least once in each of the following 3-month periods: January through March, April through June, July through September, and October through December. The examination shall be made during daylight hours unless there is insufficient rainfall or snow melt to produce a runoff event.

(1) Examinations shall be made of grab samples collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 1 hour) of when the runoff or snowmelt begins discharging. The examinations shall document observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on the samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. Where practicable, the same individual should carry out the collection and examination of discharges for entire permit term.

(2) Visual examination reports must be maintained onsite in the pollution prevention plan. The report shall include the examination date and time, examination personnel, the nature of the discharge (i.e., runoff or snow melt), visual quality of the storm water discharge (including observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution), and probable sources of any observed storm water contamination.

(3) When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may collect a sample of effluent of one of such outfall and report that the examination data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluents. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

(4) When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination and retain this documentation onsite with the records of the visual examinations. Adverse weather conditions that may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.). EPA realizes that if a facility is inactive and

unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

D. Storm Water Discharges Associated With Industrial Activity From Asphalt Paving and Roofing Materials Manufacturers and Lubricant Manufacturers

1. Discharges Covered Under This Section

On November 16, 1990 (55 FR 47990), EPA promulgated the regulatory definition of "storm water discharges associated with an industrial activity." This definition includes point source discharges of storm water from eleven major categories of facilities, including facilities commonly identified by Standard Industrial Classification (SIC) 29. Today's permit only covers storm water discharges associated with industrial activities at facilities which manufacture asphalt paving mixtures and blocks (SIC code 2951), asphalt felts and coatings (SIC code 2952), and lubricating oils and greases (SIC code 2992). Hereinafter, facilities with primary SIC codes 2951 or 2952 will be referred to as "Asphalt Facilities," and facilities with primary SIC code 2992 as "Lubricant Manufacturers."

Section XI.D of today's permit does not apply to renderers of fats and oils, petroleum refining facilities or to oil recycling facilities. Petroleum refining facilities are not eligible for coverage under today's permit, because these types of facilities did not participate in the group application process. Renderers of fats and oils are covered under Section XI.U of today's permit. Oil recycling facilities are covered under Section XI.N of today's permit. These facilities are more appropriately grouped with the liquid waste recyclers covered under Section XI.N.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

This section is applicable to storm water discharges from portable plants. Although portable plants were not included in the group application process the significant materials and industrial activities conducted at these facilities are sufficiently similar to permanent facilities to allow coverage. This section is applicable to storm water discharges from portable plants, with the condition that a new Notice of Intent (NOI) be submitted for each location and the pollution prevention plan be revised accordingly with each change in location.

a. Industry Profile. Presented below are brief descriptions of the industrial activities associated with asphalt facilities and lubricant manufacturers. Table D–1 shows some common significant materials exposed at these types of facilities.

TABLE D–1.—ACTIVITIES, POLLUTANT SOURCES, AND POLLUTANTS[i, ii]

Activity	Pollutant source	Pollutant
Asphalt Paving Manufacturing Facilities		
Material Storage and Handling	Additives, asphalt, asphalt cement, asphalt concrete, asphalt products, asphalt release agents, crushed stone, fuel, granite, granules, gravel, limestone, lubricants, mineral spirits, oil, quartzite rock, reclaimed asphalt pavement (RAP), sand, sandstone, slag.	TSS, Oil and Grease, pH, COD.
Asphalt Roofing Material Manufacturers		
Material Storage and Handling	Mineral spirits, asphalt, asphalt cutbacks, asphalt shingles, limestone, sand, slag, asphalt rolls, asphalt felt, talc oil and fuel.	TSS, Oil and Grease, pH and COD.
Lubricant Manufacturers		
Material Storage and Handling	Oils, waste solvents, petroleum distillates, lubricants, chemical additives.	Oil and Grease, pH, TSS.

[i] Storm water group applications, parts 1 and 2.
[ii] EPA. Development Document on Paving and Roofing Materials (EPA 440/1–74/049).

(1) Manufacturers of Asphalt Paving Mixtures and Blocks (SIC 2951). Manufacturers classified in SIC 2951 store purchased asphalt in above ground tanks. They stockpile a variety of raw materials such as sand, gravel, crushed limestone, and recycled asphalt products (RAP). These facilities produce asphalt concrete, and may also mold and cure asphalt concrete products such as asphalt blocks. There are two types of facilities associated with these activities, batch plants and drum plants.

Batch plants receive aggregate (sand, stone, limestone, gravel, etc.) in bulk by rail or truck. The aggregate is usually stockpiled outside. It is then transported by a conveyor or front-end loader to a rotary drier. When dried and heated the aggregate is transported to a screening unit which separates the aggregate into various sizes and deposits the graded aggregate into hot storage bins. Aggregate and mineral filler are then weighed and transported to a mixing unit or pug mill where they are mixed with heated asphalt cement to produce asphalt concrete. The resulting asphalt concrete is either stored in a heated silo or loaded directly onto trucks for transport to the job site.

At drum (cold feed) plants a measured amount of aggregate is placed in the drum where it is dried and heated. Heated asphalt cement is added to the same drum and mixed with the aggregate to produce asphalt concrete. The hot asphalt concrete produced by this process then goes to a surge bin or silo for storage until it is loaded onto trucks for delivery.

Hot-mix asphalt plants are often portable. There are three types of portable plants: portable, permanent, and semipermanent. Portable plants move from site to site, and the significant materials and equipment are removed upon completion of the job or project. Portable plants remain at a site anywhere from several days to several months. Permanent portable plants remain at a site on a permanent basis.

Like portable plants, semipermanent plants move from site to site. They differ, however, in that they return to locations on a recurring basis. Significant materials such as aggregate piles remain at the site while the plant is operating elsewhere. For the purposes of this section, semipermanent plants will be referred to as permanent plants, given that the effect on runoff from significant materials will essentially be the same at both sites. 'Asphalt facilities' includes both permanent and portable plants unless specified otherwise.

Facilities which manufacture asphalt concrete block feed the asphalt/aggregate mixture into a block molding machine where the mix is rammed, pressed or vibrated into its final form. The product is then stacked and allowed to cure.

(2) Manufacturers of Roofing Materials (SIC 2952). Manufacturers classified in standard industrial code 2952 typically produce bitumen-based roofing products such as asphalt shingles, built-up roofing (BUR), modified bitumen sheet material, asphalt saturated felts and bitumen-based root coatings, mastics and cements.

The typical manufacturing of bitumen based roofing products, such as shingles, BUR, modified bitumen sheet materials and asphalt saturated felt is a continuous stationary process performed on a roofing machine that begins with a roll of base material such as fiberglass mat, polyester or organic felt, coated or saturated with an asphalt or blend, surfaced with mineral granules, and concludes with a finished product. The sequence of indoor operations builds the product up in stages, adding different raw materials along the way and monitoring their application.

Bitumen-based coatings, mastics and cements are produced inside in a stationary process mixing raw materials received in bulk and containers and blended into finished batches of product. "Batch processing" is the common production method relying on the same piece of equipment in manufacturing a variety of products. The products are packaged in containers or stored for bulk shipment.

(3) Manufacturers of Lubricating Oils and Greases (SIC 2992). Facilities primarily engaged in blending, compounding, and re-refining lubricating oils and greases from purchased mineral, animal, and vegetable materials are identified as SIC code 2992. SIC code 2992 includes manufacturers of metalworking fluids, cutting oils, gear oils, hydraulic brake fluid, transmission fluid, and other automotive and industrial oil and greases.

Raw materials for SIC code 2992 facilities are typically petroleum or synthetic-based stocks and various additives. The majority of lubricating manufacturers store base stocks and chemical additives in tank farms or 55-gallon drums. SIC code 2992 facilities do not manufacture these raw materials, but rather blend and compound them to produce the product. Raw materials are proportioned according to the type of lubricant being produced.

"Batch processing" is the common production method relying on the same piece of equipment in manufacturing a variety of products. For example, in one "batch" a facility may combine the petroleum base stock with additive X in a 10,000 gallon blending tank to produce product "A." Using the same blending tank, the next "batch" is a mixture of the base stock and additive Y to produce product "B." Batch processing allows facilities to manufacture a variety of products. Some facilities, however, tend to specialize in producing a particular type of lubricant (e.g., solid, synthetic, or water-based), often to meet the demands of a specific industry.

Finished products are packaged in containers or stored for bulk shipment. Almost all facilities have shipping and receiving areas and are involved with marketing and interstate distribution of their products. Most facilities have immediate access roads or rail lines at their facility sites.

2. Pollutants in Storm Water Discharges Associated With Asphalt Facilities and Lubricant Manufacturers.

Impacts caused by storm water discharges from asphalt facilities and lubricant manufacturers will vary. Several factors influence to what extent significant materials from these types of facilities and processing operations may affect water quality. Such factors include: geographic location: hydrogeology; the type of industrial activity occurring outside (e.g., material storage, loading and unloading); the type of material stored outside (e.g., asphalt, aggregate, limestone, oil, etc.); the size of the operation; and type, duration, and intensity of precipitation events. These and other factors will interact to influence the quantity and quality of storm water runoff. For example, air emissions (i.e., settled dust) may be a significant source of pollutants at some facilities, while materials storage is a primary source at others. In addition, sources of pollutants other than storm water, such as illicit connections,[38] spills, and other improperly dumped materials, may increase the pollutant loadings discharged into waters of the United States.

Based on group application information and data, EPA has identified the storm water pollutants and sources resulting from asphalt facilities and lubricant manufacturers in Tables D–2 and D–3.

Based on the wide variety of industrial activities and significant materials at the facilities included in this sector, EPA believes it is appropriate to divide the asphalt paving and roofing materials manufacturers and lubricating oils and greases manufacturers industry into 2 subsectors to properly analyze sampling data and determine monitoring requirements. As a result, this sector has been divided into the following subsectors: asphalt paving and roofing materials and lubricating oils and greases manufacturers. The tables below include data for the eight pollutants that all facilities were required to monitor under Form 2F.

[38] Illicit connections are contributions of unpermitted non-storm water discharges to storm sewers from any of a number of sources including sanitary sewers, industrial facilities, commercial establishments, or residential dwellings. The probability of illicit connections at mineral mining and processing facilities is low yet it still may be applicable at some operations.

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.
[ii] Composite samples.

3. Options for Controlling Pollutants

In evaluating options for controlling pollutants in storm water discharges, EPA must achieve compliance with the technology-based standards of the Clean Water Act [Best Available Technology (BAT) and Best Conventional Technology (BCT)]. This section establishes requirements for the development and implementation of a site-specific storm water pollution prevention plan consisting of a set of BMPs that are sufficiently flexible to address different sources of pollutants at different sites.

Two types of BMPs which may be implemented to prevent, reduce or eliminate pollutants in storm water discharges are those which minimize exposure (e.g., covering, curbing, or diking) and treatment type BMPs which are used to reduce or remove pollutants in storm water discharges (e.g., oil/water separators, sediment basins, or detention ponds). EPA believes exposure minimization is an effective practice for reducing pollutants in storm water discharges from asphalt facilities and lubricant manufacturers. Exposure minimization practices lessen the potential for storm water to come in contact with pollutants. These methods are often uncomplicated and inexpensive. They can be easy to implement and require little or no maintenance. EPA also believes that in some instances more resource intensive treatment type BMPs are appropriate to reduce pollutant levels such as suspended solids and oil/grease in storm water discharges associated with asphalt facilities or lubricant manufacturers. Though these BMPs are somewhat more resource intensive, they can be effective in reducing pollutant loads and may be necessary depending on the type of discharge, types and concentrations of contaminants, and volume of flow.

Table D–4 lists some BMPs which may be effective in limiting the amount of pollutants in storm water discharges from asphalt facilities and lubricant manufacturers. Based on part 1 information, several of the BMPs suggested are already in place at many of the facilities. Part 1 submittals indicate that diking, curbing, or other types of diversion occur at approximately 57 percent of the facilities. Some form of covering is used as a BMP at 25 percent of the facilities, and detention ponds are in place at 19 percent of the facilities. In addition, 38 percent of the facilities submitting part 1 information reported they had a Spill Prevention Control and Countermeasure Plan in place.

TABLE D–4.—MEASURES TO CONTROL POLLUTANTS IN STORM WATER DISCHARGES FROM ASPHALT FACILITIES AND LUBRICANT MANUFACTURERS

Activity	Suggested BMPs
Material Storage, Handling, and Processing	Cover material storage and handling areas with an awning, tarp or roof. Practice good stockpiling practices such as: storing materials on concrete or asphalt pads; surrounding stockpiles with diversion dikes or curbs; and revegetating areas used for stockpiling in order to slow runoff. Use curbing, diking or channelization around material storage, handling and processing areas to divert runon around areas where it can come into contact with material stored or spilled on the ground. Utilize secondary containment measures such as dikes or berms around asphalt storage tanks and fuel oil tanks.

R0016141

TABLE D-4.—MEASURES TO CONTROL POLLUTANTS IN STORM WATER DISCHARGES FROM ASPHALT FACILITIES AND LUBRICANT MANUFACTURERS—Continued

Activity	Suggested BMPs
	Use dust collection systems (i.e., baghouses) to collect airborne particles generated as a result of material handling operations or aggregate drying. Properly dispose of waste materials from dust collection systems and other operations. Remove spilled material and dust from paved portions of the facility by shoveling and sweeping on a regular basis. Utilize catch basins to collect potentially contaminated storm water. Implement spill plans to prevent contact of runoff with spills of significant materials. Clean material handling equipment and vehicles to remove accumulated dust and residue. Use a detention pond or sedimentation basin to reduce suspended solids. Use an oil/water separator to reduce the discharge of oil/grease.

4. Storm Water Pollution Prevention Plan Requirements

EPA believes that pollution prevention is the most effective approach for controlling contaminated storm water discharges from asphalt facilities and lubricant manufacturers. Pollution prevention plans allow the operator of a facility to select BMPs based on site-specific considerations such as: facility size, climate, geographic location, hydrogeology, the environmental setting of each facility, and volume and type of discharge generated. This flexibility is necessary because each facility will be unique in that the source, type and volume of contaminated surface water discharges will differ from site to site.

All facilities subject to this section must prepare and implement a storm water pollution prevention plan. The establishment of a pollution prevention plan requirement reflects EPA's decision to allow operators of asphalt facilities and lubricant manufacturers to utilize BMPs as the BAT/BCT level of control for the storm water discharges covered by this section. The requirements included in pollution prevention plans provide a flexible framework for the development and implementation of site specific controls to minimize pollutants in storm water discharges. This is consistent with the approach in EPA's storm water baseline general permits finalized on September 9, 1992 (57 FR 41236).

There are two major objectives to a pollution prevention plan: (1) To identify sources of pollution potentially affecting the quality of storm water discharges associated with industrial activity from a facility; and (2) to describe and ensure implementation of practices to minimize and control pollutants in storm water discharges associated with industrial activity from a facility. Specific requirements for a pollution prevention plan for asphalt facilities and lubricant manufacturers are described below. These requirements must be implemented in addition to the baseline pollution prevention plan provisions discussed previously.

a. Description of Potential Pollution Sources. There are no additional requirements beyond those described in Part VI.C.2. of this fact sheet.

b. Measures and Controls. There are no additional requirements beyond those described in Part VI.C.3. of this fact sheet.

c. Comprehensive Site Compliance Evaluation. The storm water pollution prevention plan must describe the scope and content of comprehensive site evaluations that qualified personnel will conduct to: (1) Confirm the accuracy of the description of potential pollution sources contained in the plan; (2) determine the effectiveness of the plan, and (3) assess compliance with the terms and conditions of today's permit.

Comprehensive site compliance evaluations shall be conducted at least once a year for asphalt facilities and lubricant manufacturers. The individual or individuals who will conduct the evaluations must be identified in the plan and should be members of the pollution prevention team. Inspection reports must be retained for at least 3 years after the date of the evaluation.

Comprehensive site compliance evaluations shall be conducted at least once a year at portable plant locations. Such evaluations shall be conducted at least once at portable plant locations that are not in operation a full year.

Based on the results of each evaluation, the description of potential pollution sources, and measures and controls, the plan must be revised as appropriate within 2 weeks after each evaluation. Changes in the measures and controls must be implemented on the site in a timely manner, but no later than 12 weeks after completion of the evaluation.

For portable plants, the plan must be revised as appropriate as soon as possible, but no later than 2 weeks after each evaluation. Two weeks is adequate time for portable plants to modify their plans due to the simpler and smaller nature of these operations in comparison to permanent facilities.

5. Numeric Effluent Limitations

In addition to the numeric effluent limitations established under Part V.B, part XI.D.4 of today's permit includes numeric effluent limitations for storm water discharges resulting from the production of asphalt paving and roofing emulsions. Discharges from areas where production of asphalt paving and roofing emulsions occurs may not exceed a TSS concentration of 23.0 mg/L of runoff for any one day, nor shall the average of daily values for 30 consecutive days exceed a TSS concentration of 15.0 mg/L of runoff. Oil and grease concentrations in storm water discharges from these areas may not exceed 15.0 mg/L of runoff for any 1 day, nor should the average daily values for 30 consecutive days exceed an oil and grease concentration of 10.0 mg/L of runoff. The pH of these discharges must be within the range of 6.0 to 9.0. Facilities with such discharges must be in compliance with these effluent limitations upon commencement of coverage and for the entire term of the permit. These effluent limitations are in accordance with 40 CFR 443.12 and 40 CFR 443.13, Effluent Guidelines and Standards, Paving and Roofing Materials Point Source Category, Asphalt Emulsion Subcategory. These limitations represent the degree of effluent reduction attainable by the application of best practicable control technology and best available technology.

6. Monitoring and Reporting Requirements

a. Analytical Monitoring Requirements. Under the revised methodology for determining pollutants of concern for the various industrial sectors, only asphalt paving and roofing materials manufacturers are required to perform analytical monitoring of storm water discharges. As discussed previously, the median composite sample concentration for TSS of 145 mg/L is higher than the benchmark value for TSS of 100 mg/L for the asphalt paving and roofing materials subsector, thus triggering monitoring for TSS. The monitoring requirements are presented in Table D–5 for asphalt paving and roofing materials manufacturers.

At a minimum, storm water discharges from asphalt paving and roofing materials manufacturers must be monitored quarterly during the second year of permit coverage. Samples must be collected at least once in each of the following periods: January through March; April through June; July through September; and October through December. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Table D–5. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE D–5.—ASPHALT PAVING AND ROOFING MATERIALS MANUFACTURERS MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Suspended Solids	100 mg/L.

If the average concentration for a parameter is less than or equal to the cut-off concentration, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit. The schedule for monitoring is presented in Table D–6.

TABLE D–6.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Table B–7, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Table B–7, then no further sampling is required for that parameter.
4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Table B–7. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will be used to reassess the effectiveness of the adjusted pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

(1) Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable.

If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

(2) Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

(3) Alternative Certification. Throughout today's permit, EPA has included monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative certification described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has

determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall or on a pollutant-by-pollutant basis in lieu of monitoring described under paragraph *b.* below, under penalty of law, signed in accordance with Part VII.G. (Signatory Requirements), that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity, and that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in lieu of monitoring reports required under paragraph *b.* (below). If the permittee cannot certify for an entire period, they must submit the date exposure was eliminated and any monitoring required up until that date. This certification option is not applicable to compliance monitoring requirements associated with effluent guidelines. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

b. Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one Discharge Monitoring Report Form must be submitted per storm event sampled. For facilities conducting monitoring beyond the minimum requirements an additional Discharge Monitoring Report Form must be filed for each analysis. The permittee must include a measurement or estimate of the total precipitation, volume of runoff, and peak flow rate of runoff for each storm event sampled.

EPA also believes that between quarterly visual examinations and site compliance evaluations potential sources of contaminants can be recognized, addressed, and then controlled with BMPs. In determining the monitoring requirements, EPA considered the nature of the industrial activities and significant materials exposed at these sites, and performed a review of data provided in Part 2 group applications.

c. Quarterly Visual Examination. Quarterly visual examinations of a storm water discharge from each outfall are required at asphalt facilities and lubricant manufacturers. The examination must be of a grab sample collected from each storm water outfall. The examination of storm water grab samples shall include any observations of color, odor, turbidity, floating solids, foam, oil sheen, or other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on these samples.

The examination must be made at least once in each designated period during daylight hours unless there is insufficient rainfall or snow-melt to runoff. Where practicable, the same individual should carry out the collection and examination of discharges throughout the life of the permit to ensure the greatest degree of consistency possible. Examinations shall be conducted in each of the following periods for the purposes of inspecting storm water quality associated with storm water runoff and snow melt: January through March; April through June; July through September; October through December. Grab samples shall be collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 60 minutes) of when the runoff begins discharging. Reports of the visual examination include: the examination date and time, examination personnel, visual quality of the storm water discharge, and probable sources of any observed storm water contamination. The visual examination reports must be maintained onsite with the pollution prevention plan.

EPA believes that this quick and simple assessment will help the permittee to determine the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual inspection will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examinations. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and the effects of the management practices that are included in the plan.

When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination. Adverse weather conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

d. Compliance Monitoring Requirements. Today's permit requires permittees with storm water discharges associated with the production of asphalt paving or roofing emulsions to monitor for the presence of total suspended solids, oil and grease, and for pH at least annually. These monitoring requirements are necessary to evaluate compliance with the numeric effluent limitation imposed on these discharges. Monitoring shall be performed upon a minimum of one grab sample. All samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable. Monitoring results shall be submitted on Discharge Monitoring Report Form(s) postmarked no later than the last day of the month following collection of the sample. For each outfall, one Discharge Monitoring Report form must be submitted per storm event sampled. Facilities which discharge through a large or medium municipal separate storm sewer system (systems serving a population of 100,000 or more) must also submit signed copies of discharge monitoring reports to the operator of the municipal separate storm sewer system. Alternative Certification provisions described in Section XI.D.5 do not apply to facilities subject to compliance monitoring requirements in this section. Compliance monitoring is required at least annually for discharges subject to effluent limitations. Therefore, EPA cannot permit a facility to waive compliance monitoring.

Asphalt emulsion manufacturing facilities are not required to collect and analyze separate samples for the presence of TSS to satisfy the Compliance Monitoring requirements of Section XI.D.5.d. during a year in which the facilities have collected and analyzed samples for TSS in accordance with the Analytical Monitoring requirements of Section XI.D.5.a. The results of all TSS Analytical Monitoring analyses may also be reported as Compliance Monitoring results in accordance with Section XI.D.5.d.(3) where the monitoring methodologies are consistent.

E. Storm Water Discharges Associated With Industrial Activity From Glass, Clay, Cement, Concrete, and Gypsum Product Manufacturing Facilities

1. Discharges Covered Under This Section

On November 16, 1990 (55 FR 47990), EPA promulgated the regulatory definition of "storm water discharges associated with industrial activity." This definition included point source discharges of storm water from eleven categories of facilities. Category (ii) identifies facilities classified as Standard Industrial Classification (SIC) code 32 as having storm water discharges associated with an industrial activity.

The following section describes the industrial activities and permit conditions for storm water discharges associated with industrial activity classified under Major SIC Group 32. The discussion focuses on the industries covered by today's permit. There are industries in Major SIC Group 32 beyond those discussed below; however, representatives of these industries did not choose to participate in the group application process on which this section is based. Therefore, they are not eligible for coverage under this permit.

This section only covers storm water discharges associated with industrial activities from facilities engaged in gypsum, cement, clay, glass, and concrete products manufacturing.[39]

Facilities subject to the requirements of this section include the following types of manufacturing operations: flat glass, (SIC code 3211); glass containers, (SIC code 3221); pressed and blown glass, not elsewhere classified, (SIC code 3229); hydraulic cement, (SIC code 3241); brick and structural clay tile, (SIC code 3251); ceramic wall and floor tile, (SIC code 3253); clay refractories, (SIC code 3255); structural clay products not elsewhere classified (SIC code 3259); vitreous table and kitchen articles (SIC code 3262); fine earthenware table and kitchen articles (SIC code 3263); porcelain electrical supplies, (SIC code 3264); pottery products, (SIC code 3269); concrete block and brick, (SIC code 3271); concrete products, except block and brick (SIC code 3272); ready-mix concrete, (SIC code 3273); gypsum products, (SIC code 3275); minerals and earths, ground or otherwise treated, (SIC code 3295); and nonclay refractories, (SIC code 3297).

Wash waters from vehicle and equipment cleaning areas are process wastewaters. This section does not cover any storm water that combines with process wastewater, unless the process wastewater is in compliance with another NPDES permit. This section does not cover any discharge subject to an existing or expired NPDES general permit. The section may cover runoff which derives from the storage of materials used in or derived from the cement manufacturing process[40] unless storm water discharges are already subject to an existing or expired NPDES permit.

Discharges from several industrial activities in Major SIC Group 32 are not covered by this section. These activities are: lime manufacturing (SIC 3274); cut stone and stone products (SIC 3281); abrasive products (SIC 3291); asbestos products (SIC 3292); and mineral wool and mineral wool insulation products (SIC 3297).

These types of facilities are not covered by this (or any other) section of today's permit, because these types of industrial activities were not represented in the group application process nor are they believed to be sufficiently similar to industrial activities that were included in the group application process. Because these facilities were not included in the group application process there is no additional information with which to develop industry-specific permit language.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

a. Industry Profile. Part XI.E. of today's permit has been developed for storm water discharges from glass, clay, cement, concrete, and gypsum products manufacturers. As stated above, these facilities are regulated under category (ii) of the definition of storm water discharges associated with industrial activity. Part XI.E. of today's permit addresses the industry-specific permit requirements for storm water discharges from these industries.

There are a variety of industrial processes that occur at manufacturing facilities covered under this section. The following descriptions summarize basic operations occurring at each type of industry.

(1) Glass Product Manufacturing. Facilities primarily engaged in the manufacturing of glass and glassware, or manufacturing glass products from purchased glass are classified under standard industrial groups 321–323. Facilities covered by these SIC codes share several similar steps in the manufacturing process. Such processes include the storage of raw materials, weighing the materials, charging, melting and forming. Although the forming processes vary greatly, the steps with a potential exposure to storm water are somewhat homogeneous.

The first step in the glass manufacturing process is batch preparation. This involves the selection and storage of the raw materials that will be used in the process. Such materials may include silica sand, limestones, feldspars, borates, soda ash, boric acid, potash and barium carbonate. Once the desired characteristics of the final product are

[39] Please note that storm water discharges associated with industrial activity from facilities identified as SIC code 323 (glass products made of purchased glass) only occur where material handling equipment or activities, raw materials intermediate products, final products, waste materials, by-products or industrial machinery are exposed to storm water. SIC code 323 facilities are only required to submit storm water permit applications when activities or materials are exposed to storm water.

[40] These discharges are subject to effluent limitation guidelines under 40 CFR 412.11.

assessed, the composition of the batch is determined and the raw materials are mixed together. The batch is then conveyed to the furnaces.

Furnaces are used to melt the batch to produce glass. Most of the furnaces in the glass manufacturing industry are fueled by natural gas or oil. The batch is placed in the furnace and allowed to melt. Once the glass has been melted and conditioned it is channeled to a forming machine.

Forming operations consist of up to four major steps, the first of which involves a further conditioning process to prepare the glass for primary forming. Primary forming, which may include drawing, blowing, pressing, or casting, is the second step in the forming operation. This operation is usually followed by an annealing step. Annealing is the process of subjecting the glass to heat and slow cooling in order to toughen the product. The final process in the forming operation may include one or more secondary operations. Operations such as grinding and polishing, laminating, sealing and coating of glass are common secondary operations. Materials used for secondary operations vary, examples are the resins used to laminate glass to produce safety glass products, such as car windows.

(2) Cement Manufacturing. Facilities primarily engaged in manufacturing hydraulic cement (e.g., portland, natural, masonry, and pozzolana cements) are identified as SIC code 3241. The manufacturing process is generally the same for all facilities classified as SIC 3241. The three basic steps in cement manufacturing are: (1) Proportioning, grinding, and blending raw materials; (2) heating raw materials to produce a hard, stony substance known as "clinker"; and (3) combining the clinker with other materials and grinding the mixture into a fine powdery form.

The first step in cement manufacturing is proportioning, grinding and blending raw materials. The primary raw material is lime. Lime is typically obtained from limestone, cement rock, oyster shell marl, and chalk. Other ingredients in cement manufacturing may include silica, alumina, and iron. The blending and grinding of these raw materials is achieved through either "wet" processing or "dry" processing. Wet processing operations use water when grinding and blending raw materials, and dry processing operations grind and blend raw materials in a dried state. Until they are fed into kilns for clinker production, materials ground from wet processing are stored in slurry tanks, while dry processing materials are stored in silos.

Kilns typically are coal, gas, or oil fired. In the kiln raw materials are commonly heated to a temperature of 1600 degrees Celsius (2900 degrees Fahrenheit). At these extreme temperatures, clinker is formed as raw materials begin to fuse and harden. Air is then used to cool clinker emerging from the kiln.

The final stage of the process involves adding small amounts of gypsum or stone (used to control setting times) to the clinker and grinding the mixture into a fine powdery form. The powdery product is then cooled before storage, bagging, and shipping.

There are facilities classified as SIC 3241 which only perform the final grinding step in the cement manufacturing process. These facilities do not have kilns to heat raw materials, and so obtain clinker from manufacturing plants.

(3) Clay Product Manufacturing. Facilities primarily engaged in manufacturing clay products, including brick, tile (clay or ceramic), or pottery products are classified as standard industrial groups 325 and 326. Although clay product manufacturing facilities produce a wide variety of final products, there are several similar processing steps shared by most facilities in this industry: (1) Storage and preparation of raw materials; (2) forming; (3) drying; (4) firing; and (5) cooling.

Manufacturers classified as standard industrial groups 325 and 326 typically use clay (common, silt, kaolin and/or phyllite) and shale (mud, red, blue and/or common) as their primary raw materials. However, some industries supplement these materials with slag (cinders), cement and lime. Raw materials are generally stored outside.

Raw materials are crushed and ground prior to manufacturing. Stones are removed, and particles of raw materials are screened to ensure they are the correct size. Water is then added to raw materials in mixing chambers and "mud" is formed. The mud is molded into the desired product during the forming stage. Depending on the final product, one of several different methods will be used when forming mud into the desired shape. The most common methods use pressure or hydraulic machines to shape products.

Following the forming process, products are left to dry. Drying is necessary to reduce the moisture content prior to firing. A common method for reducing moisture content is air drying clay products in a controlled environment (e.g., a drying chamber). When the drying process is complete, the clay is ready for firing in kilns.

There are two basic types of kilns: the periodic kiln and the tunnel kiln. With a periodic kiln, products are fired for a specified period of time and then promptly removed. With a tunnel kiln, products pass through the kiln on conveyor belts, and by the time the clay reaches the end of the kiln, the firing process is complete. The primary source of energy for most firing kilns is natural gas. Natural gas is typically supplemented with coal, sawdust, or oil. Fired products may then be glazed with salt or other materials for special applications.

(4) Concrete Products. Facilities primarily engaged in manufacturing concrete products, including ready-mixed concrete, are identified as SIC group 327. Although concrete product facilities in SIC group 327 produce a variety of final products, they all have common raw materials and activities.

Concrete products manufacturers combine cement, aggregate, and water to form concrete. Aggregate generally consists of: sand, gravel, crushed stone, cinder, shale, slag, clay, slate, pumice, vermiculite, scoria, perlite, diatomite, barite, limonite, magnetite, or ilmenite. Admixtures including fly ash, calcium chloride, triethanolamine, calcium salt, lignosulfunic acid, vinosol, saponin, keratin, sulfonated hydrocarbon, fatty acid glyceride, vinyl acetate, and styrene copolymer of vinyl acetate may be added to obtain desired characteristics, such as slower or more rapid curing times.

Typically, aggregate is received in bulk quantities by rail, truck, or barge. It is stored outside, and kept moist, until it is conveyed to distribution bins. The first stage in the manufacturing process is proportioning cement, aggregate, admixtures and water, and then transporting the product to a rotary drum, or pan mixer.

To form concrete block and brick, the mixture is then fed into an automatic block molding machine that rams, presses, or vibrates the mixture into its final form. The final product is then stacked on iron framework cars where it cures for 4 hours. Decorative blocks may be produced by adding colors to the mix, or splitting the surface into desired shapes.

Precast concrete products, may contain steel structural members for increased strength. These products include transformer pads, meter boxes, pilings, utility vaults, steps, cattle guards, and balconies. After being mixed in a central mixer, concrete is poured into forms or molded in the same manner as concrete block and

R0016146

brick. Forms are often coated with a release oil to aid stripping. The concrete "sets" or cures in the forms for a number of hours (depending upon the type of admixtures used). When the concrete has cured, the forms are removed. Forms are washed for reuse, and the concrete products are stored until they can be shipped.

In addition to the permanent concrete product facilities, there are a number of portable ready mix concrete operations which operate on a temporary basis. The portable plants are typically dedicated to providing ready mix concrete to one construction project. Portable plants have the same significant materials and industrial activities as permanent facilities. Therefore, portable concrete plants are eligible for coverage under Part XI.E. of today's permit.

(5) Gypsum Products Manufacturing. Facilities primarily engaged in manufacturing plaster, wallboard, and other products composed wholly or partially of gypsum (except plaster of paris and papier-mâché) are classified as SIC code 3275.

The gypsum product manufacturing process begins with calcining the gypsum: finely ground raw gypsum (referred to as "land plaster") is fed into imp mills or calcining kettles where extreme heat removes 75 percent of the gypsum's molecular moisture. The result is a dry powder called stucco, which is cooled and conveyed to storage bins.

To produce wallboard, stucco is fed into pin mixers where it is blended with water and other additives to produce a slurry. The slurry is then applied to continuous sheets of paper to form wallboard. In addition to producing wallboard, some facilities may combine stucco with additives (excluding water) to produce plaster. Plaster is then bagged or bulked and shipped off site for purchase.

EPA considers calcining the first step in gypsum product manufacturing. Many facilities with a primary SIC code of 3275 may have mining/quarry and crushing activities at their sites. Please note, however, that because these activities are not considered part of the manufacturing operations, storm water discharges from mining/quarry and crushing are not covered under Part XI.E. of the today's permit. Discharges associated with gypsum mining activities are addressed under Part XI.J. of today's permit and VIII.J. of the fact sheet.

2. Pollutants in Storm Water Discharges Associated With Glass, Clay, Cement, Concrete, and Gypsum Product Manufacturing

Impacts caused by storm water discharges from gypsum, concrete, clay, glass, and concrete manufacturing operations will vary. Several factors influence to what extent industrial activities and significant materials from these types of facilities and processing operations can affect water quality. Such factors include: geographic location; hydrogeology; the type of industrial activity occurring outside (e.g., material storage, loading and unloading, or vehicle maintenance); the type of material stored outside (e.g., aggregate, limestone, clay, concrete, etc.); the size of the operation; and type, duration, and intensity of precipitation events. These and other factors will interact to influence the quantity and quality of storm water runoff. For example, air emissions (i.e., settled dust) may be a significant source of pollutants at some facilities, while material storage is a primary source at others. In addition, sources of pollutants other than storm water, such as illicit connections,[41] spills, and other improperly dumped materials, may increase the pollutant loadings discharged into waters of the United States.

Table E-1, Potential Sources of Pollutants in Storm Water Discharges Associated with Glass, Clay, Cement, Concrete, and Gypsum Manufacturing, summarizes the industrial activities indicated in the part 1 group applications for facilities covered under this section of today's permit. Table E-1 also lists the likely sources of contamination of storm water that are associated with this activity. The third column of the table lists the pollutants or the indicator parameters for the pollutants which may be present in the storm water discharges associated with the industrial activity. The table is limited to the industrial activities which are commonly exposed to storm water. Industrial activities which predominantly occur indoors, such as glass forming, are not listed in Table E-1.

TABLE E-1.—POTENTIAL SOURCES OF POLLUTANTS IN STORM WATER DISCHARGES ASSOCIATED WITH GLASS, CLAY, CEMENT, CONCRETE, AND GYPSUM MANUFACTURING

Activity	Pollutant source	Pollutants/indicators
Material Storage at Glass Manufacturing Facilities.	Exposed or spilled: sand, soda ash, limestone, cullet, and petroleum products.	TSS, COD, oil and grease, pH, lead.
Materials Storage at Clay Products Manufacturing Facilities.	Exposed: ceramic parts, pryophyllite ore, shale, ball clay, fire clay, kaolin, tile, silica, graphite, coke, coal, brick, sawdust, waste oil, and used solvents.	TSS, pH, COD, oil and grease, aluminum, lead, zinc.
Material Handling at Clay Products Manufacturing Facilities Including: Loading/Unloading.	Exposed: ceramic parts, liquid chemicals, ammonia, waste oil, used solvents, pryophyllite ore, shale, ball clay, fire clay, kaolin, tile, alumina, silica, graphite, coke, coal, olivine, magnesite magnesium carbonate, brick, sawdust, and wooden pallets.	TSS, pH, oil and grease, TKN, COD, BOD, aluminum, lead, zinc.
Forming/Drying Clay Products	Clay, shale, slag, cement, and lime	TSS, pH.
Material Storage at Cement Manufacturing Facilities.	Exposed: kiln dust, limestone, shale, coal, clinker, gypsum, clay, slag, and sand.	TSS, pH, COD, potassium, sulfate.
Material Handling at Cement Manufacturing Facilities.	Exposed: kiln dust, limestone, shale, coal, clinker, gypsum, clay, slag, anhydrite, and sand.	TSS, pH, COD, potassium, sulfate, oil and grease.
Crushing/Grinding at Cement Manufacturing Facilities.	Settled dust and ground limestone, cement, oyster shell, chalk, and clinker.	TSS, pH.
Material Storage at Concrete Product Manufacturing Facilities.	Exposed: aggregate (sand and gravel), concrete, shale, clay, limestone, slate, slag, and pumice.	TSS, COD, pH.

[41] Illicit connections are contributions of unpermitted non-storm water discharges to storm sewers from any of a number of sources including sanitary sewers, industrial facilities, commercial establishments, or residential dwellings.

TABLE E-1.—POTENTIAL SOURCES OF POLLUTANTS IN STORM WATER DISCHARGES ASSOCIATED WITH GLASS, CLAY, CEMENT, CONCRETE, AND GYPSUM MANUFACTURING—Continued

Activity	Pollutant source	Pollutants/indicators
Material Handling at Concrete Product Manufacturing Facilities.	Exposed: aggregate, concrete, shale, clay, slate, slag, pumice, and limestone as well as spills or leaks of cement, fly ash, admixtures and baghouse settled dust.	TSS, COD, pH, lead, iron, zinc.
Mixing Concrete	Spilled: aggregate, cement, and admixture	TSS, pH, COD, lead, iron zinc.
Casting/Forming Concrete Products	Concrete, aggregate, form release agents, reinforcing steel, latex sealants, and bitumastic coatings.	TSS, pH, oil and grease, COD, BOD.
Vehicle and Equipment Washing at Concrete Product Manufacturing Facilities.	Residual: aggregate, concrete, admixture, oil and grease	TSS, pH, COD, oil and grease.
Crushing/Grinding of Gypsum Rock	Exposed or spilled: gypsum rock and dust	TSS, pH.
Material Storage at Gypsum Manufacturing Facilities.	Exposed: gypsum rock, synthetic gypsum, recycled gypsum and wallboard, stucco, perlite ore/expanded perlite, and coal.	TSS, COD, pH.
Material Handling at Gypsum Manufacturing Facilities (including bagging and packaging).	Exposed or spilled: gypsum rock, synthetic gypsum, recycled gypsum and wallboard, stucco, perlite ore/expanded perlite, and coal.	TSS, pH, COD.
Equipment/Vehicle Maintenance	Gasoline, diesel, fuel, and fuel oil	Oil and grease, BOD, COD.
	Parts cleaning	COD, BOD, oil and grease, pH.
	Waste disposal of solvents, oily rags, oil and gas filters, batteries, coolants, and degreasers.	Oil and grease, lead, iron, zinc, aluminum, COD, pH.
	Fluid replacement including lubricating fluids, hydraulic fluid, oil, transmission fluid, radiator fluids, solvents, and grease.	Oil and grease, arsenic, lead, cadmium, chromium, COD, and benzene.

The activities common to the facilities covered under Part XI.E. of today's permit are material storage and material handling operations. All facilities covered under this section handle and store nonmetallic minerals. These minerals are typically loaded and unloaded in areas of the site that are exposed to storm water. The minerals are often stored outdoors until they are utilized in the industrial processes. Handling and storing these minerals outdoors may result in the discharge of a portion of the materials in storm water runoff. The presence of the nonmetallic minerals in the storm water is measured by the total suspended solids (TSS) test. Many of the minerals processed by the facilities are calcareous, such as limestone or chalk. The presence of these materials can elevate the pH of the storm water discharged from the site.

Vehicle fueling, repair, maintenance and cleaning occurs at many facilities covered under this section. Facilities will fuel, repair and maintain vehicles used to transport significant materials to, from or around the facility. Facilities may also perform maintenance on process or material handling equipment such as mixers or conveyors. The fueling, maintenance and repair activities may result in leaks or spills of oil from the vehicles and equipment. The spilled material may be carried off of the site in the storm water discharge.

Ready mix concrete facilities will frequently wash out the mixers of the trucks after concrete has been delivered to a job site. The wash out water contains unhardened concrete. Facilities will often wash down the exterior of their vehicles. The wash off water may contain cement, sand, gravel, clay, or other materials. The wash water from the vehicles should be either treated and discharged from the site through a sanitary sewer or NPDES permitted discharge or collected in a recycle pond where the heavy solids settle out and the water is recycled back to be used in the plant. Pollutants from the wash water may settle out on the site before it is treated or recycled. These pollutants may come into contact with storm water and be discharged from the site.

Based on the wide variety of industrial activities and significant materials at the facilities included in this sector, EPA believes it is appropriate to divide the glass, clay, cement concrete and gypsum product industry into subsectors to properly analyze sampling data and determine monitoring requirements. As a result, this sector has been divided into the following subsectors: manufacturers of flat glass, glass and glassware, pressed or blown glass products made of purchased glass; hydraulic cement manufacturers; manufacturers of clay products, pottery and related products (including nonclay refractories); and concrete, gypsum and plaster product manufacturers (including ground minerals and earth). Tables E-2, E-3, E-4 and E-5 below include data for the eight pollutants that all facilities were required to monitor for under Form 2F. The tables also list those parameters that EPA has determined merit further monitoring.

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.
[ii] Composite samples.

3. Options for Controlling Pollutants

There are a number of options for eliminating or minimizing the presence of pollutants in storm water discharges from glass, clay, cement or concrete product manufacturing facilities. In evaluating the options for controlling pollutants in the storm water discharges associated with the industrial activities covered under this section, EPA must comply with the requirements of Section 402(p)(3) of the Clean Water Act which require the compliance with the Best Available Technology (BAT) and Best Conventional Technology (BCT).

EPA believes that it is infeasible to develop effluent limitations for storm water discharges associated with glass, clay, cement, or concrete manufacturing beyond those already established in the Effluent Limitation Guidelines. There are significant variations from site to site on the industrial activity and significant materials exposed to storm water. The data collected to date is inadequate to characterize these variations. Therefore, EPA believes that the requirement for a facility operator to develop a pollution prevention plan which considers the specific conditions at his or her site satisfies the BAT/BCT requirements. The pollution prevention plan will call for the implementation of best management practices that minimize contact between the storm water and pollutant sources or which remove pollutants from the storm water before it is discharged from the site. Table E–6 lists the pollution prevention measures or best management practices which are most applicable to facilities classified in major SIC Group 32. The table is organized by the specific industrial activities which may introduce pollutants to storm water. The right column lists corresponding BMPs which may be considered.

TABLE E–6.—MEASURES TO CONTROL POLLUTANTS IN STORM WATER DISCHARGES FROM GLASS, CLAY, CEMENT, CONCRETE, AND GYPSUM FACILITIES[1]

Activity	Associated BMPs
Storing dry bulk materials including: sand, gravel, clay, cement, fly ash, kiln dust, and gypsum.	Store materials in an enclosed silo or building.
	Cover material storage piles with a tarp or awning.
	Divert runon around storage areas using curbs, dikes, diversion swales or positive drainage away from the storage piles.
	Install sediment basins, silt fence, vegetated filter strips, or other sediment removal measures downstream/downslope.
	Only store washed sand and gravel outdoors.
Handling bulk materials including: sand, gravel, clay, cement, fly ash, kiln dust, and gypsum.	Use dust collection systems (e.g., bag houses) to collect airborne particles generated as a result of handling operations.
	Remove spilled material and settled dust from paved portions of the facility by shoveling and sweeping on a regular basis.
	Periodically clean material handling equipment and vehicles to remove accumulated dust and residue.
	Install sediment basins, silt fence, vegetated filter strips, or other sediment removal measures downstream/downslope.
Mixing operations	Use dust collection systems (e.g., bag houses) to collect airborne particles generated as a result of mixing operations.
	Remove spilled material and settled dust from the mixing area by shoveling and sweeping on a regular basis.
	Clean exposed mixing equipment after mixing operations are complete.
	Install sediment basins, silt fence, vegetated filter strips, or other sediment removal measures downstream/downslope.
Vehicle and equipment washing	Designate vehicle and equipment wash areas that drain to recycle ponds or process wastewater treatment systems.
	Train employees on proper procedure for washing vehicles and equipment including a discussion of the appropriate location for vehicle washing.
	Conduct vehicle washing operation indoors or in a covered area.
	Clean wash water residue from portions of the site that drain to storm water discharges.
Dust Collection	Maintain dust collection system and baghouse. Properly remove and recycle or dispose of collected dust to minimize exposure of collected dust to.
Pouring and curing pre-cast concrete products	Pour and cure precast products in a covered area.
	Clean forms before storing outdoors.

[1] From "Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices," (EPA 832–R–92–006) EPA, 1992, and proposed pollution prevention plans submitted by group applicants.

In addition to the activity-specific best management practices listed in Table E–6 above, there are structural practices that may be effective in reducing the pollutants found in the storm water discharges from facilities in Major SIC Group 32. This section does not specifically require that these structural measures be installed; however, the permittee must consider measures such as these at the facility. The structural measures include: vegetative filter strips, grassed swales, detention ponds, retention ponds or recycle ponds. These structural measures remove pollutants from the storm water which is carrying them off site. The measures listed above are effective in removing the heavy suspended solids which are common in the storm water discharges from clay, cement, concrete, and gypsum facilities.

Vegetated filter strips are gently sloped areas covered with either natural or planted vegetation. Vegetated filter strips remove pollutants from storm water by a filtering action. Vegetated filter strips can be located along the down slope perimeter of the industrial activity but not in areas of concentrated flow. Grassed swales are similar to vegetated filter strips. Within Major SIC Group 32, four percent of the designated sampling facilities indicated in their part 1 group applications that they had vegetated filter strips at their facilities. Grassed swales also remove pollutants from storm water flows by a filtering action. A grassed swale consists of a broad, grass lined ditch or swale with gradual slopes or check dams to reduce the velocity of flow. Unlike vegetated filter strips, grassed swales can remove pollutants from concentrated storm water runoff. Over 13 percent of the designated samplers in Major SIC Group 32 indicated that there were grass lined swales at their facility.

Retention ponds and detention ponds are storm water management measures used to control the quantity and quality of storm water discharged from a site. A detention pond is a pond which temporarily detains the storm water discharged from an area. While detained in the pond, the heavy suspended particles in the storm water settle to the bottom of the pond. The result is a discharge from the detention pond with a TSS concentration which is lower than the influent concentration to the pond. Retention ponds retain the storm water within the pond with no discharge except for when extreme rainfall events occur. The water collected in the retention pond either evaporates, infiltrates, or is used as process water on site. Twenty seven percent of the designated samplers in Major SIC Group 32 indicated that there was a pond on their site which was used as a storm water management measure.

4. Special Conditions

a. Prohibition of Non-storm Water Discharges. The prohibited non-storm water discharges under this section are the same as those described under section V1.B.2 of this fact sheet with one exception. Part XI.E.2. of today's permit clarifies that the discharges of pavement washwaters from facilities covered under Part XI.E. of the permit are authorized under this section after the accumulated fly ash, cement, aggregate, kiln dust, clay, concrete or other dry significant materials handled at the facility have been removed from the pavement by sweeping, vacuuming, combination thereof or other equivalent measures, or the washwaters are conveyed into a BMP designed to remove solids prior to discharge, such as sediments basins, retention basins, and other equivalent measures. Where practicable pavement washwater shall be directed to process wastewater treatment or recycling systems. The clarification is made for this sector because EPA believes that a primary source of pollutants in the storm water discharges from facilities covered under this sector are spilled materials or settled dust from material handling processes. A primary focus of the pollution prevention plan requirements for these industries are good housekeeping measures, in particular, sweeping the paved portions of the site surrounding the material handling areas. Washing the paved areas without first sweeping or otherwise removing the accumulated solids may result in the discharge of these pollutants in the washwater unless the washwater is contained onsite or otherwise collected without discharge.

5. Storm Water Pollution Prevention Plan Requirements

a. Contents of the Plan.

(1) Description of Potential Pollutant Sources. All facilities covered by today's permit must prepare a description of the potential pollutant sources at the facility which complies with the common requirements described in Part VI.C.2. of this fact sheet. In addition to these requirements, facilities covered by this section must provide the following additional information in their pollution prevention plan.

Facilities covered under Part XI.E. of today's permit must identify on the site map the location of any: bag house or other air pollution control device; any sedimentation or process waste water recycling pond and the areas which drain to the pond. The location of the bag house or air pollution control equipment is required because this equipment stores the particulates or dust that are removed from the air in and around the material handling equipment. There is a potential that the collected dust or particulates could come into contact with storm water. Therefore the site map must indicate the location of this potential source. The site map for the facility must clearly indicate the portion of the facility which drains to sedimentation or recycle ponds that receive process wastewater. This information is necessary to illustrate the portion of the site where runoff is already controlled. The site map must also indicate the outfall locations and the types of discharges contained in the drainage areas of the outfalls (e.g. storm water and air conditioner condensate). In order to increase the readability of the map, the inventory of the types of discharges contained in each outfall may be kept as an attachment to the site map. The site map for these facilities must also indicate the portion of the site where regular sweeping or other equivalent good housekeeping measures will be implemented to prevent the accumulation of spilled materials or settled dust.

(2) Measures and Controls. Part VI.C.3. of today's fact sheet describes a number of measures and controls which are effective in controlling the discharge of pollutants in storm water discharged from a number of types of industrial activities including those facilities in Major SIC Group 32. The following section describes BMPs which EPA believes are particularly effective in controlling the pollutants discharged from glass, clay, cement, concrete or gypsum manufacturing facilities. Facilities covered under Part XI.E. are required to consider each of these BMPs or its equivalent in their pollution prevention plan.

(a) Good Housekeeping—Today's permit requires that the pollution prevention plans for facilities covered under this section must specifically address measures to minimize the discharge of spilled cement, sand, kiln dust, fly ash, settled dust or other significant materials in storm water from paved portions of the site that are exposed to storm water. Measures used to minimize the presence of these materials may include regular sweeping, or other equivalent measures. The plan shall indicate the frequency of sweeping or other measures. The frequency shall be determined based upon consideration of the amount of industrial activity occurring in the area and frequency of precipitation. This requirement is established in an effort to minimize the discharge of solids from these types of facilities. Sweeping to prevent the discharge of solids must be considered in the pollution prevention plan because it is a cost effective measure well suited to the dry, granular, and powder-like materials used at the facilities covered under this section.

This section also requires that facilities minimize the exposure of fine solids such as cement, fly ash, baghouse dust, and kiln dust to storm water. The pollution prevention plan shall consider storing these materials in enclosed silos, hoppers, or other containers, in buildings, or in covered areas of the facility. Fine solids are a particular concern because the small particles are readily suspended by storm water and carried off of the site.

(b) Preventative Maintenance—There are no additional preventative maintenance requirements beyond these described in Part VI.C.3 of this fact sheet.

(c) Spill Prevention and Response—There are no additional spill prevention and response requirements for facilities in the glass, clay, cement, concrete or gypsum products industries beyond those described in Part VI.C.3.c. of this fact sheet.

(d) Inspections—Facilities in the glass, clay, cement, concrete, and gypsum products industries are required to conduct self inspections at a frequency which they determine to be adequate to ensure proper implementation of their pollution prevention plan, but not less frequently than once per month. Monthly inspections are necessary for the facility to be able to assess the effectiveness of

the pollution prevention plan. Less frequent inspections may allow facilities to delay inspections until after periods of high activity when the greatest potential for exposure of materials occurs. This section requires that the inspections take place while the facility is in operation because this is the only time when potential pollutant sources (such as malfunctioning dust control equipment or non-storm water discharges from equipment washing operations) may be evident. The inspectors must observe several portions of the site which EPA believes are potential sources of pollutants in storm water including: material handling areas, above ground storage tanks, hoppers or silos, dust collection/ containment systems, vehicle washing, and equipment cleaning areas.

(e) Employee Training—In addition to the requirements described in Part VI.C.3.e. of this fact sheet, the pollution prevention plan training requirements for facilities in the glass, clay, cement, concrete, and gypsum industries require that the employee training program address procedures for equipment and vehicle washing. This is because these are common activities in these industries which result in process wastewater which may be discharged into the storm water conveyance system. Training programs should focus on where and how equipment should be cleaned at the facility so that there will be no unpermitted discharge of wash water to the storm water conveyance system. EPA recommends that facilities conduct training annually at a minimum. However, more frequent training may be necessary at facilities with high turnover of employees or where employee participation is essential to the storm water pollution prevention plan.

(f) Recordkeeping and Internal Reporting Procedures—There are no additional recordkeeping and internal reporting procedure requirements for facilities in the stone, clay, glass or concrete products industries beyond than those described in Part VI.C.3.f. of this fact sheet.

(g) Non-storm Water Discharges—There are no additional non-storm water discharge certification requirements for facilities in the stone, clay, glass or concrete products industries beyond those described in Part VI.C.2.d. of this fact sheet with the exception of facilities engaged in production of concrete products. These facilities must include in the certification a description of measures which insure that process wastewater which results from washing of trucks, mixers, transport buckets, forms or other equipment are discharged in accordance with NPDES requirements or are recycled. These nonprocess wastewater discharges are common to this industry. However, these discharges are not eligible for coverage under this section and it is necessary to assess the facility for the presence of these discharges so that steps may be taken to eliminate the discharges or to cover the process discharges with a separate permit.

A number of facilities in the concrete products industry maintain wash water recycle/retention ponds which receive the process wastewater from equipment cleaning and other operations. These ponds may also receive a portion or all of the runoff from the industrial site. These facilities are required to provide an estimate of the depth of the 24-hour duration storm event that would be required to cause the recycle/retention pond to overflow and discharge to the waters of the United States. Methods to make this estimate can include, but are not limited to, the original design calculations for the recycle/retention pond or historical observation.

(h) Sediment and Erosion Control—There are no additional sediment and erosion control requirements for facilities in the stone, clay, glass, or concrete products industries beyond those described in Part VI.C.3.g. of this fact sheet.

(i) Management of Runoff—There are no additional requirements for management of runoff at facilities in the stone, clay, glass, or concrete products industries beyond than those described in Part VI.C.3.h. of this fact sheet.

(3) Comprehensive Site Compliance Evaluation. Facilities in the glass, clay, cement, concrete, and gypsum product sector must perform an annual site compliance evaluation as described in Part VI.C.4. of this fact sheet. For facilities in the concrete product manufacturing industries, the evaluation must specifically address the following portions of the site: above ground storage tanks, hoppers or silos; dust collection/containment systems; truck wash down; and equipment cleaning areas. Because these areas are the most likely sources of pollutants, these portions of the site must be thoroughly evaluated.

6. Numeric Effluent Limitations

Part XI.E.4. of today's permit establishes numeric effluent limitations for storm water discharges from storage areas for materials used or produced at cement manufacturing facilities. Discharges from these areas may not exceed a maximum TSS concentration of 50 mg/L. The pH of the discharges from these areas must be within the range of 6.0 to 9.0. Untreated discharges from the facility which are a result of a storm with a rainfall depth greater than the 10-year, 24-hour storm event are not subject to this limitation. These effluent limitations are in accordance with 40 CFR 411.32 and 40 CFR 411.37. Effluent Guidelines and Standards, Cement Manufacturing Point Source Category, Materials Storage Piles Runoff Subcategory. These limitations represent the degree of effluent reduction attainable by the application of best practicable control technology and best conventional pollutant control technology. Dischargers subject to these numeric effluent limitations must be in compliance with the limits upon commencement of and for the entire term of this permit. Discharges that are associated with industrial activities that do not contain runoff from material storage areas at cement manufacturing facilities are not subject to the effluent limitation described above.

7. Monitoring and Reporting Requirements

a. Analytical Monitoring Requirements. EPA believes that glass, clay, cement, concrete, and gypsum product manufacturing may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. In order to provide a tool for evaluating the effectiveness of the pollution prevention plan, requires two of the four subsectors within the glass, clay, cement, concrete and gypsum product manufacturing sector to perform analytical monitoring.

The clay product subsector includes brick and structural clay tile manufacturers (SIC 3251), ceramic wall and floor tile manufacturers (SIC 3253), clay refractories (SIC 3255), manufacturers of structural clay products, not elsewhere classified (SIC 3259), manufacturers of vitreous china table and kitchen articles (SIC 3232), manufacturers of fine earthenware table and kitchen articles (SIC 3263), manufacturers of porcelain electrical supplies (SIC 3264), pottery products (SIC 3269) and non-clay refractories (3297). Data submitted by group applicants within this subsector show that a significant portion of the facilities discharge aluminum concentrations higher than bench mark values. Therefore facilities with these industrial activities must monitor for the pollutant identified in Table E–7.

The concrete and gypsum subsector includes concrete block and brick manufacturers (SIC 3271), concrete products manufacturers (SIC 3272), ready mix concrete manufacturers (SIC 3273), gypsum product manufacturers (SIC 3275) and manufacturers of mineral and earth products (SIC 3295). Data submitted by group applicants within this subsector show that a significant portion of the facilities discharge total suspended solids and iron in concentrations higher than bench mark values. Therefore facilities with these industrial activities must monitor for pollutants identified in Table E–8.

The glass product subsector includes flat glass manufacturers (SIC 3211), glass container manufacturers (SIC 3221), pressed and blown glass and glassware manufacturer (SIC 3229), and manufacturers of glass products made of purchased glass (SIC 3231). Monitoring data submitted by facilities within this subsector do not indicate that these facilities are likely to discharge storm water with pollutant concentrations greater than the bench marks. Therefore, this sector is not subject to analytical monitoring requirements under this permit.

The cement manufacturing subsector includes manufacturers of hydraulic cement (SIC 3241). This subsector is not subject to the analytical monitoring requirements under Section XI.E.5.a this permit. However, because these facilities are subject to numerical effluent limitations they are subject to compliance monitoring described in section XI.E.5.d of the permit.

At a minimum, storm water discharges from clay and gypsum, and concrete product manufacturing must be monitored quarterly (January through March, April through June, July through September and October through December) during the second year of permit coverage. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Tables E–7 and E–8. If the permittee collects more than four samples in this period, then they must calculate an average concentration for all parameters analyzed, not simply a minimum of four selected analysis.

TABLE E–7.—CLAY PRODUCT INDUSTRY MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Recoverable Aluminum	0.75 mg/L.

TABLE E–8.—CONCRETE AND GYPSUM PRODUCT INDUSTRY MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Suspended Solids (TSS) ...	100 mg/L.
Total Recoverable Iron	1.0 mg/L.

If the average concentration for a parameter is less than or equal to the value listed in Tables E–7 or E–8, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration listed in Tables E–7 or E–8, then the permittee is required to conduct quarterly (in the same quarterly periods listed above) monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit.

TABLE E–9.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Table E–7 or E–8, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Table E–7 or E–8, then no further sampling is required for that parameter.
4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Table E–7 or E–8. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will reassess the effectiveness of the adjusted pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

b. Alternative Certification. Throughout today's permit, there are monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall, or on a pollutant-by-pollutant basis, in lieu of sampling required under Part XI E.5 of today's permit, that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in lieu of monitoring reports required under Part XI E.5.b. The permittee is required to complete any and all sampling until the exposure is eliminated. If the facility is reporting for a partial year, the permittee must specify the exposure was eliminated. If the permittee is certifying that a pollutant was present for part of the reporting period, nothing relieves the permittee from the responsibility to sample that parameter up until the exposure was eliminated and it was determined that no significant materials remained.

This certification is not to be confused with the low concentration sampling waiver. The test for the application of this certification is whether the pollutant is exposed, or can be expected to be present in the storm water discharge. If the facility does not and has not used a parameter, or if exposure is eliminated and no significant materials remain, then the facility can exercise this certification. In the case of certifying that a pollutant is not present, the permittee must submit the certification along with the monitoring reports required under paragraph (*b*) below. If the permittee cannot certify for an entire period, they must submit the date exposure was eliminated and any monitoring required up until that date. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

c. Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one signed Discharge Monitoring Report Form must be submitted per storm event sampled. For facilities conducting monitoring beyond the minimum quarterly requirements an additional Discharge Monitoring Report Form must be filed for each analysis.

d. Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable.

If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

e. Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area (e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)) shall be provided in the plan.

f. Quarterly Visual Examination of Storm Water Quality. Quarterly visual examinations of storm water discharges from each outfall are required. Note that this requirement applies to all facilities and not just those subject to the analytical monitoring requirements under Part VI.E.7. of this fact sheet. The examination must be of a grab sample collected from each storm water outfall. The examination of storm water grab samples shall include any observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, or other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on these samples.

The examination must be made at least once every 3 months (January through March, April through June, July through September, and October through December) during permit coverage. Examinations shall be made during daylight unless there is insufficient rainfall or snow-melt to produce runoff. Whenever practicable, the same individual should carry out the collection and examination of discharges throughout the life of the permit to ensure the greatest degree of consistency possible. Grab samples shall be collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 60 minutes) of when the runoff begins discharging. Reports of the visual examination include: the examination date and time, examination personnel, visual quality of the storm water discharge, and probable sources of any observed storm water contamination. The visual examination reports must be maintained onsite with the pollution prevention plan.

EPA believes that this quick and simple assessment will allow the permittee to approximate the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examination. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and the effects of the management practices that are included in the plan.

When a discharger is unable to collect samples over the course of the monitoring period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination. Adverse weather conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

g. Compliance Monitoring Requirements. Today's permit requires permittees with discharges of runoff from material storage at cement manufacturing facilities to monitor for the presence of TSS and pH. These monitoring requirements are necessary to evaluate compliance with the numeric effluent limitation established for these discharges. Monitoring shall be performed upon a minimum of one grab sample. All samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable. Monitoring results shall be submitted on Discharge Monitoring Report Form(s) postmarked no later than the 31st day of the month following collection of the sample. Facilities which discharge through a large or medium municipal separate storm sewer system (systems serving a population of 100,000 or more) must also submit signed copies of discharge monitoring reports to the operator of the municipal separate storm sewer system. Alternative Certification provisions described in Section VI.E.5 do not apply to facilities subject to compliance monitoring requirements in this section. Compliance monitoring is required at least annually for discharges subject to effluent limitations. Therefore, EPA cannot permit a facility to waive compliance monitoring.

F. Storm Water Discharges Associated With Industrial Activity From Primary Metals Facilities

1. Discharges Covered Under This Section

On November 16, 1990 (55 FR 47990), the U.S. Environmental Protection Agency (EPA) promulgated the regulatory definition of "storm water discharges associated with industrial activity." This definition included point source discharges of storm water from 11 categories of industrial facilities. This section of today's permit includes storm water discharges associated with industrial activity from primary metals facilities. These facilities are commonly identified by Standard Industrial Classification (SIC) code 33. The SIC codes eligible for coverage under this section of today's permit include the following:

a. Steel works, blast furnaces, and rolling and finishing mills, including: steel wiredrawing and steel nails and spikes; cold-rolled steel sheet, strip, and bars; and steel pipes and tubes (SIC 331).

b. Iron and steel foundries, including: gray and ductile iron, malleable iron, steel investment, and steel foundries, not elsewhere classified (SIC 332).

c. Primary smelting and refining of nonferrous metals, including: primary smelting and refining of copper and primary production of aluminum (SIC 333).

d. Secondary smelting and refining of nonferrous metals (SIC 334).

e. Rolling, drawing, and extruding of nonferrous metals, including: rolling, drawing, and extruding of copper; aluminum extruded products; rolling, drawing, and extruding of nonferrous metals, except copper and aluminum; and drawing and insulating of nonferrous wire (SIC 335).

f. Nonferrous foundries (castings), including: aluminum die-castings, nonferrous die-castings, except aluminum, aluminum foundries, copper foundries, and nonferrous foundries, except copper and aluminum (SIC 336).

g. Miscellaneous primary metal products, not elsewhere classified, including metal heat treating (SIC 339).

Group applications were received from facilities representing each of the categories of industry eligible for coverage under this section. A large number of group applications also included facilities identified by other SIC codes. These facilities may be covered in whole, or in part, by other sections of today's permit. In other cases, SIC codes may have been assigned improperly. The special conditions reflected in this section of today's permit relate to specific operations taking place at a facility. These operations should be used as the basis for determining permit requirements appropriate for that particular facility.

Although there are many activities common to some or all of the facilities covered by this section, some of the operations discussed are unique to a particular industry group. Due to the broad range of activities conducted by facilities in this category, it would be impossible to identify all activities occurring at facilities covered by this section. This fact sheet attempts to describe the major activities representative of many of the facilities addressed by this section and provides examples of concerns associated with storm water discharges from primary metals facilities. All materials present and industrial activities taking place at a facility that have a potential impact on storm water discharges must be addressed by the facility's pollution prevention plan, whether or not the material or activity is specifically addressed by this section.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

2. Industry Profile

Facilities in the primary metals industry conduct a wide range of activities. The SIC manual lists seven industry groups (three-digit SIC codes), and 27 industry numbers (four-digit SIC codes) within the sector. Of these, facilities representing 21 four-digit SIC codes submitted group applications.

Due to the large number of alternate processes available for many activities conducted within the primary metals industry it is very difficult to characterize "typical" facilities. Facilities within the same industry can employ quite dissimilar processes to arrive at a similar product. Differences can be found in the types of raw materials, furnaces or ovens, casting processes, the degree of mechanization, and any finishing operations which may be employed by a particular facility. Considerable differences can also be seen between facilities based on their customers needs. Some facilities may operate as a job shop, providing finished parts to other companies. Other facilities could conduct more limited operations and pass the product on to other facilities that provide finishing operations exclusively.

These differences in specific processes, as well as in the general scale and scope of individual operations can make facilities with the same or similar SIC codes quite different. Due to the difficulty in subdividing the industry into distinct facility types, the following discussion briefly describes the full range of activities potentially employed by members of this industry. Despite the substantial diversity within the industry group, there are a number of general operations which characterize the majority of industrial processes.

Facilities in the primary metals industry are typically involved in one or more of the following general operations: raw material storage and handling; furnace and oven related processes; preparation of molds, casts, or dies; metal cleaning, treating and finishing; and waste handling and disposal.

a. Raw Material Storage and Handling Activities. Due to the nature of the primary metals industry, large quantities of raw materials are required for many operations. The extent to which these materials are stored outside exposed to precipitation will depend on the specific operations taking place at a facility, the size of the operation, as well as the storage space available that is covered. Some of the most common materials used are metals, fuels, fluxes, refractories, sand, and an assortment of solvents, acids, and other chemicals.

The primary raw material for all facilities in the industry is the source of metal to be used or processed. For steel works, smelters, and blast furnaces, the raw material could be metallic ores, scrap, dross, or foundry returns. Foundries may use scrap materials, borings, turnings, metal ingots, pigs or a mixture of these and other materials. Rolling mills, heat treaters, and metal finishing operations will generally use billets, slabs, blooms, bars, pigs or other cast metal pieces as their primary raw material. These may be produced at another part of the same facility, or purchased from another source. Some of these materials may arrive with protective or incidental coatings of oil, oxides, or other impurities. Due to the large size and volume of some of these materials they may be stored outside.

Energy sources for facilities within the industry are also quite varied. While steel mills with coking operations may use coal as the fuel for firing coke ovens, coal would also be the raw material that would be converted to coke. Some iron and steel foundries or mini-mills may use coke as a fuel only, or may use electric arc furnaces for melting. Smaller foundries (ferrous or nonferrous) may use gas-fired or electric induction furnaces.

A variety of fluxes are often added to the molten metal to allow impurities to be removed as slag or dross. In the iron and steel industry, limestone is probably the most common flux used. Others include dolomite, soda ash, fluorspar, and calcium carbide. Nonferrous operations may use other fluxing agents or none at all.

During the melting process, refractories are used to line and protect the furnaces. These refractories have limited lives and must be replaced periodically. The life of the refractory will depend on the type of furnace as well as the material being melted. Some large furnaces require almost constant patching of the refractory materials and thus large quantities may be stored for future use.

Another common material used in casting operations is sand. Many foundries will use sands of different types to produce the molds and cores for the production of castings. Although some facilities are able to recycle their sand, others must dispose of some or all of the used sand and thus require large amounts of fresh sand as a raw material. There are also a large number of sand additives and binders which may be used to control the properties of the mold produced. "Wet" sand may contain clay, seacoal, bentonite, wood flour, phenol, iron oxide, and numerous other acids and chemicals, some of which may be toxic.

Other processes related to finishing operations can require a wide variety of solvents, chemicals, and acids. Many facilities involved in cleaning, treating, painting, or other finishing operations may store these products in tanks or drums which may be exposed to precipitation.

b. Furnace, Rolling, and Finishing Operations. The majority of processes within the primary metals industry are conducted inside. These activities include all types of furnace operations, rolling operations, as well as all kinds of metal finishing activities. Many of these operations, however, generate significant quantities of particulate matter which, if not properly controlled, can result in exposure to precipitation.

There are many different types of furnaces. Each has advantages and limitations and are used for different types of metals. Facilities may use coal, coke, or gas fired furnaces as well as electric arc or induction furnaces.

Coke ovens, or batteries, generally use coal fired furnaces to heat coal in the absence of oxygen to drive off volatiles. The resultant product is coke which is subsequently used in other furnace operations. Blast furnaces are usually operated on a continuous basis with coke, iron ore, and fluxes charged at the top of a vertical shaft while molten pig iron and slag are tapped at different levels below.

Sintering plants burn coke breeze (particles too small to use for charging in cupola or blast furnaces) mixed with iron ore, flue dust, or other products to fuse them into materials that can then be charged with regular coke in a furnace. Cupola furnaces are used by ferrous foundries and operate in essentially the same manner as blast furnaces, allowing a range of scrap steel and iron to be charged with coke and fluxes at the top of the furnace.

Basic oxygen process furnaces use a mixture of molten iron and scrap as the charge. High-purity oxygen is injected into the furnace where it combines with impurities in the charge materials and provides heat to melt the charge of scrap.

There are two types of electric furnaces in use. Electric arc furnaces operate in a batch fashion and are often used by steel mini-mills. Scrap metal is placed in the furnace along with three electrodes which provide the energy to melt the charge. Electric induction furnaces are generally smaller than other types described above and require that cleaner metals be used.

Gas-fired furnaces are often used by nonferrous foundries. They are generally small and require relatively clean metals for melting.

One trait that all types of furnaces share is the generation of significant emissions, including particulate emissions. Blast furnaces, sintering plants, and cupola furnaces, all fired by coke, have particularly high particulate emissions. These furnaces are capable of handling a relatively "dirty" charge, with significant impurities which can lead to a variety of emissions problems. For these reasons, these types of furnaces will have emissions controls such as baghouses, wet scrubbers, or electrostatic precipitators. Electric arc furnaces are also able to melt fairly "dirty" scrap and can also have significant levels of particulate emissions.

At the other end of the spectrum are smaller electric induction and gas fired furnaces which generally require a very clean charge. Although this reduces the volume of emissions concerns significantly, they are also less likely to have as extensive pollution control and thus fugitive emissions of particulates may be significant.

The effectiveness of emissions control equipment in controlling particulate generation will depend on the furnace operation, the raw materials used, the type of control equipment in place, and the degree to which it is operating properly. Fugitive emissions, faulty or improperly maintained equipment, and "dirty" raw materials can all contribute to particulate emissions that may not be captured by pollution control equipment, and may be exposed to precipitation.

Another category of operations are rolling, drawing, and extruding operations. Facilities involved in these operations will often use furnaces similar to those described above. The metal will often be heated, and then passed through a series of rollers which alter its' dimensions, making it longer, flatter, etc. This process generally involves large amounts of contact cooling water which can contain high levels of suspended solids and oil and grease.

c. Preparation of Molds, Pouring, Cooling, and Shakeout. Foundry operations and die-casters will generally prepare the molds, casts, or dies that will determine the ultimate shape of the product to be produced. There are a number of possible operations with significant differences between them. These include sand casting, investment casing, and die casting.

Sand casting operations involve a number of possible steps and a range of materials. Casts are shaped in two sections which form the outside of the part to be produced. Cores can also be used to form inner surfaces of the parts. A variety of sands may be used and can be combined with clay and a number of other additives to give the mold the desired properties. Once the casting has cooled, it is placed on a vibrating screen which shakes loose the majority of the sand. The casting is then ready for cleaning and finishing operations. At some facilities the used sand may be recycled or some or all of the sand may need to be disposed of and replaced.

Investment casting involves the formation of a wax replica of the part to be produced, usually in a metal die. A series of wax parts may be attached to a "tree." Once a tree is completed, it is coated with a ceramic cast in a series of dipping operations. The wax may then be removed from the cast in a furnace or the metal can be poured in directly. As in sand casting, the casting is allowed to cool before the cast is removed. A separate wax form and ceramic shell must be made for each part to be produced.

Die-castings employ a more direct route from molten metal to finished part. A metal die is produced and molten metal in injected under pressure into it. Once it has cooled, the casting is removed and is ready for finishing operations. Unlike sand casting or investment casting, the die can be used over and over to produce more parts.

Like most foundry operations, molds are generally prepared indoors. There are, however, particulate emissions associated with the pouring and cooling of molten metal.

d. Metal Cleaning, Treating, and Finishing. Almost all operations in the primary metals industry result in metal products which require some degree of finishing. The type of finishing activities undertaken depend on the material being treated, as well as the properties desired in the final part and can include both mechanical and chemical operations.

Castings generally come out of their molds with metal sprues and other imperfections which must be removed. This can be done through grinding, cutting, or blasting with sand, shot, or grit. Other possible operations include drilling, threading, or dimensioning. A combination of these operations is often necessary.

Some facilities such as rolling mills will use a descaling process to remove oxides and other residues which can form on the surfaces of metallic products. Typical operations include blasting with water or sand. This produces large quantities of scale and other particulate matter which may contain other residual products such as oil.

Heat treating is another operation which can involve furnaces for controlled heating and cooling of large quantities of metal. A variety of media may be used to cool metals at different rates. Oil, water, and liquid salt baths may all be used depending on the properties desired in the finished product. Acid pickling may be used to remove unwanted material from the surface of metal. Other cleaning and finishing operations may involve a wide range of solvents, acids, or other chemicals. All of these processes can generate toxic wastes in the form of sludges, particulates, or spent baths. In addition, residuals from these operations left on the metal surface may become exposed to storm water if materials are transported or stored outside.

e. Waste Handling and Disposal. Wastes are generated from numerous sources within the primary metals industry. Some types of waste are found at a majority of facilities while others may be specific to a particular activity. Some of the common waste products include used sand, cores, butts, refractory rubble, machining and finishing wastes, slag, dross, and collected particulates such as baghouse dust.

Sand casting operations which are not able to fully recycle their sand may generate large volumes of waste or "burnt" sand. "Wet" sands may contain any one of a number of additives, depending on the specific type of casting being produced. Other related wastes include the cores and butts used in the sand casing process.

Most casting operations will produce a product which requires some degree of machining and finishing. The wastes produced will depend mainly on the material being finished and whether a mechanical or chemical process is used. Machining waste can include fines, turnings, or cuttings as well as shot, grit, and scale from blasting operations. Chemical finishing can result in waste solvents, acids, and pickling sludges and baths which contain metal wastes.

The metal melting process results in the production of slag from ferrous, or dross from nonferrous materials. The content and volume of these wastes produced will vary depending on the charge material, and any fluxing agents or additives that may be used. In general, slag is produced in greater quantities and will be more likely to be stored outside, however there is the possibility of exposure of both types of waste to precipitation.

Particulate matter generated in furnaces and during machining is another source of waste with significant potential for storm water contamination. These waste streams may be segregated at larger facilities or combined, but the concerns are essentially the same. The dusts are collected in baghouses, electrostatic precipitators, wet scrubbers, or in cyclones and disposed of. If the pollution control equipment is inadequate, or not operating effectively, there is potential for storm water contamination from these types of waste.

3. Pollutants Found in Storm Water Discharges

Impacts caused by storm water discharges from primary metals facilities will vary. A number of factors will influence to what extent the activities at a particular facility will affect water quality. These include: geographic location, hydrogeology, the amounts and types of materials stored outside, the types of processes taking place outside, the size of the operation, as well as the characteristics of a particular storm event. These and other factors will interact to affect the quantity and quality of storm water runoff. For example, particulate emissions from furnaces or ovens may be a significant source of pollutants at some facilities, while outdoor material storage such as scrap piles may be a primary source at others. In addition, sources of pollution other than storm water, such as illicit connections,[42] spills, and other improperly dumped materials, may contribute significant levels of pollutants into waters of the United States.

A summary of industrial activities conducted by primary metals facilities in the group application process is listed in Table F–1. The table also lists the sources of pollutants related to the activity and what the specific pollutants of concern are. The table is limited to those activities which are generally conducted outside, or that have potential to contribute pollutants to storm water discharges. Many processes in the primary metals industry are conducted inside and are therefore not represented in Table F–1.

TABLE F–1.—POLLUTANTS OF CONCERN FOR MAJOR ACTIVITIES WITHIN THE PRIMARY METALS INDUSTRY

Activity	Source	Pollutants
Raw material storage and handling	Metal product stored outside such as foundry returns, scrap metal, turnings, fines, ingots, bars, pigs, wire.	Residual or protective Oil and Grease, Metals, TSS, COD, TSS.
	Outdoor storage or handling of fluxes	pH (limestone).
	Storage piles, bins, or material handling of coke or coal	TSS, pH, metals.
	Storage or handling of casting sand or refractory	TSS.
Vehicle Maintenance	Vehicle fueling and maintenance or outdoor storage tanks and drums of gas, diesel, kerosene, lubricants, solvents.	Oil and grease.
Waste materials—handling, storage, and disposal.	Slag or dross stored or disposed of outside in piles or drums	Metals, pH.
	Fly ash, particulate emissions, dust collector sludges and solids, baghouse waste.	TSS.
	Storage and disposal of waste sand or refractory rubble in piles outside.	TSS, metals, misc. "wet" sand additives.
	Machining waste—fines, turnings, oil, borings, gates, sprues, scale	TSS, metals, oil and grease.
	Obsolete equipment stored outside	Oil and grease.
	Landfilling or open pit disposal of wastes onsite	See Part VIII.L.
Furnace operations and pollution control equipment.	Losses during charging of coke ovens or sintering plants and from particulate emissions.	TSS, particulates, metals, volatiles, pH.
	Particulate emissions from blast furnaces, electric arc furnaces, induction furnaces.	TSS, metals.
	Fugitive emissions from poorly maintained or malfunctioning baghouses, scrubbers, electrostatic precipitators, cyclones.	TSS, metals.
	Wastewater treatment operations exposed to precipitation	See Part VIII.T.
Rolling, casting, and finishing operations.	Exposure of wastewater used for cooling or descaling related to rolling.	Oil and grease, pH, TSS, metals, COD.
	Storage of products outside after painting, pickling, or cleaning operations.	pH, solvents, metals.
	Casting cooling or shakeout exposed to precipitation or wind	TSS, metals.
	Losses of particulate matter from machining operations (grinding, drilling, boring, cutting) through deposition or storage of products outside.	Metals, TSS.
Plant yards	Areas of the facility with unstabilized soils subject to erosion	TSS.
Illicit discharges	Improper connection of floor, sink, or process wastewater drains	Dependent on source.

Although operations at primary metals facilities may vary considerably, the elements with potential impact on storm water discharges are fairly uniform and consistent. Facilities may include considerable areas of raw and waste material storage such as coal, coke, metal, ores, sand, scale, scrap, and slag. Processes generally involve furnaces for heating and melting metals or for producing coke, any of which may result in significant particulate emissions. Due to the nature of their operations some facilities will have large areas of exposed soil and heavy vehicle traffic which can lead to erosion.

a. Raw Material Storage and Handling Activities. Raw materials with potential effects on storm water discharges fall into a number of distinct categories.

Sands used for the production of molds or cores can contribute to TSS loadings. Piles of materials may be washed away directly, or spills and windblown losses may occur during handling and process related activities.

Metal raw materials can come in numerous forms including billet, slab, pig, bar. These materials have the potential to corrode which can result in the loss of metal to a solution, i.e., water. The following metals are referred to as the galvanic (or electromotive) series and have a tendency to corrode and become soluble in water; magnesium, aluminum, cadmium, zinc, steel or iron, cast iron, chromium, tin, lead, nickel, soft and silver solder, copper, stainless steel, silver, gold, platinum, brass and bronze. For some metals, the extent and rate of corrosion is dependent on whether it occurs in an oxygen-starved or oxygen-abundant atmosphere. If materials are coated in oil to prevent corrosion, or residual chemicals used to clean or treat the metal are present, these can also be a source of pollution easily picked up by storm water runoff.

Scrap metals come in a variety of forms including machining waste such as turnings, shavings, filings, borings or as post consumer waste in a variety of forms. These materials can contribute metals, oil and grease, suspended solids, and other pollutants to storm water

[42] Illicit connections are contributions of unpermitted non-storm water discharges into storm sewers from any number of sources including sanitary sewers, industrial facilities, commercial establishments, or residential dwellings.

runoff depending on their makeup and origin.

Runoff related to storage and handling of coal and coke can contribute suspended solids, metals, as well as oil and grease to runoff. These can be released from piles, hoppers, or bins through handling or wind-blown losses. Significant losses can also occur during handling with conveyors, trucks, or while preparing charges for the furnace or sintering operations.

Fluxes such as limestone may be stored in piles, bins, or hoppers outside or become exposed to precipitation during unloading and handling activities. Limestone can increase the pH of storm water. Fluxes can also contribute to loadings of suspended solids (TSS) or have other effects depending on their makeup.

A variety of acids and solvents may be stored in drums or tanks for use in metal treating and cleaning operations. Leaks and spills from tanks and drums or during handling can result in discharges with storm water. These materials can affect pH of storm water and may be toxic.

b. Process Activities. Many processes can contribute pollutants to storm water discharges. These can include all types of furnaces, metal finishing activities, as well as material handling equipment.

Furnaces of all types can generate particulate emissions. The quantity and character of these emissions can vary greatly depending on the type of furnace, the material being melted, the fuel used, and any pollution control equipment that may be in place. In general, large coke-fired and electric arc furnaces capable of handling fairly dirty charge products will have higher emissions, but are also more likely to have sophisticated pollution control such as wet scrubbers, baghouses, and electrostatic precipitators. Smaller gas fired or electric induction furnaces generally require a fairly clean charge and have less emissions, but might also have less sophisticated controls. Settling of these emissions on roofs and plant yards are very likely to be washed away in storm water runoff. These particulates can contain a wide range of constituents which can contribute metals and suspended solids to discharges.

Material handling equipment such as conveyors, trucks, and forklifts can all contribute drippings of oil and grease as well as hydraulic fluids. This equipment may also generate or release particulate matter related to the materials being handled. Pallets, hoppers, drums, and storage bins may all contain residual materials which may become exposed to storm water.

Metal finishing operations can be divided in two general types. Mechanical operations such as grinding, blasting, boring, chipping, cutting, and descaling can all produce metal fines, chips, and turnings which may contribute metals and suspended solids to discharges. Residuals of oil or other materials on the finished goods or waste products can also contribute pollutants. Other finishing operations include acid pickling, solvent cleaning, and all types of heat treating activities. Materials that have been treated or finished may have residual chemicals on them such as pickling baths, oil or liquid salt quench media, or solvents. Exposure of these materials could contribute to pH, metals, or oil and grease in storm water discharges.

Stationary process equipment may also produce a substantial amount of residual particulate material that tends to accumulate on and around the equipment. Many materials used for primary metals production are conducive to this type of buildup. This will typically occur around rotating machinery, moving parts, bearings, conveyors and at the output of the equipment, e.g., storage containers. Particulate material that accumulates can become a source of contamination if it comes in contact with either precipitation or storm water runoff.

c. Waste Material Storage, Handling, and Disposal. Waste materials are generated in large volume from many of the facilities in this industry. These wastes can include used sand, cores and butts, refractories, slag and dross, baghouse or cyclone dusts, scrubber dusts and sludges, machining wastes, and obsolete equipment. There is potential for pollution from many of these sources if not properly stored, handled, and disposed of.

Used sands, cores, butts, and refractory rubble are all potential sources of TSS. Due to the large volumes potentially generated and their generally benign nature, these materials are often stored outside. The exposure of these materials to molten metal also presents the possibility of contamination with metals which may also get washed away with storm water.

Wastes related to pollution control equipment are particularly susceptible to being discharged with storm water if not properly controlled. These wastes could originate from baghouses, cyclones, electrostatic precipitators or scrubbers. These may be in place to control emissions from a large variety of ovens and furnaces, as well as mechanical or chemical metal finishing operations. These dusts and sludges typically contain an assortment of metals, metal oxides, and other particulate matter. The size of particulates that are able to be captured will vary from one type of equipment to the next and will depend on proper operation and maintenance.

Machining and finishing waste which is not collected as described above may also be generated in significant quantities. This material is typically metallic fines and particulate matter but may contain cutting oil or other materials as well. If stored outside in piles, drums, hoppers, or other containers these materials can contribute metals, TSS, or oil to precipitation and storm water runoff.

d. Erosion and Sediment Loss. Erosion from plant yards is another potential source of storm water contamination from primary metals facilities. Areas of vehicle traffic related to material handling, loading, unloading, material storage areas etc. may all have exposed soils with the potential for erosion. These soils can contribute to TSS loadings in storm water discharges. Exposed surfaces also limit the potential for housekeeping measures such as sweeping, making spills of other materials (particulate or liquid) harder to clean up and more likely to be washed away with storm water. The large size of many primary metals facilities makes this a concern. For example: one group application consists of 5 facilities with a total land area of 623 acres. Of this, approximately 105 acres (16.9 percent) were impervious surfaces (buildings, paved areas), leaving 83 percent of the total area potentially susceptible to erosion. Vehicle traffic, material handling, and storage activities taking place in unstabilized areas can all lead to erosion.

e. Group Application Monitoring Data. Based on the wide variety of industrial activities and significant materials at the facilities included in this sector, EPA believes it is appropriate to divide the primary metals industry into subsectors to properly analyze sampling data and determine monitoring requirements. As a result, this sector has been divided into the following subsectors: steel works, blast furnaces, and mills (SIC 331); iron and steel foundries (SIC 332); primary smelting and refining of nonferrous metals (SIC 333); secondary smelting and refining of nonferrous metals (SIC 334); nonferrous rolling and drawing (SIC 335); nonferrous foundries (SIC 336); and miscellaneous primary metals products (SIC 339). Tables F–2, F–3, F–4, and F–5 below include data for the eight pollutants that all facilities were required to monitor for under Form 2F.

The tables also list those parameters that EPA has determined may merit further monitoring. Tables are not included for primary smelting and refining of nonferrous metals manufacturing facilities; secondary smelting and refining of nonferrous metals manufacturing facilities; and miscellaneous primary metal products facilities subsectors because less than three facilities submitted data for each of these subsectors.

TABLE F–2.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY STEEL WORKS, BLAST FURNACES, AND ROLLING AND FINISHING MILLS SUBMITTING PART II SAMPLING DATA [i] (mg/L)

[ii] Composite samples.

Although there are a wide range of pollutants which may be of concern for primary metals facilities, monitoring requirements for these facilities have been determined based on industry subgroups which exceed benchmarks for certain pollutants. As Tables F–2 through F–5 illustrate, there are a variety of pollutants which must be addressed at primary metals facilities.

4. Options for Controlling Pollutants

There are five main areas of concern related to primary metals facilities. These are raw material storage and handling; waste material storage, handling, and disposal; furnace, oven, and related pollution control activities; rolling, extruding, casting, and finishing operations; plant yards; and illicit connections.

Table F–6 summarizes the primary sources of pollution in each of these categories and potential Best Management Practices (BMPs) associated with each.

TABLE F–6.—POTENTIAL BEST MANAGEMENT PRACTICES FOR SOURCES WITHIN THE PRIMARY METALS INDUSTRY

Source	Potential best management practices
Metal product stored outside such as foundry returns, scrap metal, turnings, fines, ingots, bars, pigs, wire.	Store all wastes indoors or in sealed drums, covered dumpsters, etc.
	Minimize raw material storage through effective inventory control.
	Minimize runon from adjacent properties and stabilized areas to areas with exposed soil with diversion dikes, berms, curbing, concrete pads, etc.
Outdoor storage or handling of fluxes	Store fluxes in covered hoppers, silos, or indoors and protect from wind-blown losses.
	Stabilize areas surrounding storage and material handling areas and establish schedule for sweeping.
Storage piles, bins, or material handling of coke or coal.	Where possible store coke and coal under cover or indoors and protect from wind-blown losses.
	Prevent or divert runon from adjacent areas with swales, dikes, or curbs.
	Minimize quantities of coke or coal stored onsite through implementation of effective inventory control.
	Trap particulates originating in coke or coal storage or handling areas with filter fabric fences, gravel outlet protection, sediment traps, vegetated swales, buffer strips of vegetation, catch-basin filters, retention/detention basins or equivalent.
Storage or handling of casting sand	Store raw sand in silos, covered hoppers, or indoor whenever possible.
	Prevent or divert runon from adjacent areas with swales, dikes, or curbs.
	Minimize quantities of sand stored onsite through implementation of effective inventory control.
	Tarp or otherwise cover piles.
	Trap particulates originating in coke or coal storage or handling areas with filter fabric fences, gravel outlet protection, sediment traps, vegetated swales, buffer strips of vegetation, catch-basin filters, retention/detention basins or equivalent.
Vehicle fueling and maintenance	See Part VIII.P.
Outdoor storage tanks or drums of gas, diesel, kerosene, lubricants, solvents.	Store tanks and drums inside when possible.
	Establish regular inspection of all tanks and drums for leaks, spills, corrosion, damage, etc.
	Utilize effective inventory control to reduce the volume of chemicals stored onsite.
	Prevent runon to and runoff from tank and drum storage areas, provide adequate containment to hold spills and leaks.
	Prepare and train employees in dealing with spills and leaks properly, use dry clean-up methods when possible.
Slag or dross stored or disposed of outside in piles or drums.	Collect waste waters used for granulation of slag—these are not allowed under this section.
	Store slag and dross indoors, under cover, or in sealed containers.
	Establish regular disposal of slag or dross to minimize quantities stored and handled onsite.
	Minimize runon to slag storage areas with diversion dikes, berms, curbing, vegetated swales.
	Trap particulates originating in slag storage areas with filter fabric fences, gravel outlet protection, sediment traps, vegetated swales, buffer strips of vegetation, catch-basin filters, retention/detention basins or equivalent.
Fly ash, particulate emissions, dust collector sludges and solids, baghouse dust.	Store all dusts and sludges indoors to prevent contact with storm water or losses due to wind.
	Establish regular disposal schedule to minimize quantities of pollutants stored and handled onsite.
Storage and disposal of waste sand or refractory rubble in piles outside.	Move piles under cover or tarps whenever possible.
	Establish regular disposal schedule to minimize quantities stored onsite.
	Stabilize areas of waste product storage and perform regular sweeping of area.
Scrap processing activities (shredding etc.)	See Part VIII.N.
Machining waste stored outside or exposed to storm water—fines, turnings, oil, borings, gates, sprues, scale.	Store all wastes indoors or in sealed drums, covered dumpsters, etc.
	Stabilize areas of waste product storage and perform regular sweeping and cleaning of any residues.

TABLE F–6.—POTENTIAL BEST MANAGEMENT PRACTICES FOR SOURCES WITHIN THE PRIMARY METALS INDUSTRY—Continued

Source	Potential best management practices
	Consider using booms, oil/water separators, sand filters, etc. for outfalls draining areas where oil is potentially present. Minimize runon from adjacent properties and stabilized areas to areas with exposed soil with diversion dikes, berms, curbing, concrete pads, etc.
Obsolete equipment stored outside	Where possible, dispose of unused equipment properly, or move indoors. Cover obsolete equipment with a tarp or roof. Consider using booms, oil/water separators, sand filters, etc. for outfalls draining areas where oil is potentially present. Minimize runoff coming into contact with old equipment through berms, curbs, or placement on a concrete pad.
Material losses from handling equipment such as conveyors, trucks, pallets, hoppers, etc.	Schedule frequent inspections of equipment for spills or leakage of fluids, oil, or fuel. Inspect for collection of particulate matter on and around equipment and clean. Where possible cover these areas to prevent losses to wind and precipitation. Store pallets, hoppers, etc. which have residual materials on them under cover, with tarps, or inside.
Losses during charging of coke ovens or sintering plants.	Cover any exposed areas related to furnace charging/material handling activities. Stabilize areas around all material handling areas and establish regular sweeping. Route runoff from particulate generating operations to sediment traps, vegetated swales, buffer strips of vegetation, catch-basin filters, retention/detention basins or equivalent.
Particulate emissions from blast furnaces, electric arc furnaces, induction furnaces and fugitive emissions from poorly maintained or malfunctioning baghouses, scrubbers, electrostatic precipitators, cyclones.	Establish schedule for inspection and maintenance of all pollution control equipment—check for any particulate deposition from leaks, spills, or improper operation of equipment and remedy. Route runoff from particulate generating operations to sediment traps, vegetated swales, buffer strips of vegetation, catch-basin filters, retention/detention basins or equivalent.
Storage of products outside after painting, pickling, or cleaning operations.	Store all materials inside or under cover whenever possible. Prevent runon to product storage areas through curbs, berms, dikes, etc. Consider using booms, oil/water separators, sand filters, etc. for outfalls draining areas where oil is potentially present. Remove residual chemicals from intermediate or finished products before storage or transport outside.
Casting cooling or shakeout operations exposed to precipitation or wind.	Perform all pouring, cooling, and shakeout operations indoors in areas with roof vents to trap fugitive particulate emissions. Recycle into process as much casting sand as possible.
Landfilling or open pit disposal of wastes onsite	See Part VIII.L.
Losses of particulate matter from machining operations (grinding, drilling, boring, cutting) through deposition or storage of products outside.	Store all intermediate and finished products inside or under cover. Consider using booms, oil/water separators, sand filters, etc. for outfalls draining areas where oil is potentially present. Clean products of residual materials before storage outside. Stabilize storage areas and establish sweeping schedule.
Areas of the facility with unstabilized soils subject to erosion.	Minimize runon from adjacent properties and stabilized areas to areas with exposed soil with diversion dikes, berms, vegetated swales, etc. Stabilize all high traffic areas including all vehicle entrances, exits, loading, unloading, and vehicle storage areas. Conduct periodic sweeping of all traffic areas. Trap sediment originating in unstabilized areas. Filter fabric fences, gravel outlet protection, sediment traps, vegetated swales, buffer strips of vegetation, catch-basin filters, retention/detention basins or equivalent. Inspect and maintain all BMPs on a regular basis. Provide employee training on proper installation and maintenance of sediment and erosion controls.
Improper connection of floor, sink, or process wastewater drains.	Inspect and test all floor, sink, and process wastewater drains for proper connection to sanitary sewer and remove any improper connections to storm sewer or waters of the United States.

5. Special Conditions

The following section identifies special conditions that are applicable to permittees applying for coverage under Part XI.F. of today's permit.

a. Prohibition of Non-storm Water Discharges. This section requires primary metals facilities to certify that certain non-storm water discharges are not occurring at their facilities. A list of common non-storm water discharges that are not authorized by this section has been identified. These discharges are prohibited due to the likelihood these discharges will contain substantial pollutant concentrations. This list is included in the permit only to add more specificity to the general non-storm water prohibition included in Part III.A. of the permit. The following non-storm water discharges are not authorized by this section: waste discharges to floor drains or sinks connected to the facilities storm sewer or storm drainage system; water originating from vehicle and equipment washing; steam cleaning wastewater; process wastewater; wash-water originating from cleaning plant floor areas or material receiving areas; wastewater from wet scrubbers; boiler blowdown; contact or noncontact cooling water; discharges originating from dust control spray water;

discharges originating from the cleaning out of oil/water separators or sumps; discharges from bermed areas with a visible oily sheen or other visible signs of contamination; discharges resulting from casting cleaning or casting quench operations; discharges from slag quench or slag rinsing operations; and discharges from wet sand reclamation operations.

This final list of non-storm water discharges does not include discharges from oil/water separators and sumps, as was proposed. EPA intended to include only discharges originating from the cleaning or maintenance of these devices in this list.

The operators of non-storm water discharges must seek coverage under a separate NPDES permit if discharging to either a municipal separate storm sewer system or to waters of the United States.

6. Storm Water Pollution Prevention Plan Requirements

a. Contents of the Plan. All facilities covered by this section must identify a pollution prevention team, prepare a description of all potential pollutant sources at the facility, and identify measures and controls appropriate for the facility. These items must comply with the common requirements described in Part VI.C. of this fact sheet. In addition to these requirements, facilities covered by Part XI.F. of today's permit must provide the following additional information in their pollution prevention plan.

(1) Description of Potential Pollutant Sources. Facilities must identify on the site map the location of any and all pollution control equipment such as baghouses, wet scrubbers, electrostatic precipitators, etc. as well as any uncontrolled stack emissions which may be located onsite. The site map must also indicate the outfall locations and the types of discharges contained in the drainage areas of the outfalls (e.g. storm water and air conditioner condensate). In order to increase the readability of the map, the inventory of the types of discharges contained in each outfall may be kept as an attachment to the site map. Due to the hazardous nature of pollutants generated in this industry, and the potential for deposition of particulate matter from emissions, these emissions can be a significant contributor to pollutants at a facility and should be identified.

(2) Measures and Controls. There are typically five types of activity and materials present at facilities in the primary metals industry with potential impacts on storm water discharges. These have been discussed in today's fact sheet and include: raw materials storage and handling; process activities related to furnace operations, casting, rolling, and extruding; waste material storage, handling, and disposal; erosion from unstabilized plant areas; and illicit discharges, spills, and leaks. Each of these areas that is applicable to a facility must be identified in the pollution prevention plan and evaluated with regard to the BMPs discussed.

(a) Good Housekeeping—This section requires that facilities implement measures to limit the amount of spilled, settled, and leaked materials which are washed away by storm water. These materials include coal dust or coke breeze, metal fines from finishing operations, particulate emissions from furnaces and ovens, as well as dust and dirt from plant yards. In paved or other impervious areas sweeping is an easy and effective way to reduce these pollutants. Sweeping frequency should be determined based on the rates of accumulation of a particular material and its potential impact on storm water discharges. Where significant particulates are generated in unstabilized areas of the plant, other measures may be necessary.

The large number of particulate generating processes and the makeup of these pollutants makes this an especially important aspect of pollution prevention at many facilities. Permittees must consider the storage of all such products under roof, in silos or covered hoppers, or under tarps to minimize exposure of particulates to precipitation and wind-blown losses.

Unstabilized areas at a site which may be related to material handling and storage or vehicle and equipment traffic should be considered for paving. These areas can build up significant levels of particulates from materials and material handling as well as soil and dust particles. Paving these areas allow good housekeeping measures to be practiced and make spills easier to clean up.

(b) Source Controls—Permittees must consider preventative measures to minimize the exposure of significant materials to storm water. Due to the large volumes of materials used in the primary metals industry, they are a significant potential source of pollutants in storm water discharges. Storage of a wide range of materials outside is common among many facilities and measures should be taken to reduce the potential for contamination of storm water.

Measures include moving materials inside, under roof or cover, removing waste materials from the premises, and establishing scheduled removal of wastes to minimize storage onsite. Other measures to prevent runoff from contacting materials include swales, berms, dikes, or curbs to divert runoff away from significant materials or processes.

Source controls offer the most effective way to reduce pollutants in storm water discharges and are generally easier to implement than treatment measures.

(c) Preventive Maintenance—Facilities must incorporate into their plan the inspection and maintenance of all equipment which could lead to releases of pollutants. This includes all particulate emissions control equipment, storage tanks and piping systems, and any other material handling equipment which could fail and release pollutants.

All particulate pollution control equipment must be maintained to operate properly and effectively to control settling of particulate matter. The inspection of emissions control is particularly important as failures may not be immediately obvious and could lead to significant releases of particulate matter. Leaks or blockage in ducts, overflows of dust collection systems, or mechanical breakdown of scrubbers could all lead to heavy particulate emission which can be easily washed away by storm water discharges. Other potential losses include leaking tanks or valves which could contain a variety of acids, solvents, or other chemicals.

(d) Spill Prevention and Response Procedures—There are no additional requirements beyond those described in Part VI.C. of this fact sheet.

(e) Inspections—Primary metals facilities are required to conduct self inspections of all storage, process, and plant yard areas at least quarterly. These inspections will allow the effectiveness of the pollution prevention plan to be monitored. The potential for problems which could affect storm water are extremely varied and can have significant impacts over a short time period. These inspections are necessary to ensure that problems are identified and remedied as quickly as possible. Points of particular importance include pollution control equipment, material handling areas, and waste collection and disposal areas. Tanks, drums, silos, bins, and hoppers are other areas of potential concern.

(f) Employee Training—There are no additional requirements beyond those described in Part VI.C. of this fact sheet. EPA recommends that facilities conduct training annually at a minimum. However, more frequent training may be necessary at facilities with high turnover of employees or where employee participation is essential to

the storm water pollution prevention plan.

(g) Recordkeeping and Internal Reporting Procedures—There are no additional requirements beyond those described in Part VI.C. of this fact sheet.

(h) Non-storm Water Discharges—There are no additional requirements beyond those described in Part VI.C. of this fact sheet.

(i) Sediment and Erosion Control—There are no additional requirements beyond those described in Part VI.C. of this fact sheet.

(j) Management of Runoff—Facilities shall consider implementation of a range of management practices to control or treat storm water runoff. These include vegetative buffer strips or swales, filter fences and other types of filters, oil/water separators, and all types of settling basins and ponds. These practices allow the capture of pollutants from storm water before it leaves the site.

Due to the large size of many primary metals facilities, source controls may not be practical. In some cases, it may not be feasible to cover or otherwise protect large areas of material storage or exposed plant yards. Deposition of particulates from furnace or other process emissions may be relatively diffuse over a large area of the facility, and very difficult to control. In these cases management practices such as settling basins, retention or detention ponds, or recycle ponds can provide effective treatment of runoff. For smaller areas, filter fabric, booms, or other types of filters may be appropriate. In areas where oil and grease is a concern, oil/water separators may be appropriate and should be considered.

b. Comprehensive Site Compliance Evaluation. The storm water pollution prevention plan must describe the scope and content of comprehensive site evaluations that qualified personnel will conduct to 1) confirm the accuracy of the description of potential pollution sources contained in the plan, 2) determine the effectiveness of the plan, and 3) assess compliance with the terms and conditions of the permit. Comprehensive site compliance evaluations should be conducted on an annual basis. The individual or individuals that will conduct the evaluations must be identified in the plan and should be members of the pollution prevention team. Evaluation reports must be retained for at least 3 years after the date of the compliance evaluation that the permit expires.

Based on the results of each evaluation, the description of potential pollution sources, and measures and controls, the plan must be revised as appropriate within 2 weeks after each evaluation. Changes in the measures and controls must be implemented on the site in a timely manner, and never more than 12 weeks after completion of the evaluation.

7. Monitoring and Reporting Requirements

a. Analytical Monitoring Requirements. EPA believes that primary metals facilities may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. In order to provide a tool for evaluating the effectiveness of the pollution prevention plan and to characterize the discharge for potential environmental impacts, the permit requires some primary metals facilities to collect and analyze samples of their storm water discharges for the pollutants listed in Table F–7. Data submitted to EPA has been analyzed at the 3-digit SIC code level. Industry subgroups that had pollutant levels above benchmark levels are required to monitor for those pollutants. Because these pollutants have been reported at benchmark levels from primary metals facilities, EPA is requiring monitoring after the pollution prevention plan has been implemented to assess the effectiveness of the pollution prevention plan and to help ensure that a reduction of pollutants is realized.

Under the Storm Water Regulations at 40 CFR 122.26(b)(14), EPA defined "storm water discharge associated with industrial activity". The focus of today's permit is to address the presence of pollutants that are associated with the industrial activities identified in this definition and that might be found in storm water discharges. Under the methodology for determining analytical monitoring requirements, described in section VI.E.1 of this fact sheet, nitrate plus nitrite nitrogen is above the bench mark concentrations for the non-ferrous rolling and drawing and the non-ferrous foundries subsectors and pyrene is above the bench mark concentrations for the iron and steel foundries subsector. After a review of the nature of industrial activities and the significant materials exposed to storm water described by facilities in these subsectors, EPA has determined that the higher concentrations of nitrate plus nitrite nitrogen and pyrene are not likely to be caused by the industrial activity, but may be primarily due to non-industrial activities on-site. Today's permit does not require non-ferrous rolling and drawing, the non-ferrous foundries or iron and steel foundries facilities to conduct analytical monitoring for these parameters.

At a minimum, storm water discharges from selected primary metals facilities must be monitored quarterly during the second year of permit coverage. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter that they were required to monitor as listed in Tables F–7 through F–10, after taking into account possible waivers based on the alternative certification. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE F–7.—STEEL WORKS, BLAST FURNACES, AND ROLLING AND FINISHING MILLS (SIC 331) MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Recoverable Aluminum	0.75 mg/L
Total Recoverable Zinc	0.117 mg/L

TABLE F–8.—IRON AND STEEL FOUNDRIES (SIC 332) MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Recoverable Aluminum	0.75 mg/L
Total Suspended Solids (TSS)	100 mg/L
Total Recoverable Copper	0.0636 mg/L
Total Recoverable Iron	1 mg/L
Total Recoverable Zinc	0.117 mg/L

TABLE F–9.—ROLLING, DRAWING, AND EXTRUDING OF NON-FERROUS METALS (SIC 335) MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Recoverable Copper	0.0636 mg/L
Total Recoverable Zinc	0.117 mg/L

TABLE F–10.—NON-FERROUS FOUNDRIES (SIC 336) MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Recoverable Copper	0.0636 mg/L
Total Recoverable Zinc	0.117 mg/L

If the average concentration for a parameter is less than or equal to the value listed in Tables F–7 through F–10, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration listed in Tables F–7 through F–10, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit. The schedule for monitoring is presented in Table F–11.

TABLE F–11.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Tables F–7 through F–10, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Tables F–7 through F–10, then no further sampling is required for that parameter.
4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Tables F–7 through F–10. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will reassess the effectiveness of the adjusted pollution prevention plan.

The monitoring cut off concentrations listed in Tables F–7 through F–10 are not numerical effluent limitations. These values represent a level of pollutant discharge which facilities may achieve through the implementation of pollution prevention plans. At least half of the facilities which submitted Part 2 data, reported concentrations greater than or equal to the values listed in Tables F–7 through F–10. Facilities that achieve average discharge concentrations which are less than or equal to the values in Tables F–7 through F–10 are not relieved from the pollution prevention plan requirements or any other requirements of the permit.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

(1) Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hours storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable. If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

(2) Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area (e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)) shall be provided in the plan.

(3) Alternative Certification. Throughout today's permit, EPA has required monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall, or on a pollutant-by-pollutant basis in lieu of monitoring described in Tables F–10 through F–13, under penalty of law, signed in accordance with Part VII.G. of the pursuit (Signatory Requirements), that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA along with the monitoring reports required under paragraph *b.* below. If the permittee cannot certify for an entire period, they must submit the date exposure was eliminated and any monitoring required up until that date. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

b. Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one Discharge Monitoring Report must be submitted per storm event sampled. For facilities conducting monitoring beyond the minimum quarterly requirements an additional Discharge Monitoring Report Form must be filed for each analysis.

c. Quarterly Visual Examination of Storm Water Quality. Quarterly visual inspections of a storm water discharge from each outfall are required at primary metals facilities. The examination must be of a grab sample collected from each storm water outfall. The examination of storm water grab samples shall include any observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, or other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on these samples.

The examination must be made at least once per quarter during the term of the permit during daylight unless there is insufficient rainfall or snow-melt to runoff. Whenever practicable, the same individual should carry out the collection and examination of discharges throughout the life of the permit to ensure the greatest degree of consistency possible. Grab samples shall be collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 1 hour) of when the runoff begins discharging. Reports of the visual examination include: the examination date and time, examination personnel, visual quality of the storm water discharge, and probable sources of any observed storm water contamination. The visual examination reports must be maintained onsite with the pollution prevention plan.

When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination. Adverse weather conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (e.g., drought, extended frozen conditions, etc.).

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

EPA believes that this quick and simple assessment will allow the permittee to approximate the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examinations. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and the effects of the management practices that are included in the plan.

G. Storm Water Discharges Associated With Industrial Activity From Metal Mining (Ore Mining and Dressing)[43] *Facilities*

1. Industrial Profile

On November 16, 1990 (55 FR 47990), the U.S. Environmental Protection Agency (EPA) promulgated the regulatory definition of "storm water discharges associated with industrial activity." This definition included point source discharges of storm water from eleven major categories of facilities, including: "(i) facilities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutant effluent standards under 40 CFR subchapter N * * * ." and "* * * (iii) facilities classified as Standard Industrial Classifications 10 through 14 (metal mining industry) including active or inactive mining operations (except for areas of coal mining operations no longer meeting the definition of a reclamation area under 40 CFR 434.11(l) because the performance bond issued to the facility by the appropriate SMCRA authority has been released, or except for areas of noncoal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990) and oil and gas exploration, production, processing, or treatment operations, or that has come into contact with, any overburden, raw material, intermediate products, finished products, by-products or waste products located on the site of such operations."

This section of today's general permit only applies to the portions of categories (i) and (iii) identified by 40 CFR Part 440 and the metal mining industry (Standard Industrial Classification (SIC) code 10). SIC code 10 includes establishments primarily engaged in mining, developing mines, or exploring for metallic minerals (ores). This group also includes all ore dressing and beneficiating operations, whether performed at mills operated in conjunction with the mines served or at mills, such as custom mills, operated separately. Common activities at these mills include: crushing, grinding, and separation by gravity concentration, magnetic separation, electrostatic separation, flotation, or leaching[44]. The following is a listing of the types of mining/milling facilities that are covered under SIC code 10: Iron Ores (SIC Code 1011); Copper Ores (SIC Code 1021); Lead and Zinc Ores (SIC Code 1031); Gold Ores (SIC Code 1041); Silver Ores (SIC Code 1044); Ferroalloy Ores, Except Vanadium (SIC Code 1061); Uranium-Radium-Vanadium Ores (SIC Code 1094); and Miscellaneous Metal Ores, Not Elsewhere Classified (SIC Code 1099).

This section does not cover any discharge subject to effluent limitation guidelines, including storm water that combines with process wastewater and mine drainage. Storm water that does not come into contact with any overburden, raw material, intermediate product, finished product, by-product, or waste product located on the site of

[43] For the purposes of this part of the fact sheet, the term "metal mining" includes all ore mining and/or dressing and beneficiating operations, whether performed at mills operated in conjunction with the mines served or at mills, such as custom mills, operated separately.

[44] For more information on metal mines/mills see EPA, Effluent Guidelines Division. November 1982. "Development Document for Effluent Limitations Guidelines and Standards for the Ore Mining and Dressing Point Source Category." EPA 440/1-82/061.

R0016166

the operation is not subject to permitting under this section according to Section 402(l)(2) of the Clean Water Act. Storm water discharges associated with industrial activity from inactive mining operations occurring on Federal lands where an operator cannot be identified cannot be covered by this permit.

Storm water discharges from mining claims where no mining activities have been undertaken (including no historic activities) except minimal activities undertaken for the purpose of maintaining a mining claim do not need to be covered by a permit. (This applies to Federal and private lands.)

This section is applicable to all phases of mining operations, whether active or inactive, as long as there is exposure to significant materials. This includes land disturbance activities such as the expansion of current extraction sites, active and inactive mining stages, and reclamation activities.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

There are typically three phases to a mining operation: the exploration and construction phase; the active phase; and the reclamation phase. The exploration and construction phase entails exploration and a certain amount of land disturbance to determine the financial viability of a site. Construction includes building of site access roads, and removal of overburden and waste rock to expose minable ore. These land-disturbing activities are significant potential sources of storm water contaminants. The active phase includes each step from extraction through production of a saleable product. The active phase may include periods of inactivity due to the seasonal nature of these metal mining activities. The final phase of reclamation is intended to return the land to its pre-mining state.

Because of the land-disturbing nature of the ore mining and dressing industry, contaminants of concern generated by industrial activities in this industry include total suspended solids (TSS), total dissolved solids (TDS), turbidity, pH, and heavy metals. Table G-1 lists potential pollutant source activities, and related pollutants associated with ore mining and dressing facilities.

TABLE G-1.—ACTIVITIES, POLLUTANT SOURCES, AND POLLUTANTS

Activity	Pollutant source	Pollutant
Site Preparation	Road Construction	Dust, TSS, TDS, turbidity.
	Removal of Overburden	Dust, TSS, TDS, turbidity.
	Removal of waste rock to expose the metal	Dust, TSS, TDS, turbidity.
Mineral Extraction	Blasting activities	Dust, TSS, nitrate/nitrite.
Beneficiation Activities	Milling	Dust, TSS, TDS, pH, turbidity, fines, heavy metals.
	Flotation	Dust, TSS, TDS, pH, turbidity, fines, chemical reagents, acids, heavy metals.
	Gravity Concentration	TSS, TDS, pH, turbidity, heavy metals.
	Amalgamation	Dust, TSS, TDS, pH, turbidity, heavy metals, mercury.
	Waste Rock Storage	Dust, TSS, TDS, turbidity, pH, heavy metals.
	Raw Material Loading	Dust, TSS, TDS, turbidity, heavy metals.
	Processing materials unloading	Diesel fuel, oil, gasoline, chemical reagents.
	Raw or Waste Material Transportation	Dust, TSS, TDS, turbidity, heavy metals.
Leaching	Heap leach piles	Dust, TSS, TDS, turbidity, pH, heavy metals, cyanide.
Other Activities.	Sedimentation pond upsets	TSS, TDS, turbidity, pH, heavy metals.
	Sedimentation pond sludge removal and disposal	Dust, TSS, TDS, turbidity, pH, heavy metals.
	Air emission control device cleaning	Dust, TSS, TDS, turbidity.
Equipment/Vehicle Maintenance	Fueling activities	Diesel fuel, gasoline, oil.
	Parts cleaning	Solvents, oil, heavy metals, acid/alkaline wastes.
	Waste disposal of oily rags, oil and gas filters, batteries, coolants, degreasers.	Oil, heavy metals, solvents, acids
	Fluid replacement including hydraulic fluid, oil, transmission fluid, radiator fluids, and grease.	Oil, arsenic, lead, cadmium, chromium, benzene, TCA, TCE, PAHs, solvents.
Reclamation Activities	Site preparation for stabilization	Dust, TSS, TDS, turbidity, heavy metals.

Sources: Storm Water Group Applications, Parts 1 and 2 and EPA. "Development Document for Effluent Limitations Guidelines and Standards for the Ore Mining and Dressing Point Source Category." (EPA 440/1-82/061) November 1982.

Industrial activities, significant materials, and material management practices associated with ore mining and dressing methods are typically similar, varying only in the type of rock being mined. Examples of mineral commodities obtained from ore mining and dressing facilities include: iron; copper; lead; zinc; gold; silver; ferroalloy ores such as molybdenum, manganese, chromium, cobalt, nickel, and tungsten; uranium; radium; vanadium; aluminum; antimony; bauxite; platinum; tin; and titanium. Industrial activities include, ". . . but [are] not limited to, storm water discharges from industrial plant yards; immediate access roads and rail lines used or traveled by carriers of raw materials, manufactured products, waste material, or by-products used or created by the facility; material handling sites; refuse sites; sites used for the application or disposal of process wastewaters (as defined at 40 CFR Part 401); sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage, or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials and intermediate and finished materials; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water" (40 CFR 122.26(b)(14)). The most common industrial activities at metallic mine sites include extraction of the metal, material crushing, and product separation. While all of these industrial activities can occur at metal mines, storm water discharges from some of the areas listed cannot be covered by this permit (see Part VIII.G.4. Discharges Covered Under This Section).

Significant materials include, "... but [are] not limited to: raw materials, fuels, materials such as solvents, detergents, and plastic pellets; finished materials such as metallic products; ... hazardous substances designated under Section 101(14) of CERCLA; any chemical facilities required to report pursuant to Section 313 of title III of SARA; fertilizers; pesticides; and waste products such as ashes, slag, and sludge that have the potential to be released with storm water discharge" (40 CFR 122.26(b)(12)). Significant materials commonly found at mining facilities include: overburden; waste rock; sub-ore piles; tailings; petroleum-based products; solvents and detergents; manufactured products; and other waste materials.

Materials management practices are defined as those practices employed to diminish contact by significant materials with precipitation and storm water runon, or practices utilized to reduce the offsite discharge of contaminants. To this end, sediment ponds, discharge diversion techniques, as well as methods of dispersion, are used to minimize impacts of significant materials on storm water. For mine sites requiring additional sources of water for processing operations, rainfall events as well as storm water runon will be managed for use in dust suppression, processing, and washing activities. Many mine sites are already equipped with sedimentation ponds and other established process wastewater treatment methods in order to meet effluent limitation guidelines. Additional storm water management practices used at mineral mining facilities include: discharge diversions; drainage/storm water conveyances; runoff dispersion; sediment control and collection practices; vegetation/soil stabilization; capping contaminated sources; and treatment.

Metals are recovered by three basic extraction techniques: surface mining; underground mining; and placer mining. Each type of extraction method may be followed by varying methods of beneficiation and processing. Presented below are brief descriptions of the industrial activities, significant materials, and materials management practices associated with these four extraction processes and associated beneficiation activities. Due to similarities in mining operations for many of the minerals within this sector, industrial activities, significant materials, and materials management practices are fairly uniform across this sector. Unique practices are noted.

a. Surface Mining. Many mining facilities access metal deposits using surface extraction techniques such as strip mining, open-pit, open-cut, and open-cast. Surface mining is more economical than underground especially when the ore body is large and near the surface.

(1) Industrial Activities. Extraction activities include removal of overburden and waste rock to access metal deposits. These land-disturbing activities generate piles of topsoil and other overburden as well as waste rock, which are typically stored beside, or within, the pit or quarry. In addition, land disturbance, drilling, blasting, stripping, and materials handling activities create large amounts of dust that are either dispersed by local wind patterns or collected in air pollution control mechanisms. At closure, overburden and waste rock may or may not be used to reclaim the pit or quarry depending on Federal, State, and local requirements. In addition, access roads and rail spurs, and associated loading and unloading areas, are found onsite.

Following extraction, the mined materials may be transferred to a nearby beneficiation/processing facility. At an ore beneficiation facility, the valuable metals are separated from the less valuable rock to yield a product which is higher in metal content. To accomplish this, the ore must be crushed and ground small enough so that each particle contains mostly the mineral to be recovered or mostly the less valuable, or gangue, material. Valuable minerals are separated from the gangue by gravity concentration, magnetic separation, electrostatic separation, flotation, and leaching.

(2) Significant Materials. Significant materials generated by most extraction activities at surface mines include overburden piles, waste rock piles, ore and subore piles, and materials spilled from loading and unloading activities. Other exposed materials that can be generated at these types of operations (as well as other metal mines), include: tailings from flotation and other separation stages; soils impacted by fugitive dust emissions; settling ponds that receive process wastewaters; dredged sediment disposal areas; as well as raw material and product storage. Dust and particulate matter collected in air pollution control mechanisms may also be disposed of in onsite waste piles.

(3) Materials Management Practices. Materials management practices at surface mines are typically designed to control dust emissions and soil erosion from extraction activities, and offsite transport of significant materials. Settling ponds and impoundments are commonly used to reduce total suspended solids (TSS), total dissolved solids (TDS), and other contaminants in process generated wastewaters. These controls may also be used to manage storm water runoff and runon with potentially few alterations to onsite drainage systems. Few sampling facilities indicated the presence of traditional BMPs. Only 29 percent of the sampling facilities have ponds or impoundments as a storm water control.

Tailings impoundments are used to manage tailings generated at facilities engaged in flotation or heavy media separation operations. These impoundments are used to manage beneficiation/processing wastewaters generated at the facility and may also be used to manage storm water runoff.

b. Underground Mining. Underground mining techniques are used to access metals located too far underground to access economically from the surface. Though typically a more expensive form of extraction, advantages to underground mining operations include year-round operation, less noise (applicable to facilities located near residential areas), and less surface land disturbance. The two main underground mining methods are stoping and caving. Both of these methods can be used in several variations depending on the characteristics of the ore body. Common stoping methods include cut-and-fill, square cut (timbered), shrinkage, and open. Caving methods include undercut, block, and sub-level. Underground mining is usually independent of surface mining, but sometimes underground mining precedes or follows surface mining.

(1) Industrial Activities/Significant Materials. Industrial activities that may be associated with storm water discharges include: loading/unloading activities; haul roads; products and materials storage; waste piles; and processing activities. Exposed materials

associated with surface beneficiation and processing facilities at underground mines are similar to those associated with surface mining facilities.

(2) Materials Management Practices. Materials management practices for significant materials at the surface of underground mining facilities are similar to those materials management practices used at surface mining operations. However, waste rock or mill tailings are in some cases being returned to the mine as fill for the mined-out areas or may be directed to a disposal basin.

c. Placer Mining. Placer mining is used to mine alluvial sands and gravels containing valuable metallic minerals. Placer deposits are usually mined exclusively for gold material but smaller amounts of platinum, tin, and tungsten may also be recovered. There are three main placer mining techniques including dredge, hydraulic, and open cut methods.

(1) Industrial Activities. The industrial activities at dredging placer mines excavate underwater gold deposits by bucketline, dragline, or by suction. The excavation devices dig, wash, and screen gold values which are then recovered using gravity concentration methods. Hydraulic placer mines characteristically use high pressure water jets to excavate value-laden gravel banks. The most commonly used placer mining extraction method is the open cut. It involves stripping away topsoil and overburden to expose the auriferous gravels. The gold bearing gravels are excavated in sections and pushed to a placer wash plant for processing. Gravitational concentration is the common beneficiating technique at placer mines.

(2) Significant Materials. Significant materials generated at placer operations include overburden, mine development rock, ore, sub-ore piles, mine waste dumps, tailings ponds and piles. Potential natural constituents include mercury, arsenic, bismuth, antimony, thallium, pyrite, and pyrrhotite. After settling, the liquid portion of the slurry is returned to the mill as process water and the remaining slurried waste is pumped to tailings. In placer operations, however, tailings are disposed of in streams or on land.

(3) Materials Management Practices. Settling ponds are used to manage process wastewaters and are in some cases being used to manage contaminated storm water runoff. Few materials management practices were indicated in the part 1 group applications.

d. Inactive Mine Sites. Inactive ore mining and dressing operations are those where industrial activities are no longer occurring. When active, mineral extraction could have occurred from surface mines, solution mines, placer operations, or underground mines. These sites are included in this section because significant materials may remain onsite. These materials, if exposed, are potential sources of storm water contamination. Until an inactive metals mine and/or beneficiation operation has been reclaimed under applicable State or Federal laws after December 17, 1990, the site is considered associated with an "industrial activity" and is subject to the conditions of this section. Due to the seasonal nature of this industry, mine sites can become temporarily inactive for extended periods of time. Temporarily inactive sites are not viewed the same as permanently inactive sites.

2. Pollutants Found in Storm Water Discharges From Metal Mining

The volume of storm water discharges and the type and concentrations of pollutants found in storm water discharges from active and inactive metal mining facilities will vary according to several factors. Such factors include: geographic location; hydrogeology; the physical and chemical characteristics of the ores extracted; the physical and chemical characteristics of the waste rock and overburden removed; how the ore was extracted (e.g., open pit, underground, solution or dredging); the type of industrial activities occurring onsite (e.g., extraction, crushing, washing, milling, reclamation, etc.); the size of the operation; type, duration, and intensity of precipitation events; temperature ranges and variations; and the types of pollutant control measures used at the site. Each of these, and other factors will interact to influence the quantity and quality of storm water runoff. For example, air emissions (i.e., dust) may be a significant source of pollutants at some facilities, while roads constructed of waste rock may be a primary source at others. In addition, sources of pollutants other than storm water, such as illicit connections, spills, and other improperly dumped materials, may increase the pollutant loadings discharged into waters of the United States.

Based on the wide variety of industrial activities and significant materials at the facilities included in this sector, EPA believes it is appropriate to divide the metal mining (ore mining and dressing) industry into subsectors to properly analyze sampling data and determine monitoring requirements. As a result, this sector has been divided into the following subsectors: iron ore; copper ores; lead and zinc ores, gold and silver ores; ferroalloy ores, except vanadium; metal mining services; and miscellaneous metal ores (including uranium-radium-vanadium ores). Table G–2 below includes data for the eight pollutants that all facilities were required to monitor for under Form 2F. The table also lists those parameters that EPA has determined merit further monitoring.

A table has not been included for the following subsectors because less than 3 facilities submitted data in that subsector; iron ores; lead and zinc ores; gold and silver ores; ferroalloy ores, except vanadium; metal mining services; and miscellaneous metal ores (including uranium-radium-vanadium ores).

TABLE G–2.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY COPPER ORE MINING FACILITIES SUBMITTING PART II SAMPLING DATA[i] (mg/L)

Pollutant Sample type	No. of facilities				No. of samples		Minimum		Maximum		Median		95th percentile		99th percentile	
	Grab	Comp[ii]	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.

[ii] Composite samples.

R0016169

3. Options for Controlling Pollutants From Metal Mines

There are two options for reducing pollutants in storm water discharges; end-of-pipe treatment and implementing Best Management Practices to prevent and/or eliminate pollution. Discharges from mining operations are in some ways dissimilar to other types of industrial facilities. Mining facilities are often in remote locations and may operate only seasonally or intermittently, yet need year-round controls because significant materials remain exposed to precipitation when reclamation is not completed. These characteristics make resource intensive end-of-pipe management controls less desirable. A comprehensive storm water management program for a given plant may include controls from each of these categories. Development of comprehensive control strategies should be based on a consideration of site and facility plant characteristics.

a. End-of-Pipe Treatment. At many ore mining and dressing facilities, it may be appropriate to collect and treat the runoff from targeted areas of the facility. This approach was taken with 11 industrial subcategories within the ore mining and dressing industry, subject to national effluent limitation guidelines mill process wastewater and mine drainage. There are several areas where effluent limitation guidelines influence the permitting strategy for storm water discharges: whenever storm water and mill process wastewater and mine drainage combine, the storm water discharge is also subject to effluent limitation guidelines; to meet the numeric effluent limitation guidelines, most, if not all, facilities must collect and temporarily store onsite runoff from targeted areas of the plant; the effluent limitation guidelines do not apply to discharges whenever rainfall events, either chronic or catastrophic, cause an overflow of storage devices designed, constructed, and maintained to contain a 10-year, 24-hour storm; and most technology-based treatment standards, used for treating discharges subject to effluent limitation guidelines, are based on relatively simple technologies such as settling of solids, neutralization, and drum filtration.

For storm water discharges that are not covered by the effluent limitations guidelines, BMPs may be an appropriate means for limiting pollutant contributions. However, in cases of poor quality storm water discharges (e.g., low pH, high metals, etc.), treatment may be necessary to protect receiving waters.

b. Best Management Practices. Effective storm water management controls for limiting the offsite discharge of storm water pollutants from ore mining and dressing facilities are source reduction BMPs. Source reduction BMPs are methods by which discharges of contaminants are controlled with little or no required maintenance. Examples of these types of controls include source reduction diversion dikes, vegetative covers, and berms. Source reduction practices are typically (but not always) low in cost and relatively easy to implement. In some instances, more resource intensive treatment BMPs, including sedimentation ponds, may be necessary depending upon the type of discharge, types and concentrations of contaminants, and volume of flow.

The selection of the most effective BMPs will be based on site-specific considerations such as: facility size, climate, geographic location, hydrogeology and the environmental setting of each facility, and volume and type of discharge generated. Each facility will be unique in that the source, type, and volume of contaminated storm water discharges will differ. In addition, the fate and transport of pollutants in these discharges will vary. The management practices discussed herein are well suited mechanisms to prevent or control the contamination of storm water discharges associated with mining activity.

The following four categories describe best management practice options for reducing pollutants in storm water discharges from ore mining and dressing facilities: discharge diversions; sediment and erosion control; capping of contaminated sources; treatment.

Because ore mining and dressing is largely a land disturbance activity, BMPs that minimize erosion and sedimentation will be most effective if installed at the inception of operations and maintained throughout active operations and reclamation of the site. From the construction of access and haul roads, to closure and reclamation activities, implementation of BMPs is often essential to minimizing long-term environmental impacts to an area.

Part 1 group application data indicates that few storm water BMPs have been implemented at sampling facilities. The group application process did not require a description of BMP locations, and did not require applicants to describe the number of identical BMPs implemented at each site. As a result, the effectiveness of BMPs, for storm water management, at these facilities cannot be evaluated.

Many BMPs were not listed by facilities because they have been implemented to treat waters subject to effluent limitation guidelines, and are not exclusively used for storm water management. For instance, 29 percent of the sampling subgroup reported using ponds for sediment control and collection. Since some facilities classified as SIC Code 10 are subject to effluent limitation guidelines, sedimentation ponds may be implemented at greater proportions than indicated in part 1 of the group applications.

Because BMPs described in the part 1 data are limited, EPA is providing an overview of supplementary BMPs for use at ore mining and dressing facilities. However, due to the site-specific nature of facilities within this sector, BMPs cited do not preclude the use of other viable BMP options. Table G–3 summarizes BMP options as they apply to land disturbance activities at ore mining and dressing facilities. Sources of BMP information include: "Sediment and Erosion Control: An Inventory of Current Practices—Draft," EPA, April 20, 1990; "Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices," EPA, September, 1992, (EPA 832–R–92–006); "Best Management Practices for Mining in Idaho," Idaho Department of Lands, November 1992; and "Erosion & Sediment Control Handbook," Goldman et al., McGraw-Hill Book Company, 1986.

TABLE G-3.—SUMMARY OF MINE AREAS AND APPLICABLE BEST MANAGEMENT PRACTICES

Land-disturbed area	Discharge diversions	Conveyance systems	Runoff dispersion	Sediment control & collection	Vegetation	Containment	Treatment
Haul Roads and Access Roads.	Dikes, Curbs, Berms.	Channels, Gutters, Culverts, Rolling Dips, Road Sloping, Roadway Water Deflectors.	Check Dams, Rock Outlet Protection, Level Spreaders, Stream Alteration, Drop Structures.	Gabions, Riprap, Native Rock Retaining Walls, Straw Bale Barriers, Sediment Traps/Catch Basins, Vegetated Buffer Strips.	Seeding, Willow Cutting Establishment.		
Pits/Quarries or Underground Mines.	Dikes, Curbs, Berms.	Channels, Gutters.	Serrated Slopes, Benched Slopes, Contouring, Stream Alteration.	Sediment Settling Ponds, Straw Bale Barrier, Siltation Berms.	Seeding	Plugging and Grouting.	Chemical/Physical Treatment.
Overburden, Waste Rock and Raw Material Piles.	Dikes, Curbs, Berms.	Channels, Gutters.	Serrated Slopes, Benched Slopes, Contouring, Stream Alteration.	Plastic Matting, Plastic Netting, Erosion Control Blankets, Mulch-straw, Compaction, Sediment/Settling Ponds, Silt Fences, Siltation Berms.	Topsoiling, Seedbed Preparation, Seeding.	Capping	Chemical/Physical Treatment. Artificial Wetlands.
Reclamation	Dikes, Curbs, Berms.	Channels, Gutters.	Check Dams, Rock Outlet Protection, Level Spreaders, Serrated Slopes, Benched Slopes, Contouring, Drain Fields, Stream Alteration, Drop Structures.	Gabions, Riprap, and Native Rock Retaining Walls, Biotechnical Stabilization, Straw Bale Barriers, Sediment Traps/Catch Basins, Vegetative Buffer Strips, Silt Fences, Siltation Berms, Brush Sediment Barriers.	Topsoiling, Seedbed Preparation, Seeding, Willow Cutting Establishment.	Capping, Plugging and Grouting.	Chemical/Physical Treatment, Wetlands.

Haul Roads and Access Roads—Placement of haul roads or access roads should occur as far as possible from natural drainage areas, lakes, ponds, wetlands or floodplains where soil will naturally be less stable for heavy vehicle traffic. If a haul road must be constructed near water, as little vegetation as possible should be removed from between the road and the waterway, as vegetation is a useful buffer against erosion and is an efficient sediment collection mechanism. The width and grade of haul or access roads should be minimal and should be designed to match natural contours of the area. Construction of haul roads should be supplemented by BMPs that divert runoff from road surfaces, minimize erosion, and direct flow to appropriate channels for discharge to treatment areas.

Pits or Quarries—Excavation of a pit or quarry must be accompanied by BMPs to minimize impacts to area surface waters. As discussed in construction of haul roads, as little vegetation as possible should be removed from these areas during excavation activities to minimize exposed soils. In addition, stream channels and other sources of water that may discharge into a pit or quarry should be diverted around that area to prevent contamination.

BMPs can be used to control total suspended solids levels in runoff from unvegetated areas. These can include sediment/settling ponds, check dams, silt fences, and straw bale barriers.

Overburden, Waste Rock, and Raw Material Piles—Overburden, topsoil, and waste rock, as well as raw material and intermediate and final product stockpiles should be located away from surface waters and other sources of water, and from geologically unstable areas. If this is not practicable, surface water should be diverted around the piles. As many piles as possible should be revegetated, (even if only on a temporary basis.) At closure, remaining units should be reclaimed.

Reclamation Activities—When a mineral deposit is depleted and operations cease, a mine site must be reclaimed according to appropriate State or Federal standards. Closure activities typically include restabilization of any disturbed areas such as access or haul roads, pits or quarries, sedimentation ponds or work-out pits, and any remaining waste piles. Overburden and topsoil stockpiles may be used to fill in a pit or quarry (where practical.) Recontouring and revegetation should be performed to stabilize soils, and prevent erosion.

Major reclamation activities such as recontouring roads and filling in a pit or quarry can only be performed after operations have ceased. However, reclamation activities such as stabilization of banks, and reseeding and revegetation should be implemented in mined out portions, or inactive areas of a site as active mining moves to new areas.

EPA recognizes that quarries are frequently converted into reservoirs, or recreational areas, after the mineral deposit is depleted. However, this does not preclude the reclamation of disturbed areas above the quarry rim.

(1) Discharge Diversions. Discharge diversions provide the first line of defense in preventing the contamination of discharges, and subsequent contamination of receiving waters of the United States. Discharge diversions are temporary or permanent structures installed to divert flow, store flow, or limit storm water runon and runoff.

These diversion practices have several objectives. First, diversion structures can be designed to prevent otherwise uncontaminated (or less contaminated) water from crossing disturbed areas or areas containing significant amounts of contaminated materials, where contact may occur between runon and significant materials. These source reduction measures may be particularly effective for metal mining facilities to prevent runon of uncontaminated discharges from contacting exposed materials and/or reduce the flow across disturbed areas, thereby lessening the potential for erosion. Second, diversion structures can be used to collect or divert waters for later treatment, if necessary. The usefulness of these control measures are limited by such factors as the size of the area to be controlled and the type and nature of materials exposed and precipitation events.

Diversion dikes, curbs, and berms are temporary or permanent diversion structures that prevent runoff from passing beyond a certain point, and divert runoff away from its intended path. Dikes, curbs or berms may be used to surround and isolate areas of concern at metal mining sites, diverting flow around piles of overburden, waste rock, and storage areas, to minimize discharge contact with contaminated materials and to limit discharges of contaminated water from confined areas. The BMPs described below may be useful for storm water diversion at metal mining sites.

Channels or Gutters—Channels or gutters collect storm water runoff and direct its flow. Channels or gutters may act to divert runoff away from a potential source of contamination, but may also be used to channel runoff to a collection and/or treatment area including settling ponds, basins or work-out pits.

Open Top Box Culverts and Waterbars—These structures are temporary or permanent structures that divert water from a roadway surface. Open top box culverts may be used on steeply graded, unpaved roads in place of pipe culverts to divert surface runoff and flow from inside ditches onto the downhill slope of a road. These structures are typically made of wood and should periodically be monitored and repaired if necessary.

Rolling Dips and Road Sloping—Rolling dips and road sloping are permanent water diversion techniques installed using natural contours of the land during road construction. These BMPs prevent water accumulation on road surfaces and divert surface runoff toward road ditches, which then convey the storm water to ponds or other management areas.

Roadway Surface Water Deflector—A roadway surface water deflector is another technique to prevent accumulation of water on road surfaces. The structure uses a conveyor belt sandwiched between two pieces of treated wood and placed within the road to deflect water. This is a useful technique for steeply graded, unpaved roads.

Culverts—Culverts are permanent surface water diversion mechanisms used to convey water off or underneath a road. Made of corrugated metal, they must extend across the entire width of the road and beyond the fill slope. Additional erosion control mechanisms may need to be installed at the discharge end of the culvert.

Drainage systems are most effective when used in conjunction with runoff dispersion devices designed to slow the flow of water discharged from a site. These devices also aid storm water infiltration into the soil and flow attenuation. Some examples of velocity dissipation devices include check dams, rock outlet protection, level spreaders, and serrated and benched slopes.

Check Dams—Check dams are small temporary dams constructed across swales or drainage ditches to reduce the velocity of runoff flows, thereby reducing erosion and failure of the swale or ditch. This slowing reduces erosion and gullying in the channel and allows sediments to settle.

Rock Outlet Protection—Rock protection placed at the outlet end of culverts, channels, or ditches reduces the depth, velocity, and destructive energy of water such that the flow will not erode the downstream reach.

Level Spreaders—Level spreaders are outlets for dikes and diversions consisting of an excavated depression constructed at zero grade across a slope. Level spreaders diffuse storm water point sources and release it onto areas stabilized by existing vegetation.

Serrated Slopes and Benched Slopes—These runoff dispersion methods break up flow of runoff from a slope, decreasing its ability to erode. Serrated and benched slopes provide flat areas that allow water to infiltrate, and space for vegetation to grow and reinforce soils.

Contouring—Surface contouring is the establishment of a rough soil surface amenable to revegetation, through creating horizontal grooves, depressions, or steps that run with the contour of the land. Surface roughening aids in the establishment of vegetative cover by reducing runoff velocity and giving seed an opportunity to take hold and grow.

Drain Fields—Drain fields are used to prevent the accumulation of water and/or ground water at a site, by diverting infiltrating sources through gravity flow or pumping.

Stream Alteration—Altering or channelizing the path of a stream to bypass all or some disturbed areas on a site allows additional mining activities and avoids contamination of stream water by disturbed lands. This practice is complicated, however, by the need to restore the channel when mining operations end.

Drop Structures—Drop structures are large angular rocks placed in a V-shaped pattern to slow the velocity of storm water runoff. These structures are typically reinforced by logs or large rocks imbedded in the streambanks.

(2) Erosion and Sediment Controls. Erosion and sediment controls limit movement and retain sediments from being transported offsite. Several structural collection devices have been developed to remove sediment from runoff before it leaves the site. Several methods of removing sediment from site runoff involve diversion mechanisms previously discussed, supplemented by a trapping or storage device. Structural practices typically involve filtering diffuse storm water flows through temporary structures such as straw bale dikes, silt fences, brush barriers or vegetated areas.

Structural practices are typically low in cost. However, structural practices require periodic removal of sediment to remain functional. As such, they may not be appropriate for permanent use at inactive mines. However, these practices may be effectively used as temporary measures during active operation and/or prior to the final implementation of permanent measures.

(a) Structural Practices.

(i) Sediment/Settling Ponds—Sediment ponds function as sediment traps by containing runoff for long periods of time, allowing suspended solids to settle. These structures can achieve a high removal rate of sediment for both process wastewater and storm water discharges.

Discharge ponds may also be designed to act as surge ponds which are designed to contain storm surges and then completely drain in about 24 to 40 hours, and remain dry during times of no rainfall. They can provide pollutant removal efficiencies that are similar to those of detention ponds.[45]

(ii) Gabions, Riprap, and Native Rock Retaining Walls—These BMPs are all forms of slope stabilization. Gabions consist of rocks (riprap) contained by rectangular wire boxes or baskets for use as permanent erosion control structures. Riprap consists of loose rocks placed along embankments to prevent erosion.

(iii) Biotechnical Stabilization—Biotechnical stabilization uses live brush imbedded in the soils of a steep slope to prevent erosion. This method relies on the premise that the imbedded vegetation will eventually root and help stabilize the slope.

(iv) Straw Bale Barrier—Straw bales may be used as temporary berms, barriers, or diversions, capturing sediments, filtering runoff. When installed and maintained properly, these barriers remove approximately 67 percent of the sediment load.[46]

(v) Sediment Traps or Catch Basins—These temporary or permanent structures are useful for catching and storing sediment laden storm water runoff and are particularly useful during construction activities to contain runoff. The effectiveness of these BMPs is better in smaller drainage basin areas. Sediment traps are less than 50 percent effective in removing sediment from storm water runoff.[47]

(vi) Vegetated Buffer Strips—The installation of vegetated buffer strips will reduce runoff and prevent erosion at a removal efficiency rate of 75 to 99 percent depending upon the ground cover.[48]

(vii) Silt Fence/Filter Fence—A low fence made of filter fabric, wire and steel posts, should be used on small ephemeral drainage areas where storm water collects or leaves a mine site. Silt fences remove 97 percent of the sediment load and are easier to maintain and remove without creating lasting impacts to the environment.[49]

(viii) Siltation Berms—Siltation berms are typically placed on the downslope side of a disturbed area to act as an impermeable barrier for the capture and retention of sediments in surface water runoff. Plastic sheeting is typically used to cover the berm. The berm and the plastic sheeting may require periodic maintenance and repair.

(ix) Brush Sediment Barriers—Brush barriers are temporary sediment barriers composed of tree limbs, weeds, vines, root mat, soil, rock and other cleared materials placed at the toe of a slope. A brush barrier is effective only for small drainage areas, usually less than 1/4 acre, where the slope is minimal.

(b) Stabilization—Stabilization practices involve establishing a sustainable ground cover by permanent seeding, mulching, sodding, and other such practices. A vegetative cover reduces the potential for erosion of a site by: absorbing the kinetic energy of raindrops which would otherwise impact soil; intercepting water so it can infiltrate into the ground instead of running off and carrying contaminated discharges; and by slowing the velocity of runoff to promote onsite deposition of sediment. Stabilization controls are often the most important measures taken to prevent offsite sediment movement, and can provide a six-fold reduction in the discharge of suspended sediment levels.[50] Permanent seeding has been found to be 99 percent effective in controlling erosion for disturbed land areas.[51] Many states require that topsoil be segregated from other overburden for use during reclamation. While stored, topsoil stockpiles should be vegetated. This temporary form of vegetation can often be used for other piles of stored materials and for intermittent/seasonal operations.

Typically, the costs of stabilization controls are low relative to other discharge mitigation practices. Given the limited capacity to accept large volumes of runoff, and potential erosion problems associated with large concentrated flows, stabilization controls should typically be used in combination with other management practices. These measures have been documented as particularly appropriate for mining sites.

(i) Topsoiling, Seedbed Preparation—The addition of a layer of topsoil or plant growth material provides an improved soil medium for plant growth. Seedbed preparation may include the addition of topsoil ingredients to be mixed in with soils used for seedbed preparation.

(ii) Broadcast Seeding and Drill Seeding—Seeding and vegetative planting are methods used to revegetate an area. Broadcast seeding spreads seeds uniformly, by hand or machine, to steep sloped or rocky areas, flat surfaces, and areas with limited access.

(iii) Willow Cutting Establishment—Willow cutting establishment describes a method of soil stabilization useful for stream banks and other areas located adjacent to water. Similar to biotechnical stabilization, willow cuttings are used to promote growth in an area needing stabilization. Willow cuttings are typically used to reinforce a streambank or other moist area.

(iv) Plastic Matting, Plastic Netting, and Erosion Control Blankets—These BMPs are used to protect bare soils to control dust and erosion. Mats and blankets help to promote vegetative growth by maintaining moisture and heat within the soil.

[51] "Sediment and Erosion Control: An Inventory of Current Practices—Draft," EPA, April 20, 1990, page IV–4.

(v) Mulch-straw or Wood Chips—Mulches and wood chips are useful temporary covers for bare or seeded soils, with an erosion control effectiveness rating of 75 to 98 percent.[52] Like matting, mulch-straw or wood chips help soils retain moisture and warmth to promote vegetative growth.

(vi) Compaction—Soil compaction using a roller or other heavy equipment increases soil "strength" by increasing its density. More dense soil is less prone to erosion and long-term soil settlement.

(3) Capping. In some cases, the elimination of a pollution source through capping contaminant sources may be the most cost effective control measure for discharges from inactive ore mining and dressing facilities. Depending on the type of management practices chosen the cost to eliminate the pollutant source may be very high. Once completed, however, maintenance costs will range from low to nonexistent.

Capping or sealing of waste materials is designed to prevent infiltration, as well as to limit contact between discharges and potential sources of contamination. Ultimately, capping should reduce or eliminate the contaminants in discharges. In addition, by reducing infiltration, the potential for seepage and leachate generation may also be lessened.

EPA has identified a wide variety of best management practices (BMPs) that may be used to mitigate discharges of contaminants at active and inactive metal mines. Many of the practices focus on sediment and erosion control and are similar to BMPs used in the construction industry. These controls to prevent erosion and control sedimentation are the most effective if they are installed at the inception of operations and maintained throughout active operations and reclamation of the site. For more details on the use and implementation of these practices the reader is encouraged to obtain a copy of one or more of the many good sediment and erosion control books available on the market.[53] In some cases (e.g., low pH and/or high metals concentrations), BMPs, and sediment and erosion controls may not be adequate to produce an acceptable quality of storm water discharge. Under those circumstances additional physical or chemical treatment systems may be necessary to protect the receiving waters.

(4) Treatment. Treatment practices are those methods of control which normally are thought of as being applied at the "end of the pipe" to reduce the concentration of pollutants in water before it is discharged. This is in contrast to many BMPs, where the emphasis is on keeping the water from becoming contaminated. Treatment practices may be required where flows are currently being affected by exposed materials and other BMPs are insufficient to meet discharge goals. These practices are usually the most resource intensive, as they often require significant construction costs, and monitoring and maintenance on a frequent and regular basis. Treatment options may range from high maintenance controls to low maintenance controls. High maintenance treatment techniques require manpower to operate and maintain the BMP. Low maintenance cost techniques have initial capital costs but operate with low long-term maintenance after being implemented. At a few sites, treatment measures other than high maintenance measures may be appropriate to address specific pollutants.

(a) Chemical/Physical Treatment—An example of a high maintenance technology that is found at many active metal mining facilities is chemical/physical treatment. The most common type of chemical/physical treatment involves the addition of lime or other such caustics to neutralize the discharges and/or precipitate metals. Metals may be removed from wastewater by raising the pH of the wastewater to precipitate them out as hydroxides.

(b) Oil/Water Separators—Another example of a high maintenance treatment technology is an oil/water separator. An American Petroleum Institute (API) oil/water separator or similar type of treatment device which acts to skim oil and settle sludge can be used to remove oil from water.

(c) Artificial Wetlands—This type of BMP system can be an effective system for improving water quality either alone or in conjunction with other treatment practices. Wetland processes are able to filter sediments, and absorb and retain chemical and heavy metal pollutants through biological degradation, transformation, and plant uptake.

Natural wetlands should not be considered as part of the treatment system because they are considered to be waters of the United States. The necessary controls, or BMPs, must be provided prior to discharging the storm water runoff to natural wetlands or other receiving waters.

In summary, a wide variety of BMPs are available for use at active and inactive metallic mining and milling facilities. These measures range from simple low cost, low maintenance source reduction practices such as diversion structures to high cost, maintenance intensive practices such as wetlands treatment. Clearly, the selection of a practice or group of practices will be site-specific depending on conditions and potential impacts as well as the resources available at each site. A specific best available technology (or technologies) cannot be determined because of the differences between sites and the quantities and characteristics of their discharges.

(4) Discharges Covered Under This Section

Coverage under this section of today's permit is limited to all storm water discharges from inactive metal mining facilities and storm water discharges from the following areas of active metal mining facilities: topsoil piles; offsite haul/access roads if off active area; onsite haul roads if not constructed of waste rock or spent ore, and mine water is not used for dust control; runoff from tailings dams/dikes when not constructed of waste rock/tailings and no process fluids are present; concentration building, if no contact with material piles; mill site, if no contact with material piles; chemical storage area; docking facility, if no excessive contact with waste product; explosive storage; reclaimed areas released from reclamation bonds prior to December 17, 1990; and partially/inadequately reclaimed areas or areas not released from reclamation bonds.

Storm water discharges, or mine drainage discharges, which are subject to existing effluent limitations guidelines addressing storm water (or a combination of storm water and non-storm water) cannot be covered by this section. The effluent limitations guidelines that apply to active metal mining operations are contained in 40 CFR Part 440, Ore Mining and Dressing Point Source Category. These effluent guidelines include specific numeric limitations for mine drainage and discharges from mills, or "no discharge" requirements. Table G–4 identifies the discharge and source of the discharge from active metal mining facilities, that are subject to process wastewater limitations, mine drainage limitations, and storm water reporting requirements. Storm water discharges that are eligible

for coverage under today's permit are identified under the coverage section of the permit. At all metal mining facilities, coverage under this section does not include adit drainage or contaminated springs or seeps. Table G-4 clarifies the applicability of the Effluent Limitations Guidelines found in 40 CFR Part 440. This table does not expand or redefine these Effluent Limitations Guidelines.

TABLE G-4.—APPLICABILITY OF 40 CFR PART 440 EFFLUENT LIMITATIONS GUIDELINES TO STORM WATER RUNOFF FROM ACTIVE ORE (METAL) MINING AND DRESSING SITES

Discharge/source of discharge	Applicable ELG, if any (see key)	Note/comment
Land application area runoff	MD	PW—if Process fluids present.
Crusher area	MD	PW—if Process fluids present.
Piles (seepage and/or runoff):		
Spent ore	MD	PW—if Process fluids present.
Surge/Ore	MD	PW—if Process fluids present.
Waste rock/overburden	MD	
Topsoil	SW	
Drainage:		
Pit drainage (unpumped)	MD	
Pit drainage (removed by pumping)	MD	
Mine water from underground mines (unpumped), adit discharges.	MD	
Mine water from underground mines (pumped)	MD	
Seeps/French drains	MD	PW—if Process fluids present.
Roads constructed of waste rock or spent ore:		
Onsite haul roads	MD	
Offsite haul/access roads	SW	(if off Active Area).
Roads not constructed of waste rock or spent ore:		
Onsite haul roads	SW	MD—if dust control with MD water.
Offsite haul/access roads	SW	
Milling/concentrating:		
Tailings impoundment/pile	PW	
Runoff from tailings dams/dikes when constructed of waste rock/tailings.	MD	PW—if Process fluids present.
Runoff from tailings dams/dikes when not constructed of waste rock/tailings.	SW	PW—if Process fluids present.
Heap leach pile runoff/seepage	PW	
Pregnant pond (barren and surge ponds also)	PW	
Polishing pond	PW	
Concentration building	SW	If storm water only, and no contact with piles.
Concentrate pile (product storage)	PW	
Mill site	SW	Same as concentration bldg.
Ancillary areas:		
Office/administrative building and housing	UC	Unless mixed with SW from industrial area, then SW.
Chemical storage area	SW	
Docking facility	SW	Excessive contact with waste product could constitute MD.
Explosive storage	SW	
Fuel storage (oil tanks/coal piles)	SW	
Vehicle/equipment maintenance area/building	SW	
Parking areas	SW	UC if only employee and visitor type parking.
Power plant	SW	
Truck wash area	SW	Excessive contact with waste product could constitute MD.
Reclamation-related areas:		
Any disturbed area (unreclaimed)	MD	SW if inactive area.
Reclaimed areas released from reclamation bonds after Dec. 17 1990.	UC	
Reclaimed areas released from reclamation bonds prior to Dec. 17 1990.	SW	
Partially/inadequately reclaimed areas or areas not released from reclamation bond.	SW	

KEY: UC—Unclassified; Not Subject to Storm Water Program or 40 CFR Part 440 Effluent Limitations Guidelines (ELG); MD—Subject to 40 CFR Part 440 ELG for mine drainage; PW—Subject to 40 CFR Part 440 ELG for mill discharge or process (including zero discharge ELG); SW—Storm water runoff from these sources are subject to the Storm Water Program, but are not subject to 40 CFR 440 ELG unless mixed with discharges subject to the 440 CFR 440 ELG that are not regulated by another permit prior to mixing. Non-storm water discharges from these sources are subject to NPDES permitting and may be subject to the effluent limitation guidelines under 40 CFR 440.

Temporarily inactive (e.g., winter closure, and portions of active mines that are no longer being mined, and where reclamation has not begun) mines will be permitted as an active mine. The following definitions apply to this section and are intended to provide clarification as to what is considered active, inactive, and temporarily inactive:

The following definitions are only for this section of today's permit and are not intended to supersede the definitions of active and inactive mining facilities established by 40 CFR 122.26(b)(14)(iii):

"Active Metal Mining Facility" is a place where work or other related

activity to the extraction, removal, or recovery of metal ore is being conducted. With respect to surface mines, an "active metal mining facility" does not include any area of land on or in which grading has been completed to return the earth to a desired contour and reclamation work has begun.

"Inactive Metal Mining Facility" means a site or portion of a site where metal mining and/or milling activities occurred in the past but is not an active metal mining facility, as defined in this permit and that portion of the facility does not have an active mining permit issued by the applicable (federal or state) government agency that authorizes mining at the site.

"Temporarily Inactive Metal Mining Facility" means a site or portion of a site where metal mining and/or milling activities occurred in the past, but currently are not being actively undertaken, and the facility has an active mining permit issued by the applicable (federal or state) governmental agency that authorizes mining at the site.

Operators of storm water discharges from mining related industrial activities such as vehicle maintenance, or power plants should refer to the appropriate sections of today's permit for specific guidance or requirements. Clearing, grading, and excavation activity that disturbs 5 or more acres during the exploration or preparation for beginning active mining operations cannot be covered by this section. Coverage for this type of pre-mining activity can be covered by EPA's general permit for storm water discharges from construction activities or an applicable State-issued permit. Land disturbance activities associated with the active mining operations such as expansion of existing pits, can be covered by this section.

5. Storm Water Pollution Prevention Plan Requirements

All facilities subject to this section must prepare and implement a storm water pollution prevention plan. The establishment of a pollution prevention plan requirement reflects EPA's decision to allow operators of ore mining and dressing facilities to utilize BMPs as the BAT/BCT level of control for the storm water discharges covered by this section. The requirements included in pollution prevention plans provide a flexible framework for the development and implementation of site specific controls to minimize pollutants in storm water discharges. This approach is consistent with the approach used in the baseline general permits finalized on September 9, 1992 (57 FR 41236).

Pollution prevention can be an effective approach for controlling contaminated storm water discharges from metal mining facilities. Pollution prevention plans allow the operator of a facility to select BMPs based on site-specific considerations such as: facility size; climate; geographic location; hydrogeology; the environmental setting of each facility; and volume and type of discharge generated. This flexibility is necessary because each facility will be unique in that the source, type, and volume of contaminated surface water discharges will differ from site to site. In addition, EPA believes that the adoption of BMPs reduces environmental impacts by minimizing land disturbed areas susceptible to storm water runoff. Early implementation and maintenance of BMPs facilitates ongoing reclamation activities, reducing final reclamation costs associated with site closure. BMPs are also effective at temporarily or permanently inactive mine sites.

There are two major objectives to a pollution prevention plan: 1) to identify sources of pollution potentially affecting the quality of storm water discharges associated with industrial activity from a facility; and 2) to describe and ensure implementation of practices to minimize and control pollutants in storm water discharges associated with industrial activity from a facility.

Specific requirements for a pollution prevention plan for ore mining and dressing facilities are described below. These requirements must be implemented in addition to the baseline pollution prevention plan provisions discussed previously.

a. Active and Temporarily Inactive Metal Mining Facilities.

(1) Description of Mining Activities. The storm water pollution prevention plan shall provide a narrative description of the mining and associated activities taking place at the site which affect or may affect storm water runoff intended to be covered by this section. The narrative description shall report the total acreage within the mine site, an estimate of the acreage of land currently disturbed, and an estimate of the total acreage that will be disturbed throughout the life of the mine. A general description of the mining site relative to major transportation routes and communities shall also be provided.

(2) Description of Potential Pollution Sources. Each storm water pollution prevention plan must describe activities, materials, and physical features of the facility that may contribute to storm water runoff or, during periods of dry weather, result in dry weather flows and mine pumpout. This assessment of storm water pollution will support subsequent efforts to identify and set priorities for necessary changes in materials, materials management practices, or site features, as well as aid in the selection of appropriate structural and nonstructural control techniques. In addition to the baseline general requirements storm water pollution prevention plans must describe the following elements:

(a) Drainage—The plan must contain a map of the site that shows the pattern of storm water drainage, structural features that control pollutants in storm water runoff [54] and process wastewater discharges (including mine drainage), surface water bodies (including wetlands), places where significant materials [55] are exposed to rainfall and runoff, and locations of major spills and leaks that occurred in the 3 years prior to the date of the submission of a Notice of Intent (NOI) to be covered under this permit. The map also must show areas where the following activities take place: fueling, vehicle and equipment maintenance and/or cleaning, loading and unloading, material storage (including tanks or other vessels used for liquid or waste storage), material processing, waste disposal, haul roads, access roads, and rail spurs. The site map must also indicate the outfall locations and the types of discharges contained in the drainage areas of the outfalls (e.g. storm water and air conditioner condensate). In order to increase the readability of the map, the inventory of the types of discharges contained in each outfall may be kept as an attachment to the site map.

(b) Inventory of Exposed Materials—Facility operators are required to carefully conduct an inspection of the site and related records to identify significant materials that are or may be exposed to storm water. The inventory

[54] Nonstructural features such as grass swales and vegetative buffer strips also should be shown.

[55] Significant materials include, "* * * but [are] not limited to: raw materials, fuels, materials such as solvents, detergents, and plastic pellets; finished materials such as metallic products; * * * hazardous substances designated under section 101(14) of CERCLA; any chemical facilities required to report pursuant to section 313 of title III of SARA; fertilizers; pesticides; and waste products such as ashes, slag, and sludge that have the potential to be released with storm water discharge" (40 CFR 122.26(b)(12)). Significant materials commonly found at mining facilities include: overburden; raw materials; waste rock piles; tailings; petroleum based products; solvents and detergents; heap leach pads; tailings piles/ponds, both proposed and existing; and manufactured products, waste materials or by-products used or created by the facility.

must address materials that within 3 years prior to the date of the submission of a Notice of Intent (NOI) to be covered under this permit have been handled, stored, processed, treated, or disposed of in a manner to allow exposure to storm water. Findings of the inventory must be documented in detail in the pollution prevention plan. At a minimum, the plan must describe the method and location of onsite storage or disposal; practices used to minimize contact of materials with rainfall and runoff; existing structural and nonstructural controls that reduce pollutants in storm water runoff; existing structural controls that limit process wastewater discharges; and any treatment the runoff receives before it is discharged to surface waters or a separate storm sewer system. The description must be updated whenever there is a significant change in the types or amounts of materials, or material management practices, that may affect the exposure of materials to storm water.

In addition, any existing ore or waste rock/overburden characterization data, including results of testing for acid rock generation potential must be included in the pollution prevention plan. The intent is to get an idea of the pollutants (e.g., heavy metals) that may be present in the ore and waste rock/overburden.

(3) Measures and Controls. Following completion of the source identification and assessment phase, the permittee must evaluate, select, and describe the pollution prevention measures, best management practices (BMPs), and other controls that will be implemented at the facility. The permittee must assess the applicability of the following BMPs for their site: discharge diversions, drainage/storm water conveyance systems, runoff dispersions, sediment control and collection mechanisms, vegetation/soil stabilization, capping of contaminated sources, and treatment of storm water discharges. In addition, BMPs include processes, procedures, schedules of activities, prohibitions on practices, and other management practices that prevent or reduce the discharge of pollutants in storm water runoff.

The pollution prevention plan must discuss the reasons each selected control or practice is appropriate for the facility and how each will address the potential sources of storm water pollution. The plan also must include a schedule specifying the time or times during which each control or practice will be implemented. In addition, the plan should discuss ways in which the controls and practices relate to one another and, when taken as a whole, produce an integrated and consistent approach for preventing or controlling potential storm water contamination problems.

Under the inspection requirements of the pollution prevention plan, operators of active facilities are required to conduct monthly visual inspections of BMPs and designated equipment and mine areas. Owner/operators of temporarily inactive mining sites are required to conduct quarterly inspections. If weather conditions make the mine site inaccessible, the quarterly inspection will not be required. Active mining sites have frequent inspection periods because members of the pollution prevention team will be onsite, and the fact that they are active means there is a greater potential for pollution. The inspections shall include: (1) an assessment of the integrity of storm water discharge diversions, conveyance systems, sediment control and collection systems, and containment structures; (2) visual inspections of vegetative BMPs, serrated slopes, and benched slopes to determine if soil erosion has occurred; and (3) visual inspections of material handling and storage areas and other potential sources of pollution for evidence of actual or potential pollutant discharges of contaminated storm water.

Under the employee training requirements of the pollution prevention plan, facility operators are required to conduct employee training programs at least annually. The intent of this frequency is to provide a reminder to the employees of the requirements of the storm water pollution prevention plan.

(4) Non-storm Water Discharges. Each pollution prevention plan must include a certification, signed by an authorized individual, that discharges from the site have been tested or evaluated for the presence of non-storm water discharges, including discharges that are subject to 40 CFR Part 440. The certification must describe possible significant sources of non-storm water, the results of any test and/or evaluation conducted to detect such discharges, the test method or evaluation criteria used, the dates on which tests or evaluations were performed, and the onsite drainage points directly observed during the test or evaluation. Pollution prevention plans must identify and ensure the implementation of appropriate pollution prevention measures for the non-storm water discharge.

Under the non-storm water discharge section of the pollution prevention plan, EPA will allow non-storm water discharges that mix with storm water under this section provided that the plan includes a certification that any non-storm water discharge which mixes with storm water is subject to a separate NPDES permit that applies applicable effluent limitations prior to the mixing of non-storm water and storm water. In such cases, the certification shall identify the non-storm water discharge(s), the applicable NPDES permit(s), the effluent limitations placed on the non-storm water discharge by the NPDES permit(s), and the point(s) at which the limitations are applied. In addition, Part III.A.2 of today's permit discusses non-storm water discharges that may be eligible for coverage under the permit.

b. Inactive Metal Mining Facilities

(1) Pollution Prevention Team. The storm water pollution prevention plan must identify specific individual(s) who are responsible for the development, implementation, maintenance, and revision of the pollution prevention plan. The plan shall clearly identify the responsibilities of each team member. The activities and responsibilities of the team shall address all aspects of the storm water pollution prevention plan at the inactive facility. Members of the pollution prevention team do not have to be permanently located at the inactive facility, such as the requirement for any active facility.

(2) Description of Mining Activities. The storm water pollution prevention plan shall provide a narrative description of the mining and associated activities that took place at the site. The narrative description shall report the approximate dates of operation, total acreage within the mine site and/or processing site, an estimate of the total acreage disturbed, and the activities (reclamation, etc.) that are currently taking place at the facility. A general description of the mining site relative to major transportation routes and communities shall also be provided.

(3) Description of Potential Pollution Sources. Each storm water pollution prevention plan must describe activities, materials, and physical features of the facility that may contribute to storm water runoff or, during periods of dry weather, result in dry weather flows. This assessment of storm water pollution will support subsequent efforts to identify and set priorities for necessary changes in materials, materials management practices, or site features, as well as aid in the selection of appropriate structural and nonstructural control techniques. In addition to the baseline general requirements storm water pollution prevention plans must describe the following elements:

(3) Drainage—The plan must contain a map of the site that shows the pattern of storm water drainage, structural features that control pollutants in storm water runoff[56] and process wastewater discharges (including mine drainage), surface water bodies (including wetlands), places where significant materials[57] are exposed to rainfall and runoff. The map also must show the location of the following: any remaining equipment storage, fueling, and maintenance areas; areas used for outdoor manufacturing, storage, or disposal of materials; the boundaries of former mining and milling sites; the location of each storm water outfall and an outline of the portions of the drainage area that are within the facility boundaries; tailings piles and ponds; mine drainage or any other process water discharge point; and an estimate of the direction of flow. In addition, the site map must also indicate the types of discharges contained in the drainage areas of the outfalls (e.g., storm water and air conditioner condensate). In order to increase the readability of the map, the inventory of the types of discharges contained in each outfall may be kept as an attachment to the site map.

(b) Inventory of Exposed Materials—The storm water pollution prevention plan shall include, for each outfall, an inventory and narrative description of any significant materials that may still be at the site. The description and locations of the significant materials should be consistent with those shown on the site map. Findings of the inventory must be documented in detail in the pollution prevention plan. At a minimum, the plan must describe the method and location of onsite storage or disposal; practices used to minimize contact of materials with rainfall and runoff; existing structural and nonstructural controls that reduce pollutants in storm water runoff; existing structural controls that limit process wastewater discharges; and any treatment the runoff receives before it is discharged to surface waters or a separate storm sewer system.

(c) Risk Identification and Summary of Potential Pollutant Sources—The description of potential pollution sources culminates in a narrative assessment of the risk potential that sources of pollution pose to storm water quality. This assessment should clearly point to activities, materials, and physical features of the facility that have a reasonable potential to contribute significant amounts of pollutants to storm water. The assessment must list any significant pollution sources at the site and identify the pollutant parameter or parameters (i.e., total suspended solids, arsenic, etc.) associated with each source.

(4) Measures and Controls. Following completion of the source identification and assessment phase, the permittee must evaluate, select, and describe the pollution prevention measures, best management practices (BMPs), and other controls that will be implemented at the facility. The permittee must assess the applicability of the following BMPs for their site: discharge diversions, drainage/storm water conveyance systems, runoff dispersions, sediment control and collection mechanisms, vegetation/soil stabilization, capping of contaminated sources, and treatment of storm water discharges. In addition, BMPs include processes, procedures, schedules of activities, prohibitions on practices, and other management practices that prevent or reduce the discharge of pollutants in storm water runoff. EPA recognizes that inactive mine sites and abandoned mine sites will most likely require different storm water controls because the sources and types of contamination may vary. EPA notes that inactive facilities are not required to conduct inspections such as those described in Part XI.G.3.a.(4)(d) of the permit for active and temporarily inactive facilities. Inactive sites must, however, conduct comprehensive site compliance evaluations as discussed in paragraph (5) below.

The pollution prevention plan must discuss the reasons each selected control or practice is appropriate for the facility and how each will address the potential sources of storm water pollution. The plan also must include a schedule specifying the time or times during which each control or practice will be implemented. In addition, the plan should discuss ways in which the controls and practices relate to one another and, when taken as a whole, produce an integrated and consistent approach for preventing or controlling potential storm water contamination problems.

(5) Comprehensive Site Compliance Evaluation. Where annual site compliance evaluations are shown in the plan to be impractical for inactive mining sites due to the remote location and inaccessibility of the site, site evaluations required under this part shall be conducted at appropriate intervals specified in the plan, but, in no case less than once in 3 years.

6. Monitoring and Reporting Requirements

a. Analytical Monitoring Requirements. EPA believes that active copper ore mining facilities may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. In order to provide a tool for evaluating the effectiveness of the pollution prevention plan and to characterize the discharge for potential environmental impacts, the permit requires active copper ore mining and dressing facilities to collect and analyze samples of their storm water discharges for the pollutants listed in Table G–5. The pollutants listed in Table G–5 were found to be above levels of concern for a significant portion of active copper ore mining and dressing facilities that submitted quantitative data in the group application process. Because these pollutants have been reported at levels of concern from active copper ore mining and dressing facilities, EPA is requiring monitoring after the pollution prevention plan has been implemented to assess the effectiveness of the pollution prevention plan and to help ensure that a reduction of pollutants is realized.

At a minimum, storm water discharges from active metal mining facilities must be monitored quarterly during the second year of permit coverage. Samples must be collected at least once in each of the following periods: January through March; April through June; July through September; and October through December. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Table G–5. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

[56] Nonstructural features such as grass swales and vegetative buffer strips also should be shown.

[57] Significant materials include, "* * * but [are] not limited to: raw materials, fuels, materials such as solvents, detergents, and plastic pellets: finished materials such as metallic products; * * * hazardous substances designated under section 101(14) of CERCLA; any chemical facilities required to report pursuant to section 313 of title III of SARA; fertilizers; pesticides; and waste products such as ashes, slag, and sludge that have the potential to be released with storm water discharge" (40 CFR 122.26(b)(12)). Significant materials commonly found at mining facilities include: overburden; raw materials; waste rock piles; tailings; petroleum based products; solvents and detergents; heap leach pads; tailings piles/ponds, both proposed and existing; and manufactured products, waste materials or by-products used or created by the facility.

TABLE G–5.—INDUSTRY MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Chemical Oxygen Demand (COD)	120 mg/L
Total Suspended Solids (TSS)	100 mg/L
Nitrate plus Nitrite Nitrogen	0.68 mg/L

If the average concentration for a parameter is less than or equal to the value listed in Table G–5, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration listed in Table G–5, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit.

TABLE G–6.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Table G–5, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Table G–5, then no further sampling is required for that parameter.
4th Year of Permit Coverage.	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Table G–5. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will reassess the effectiveness of the adjusted pollution prevention plan.

The monitoring cut off concentrations listed in Table G–5 are not numerical effluent limitations. These values represent a level of pollutant discharge which facilities may achieve through the implementation of pollution prevention plans. At least half of the facilities which submitted Part 2 data, reported concentrations greater than or equal to the values listed in Table G–5. Facilities that achieve average discharge concentrations which are less than or equal to the values in Table G–5 are not relieved from the pollution prevention plan requirements or any other requirements of the permit.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

b. Alternative Certification. Throughout today's permit, EPA has included monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall, or on a pollutant-by-pollutant basis in lieu of the monitoring reports required under paragraph *c* below, under penalty of law, signed in accordance with Part VII.G. of the permit (Signatory Requirements), that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity, that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in accordance with Part VI.C. of this permit. In the case of certifying that a pollutant is not present, the permittee must submit the certification along with the monitoring reports required under paragraph (*b*) below. If the permittee cannot certify for an entire period, they must submit the date exposure was eliminated and any monitoring required up until that date. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

c. Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one signed Discharge Monitoring Report form must be submitted to the Director per storm event sampled. For facilities conducting monitoring beyond the minimum quarterly requirements an additional Discharge Monitoring Report Form must be filed for each analysis.

d. Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable.

If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

e. Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one such outfall and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

F. Visual Examination of Storm Water Quality. Metal mining facilities shall perform and document a visual examination of a storm water discharge associated with industrial activity from each outfall, except discharges exempted below. The examination of storm water quality must be conducted at least once in each of the following 3-month periods: January through March, April through June, July through September, and October through December. The examination shall be made during daylight hours unless there is insufficient rainfall or snow melt to produce a runoff event.

(1) Examinations shall be made of grab samples collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 1 hour) of when the runoff or snowmelt begins discharging. The examinations shall document observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on the samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. Where practicable, the same individual should carry out the collection and examination of discharges for entire permit term.

(2) Visual examination reports must be maintained onsite in the storm water pollution prevention plan. The report shall include the examination date and time, examination personnel, the nature of the discharge (i.e., runoff or snow melt), visual quality of the storm water discharge (including observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution), and probable sources of any observed storm water contamination.

(3) When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may collect a sample of effluent of one of such outfalls and report that the examination data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluents. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

(4) When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination and retain this documentation onsite with the records of the visual examinations. Adverse weather conditions that may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

(5) EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

EPA believes that this quick and simple assessment will allow the permittee to approximate the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examinations. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and the effects of the management practices that are included in the plan.

7. Numeric Effluent Limitations.

There are no numeric effluent limitations beyond those described in Part VI.B. of this permit.

H. Storm Water Discharges Associated With Industrial Activity From Coal Mines and Coal Mining-Related Facilities

1. Discharges Covered Under This Section

On November 16, 1990 (55 FR 47990), EPA promulgated the regulatory definition of "storm water associated with industrial activity." This definition includes point source discharges of storm water from eleven major categories of facilities, including: "* * * (iii) facilities classified as Standard Industrial Classification (SIC) codes 10 through 14 including active or inactive mining operations (except for areas of coal mining operations no longer meeting the definition of a reclamation area under 40 CFR 434.11(l) because the performance bond issued to the facility by the appropriate SMCRA authority has been released, or except for areas of noncoal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990) and oil and gas exploration, production, processing, or treatment operations, or storm water contaminated by contact with any overburden, raw material, intermediate products, finished products, by-products or waste products located on the site of such operations."

This section only covers storm water discharges associated with industrial activities from inactive[58] coal mines and from access roads, haul roads, and rail lines at active coal mines. Coal mines and coal mining-related facilities subject to requirements under this section include the following types of operations: bituminous coal and lignite surface mining (SIC 1221); bituminous coal underground mining (SIC 1222); anthracite mining (SIC 1231); and coal mining services (SIC 1241).

Storm water discharges authorized by this section include storm water discharges at inactive coal mines where precipitation and storm water runon come into contact with significant materials including, but not limited to, raw materials, waste products, and by-products, overburden, and stored materials. This section also authorizes storm water discharges from haul roads, access roads, and rail lines used or traveled by carriers of raw materials, manufactured products, waste materials, or by-products created by active coal mining facilities. The following activities are covered under this section:

Haul Roads—Nonpublic roads on which coal or coal refuse is conveyed
Access Roads—Nonpublic roads providing light vehicular traffic within the facility property and to public roadways
Railroad Spurs, Sidings, and Internal Haulage Lines—Rail lines used for hauling coal within the facility property and to offsite commercial railroad lines or loading areas
Conveyor Belts, Chutes, and Aerial Tramway Haulage Areas—Areas under and around coal or refuse conveyor areas, including transfer stations
Equipment Storage and Maintenance Yards
Coal Handling Buildings and Structures
Inactive Coal Mines and Related Areas—Abandoned and other inactive mines, refuse disposal sites and other mining-related areas. This includes abandoned mine sites being reclaimed under Title IV of the Surface Mining Control and Reclamation Act. Not covered by this section are discharges from sites, or parts of sites, which are determined to cause or contribute to water quality standards violations.

This section does not cover any discharge subject to effluent limitation guidelines. Discharges from active facilities and those under reclamation are subject to NPDES permits and require treatment to meet specific effluent guideline limits as specified in 40 CFR Part 434 for pH, iron, manganese, suspended solids, and settleable solids. Storm water that does not come into contact with any overburden, raw material, intermediate product, finished product, byproduct, or waste product located on the site of the operation are not subject to permitting under this section according to Section 402(l)(2) of the Clean Water Act.

This section also does not cover storm water discharges associated with industrial activity from inactive coal mines located on Federal lands, unless an operator can be identified. These discharges are not eligible because they are more appropriately covered under an NPDES permit currently being developed.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

Coal is a black, primarily organic substance formed from compressed layers of decaying organic matter millions of years ago.[59] Factors such as the fixed carbon content, volatile matter fraction, and heating value, determine whether coal is classified as lignite, sub-bituminous, bituminous, or anthracite. The coal mining and related facilities industry extracts and processes coal. There are two methods of coal mining: surface mining and underground mining. Surface mining is a method utilized when the coal is close to the earth's surface and it is economically viable to remove and store the overburden, which can later be used for reclamation. Underground mining occurs when coal is too deep to be surface mined or environmental restrictions prohibit surface mining.

Coal preparation activities increase the value of coal by removing impurities through size reduction, screening, gravity separation, dewatering, and drying. After this step, coal is ready to be shipped for further processing. The impurities, including shales, clays, low reject coal, and possibly some acidic materials, are then conveyed to refuse disposal facilities.

These mining methods and coal preparation activities occur during the active phase of mining and are not authorized by this section nor are they included in the storm water regulation. Most areas at active mine sites are covered by the Surface Mining Control and Reclamation Act (SMCRA). Discharges from these areas are considered process wastewaters and are covered under a separate NPDES permit. Today's permit only addresses storm water discharges from coal mines and related areas that are not already subject to effluent limitation guidelines under 40 CFR Part 434. Storm water discharges not subject to the effluent limitation guidelines may include discharges from the following areas:

a. Access Roads, Haul Roads, and Rail Lines. Access roads, haul roads, and rail lines are used for the transportation of coal, refuse (waste materials, old equipment, etc.), and overburden away from the mine workings. To build access and haul roads, common land disturbing activities such as vegetation clearing and soil grading are necessary. Refuse coal and overburden may be used as a road base material. Road building activities increase the potential for the offsite discharge of sediment in storm water runoff. In addition, coal, overburden, and refuse materials may be spilled during loading and unloading operations and during the transport of such materials along access roads, haul roads, and rail spurs.

b. Inactive Mine Sites. Although industrial processes have ended at inactive mine sites, the significant materials associated with those

[58] Inactive mining operations are mining sites that are not being actively mined, but which have an identifiable owner/operator.

[59] "Development Document for Final Effluent Limitations Guideline, New Source Performance Standards, and Pretreatment Standards for the Coal Mining Point Source Category." EPA. 1982.

industrial processes may remain at the site and contaminate storm water discharges. The areas at inactive surface or underground coal mines which are included in the storm water regulation include former locations of: conveyor belts, chutes, and aerial tramways; equipment storage and maintenance yards; coal preparation plants; and coal handling buildings and storage areas.

Inactive mine sites are regulated because significant materials remain onsite. The significant materials include, but are not limited to: coal piles, including coal refuse piles; used and old equipment, including boneyards; overburden; waste disposal sites; and waste materials. In addition, in certain areas where machinery has been intensively used or abandoned, waste lubricating fluids, solvents, and contaminated soils may be present. These materials are typically present outdoors and are exposed to storm water discharges.

2. Pollutants Found in Storm Water Discharges

Impacts caused by storm water discharges from active haul roads, access roads and rail lines and inactive coal mine and coal mining-related facilities will vary. Several factors influence to what extent significant materials from coal mines and coal mining-related facilities may affect water quality. Such factors include: geographic location; hydrogeology; the type of coal extracted; the mineralogy of the extracted resource and the surrounding rock; how the coal was extracted; the type of industrial activities occurring onsite; the size of the operation; and type, duration, and intensity of precipitation events. Each of these, and other, factors will interact to influence the quantity and quality of storm water runoff. For example, overburden may be a significant source of pollutants at some facilities, while storage areas are a primary source at others. In addition, sources of pollutants other than storm water, such as illicit connections,[60] spills, and other improperly dumped materials, may increase the pollutant loads discharged into waters of the United States.

Storm water discharges from haul roads of active sites and inactive mine sites may include many of the pollutants common to active coal mining operations. These pollutants may include acids, suspended solids, dissolved solids, iron, manganese, and traces of other metals. Table H–1 indicates the pollutant sources and pollutants for a number of industrial activities for coal mines authorized by this section.

Another problem at coal mines is acid mine drainage. In general, the problems of acid mine drainage are confined to western Maryland, northern West Virginia, Pennsylvania, western Kentucky, and along the Illinois-Indiana border. Acid mine drainage is not a problem in the West because the coals and overburden contain little pyrite, the precursor for acid mine drainage, and because of low annual precipitation.

TABLE H–1.—ACTIVITIES, POLLUTANT SOURCES, AND POLLUTANTS

Activity	Pollutant source	Pollutant
Road and Rail Construction and Maintenance—Active Sites.	Surface grading and exposure of soils	Dust, TSS, TDS, turbidity, pH.
Raw or Waste Material Transportation.	Material spills	Dust, TSS, TDS, turbidity, pH, sulfates, iron.
Location of Mining and Processing Activities at Inactive Coal Mines.	Raw Material Storage	Dust, TSS, TDS, turbidity, pH sulfates, iron.
	Waste Rock Storage	Dust, TSS, TDS, turbidity, sulfates, iron, pH.
	Disposal Areas	Dust, TSS, TDS, turbidity, pH, oil & grease.
	Surface and Underground Mines	Dust, TSS, TDS, turbidity, pH, sulfates, iron.
	Materials Handling and Loading/Unloading	Dust, TSS, TDS, turbidity, pH, sulfates, iron.
Equipment/Vehicle Maintenance.	Fueling Activities	Diesel fuel, gasoline, oil, COD.
	Parts Cleaning	Solvents, oil, heavy metals, acid/alkaline wastes.
	Waste disposal of oily rags, oil and gas filters, batteries, coolants, degreasers.	Oil, heavy metals, solvents, acids, COD.
Reclamation Activities	Site preparation for stabilization	Dust, TSS, TDS, turbidity.

Based on the similarities of the facilities included in this sector in terms of industrial activities and significant materials, EPA believes it is appropriate to discuss the potential pollutants at coal mining facilities as a whole and not subdivide this sector. Therefore, Table H–2 lists data for selected parameters from facilities in the coal mining sector. These data include the eight pollutants that all facilities were required to monitor for under Form 2F, as well as the pollutants that EPA determined merit further monitoring.

TABLE H–2.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY COAL MINES AND COAL MINING-RELATED FACILITIES SUBMITTING PART II SAMPLING DATA[i] (mg/L)

Pollutant Sample type	No. of Facilities		No. of Samples		Mean		Minimum		Maximum		Median		95th percentile		99th percentile

[60] Illicit connections are contributions of unpermitted non-storm water discharges to storm sewers from any number of sources including sanitary sewers, industrial facilities, commercial establishments, or residential dwellings. The probability of illicit connections at coal mines and coal mining related facilities is low yet it still may be applicable at some operations.

R0016182

TABLE H-2.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY COAL MINES AND COAL MINING-RELATED FACILITIES SUBMITTING PART II SAMPLING DATA [i] (mg/L)—Continued

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.

[ii] Composite samples.

Storm water discharges from inactive and abandoned coal mines, preparation, refuse disposal sites, haul roads and other inactive mining-related areas may contain substantial amounts of pollutants without the benefits of sediment and erosion control measures. Sampling data in the EPA 1982 "Development Document for Effluent Guidelines and Standards for Coal Mining" reveal typical ranges for untreated mine drainage and are indicated in Table H-3. The data are based on untreated surface and underground drainage and may not be typical of inactive sites subject only to storm water runoff. For example, a high proportion of underground mines in the survey may have resulted in the relatively low median levels of suspended solids. However, it does indicate the potential array of conventional mining pollutants which could be present in abandoned mine drainage.

3. Options for Controlling Pollutants

Mining facilities are often dissimilar to other types of industrial facilities because they may be situated in remote locations, operate only seasonally or intermittently, yet need year-round storm water management controls. EPA believes that the most effective storm water management controls for limiting the offsite discharge of storm water pollutants from active and inactive coal mines are source reduction BMPs. Source reduction BMPs are methods by which discharges of contaminants are controlled with little or no required maintenance. Examples of these types of controls include diversion dikes, vegetative covers, and berms. Source reduction practices are typically (but not always) low in cost and relatively easy to implement. In some instances, more resource intensive treatment BMPs, including sedimentation ponds and infiltration trenches, may be necessary depending upon the type of discharge, types and concentrations of contaminants, and volume of flow.

The selection of the most effective BMPs will be based on site-specific considerations such as: facility size, climate, geographic location, hydrogeology and the environmental setting of each facility, and volume and type of discharge generated. Each facility will be unique in that the source, type, and volume of contaminated storm water discharges will differ. In addition, the fate and transport of pollutants in these discharges will vary. EPA believes that the management practices discussed herein are well suited mechanisms to prevent or control the contamination of storm water discharges associated with active and inactive coal mines.

BMPs that minimize erosion and sedimentation are effective for areas along haul and access roads, and for inactive mines. Many BMPs were not listed by part 1 group application participants because the major application submitted by the National Coal Association and the American Mining Congress was comprised of only active mine sites. The only portions of an active mine site to which this section of today's permit applies are haul roads, railways, and conveyor belts, chutes, and aerial tramway haulage areas. Because the scope of storm water program, as it applies to active coal mining sites, is limited, the applicants were not required to provide EPA with BMP data for process wastewater discharges. Furthermore, active surface mines are subject to 30 CFR Part 816 and active underground mines are subject to 30 CFR Part 817, both which require the implementation of BMPs.

Since many coal facilities are required to have BMPs, the data presented in part 1 of the application may underestimate the percentage of facilities with storm water BMPs.

Because BMPs described in the part I data are limited, EPA is providing an overview of supplementary BMPs for use by facility operators to determine appropriate BMPs for haul and access roads at active coal mines and for inactive coal mines. However, due to the site-specific nature of facilities within this sector, BMPs cited do not preclude the use of other viable BMP options. Table H-3 summarizes BMP options as they apply to land disturbance activities at active and inactive coal mining facilities. Sources of BMP information include: "Sediment and Erosion Control: An Inventory of Current Practices—Draft," EPA, April 20, 1990; "Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices," EPA, September, 1992, (EPA 832-R-92-006); "Best Management Practices for Mining in Idaho," Idaho Department of Lands, November 1992; and "Erosion & Sediment Control Handbook," Goldman et al., McGraw-Hill Book Company, 1986.

Haul Roads and Access Roads—Placement of haul roads or access roads should occur as far as possible from natural drainage areas, lakes, ponds, wetlands or floodplains where soil will naturally be less stable for heavy vehicle traffic. If a haul road must be constructed near water, as little vegetation as possible should be removed from between the road and the waterway, as vegetation is a useful buffer against erosion and is an efficient sediment collection mechanism. The width and grade of haul or access roads should be minimal and should be designed to match natural contours of the area. Construction of haul roads should be supplemented by BMPs that divert runoff from road surfaces, minimize erosion, and direct flow to appropriate channels for discharge to treatment areas. Existing haul roads and nearby ditches, without BMPs, can be altered or modified to accommodate the construction of BMPs.

Surface Mines—BMPs can be used to control total suspended solids levels in runoff from unvegetated areas. These can include sediment/settling ponds, check dams, silt fences, and straw bale barriers.

Overburden, Waste Rock, and Raw Material Piles—Overburden, topsoil, and waste rock should be stabilized, recontoured if necessary, and vegetated. In addition surface waters and other sources of water should be diverted around the piles. As many piles as possible should be revegetated (even if only on a temporary basis).

Reclamation Activities—When a coal seam is depleted and operations cease, a mine site must be reclaimed according to appropriate State or Federal standards. Closure activities typically include restabilization of any disturbed areas such as access or haul roads, pits or quarries, sedimentation ponds or work-out pits, and any remaining waste piles. Overburden and topsoil stockpiles may be used to fill in a pit or quarry (where practical.) Recontouring and vegetation should be performed to stabilize soils and prevent erosion.

Major reclamation activities such as recontouring roads and filling in a pit or quarry can only be performed after operations have ceased. However, reclamation activities such as stabilization of banks, and reseeding and revegetation should be implemented in mined out portions, or inactive areas of a site as active mining moves to new areas.

The following seven categories describe best management practice options for reducing pollutants in storm water discharges from haul and access roads for active coal mines and for inactive mines: discharge diversions; drainage/storm water conveyance systems; runoff dispersion; sediment control and collection; vegetation/soil stabilization; capping of contaminated sources; and treatment.

a. Discharge Diversions. Discharge diversions provide the first line of defense in preventing the contamination of discharges, and subsequent contamination of receiving waters of the United States. Discharge diversions are temporary or permanent structures installed to divert flow, store flow, or limit storm water runon and runoff.

These diversion practices have several objectives. First, diversion structures can be designed to prevent otherwise uncontaminated (or less contaminated) water from crossing disturbed areas or areas containing significant amounts of contaminated materials, where contact may occur between runon and significant materials. These source reduction measures may be particularly effective for inactive coal mine sites because they prevent runon of uncontaminated discharges from contacting exposed materials and/or reduce the flow across disturbed areas, thereby lessening the potential for erosion. Second, diversion structures can be used to collect or divert waters for later treatment, if necessary. The usefulness of these control measures are limited by such factors as the size of the area to be controlled and the type and nature of materials exposed and precipitation events.

Diversion dikes, curbs, and berms are temporary or permanent diversion structures that prevent runoff from passing beyond a certain point, and divert runoff away from its intended path. Dikes, curbs or berms may be used to surround and isolate areas of concern, diverting flow around piles of overburden, waste rock, and storage areas, to minimize discharge contact with contaminated materials and to limit discharges of contaminated water from confined areas.

b. Drainage/Storm Water Conveyance Systems. Drainage or storm water conveyance systems can provide either a temporary or a permanent management practice which functions to channel water away from eroded or unstabilized areas, convey runoff without causing erosion, and/or carry discharges to more stabilized areas. The use of drainage systems as a permanent measure may be most appropriate in areas with extreme slopes, areas subject to high velocity runoff, and other areas where the establishment of substantial vegetation is infeasible or impractical. For instance, several BMPs described below may be useful storm water and erosion control methods applicable to haul roads and access roads.

Channels or Gutters—Channels or gutters collect storm water runoff and direct its flow. Like diversion systems, channels or gutters may act to divert runoff away from a potential source of contamination, but may also be used to channel runoff to a collection and/or treatment area including settling ponds, basins or work-out pits.

Open Top Box Culverts, and Waterbars—These structures are temporary or permanent structures that divert water from a roadway surface. Open top box culverts may be used on steeply graded, unpaved roads in place of pipe culverts to divert surface runoff and flow from inside ditches onto the downhill slope of a road. These structures are typically made of wood and should periodically be monitored and repaired if necessary.

Waterbars are berms built by a dozer, or by hand, to a one to two foot height. They serve to extend the entire width of the road, with a downslope angle between 30 and 40 percent. Waterbars are kept open at a discharge end to allow water to flow away from the road, and require little maintenance. These berms may be used as temporary or permanent structures.

Rolling Dips and Road Sloping—Rolling dips and road sloping are permanent water diversion techniques installed using natural contours of the land during road construction. These BMPs prevent water accumulation on road surfaces and divert surface runoff toward road ditches, which then convey the storm water to ponds or other management areas.

Roadway Surface Water Deflector—A roadway surface water deflector is another technique to prevent accumulation of water on road surfaces. The structure uses a conveyor belt sandwiched between two pieces of treated wood and placed within the road to deflect water. This is a useful technique for steeply graded, unpaved roads.

Culverts—Culverts are permanent surface water diversion mechanisms used to convey water off of, or underneath a road. Made of corrugated metal, they must extend across the entire width of the road, and beyond the fill slope. Additional erosion control mechanisms may need to be installed at the discharge end of the culvert.

c. Runoff Dispersion. Drainage systems are most effective when used in conjunction with runoff dispersion devices designed to slow the flow of water discharged from a site. These devices also aid storm water infiltration into the soil and flow attenuation. Some examples of velocity dissipation devices include check dams, rock outlet protection, level spreaders, and serrated and benched slopes.

Check Dams—Check dams are small temporary dams constructed across swales or drainage ditches to reduce the velocity of runoff flows, thereby reducing erosion and failure of the swale or ditch. This slowing reduces erosion and gullying in the channel and allows sediments to settle.

Check dams may be installed in small temporary or permanent channels where vegetation of the channel lining is not feasible and where there is danger of erosion. These may be areas where installation of nonerosive liners are not cost effective.

Check dams diminish the need for more stringent erosion control practices in the drainage ditch since they decrease runoff velocity. When constructing check dams, the use of overburden or waste rock should be avoided where there is the potential for contamination.

Rock Outlet Protection—Rock protection placed at the outlet end of culverts, channels, or ditches reduces the depth, velocity, and destructive energy of water such that the flow will not erode the downstream reach. The use of some materials (e.g., mine waste rock or ore) should be avoided where contamination may occur. As with check dams, rock outlet protection may also be used as a source reduction treatment mechanism by using rocks containing limestone or other alkaline materials to neutralize acidic discharges.

Level Spreaders—Level spreaders are outlets for dikes and diversions consisting of an excavated depression constructed at zero grade across a slope. Level spreaders diffuse storm water point sources and release it onto areas stabilized by existing vegetation.

Serrated Slopes and Benched Slopes—These runoff dispersion methods break up flow of runoff from a slope, decreasing its ability to erode. Serrated and benched slopes provide flat areas that allow water to infiltrate, and space for vegetation to grow and reinforce soils. Serrated slopes are equipped with small steps, from one to two feet of horizontal surface exposed on each step. Benched slopes have larger steps, with vertical cuts between two and four feet high.

Contouring—Surface contouring is the establishment of a rough soil surface amenable to revegetation, through creating horizontal grooves, depressions, or steps that run with the contour of the land. Slopes may also be left in a roughened condition to reduce discharge flow and promote infiltration. Surface roughening aids in the establishment of vegetative cover by reducing runoff velocity and giving seed an opportunity to take hold and grow. This technique is appropriate for all slopes steeper than 3:1 in order to facilitate stabilization of the slope and promote the growth of a vegetative cover. Once areas have been contoured, they should be seeded as quickly as possible.

Drain Fields—Drain fields are used to prevent the accumulation of water and/or ground water at a site, by diverting infiltrating sources through gravity flow or pumping. Typically filled with porous, permeable materials such as graded rock, or perforated pipe, and lined with geotextile fabric, these mechanisms are useful underneath significant materials, reducing the amount of water that ultimately comes into contact with significant materials.

Stream Alteration—Altering or channelizing the path of a stream to bypass all or some disturbed areas on a site, allows additional mining activities, and avoids contamination of stream water by disturbed lands. This practice is complicated, however, by the need to restore the channel when mining operations end.

Drop Structures—Drop structures are large angular rocks placed in a V-shaped pattern to slow the velocity of storm water runoff. These structures are typically reinforced by logs or large rocks imbedded in the streambanks.

d. Sediment Control and Collection. Sediment control and collection limits movement and retains sediments from being transported offsite. Several structural collection devices have been developed to remove sediment from runoff before it leaves the site. Several methods of removing sediment from site runoff involve diversion mechanisms previously discussed, supplemented by a trapping or storage device. Structural practices typically involve filtering diffuse storm water flows through temporary structures such as straw bale dikes, silt fences, brush barriers or vegetated areas.

Structural practices are typically low in cost. However, structural practices require periodic removal of sediment to remain functional. As such, they may not be appropriate for permanent use at inactive mines. However, these practices may be effectively used as temporary measures along haul roads and access roads.

Plastic Matting, Plastic Netting, and Erosion Control Blankets—These BMPs are used to protect bare soils to control dust and erosion. Mats and blankets help to promote vegetative growth by maintaining moisture and heat within the soil. Plastic matting and netting improve slope stabilization and may be used as a permanent treatment to encourage grass growth. Plastic netting is a more effective material to use while promoting growth of vegetation as it permits sunlight to penetrate through to the soils. Erosion control blankets also stabilize slopes, and control erosion. These blankets may be made of jute, or plastic netting, but are more expensive than straw.

Mulch-straw or Wood Chips—Mulches and wood chips are useful temporary covers for bare or seeded soils, with an erosion control effectiveness rating of 75 to 98 percent.[61] Like matting, mulch-straw or wood chips help soils retain moisture and warmth to promote vegetative growth. Used on slopes and/or in combination with nylon netting, these materials may prevent erosion by wind and water. Over time, however, the mulch cover will decrease in effectiveness.

Compaction—Soil compaction using a roller or other heavy equipment increases soil "strength" by increasing its density. More dense soil is less prone to erosion and long-term soil settlement. The surface of compacted soils should be roughed and seeded or vegetated to increase its durability.

Sediment/Settling Ponds—Sediment ponds function as sediment traps by containing runoff for long periods of time, allowing suspended solids to settle. These structures can achieve a high removal rate of sediment for both process wastewater and storm water discharges. Sediment/settling ponds are easily constructed and require minimal maintenance. Their flexibility to treat both process wastewater and storm water makes the use of ponds a desirable treatment for discharges from ore mining and dressing facilities. Of course, site characteristics must be such that some or all discharges can be practically channeled to a centralized area for treatment. Where this is not practical, the cost of constructing multiple sediment ponds may become prohibitive. In addition, periodic dredging may be required in order to maintain the capacity of these ponds.

Discharge ponds may also be designed to act as surge ponds which are designed to contain storm surges and then completely drain in about 24 to 40 hours, and remain dry during times of no rainfall. They can provide pollutant removal efficiencies that are similar to those of detention ponds.[62] Storm surge ponds are typically designed to provide both water quality and water quantity (flood control) benefits.

Gabions, Riprap, and Native Rock Retaining Walls—These BMPs are all forms of slope stabilization. Gabions consist of rocks (riprap) contained by rectangular wire boxes or baskets for use as permanent erosion control structures. Riprap consists of loose rocks placed along embankments to prevent erosion. Native rock retaining walls are another form of slope stabilization, with walls up to five feet in height, constructed from native rock to reinforce a steep slope.

Biotechnical Stabilization—Biotechnical stabilization uses live brush imbedded in the soils of a steep slope to prevent erosion. This method relies on the premise that the imbedded vegetation will eventually take root and help stabilize the slope.

Straw Bale Barrier—Straw bales may be used as temporary berms, barriers, or diversions, capturing sediments and filtering runoff. When installed and maintained properly, these barriers remove approximately 67 percent of the sediment load.[63] These barriers are applicable across small swales, in ditches, and at the toe of bare slopes where there is a temporary, large volume of sediment laden runoff.

Sediment Traps or Catch Basins—These temporary or permanent structures are useful for catching and storing sediment laden storm water runoff and are particularly useful during construction activities to contain runoff. The effectiveness of these BMPs is better in smaller drainage basin areas. Sediment traps are less than 50 percent effective in removing sediment from storm water runoff.[64]

Vegetated Buffer Strips—The installation of vegetated buffer strips will reduce runoff and prevent erosion at a removal efficiency rate of 75 to 99 percent depending upon the ground cover.[65] In addition, vegetated buffer strips catch and settle sediment contained in the storm water runoff prior to reaching receiving waters.

Silt Fence/Filter Fence—A low fence made of filter fabric, wire and steel posts, should be used on small ephemeral drainage areas where storm water collects or leaves a mine site. Silt fences remove 97 percent of the sediment load and are easier to maintain and remove without creating lasting impacts to the environment.[66] Silt and filter fences need to be inspected periodically, and may not be as effective as straw bales, since fabric may become clogged with fine particles preventing water flow.

Silt fences may have limited applicability for large areas: they are most effective for use in small drainage areas. These fences may also be used in conjunction with nonstructural practices to maintain the integrity of soil prior to the establishment of vegetation.

Siltation Berms—Siltation berms are typically placed on the downslope side of a disturbed area to act as an impermeable barrier for the capture and

[65] "Sediment and Erosion Control: An Inventory of Current Practices—Draft," EPA, April 20, 1990, page IV–7.

[66] "Sediment and Erosion Control: An Inventory of Current Practices—Draft," EPA, April 20, 1990, page IV–75.

retention of sediments in surface water runoff. Plastic sheeting is typically used to cover the berm. The berm and the plastic sheeting may require periodic maintenance and repair.

Brush Sediment Barriers—Brush barriers are temporary sediment barriers composed of tree limbs, weeds, vines, root mat, soil, rock and other cleared materials placed at the toe of a slope. A brush barrier is effective only for small drainage areas, usually less than ¼ acre, where the slope is minimal.

Brush barriers do not function as permanent barriers since over time the barrier itself will degrade. This BMP is most effective when located at the toe of a slope of an area in which vegetation is being grown or during temporary operations. The brush barriers remove any excessive sediment which is generated by erosion prior to the establishment of vegetation.

e. Vegetation Practices. Vegetation practices involve establishing a sustainable ground cover by permanent seeding, mulching, sodding, and other such practices. A vegetative cover reduces the potential for erosion of a site by: absorbing the kinetic energy of raindrops which would otherwise impact soil; intercepting water so it can infiltrate into the ground instead of running off and carrying contaminated discharges; and by slowing the velocity of runoff to promote onsite deposition of sediment. Vegetative controls are often the most important measures taken to prevent offsite sediment movement, and can provide a six-fold reduction in the discharge of suspended sediment levels.[67] Permanent seeding has been found to be 99 percent effective in controlling erosion for disturbed land areas.[68]

Typically, the costs of vegetative controls are low relative to other discharge mitigation practices. Given the limited capacity to accept large volumes of runoff, and potential erosion problems associated with large concentrated flows, vegetative controls should typically be used in combination with other management practices. These measures have been documented as particularly appropriate for mining sites.

Topsoiling, Seedbed Preparation—The addition of a layer of topsoil or plant growth material provides an improved soil medium for plant growth. Seedbed preparation may include the addition of topsoil ingredients to be mixed in with soils used for seedbed preparation. Ripping, dicing, and mixing soils promotes weed control and aerates the soil, encouraging seedling growth.

Broadcast Seeding and Drill Seeding—Seeding and vegetative planting are methods used to revegetate an area. Broadcast seeding spreads seeds uniformly, by hand or machine, to steep sloped or rocky areas, flat surfaces, and areas with limited access. Drill seeding is performed using a rangeland drill seeder and may not be used on rocky surfaces. Drill seeding is more suitably performed on flat, nonrocky surfaces, where the machine can insert seeds into the soil.

Willow Cutting Establishment—Willow cutting establishment describes a method of soil stabilization useful for stream banks and other areas located adjacent to water. Similar to biotechnical stabilization, willow cuttings are used to promote growth in an area needing stabilization. Willow cuttings are typically used to reinforce a streambank or other moist area. Willow cuttings require a great deal of moisture and must be planted in areas that remain moist for long periods in order to take hold and grow.

F. Capping. In some cases, the elimination of a pollution source through capping contaminant sources may be the most cost effective control measure for some discharges from inactive coal mines. Depending on the type of management practices chosen the cost to eliminate the pollutant source may be very high. Once completed, however, maintenance costs will range from low to nonexistent.

Capping or sealing of waste materials is designed to prevent infiltration, as well as to limit contact between discharges and potential sources of contamination. Ultimately, capping should reduce or eliminate the contaminants in discharges. In addition, by reducing infiltration, the potential for seepage and leachate generation may also be lessened.

The use of this practice depends on the level of control desired, the materials available, and cost considerations. Many common liners may be effective including common soil, clay, and/or synthetic liners. Generally, soil liners will provide appreciable control for the lowest cost. Synthetic or clay liners may be appropriate to cover materials known to have a significant potential to impact water quality.

EPA has identified a wide variety of best management practices (BMPs) that may be used to mitigate discharges of contaminants at coal mines. Many of the practices focus on sediment and erosion control and are similar to BMPs used in the construction industry. For more details on the use and implementation of these practices the reader is encouraged to obtain a copy of one or more of the many good sediment and erosion control books available on the market.[69] In some cases (e.g., low pH and/or high metals concentrations), BMPs, and sediment and erosion controls may not be adequate to produce an acceptable quality of storm water discharge. Under those circumstances additional physical or chemical treatment systems may be necessary to protect the receiving waters.

g. Treatment. Treatment practices are those methods of control which are normally used to reduce the concentration of pollutants in water before it is discharged. This is in contrast to many BMPs where the emphasis is on keeping the water from becoming contaminated. Treatment practices may be required where flows are currently being affected by exposed materials and where other BMPs are insufficient to meet discharge goals. These practices are usually the most resource intensive as they often entail significant construction costs and require monitoring and maintenance on a frequent and regular basis. Treatment options may range from high maintenance controls to low maintenance. High maintenance treatment techniques require periodic manpower to operate and maintain the BMP. Low maintenance cost techniques have initial capital costs but operate with little long-term maintenance after they are implemented. At a few sites, treatment measures other than high maintenance measures may be appropriate to address specific pollutants.

Chemical/Physical Treatment—An example of a high maintenance technology that is found at coal mining facilities is chemical/physical treatment. The most common type of chemical/physical treatment involves the addition of limestone to reduce the acidity of the discharge and/or precipitate metals. Metals may be removed from wastewater by raising the pH of the wastewater to precipitate them out as hydroxides. Typically, the pH of the wastewater must be raised to 9 to 12 standard units in order to achieve the

[67] "Performance of Current Sediment Control Measures at Maryland Construction Sites," January 1990, Metropolitan Washington Council of Governments, page X.

[68] "Sediment and Erosion Control: An Inventory of Current Practices—Draft," EPA, April 20, 1990, page IV–4.

[69] "Best Management Practices for Mining in Idaho," Idaho Department of State Lands, November 1992; "Storm Water Management for Construction Activities: Developing Pollution Prevention Plans and Best Management Practices," EPA, September 1992, (EPA 832–R–92–005); and "Erosion & Sediment Control Handbook," Goldman et al., McGraw-Hill Book Company, 1986.

desired precipitation of metals. After metals precipitation, the addition of some form of acid or carbon dioxide may be required to reduce the pH to acceptable levels. Polymer addition may be required to enhance the settling characteristics of the metal hydroxide precipitate. In general, this practice requires significant operator participation to ensure proper neutralization and/or precipitation and thus may not be cost effective for most storm water discharges.

Artificial Wetlands—This type of BMP system is gaining popularity as a method of treating process wastewater from inactive coal mines. They can be an effective system for improving water quality either alone or in conjunction with other treatment practices. The complex hydrologic, biological, physical, and chemical interactions that take place within a wetland result in a natural reduction and cleansing of influent pollutants. Wetland processes are able to filter sediments, and absorb and retain chemical and heavy metal pollutants through biological degradation, transformation, and plant uptake.

Artificial wetlands are designed to maintain a permanent pool of water. Properly installed and maintained retention structures (also known as wet ponds) and artificial wetlands will be most cost-effective when used to control runoff from larger, intensively developed sites. These artificial wetlands are created to provide treatment but also provide a wildlife habitat, and enhance recreation and landscape amenities. Artificial wetlands are being intensely researched by the Bureau of Mines as a means of mitigating acid mine drainage.

EPA strongly discourages the use of natural wetlands as part of the treatment system because they are considered to be waters of the United States. The necessary controls, or BMPs, must be provided prior to discharging the storm water runoff to natural wetlands or other receiving waters.

In summary, a wide variety of BMPs are available for inactive coal mines and for use along haul roads and access roads at active coal mines. These measures range from simple low cost, low maintenance source reduction practices such as diversion structures to high cost, maintenance intensive practices such as wetlands treatment. Clearly, the selection of a practice or group of practices will be site-specific depending on conditions and potential impacts as well as the resources available at each site. A specific best available technology (or technologies) cannot be determined because of the differences between sites and the quantities and characteristics of their discharges.

4. Storm Water Pollution Prevention Plan Requirements

Specific requirements for the pollution prevention plan for coal mines and coal mining related facilities are described below. These requirements must be implemented in addition to the common pollution plan provisions described in Section VI.C. of this fact sheet.

a. Contents of the Plan. Under the description of potential pollutant sources section, all coal mining and related facilities are required to describe all potential pollutant sources and provide the locations of these sources.

(1) A site map, such as a drainage map required for SMCRA permits, must indicate drainage areas and storm water outfalls from the potential pollutant sources as indicated in item 1 above. The map should provide, but not be limited to, the following information:

(a) Drainage direction and discharge points from all applicable mining-related areas, including culvert and sump discharges from roads and rail beds and also from equipment and vehicle maintenance areas, lubricants and other potentially harmful liquids
(b) Location of each existing erosion and sedimentation control structure and other control measures for reducing pollutants in storm water runoff
(c) Receiving streams or other surface water bodies
(d) Locations exposed to precipitation which contain acidic or metal ladened spoil, refuse, or unreclaimed disturbed areas
(e) Locations where major spills or leaks of toxic or hazardous pollutants have occurred
(f) Locations where liquid storage tanks containing potential pollutants, such as caustics, hydraulic fluids and lubricants, are exposed to precipitation
(g) Locations where fueling stations, vehicle and equipment maintenance areas are exposed to precipitation

The site map must also indicate the outfall locations and the types of discharges contained in the drainage areas of the outfalls (e.g. storm water and air conditioner condensate). In order to increase the readability of the map, the inventory of the types of discharges contained in each outfall may be kept as an attachment to the site map.

Under the measures and controls section, operators of the inactive and active coal mines are required to describe storm water management controls for coal mining-related facilities, including the following:

(2) Compliance with SMCRA Requirements. The Surface Mining Control and Reclamation Act (SMCRA) regulations require sediment and erosion control measures and practices for haul roads and most of the other active mining-related areas covered by this section. All such SMCRA requirements are also requirements of the pollution prevention plan and other applicable conditions of this section.

(3) Good Housekeeping Practices. The purpose of good housekeeping practices is to remove or lessen the potential pollution sources before they come into contact with storm water. This includes collection and removal of waste oils collected in traps; cleaning up exposed maintenance areas of spilled lubricants and fuels, and similar measures; and preventing the offsite movement of dust by sweeping or by road watering.

(4) Preventive Maintenance. A timely maintenance program should include: inspections for preventing breakdowns, corrosion of tanks and deterioration of pressure fuel or slurry pressure lines; periodic removal and disposal of accumulated solids in sediment traps; and replacement of straw bales and other control measures subject to weathering and deterioration.

(5) Inspections. For all SMCRA regulated active mining-related sites, which include most of the active facilities under this section, SMCRA authorities are required to conduct regular quarterly inspections. Coordinated inspections by the facility representative would be expected to take place either before, during or after the complete SMCRA inspections. Therefore, inspections by the facility representative would not be placing an undue burden on the facility. In addition, sediment and erosion control measures should be evaluated at least once yearly during a storm period of at least 0.1 inch rainfall where effectiveness can be evaluated first hand. Observations should also be made at this time of resulting impact of any settled solids in the receiving stream.

Inactive coal mines should be inspected at least once yearly, except where very remote, to maintain an appraisal of sediment and erosion control measures, determine outstanding problem areas, and plan for improved measures.

(6) Employee Training. There are no employee training requirements beyond those described in Section VI.C.

(7) Prohibition of Non-storm Water Discharges. Many inactive mines and portions of inactive mines are

abandoned underground mines which have seeps or other discharges which are not in response to storm events. These type discharges from inactive mines are not covered by this section. In addition, floor drains from maintenance buildings and other similar drains in mining and preparation plant areas may contain contaminants and are prohibited from inclusion in this section.

(8) Sediment, Erosion and Flow Management Controls. The plan must describe all sediment, erosion, and flow management controls used to control storm water discharges. The plan should also address the reasonableness and appropriateness of each sediment, erosion, and flow management control, and identify when they are required by State or Federal SMCRA regulations. For the most part, these measures are best management practices expected of construction and other activities which are subject to storm runoff. However, construction activities are usually much more short term than mining activities, so greater emphasis must be placed on implementing long term measures for haul roads and other mining-related facilities.

b. Comprehensive Site Compliance Evaluation. In addition to the comprehensive site compliance evaluation described in Section VI.C.4. of this fact sheet, the plan must be implemented and, where erosion control and pollution prevention measures described in the plan are found deficient, the plan must be revised to include reasonable and appropriate control measures. Reports including observations and incidences of noncompliance must be prepared and kept on file for possible review.

5. Numeric Effluent Limitation

Based on the lack of sampling data, it is infeasible for EPA to calculate effluent limitations at this time. The main pollutant concern is excess solids runoff and discharge, but there are no widely accepted solids limits which could be expected from the recommended sediment and erosion control measures. The 0.5 ml/L settleable solids limit, as required by 40 CFR Part 434 for storm discharges from surface mine settling ponds, can be considered a goal but not a requirement for control measures, which for the most part, consist of sediment ditches, straw bales and similar structures normally used for haul roads. The permit does not cover facilities that are in violation of water quality standards and where water quality-based effluent limits apply.

6. Monitoring and Reporting Requirements

a. Monitoring Requirements. EPA believes that coal mining facilities may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. In order to provide a tool for evaluating the effectiveness of the pollution prevention plan and to characterize the discharge for potential environmental impacts, Table H–4 lists the pollutants that coal mining facilities are required to collect and analyze in their storm water discharges. The pollutants listed in Table H–4 were found to be above levels of concern for a significant portion of coal mining facilities that submitted quantitative data in the group application process. Because these pollutants have been reported at benchmark levels from coal mining facilities, EPA is requiring monitoring after the pollution prevention plan has been implemented to assess the effectiveness of the pollution prevention plan and to help ensure that a reduction of pollutants is realized.

Permittees can exercise the alternative certification on a pollutant-by-pollutant basis as described under Section (1) below. Any pollutant(s) for which the facility is unable to certify to no exposure must, at a minimum, monitor storm water discharges from coal mining facilities on a quarterly basis during the second year of permit coverage. Monitoring must be performed during the following periods: January through March; April through June; July through September; and October through December. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Table H–4. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE H–4.—MONITORING REQUIREMENTS COAL MINING FACILITIES MG/L

Pollutants of concern	Monitoring cut-off concentration
Total Recoverable Aluminum	0.75 mg/L
Total Recoverable Iron	1.0 mg/L
Total Suspended Solids (TSS)	100 mg/L

If the average concentration for a parameter is less than or equal to the appropriate cut-off concentration, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration listed in Table H–4, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit. The schedule for monitoring is presented in Table H–5.

TABLE H–5.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Table H–4, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Table H–4, then no further sampling is required for that parameter.

TABLE H-5.—SCHEDULE OF MONITORING—Continued

4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Table H-4. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will be used to reassess the effectiveness of the adjusted pollution prevention plan.

The monitoring cut-off concentrations listed in Table H-4 are not numerical effluent limitations. These values represent a level of pollutant discharge which facilities may achieve through the implementation of pollution prevention plans. At least half of the facilities which submitted Part 2 data reported concentrations greater than or equal to the values listed in Table H-4. Facilities that achieve average discharge concentrations which are less than or equal to the appropriate cut-off concentration values are not relieved from the pollution prevention plan requirements or any other requirements of the permit.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

(1) Alternative Certification. Throughout today's permit, EPA has included monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative certification described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall or on a pollutant-by-pollutant basis in lieu of monitoring described in Table H-4, under penalty of law, signed in accordance with Part VII.G. (Signatory Requirements), that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity, and that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in accordance with Part VI.C. of this permit. In the case of certifying that a pollutant is not present, the permittee must submit the certification along with the monitoring reports required under paragraph (*2*) below. If the permittee cannot certify for an entire period, they must submit the date exposure was eliminated and any monitoring required up until that date. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

(2) Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one signed Discharge Monitoring Report form must be submitted to the Director per storm event sampled. For facilities conducting monitoring beyond the minimum quarterly requirements, an additional Discharge Monitoring Report Form must be filed for each analysis.

(3) Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable.

If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable, permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

(4) Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

b. Visual Examination of Storm Water Quality. Visual examinations of a storm water discharge from each outfall are required except at inactive areas not under SMCRA bond. Active areas under SMCRA bond that are located in areas with an average annual precipitation greater than 20 inches must perform the visual examinations quarterly. Active areas under SMCRA bond with an average annual precipitation less than or equal to 20 inches are required to perform visual examinations on a semiannual basis. The examination must be of a grab sample collected from each storm water outfall. The examination of storm water grab samples shall include any observations of color, odor, turbidity, floating solids, foam, oil sheen, or other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on these samples.

The examination must be made at least once in each designated period during daylight hours unless there is insufficient rainfall or snow-melt to runoff. Whenever practicable, the same individual should carry out the collection and examination of discharges throughout the life of the permit to ensure the greatest degree of consistency possible. Examinations shall be conducted in each of the following periods for the purposes of inspecting storm water quality associated with storm water runoff and snow melt: January through March; April through June; July through September; October through December. Grab samples shall be collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 1 hour) of when the runoff begins discharging. Reports of the visual examination include: the examination date and time, examination personnel, visual quality of the storm water discharge, and probable sources of any observed storm water contamination. The visual examination reports must be maintained onsite with the pollution prevention plan.

When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination and retain this documentation onsite with the records of the visual examinations. Adverse weather conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.). For facilities that have an average annual precipitation of 20 inches or less or are designated inactive by SMCRA, EPA requires semiannual visual examinations instead of quarterly.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

EPA believes that this quick and simple assessment will help the permittee to determine the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examination. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and the effects of the management practices that are included in the plan.

I. Storm Water Discharges Associated With Industrial Activity From Oil and Gas Extraction Facilities

1. Industry Profile

On November 16, 199C (55 FR 47990), EPA promulgated the regulatory definition of "storm water discharges associated with an industrial activity." This definition includes point source discharges of storm water from eleven major categories of facilities, including: "* * * (iii) facilities classified as Standard Industrial Classification (SIC) codes 10 through 14, including * * * oil and gas exploration, production, processing, or treatment operations, or transmission facilities that discharge storm water contaminated by contact with or that has come into contact with, any overburden, raw material, intermediate products, finished products, by-products, or waste products located on the site of such operations."

As stated above and at 40 CFR 122.26(b)(14)(iii), only those oil and gas facilities that discharge 'contaminated' storm water are required to submit permit applications under the November 16, 1990, storm water rule. For oil and gas facilities, contamination means that there has been a release of a Reportable Quantity (RQ) of oil or hazardous substances in storm water since November 16, 1987 (hereinafter referred to as 'an RQ release'). Only those facilities that have had an RQ release are required to submit a storm water permit application.

This section of today's permit only covers storm water discharges associated with industrial activities from oil and gas exploration, production, processing, or treatment operations, or transmission facilities. Hereinafter, the facilities listed above will be referred to as "oil and gas facilities." Oil and gas facilities eligible to seek coverage under this section include the following types of operations: crude petroleum and natural gas (SIC Code 1311), natural gas liquids (SIC Code 1321), drilling oil and gas wells (SIC Code 1381), oil and gas field exploration services (SIC Code 1382), oil and gas field services, not elsewhere classified (SIC Code 1389).

These industries include the extraction and production of crude oil, natural gas, oil sands and shale; the production of hydrocarbon liquids and natural gas from coal; and associated oil field service, supply and repair industries. Many of the oil field service facilities may also manufacture oil field equipment. Discharges associated with these manufacturing activities shall be covered by this section if the primary activity of the facility is grouped under Major SIC Group 13.

Pursuant to Section 311 of the Clean Water Act and Section 102 of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), RQs were established for oil and hazardous substances. As defined at 40 CFR Part 110, an RQ is "the amount of oil that violates applicable water quality standards or causes a film or sheen upon or a discoloration of the surface of the water or adjoining shorelines or causes a sludge or emulsion to be deposited beneath the surface of the water or upon adjoining shorelines." The RQs for other substances are listed in 40 CFR 117.3 and 302.4 in terms of pounds released over any 24-hour period.

Discharges covered by this section include all storm water discharges from facilities which have had an RQ release where precipitation and storm water runon come into contact with significant materials including, but not limited to, drilling and production equipment and other machinery, raw materials, waste products, by-products, finished products, stored materials, and fuels. This includes storm water discharges from access roads, and rail lines used or traveled by carriers of raw materials, manufactured products, waste

R0016191

materials, or by-products created by the facility.

This section does not cover storm water discharges from inactive oil and gas extraction facilities located on Federal lands, unless an operator of the activity can be identified. These discharges are more appropriately covered under a permit currently being developed by EPA.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

Oil and gas exploration and production includes all activities related to the search for, and extraction of, liquid and gas petroleum from beneath the earth's surface. Found almost exclusively in sedimentary rocks, oil and natural gas accumulate in geologic confinements called traps which, by virtue of an impermeable overlying layer, have stopped the migration of the fluid. The volume of petroleum contained in a trap can vary from negligible to billions of barrels.

Though at one time such traps may have been close enough to the surface to allow easy detection (i.e., surface seepage), modern exploration relies on sophisticated geophysical testing techniques to locate potentially producible formations. Gravitational and seismic surveys of subsurface geology provide indirect indications of the likelihood of finding promising geological formations. This process is complicated by the fact that, at least in the U.S., the average depth at which one may reasonably expect to find oil is increasing since many of the largest shallow formations are assumed to have been found already.

Drilling operations require construction of access roads, drill pads, mud pits, and possibly work camps or temporary trailers. Drill pads are areas used to stage the drilling operation and generally range from 2 to 5 acres. The pad accommodates the drilling rig and associated operations including pumps, reserve pits, and mud tanks.

Modern well drilling involves the use of a rotary drill to bore through soil and rock to the desired well depth. The drill bit is constantly washed with a circulating drilling fluid, or "mud," which serves to cool and lubricate the bit and remove the cuttings to the surface. The drilling mud also serves to prevent "blowouts" from overpressured water and gas bearing formations. If the drill reaches the desired depth and fails to locate a producible deposit of oil or gas, the well must be plugged and the site abandoned. Even if oil and/or gas is found the well may not be producible. If the formation fails to exhibit the right combination of expected volume, porosity, and permeability, the costs of extraction would be prohibitive.

After a well has been drilled, it is "completed" if well logging data indicate that the well is capable of producing commercial quantities of oil or gas. Completion includes a number of operations that may be necessary to allow the well to produce oil or gas. These include installing and cementing casing, installing the production tubing and downhole equipment, repairing damage that drilling may have caused to the formation, and possibly stimulating the well. During a well's active life, periodic "workovers" are necessary. Workovers can include a number of procedures intended to maintain or enhance production. These can include repairing or replacing downhole equipment, removing accumulated scale or paraffin from tubing or casing, and stimulating the formation to restore or enhance production. Wells are stimulated, whether by treating with acid or fracturing, during completion or workover or both: it is common for wells to be stimulated at completion and then periodically throughout their lives.

Acid stimulation involves introducing an acid solution to the formation. The acid dissolves the rock, thus creating or enlarging flow path openings. Acids are also used to repair damage to formations caused by drilling or other operations. In addition, they may be used for scale removal and other purposes. Fracturing by hydraulic pressure is achieved by pumping fluids at high pressure (i.e., at high rates) into the well, thereby causing material failure of the rock in the formation of interest (i.e., fractures). Fracturing is also done using explosive devices to fire projectiles into the formation of interest. The fractures induced in the formations serve as flow paths for hydrocarbons.

In instances where the reservoir is sufficiently large, "delineation" wells are drilled to determine the boundary of the reservoir and additional "development" wells are drilled to increase the rate of production from the "field." Because few new wells in the U.S. have sufficient energy (pressure) to force oil all the way to the surface, surface or submersible pumps are placed at the wells and production begins.

This first phase of production, primary production, may continue for several to many years, requiring only routine maintenance to the wells as they channel oil to the surface for delivery to refineries. However, as the oil is removed from the formation, the formation pressure decreases until the wells will no longer produce. Because 70 percent of the total recoverable oil may remain in the formation, additional energy may be supplied by the controlled injection of water from the surface into the formation. The injected water acts to push the oil toward the well bores. Such secondary recovery or "water flooding" projects may employ hundreds of injection wells throughout a field to extend the life of the wells. Much of the water used for injection is pumped along with oil from the producing well, separated from the oil, and then reinjected.

Produced fluid, as pumped from a well, is sent through one or more process units to separate the waste fractions (e.g., produced water, emulsions, scale, and produced sand) from the salable hydrocarbon.

As oil and gas are recovered from wells, they are collected or gathered in pipelines for transport to produced fluid treatment facilities. These facilities separate marketable gas and crude oil from water and sand.

Often, service companies are hired by the oil company to perform many of the activities described above. Typically these contractors drill the wells and perform other specific tasks such as installing casing, conducting formation tests, and managing wastes, etc. When a well or field ceases to produce oil or gas at an economically feasible rate, the field must be abandoned and reclaimed.

2. Pollutants in Storm Water Discharges Associated with Oil and Gas Facilities

Exploration and production techniques will vary depending on the type and characteristics of formations, pollutants present, and waste management controls. Therefore, impacts associated with storm water discharges from oil and gas facilities will vary. Several other factors influence to what extent significant materials from these types of facilities and processing operations can affect water quality.

Such factors include: hydrology/geology; the types of chemical additives and lubricating fluids used; the procedure for waste management; the nature and size of the RQ release; the amount of contamination remaining after the RQ release; the size of the operation; and type, duration, and intensity of precipitation events. These and other factors will interact to influence the quantity and quality of storm water runoff. In addition, sources of pollutants other than storm water, such as illicit connections,[70] spills, and other improperly dumped materials, may increase the pollutant loadings discharged into waters of the United States.

Based on information submitted with the group applications and other documents, EPA has identified some storm water pollutants and sources typically associated with oil and gas facilities in Table I–1. Due to distinct industrial activities and materials used at facilities, however, sources and associated pollutants will vary from site to site. The pollutants listed in Table I–1 are not meant to be a comprehensive listing of all potential storm water pollutants at oil and gas facilities.

TABLE I–1.—ACTIVITIES, POLLUTANT SOURCES, AND POLLUTANTS

Activity	Pollutant source	Pollutant
Construction of: —Access Roads —Drill Pads —Reserve Pits —Personnel Quarters —Surface Impoundments	Soil/dirt, leaking equipment and vehicles	TSS, TDS, oil and grease.
Well Drilling	Drilling fluid,[i] lubricants, mud, cuttings, produced water	TSS, TDS, oil and grease, COD, chlorides, barium, naphthalene, phenanthrene, benzene, lead, arsenic, fluoride.
Well Completion/Stimulation	Fluids (used to control pressure in well), cement, residual oil, acids, surfactants, solvents, produced water, sand.	TSS, TDS, oil and grease, COD, pH, acetone, toluene, ethanol xylenes.
Production	Produced water, oil, waste sludge, tank bottoms, acids, oily debris, emulsions.	Chlorides, TDS, oil and grease, TSS, pH, benzene, phenanthrene, barium, arsenic, lead, antimony.
Equipment Cleaning and Repairing.	Cleaning solvents, lubricants, chemical additives	TSS, TDS, oil and grease, pH.
Site Closures	Residual muds, oily debris	TSS, TDS, oil and grease.

[i] The potential contaminants to be found in drilling fluid varies from site to site, depending on the components of the fluid and any pollutants added due to use of the fluid. Storm water discharges that come into contact with used drilling fluids may include the following pollutants, among others: toluene, ethyl benzene, phenol, benzene, and phenanthrene. Used drilling fluids may also contain inorganic pollutants from additives or downhole exposure, such as arsenic, chromium, lead, aluminum, sulfur, and various sulfates.

Based on the similarities of the facilities included in this sector in terms of industrial activities and significant materials, EPA believes it is appropriate to discuss the potential pollutants at oil and gas extraction facilities as a whole and not subdivide this sector. Therefore, Table I–2 lists data for selected parameters from facilities in the oil and gas extraction sector. These data include the eight pollutants that all facilities were required to monitor under Form 2F.

TABLE I–2.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY OIL AND GAS EXTRACTION FACILITIES SUBMITTING PART II SAMPLING DATA[i] (MG/L)

Pollutant	No. of facilities		No. of samples		Mean		Minimum		Maximum		Median		95th percentile		99th Percentile	
Sample type	Grab	Comp[ii]	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp
BOD_5	34	32	39	37	13.9	10.7	0.0	0.0	116.0	90.0	10.4	7.0	32.9	26.8	52.9	44.8
COD	35	32	40	35	138.3	112.2	14.0	0.0	1050.0	450.0	78.5	78.0	401.9	330.4	755.3	601.4
Nitrate + Nitrite Nitrogen	34	31	39	35	0.47	0.54	0.00	0.00	5.50	9.90	0.15	0.09	2.06	2.10	6.17	7.15

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.
[ii] Composite samples.

3. Options for Controlling Pollutants

In evaluating options for controlling pollutants in storm water discharges, EPA must achieve compliance with the technology-based standards of the Clean Water Act [Best Available Technology (BAT) and Best Conventional Technology (BCT)]. The Agency does not believe it is necessary to establish specific numeric effluent limitations or a specific design or performance standard in this section for storm water discharges associated with industrial activity from oil and gas facilities to meet the BAT/BCT standards of the Clean Water Act. Rather than setting limits, this section establishes requirements for the development and implementation of a site-specific storm water pollution prevention plan consisting of a set of BMPs that are sufficiently flexible to address different sources of pollutants at different sites.

[70] Illicit connections are contributions of unpermitted non-storm water discharges to storm sewers from any of a number of sources including sanitary sewers, industrial facilities, commercial establishments, or residential dwellings. The probability of illicit connections at mineral mining and processing facilities is low yet it still may be applicable at some operations.

The selection of the most effective BMPs will be based on site-specific considerations such as: facility size, climate, geographic location, geology/hydrology and the environmental setting of each facility, and volume and type of discharge generated. Each facility will be unique in that the source, type and volume of contaminated storm water discharges will differ. In addition, the fate and transport of pollutants in these discharges will vary. EPA believes that the management practices discussed herein are well suited mechanisms to prevent or control the contamination of storm water discharges associated with facilities in this category.

Two types of BMPs which may be implemented to prevent, reduce or eliminate pollutants in storm water discharges are those which minimize exposure (e.g., covering, curbing, or diking) and treatment type BMPs which are used to reduce or remove pollutants in storm water discharges (e.g., oil/water separators, sediment basins, or detention ponds). EPA believes exposure minimization is an effective practice for reducing pollutants in storm water discharges from oil and gas facilities. Exposure minimization practices lessen the potential for storm water to come in contact with pollutants. These methods are often uncomplicated and inexpensive. They can be easy to implement and require little or no maintenance. EPA also believes that in some instances more resource intensive treatment type BMPs are appropriate to reduce pollutants such as suspended solids and oil/grease in storm water discharges associated with oil and gas facilities. Though these BMPs are somewhat more resource intensive, they can be effective in reducing pollutant loads and may be necessary depending on the type of discharge, types and concentrations of contaminants, and volume of flow.

The types of BMPs used may depend upon the methods of waste management utilized at a facility. Waste management and disposal practices at oil and gas facilities may vary significantly. For example, techniques for disposal of produced water and associated wastes include the following: landfarming/spreading (spreading wastes on land surfaces to stimulate biological degradation); backfilling (storing wastes in a pit and then covering with dirt or other materials); evaporation (in more arid parts of the country, liquid wastes are left exposed and eventually evaporate or percolate into the ground); discharging wastes (sometimes treated) to waters of the United States (NPDES permits are required for such discharges); injection (injecting wastes back into the ground for disposal); and offsite disposal (wastes are taken offsite to a commercial facility for disposal).

The pollutants of concern and the BMPs employed at an oil and gas facility depend upon which, if any, of the disposal techniques listed above are utilized. Where wastes are used for onsite road application, for example, all pollutant constituents of that waste need to be considered a potential contributor to contaminated storm water discharges. In addition, the areas at the facility where road application occurs must also be considered when BMPs are being implemented. In contrast, if all waste is taken to an offsite disposal facility, the waste will most likely not affect the storm water discharges and the areas of concern will not be expanded.

Table I–3 lists some BMPs which may be effective in limiting the amount of pollutants in storm water discharges from oil and gas facilities. The BMPs listed are not necessarily required to be implemented. Rather, BMPs should be chosen based on the specific nature of the storm water discharges at each oil and gas facility and implemented as appropriate. Some of these BMPs involve reducing the amount of waste produced and stored onsite which can potentially contaminate storm water. Based on part 1 information, several of the BMPs suggested are already in place at many of the facilities. Part 1 submittals indicate that diking or other types of diversion occur at approximately 57 percent of the sampling facilities. Thirty percent of the sampling facilities noted that they use some form of covering as a BMP, and catch basins are in place at 12 percent of the sampling facilities. In addition, 11 percent of the facilities designated as samplers in part 1 information reported they had a Spill Prevention Control and Countermeasure Plan in place, and 16 percent had a material management plan.

TABLE I–3.—SUGGESTED BMPS FOR OIL AND GAS FACILITIES

Suggested BMPs
Utilize diking and other forms of containment and diversion around storage tanks, drums of oil, acid, production chemicals, and liquids, reserve pits, and impoundments.
Use diking and other forms of containment and diversion around material handling and processing areas.
Use porous pads under drum and tank storage areas.
Use covers and/or lining for waste reserve and sludge pits to avoid overflows and leaks.
Use drip pans, catch basins, or liners during handling of materials such as tank bottoms.
Reinject or treat produced water instead of discharging it.
Limit the amount of land disturbed during construction of access roads and facilities.
Employ spill plans for pipelines, tanks, drums, etc.
Recycle oily wastes, drilling fluids and other materials onsite, or dispose of properly.
Take wastes offsite to be disposed of instead of burying them.
Use oil water separators.

4. Special Conditions

There are no additional requirements beyond those described in Part VI.B. of this fact sheet.

5. Storm Water Pollution Prevention Plan Requirements

a. Contents of the Plan. Specific requirements for the pollution prevention plan for oil and gas extraction facilities are described below. These requirements must be implemented in addition to the common prevention plan provisions discussed in Section VI.C. of this fact sheet.

(1) Description of Potential Pollutant Sources. Facilities under this section cover a broad range of oil field activities and service industries.

Drilling sites have large disturbed areas which will contribute additional sediments and suspended solids to the storm water runoff. Well drilling includes the use of many hazardous chemicals and materials. These include drilling muds, well casing cement, fractionating gels, and well treatments. The storage, mixing, and handling of these materials are potential pollutant sources.

Oil field service industries provide a variety of services for exploration and production activities. These service industries often store and mix chemicals for drilling muds, well casing cement, fractionating gels, and well treatments at the facility. The storage and mixing areas are potential pollutant sources. Often, mixing areas and equipment are exposed to storm water. Many oil field service facilities manufacture some oil field equipment components. The exposed raw materials, intermediate products, finished products, and waste products are potential sources of pollutants in storm water.

In its description of potential pollutant sources, a facility must include information about the RQ release which triggered the permit application requirements. Such information must include: the nature of the release (e.g., spill of oil from a drum storage area); the amount of oil or hazardous substance released; amount of substance recovered; date of the release; cause of the release (e.g., poor handling techniques as well as lack of containment in area); area affected by release, including land and waters; procedure to cleanup release; and remaining potential contamination of storm water from release.

(2) Measures and Controls.

(a) RQ Releases—The permittee must describe the measures taken to clean up RQ releases or related spills of materials, as well as measures proposed to avoid future releases of RQs. Such measures may include, among others: improved handling or storage techniques; containment around handling areas of liquid materials; and use of improved spill cleanup materials and techniques.

(b) Vehicle and Equipment Storage Areas—Vehicles and equipment associated with oil field activity are often coated with oil, oil field drilling muds, and the chemicals associated with drilling. These vehicles and equipment are a significant source of pollutants. The permittee must address these areas, and institute practices to minimize pollutant runoff from this area.

(c) Vehicle and Equipment Cleaning and Maintenance Areas—The plan must describe measures that prevent or minimize contamination of the storm water runoff from all areas used for vehicle and equipment cleaning. The facility may consider performing all cleaning operations indoors, covering the cleaning operation, and/or collecting the storm water runoff from the cleaning area and providing treatment or recycling. These cleaning and maintenance activities can result in the exposure of cleaning solvents, detergents, oil and grease and other chemicals to storm water runoff. The use of drip pans, maintaining an organized inventory of materials used in the shop, draining all parts of fluids prior to disposal, prohibiting the practice of hosing down the shop floor where the practice would result in the exposure of pollutants to storm water, using dry cleanup methods, and/or collecting the storm water runoff from the maintenance area and providing treatment or recycling may reduce the pollutants discharged in storm water runoff.

(d) Materials Storage Areas—Storage units of all chemicals and materials (e.g., fuels, oils, used filters, spent solvents, paint wastes, radiator fluids, transmission fluids, hydraulic fluids, detergents drilling mud components, acids, organic additives) may result in the contamination of storm water discharges. Labeling of all storage containers helps facility personnel to respond effectively to spills or leaks. Additionally, covered storage of the materials and/or installation of berming and diking at the area can be effective BMPs.

(e) Chemical Mixing Areas—Chemical mixing (e.g., the mixing of drilling muds, fractionating gels, mixing well casing cement, and well treatment acids and solvents) at both well sites and at facilities with service drilling activities have significant potential to contaminate storm water runoff. The facility should consider covering the mixing area, using spill and overflow protection, minimizing runon of storm water to the mixing area, using dry cleanup methods, and/or collecting the storm water runoff and providing treatment or recycling. The facility should consider installation of berming and diking of the area. The waste water pollutants associated with produced waters, drilling muds, drill cuttings and produced sand from any source associated with onshore oil and gas production, field exploration, drilling, well completion, or well treatment are prohibited from being discharged (40 CFR 435.32).

(f) Preventive Maintenance—The preventive maintenance program must include the inspection of all onsite and offsite mixing tanks and equipment, and inspection of all vehicles which carry supplies and chemicals to oil field activities. These mixing tanks and vehicles carry large volumes of fractionating chemicals and gels, cements, drilling muds, and well treatment chemicals and acids that potentially may contaminate waters of the United States if leaks or spills occur.

(g) Inspection Frequency—All equipment and areas addressed in the pollution prevention plan shall be inspected semiannually. Equipment and vehicles which store, mix or transport hazardous materials will be inspected quarterly. Inspections shall also include the inspection of all onsite mixing tanks and equipment, and inspection of all vehicles which carry supplies and chemicals to oil field activities. These mixing tanks and vehicles carry large volumes of fractionating chemicals and gels, cements, drilling muds, and well treatment chemicals and acids that potentially may contaminate waters of the United States if leaks or spills occur.

6. Numeric Effluent Limitation

There are no additional numerical effluent limitations beyond those listed in Part V.B. of today's permit.

7. Monitoring and Reporting Requirements

a. Monitoring Requirements. The regulatory modifications at 40 CFR 122.44 (i)(2) established on April 2, 1992, grant permit writers the flexibility to reduce monitoring requirements in storm water discharge permits. EPA has determined that the potential for storm water discharges to contain pollutants above benchmark levels, because of the industrial activities and materials exposed to precipitation, does not support sampling at oil and gas facilities. Based on a consideration of the BMPs typically used at these facilities, and generally low pollutant values from the application data, EPA believes that the pollution prevention plan with visual examinations of storm water discharges will help to ensure storm water contamination is minimized. Because permittees are not required to conduct sampling, they will be able to focus their resources on developing and implementing the pollution prevention plan.

Quarterly visual examinations of a storm water discharge from each outfall are required at oil and gas facilities. The examination must be of a grab sample collected from each storm water outfall. The examination of storm water grab samples shall include any observations of color, odor, turbidity, floating solids, foam, oil sheen, or other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on these samples.

The examination must be made at least once in each designated period during daylight hours unless there is insufficient rainfall or snow-melt to produce a runoff. Whenever practicable, the same individual should carry out the collection and examination of discharges throughout the life of the permit to ensure the greatest degree of consistency possible. Examinations shall be conducted in each of the following periods for the purposes of visually inspecting storm water quality associated with storm water runoff and snow melt: January through March; April through June; July through September; October through December. Grab samples shall be collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 60 minutes) of when the runoff begins discharging. Reports of the visual examination include: the examination date and time, examination personnel, visual quality of the storm water discharge, and probable sources of any observed storm water contamination. The visual examination reports must be maintained onsite with the pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

EPA believes that this quick and simple assessment will help the permittee to determine the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examinations. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and the effects of the management practices that are included in the plan.

When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination and retain this documentation onsite with the records of the visual examination. Adverse weather conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

As discussed above, EPA does not believe that chemical monitoring is necessary for oil and gas facilities. EPA believes that between quarterly visual examinations and site compliance evaluations potential sources of contaminants can be recognized, addressed, and then controlled with BMPs. In determining the monitoring requirements, EPA considered the nature of the industrial activities and significant materials exposed at these sites, and performed a review of data provided in Part 2 group applications.

J. Storm Water Discharges Associated With Industrial Activity From Mineral Mining and Processing Facilities

1. Industry Profile

On November 16, 1990 (55 FR 47990), EPA promulgated the regulatory definition of "storm water discharges associated with industrial activity." This definition included point source discharges of storm water from eleven major categories of facilities, including: "* * * (iii) facilities classified as Standard Industrial Classifications 10 through 14 (mineral industry) including active or inactive mining operations (except for areas of coal mining operations no longer meeting the definition of a reclamation area under 40 CFR 434.11(l) because the performance bond issued to the facility by the appropriate SMCRA authority has been released, or except for areas of noncoal mining operations which have been released from applicable State or Federal reclamation requirements after December 17, 1990) and oil and gas exploration, production, processing, or treatment operations, or storm water contaminated by contact with, any overburden, raw material, intermediate products, finished products, by-products or waste products located on the site of such operations."

This section only covers storm water discharges associated with industrial activities from active and inactive mineral mining and processing facilities. Mineral mining and processing facilities eligible to seek coverage under this section include the following types of operations: Dimension Stone (SIC Code 1411); Crushed and Broken Limestone (SIC Code 1422); Crushed and Broken Granite (SIC Code 1423); Crushed and Broken Stone (SIC Code 1429); Construction Sand and Gravel (SIC Code 1442); Industrial Sand and Gravel (SIC Code 1446); Kaolin and Ball Clay (SIC Code 1455); Clay, Ceramic, and Refractory Minerals (SIC Code 1459); Potash, Soda, and Borate Minerals (SIC Code 1474); Phosphate Rock (SIC Code 1475); Chemical and Fertilizer Mineral Mining (SIC Code 1479); and Miscellaneous Nonmetallic Minerals, Except Fuels (SIC Code 1499).

Storm water discharges covered by this section include all discharges where precipitation and storm water runon come into contact with significant materials including, but not limited to, raw materials, waste products, by-products, overburden, stored materials, and fuels. This includes storm water discharges from haul roads, access roads, and rail lines used or traveled by carriers of raw materials, manufactured products, waste materials, or by-products created by the facility.

This permit may authorize storm water discharges associated with industrial activity that are mixed with storm water discharges associated with industrial activity from construction activities, provided that the storm water discharge from the construction activity is in compliance with the terms, including applicable Notice of Intent (NOI) or application requirements, of a different NPDES general permit or individual permit authorizing such discharges.

This section does not cover any discharge subject to effluent limitation guidelines, unless otherwise specified, including storm water that combines with process wastewater. Storm water that does not come into contact with any overburden, raw material, intermediate product, finished product, by-product, or waste product located on the site of the operation are not subject to permitting under this section according to Section 402(l)(2) of the Clean Water Act. Today's permit contains additional coverage provisions applicable only to mineral mining and processing facilities located in Region VI and Region IX (the States of Louisiana, New Mexico, Oklahoma, and Texas and Arizona). Mine dewatering discharges, which are composed entirely of storm water or ground water seepage, and that are not commingled with any process waste water from construction sand and gravel, industrial sand, and crushed stone mine facilities located in Region VI and Region IX are eligible for coverage under today's permit. Such discharges, however, are subject to the numeric limitations and compliance monitoring provisions listed in the permit.

This section is applicable to all phases of mining operations, whether active or inactive, as long as there is exposure to significant materials. This includes land disturbance activities such as the expansion of current extraction sites, active and inactive mining stages, and reclamation activities.

This section does not apply to storm water discharges from inactive mining operations occurring on Federal lands, unless an operator can be identified. These discharges are more appropriately covered under a permit currently being developed by EPA.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

There are typically three phases to a mining operation: the exploration and construction phase; the active phase; and the reclamation phase. The exploration and construction phase entails exploration and a certain amount of land disturbance to determine the financial viability of a site. Construction includes building of site access roads, and removal of overburden and waste rock to expose minable ore. These land-disturbing activities are significant potential sources of storm water contaminants. The active phase includes each step from extraction through production of a saleable product. The active phase may include periods of inactivity due to the seasonal nature of these mineral mining activities. The final phase of reclamation is intended to return the land to its pre-mining state.

Because of the land-disturbing nature of the mineral mining and processing industry, contaminants of concern generated by industrial activities in this industry include total suspended solids (TSS), total dissolved solids (TDS), turbidity, and pH. Table J–1 lists potential pollutant source activities, and related pollutants associated with mineral mining and processing facilities.

Industrial activities, significant materials, and material management practices associated with mineral mining and processing methods are typically similar, varying only in the type of rock being mined. Examples of mineral commodities obtained from mineral mining and processing facilities include: crushed stone; construction sand and gravel; industrial sand; gypsum; asphaltic minerals; asbestos and wollastonite; lightweight aggregates; mica and sericite; barite; fluorspar; salines from brine lakes; borax minerals; potash; sodium sulfate; trona; rock salt; phosphate rock; frasch sulfur; mineral pigments; lithium; bentonite; magnesite; diatomite; jade; novaculite; fire clay; attapulite and montmorillonite; kyanite; shale and common clay; aplite; tripoli; kaolin; ball clay; feldspar; talc, steatite, soapstone and pyrophylite; garnet; and graphite.

Industrial activities include, "* * * but [are] not limited to, storm water discharges from industrial plant yards; immediate access roads and rail lines used or traveled by carriers of raw materials, manufactured products, waste material, or by-products used or created by the facility; material handling sites; refuse sites; sites used for the application or disposal of process wastewaters (as defined at 40 CFR Part 401); sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage, or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials and intermediate and finished materials; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water" (40 CFR 122.26(b)(14)). The most common industrial activities at mineral mine sites include extraction of the mineral, material sizing by crushers, material sorting, and product washing.

TABLE J–1.—ACTIVITIES, POLLUTANT SOURCES, AND POLLUTANTS

Activity	Pollutant source	Pollutant
Site Preparation	Road Construction	Dust, TSS, TDS, turbidity.
	Removal of Overburden	Dust, TSS, TDS, turbidity.
	Removal of waste rock to expose the mineral body	Dust, TSS, TDS, turbidity.
Mineral Extraction	Blasting activities	Dust, TSS.
Mineral Processing Activities	Rock Sorting	Dust, TSS, TDS, turbidity, fines.
	Rock Crushing	Dust, TSS, TDS, turbidity, fines.
	Rock Washing	TSS, TDS, turbidity, pH.
	Raw Material Storage	Dust, TSS, TDS, turbidity.
	Waste Rock Storage	Dust, TSS, TDS, turbidity, pH.
	Raw Material Loading	Dust, TSS, TDS, turbidity.
	Processing materials unloading	Diesel fuel, gasoline, oil, lime.
	Raw or Waste Material Transportation	Dust, TSS, TDS, turbidity.
Other Activities	Sedimentation pond upsets	TSS, TDS, turbidity, pH.
	Sedimentation pond sludge removal and disposal	Dust, TSS, TDS, turbidity, pH.
	Air emission control cleaning	Dust, TSS, TDS, turbidity.
Equipment/Vehicle Maintenance.	Fueling activities	Diesel fuel, gasoline, oil.
	Parts cleaning	Solvents, oil, heavy metals, acid/alkaline wastes.
	Waste disposal of oily rags, oil and gas filters, batteries, coolants, degreasers.	Oil, heavy metals, solvents, acids.
	Fluid replacement including hydraulic fluid, oil, transmission fluid, radiator fluids, and grease.	Oil, arsenic, lead, cadmium, chromium, benzene, TCA, TCE, PAHs, solvents.
Reclamation Activities	Site preparation for stabilization	Dust, TSS, TDS, turbidity.

TABLE J–1.—ACTIVITIES, POLLUTANT SOURCES, AND POLLUTANTS—Continued

Activity	Pollutant source	Pollutant
	Fertilizers	Nitrogen, phosphorus.

Sources: Storm water group applications, Part 1 and 2 and EPA. "Development Document on the Mineral Mining and Processing Point Source Category." (EPA 440/1–76/059b). July 1979.

Significant materials include, "* * * but [are] not limited to: raw materials, fuels, materials such as solvents, detergents, and plastic pellets; finished materials such as metallic products; * * * hazardous substances designated under Section 101(14) of CERCLA; any chemical facilities required to report pursuant to Section 313 of Title III of SARA; fertilizers; pesticides; and waste products such as ashes, slag, and sludge that have the potential to be released with storm water discharge" (40 CFR 122.26(b)(12)). Significant materials commonly found at mining facilities include: overburden; waste rock; sub-ore piles; tailings; petroleum-based products; solvents and detergents; manufactured products; and other waste materials.

Materials management practices are defined as those practices employed to diminish contact by significant materials with precipitation and storm water runon, or practices utilized to reduce the offsite discharge of contaminants. To this end, sediment ponds, discharge diversion techniques, as well as methods of dispersion, are used to minimize impacts of significant materials on storm water. For mine sites requiring additional sources of water for processing operations, rainfall events as well as storm water runon will be managed for use in dust suppression, processing, and washing activities. Many mine sites are already equipped with sedimentation ponds and other established process wastewater treatment methods in order to meet effluent limitation guidelines. Additional storm water management practices used at mineral mining facilities include: discharge diversions; drainage/storm water conveyances; runoff dispersion; sediment control and collection practices; vegetation/soil stabilization; and capping contaminated sources.

Nonmetallic minerals are recovered using four basic forms of extraction techniques: open pit, open face or quarry mining; dredging; solution mining; and underground mining. Each type of extraction method may be followed by varying methods of beneficiation and processing. Presented below are brief descriptions of the industrial activities, significant materials, and materials management practices associated with these four extraction processes and associated beneficiation activities. Due to similarities in mining operations for many of the minerals within this sector, industrial activities, significant materials, and materials management practices are fairly uniform across this sector. Unique practices are noted.

a. Open Pit, Open Face, or Quarry Mining. Many mineral mining and processing industries access mineral deposits using open pit, open face or quarrying extraction techniques. For facilities producing dimension stone, crushed and broken stone, construction and industrial sand and gravel, clays, as well as other minerals (borate, phosphate, potash), surface mining is generally the most economical form of extraction.

(1) *Industrial Activities.* Extraction activities include removal of overburden and waste rock to access mineral deposits. These land-disturbing activities generate piles of topsoil and other overburden as well as waste rock, which are typically stored beside, or within, the pit or quarry. In addition, land disturbance, blasting, crushing, and materials handling activities create large amounts of dust that are either dispersed by local wind patterns or collected in air pollution control mechanisms. At closure, overburden and waste rock may or may not be used to reclaim the pit or quarry depending on Federal, State and local requirements. In addition, access roads and rail spurs, and associated loading and unloading areas, are found onsite.

Following extraction, the mined materials may be transferred to a nearby beneficiation/processing facility or may be beneficiated within the pit or quarry. At a beneficiation/processing facility, unfinished materials may be subjected to dry or wet processing methods. Dry forms of processing include crushing, grinding, sawing, and splitting of the mined material. Wet processing may include simple washing, flotation, or heavy media separation.

(2) *Significant Materials.* Significant materials generated by most extraction activities at open pit, open face, and quarry mines include overburden piles, waste rock piles, ore and subore piles, and materials spilled from loading and unloading activities. Other exposed materials that can be generated at these types of operations (as well as other mineral mines), include: tailings from flotation and other separation stages; soils impacted by fugitive dust emissions; other process wastes such as clays from phosphate mines; settling ponds that receive process wastewaters; dredged sediment disposal areas; as well as raw material and product storage. Dust and particulate matter collected in air pollution control mechanisms may also be disposed of in onsite waste piles.

(3) *Materials Management Practices.* Materials management practices at open pit or quarry mining facilities are typically designed to control dust emissions and soil erosion from extraction activities, and offsite transport of significant materials. At many facilities structural Best Management Practices (BMPs) may have already been implemented to manage process wastewaters subject to effluent limitation guidelines. Settling ponds and impoundments are commonly used to reduce Total Suspended Solids (TSS), Total Dissolved Solids (TDS), and other contaminants in process generated wastewaters. These controls may also be used to manage storm water runoff and runon with potentially few alterations to onsite drainage systems. Some facilities included in part 1 of the group applications reported the use of storm water diversions to divert storm water away from pits and quarries, raw material piles, overburden, and waste rock piles.

Tailings impoundments are used to manage tailings generated at facilities engaged in flotation or heavy media separation operations. These impoundments are used to manage beneficiation/processing wastewaters generated at the facility and may also be used to manage storm water runoff.

b. Dredging. Dredging is an extraction method used to access nonmetallic mineral deposits located in quarries or pits (where completely or partially below the water table); in rivers; or estuaries; or offshore, in open bays or sounds. For these types of operations, ore is recovered using scooping devices and suction dredges. Minerals commonly excavated by dredging include sand and gravel, and calcium carbonate.

R0016198

(1) Industrial Activities. The industrial activities at dredging facilities include excavation of ore from underwater deposits (e.g., in stream beds of perennial or ephemeral streams) by dredges. Processing operations may occur on the dredge barges or at adjacent facilities. On-board processing activities may include: screening; crushing of oversized material; washing; sand classification with hydraulic classifying tanks; gravel sizing; heavy media separation; and product loading/unloading.

Dredges that do not perform on-board processing operations load raw material on a tow-barge for transport to a land-based processing facility. Processing at land facilities typically includes washing to remove clay and other impurities; screening; sizing; crushing; classifying; and heavy media separation.

(2) Significant Materials. Significant materials generated at dredging facilities include ore material piles, waste material piles of oversized, or otherwise unusable materials, and float waste from heavy media separation. Clays and undersized fines are dredging waste by-products that may be returned to the water but may also be stored in piles. Sand fines from gravel crushing operations that cannot be sold, are a major source of exposed waste material at land-based processing facilities. In addition, land-based facilities may also manage dredged sediments removed from onsite settling ponds. Haul roads, storage piles, on-land waste piles, processing operations, and loading/unloading operations are other potential sources of storm water pollutants at these facilities.

(3) Materials Management Practices. Hydraulic dredging operations in open pits or quarries, or land-based processing facilities, use settling ponds for the removal of clay particles, fines, and impurities from process wastewaters. These ponds may also be used to manage contaminated storm water runoff. Water from the settling ponds or basins may be returned to the wet pit to maintain water levels in the pit, or may be discharged offsite. Worked out pits may also be used to contain solid wastes such as fines and oversized materials. These pits are another potential source of storm water contamination in the event of heavy precipitation and subsequent overflow.

Dredging operations in open waters typically discharge process wastewater containing fines to the water body without treatment under the operator's Clean Water Act Section 404 permit.

c. *Solution Mining.* Solution mining extracts minerals from hard rock mineral or natural brine sources by underground injection of a lixiviant into the ore zone. Minerals are recovered from solution, after the solution is brought to the surface, through evaporation or flotation. Since most solution mining extraction activities occur underground using water to extract values, the potential for these mineral deposits to be exposed to storm water is minimal. However, at the surface of solution mining operations, industrial activities and significant materials, such as haul roads, chemical storage areas, and raw material piles, are common to most sites. These industrial activities and significant materials are all susceptible to storm water exposure and require appropriate storm water management controls.

Descriptions of industrial activities performed by each type of solution mining are provided below. Since the mineral deposits are not exposed to storm water for this type of mining, "industrial activities" describes the type of extraction method used to obtain minerals, not activities susceptible to storm water exposure. Significant materials, and materials management practices do refer to those materials exposed to storm water, and to the subsequent management practices used to control storm water.

Some of the minerals extracted using solution mining include: potash; soda; rock salt; borate minerals; chemical and fertilizer minerals such as barite, fluorspar, salines from lake brines; lithium; and mineral pigments. Many of these minerals may also be recovered using surface and/or underground extraction methods.

(1) Solution Mining—Injection.

(a) Industrial Activities—Rock salt and potash minerals may be recovered by injecting water into subsurface deposits and removing minerals in solution. Water is injected through a cased pipe drilled into a deposit. Saturated solution is then pumped to the surface for processing or storage. Processing may include evaporation, and/or flotation to separate the final product.

(b) Significant Materials—Significant materials at an injection solution mining site may include product storage piles, chemical storage areas, and haul roads. Very little extracted solution remains onsite, since it is often re-injected into the formation.

(c) Materials Management Practices—Solution mining facilities typically operate in arid regions, and are able to use solar evaporation ponds to recover minerals from solution. Due to typically low precipitation and high evaporation rates in these areas, storm water materials management practices may not be prevalent.

(2) Solution Mining—Frasch Sulfur.

(a) Industrial Activities—Sulfur is recovered from deposits using the Frasch sulfur process, which injects hot, purified, water into the subsurface to melt the mineral. Molten sulfur is pumped directly to heated tanks at the surface to maintain a saleable product in liquid form.

(b) Significant Materials—Significant materials generated from Frasch sulfur mining include elemental sulfur, scrap sulfur, tank bottoms, water treatment sludge, bleedwater produced from bleed wells used to remove excess injection water, and drilling wastes such as muds, acidizing fluids and well workover fluids. Since molten sulfur product is piped directly from underground to enclosed storage tanks on the surface, it is not exposed to storm water.

(c) Materials Management Practices—Solid wastes such as elemental and scrap sulfur, tank bottoms, and water treatment sludge may be disposed of in onsite piles. Liquid wastes such as bleedwater, drilling muds, acidizing fluids and workover fluids are typically disposed of in reserve pits and/or workover pits. At the completion of drilling, pit contents may be dried prior to being covered by a liner and buried. Accumulated solids from these pits may also be mixed with clay for use as an additive in drilling muds.

Rainfall runoff and boiler blowdown may be discharged offsite without treatment. Other waste generated at these facilities include power plant wastes and wastewaters, wastewater from sealing wells, sanitary wastes, and miscellaneous other wastewaters collected in drips and drains.

(3) Solution Mining—Evaporation.

(a) Industrial Activities—Another form of solution mining uses evaporation and crystallization of saline waters to produce minerals. Potash, soda, borate, and other minerals, are produced from naturally occurring fluids such as sea water, or from evaporite mineral deposits such as western lake brines. Brines are typically pumped from beneath the crystallized surface of a lake and processed by evaporation and crystallization. Recovered salts are washed, dried and packaged for shipment.

(b) Significant Materials/Materials Management Practices—Significant materials associated with these facilities include raw material piles, evaporation ponds, and residual brines consisting of salts and end liquors, including various added process wastewaters. Residual brines generated may be left in solar

evaporation ponds or dissolved and returned to the lake or injection wells.

d. Underground Mining. Underground mining techniques are used to access mineral deposits located too far underground to access economically from the surface. Though typically a more expensive form of extraction, advantages to underground mining operations include year-round operation, less noise (applicable to facilities located near residential areas), and less surface land disturbance. While most nonmetallic minerals are extracted from surface operations, some minerals existing in bedded or other sedimentary deposits may be accessed by underground extraction techniques. Potash, salt, soda, and borate minerals, as well as chemical and fertilizer minerals, are some of the minerals extracted using this mining method.

(1) Industrial Activities/Significant Materials. Industrial activities that may be associated with storm water discharges include: loading/unloading activities; haul roads; products and materials storage; waste piles; and processing activities. Exposed materials associated with surface beneficiation and processing facilities at underground mines are similar to those associated with open pit, open face, and quarrying facilities.

(2) Materials Management Practices. Materials management practices for significant materials at the surface of underground mining facilities are similar to those materials management practices used at open pit, open face, and quarrying operations.

e. Inactive Mine Sites. Inactive mineral mining and processing operations are those where industrial activities are no longer occurring. When active, mineral extraction could have occurred from open pits or open face mines, solution mines, dredging operations, or underground mines. These sites are included in this section because significant materials may remain onsite. These materials, if exposed, are potential sources of storm water pollutants. Until an inactive mineral mining and processing facility has been reclaimed under applicable State or Federal laws, the site is considered associated with an "industrial activity" and is subject to this section. Due to the seasonal nature of this industry, many mine sites can become temporarily inactive for extended periods.

2. Pollutants in Storm Water Discharges Associated With Mineral Mining and Processing Facilities

Impacts caused by storm water discharges from active and inactive mineral mining and processing operations will vary. Several factors influence to what extent significant materials from mineral mining and processing operations may affect water quality. Such factors include: geographic location; hydrogeology; the type of mineral extracted; the mineralogy of the extracted resource and the surrounding rock; how the mineral was extracted (e.g., quarrying/open face, dredging, solution, or underground mining operations); the type of industrial activities occurring onsite (e.g., extraction, crushing, washing, processing, reclamation etc.); the size of the operation; and type, duration, and intensity of precipitation events. Each of these and other factors will interact to influence the quantity and quality of storm water runoff. For example, air emissions (i.e., settled dust) may be a significant source of pollutants at some facilities while materials storage is a primary source at others. In addition, sources of pollutants other than storm water, such as illicit connections,[71] spills, and other improperly dumped materials, may increase the pollutant loadings discharged into waters of the United States.

The part 2 group application data requirements did not identify individual site characteristics which may be responsible for elevated or insignificant conventional pollutant loadings.

Based on the wide variety of industrial activities and significant materials at the facilities included in this sector, EPA believes it is appropriate to divide the mineral mining and processing industry into subsectors to properly analyze sampling data and determine monitoring requirements. As a result, this sector has been divided into the following subsectors: dimension stone, crushed stone mining and nonmetallic minerals mining (except fuels); sand and gravel mining; clay, ceramic, and refractory materials mining; chemical and fertilizer mineral mining. The tables below include data for the eight pollutants that all facilities were required to monitor for under Form 2F. The tables also list those parameters that EPA has determined merit further monitoring. A table has not been included for the following facilities because less than 3 facilities submitted data in these subsectors: clay, ceramic, and refractory materials mining; and chemical and fertilizer mineral mining facilities.

TABLE J–2.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY DIMENSION STONE AND CRUSHED PRODUCTS FACILITIES SUBMITTING PART II SAMPLING DATA[i] (mg/L)

[71] Illicit connections are contributions of unpermitted non-storm water discharges to storm sewers from any of a number of sources including sanitary sewers, industrial facilities, commercial establishments, or residential dwellings. The probability of illicit connections at mineral mining and processing facilities is low yet it still may be applicable at some operations.

3. Options for Controlling Pollutants

There are two options for reducing pollutants in storm water discharges: end-of-pipe treatment and implementing Best Management Practices to prevent and/or eliminate pollution. Discharges from mining operations are in some ways dissimilar to other types of industrial facilities. Mining facilities are often in remote locations and may operate only seasonally or intermittently, yet need year-round controls because significant materials remain exposed to precipitation when reclamation is not completed. These characteristics make resource intensive end-of-pipe management controls less desirable.

A comprehensive storm water management program for a given plant may include controls from each of these categories. Development of comprehensive control strategies should be based on a consideration of site and facility plant characteristics.

a. End-of-Pipe Treatment. At many mineral mining and processing operations, it may be appropriate to collect and treat the runoff from targeted areas of the facility. This approach was taken with 12 industrial categories within the mineral mining and processing industry, subject to national effluent limitation guidelines for process water. Table J–4 identifies the effluent limitation guidelines for process water and for the mineral mining and processing sector. There are several areas where process wastewater guidelines influence the permitting strategy for storm water discharges. Whenever storm water and process wastewater combine, the storm water is treated as process wastewater. To meet the numeric effluent limitation for process water, most, if not all, facilities must collect and temporarily store onsite runoff from targeted areas of the plant. The effluent limitation guidelines do not apply to discharges whenever rainfall events, either chronic or catastrophic, cause an overflow of storage devices designed, constructed, and maintained to contain a 10-year, 24-hour storm. Most technology-based treatment standards, used for treating process waters, are based on relatively simple technologies such as settling of solids, neutralization, and drum filtration.

TABLE J–4.—Mineral Mining and Processing: Effluent Limitation Guidelines

SIC Code	Category	Subcategory	Effluent guidelines
1411	Dimension Stone	N/A	Reserved
1422	Crushed and Broken Limestone	N/A	For Facilities that recyle process waste water: pH 6.0–9.0.
1423	Crushed and Broken Granite		Mine dewatering discharges: pH 6.0–9.0.
1429	Crushed and Broken Stone, Not Elsewhere Classified.		In no case shall a pH limitation outside the range of 5.0–9.0 be permitted.
1442	Construction Sand and Gravel	N/A	For facilities that recycle process waste water: pH 6.0–9.0.
			Mine dewatering discharges: pH 6.0–9.0.
			In no case shall a pH limitation outside the range of 5.0–9.0 be permitted.
1446	Industrial Sand	N/A	All operations except HF flotation:
			TSS: Not to exceed 45mg/L maximum for any 1 day; Average over 30 days not to exceed 25 mg/L.
			pH Within range 6.0–9.0.
			For facilities using HF flotation:
			TSS: Not to exceed 0.046 mg/L maximum for any 1 day; Average over 30 days not to exceed 0.023 mg/L.
			Total Fluoride: Maximum for 1 day: 0.006 mg/L; Average over 30 days: 0.003 mg/L.
			pH Within range 6.0–9.0.
			Mine dewatering discharges:
			TSS: Maximum for 1 day: 45 mg/L; Average over 30 days: 25 mg/L.
			pH: Within range 6.0–9.0.
1455	Kaolin and Ball Clay	Ball Clay Kaolin	Reserved.
1459	Clay, Ceramic, and Refractory Minerals, Not Elsewhere Classified.	Bentonite Magnesite	No Discharge.

TABLE J–4.—Mineral Mining and Processing: Effluent Limitation Guidelines—Continued

SIC Code	Category	Subcategory	Effluent guidelines
		Feldspar, Fire Clay, Attapulgite, and Montmovillonite, Kyanite, Shale and Common Clay Aplite.	Reserved.
1474	Potash, Soda, and Borate Minerals	Borax, Potash, Sodium Sulfate	No Discharge.
		Trona, Rock Salt	Reserved.
1475	Phosphate Rock	N/A	Existing Sources.
			TSS: Maximum for any 1 day: 60 mg/L; Average over 30 days: 30 mg/L.
			pH: Within range 6.0–9.0.
			New sources, process generated wastewater and mine dewatering discharges:
			TSS: Maximum for any 1 day: 60 mg/L; Average over 30 days: 30 mg/L.
			pH: Within range 6.0–9.0.
1479	Chemical and Fertilizer Mineral Mining, Not Elsewhere Classified.	Barite, Fluorspar, Salines from Brine Lakes, Frasch Sulfur.	No Discharge.
		Mineral Pigments, Lithium	Reserved.
1499	Miscellaneous Nonmetallic Minerals, Except Fuels.	Graphite	Process waste water and mine drainage subject to ELG:
			TSS: Maximum for any 1 day: 20 mg/L; Average over 30 days: 10 mg/L.
			Total Fe: Maximum for any 1 day: 2 mg/L; Average over 30 days: 1 mg/L.
			pH: Within range 6.0–9.0.
		Gypsum, Asphaltic Minerals, Asbestos and Wollastonite, Diatomite, Jade, Tripoli (Dry Processes Only).	No discharge.
		Garnet, Talc, Steatite, Soapstone, Pyrophyllite, Mica and Sericite.	Reserved.

End-of-pipe treatments are effective means to control process wastewaters because the types of pollutants and the volume of water to be treated are known. However, storm water discharges from mineral mining and processing facilities can be numerous, intermittent, and of various volumes. Channelization of all storm water that comes into contact with significant materials into a single treatment facility, or construction of numerous treatment devices for each discharge is too burdensome for the regulated community. Therefore, EPA believes that the most appropriate means of storm water management at mineral mining and processing facilities are BMPs. BMPs allow the mine site operator to choose a particular BMP that is best for the characteristics of a particular site and to control parameters of concern.

b. Best Management Practices. EPA believes that the most effective storm water management controls for limiting the offsite discharge of storm water pollutants from mineral mining and processing facilities are source reduction BMPs. Source reduction BMPs are methods by which discharges of contaminants are controlled with little or no required maintenance. Examples of these types of controls include source reduction diversion dikes, vegetative covers, and berms. Source reduction practices are typically (but not always) low in cost and relatively easy to implement. In some instances, more resource intensive treatment BMPs, including sedimentation ponds, may be necessary depending upon the type of discharge, types and concentrations of contaminants, and volume of flow.

The selection of the most effective BMPs will be based on site-specific considerations such as: facility size, climate, geographic location, hydrogeology and the environmental setting of each facility, and volume and type of discharge generated. Each facility will be unique in that the source, type, and volume of contaminated storm water discharges will differ. In addition, the fate and transport of pollutants in these discharges will vary. EPA believes that the management practices discussed herein are well suited mechanisms to prevent or control the contamination of storm water discharges associated with mining activity.

The following six categories describe best management practice options for reducing pollutants in storm water discharges from mineral mining and processing operations: discharge diversions; drainage/storm water conveyance systems; runoff dispersion; sediment control and collection; vegetation/soil stabilization; capping of contaminated sources.

Typical land disturbance activities at mineral mining and processing sites include roads, open pits and quarries, topsoil, overburden, waste rock, subore, ore and product piles; materials storage, mill tailings, ponds and piles, as well as vehicle maintenance and storage areas. Because mineral mining and processing is largely a land disturbance activity, BMPs that minimize erosion and sedimentation will be most effective if installed at the inception of operations and maintained throughout active operations and reclamation of the site. From the construction of access and haul roads to closure and reclamation activities, implementation of BMPs is often essential to minimizing long-term environmental impacts to an area.

Part 1 group application data indicate that several types of BMPs have been implemented at sampling facilities. Commonly used BMPs were sediment control and collection and discharge diversion devices. However, the group application process did not require a description of BMP locations and did not require applicants to describe the number of identical BMPs implemented at each site. As a result, the effectiveness of BMPs for storm water management, at these facilities cannot be evaluated.

In addition, many of the BMPs listed by facilities may have been implemented as process wastewater treatment mechanisms and are not exclusively used for storm water management. For instance, 43 percent of the sampling subgroup reported using ponds for sediment control and collection. Since some facilities classified as SIC Code 14 are subject to process water effluent limitation guidelines, sedimentation ponds may have been implemented to meet the limit.

Because BMPs described in the part 1 data are limited, EPA is providing an overview of supplementary BMPs for use at mineral mining and processing facilities. However, due to the site-specific nature of facilities within this sector, BMPs cited do not preclude the use of other viable BMP options. Table J–5 summarizes BMP options as they apply to land disturbance activities at mineral mining and processing facilities. Sources of BMP information include: "Sediment and Erosion Control: An Inventory of Current Practices—Draft," EPA, April 20, 1990; "Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices," EPA, September, 1992 (EPA 832–R–92–006); "Best Management Practices for Mining in Idaho," Idaho Department of Lands, November 1992; and "Erosion & Sediment Control Handbook," Goldman et al., McGraw-Hill Book Company, 1986.

TABLE J–5.—SUMMARY OF MINE AREAS AND APPLICABLE BEST MANAGEMENT PRACTICES

Land-disturbed area	Discharge diversions	Conveyance systems	Runoff dispersion	Sediment control & collection	Vegetation	Containment
Haul Roads and Access Roads.	Dikes, Curbs, Berms.	Channels, Gutters, Culverts, Rolling Dips, Road Sloping, Roadway Water Deflectors.	Check Dams, Rock Outlet Protection, Level Spreaders, Stream Alteration, Drop Structures.	Gabions, Riprap, Native Rock Retaining Walls, Straw Bale Barriers, Sediment Traps/Catch Basins, Vegetated Buffer Strips.	Seeding, Willow Cutting Establishment.	
Pits/Quarries or Underground Mines.	Dikes, Curbs, Berms.	Channels, Gutters	Serrated Slopes, Benched Slopes, Contouring, Stream Alteration.	Sediment Settling Ponds, Straw Bale Barrier, Siltation Berms.	Seeding	Plugging and Grouting
Overburden, Waste Rock and Raw Material Piles.	Dikes, Curbs, Berms.	Channels, Gutters	Serrated Slopes, Benched Slopes, Contouring, Stream Alteration.	Plastic Matting, Plastic Netting, Erosion Control Blankets, Mulch-straw, Compaction, Sediment/Settling Ponds, Silt Fences, Siltation Berms.	Topsoiling, Seedbed Preparation, Seeding.	Capping
Reclamation	Dikes, Curbs, Berms.	Channels, Gutters	Check Dams, Rock Outlet Protection, Level Spreaders, Serrated Slopes, Benched Slopes, Contouring, Drain Fields, Stream Alteration, Drop Structures.	Gabions, Riprap, and Native Rock Retaining Walls, Biotechnical Stabilization, Straw Bale Barriers, Sediment Traps/ Catch Basins, Vegetative Buffer Strips, Silt Fences, Siltation Berms, Brush Sediment Barriers.	Topsoiling, Seedbed Preparation, Seeding, Willow Cutting Establishment.	Capping, Plugging and Grouting

Haul Roads and Access Roads—Placement of haul roads or access roads should occur as far as possible from natural drainage areas, lakes, ponds, wetlands or floodplains where soil will naturally be less stable for heavy vehicle traffic. If a haul road must be constructed near water, as little vegetation as possible should be removed from between the road and the waterway, as vegetation is a useful buffer against erosion and is an efficient sediment collection mechanism. The width and grade of haul or access roads should be minimal and should be designed to match natural contours of the area. Construction of haul roads should be supplemented by BMPs that divert runoff from road surfaces, minimize erosion, and direct flow to appropriate channels for discharge to treatment areas.

Pits or Quarries—Excavation of a pit or quarry must be accompanied by BMPs to minimize impacts to area surface waters. As discussed in construction of haul roads, as little vegetation as possible should be removed from these areas during excavation activities to minimize exposed soils. In addition, stream channels and other sources of water that may discharge into a pit or quarry should be diverted around that area to prevent contamination.

Overburden, Waste Rock, and Raw Material Piles—Overburden, topsoil, and waste rock, as well as raw material and intermediate and final product stockpiles should be located away from surface waters and other sources of water, and from geologically unstable areas. If this is not practicable, surface water should be diverted around the piles. As many piles as possible should be revegetated (even if only on a temporary basis). At closure, remaining units should be reclaimed.

BMPs can be used to control total suspended solids levels in runoff from unvegetated areas. These can include sediment/settling ponds, check dams, silt fences, and straw bale barriers.

Reclamation Activities—When a mineral deposit is depleted and operations cease, a mine site must be reclaimed according to appropriate State or Federal standards. Closure activities typically include restabilization of any disturbed areas such as access or haul roads, pits or quarries, sedimentation ponds or work-out pits, and any remaining waste piles. Overburden and topsoil stockpiles may be used to fill in a pit or quarry (where practical). Recontouring and vegetation should be performed to stabilize soils, and prevent erosion.

Major reclamation activities such as recontouring roads and filling in a pit or quarry can only be performed after operations have ceased. However, reclamation activities such as stabilization of banks and reseeding and revegetation should be implemented in mined out portions, or inactive areas of a site as active mining moves to new areas.

EPA recognizes that quarries are frequently converted into reservoirs or recreational areas, after the mineral deposit is depleted. However, this does not preclude the reclamation of disturbed areas above the quarry rim.

(1) Discharge Diversions. Discharge diversions provide the first line of defense in preventing the contamination of discharges and the subsequent contamination of receiving waters of the United States. Discharge diversions are temporary or permanent structures installed to divert flow, store flow, or limit storm water runon and runoff.

These diversion practices have several objectives. First, diversion structures can be designed to prevent otherwise uncontaminated (or less contaminated) water from crossing disturbed areas or areas containing significant amounts of contaminated materials, where contact may occur between runon and significant materials. These source reduction measures may be particularly effective for mineral mining and processing operations to prevent runon of uncontaminated discharges from contacting exposed materials and/or reduce the flow across disturbed areas, thereby lessening the potential for erosion. Second, diversion structures can be used to collect or divert waters for later treatment if necessary. The usefulness of these control measures are limited by such factors as the size of the area to be controlled and the type and nature of materials exposed and precipitation events.

Diversion dikes, curbs, and berms are temporary or permanent diversion structures that prevent runoff from passing beyond a certain point, and divert runoff away from its intended path. Dikes, curbs or berms may be used to surround and isolate areas of concern at mineral mining and processing sites, diverting flow around piles of overburden, waste rock, and storage areas, to minimize discharge contact with contaminated materials and to limit discharges of contaminated water from confined areas.

(2) Drainage/Storm Water Conveyance Systems. Drainage or storm water conveyance systems can provide either a temporary or a permanent management practice which functions to channel water away from eroded or unstabilized areas, convey runoff without causing erosion, and/or carry discharges to more stabilized areas. The use of drainage systems as a permanent measure may be most appropriate in areas with extreme slopes, areas subject to high velocity runoff, and other areas where the establishment of substantial vegetation is infeasible or impractical. For instance, several BMPs described below may be useful storm water and erosion control methods applicable to road construction and maintenance activities.

Channels or Gutters—Channels or gutters collect storm water runoff and direct its flow. Like diversion systems, channels or gutters may act to divert runoff away from a potential source of contamination, but may also be used to channel runoff to a collection and/or treatment area including settling ponds, basins or work-out pits.

Open Top Box Culverts, and Waterbars—These structures are temporary or permanent structures that divert water from a roadway surface. Open top box culverts may be used on steeply graded, unpaved roads in place of pipe culverts to divert surface runoff and flow from inside ditches onto the downhill slope of a road. These structures are typically made of wood and should periodically be monitored and repaired if necessary.

Waterbars are berms built by a dozer or by hand to a one to two foot height. They serve to extend the entire width of the road, with a downslope angle between 30 and 40 percent. Waterbars are kept open at a discharge end to allow water to flow away from the road and require little maintenance. These berms may be used as temporary or permanent structures.

Rolling Dips and Road Sloping—Rolling dips and road sloping are permanent water diversion techniques installed using natural contours of the land during road construction. These BMPs prevent water accumulation on road surfaces and divert surface runoff toward road ditches which then convey the storm water to ponds or other management areas.

Roadway Surface Water Deflector—A roadway surface water deflector is another technique to prevent accumulation of water on road surfaces. The structure uses a conveyor belt sandwiched between two pieces of treated wood and placed within the road to deflect water. This is a useful technique for steeply graded, unpaved roads.

Culverts—Culverts are permanent surface water diversion mechanisms used to convey water off of, or underneath a road. Made of corrugated metal, they must extend across the entire width of the road and beyond the fill slope. Additional erosion control mechanisms may need to be installed at the discharge end of the culvert.

(3) Runoff Dispersion. Drainage systems are most effective when used in conjunction with runoff dispersion devices designed to slow the flow of water discharged from a site. These devices also aid storm water infiltration into the soil and flow attenuation. Some examples of velocity dissipation devices include check dams, rock outlet protection, level spreaders, and serrated and benched slopes.

Check Dams—Check dams are small temporary dams constructed across swales or drainage ditches to reduce the velocity of runoff flows thereby reducing erosion and failure of the swale or ditch. This slowing reduces erosion and gullying in the channel and allows sediments to settle.

Check dams may be installed in small temporary or permanent channels where vegetation of the channel lining is not feasible and where there is danger of erosion. These may be areas where installation of nonerosive liners are not cost effective.

Check dams diminish the need for more stringent erosion control practices in the drainage ditch since they decrease runoff velocity. When constructing check dams, the use of overburden or waste rock should be avoided where there is the potential for contamination.

Rock Outlet Protection—Rock protection placed at the outlet end of culverts, channels, or ditches reduces the depth, velocity, and destructive energy of water such that the flow will not erode the downstream reach. The use of some materials (e.g., mine waste rock or ore) should be avoided where contamination may occur. As with check dams, rock outlet protection may also be used as a source reduction treatment mechanism by using rocks containing limestone or other alkaline materials to neutralize acidic discharges.

Level Spreaders—Level spreaders are outlets for dikes and diversions consisting of an excavated depression constructed at zero grade across a slope. Level spreaders diffuse storm water point sources and release it onto areas stabilized by existing vegetation.

Serrated Slopes and Benched Slopes—These runoff dispersion methods break up flow of runoff from a slope, decreasing its ability to erode. Serrated and benched slopes provide flat areas that allow water to infiltrate, and space for vegetation to grow and reinforce soils. Serrated slopes are equipped with small steps, from one to two feet of horizontal surface exposed on each step. Benched slopes have larger steps with vertical cuts between two and four feet high.

Contouring—Surface contouring is the establishment of a rough soil surface amenable to revegetation through creating horizontal grooves, depressions, or steps that run with the contour of the land. Slopes may also be left in a roughened condition to reduce discharge flow and promote infiltration. Surface roughening aids in the establishment of vegetative cover by reducing runoff velocity and giving seed an opportunity to take hold and grow.

This technique is appropriate for all slopes steeper than 3:1 in order to facilitate stabilization of the slope and promote the growth of a vegetative cover. Once areas have been contoured, they should be seeded as quickly as possible.

Drain Fields—Drain fields are used to prevent the accumulation of water and/or ground water at a site by diverting infiltrating sources through gravity flow or pumping. Typically filled with porous, permeable materials such as graded rock, or perforated pipe, and lined with geotextile fabric, these mechanisms are useful underneath significant materials, reducing the amount of water that ultimately comes into contact with significant materials.

Stream Alteration—Altering or channelizing the path of a stream to bypass all or some disturbed areas on a site, allows additional mining activities and avoids contamination of stream water by disturbed lands. This practice is complicated, however, by the need to restore the channel when mining operations end.

Drop Structures—Drop structures are large angular rocks placed in a V-shaped pattern to slow the velocity of storm water runoff. These structures are typically reinforced by logs or large rocks imbedded in the streambanks.

(4) Sediment Control and Collection. Sediment control and collection limits movement and retains sediments from being transported offsite. Several structural collection devices have been developed to remove sediment from runoff before it leaves the site. Several methods of removing sediment from site runoff involve diversion mechanisms previously discussed, supplemented by a trapping or storage device. Structural practices typically involve filtering diffuse storm water flows through temporary structures such as straw bale dikes, silt fences, brush barriers or vegetated areas.

Structural practices are typically low in cost. However, structural practices require periodic removal of sediment to remain functional. As such, they serve as more active-type practices which may not be appropriate for permanent use at inactive mines. However, these practices may be effectively used as temporary measures during active operation and/or prior to the final implementation of permanent measures.

(a) Temporary Treatments

Plastic Matting, Plastic Netting, and Erosion Control Blankets—These BMPs are used to protect bare soils and control dust and erosion. Mats and blankets help to promote vegetative growth by maintaining moisture and heat within the soil. Plastic matting and netting improve slope stabilization and may be used as a permanent treatment to encourage grass growth. Plastic netting is a more effective material to use while promoting growth of vegetation as it permits sunlight to penetrate through to the soils. Erosion control blankets also stabilize slopes and control erosion. These blankets may be made of jute or plastic netting which are more expensive than straw.

Mulch-straw or Wood Chips—Mulches and wood chips are useful temporary covers for bare or seeded soils with an erosion control effectiveness rating of 75 to 98 percent.[72] Like matting, mulch-straw or wood chips help soils retain moisture and warmth to promote vegetative growth. Used on slopes and/or in combination with nylon netting, these materials may prevent erosion by wind and water. Over time, however, the mulch cover will decrease in effectiveness.

Compaction—Soil compaction using a roller or other heavy equipment increases soil "strength" by increasing its density. More dense soil is less prone to erosion and long-term soil settlement. The surface of compacted soils should be roughed and seeded or vegetated to increase its durability.

(b) Permanent Treatments

Sediment/Settling Ponds—Sediment ponds function as sediment traps by containing runoff for long periods of time, allowing suspended solids to settle. These structures can achieve a high removal rate of sediment for both process wastewater and storm water discharges. Sediment/settling ponds are easily constructed and require minimal maintenance. Their flexibility to treat both process wastewater and storm water makes the use of ponds a desirable treatment for discharges from mineral mining and processing facilities. Of course, site characteristics must be such that some or all discharges can be practically channeled to a centralized area for treatment. Where this is not practical, the cost of constructing multiple sediment ponds may become prohibitive. In addition, periodic dredging may be required in order to maintain the capacity of these ponds.

Discharge ponds may also be designed to act as surge ponds which are designed to contain storm surges and then completely drain in about 24 to 40 hours, and remain dry during times of no rainfall. They can provide pollutant removal efficiencies that are similar to those of detention ponds.[73] Storm surge ponds are typically designed to provide both water quality and water quantity (flood control) benefits.[74]

Gabions, Riprap, and Native Rock Retaining Walls—These BMPs are all forms of slope stabilization. Gabions consist of rocks (riprap) contained by rectangular wire boxes or baskets for use as permanent erosion control structures.

---

[72] "Sediment and Erosion Control: An Inventory of Current Practices—Draft," EPA, April 20, 1990.

[73] "Urban Targeting and BMP Selection," EPA, Region V, November 1990.

[74] "Urban Surface Water Management," Walesh, S.G., Wiley, 1989.

Riprap consists of loose rocks placed along embankments to prevent erosion. Native rock retaining walls are another form of slope stabilization, with walls up to five feet in height, constructed from native rock to reinforce a steep slope.

Biotechnical Stabilization—Biotechnical stabilization uses live brush imbedded in the soils of a steep slope to prevent erosion. This method relies on the premise that the imbedded vegetation will eventually root and help stabilize the slope.

Straw Bale Barrier—Straw bales may be used as temporary berms, barriers, or diversions; capturing sediments, filtering runoff. When installed and maintained properly, these barriers remove approximately 67 percent of the sediment load.[75] These barriers are applicable across small swales, in ditches, and at the toe of bare slopes where there is a temporary large volume of sediment laden runoff.

Sediment Traps or Catch Basins—These temporary or permanent structures are useful for catching and storing sediment laden storm water runoff and are particularly useful during construction activities to contain runoff. The effectiveness of these BMPs is better in smaller drainage basin areas. Sediment traps are less than 50 percent effective in removing sediment from storm water runoff.[76]

Vegetated Buffer Strips—The installation of vegetated buffer strips will reduce runoff and prevent erosion at a removal efficiency rate of 75 to 99 percent depending upon the ground cover.[77] In addition, vegetated buffer strips catch and settle sediment contained in the storm water runoff prior to reaching receiving waters.

Silt Fence/Filter Fence—A low fence made of filter fabric, wire and steel posts, should be used on small ephemeral drainage areas where storm water collects or leaves a mine site. Silt fences remove 97 percent of the sediment load and are easier to maintain and remove without creating lasting impacts to the environment.[78] Silt and filter fences need to be inspected periodically and may not be as effective as straw bales, since fabric may become clogged with fine particles preventing water flow.

Silt fences may have limited applicability for large areas. They are most effective for use in a small drainage areas. These fences may also be used in conjunction with nonstructural practices to maintain the integrity of soil prior to the establishment of vegetation.

Siltation Berms—Siltation berms are typically placed on the downslope side of a disturbed area to act as an impermeable barrier for the capture and retention of sediments in surface water runoff. Plastic sheeting is typically used to cover the berm. The berm and the plastic sheeting may require periodic maintenance and repair.

Brush Sediment Barriers—Brush barriers are temporary sediment barriers composed of tree limbs, weeds, vines, root mat, soil, rock and other cleared materials placed at the toe of a slope. A brush barrier is effective only for small drainage areas, usually less than 1/4 acre, where the slope is minimal.

Brush barriers do not function as permanent barriers since over time the barrier itself will degrade. This BMP is most effective when located at the toe of a slope of an area in which vegetation is being grown or during temporary operations. The brush barriers remove any excessive sediment generated by erosion prior to the establishment of vegetation.

(5) Vegetation Practices. Vegetation practices involve establishing a sustainable ground cover by permanent seeding, mulching, sodding, and other such practices. A vegetative cover reduces the potential for erosion of a site by: absorbing the kinetic energy of raindrops which would otherwise impact soil; intercepting water so it can infiltrate into the ground instead of running off and carrying contaminated discharges; and by slowing the velocity of runoff to promote onsite deposition of sediment. Vegetative controls are often the most important measures taken to prevent offsite sediment movement and can provide a six-fold reduction in the discharge of suspended sediment levels.[79] Permanent seeding has been found to be 99 percent effective in controlling erosion for disturbed land areas.[80] Many States require that topsoil be segregated from other overburden for use during reclamation. While stored, topsoil stockpiles should be vegetated. This temporary form of vegetation can often be used for other piles of stored materials and for intermittent/seasonal operations.

Typically, the costs of vegetative controls are low relative to other discharge mitigation practices. Given the limited capacity to accept large volumes of runoff and potential erosion problems associated with large concentrated flows, vegetative controls should typically be used in combination with other management practices. These measures have been documented as particularly appropriate for mining sites.

Topsoiling, Seedbed Preparation—The addition of a layer of topsoil or plant growth material provides an improved soil medium for plant growth. Seedbed preparation may include the addition of topsoil ingredients to be mixed in with soils used for seedbed preparation. Ripping, dicing, and mixing soils promotes weed control and aerates the soil, encouraging seedling growth.

Broadcast Seeding and Drill Seeding—Seeding and vegetative planting are methods used to revegetate an area. Broadcast seeding spreads seeds uniformly, by hand or machine, to steep sloped or rocky areas, flat surfaces, and areas with limited access. Drill seeding is performed using a rangeland drill seeder and may not be used on rocky surfaces. Drill seeding is more suitably performed on flat, nonrocky surfaces, where the machine can insert seeds into the soil.

Willow Cutting Establishment—Willow cutting establishment describes a method of soil stabilization useful for stream banks and other areas located adjacent to water. Similar to biotechnical stabilization, willow cuttings are used to promote growth in an area needing stabilization. Willow cuttings are typically used to reinforce a streambank or other moist area. Willow cuttings require a great deal of moisture and must be planted in areas that remain moist for long periods in order to take hold and grow.

(6) Capping. In some cases, the elimination of a pollution source through capping contaminant sources may be the most cost effective control measure for discharges from inactive mineral mining and processing operations. Depending on the type of management practices chosen, the cost to eliminate the pollutant source may be very high. Once completed, however, maintenance costs will range from low to nonexistent.

Capping or sealing of waste materials is designed to prevent infiltration, as well as to limit contact between discharges and potential sources of

contamination. Ultimately, capping should reduce or eliminate the contaminants in discharges. In addition, by reducing infiltration, the potential for seepage and leachate generation may also be lessened.

The use of this practice depends on the level of control desired, the materials available, and cost considerations. Many common liners may be effective including common soil, clay, and/or synthetic liners. Generally, soil liners will provide appreciable control for the lowest cost. Synthetic or clay liners may be appropriate to cover materials known to have a significant potential to impact water quality.

4. Storm Water Pollution Prevention Plan Requirements

Specific requirements for a pollution prevention plan for mineral mining and processing facilities are described below. These requirements must be implemented in addition to the common pollution prevention plan provisions discussed previously.

Under the description of potential pollution services, each storm water pollution prevention plan must describe activities, materials, and physical features of the facility that may contribute to storm water runoff or, during periods of dry weather, result in dry weather flows and mine pumpout. This assessment of storm water pollution will support subsequent efforts to identify and set priorities for necessary changes in materials, materials management practices, or site features, as well as aid in the selection of appropriate structural and nonstructural control techniques. Plans must describe the following elements:

The plan must contain a map of the site that shows the pattern of storm water drainage, structural features that control pollutants in storm water runoff[81] and process wastewater discharges, surface water bodies (including wetlands), places where significant materials[82] are exposed to rainfall and runoff, and locations of major spills and leaks that occurred in the 3 years prior to the date of the submission of a Notice of Intent (NOI) to be covered under this permit. The map also must show areas where the following activities take place: fueling, vehicle and equipment maintenance and/or cleaning, loading and unloading, material storage (including tanks or other vessels used for liquid or waste storage), material processing, and waste disposal, haul roads, access roads, and rail spurs. In addition, the site map must also indicate the outfall locations and the types of discharges contained in the drainage areas of the outfalls (e.g. storm water and air conditioner condensate). In order to increase the readability of the map, the inventory of the types of discharges contained in each outfall may be kept as an attachment to the site map.

Facility operators are required to carefully conduct an inspection of the site and related records to identify significant materials that are or may be exposed to storm water. The inventory must address materials that within 3 years prior to the date of the submission of a Notice of Intent (NOI) to be covered under this permit have been handled, stored, processed, treated, or disposed of in a manner to allow exposure to storm water. Findings of the inventory must be documented in detail in the pollution prevention plan. At a minimum, the plan must describe the method and location of onsite storage or disposal; practices used to minimize contact of materials with rainfall and runoff; existing structural and nonstructural controls that reduce pollutants in storm water runoff; existing structural controls that limit process wastewater discharges; and any treatment the runoff receives before it is discharged to surface waters or a separate storm sewer system. The description must be updated whenever there is a significant change in the types or amounts of materials, or material management practices, that may affect the exposure of materials to storm water.

The description of potential pollution sources culminates in a narrative assessment of the risk potential that those sources of pollution pose to storm water quality. This assessment should clearly point to activities, materials, and physical features of the facility that have a reasonable potential to contribute significant amounts of pollutants to storm water. Any such activities, materials, or features must be addressed by the measures and controls subsequently described in the plan. In conducting the assessment, the facility operator must consider the following activities: loading and unloading operations; outdoor storage activities; outdoor processing activities; significant dust or particulate generating processes; and onsite waste disposal practices. The assessment must list any significant pollution sources at the site and identify the pollutant parameter or parameters (i.e., total suspended solids, total dissolved solids, etc.) associated with each source.

Under the measures and controls section of the pollution prevention plan, the permittee must evaluate, select, and describe the pollution prevention measures, best management practices (BMPs), and other controls that will be implemented at the facility. The permittee must assess the applicability of the following BMPs for their site: discharge diversions, drainage/storm water conveyance systems, runoff dispersions, sediment control and collection mechanisms, vegetation/soil stabilization, and capping of contaminated sources. In addition, BMPs include processes, procedures, schedules of activities, prohibitions on practices, and other management practices that prevent or reduce the discharge of pollutants in storm water runoff.

The pollution prevention plan must discuss the reasons each selected control or practice is appropriate for the facility and how each will address the potential sources of storm water pollution. The plan also must include a schedule specifying the time or times during which each control or practice will be implemented. In addition, the plan should discuss ways in which the controls and practices relate to one another and, when taken as a whole, produce an integrated and consistent approach for preventing or controlling potential storm water contamination problems.

Under the preventive maintenance requirements of the pollution prevention plan, permittees are required to develop a preventive maintenance program that includes regular inspections and maintenance of storm water BMPs. The maintenance program requires periodic removal of debris from discharge diversions and conveyance systems. These activities should be conducted in the spring, after snowmelt, and during the fall season. Permittees already controlling their storm water runoff frequently use impoundments or sedimentation ponds. Maintenance schedules for these ponds must be provided in the pollution prevention plant.

Under the inspection requirements of the pollution prevention plan, operators

[81] Nonstructural features such as grass swales and vegetative buffer strips also should be shown.

[82] Significant materials include, "* * * but [are] not limited to: raw materials, fuels, materials such as solvents, detergents, and plastic pellets; finished materials such as metallic products; * * * hazardous substances designated under section 101(14) of CERCLA; any chemical facilities required to report pursuant to section 313 of title III of SARA; fertilizers; pesticides; and waste products such as ashes, slag, and sludge that have the potential to be released with storm water discharge." (40 CFR 122.26(b)(12)) Significant materials commonly found at mining facilities include: overburden; raw materials; waste rock piles; tailings; petroleum based products; solvents and detergents; and manufactured products, waste materials or by-products used or created by the facility.

of active facilities are required to conduct quarterly visual inspections of BMPs. Temporary and permanently inactive operations are required to perform annual inspections. Active sites have more frequent inspections than inactive sites because members of the pollution prevention team will be onsite, and the fact that they are active means there is a greater potential for pollution. The inspections shall include: (1) An assessment of the integrity of storm water discharge diversions, conveyance systems, sediment control and collection systems, and containment structures; (2) visual inspections of vegetative BMPs, serrated slopes, and benched slopes to determine if soil erosion has occurred; and (3) visual inspections of material handling and storage areas and other potential sources of pollution for evidence of actual or potential pollutant discharges of contaminated storm water.

The inspection must be made at least once in each designated period during daylight hours. Inspections for active facilities shall be conducted in each of the following periods: January through March; April through June; July through September; October through December.

EPA believes that this quick and simple description will allow the permittee to assess the effectiveness of his/her plan on a regular basis at very little cost. The frequency of this visual inspection will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow up procedures must be used to ensure that appropriate actions are taken in response to the inspections. The visual inspection is intended to be performed by facility staff. This hands-on inspection will also enhance the staff's understanding of the storm water problems on that site and effects on the management practices that are included in the plan.

Under the recordkeeping and internal reporting procedures of the pollution prevention plan, the permittee must describe procedures for developing and retaining records on the status and effectiveness of plan implementation. The plan must address spills, monitoring, and BMP inspection and maintenance activities. Ineffective BMPs must be reported and the date of their corrective action noted.

Under the sediment and erosion control requirements of the pollution prevention plan, permittees must indicate the location and design for proposed BMPs to be implemented prior to land disturbance activities. For sites already disturbed but without BMPs, the permittee must indicate the location and design of BMPs that will be implemented. The permittee is required to indicate plans for grading, contouring, stabilization, and establishment of vegetative cover for all disturbed areas, including road banks. Reclamation activities must continue until final closure notice has been issued.

According to the pollution prevention runoff requirements, the permittee must evaluate the appropriateness of each storm water BMP that diverts, infiltrates, reuses, or otherwise reduces the discharge of contaminated storm water. In addition, the permittee must describe the storm water pollutant source area or activity (i.e., loading and unloading operations, raw material storage piles etc.) to be controlled by each storm water management practice.

a. Comprehensive Site Compliance Evaluation. The storm water pollution prevention plan must describe the scope and content of comprehensive site evaluations that qualified personnel will conduct to (1) confirm the accuracy of the description of potential pollution sources contained in the plan, (2) determine the effectiveness of the plan, and (3) assess compliance with the terms and conditions of this section. Comprehensive site compliance evaluations should be conducted once a year. When annual comprehensive site compliance evaluations are shown in the plan to be impractical for inactive mining sites, due to remote location and inaccessibility, site evaluations must be conducted at least once every 3 years. The individual or individuals who will conduct the evaluations must be identified in the plan and should be members of the pollution prevention team. Evaluation reports must be retained for at least 3 years after the date of the evaluation.

Based on the results of each evaluation, the description of potential pollution sources, and measures and controls, the plan must be revised as appropriate within 2 weeks after each evaluation. Changes in the measures and controls must be implemented on the site in a timely manner, and never more than 12 weeks after completion of the evaluation.

5. Numeric Effluent Limitation

Except as discussed below, there are no additional numeric effluent limitations under this section beyond those stated in section V.B of today's permit. Part XI.J.4. of today's permit establishes numeric effluent limitations for mine dewatering discharges that are composed entirely of storm water or ground water seepage from construction sand and gravel, industrial sand and crushed stone mines that are located in Region VI (the States of Louisiana, New Mexico, Oklahoma, and Texas). Discharges from these areas may not exceed a maximum TSS concentration of 45 mg/L for any one day or 25 mg/L for the average of daily values for 30 consecutive days. The pH of the discharges from these areas must be within the range of 6.0 to 9.0. These effluent limitations are in accordance with the Crushed Stone, Construction Sand and Gravel, and Industrial Sand Subcategories of the Mineral Mining and Processing Point Source Categories (40 CFR 436.20, 436.30 and 40 CFR 436.40). These limitations represent the degree of effluent reduction attainable by the application of best practicable control technology and best conventional pollutant control technology. Dischargers subject to these numeric effluent limitations must be in compliance with the limits upon commencement of and for the entire term of this permit.

6. Monitoring and Reporting Requirements

a. Monitoring Requirements. Under the revised methodology for determining pollutants of concern in the various industrial categories, dimension and crushed stone and nonmetallic minerals (except fuels) mining and sand and gravel mining facilities are required to monitor for the pollutants listed in the applicable table below (Table J–6 or J–7). The pollutants listed in this table were found to be above benchmark levels. EPA is requiring monitoring after the pollution prevention plan has been implemented to assess the effectiveness of the pollution prevention plan and to help ensure that a reduction of pollutants is realized.

TABLE J–6.—MONITORING REQUIREMENTS FOR DIMENSION AND CRUSHED STONE AND NONMETALLIC MINERALS (EXCEPT FUELS) (MG/L)

Pollutant of concern	Monitoring cut-off concentration
Total suspended solids.	100 mg/L.

R0016208

TABLE J-7.—MONITORING REQUIREMENTS FOR SAND AND GRAVEL MINING

Pollutants of concern	Monitoring cut-off concentration
Total suspended solids.	100 mg/L.
Nitrate plus Nitrite Nitrogen.	0.68 mg/L.

At a minimum, storm water discharges from dimension and crushed stone, sand and gravel and nonmetallic mineral (except fuels) mining must be monitored quarterly during the second year of permit coverage. Samples must be collected at least once in each of the following periods: January through March; April through June; July through September; and October through December. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in the applicable table (Table J-6 or J-7). If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

If the average concentration for a parameter is less than or equal to the cut-off concentration, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit. The schedule for monitoring is presented in Table J-8.

TABLE J-8.—SCHEDULE OF MONITORING

2nd year of permit coverage.	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Table J-6 or J-7, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Table J-6 or J-7, then no further sampling is required for that parameter.
4th year of permit coverage.	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Table J-6 or J-7. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will be used to reassess the effectiveness of the adjusted pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

Alternative Certification. Throughout today's permit, EPA has included monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative certification described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall or on a pollutant-by-pollutant basis in lieu of monitoring reports described in paragraph (*2*) below, under penalty of law, signed in accordance with Part VII.G. (Signatory Requirements), that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity, and that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in lieu of monitoring reports required under paragraph (*2*) below. The permittee is required to complete any and all sampling until the exposure is eliminated. If the facility is reporting for a partial year, the permittee must specify the date exposure was eliminated. If the permittee is certifying that a pollutant was present for part of the reporting period, nothing relieves the permittee from the responsibility to sample that parameter up until the exposure was eliminated and it was determined that no significant materials remained. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

(2) Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one signed Discharge Monitoring Report Form must be submitted to the Director per storm event sampled. For facilities conducting monitoring beyond the minimum requirements, an additional signed Discharge Monitoring Report Form must be filed for each analysis. The permittee must include a measurement or estimate of the total precipitation, volume of runoff, and peak flow rate of runoff for each storm event sampled.

(3) Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-

hour interval is representative for local storm events during the season when sampling is being conducted. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. if the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable.

If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable, permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

(4) Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

(5) Adverse Conditions. When a discharger is unable to collect samples within a specified sampling period due to adverse climatic conditions, the discharger shall collect a substitute sample from a separate qualifying event in the next period and submit the data along with data for the routine sample in that period. Adverse weather conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

B. Quarterly Visual Examination of Storm Water Quality. Mineral mining and processing facilities shall perform and document a visual examination of a storm water discharge associated with industrial activity from each outfall, except discharges exempted below. The examination(s) must be made at least once in each of the following three-month periods: January through March, April through June, July through September, and October through December. The examination shall be made during daylight hours unless there is insufficient rainfall or snow melt to produce a runoff event.

(1) Examinations shall be made of grab samples collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 1 hour) or when the runoff or snowmelt begins discharging. The examinations shall document observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on the samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. Where practicable, the same individual should carry out the collection and examination of discharges for entire permit term.

(2) Visual examination reports must be maintained onsite in the pollution prevention plan. The report shall include the examination date and time, examination personnel, the nature of the discharge (i.e., runoff or snow melt), visual quality of the storm water discharge (including observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution), and probable sources of any observed storm water contamination.

(3) When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may collect a sample of effluent of one of such outfalls and report that the examination data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluents. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

(4) When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination and retain this documentation onsite with the records of the visual examinations. Adverse weather conditions that may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes,electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

(5) EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

EPA believes that this quick and simple assessment will help the permittee to determine the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examinations. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and the effects of the management practices that are included in the plan.

EPA believes that between quarterly visual examinations, site compliance evaluations and the limited analytical monitoring required of the specified subsectors, potential sources of contaminants can be recognized, addressed, and then controlled with BMPs. In determining the monitoring requirements, EPA considered the nature of the industrial activities and significant materials exposed at these sites and performed a review of data provided in Part 2 group applications.

c. Compliance Monitoring Requirements. Today's permit requires permittees with mine dewatering discharges from construction sand and gravel, industrial sand, and crushed stone mine facilities to monitor for the presence of TSS and pH. These monitoring requirements are necessary to evaluate compliance with the numeric effluent limitation established for these discharges. Monitoring shall be performed quarterly upon a minimum of one grab sample. All samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable. Monitoring results shall be submitted on signed Discharge Monitoring Report Form(s) postmarked no later than the 31st day of the month following collection of the sample. Facilities which discharge through a large or medium municipal separate storm sewer system (systems serving a population of 100,000 or more) must also submit signed copies of discharge monitoring reports to the operator of the municipal separate storm sewer system.

Alternative Certification provisions described in Section XI.J.5 do not apply to facilities subject to compliance monitoring requirements in this section. Compliance monitoring is required at least annually for discharges subject to effluent limitations. Therefore, EPA cannot permit a facility to waive compliance monitoring.

Construction sand and gravel, industrial sand and crushed stone mining facilities are not required to collect and analyze separate samples for the presence of TSS to satisfy the Compliance Monitoring requirements of Section XI.J.5.d. during a year in which the facilities have collected and analyzed samples for TSS in accordance with the Analytical Monitoring requirements of Section XI.J.5.a. The results of all TSS Analytical Monitoring analyses may also be reported as Compliance Monitoring results in accordance with Section XI.J.5.d.(3) where the monitoring methodologies are consistent.

7. Definitions

"Overburden" means any material of any nature, consolidated or unconsolidated, that overlies a mineral deposit, excluding topsoil or similar naturally occurring surface materials that are not disturbed by mining operations.

"Overflow" means a precipitation induced overflow of a facility that is designed, constructed, and maintained to contain, or treat, the volume of wastewater which would result from 10-year, 24-hour precipitation events.

Storm Water Discharges Associated With Industrial Activity from Hazardous Waste Treatment, Storage, or Disposal Facilities

Industry Profile

On November 16, 1990 (55 FR 47990), EPA promulgated the regulatory definition of "storm water discharge associated with industrial activity." This definition includes point source discharges of storm water from 11 categories of facilities, including "* * * (iv) Hazardous waste treatment, storage, or disposal facilities, including those that are operating under interim status or a permit under Subtitle C of RCRA * * * ." Part XI.K. of today's permit only covers storm water discharges from facilities that treat, store, or dispose of hazardous wastes.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

Some industrial facilities that generate hazardous waste have onsite capacity to store, treat, and even dispose of their waste. Many hazardous waste generators, however, send their waste offsite to a treatment, storage, or disposal facility (TSDF). Generators of hazardous waste must arrange for a transporter who has obtained an EPA ID number to transport the generator's waste to a designated facility (i.e., a facility that is permitted under RCRA to receive and treat, store, or dispose of hazardous waste).

Once wastes are accepted by the TSDF, any number of activities may follow. For example, some wastes are disposed without any intervening storage or treatment, while other wastes are held in storage prior to treatment or disposal. Hazardous wastes are generally stored in containers and tanks, which are enclosed by a bermed area to prevent any releases to the environment from the storage units.

The processes for treating hazardous wastes can be divided into two major categories based on whether the waste is organic or inorganic in nature. Organic wastes are treated by destructive technologies, like incineration, whereas inorganic wastes are treated using fixation technologies, like stabilization, in which the hazardous constituents are immobilized in the residual matrix. Residuals from fixation processes are usually land-disposed where the stabilized constituents are much less likely to leach into the environment.

As mentioned above, some wastes are treated prior to disposal while others are disposed as-generated. Hazardous waste disposal units include landfills, surface impoundments, waste piles, and land treatment units. Such disposal units may have specific requirements under RCRA Subtitle D. Wastes are also disposed by being burned in incinerators. Some liquid hazardous wastes are underground-injected into deep wells regulated under the Underground Injection Control (UIC) program in 40 CFR Parts 144 to 148. The RCRA regulations governing the different types of hazardous waste treatment, storage, and disposal units are located in 40 CFR Part 264, Subparts I through O and Subpart W.

Hazardous wastes are also recycled at TSDFs. Recycling is considered a form of treatment, however, the recycling process itself is not generally regulated under RCRA. Recycling activities include reclamation, regeneration, reuse, burning for energy or materials recovery, and use in a manner constituting disposal (i.e., land application of hazardous waste or products containing hazardous waste).

2. Pollutants in Storm Water Discharges Associated With Hazardous Waste Treatment, Storage, or Disposal Facilities

Given the diversity and amount of hazardous wastes handled at TSDFs, pollutants in storm water discharges may vary considerably. Contaminated storm water discharges may result from precipitation coming in contact with spills or leaks of hazardous waste. TSDFs regulated under RCRA Subtitle C, however, are required to control much of their storm water runoff through secondary containment (e.g., secondary containment for tank systems; 40 CFR 264.193). When a spill of a listed hazardous waste occurs, for example, the spilled material and any storm water that comes into contact with the material is a hazardous waste under RCRA and must be cleaned up and managed in accordance with all applicable regulations.

In addition to the types of hazardous materials handled and the procedures for controlling runoff at a particular TSDF, several other factors influence to what extent significant materials from these types of facilities and processing operations can affect water quality. Such factors include: hydrology/geology; volume of wastes handled; extent of industrial activities at a TSDF (i.e., only storage, or storage plus treatment and disposal); and type, duration, and intensity of precipitation events. These and other factors will interact to influence the quantity and quality of storm water runoff. In addition, sources of pollutants other than storm water, such as illicit connections,[16] spills, and other improperly dumped materials, may increase the pollutant loadings discharged into waters of the United States.

Pollutants in storm water discharges from TSDFs may consist of, in the case of spills or leaks which are not properly contained or cleaned up, hazardous wastes and/or their constituents. 40 CFR Part 261 Subpart D contains the lists of hazardous wastes, and Appendix VII to Part 261 is a list of the hazardous constituents for which each of these wastes is listed.

Based on the similarities of the facilities included in this sector in terms of industrial activities and significant materials, EPA believes it is appropriate to discuss the potential pollutants at TSDFs facilities as a whole and not subdivide this sector. Therefore, Table K–1 lists data for selected parameters from facilities in the TSDF sector. These data include the eight pollutants that all facilities were required to monitor for under Form 2F.

TABLE K–1.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY HAZARDOUS WASTE TREATMENT STORAGE OR DISPOSAL FACILITIES SUBMITTING PART II SAMPLING DATA [i] (mg/L)

Pollutant	No. of facilities		No. of Samples		Mean		Minimum		Maximum		Median		95th Percentile		99th Percentile	
Sample type	Grab	Comp[ii]	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp
BOD_5	3	4	8	9	17.8	9.44	0.0	0.0	45.0	45.0	11.5	7.0	49.7	35.7	82.3	62.9
COD	3	4	8	9	117.6	51.9	12.0	10.0	500.0	131.0	56.5	45.0	419.2	158.9	910.3	285.8
Nitrate + Nitrite Nitrogen	4	4	9	9	0.46	0.39	0.15	0.07	0.79	0.67	0.47	0.34	1.07	1.06	1.59	1.72
Total Kjeldahl Nitrogen	4	4	9	9	1.43	1.07	0.64	0.25	3.00	3.92	1.30	0.92	2.64	2.96	3.52	5.21

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.
[ii] Composite samples.

3. Pollutant Control Measures Required Through Other EPA Programs

As part of the RCRA program, 40 CFR Part 264 sets standards for treatment, storage and disposal facilities. EPA realizes that some of the conditions of this section are already addressed by the requirements set forth in Part 264. Under the RCRA program, for example, secondary containment is required for tank systems in order to prevent the release of hazardous waste or hazardous constituents to the environment. Such secondary containment must either be capable of preventing storm water runon from entering the system, or have the capacity to contain the volume of the tank plus precipitation from a 25-year, 24-hour rainfall event (40 CFR 264.193).

Conditions such as those set forth for secondary containment at TSDFs are pertinent because they may overlap with aspects of the pollution prevention plan (PPP) required as part of this section. Therefore, in developing a storm water pollution prevention plan, a TSDF should include as Best Management Practices (BMPs) any controls relevant to storm water that have already been implemented under 40 CFR Part 264.

Other areas where RCRA requirements may overlap with the conditions set forth in this section include inspections and employee training. Daily and weekly inspections of tank systems and containers are required, respectively, under Part 264. Therefore, these inspections will be incorporated into the pollution prevention plan for this storm water permit. Similarly, employee training, required under 40 CFR 264.16, does not need to be repeated as part of implementation of the pollution prevention plan, but rather expanded as necessary to include issues concerning storm water management.

4. Options for Controlling Pollutants

In evaluating options for controlling pollutants in storm water discharges, EPA must achieve compliance with the

[16] Illicit connections are contributions of unpermitted non-storm water discharges to storm sewers from any of a number of sources including sanitary sewers, industrial facilities, commercial establishments, or residential dwellings. The probability of illicit connections at mineral mining and processing facilities is low yet it still may be applicable at some operations.

R0016212

technology-based standards of the Clean Water Act [Best Available Technology (BAT) and Best Conventional Technology (BCT)]. The Agency does not believe that it is appropriate to establish specific numeric effluent limitations or a specific design or performance standard in this section for storm water discharges associated with industrial activity from hazardous waste treatment, storage, and disposal facilities to meet BAT/BCT standards of the Clean Water Act at this time. Instead, this section establishes requirements for the development and implementation of site-specific storm water pollution prevention plans consisting of a set of Best Management Practices (BMPs) that are sufficiently flexible to address different sources of pollutants at different sites.

Generally, BMPs are implemented to prevent and/or minimize exposure of pollutants from industrial activities to storm water discharges. EPA believes the most effective BMPs for reducing pollutants in storm water discharges are exposure minimization practices. Exposure minimization practices lessen the potential for storm water to come into contact with pollutants. Good housekeeping practices ensure that facilities are sensitive to routine and nonroutine activities which may increase pollutants in storm water discharges. The BMPs which address good housekeeping and exposure minimization are easily implemented, inexpensive, and require little, if any, maintenance. BMP expenses may include construction of roofs for storage areas or other forms of permanent cover and the installation of berms/dikes. Other BMPs such as detention/retention ponds and filtering devices may be needed at these facilities because of the contaminant level in the storm water discharges.

The selection of the most effective BMPs will be based on site-specific considerations such as: facility size, climate, geographic location, hydrogeology and the environmental setting of each facility, and volume and type of discharge generated. Each facility will be unique in that the source, type, and volume of contaminated storm water discharges will differ. In addition, the fate and transport of pollutants in these discharges will vary. EPA believes that the management practices discussed herein are well suited mechanisms to prevent or control the contamination of storm water discharges associated with hazardous waste treatment, storage, or disposal facilities that are not already addressed by RCRA subtitle C.

Facilities covered under this section must already be in compliance with the standards for operating a hazardous waste treatment, storage, or disposal facility as established by 40 CFR Part 264. As discussed in greater detail in the previous section (Pollutant Control Measures Required Through Other EPA Programs), EPA believes that because of the requirements previously imposed on hazardous waste treatment, storage, or disposal facilities, storm water BMPs are already employed at most TSDFs. This belief is supported by part 1 group application data, which indicated that 97 percent of the representative sampling facilities already have SPCC plans in place at their sites.

Because of the potential for spills of hazardous materials during loading and unloading operations, and the absence of an individual discussion of these operations in 40 CFR Part 264, Table K–2 is provided to identify BMPs associated with these activities at hazardous waste treatment, storage, or disposal facilities.

TABLE K–2.—GENERAL LOADING AND UNLOADING STORM WATER BMPS FOR HAZARDOUS WASTE TREATMENT, STORAGE, OR DISPOSAL FACILITIES

Activity	Best management practices (BMPs)
Outdoor Unloading and Loading	Confine loading/unloading activities to a designated area. Consider performing loading/unloading activities indoors or in a covered area. Consider covering loading/unloading area with permanent cover (e.g., roofs) or temporary cover (e.g., tarps). Close storm drains during loading/unloading activities in surrounding areas. Avoid loading/unloading materials in the rain. Inspect the unloading/loading areas to detect problems before they occur. Inspect all containers prior to loading/unloading of any raw or spent materials. Consider berming, curbing, or diking loading/unloading areas. Use dry clean-up methods instead of washing the areas down. Train employees on proper loading/unloading techniques.

Sources: NPDES Storm Water Group Applications—Part 1. Received by EPA, March 18, 1991 through December 31, 1992 EPA, Office of Water. September 1992. "Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices." EPA 832–R–92–006.

5. Storm Water Pollution Prevention Plan Requirements.

EPA believes that pollution prevention is the most effective approach for controlling contaminated storm water discharges from hazardous waste treatment, storage, or disposal facilities. The requirements included in the pollution prevention plans provide a flexible framework for the development and implementation of site-specific controls to minimize the pollutants in storm water discharges. This flexibility is necessary because each facility is unique in that the source, type, and volume of contaminated storm water discharge will vary from site to site.

There are two major objectives to a pollution prevention plan: (1) to identify sources of pollution potentially affecting the quality of storm water discharges associated with industrial activity from a facility; and (2) to describe and ensure implementation of practices to minimize and control pollutants in storm water discharges associated with industrial activity from a facility.

The pollution prevention plan requirement reflects EPA's decision to allow hazardous waste treatment, storage, or disposal facilities to utilize BMPs as the BAT/BCT level of control for the storm water discharges covered by this section.

As previously discussed, many of the storm water pollution prevention plan requirements discussed in this section of today's permit and fact sheet are already addressed by the RCRA program and employed at hazardous waste treatment, storage, or disposal facilities. Please note that if RCRA does not address a particular condition which is stipulated in the storm water pollution prevention plan, the facility still must comply with that requirement of the plan.

6. Numeric Effluent Limitations.

There are no additional requirements under this section other than those stated in Part V.B of the permit.

7. Monitoring and Reporting Requirements

a. Analytical Monitoring Requirements. EPA believes that treatment, storage, or disposal facilities (TSDFs) may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. In order to provide a tool for evaluating the effectiveness of the pollution prevention plan and to characterize the discharge for potential environmental impacts, the permit requires TSDFs to collect and analyze samples of their storm water discharges for the pollutants listed in Table K–3. The pollutants listed in Table K–3 were not found to be above benchmark levels in the limited amount of data that was submitted in the group application process, but are believed to be present based upon the description of industrial activities and significant materials exposed. EPA is requiring monitoring after the pollution prevention plan has been implemented to assess the effectiveness of the pollution prevention plan and to help ensure that a reduction of pollutants is realized.

At a minimum, storm water discharges from TSDFs must be monitored quarterly during the second year of permit coverage. Samples shall be collected at least once in each of the following periods: January through March; April through June; July through September; and October through December. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Table K–3. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE K–3.—Industry Monitoring Requirements

Pollutants of concern	Cut-off concentration (mg/L)
Ammonia	19
Total Recoverable Magnesium*	0.0636
Chemical Oxygen Demand (COD)	120
Total Recoverable Arsenic.	16854
Total Recoverable Cadmium	0.0159
Total Cyanide**	0.0636
Total Recoverable Lead	0.0816
Total Recoverable Mercury	0.0024
Total Recoverable Selenium	0.2385
Total Recoverable Silver	0.0318

*The MDL for magnesium is 0.02 mg/L method 200.6.

**The MDL for cyanide is 0.02 mg/L method 335.1, .2, or .3.

If the average concentration for a parameter is less than or equal to the value listed in Table K–3, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration listed in Table K–3, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit. The schedule for monitoring is presented in Table K–4.

TABLE K–4.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Table K–3, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Table K–3, then no further sampling is required for that parameter.
4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Table K–3. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will reassess the effectiveness of the adjusted pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

b. Alternative Certification. Throughout today's permit, EPA has included monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall or on a pollutant-by-pollutant basis in lieu of monitoring described in Table K–3, under penalty of law, signed in accordance with Part VII.G. (Signatory Requirements), that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity, that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in accordance with Part VI.B. of this permit. In the case of certifying that a pollutant is not present, the permittee must submit the certification along with the monitoring reports required under paragraph (C) below. If the permittee cannot certify for an entire period, they must submit the date exposure was eliminated and any monitoring required up until that date. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

c. Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one signed Discharge Monitoring Report form must be submitted to the Director per storm event sampled. For facilities conducting monitoring beyond the minimum quarterly requirements an additional Discharge Monitoring Report Form must be filed for each analysis.

d. Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable.

If storm water discharges associated with industrial activity commingle with process or non-process water, then where practicable permittees must attempt to sample the storm water discharges before it mixes with the non-storm water discharge.

e. Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

f. Quarterly Visual Examination of Storm Water Quality. Quarterly visual examinations of storm water discharges from each outfall are required at TSDFs. The examination must be of a grab sample collected from each storm water outfall. The examination of storm water grab samples shall include any observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, or other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on these samples.

The examination must be made at least once in each of the following designated periods: January through March; April through June; July through September; and October through December, during daylight unless there is insufficient rainfall or snow-melt to runoff. Whenever practicable, the same individual should carry out the collection and examination of discharges throughout the life of the permit to ensure the greatest degree of consistency possible. Grab samples shall be collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 1 hour) of when the runoff begins discharging. Reports of the visual examination include: the examination date and time, examination personnel, visual quality of the storm water discharge, and probable sources of any observed storm water contamination. The visual examination reports must be maintained onsite with the pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

EPA believes that this quick and simple assessment will allow the permittee to approximate the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the inspections. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of storm water problems on that site and the effects of the management practices that are included in the plan.

When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not collecting samples. Adverse weather conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

8. Region-specific Conditions

Region VI intends for this permit to cover all eligible hazardous waste treatment, storage, and disposal facilities, except those that treat and dispose exclusively commercial hazardous waste. Region VI believes that more careful compliance tracking is warranted for facilities that treat and dispose of commercially produced hazardous waste due to the wide range of chemicals and large quantities of hazardous waste materials that are generally disposed as a service to generators. Region VI has determined this to be a priority industry and required individual permits in the past with limits. This affects permits issued by EPA Region VI for Louisiana (LAR05*###), New Mexico (NMR05*###), Oklahoma (OKR05*###), Texas (TXR05*###), and Federal Indian Reservations in these States (LAR05*##F, NMR05*##F, OKR05*##F, or TXR05*##F).

L. Storm Water Discharges Associated With Industrial Activity From Landfills and Land Application Sites

1. Industry Profile.

This section of today's permit addresses special requirements for storm water discharges associated with industrial activity from landfill and land application sites. Pursuant to 40 CFR 122.26, storm water discharges from landfills, land application sites, and open dumps that receive or have received industrial waste, including sites subject to regulation under Subtitle D of the Resource Conservation and Recovery Act (RCRA), are required to seek permit coverage. Under this section, industrial waste is defined as waste generated by any of the industrial activities described at 40 CFR 122.26(b)(14).

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

Special conditions contained in this section apply to land disposal sites that meet the definition of a landfill under RCRA Subtitle D contained at 40 CFR Part 257, which establishes criteria for the classification of solid waste disposal facilities and practices. Part 257 defines landfills as areas of land or excavation in which wastes are placed for permanent disposal, and that are not land application units, surface impoundments, injection wells, or waste piles. Included in this definition are municipal solid waste landfills (MSWLFs) and industrial solid nonhazardous waste landfills. (Many of the 1,410 landfill facilities participating in the group application process are classified as MSWLFs). Therefore, the special conditions in this section apply to both MSWLFs and industrial landfills as defined under Part 257. This section also applies to industrial waste land application sites. Land application sites are defined as facilities at which wastes are applied onto or incorporated into the soil surface for the purpose of beneficial use or waste treatment and disposal. No open dumps were included in the facilities participating in the group application process (open dumps are defined as solid waste disposal units not in compliance with State/Federal criteria established under RCRA Subtitle D) and operation of an open dump is prohibited under RCRA Section 4004. Therefore, storm water discharges from open dumps are not addressed by this section. This section also does not apply to inactive landfills or inactive land application sites located on Federal lands, unless an operator can be identified. These discharges are more appropriately covered under a permit currently being developed by EPA.

The following sections describe industrial and municipal solid waste landfills and industrial waste land application sites.

a. Municipal Solid Waste Landfills. In 1988, EPA estimated that there were approximately 9,300 MSWLFs in the United States. The wastes which are disposed of in MSWLF landfills are highly variable. Examples include household waste (including household hazardous waste which is excluded from RCRA hazardous waste regulation), nonhazardous incinerator ashes, commercial wastes, yard wastes, tires, white goods, construction wastes, municipal and industrial sludges, asbestos, and other industrial wastes. Only a small percentage of all wastes disposed of in MSWLFs are industrial wastes. In 1988, EPA's Report to Congress on solid waste generation indicated that nearly 90 percent of wastes disposed of in all MSWLFs were household or commercial (office) wastes. Industrial process wastes represented only 2.73 percent of the total wastestream (although most MSWLFs currently or have previously accepted industrial wastes and are therefore subject to storm water permitting requirements). The Report also indicated that about half of the total number of MSWLFs received small quantity generator hazardous wastes. In addition, MSWLFs that operated prior to the implementation of RCRA hazardous waste management requirements in 1980 may have received wastes that after that date that would have been classified as hazardous wastes under current RCRA requirements.

A typical MSWLF is a constantly evolving facility which is constructed over its operating life as received wastes are spread, compacted, and covered. Most modern landfills contain one or more separate "units," planned final waste containment areas. Active units continue to receive wastes until they have reached disposal capacity. When capacity is reached, a unit is capped with a final cover, and additional wastes must be placed in other active units. As a result, a landfill may consist of multiple inactive and active units at various stages of completion.

Within each unit, wastes are added in layers referred to as lifts. Received wastes are spread across the working face of the landfill to a depth of six to twenty feet and then compacted. At the end of each working day a thin layer of soil (daily cover) is spread on top of the added wastes and compacted. A large unit may consist of multiple lifts, depending on the planned final depth.

Historically, landfills have been constructed according to one of two generic designs, the trench method and the area method, or a combination of these. The trench method requires the excavation of a trench into which wastes will be placed. Soil from the excavation provides the cover material as disposal continues. In the area method, wastes are placed directly on the ground surface and disposal follows the natural contours of the land. Some landfills use combinations of the two methods at different times depending on the location of the active unit.

MSWLF construction creates constant changes in the contours of the facility resulting in changing patterns of storm water runon and runoff. Controlling erosion of landfill slopes is among the primary concerns of the landfill operator. Current practices generally include a combination of temporary controls (straw bales, silt fences, etc.), in active disposal areas, and permanent controls (recontouring, revegetation, etc.), in areas where waste disposal has been completed.

Daily and intermediate covers serve primarily to protect against disease vectors and to prevent fires and the blowing of refuse. Typically, daily covers consist of the minimum amount of soil excavated from the site needed to cover exposed wastes in the active areas of the landfill. After spreading, the cover is usually compacted to reduce loss from erosion. Intermediate covers, which are also typically soil excavated from the site, are often applied to areas of a unit which will be inactive for periods of 30 days or more. Deeper than daily covers, intermediate covers may be applied in conjunction with runoff control measures to minimize pooling and high-velocity flow patterns. Both daily and intermediate covers promote infiltration to some extent, depending on depth and soil material.

When a landfill (or landfill unit) has reached disposal capacity, a final cover is applied. Final covers generally provide a relatively impermeable cap over which topsoil is placed and vegetation is established. Permanent runoff controls (diversion channels, recontouring, terracing, etc.) may be constructed to minimize erosion and ponding. Final cover materials in older landfills, which are generally subject to limited regulatory requirements, often consist of a single layer of natural soils. However, at newer landfills subject to more stringent regulatory requirements, other cover materials (polymers, sand and gravel, sewage sludge, etc.) are frequently combined with soil in multiple layers.[84]

b. Industrial Landfills. Industrial landfills only receive wastes from industrial facilities such as factories, processing plants, and manufacturing sites. These facilities may also receive hazardous wastes from very small quantity hazardous waste generators (less than 100 kilograms per month), as defined in RCRA Subtitle C. Included in these waste streams are some PCB-contaminated wastes. The Toxic Substances Control Act PCB disposal regulations allow limited categories of PCB materials to be disposed of in RCRA Subtitle D landfills.[85] In 1988, EPA estimated that there were at least 3,511 industrial Subtitle D landfills (this would presumably be the maximum number of non-MSWLF facilities regulated by the storm water program). The specific number of these units that are onsite and offsite facilities (i.e., centralized waste management units) was not available. Because wastes generated by industrial facilities vary considerably, both between and within industries, the wastes disposed of at industrial landfills can be highly variable. For example, the industrial nonhazardous waste category includes wastes from the pulp and paper industry, the organic chemical industry, the textile manufacturing industry, and a variety of other industries. Consequently, these waste streams may vary in chemical composition and/or physical form. Most industrial landfills are privately owned.[86]

Currently, there are limited data available on industrial landfills. Specific industrial waste streams have not been well characterized and little is known about the hazards they may pose. Limited data are also available regarding the design, operation, and location of these facilities. It has been documented, however, that there has been only sporadic application of design and operating controls at industrial landfills. In 1988, only about 12 percent of industrial landfills (including both onsite and offsite facilities) had any type of liner, and fewer than 35 percent employed runon/runoff controls.[87] The use of these controls (including runon and runoff controls) at industrial waste landfills is likely to increase as State industrial waste programs continue to evolve.

c. Land Application Sites. In 1988, EPA estimated that there were approximately 5,605 land application sites in the United States. These sites receive wastes (primarily wastewaters and sludges) from facilities in virtually every major industrial category. More than half of all land application sites cover less than 50 acres and receive less than 50 tons of waste annually. The largest number of active land application sites in 1988 were observed in the food and kindred products industry, however the pulp and paper industry managed the largest gross quantity of waste using this practice. Similar to landfills, the variability in types of waste that are land applied precludes any general characterization of the materials that may be exposed to storm water. Typically, individual land applications will only dispose of wastes with specific characteristics. However, the criteria for selection are site-specific depending on type of process used and the soil characteristics. Waste application techniques are dependent on waste characteristics.

In 1988, EPA found that 68.5 percent of all industrial waste land application units had runon and runoff controls. No information was available on the extent of closure requirements applicable to land application units.

2. Potential Pollutant Sources and Options for Controlling Pollutants at Landfill and Land Application Sites

a. Landfills. At landfill sites, runoff carrying suspended sediments and commingling of runoff with uncontrolled leachate are the two primary sources of pollutants that this section is intended to address. Other potential sources of pollutants at landfills, those from ancillary areas of the landfill and which are not directly associated with landfill activities (i.e., vehicle maintenance, truck washing, etc.) may be subject to requirements in other sections of today's permit.

Total Suspended Solids. Storm water discharges from landfill sites often contain high TSS levels because of the extensive land disturbance activities associated with landfill operations. Suspended solids can adversely affect fisheries by covering the bottom of a stream or lake with a blanket of material that destroys the fish food bottom fauna or spawning grounds. In addition, while they remain in suspension, suspended solids can increase turbidity, reduce light penetration, and impair the photosynthetic activity of aquatic plants.[88] Specific sources of TSS loadings from landfill operations and typical Best Management Practices (BMPs) used to control TSS levels in storm water runoff are shown in Table L–1. The listed BMPs are consistent with the BMPs identified in part 1 of the permit applications submitted by landfill group applicants.

TABLE L–1.—SOURCES OF TSS LOADINGS AND TYPICAL BMPs USED FOR EROSION CONTROL AT LANDFILLS

Potential pollutant sources	BMPs
Erosion from: Exposed soil from excavating cells/trenches. Exposed stockpiles of cover materials. Inactive cells with final cover but not yet finally stabilized. Daily or intermediate cover placed on cells or trenches. Erosion from haul roads (including vehicle tracking of sediments).	Stabilize soils with temporary seeding, mulching, and geotextiles; leave vegetative filter strips along streams. Implement structural controls such as dikes, swales, silt fences, filter berms, sediment traps and ponds, outlet protection, pipe slope drains, check dams, and terraces to convey runoff, to divert storm water flows away from areas susceptible to erosion, and to prevent sediments from entering water bodies. Frequently inspect all stabilization and structural erosion control measures and perform all necessary maintenance and repairs. Stabilize haul roads and entrances to landfill with gravel or stone. Construct vegetated swales along road. Clean wheels and body of trucks or other equipment as necessary to minimize sediment tracking (but contain any wash waters [process wastewaters]). Frequently inspect all stabilization and structural erosion control measures and perform all necessary maintenance and repairs.

(2) *Other Pollutants.* Table L–2 presents potential sources of other pollutants in storm water discharges from landfill operations. The specific pollutants associated with each of these sources are highly variable, depending upon individual site operations and waste types received. Table L–2 also lists BMPs that would be expected to be used in these areas to minimize potential pollutant loadings. Several of these BMPs were identified in the group permit applications submitted by landfill operators.

TABLE L–2.—SOURCES AND BMP CONTROLS OF POTENTIAL POLLUTANTS (OTHER THAN TSS)

Potential pollutant source	BMPs
Application of fertilizers, pesticides, and herbicides.	Observe all applicable Federal, State, and local regulations when using these products. Strictly follow recommended application rates and methods (i.e., do not apply in excess of vegetative requirements).
Exposure of chemical material storage areas to precipitation (including pesticides, fertilizers, and herbicides).	Have materials such as absorbent pads easily accessible to clean up spills. Provide barriers such as dikes to contain spills. Provide cover for outside storage areas.
Exposure of waste at open face	Have materials such as absorbent pads easily accessible to clean up spills. Minimize the area of exposed open face as much as is practicable. Divert flows around open face using structural measures such as dikes, berms, swales, and pipe slope drains. Frequently inspect erosion and sedimentation controls.
Waste tracking onsite and haul roads, solids transport on wheels and exterior of trucks or other equipment (common with incinerator ash).	Clean wheels and exterior of trucks or other equipment as necessary to minimize waste tracking (but contain any wash waters [process wastewaters]).
Uncontrolled leachate (commingling of leachate with runoff or runon).	Frequently inspect leachate collection system and landfill for leachate leaks. Maintain landfill cover and vegetation. Maintain leachate collection system.

Based on the similarities of the facilities included in this sector in terms of industrial activities and significant materials, EPA believes it is appropriate to discuss the potential pollutants at landfills and land applications sites as a whole and not subdivide this sector. Therefore, Table L–3 lists data for selected parameters from facilities in the landfill and land application sector. These data include the eight pollutants that all facilities were required to monitor for under Form 2F, as well as any pollutants that EPA has determined may merit further monitoring.

TABLE L–3.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY LANDFILLS AND LAND APPLICATION SITES SUBMITTING PART II SAMPLING DATA [i] (mg/L)

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.

[ii] Composite samples.

b. Land Application Sites. At land application sites, TSS may also be found at elevated levels in storm water discharges (because of the extensive soil disturbance). The occurrence and levels of other pollutants in storm water discharges are dependent on the types of wastes applied and facility design and operation (including use of storm water management/treatment practices. No part 2 data for TSS or any other pollutants were submitted for land application sites nor was such data available from other sources.

There are no Federal criteria for industrial landfill or land application unit design, operation, closure or post-closure care. State programs that address industrial landfills and land application sites vary considerably. As noted above, in 1988, only 35 percent of all industrial landfills had runon/runoff controls. However, many are subject to closure requirements.

3. Pollutant Control Measures Required by Other EPA Programs

EPA recognizes that requirements under other Federal and State programs currently address reclamation/closure of and storm water management at landfill and land application sites. In developing requirements under this section, the Agency has considered how these other program requirements affect the characteristics of storm water discharges (e.g., by limiting contact with potential pollutant sources). Of specific note are recently imposed RCRA criteria at 40 CFR Parts 257 and 258 that address the design, operation, and closure of MSWLFs. These regulations are summarized below.

Regulations at 40 CFR Part 257 classify solid waste disposal facilities and practices. Regulations at 40 CFR Part 258 establish criteria for municipal solid waste landfills. The types of criteria required include: location restrictions, operating criteria, design criteria, ground water monitoring and corrective action, closure and postclosure care, and financial assurance criteria. All States must implement the Federal MSWLF criteria primarily through State solid waste management plans.

As part of the operating criteria, Part 258 requires that all discrete units within MSWLFs receiving waste provide for the following by October 1993 (it should be noted that EPA has proposed an extension of this deadline to April 1994):

(a) Owners or operators of all MSWLF units must design, construct, and maintain:

(1) A runon control system to prevent flow onto the active portion of the landfill during the peak discharge from a 25-year storm:

(2) A runoff control system from the active portion of the landfill to collect and control at least the water volume resulting from a 24-hour, 25-year storm event.

In addition, all MSWLF units that received wastes after October 1991 are required to meet specific closure standards (see 40 CFR 258.60). These standards include installation of a final cover consisting of a minimum of 6 inches of topsoil over a minimum of 18 inches of clay. The cover must be no more permeable than the unit's liner. The criteria also imply, but do not explicitly require, that revegetation should be performed.

These criteria indicate that for all but the most severe storm events (i.e., greater than the 24-hour, 25-year storm event), new units within MSWLFs will be required to separate storm water discharges from active and inactive areas. (Active areas are defined as those that have not yet received a final cover [as required under 258.60].) Further, the closure/final cover criteria described above are intended to prevent contact with waste materials and minimize erosion.

4. Storm Water Pollution Prevention Plans Requirements

The requirements for storm water pollution prevention plans under this section build upon the requirements included in the common pollution prevention requirements discussed in the front of this fact sheet. As such, the following discussion focuses on the plan requirements that are specific to landfills and land application sites. The rationale for the common requirements applicable to all types of facilities covered under today's permit (including landfills) is provided in Part VI of this fact sheet.

a. Description of Potential Pollutant Sources. The first step in preventing pollution of storm water from landfills is to identify potential sources of storm water contamination. Consequently, EPA is requiring that landfill and land application site operators include, in their pollution prevention plan, a narrative description of activities at their facilities. The Agency is also requiring landfill permittees to identify on a site map the locations of active and closed cells or trenches, any known leachate springs or other areas where leachate may commingle with runoff, the locations of any leachate collection and handling systems, and the locations of stockpiles of landfill cover material. The Agency is requiring land application site permittees to identify on their site maps the locations of active and inactive land application areas and the types of wastes applied in those areas, any known leachate springs or other areas where leachate may commingle with runoff, the locations of any leachate collection and handling systems, and the locations of temporary waste storage areas. EPA believes these requirements will, in the event contamination is detected in storm water, facilitate the identification of any source of contamination.

EPA is also requiring owners or operators to summarize all available sampling data for storm water and leachate generated at the site because the Agency believes these data will help to determine whether storm water is commingling with any leachate produced at the site. Finally, operators must identify any current NPDES-permitted discharges at their sites.

b. Measures and Controls. EPA is requiring good housekeeping practices for materials storage areas exposed to precipitation and for vehicle tracking of sediment and waste. EPA believes good housekeeping practices provide a simple and inexpensive means of controlling pollutants from entering storm water and therefore will not be overly burdensome to regulated facilities.

EPA believes that frequent and thorough inspections are necessary to ensure adequate functioning of: sediment and erosion controls, leachate collection systems, intermediate and final covers, and significant materials storage containers. Failure of any of the aforementioned items could cause contamination of storm water with sediment, leachate, or significant materials stored onsite. EPA believes it is necessary to conduct inspections both during storm events and during dry weather. Inspections during dry periods allow facilities to identify and address any problems prior to a storm event, thereby minimizing the chance for storm water contamination. Inspections during significant storm events ensure that measures are functioning as originally intended and provide an opportunity for facilities to observe what materials and/or activities are exposed to storm water. Pollution prevention plans must address the specific inspection requirements for active and inactive landfills and land application sites described in Part XI.L.3.a.(3).(d) of today's permit.

Failures of significant materials storage containers, leachate collection and treatment systems, cover materials, and sedimentation and erosion controls can result in storm water contamination. EPA believes it is necessary to maintain these items in good working order to prevent storm water contamination. Consequently, EPA is requiring (in pollution prevention plans) that owners or operators ensure the maintenance of material storage areas to prevent leaking or rupture and all elements of leachate collection and treatment systems to prevent commingling of leachate with storm water. Pollution prevention plans must also describe measures to be taken to protect the integrity and effectiveness of any intermediate and final covers.

EPA believes controls are needed to reduce potential TSS contamination of storm water and to reduce suspended solids which have been carried by storm water before the discharge leaves the site. Therefore, EPA has chosen to require that pollution prevention plans address both stabilization and structural controls to reduce potential TSS loadings to surface waters.

5. Monitoring and Reporting Requirements

a. Analytical Monitoring Requirements. This section establishes separate requirements for municipal solid waste landfills (MSWLFs) and industrial landfills. These requirements are discussed below.

(1) MSWLFs. The Agency believes that the MSWLF criteria in 40 CFR 258.60 will effectively separate runoff from active and inactive areas at newer landfills. As a result, separate requirements have been established for active and inactive areas at MSWLF sites.

For discharges from active landfill areas, the Agency believes that there is reasonable potential for runoff to contact waste materials. In these areas, runoff may also become commingled with leachate. In fact, a significant percentage of landfill facilities that submitted group applications, identified leachate and wastes as "exposed materials." In addition, total suspended solids (TSS) levels are also likely to be elevated where contact occurs with wastes, disturbed areas, and daily/intermediate cover materials.

At this time, the Agency does not believe that there are sufficient data available to establish numeric limits based on best available technology for storm water discharges from active MSWLF areas. The data submitted in the part 2 applications, as well as leachate data from available literature, suggest that a variety of constituents may be present at levels that are highly site-specific depending on the types and extent of contact with exposed wastes and extent of commingling with leachate. Furthermore, the volumes of runoff generated will be dependent on the frequency and intensity of precipitation events. For TSS, little or no data are available to characterize the TSS levels in active landfill area runoff and to assess the performance of treatment technologies/best management practices currently in use.

Therefore, in this section, EPA is requiring that landfill operators develop storm water pollution prevention plans. For active landfill areas, these plans should be tailored toward minimizing contact of storm water with waste materials. The plans should also include design and implementation of best management practices and/or treatment methods to control the pollutants likely to be found in runoff at the site. For the active portion of the landfill, this section also requires quarterly monitoring for TSS and total recoverable iron (see below) to quantify the performance of BMPs/treatment measures. These data may be used in the future in the development of individual and/or general permits to establish numeric limitations based on best available technology. It should also be noted that EPA is currently in the process of developing effluent limitation guidelines for discharges of leachate from waste management facilities (including MSWLFs). Where these effluent guidelines apply to discharges from active areas, facilities will be required to comply with these requirements on the effective date.

For units/areas that ceased receiving wastes after October 1991, EPA believes that closure criteria under 40 CFR 258.60 will minimize or eliminate pollutant loadings from waste materials to storm water. For MSWLF units closed in accordance with these criteria, TSS should be the only pollutant of concern. Again, EPA does not believe that adequate data are currently available to establish a numeric limitation based on best available technology (BAT) for TSS in storm water discharges from inactive areas. TSS concentrations in untreated storm water discharges have not been sufficiently well characterized to address the site-specific variability arising from local geology and topography along with individual cover materials and reclamation practices. Furthermore, the available data do not support an assessment of the relative performance of specific BMPs/treatment measures. Quarterly TSS monitoring is required to provide additional data to evaluate the effectiveness of specific control measures.

The Agency is uncertain whether all MSWLF units which ceased receiving wastes prior to October 1991 will have been closed in such a manner to ensure long term stability and minimize the potential for runoff to contact wastes and leachate. Therefore, operators of units that were closed prior to October 1991 are required to conduct the same monitoring as required for active areas. This monitoring is intended to evaluate the integrity and performance of final cover materials in minimizing pollutant loadings to storm water discharges. Based on the results of this monitoring, the permitting authority may elect to continue/modify or terminate the required monitoring, provide for additional permit conditions (including specific BMPs and/or numeric limitations), or terminate coverage under the permit, as appropriate.

An exception from most monitoring requirements is provided for older landfill areas closed prior to October 1991 in accordance with State requirements that meet or exceed the final cover criteria in 40 CFR 258.60. Similar to newer units, TSS should be the only pollutant of concern at these sites and only quarterly TSS monitoring is required.

(2) Industrial Landfills. As discussed above, minimal data are available to characterize storm water discharges or management practices for industrial solid waste landfills. EPA recognizes that onsite landfills are likely to be dedicated waste management units. However, the 1988 Report to Congress indicates that these onsite units can be found at sites in virtually every major industrial category. Offsite landfills can receive industrial wastes from almost any sources. Further, there are no current or planned Federal minimum requirements for runon/runoff control and closure of these onsite and offsite facilities. As a result, existing State programs vary. Some States have extensive permitting and design standard requirements for industrial landfills, often for specific waste types. In contrast, other States have much more limited industrial solid waste programs.

Because of the variability between sites, the need for representative runoff characterization data, and the lack of information on BMP/treatment method performance, this section does not establish effluent limitations for storm water discharges from industrial landfills. At this time, best available technology shall consist of development and implementation of pollution prevention plans. In addition, to ensure protection of water quality, the Agency has established monitoring requirements based on the potential for elevated TSS levels (due to erosion) and the concern that runoff from industrial landfills may contact waste materials and/or leachate.

(3) Land Application Sites. This section includes the same requirements for land application sites as for industrial landfills (as described above). The Agency does not currently have sufficient data to identify specific pollutants common to land application sites and develop numeric limitations. Therefore, the Agency believes that requiring implementation of pollution prevention plans along with TSS and Total Recoverable iron monitoring requirements is appropriate.

In summary, EPA believes that landfill/land application sites may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. In order to provide a tool for evaluating the effectiveness of the pollution prevention plan and to characterize the discharge for potential environmental impacts, the permit requires landfill/land application sites to collect and analyze samples of their storm water discharges for the pollutants listed in Table L–5.

At a minimum, storm water discharges from landfill/land application sites must be monitored quarterly during the second year of permit coverage. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Table L–5. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE L–5.—INDUSTRY MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Suspended Solids (TSS) [i]	100 mg/L.
Total Recoverable Iron [ii]	1.0 mg/L.

[i] Applicable to all landfill and land application sites.
[ii] Applicable to all facilities except MSWLF areas closed in accordance with 40 CFR 258.60 requirements.

If the average concentration for a parameter is less than or equal to the value listed in Table L–5, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration listed in Table L–5, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit. The schedule of monitoring is presented in Table L–6.

TABLE L–6.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Table L–5, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Table L–5, then no further sampling is required for that parameter.
4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Table L–5. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will reassess the effectiveness of the adjusted pollution prevention plan.

The monitoring cut off concentrations listed in Table L–5 are not numerical effluent limitations. These values represent a level of pollutant discharge which facilities may achieve through the implementation of pollution prevention plans. At least half of the facilities which submitted Part 2 data, reported concentrations greater than or equal to the values listed in Table L–5. Facilities that achieve average discharge concentrations which are less than or equal to the values in Table L–5 are not relieved from the pollution prevention plan requirements or any other requirements of the permit.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

b. Alternative Certification. Throughout today's permit, EPA has included monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall, or on a pollutant-by-pollutant basis in lieu of monitoring reports described in (*c*) below, under penalty of law, signed in accordance with Part VII.G. (Signatory Requirements), that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity, that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in accordance with Part VI.C. of this permit. In the case of certifying that a pollutant is not present, the permittee must submit the certification along with the monitoring reports required under paragraph (*c*) below. If the permittee cannot certify for an entire period, they must submit the date exposure was eliminated and any monitoring required up until that date. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

c. Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. Such permittees must submit monitoring results on signed Discharge Monitoring Report Forms to the Director. For each outfall, one Discharge Monitoring Reporting Form must be submitted per storm event sampled. For facilities conducting monitoring beyond the minimum quarterly requirements an additional Discharge Monitoring Report Form must be filed for each analysis.

d. Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable.

If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

e. Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

f. Quarterly Visual Examination of Storm Water Quality. Landfills and land application sites shall perform and document a visual examination of a storm water discharge associated with industrial activity from each outfall, except discharges exempted under paragraph (3) below. The examination(s) must be made at least once in each of the following three-month periods: January through March, April through June, July through September, and October through December. The examination shall be made during daylight hours unless there is insufficient rainfall or snow melt to produce a runoff event.

(1) Examinations shall be made of grab samples collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 1 hour) of when the runoff or snowmelt begins discharging. The examinations shall document observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on the samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. Where practicable, the same individual should carry out the collection and examination of discharges for entire permit term.

(2) Visual examination reports must be maintained onsite in the pollution prevention plan. The report shall include the examination date and time, examination personnel, the nature of the discharge (i.e., runoff or snow melt), visual quality of the storm water discharge (including observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, and other obvious indicators of storm water pollution), and probable sources of any observed storm water contamination.

(3) When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials,

and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may collect a sample of effluent of one of such outfalls and report that the observation data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluents. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage are (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

(4) When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination and retain this documentation onsite with the records of the visual examinations. Adverse weather conditions that may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

(5) EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

EPA believes that this quick and simple assessment will allow the permittee to approximate the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examinations. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and effects on the management practices that are included in the plan.

M. Storm Water Discharges Associated With Industrial Activity From Automobile Salvage Yards

1. Industry Profile

On November 16, 1990 (55 FR 47990), EPA promulgated the regulatory definition of "storm water discharges associated with industrial activity." This definition included point source discharges of storm water from eleven categories of facilities, including "* * * battery reclaimers, salvage yards, and automobile recyclers, including but limited to those classified as Standard Industrial Classification 5015.* * *"

This section establishes special conditions for the storm water discharges associated with industrial activities at automobile salvage yards. Washwaters from vehicle, equipment, and parts cleaning areas are process wastewaters. Discharges of process wastewater and discharges subject to process wastewater effluent limitation guidelines are not eligible for coverage under this section.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

This section has been developed for storm water discharges associated with activities related to dismantling of used motor vehicles for the purpose of selling parts. As stated above, category (vi) of the definition of storm water discharges associated with industrial activity includes facilities primarily engaged in the wholesale or retail distribution of used motor vehicle parts and classified as SIC code 5015. Dismantlers are a major source for replacement parts for motor vehicles in service.

The following description summarizes operations that might occur at a typical automobile dismantling facility. The primary activity involves the dismantling or wrecking of used motor vehicles. Some facilities, however, perform vehicle maintenance and may rebuild vehicles for resale.

Typically, automobile dismantling facilities receive vehicles that are either uneconomical to run or wrecks that are uneconomical to repair. The nature of operations generally depends on the size and location of the facility. In urban areas where land is more valuable, vehicles are typically dismantled upon arrival, parts are segregated, cleaned, and stored. Remaining hulks are generally sold to scrap dealers rather than stored onsite due to limited space. In more rural areas, discarded vehicles are typically stored on the lot and parts removed as necessary. Remaining hulks are sold to scrap dealers less frequently.

Once a used vehicle is brought to the site, fluids may be drained and the tires, gas tank, radiator, engine and seats may be removed. The dismantler may separate and clean parts. Such cleaning may include steam cleaning of the engine and transmission as well as the use of solvents to remove oil and grease and other residues. Usable parts are then inventoried and stored for resale. The remaining car and/or truck bodies are stored onsite for future sale of the sheet metal and glass. Stripped vehicles and parts that have no resale value are typically crushed and sold to a steel scrapper. Some operations may, however, convert used vehicles and parts into steel scrap as a secondary operation. This is accomplished by incineration, shearing (bale shearer), shredding, or baling.

According to the 1987 census, 6,075 establishments reported SIC code 5015 as their primary SIC code, although some estimates indicate that there may be as many as 11,000 to 12,000 of these facilities.[89] Vehicle wreckers and dismantlers are generally small, privately owned businesses. Most facilities employ 10 or fewer employees and derive the majority of their profits from the sale of usable parts. Only a small percentage of this universe consists of large establishments with fleets of trucks, cranes, mobile balers and computers to maintain inventories of parts.[90]

Table M–1 below lists potential pollutant sources from activities that commonly take place at automobile salvage yards.

[89] "The Automobile Scrap Processing Industry," Howard Ness, P.E., 1984.

[90] Ibid.

TABLE M–1.—COMMON POLLUTANT SOURCES

Activity	Pollutant source	Pollutants
Vehicle Dismantling	Oil, anti-freeze, batteries, gasoline, diesel fuel, hydraulic fluids.	Oil and grease, ethylene glycol, heavy metals.
Used Parts Storage	Batteries, chrome bumpers, wheel balance weights, tires, rims, filters, radiators, catalytic converters, engine blocks, hub caps, doors, drivelines, galvanized metals, mufflers.	Sulfuric acid, galvanized metals, heavy metals, petroleum hydrocarbons, suspended solids.
Outdoor Vehicle and Equipment Storage	Leaking engines, chipping/corroding bumpers, chipping paint, galvanized metal.	Oil and grease, arsenic, organics, heavy metals, TSS.
Vehicle and Equipment Maintenance	Parts cleaning	Chlorinated solvents, oil and grease, heavy metals, acid/alkaline wastes.
	Waste disposal of greasy rags, oil filters, air filters, batteries, hydraulic fluids, transmission fluids, radiator fluids, degreasers.	Oil, heavy metals, chlorinated solvents, acid/alkaline wastes oil, heavy metals, chlorinated solvents, acid/alkaline wastes, ethylene glycol.
	Spills of oil, degreasers, hydraulic fluids, transmission fluid, and radiator fluids.	Oil, arsenic, heavy metals, organics, chlorinated solvents, ethylene glycol
	Fluids replacement, including oil, hydraulic fluids, transmission fluid, and radiator fluids.	Oil, arsenic, heavy metals, organics, chlorinated solvents, ethylene glycol.
Vehicle, Equipment, and Parts Washing Areas.	Washing and steam cleaning waters	Oil and grease, detergents, heavy metals, chlorinated solvents, phosphorus, salts, suspended solids.
Liquid Storage in Above Ground Storage Tanks	External corrosion and structural failure	Fuel, oil and grease, heavy metals, materials being stored.
	Installation problems	Fuel, oil and grease, heavy metals, materials being stored.
	Spills and overfills due to operator error	Fuel, oil and grease, heavy metals, materials being stored.
Illicit Connection to Storm Sewer	Process wastewater	Dependent on operations.
	Sanitary water	Bacteria, biochemical oxygen demand (BOD), suspended solids.
	Floor drain	Oil and grease, heavy metals, chlorinated solvents, fuel, ethylene glycol.
	Vehicle washwaters	Oil and grease, detergents, metals, chlorinated solvents, phosphorus, suspended solids.
	Radiator flushing wastewater	Ethylene glycol.
	Leaking underground storage tanks	Materials stored or previously stored.

2. Pollutants in Storm Water Discharges Associated With Automobile Salvage Yards.

Impacts caused by storm water discharges from automobile salvage yards will vary. Several factors influence to what extent operations at the site can affect water quality. Such factors include: geographic location; hydrogeology; the types of industrial activity occurring outside (e.g., dismantling, vehicle and parts storage, or steam cleaning); the size of the operation; and the type, duration, and intensity of precipitation events. Each of these, and other factors, will interact to influence the quantity and quality of storm water runoff. For example, outdoor storage of leaking engine blocks may be a significant source of pollutants at some facilities, while dismantling operations is the primary source at others. In addition, sources of pollutants other than storm water, such as illicit connections,[91] spills, and other improperly dumped materials, may increase the pollutant loading discharged into waters of the United States.

[91] Illicit connections are contributions of unpermitted non-storm water discharges to storm sewers from any number of sources including improper connections, dumping or spills from industrial facilities, commercial establishments, or residential dwellings. The probability of illicit connections at used motor vehicle parts facilities is low yet it may be applicable at some operations.

EPA has identified the storm water pollutants and sources resulting from various automobile salvage yard activities in Table M–1. Table M–1 identifies oil, heavy metals, acids, and ethylene glycol as some of the parameters of concern at automobile salvage yards.

Based on the similarities of the facilities included in this sector in terms of industrial activities and significant materials, EPA believes it is appropriate to discuss the potential pollutants at automobile salvage yards as a whole and not subdivide this sector. Therefore, Table M–2 lists data for selected parameters from facilities in the automobile salvage yards sector. These data include the eight pollutants that all facilities were required to monitor under Form 2F, as well as the pollutants that EPA determined merit further monitoring.

TABLE M–2.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY AUTOMOBILE SALVAGE YARDS SUBMITTING PART II SAMPLING DATA [i] (mg/L)

Pollutant Sample type	No. of facilities		No. of samples		Mean		Minimum		Maximum		Median		95th percentile		99th percentile	
	Grab	Comp [ii]	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.
[ii] Composite samples.

3. Options for Controlling Pollutants

In evaluating options for controlling pollutants in storm water discharges, EPA must achieve compliance with the technology-based standards of the Clean Water Act [Best Available Technology (BAT) and Best Conventional Technology (BCT)]. The Agency does not believe that it is appropriate to establish specific numeric effluent limitations or a specific design or performance standard in this section for storm water discharges associated with industrial activity from automobile salvage yard operations to meet the BAT/BCT standards of the Clean Water Act. Because of the diversity of operations at automobile salvage yards and the lack of sufficient storm water water quality data currently available to EPA, establishing numeric effluent limitations is not feasible at this time. Rather, this section establishes requirements for the development and implementation of a site-specific storm water pollution prevention plan consisting of a set of Best Management Practices that are sufficiently flexible to address different sources of pollutants at different sites.

Best Management Practices (BMPs) are implemented to prevent and/or eliminate pollutants in storm water discharges. EPA believes the most effective BMPs for reducing pollutants in storm water discharges from automobile salvage yards is through exposure minimization practices. Exposure minimization practices minimize the potential for storm water to come in contact with pollutants. These BMP methods are generally uncomplicated and inexpensive practices. They are easy to implement, and require little or no maintenance. In some instances, more resources-intensive BMPs, including detention ponds or filtering devices, may be necessary depending on the type of discharge, types and concentrations of contaminants, and volume of flow.

The selection of the most effective BMPs will be based on site-specific considerations such as: facility size, climate, geographic location, hydrogeology and the environmental setting of each facility, and volume and type of discharge generated. Each facility will be unique in that the source, type, and volume of contaminated storm water discharges will differ. In addition, the fate and transport of pollutants in these discharges will vary. EPA believes that the management practices discussed herein are well suited mechanisms to prevent or control the contamination of storm water discharges associated with automobile salvage yards.

Part 1 group application data indicate that BMPs have not been widely implemented at the representative sampling facilities. Less than 5 percent of the sampling subgroup list indoor storage as a material management practice. Less than 8 percent of the representative sampling facilities use covering at their storage areas. Less than 3 percent of the representative facilities utilize waste minimization practices. The most commonly listed (approximately 20 percent) material management practice is draining fluids from vehicles prior to storage. Because BMPs described in part 1 data are limited, Table M–3 is provided to identify BMPs associated with activities that may be employed at automobile salvage yards.

TABLE M–3.—STORM WATER BMPS FOR AUTOMOBILE SALVAGE YARDS

Activity	BMPs
Dismantling and vehicle maintenance	Drain all fluids from vehicles upon arrival at the site. Segregate the fluids and properly store or dispose of them. Maintain an organized inventory of materials used in the maintenance shop. Keep waste streams separate (e.g., waste oil and mineral spirits). Nonhazardous substances that are contaminated with a hazardous substance is considered a hazardous substance. Recycle anti-freeze, gasoline, used oil, mineral spirits, and solvents. Dispose of greasy rags, oil filters, air filters, batteries, spent coolant, and degreasers properly. Label and track the recycling of waste material (e.g., used oil, spent solvents, batteries). Drain oil filters before disposal or recycling.

TABLE M-3.—STORM WATER BMPS FOR AUTOMOBILE SALVAGE YARDS—Continued

Activity	BMPs
	Store cracked batteries in a nonleaking secondary container. Promptly transfer used fluids to the proper container. Do not leave full drip pans or other open containers around the shop. Empty and clean drip pans and containers. Do not pour liquid waste down floor drains, sinks, or outdoor storm drain inlets. Plug floor drains that are connected to the storm or sanitary sewer. If necessary, install a sump that is pumped regularly. Inspect the maintenance area regularly for proper implementation of control measures. Filtering storm water discharges with devices such as oil-water separators. Train employees on proper waste control and disposal procedures.
Outdoor vehicle, equipment, and parts storage .	Use drip pans under all vehicles and equipment waiting for maintenance and during maintenance. Store batteries on impervious surfaces. Curb, dike or berm this area. Confine storage of parts, equipment and vehicles to designated areas. Cover all storage areas with a permanent cover (e.g., roofs) or temporary cover (e.g., canvas tarps). Install curbing, berms or dikes around storage areas. Inspect the storage yard for filling drip pans and other problems regularly. Train employees on procedures for storage and inspection items.
Vehicle, equipment and parts washing areas	Avoid washing parts or equipment outside. Use phosphate-free biodegradable detergents. Consider using detergent-based or water-based cleaning systems in place of organic solvent degreasers. Designate an area for cleaning activities. Contain steam cleaning washwaters or discharge under an applicable NPDES permit. Ensure that washwaters drain well. Inspect cleaning area regularly. Install curbing, berms or dikes around cleaning areas. Train employees on proper washing procedures.
Liquid storage in above ground containers	Maintain good integrity of all storage containers. Install safeguards (such as diking or berming) against accidental releases at the storage area. Inspect storage tanks to detect potential leaks and perform preventive maintenance. Inspect piping systems (pipes, pumps, flanges, couplings, hoses, and valves) for failures or leaks. Train employees on proper filling and transfer procedures.
Improper connection with storm sewers	Plug all floor drains if it is unknown whether the connection is to storm sewer or sanitary sewer systems. Alternatively, install a sump that is pumped regularly. Perform dye testing to determine if interconnections exist between sanitary water system and storm sewer system. Update facility schematics to accurately reflect all plumbing connections. Install a safeguard against vehicle washwaters and parts cleaning waters entering the storm sewer unless permitted. Maintain and inspect the integrity of all underground storage tanks; replace when necessary. Train employees on proper disposal practices for all materials.

4. Pollutant Control Measures Required Through Other EPA Programs

Because hazardous substance including oil, gasoline, and lead are commonly found at automobile salvage yards, such facilities may be subject to other State or Federal environmental protection programs. In particular, as described below, the Resource Conservation and Recovery Act (RCRA) and the Underground Storage Tank (UST) programs require careful management of materials used onsite which decreases the probability that storm water from such areas will be contaminated by these materials.

Under the RCRA program, on September 10, 1992, EPA promulgated standards in 40 CFR Part 279 for the management of used oils that are recycled (57 FR 41566). These standards include requirements for used oil generators, transporters, processors/re-refiners, and burners. The standards for used oil generators apply to all generators, regardless of the amount of used oil they generate. Do-it-yourself (DIY) generators which generate used oil from the maintenance of their personal vehicles, however, are not subject to the management standards in 40 CFR 279.20(a)(1)).

The requirements for used oil generators were designed to impose a minimal burden on generators while protecting human health and the environment from the risks associated with managing used oil. Under Subpart C of 40 CFR Part 279, used oil generators must not store used oil in units other than tanks, containers, or units subject to regulation under 40 CFR Parts 264/265 (Section 279.22(a)). In other words, generators may store used oil in tanks or containers that are not subject to Subpart J (hazardous waste

R0016226

tanks) or Subpart I (containers) of 40 CFR Parts 264/265, as long as such tanks or containers are maintained in compliance with the used oil management standards. This does not preclude generators from storing used oil in Subpart J tanks or Subpart I containers or other units, such as surface impoundments (Subpart K), that are subject to regulation under 40 CFR Part 264 or 265.

Storage units at generator facilities must be maintained in good condition and labeled with the words "used oil." Upon detection of a release of used oil to the environment, a generator must take steps to stop the release, contain the released used oil, and properly manage the released used oil and other materials [40 CFR 279.22 (b) to (d)]. Generators storing used oil in underground storage tanks are subject to the UST regulations in 40 CFR Part 280.

If used oil generators ship used oil offsite for recycling, they must use a transporter who has notified EPA and obtained an EPA identification number [40 CFR 279.24].

The technical standards for USTs at 40 CFR Part 280 require that new UST systems (defined as systems for which installation commenced after December 12, 1988) use overfill prevention equipment that will: 1) automatically shut off flow into the tank when the tank is no more than 95 percent full; or 2) alert the transfer operator when the tank is no more than 90 percent full by restricting the flow into the tank or triggering a high level alarm. The preceding requirements do not apply to systems that are filled by transfers of no more than 25 gallons at one time. Existing UST systems (defined as systems for which installation has commenced on or before December 12, 1988) are required to have installed the described overfill prevention equipment by December 12, 1998.

5. Storm Water Pollution Prevention Plan Requirements

EPA believes that pollution prevention is the most effective approach for controlling contaminated storm water discharges from automobile salvage yards. Pollution prevention plans allow the operator of a facility to select BMPs based on site-specific considerations such as: facility size; climate; geographic location; geology/hydrology; the environmental setting of each facility; and volume and type of discharge generated. This flexibility is necessary because each facility will be unique in that the source, type, and volume of contaminated surface water discharges will differ from site to site.

Under today's general permit, all facilities must prepare and implement a storm water pollution prevention plan. The establishment of a pollution prevention plan requirement reflects EPA's decision to allow operators of automobile salvage yards to utilize BMPs as the BAT/BCT level of control for the storm water discharges covered by this section. The requirements included in pollution prevention plans provide a flexible framework for the development and implementation of site specific controls to minimize pollutants in storm water discharges. This approach and associated deadlines are consistent with EPA's storm water general permits finalized on September 9, 1992 and September 25, 1992 for discharges in nonauthorized NPDES States (57 FR 41236).

There are two major objectives to a pollution prevention plan: 1) to identify sources of pollution potentially affecting the quality of storm water discharges associated with industrial activity from a facility; and 2) to describe and ensure implementation of practices to minimize and control pollutants in storm water discharges associated with industrial activity from a facility.

Specific requirements for a pollution prevention plan for automobile salvage yards are described below. These requirements must be implemented in addition to the baseline pollution prevention plan provisions discussed previously.

a. Contents of the Plan. Storm water pollution prevention plans are intended to aid operators of automobile salvage yards to evaluate all potential pollution sources at a site, and assist in the selection and implementation of appropriate measures designed to prevent, or control, the discharge of pollutants in storm water runoff. EPA has developed guidance entitled "Storm Water Management for Industrial Activities: Developing Pollution Prevention Plans and Best Management Practices," EPA, 1992, (EPA 832–R–92–006) to assist permittees in developing and implementing pollution prevention measures.

(1) Description of Potential Pollution Sources. There are no requirements beyond those described in Part VI.C.2 of this fact sheet.

(2) Measures and Controls. Following completion of the source identification and assessment phase, the permittee must evaluate, select, and describe the pollution prevention measures, best management practices (BMPs), and other controls that will be implemented at the facility. For the following areas at the site, the permittee must assess the applicability of the corresponding BMPs:

Vehicle Dismantling and Maintenance Areas—The plan must describe measures that prevent or minimize contamination of the storm water runoff from all areas used for vehicle dismantling and maintenance. The facility must consider draining and segregating all fluids from vehicles upon arrival at the site, or as soon as feasible thereafter. The facility must consider performing all maintenance activities indoors, maintaining an organized inventory of materials used in the shop, draining all parts fluids prior to disposal, prohibiting the practice of hosing down the shop floor, using dry cleanup methods, and/or collecting the storm water runoff from the maintenance area and providing treatment. Where dismantling and maintenance activities can not take place indoors, facilities may consider methods for containing oil or other fluid spillage during parts removal. Drip pans, large plastic sheets, or canvas may be considered for placement under vehicles or equipment during maintenance and dismantling activities. Where drip pans are used, they should not be left unattended to prevent accidental spills.

Vehicle, Parts, and Equipment Storage Areas—The storage of vehicles, parts, and equipment must be confined to designated areas (delineated on the site map). The plan must describe measures that prevent or minimize contamination of the storm water runoff from these areas. The facility must consider the use of drip pans, large sheets of plastic, canvas (or equivalent measures) under vehicles, parts, and equipment. Canvas or sheets of plastic may be used as temporary coverage of storage areas. Indoor storage of vehicles, parts and equipment, as well as the installation of roofs, curbing, berming and diking of these areas must be considered. Large plastic or metal bins with secure lids should be used to store oily parts (e.g., small engine parts). Used batteries should be stored within nonleaking secondary containment or by other equivalent means to prevent leaks of acid into storm water discharges.

Material Storage Areas—As part of a good housekeeping program, consider labeling storage units of all materials (e.g., used oil, used oil filters, spent solvents, paint wastes, radiator fluids, transmission fluids, hydraulic fluids). Maintain such containers and units in good condition, so as to prevent contamination of storm water. The plan must describe measures that prevent or minimize contamination of the storm water runoff from such storage areas. The facility may consider indoor storage of the materials and/or installation of berming and diking of the area.

Vehicle, Equipment, and Parts Cleaning Areas—The plan must describe measures that prevent or minimize contamination of storm water from all areas used for vehicle, equipment, and parts cleaning. The facility must consider performing all cleaning operations indoors. In addition, the facility must consider covering or berming the cleaning operation area. Washwaters from vehicle, equipment, and parts cleaning areas are process wastewaters that are not authorized discharges under this section.

These four areas are sources of pollutants in storm water from automobile salvage yards. EPA believes that the incorporation of BMPs such as those suggested, in conjunction with a pollution prevention plan, will substantially reduce the potential of storm water contamination from these areas. In addition, EPA believes that these requirements continue to provide the necessary flexibility to address the variable risk for pollutants in storm water discharges associated with different facilities.

(a) Preventive Maintenance—Permittees are required to develop a preventive maintenance program that includes regular inspections and maintenance of storm water BMPs. The purpose of the inspections, which may coincide with the inspections required in (b) below, is to check on the effectiveness of the storm water pollution prevention plan. The inspections allow facility personnel to monitor the success or failure of elements of the plan on a regular basis. The use of an inspection checklist should be considered. The checklist will ensure that all required areas are inspected, as well as help to meet the recordkeeping requirements. In addition to regular inspections, employees identifying potential problems during their daily activities, such as leaks or spills, shall take appropriate measures to address these problems as soon as feasible.

(b) Inspections—This section requires that in addition to the comprehensive site evaluation required under Part XI.M.3.a. of today's permit, qualified facility personnel shall be identified to inspect: upon arrival, or as soon as feasible thereafter, all vehicles for leaks; any equipment containing oily parts, hydraulic fluids, or any other fluids, at least quarterly for leaks; and any outdoor storage containers for liquids, including, but not limited to, brake fluid, transmission fluid, radiator water, and anti-freeze, at least quarterly for leaks.

In addition, qualified facility personnel are required to conduct, at a minimum, quarterly visual inspections of BMPs. The inspections shall include: (1) an assessment of the integrity of any flow diversion or source minimization systems; and (2) visual inspections of dismantling areas; outdoor vehicle, equipment, and parts storage area; vehicle and equipment maintenance areas; vehicle, equipment, and parts washing areas; and liquid storage in above ground containers. A set of tracking or follow-up procedures shall be used to ensure that appropriate actions are taken in response to the inspections.

The quarterly inspections must be made at least once in each of the following designated periods during daylight hours: January through March (storm water runoff or snow melt); April through June (storm water runoff); July through September (storm water runoff); October through December (storm water runoff). Records of inspections shall be maintained as part of the plan.

(c) Employee Training—Permittees are required to include a schedule for conducting training in the plan. EPA recommends that facilities conduct training annually at a minimum. However, more frequent training may be necessary at facilities with high turnover of employees or where employee participation is essential to the storm water pollution prevention plan. Employee training must, at a minimum, address the following areas when applicable to a facility: used oil management; spill prevention and response; good housekeeping practices; used battery management; and proper handling (i.e., collection, storage, and disposal) of all fluids. This training should serve as: (1) training for new employees; (2) a refresher course for existing employees; and (3) training for all employees on any storm water pollution prevention techniques recently incorporated into the plan, where appropriate, contractor personnel also must be trained in relevant aspects of storm water pollution prevention.

(d) Recordkeeping and Internal Reporting—Permittees must describe procedures for developing and retaining records on the status and effectiveness of plan implementation. The plan must address spills, monitoring, and BMP inspection and maintenance activities. Ineffective BMPs must be reported and the date of their corrective action noted.

(e) Storm Water Management—The permittee must evaluate the appropriateness of each storm water BMP that diverts, infiltrates, reuses, or otherwise reduces the discharge of contaminated storm water. In addition, the permittee must describe the storm water pollutant source area or activity (i.e., loading and unloading operations, raw material storage piles etc.) to be controlled by each storm water management practice.

(3) Comprehensive Site Compliance Evaluation. The storm water pollution prevention plan must describe the scope and content of comprehensive site evaluations that qualified personnel will conduct to: (1) confirm the accuracy of the description of potential pollution sources contained in the plan; (2) determine the effectiveness of the plan; and (3) assess compliance with the terms and conditions of this section. Comprehensive site compliance evaluations should be conducted at least once a year for automobile salvage yards. These evaluations are intended to be more in depth than the quarterly visual inspections. The individual or individuals who will conduct the evaluations must be identified in the plan and should be members of the pollution prevention team. Evaluation reports must be retained for at least 3 years after the date of the evaluation.

Based on the results of each evaluation, the description of potential pollution sources, and measures and controls, the plan must be revised as appropriate within 2 weeks after each evaluation. Changes in the measures and controls must be implemented on the site in a timely manner, and never more than 12 weeks after completion of the evaluation.

6. Monitoring and Reporting Requirements

a. Analytical Monitoring Requirements. EPA believes that automobile salvage yards may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. In order to provide a tool for evaluating the effectiveness of the pollution prevention plan and to characterize the discharge for potential environmental impacts, the permit requires automobile yards to collect and analyze samples of their storm water discharges for the pollutants listed in Table M–4. The pollutants listed in Table M–4 were found to be above benchmark levels for a significant portion of sampling facilities that submitted quantitative data in the group application process. EPA is requiring monitoring for these pollutants after the pollution prevention plan has been implemented to assess the effectiveness of the pollution prevention plan and to help ensure that a reduction of pollutants is realized.

At a minimum, storm water discharges from automobile salvage yards must be monitored quarterly during the second year of permit coverage, unless the facility exercises the Alternative Certification in Section VI.E.3 of this fact sheet. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Table M–4. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE M–4.—INDUSTRY MONITORING REQUIREMENTS

Pollutants of concern	Cut-off concentration
Total Suspended Solids	100 mg/L.
Total Recoverable Aluminum	0.75 mg/L.
Total Recoverable Iron	1.0 mg/L.
Total Recoverable Lead	0.0816 mg/L.

If the average concentration for a parameter is less than or equal to the value listed in Table M–4, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration listed in Table M–4, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit. The schedule of monitoring is presented in Table M–5.

TABLE M–5.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Table M–4, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Table M–4, then no further sampling is required for that parameter.
4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Table M–4. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will reassess the effectiveness of the adjusted pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

b. Alternative Certification. Throughout today's permit, EPA has included monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative certification described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall or on a pollutant-by-pollutant basis, in lieu of sampling described under Part VIII.M.6.a of this factsheet, under penalty of law, signed in accordance with Part VII.G (Signatory Requirements), that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity, that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in lieu of monitoring reports. The permittee is required to complete any and all sampling until the exposure is eliminated. If the facility is reporting for a partial year, the permittee must specify the date exposure was eliminated. If the permittee is certifying that a pollutant was present for part of the reporting period, nothing relieves the permittee from the responsibility to sample that parameter up until the exposure was eliminated and it was determined that no significant materials remained. This certification is not to be confused with the low concentration sampling waiver. The test for the application of this certification is whether the pollutant is exposed, or can reasonably be expected to be present in the storm water discharge. If the facility does not and has not used a parameter, or if exposure is eliminated and no significant materials remain, then the facility can exercise this certification. The Agency does not expect that

50952 Federal Register / Vol. 60, No. 189 / Friday, September 29, 1995 / Notices

facilities will be able to use the alternative certification for indicator parameters such as TSS and BOD. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

c. Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one signed Discharge Monitoring Report Form must be submitted per storm event sampled. For facilities conducting monitoring beyond the minimum requirements an additional Discharge Monitoring Report Form must be filed for each analysis.

d. Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable. If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

e. Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

f. Quarterly Visual Examination of Storm Water Quality. All automobile salvage yard facilities are required to conduct quarterly visual examinations of storm water discharges from each outfall. The examination of storm water grab samples shall include any observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, or other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on these samples. The examinations must be of a grab sample collected from each storm water outfall.

The examination must be made at least once in each of the following three-month periods: January through March, April through June, July through September, and October through December. The examinations shall be made during daylight unless there is insufficient rainfall or snow-melt to runoff. Whenever practicable, the same individual should carry out the collection and examination of discharges throughout the life of the permit to ensure the greatest degree of consistency possible. Grab samples shall be collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 1 hour) of when the runoff begins discharging. Reports of the visual examination include: the examination date and time, examination personnel, visual quality of the storm water discharge, and probable sources of any observed storm water contamination. The visual examination reports must be maintained onsite with the pollution prevention plan.

When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination and retain this documentation onsite with the records of the visual examinations. Adverse weather conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

EPA believes that this quick and simple assessment will allow the permittee to approximate the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the examinations. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and the effects of the management practices that are included in the plan.

N. Storm Water Discharges Associated With Industrial Activity From Scrap Recycling and Waste Recycling Facilities

1. Industry Profile

Specific requirements have been established for those facilities that are engaged in the processing, reclaiming and wholesale distribution of scrap and recyclable waste materials. As background, the storm water regulations define 11 categories of storm water discharges associated with industrial activity in 40 CFR 122.26(b)(14). Category (vi) includes facilities that are engaged in the recycling of materials, including metal scrapyards, battery reclaimers, and salvage yards, including but limited to those classified Standard Industrial Classification (SIC) 5093. For purposes of this section, special conditions have been included for those facilities engaged in the reclaiming and retail/wholesale distribution of used

R0016230

motor vehicle parts identified as SIC 5015 in Part XI.M.

SIC 5093 includes establishments engaged in assembling, breaking up, sorting and the wholesale distribution of scrap and recyclable waste materials including bag, bottle and box wastes, fur cuttings, iron and steel scrap, metal and nonferrous metal scrap, oil, plastics, rags, rubber, textiles, waste paper, aluminum and tin cans, and rag wastes. For purposes of this permit, the term waste recycling facility applies to those facilities that receive a mixed wastestream of non-recyclable and recyclable wastes. The term recycling facility applies to those facilities that receive only source-separated recyclable materials primarily from non-industrial and residential sources. For purposes of this permit the term recycling facility also applies to those facilities commonly identified as material recovery facilities (MRF).

Part XI.N of the permit is segregated into three separate classes of recycling facilities: (1) scrap recycling and waste recycling facilities (non-liquid recyclable wastes); (2) liquid recyclable waste facilities; and (3) recycling facilities. Each of these three classes of recycling facilities have separate pollution prevention plan and monitoring requirements. EPA further clarifies that battery reclaimers engaged in the breaking up of used lead-acid batteries are not eligible for coverage under this permit. Facilities that participated in U.S. Environmental Protection Agency (EPA) Group Permit Applications 195, 274, 467, 896, 647 (except facilities identified as SIC 4212), 828, 1035, 1145 and 1204 are eligible for coverage under this section.

When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

2. Pollutants Found in Storm Water Discharges

This fact sheet is organized into three major subsections: scrap and waste recycling facilities (nonliquid wastes); industrial activities engaged in reclaiming and recycling liquid wastes, e.g., used oils, solvents, mineral spirits and antifreeze; and recycling facilities (including material recovery facilities) that receive only source-separated recyclable materials primarily from non-industrial and residential sources including waste paper, newspaper, glass bottles, plastic containers, aluminum and tin cans, and cardboard. Industrial operations and BMPs associated with these three groups are dissimilar enough to warrant establishing separate permit conditions for each group. Therefore, conditions for each of these three groups are identified separately.

a. Scrap and Waste Recycling Facilities (SIC 5093) (nonliquid recyclable wastes). The scrap recycling and waste recycling industry reclaims, processes and provides wholesale distribution of a diversity of materials and products. Typical recyclable materials include ferrous and nonferrous metals, paper, cardboard, animal hides, glass and plastic. Inbound recyclable materials are processed onsite in order to achieve a uniform grade product that meets a particular manufacturer's specifications. A significant inventory of processing equipment is frequently required to process recyclable waste material into a uniform grade. Processing equipment typically employ enormous physical forces such as shearing, shredding, and compacting in the process of eventually achieving a desired uniform grade product.

Individual scrap and waste recycling facilities may process one or more types of recyclable materials at a single site. Depending on the requirements of a manufacturer, recyclable waste materials, e.g., paper and cardboard, may need to be stored under cover to prevent deterioration. The bulk size of the recyclable waste materials and the processing equipment associated with these facilities frequently necessitates stockpiling materials and equipment outdoors. Consequently, there is significant opportunity for exposure of storm water runoff to pollutants. The extent of material potentially exposed to storm water runoff is illustrated in the following table based on information provided from one group application consisting of approximately 1,100 members.

TABLE N–1.—PERCENTAGE OF APPLICANTS IN ONE GROUP APPLICATION THAT PROVIDE COVER OVER MATERIALS OR PROCESSES

Material/processes	Percent of applicants
Ferrous Materials	6.6
Nonferrous Materials	53
Glass/plastic/paper	14
Other Materials	1.7
Material Processing Equipment	43

There are at least four types of activities that are common to most scrap and waste recycling facilities, they include: scrap waste material stockpiling, material processing, segregating processed materials into uniform grades, and collecting nonrecyclable materials for disposal. This fact sheet outlines pollutants of concern associated with each of these types of activities. Other operations of concern, including vehicle and equipment maintenance, are also discussed in this fact sheet.

(1) Pollutants Associated With Material Stockpiling. During material stockpiling, including unloading and loading areas, the potential exists for some types of inbound recyclable materials to deposit residual fluids on the ground. Used automotive engines, radiators, brake fluid reservoirs, transmission housings, and lead-acid from batteries may contain residual fluids that, if not properly managed, can eventually come in contact with storm water runoff. For example, sampling data from two group applications indicated the presence of oil and grease in 103 individual grab samples. In response to other Federal and State environmental regulations, such as the Resource Conservation and Recovery Act (RCRA), many scrap recycling and waste recycling facilities have instituted inspection and supplier education programs to minimize or eliminate the amount of inbound recyclable materials containing fluids and other potentially hazardous materials prior to their acceptance. Part XI.N.3.a.(3)(a)(i) of today's permit imposes conditions that will make an inbound recyclable materials inspection program part of the pollution prevention plan.

Another concern of outdoor stockpiling, including unloading and loading areas, is associated with deterioration of materials. Metal surfaces that are stockpiled for extended periods may be subject to corrosion. Corrosion is the deterioration of metal surfaces that typically results in the loss of metal to a solution, i.e., water. The following metals are referred to as the

R0016231

galvanic (or electromotive) series and have a tendency to corrode and become soluble in water; magnesium, aluminum, cadmium, zinc, steel or iron, cast iron, chromium, tin, lead, nickel, soft and silver solder, copper, stainless steel, silver, gold, platinum, brass and bronze. For some metals, the extent and rate of corrosion is dependent on whether it occurs in an oxygen-starved or oxygen-abundant atmosphere.

Corrosion of stockpiled materials at scrap recycling facilities is a potential source of pollutants given that metals such as copper, lead, nickel, zinc, chromium and cadmium were frequently detected in sampling data. In addition, the majority of these metals are associated with recyclable materials handled by the scrap recycling industry. Part XI.N.3.a.(3) of today's permit identifies BMP options to address these sources.

Another significant material of concern is the acceptance and temporary storage of scrap lead acid batteries from automotive vehicles and equipment. If a battery casing becomes cracked or damaged, special precautions are necessary to ensure that the contents do not come in contact with storm water runoff. This includes battery terminals with visible corrosion. In all cases, used batteries shall be handled and stored in such a manner as to prevent exposure to either precipitation or runoff. Part XI.N.3.a.(3) addresses conditions for these sources.

The following table presents a list of typical materials that may be received and processed at a scrap and waste recycling facility and which may be potential pollutant sources if they are not managed properly.

TABLE N–2.—SIGNIFICANT MATERIALS POTENTIALLY EXPOSED TO STORM WATER RUNOFF AT SCRAP AND WASTE RECYCLING FACILITIES[1]

Significant materials	Potential sources	Pollutants of concern
White goods (appliances)	Leaking oil-filled capacitors, ballasts, leaking compressors, pumps, leaking pressure vessels, reservoirs, sealed electrical components and chipped or deteriorated painted surfaces.	PCBs, oil, lubricants, paint pigments or additives such as lead, and other heavy metals.
Ferrous and nonferrous turnings and cuttings	Cutting oil residue, metallic fines	Oil, heavy metals.
Materials from demolition projects	Deteriorated/damaged insulation, chipped painted surfaces, lead, copper, and steel pipes.	Asbestos fibers, lead, copper, zinc, cadmium, other metals, TKN.
Electrical components, transformers, switch gear, mercury float switches, sensors.	Leaking oil-filled transformer casings, oil-filled switch, float switches, radioactive materials in gauges, sensors.	PCBs, oils, mercury, ionizing radioactive isotopes.
Fluorescent lights, light fixtures	Leaking ballasts	PCBs, oil.
Food/beverage dispensing equipment	Leaking fluorescent light ballasts, chipped painted surfaces.	PCBs, oil, heavy metals from paint pigments and additives.
Hospital and dental waste and equipment	Drums/containers of hospital waste, shielding from diagnostic and other medical equipment, radioactive materials from gauges, sensors and diagnostic equipment.	Infectious/bacterial contamination, lead, ionizing radioactive isotopes.
Instruments	Radioactive material from thickness gages	Ionizing radioactive isotopes.
Insulated wire	Insulation and other coatings, wire	Lead, zinc, copper.
Lawnmowers, snowmobiles, motorcycles	Leaking engines, transmissions, fuel, oil reservoirs,leaking batteries.	Oils, transmission and brake fluids, fuel, grease, battery acid, lead acid.
Light gage materials	Deteriorating insulation, painted surfaces and other coatings.	Asbestos, lead, chromium.
Locomotives, rail cars	Leaking fuel reservoirs, fittings, hydraulic components, engines, bearings, compressors, oil reservoirs, worn brake pads, damaged insulation.	PCBs, diesel fuel, hydraulic oil, oil, brake fluid, grease from fittings, asbestos.
Motor vehicle bodies, engines, transmissions, exhaust systems.	Leaking fuel tanks, oil reservoirs, transmission housings, brake fluid reservoir and lines, brake cylinders, shock absorber casing, engine coolant, wheel weights, leaking battery casings/housings and corroded terminals, painted surfaces and corrosion inhibitors, exhaust system, catalytic converters.	Fuel, benzene, oil, hydraulic oil, transmission fluids, brake fluids, ethylene glycol (antifreeze), lead, lead acid, lead oxides, cadmium, zinc, other heavy metals.
Miscellaneous machinery and obsolete equipment.	Leaking reservoirs, damaged or chipped painted surfaces coatings.	Fuel, oil, lubricants, lead, cadmium, zinc.
Pipes/materials from chemical and industrial plants.	Chemical residue, insulation, lead piping, chipped or damaged painted surfaces and protective coatings.	Chemical residue, oil, lubricants, damaged insulation (asbestos), lead, cadmium, zinc, copper.
Sealed containers, hydraulic cylinders	Leaking liquid reservoirs, containers, cylinders, miscellaneous chemicals.	Oil, PCBs, solvents, chemical residue.
Salvaged construction materials	Chemical residues, oils, solvents, lubricants, damaged insulation, chipped painted surfaces and protective coatings.	Chemical residue, oily wastes, asbestos, lead, cadmium, zinc.
Tanks, containers, vessels, cans, drums	Leaking or damaged containers	Chemical residue, oily wastes, petroleum products, heating oil.
Transformers (oil filled)	Leaking transformer housings	PCBs, oil.

[1] Institute of Scrap Recycling Industries, Inc.'s "Environmental Operating Guidelines." (April 1992)

R0016232

Federal Register / Vol. 60, No. 189 / Friday, September 29, 1995 / Notices 50955

(2) Material Processing. The type of processes employed at a particular facility depends on the type of recyclable and waste material. Typical processes include: torch cutting, shredding, baling, briquetting, wire stripping and chopping, and compacting. Processes such as shredding and shearing reduce the bulk size of recyclable scrap and waste into a size that is more easily transportable and which allows separation into uniform grades based on manufacturer specifications. Processes such as shredding of automotive bodies include a means of segregating materials into their ferrous and nonferrous fractions.

Process equipment at scrap recycling and waste recycling facilities are also potential sources of pollutants in storm water runoff. The sources of concern will be discussed separately. Scrap process equipment such as shearers are often actuated by a hydraulic system. Components such as hydraulic reservoirs, hydraulic pumps, motors, cylinders, control valves, accumulators, filters, and fittings are prone to leaking hydraulic fluid. Some hydraulic machinery also require frequent lubrication of cutting and wear surfaces. Storm water runoff exposure to hydraulic fluids and other lubricants is very likely unless adequate source control measures such as good housekeeping, preventive maintenance, diversion and/or containment are provided.

Stationary process equipment also produce a substantial amount of residual particulate material that tends to accumulate on and around the equipment, particularly rotating machinery, moving parts, bearings, conveyors and at the output of the equipment, e.g., storage containers. Particulate material that accumulates can become a source of contamination if it comes in contact with both precipitation and storm water runoff. Other sources of residual particulate and waste material include air pollution equipment, material handling equipment and processing equipment. In the case of shredding equipment, there are typically three (3) separate material streams produced. Shredded material is ultimately separated into its ferrous and nonferrous fractions, and a third stream referred to as fluff. The fluff material consists of a heterogeneous mix of materials including, but not limited to, small metal fragments, plastics, rubber, wood and textiles. After the material exits the shredder (hammermill), it typically enters an air classification system that separates the lightweight fraction, e.g., particulates, from the more dense fraction. The ferrous metal fraction is then separated from the nonferrous fraction and fluff by the use of a magnetic separator (typically a belt- or drum-type magnetic separator). The separated material may be collected in a hopper or it may accumulate on the ground. If recyclable and nonrecyclable waste material is allowed to accumulate on the ground, a greater potential exists for this material to come in contact with either precipitation or storm water runoff.

The scrap and recycling industry uses a diversity of processes to reclaim and recycle materials that can contribute pollutants to storm water runoff. The following table presents a list of typical scrap equipment operations which are potential pollutant sources.

TABLE N-3.—TYPICAL PROCESS AND EQUIPMENT OPERATIONS THAT ARE LIKELY SOURCES OF POLLUTANTS[1]

Activity	Potential sources	Pollutants of concern
Air Pollution Equipment (including incinerators, furnaces, wet scrubbers, filter houses, bag houses).	Normal equipment operations that include the collection and disposal of filter bag material and ash, process wastewater from scrubbers, accumulation of particulate matter around leaking joint connections, malfunctioning pumps and motors, e.g., leaking gaskets, seals or pipe connections, leaking oil-filled transformer casings.	Hydraulic fluids, oils, fuels, grease and other lubricants, accumulated particulate matter, chemical additives, PCBs from oil-filled electrical equipment.
Combustion Engines	Spills and/or leaks from fueling tanks, spills/leaks from oil/hydraulic fuel reservoirs, faulty/leaking hose connections, worn gaskets, leaking transmission crankcases and brake systems (if applicable), leaking battery casings and/or corroded terminals.	Accumulated particulate matter, oil/lubricants, fuel (gas/diesel), fuel additives, antifreeze (ethylene glycol), battery acid, products of incomplete combustion.
Material Handling Systems (forklifts, cranes, conveyors).	Normal operations including spills and leaks from fuel tanks, hydraulic and oil reservoirs due to malfunction parts, e.g., worn gaskets and parts, leaking hose connections, and faulty seals. Damaged or faulty electrical switches (mercury filled) Damaged or leaking battery casings, including exposed corroded battery terminals. Damaged or worn bearing housings.	Hydraulic fluids, oils, fuels and fuel additives, grease and other lubricants, accumulated particulate matter, chemical additives, mercury, lead, battery fluids.
Stationary Scrap Processing Facilities (balers, briquetters, shredders, shearers, compactors, engine block/cast iron breakers, wire chopper, turnings crusher).	Normal equipment operations including leaks from hydraulic reservoirs, hose and fitting connections, worn gaskets, spills or leaks from fuel tanks, particulates/residue from scrap processing, malfunctioning pumps and motors, e.g., leaking gaskets, seals or pipe connections, leaking oil-filled transformer casings.	Heavy metals, e.g., zinc, copper, lead, cadmium, chromium, hydraulic fluids.
Hydraulic equipment and systems, balers/briquetter, shredders, shearers, compactors, engine block/cast iron breaker, wire chopper, turnings crusher.	Particulate/residue from material processing, spills and/or leaks from fueling tanks, spills/leaks from oil/hydraulic fuel reservoirs, faulty/leaking hose connections/fittings, leaking gaskets.	Hydraulic fluids/oils, lubricants, particulate matter from combustion engines, PCBs (oil-filled electrical equipment components), heavy metals (nonferrous, ferrous).

R0016233

TABLE N-3.—TYPICAL PROCESS AND EQUIPMENT OPERATIONS THAT ARE LIKELY SOURCES OF POLLUTANTS[1]—Continued

Activity	Potential sources	Pollutants of concern
Electrical Control Systems (transformers, electrical switch gear, motor starters).	Oil leakage from transformers, leakage from mercury float switches, faulty detection devices.	PCBs, mercury (float switches), ionizing radioactive material (fire/smoke detection systems).
Torch cutting	Residual/accumulated particulates	Heavy metal fragments, fines.

[1] Institute of Scrap Recycling Industries, Inc.'s "Environmental Operating Guidelines." (April 1992)

(3) Segregation of Processed Materials into Uniform Grades. Processing, e.g., shearing, shredding, baling, etc., of recyclable materials is followed by its segregation into uniform grades to meet a particular manufacturer's specifications. If segregated recyclable material remains exposed to precipitation, the potential still exists for storm water contamination.

(4) Disposal of Nonrecyclable Waste Materials. During recycling of scrap and waste materials, a significant fraction of nonrecyclable waste materials is generated and must be disposed of properly. The volume or quantity of material that remains nonrecyclable may be too large to allow covered storage prior to shipment. Consequently, nonrecyclable waste materials may be left exposed to both precipitation and runoff and, therefore, they are a likely source of storm water pollutants.

(5) Other Operations of Concern. There are a number of activities of concern that frequently occur at scrap and waste recycling facilities including, heavy vehicle traffic over unstabilized areas, vehicle maintenance and fueling, and material handling operations. Operations associated with the receipt, handling, and processing of scrap and waste material frequently occur over areas that are not stabilized to prevent erosion. Unless specific measures or controls are provided to either prevent erosion or trap the sediment, this material will be carried away in storm water runoff and eventually exit the site. Suspended solids are of significant concern given the potential amount of unstabilized area and the significant amount of particulate matter that is often produced at these facilities. For example, many facilities use spray water for dust control on heavily traveled areas. Both organic and inorganic pollutants can become bound up or absorbed to suspended solids in runoff. For this reason, today's proposed permit identifies conditions to minimize the contribution of suspended solid loadings from these facilities.

Some scrap and waste recycling facilities may also conduct vehicle maintenance onsite. Although vehicle maintenance frequently occurs indoors, there are specific activities which could contribute pollutants to storm water. This includes washdown of vehicle maintenance areas, leaks or spills of fuel, hydraulic fluids and oil and outdoor storage of lubricants, fluids, oils and oily rags. Fueling stations are also frequently located outdoors without any roof cover. Activities such as topping off fuel tanks, or overfilling storage tanks (without high-level alarms or automatic shut-offs) are also activities that can cause contamination of runoff. Vehicle washing can result in accumulated residue material being discharged to a storm sewer system.

The following table highlights activities associated with vehicle maintenance and material handling that are potential sources of storm water contamination.

TABLE N-4.—OTHER POTENTIAL POLLUTANT SOURCE ACTIVITIES

Activity	Potential sources	Pollutants of concern
Material Handling Systems (forklifts, cranes, conveyors).	Spills and/or leaks from fueling tanks, spills/leaks from oil/hydraulic fuel reservoirs, faulty/leaking hose connections/fittings, leaking gaskets.	Accumulated particulate matter (ferrous and nonferrous metals, plastics, rubber, other), oil/lubricants, PCBs (electrical equipment), mercury (electrical controls), lead/battery acids.
Vehicle Maintenance	Parts cleaning, waste disposal of rags, oil filters, air filters, batteries, hydraulic fluids, transmission fluids, brake fluids, coolants, lubricants, degreasers, spent solvents.	Fuel (gas/diesel), fuel additives, oil/lubricants, heavy metals, brake fluids, transmission fluids, chlorinated solvents, arsenic.
Fueling Stations	Spills and leaks during fuel transfer, spills due to "topping off" tanks, runoff from fueling areas, washdown of fueling areas, leaking storage tanks, spills of oils, brake fluids, transmission fluids, engine coolants.	Gas/diesel fuel, fuel additives, oil, lubricants, heavy metals.
Vehicle and Equipment Cleaning and Washing	Washing and steam cleaning	Solvent cleaners, oil/lubricants/additives, antifreeze (ethylene glycol).

(6) Pollutants Found in Storm Water Discharges. Sampling data provided in part 2 of the group application process revealed that storm water discharges from scrap and waste recycling facilities contain pollutants such as heavy metals, Biochemical Oxygen Demand (BOD), Chemical Oxygen Demand (COD), TSS, nutrients and oil and grease. The following table summarizes the statistical analysis of sampling data provided in part 2 group applications. Table N-6 provides a comparison of a selected subset of these pollutants to benchmark concentrations.

b. Waste Recycling Facilities (SIC 5093)—(Liquid Recyclable Wastes). **This subsection applies to those facilities engaged in the reclaiming and recycling of liquid wastes such as "spent solvents," "used oil," and "used ethylene glycol" typically identified under SIC 5093. This subsection is particularly applicable to those facilities that participated in EPA group application number 198. EPA received a single group application in this category of waste recycling facilities. The following is a profile of industrial activities and the types of significant materials associated with facilities participating in this group activity.**

Group application number 198 included 220 facilities of which 214 were classified as service centers. Service centers accumulate spent solvent, used oil and antifreeze, filter cartridges and still bottoms **contaminated** with dry cleaning **solvents** (typically perchloroethylene), **and used** lacquer thinner from paint gun **cleaning** machines. The typical service **center has** individual containers with **storage** capacity of up to 10,000 gallons **each, and tanks** with storage capacity of **up** to 20,000 gallons each. Service **centers are** typically limited to a **maximum** of 6 tanks (a total of 120,000 **gallons).** Twenty (20) of the service **centers also** function as accumulation **centers where** they have a maximum **storage** capacity of 70,000 gallons of **liquid materials** in containers. None of **the containers are** opened except under **conditions** where a container begins to **leak or is damaged.**

The group application also included **four (4)** facilities that operated only as **container** transfer stations and do not **operate storage tanks. These facilities are largely enclosed warehouses that provide secondarily contained storage areas. Three (3) facilities were identified as used oil depots where only oily water and/or used oil are accumulated in storage tanks. Storage tanks are limited to a maximum capacity of 20,000 gallons each. Used oil is transported to the facility in tanker trucks (3,500 gallons) and shipped out in tanker trucks (7,500 gallons). The used oil is ultimately transported to a processing or re-refining facility (not covered under this section). The following table summarizes the percentage of facilities with significant materials stored.**

R0016235

TABLE N-7. SIGNIFICANT MATERIALS REPORTED IN GROUP APPLICATION NUMBER 195

Significant materials	Percent of facilities
Mineral Spirits	98
Immersion Cleaner	98
Dry Cleaner Solvents	98
Paint Solvents	83
Industrial Solvents	81
Spent Antifreeze	59
Used Oil	57
Allied Products	98

The types of materials identified in Table N-7 are potential sources of storm water runoff contamination. Since these materials are stored and transported in individual drums and bulk storage tanks, the potential exists for spills and/or leaks during all phases of waste transport, waste transfer, container/drum handling and shipping.

There are a number of operations at these facilities that have significant potential to release pollutants to the environment if recyclable waste materials are not managed properly. Potential sources of pollutants are discussed in Part XI.N.3.a.(2) of today's permit. However, in response to other Federal and State environmental regulations, such as RCRA and 40 CFR Part 112 (Oil Pollution Prevention), facilities in this group application currently employ a range of the BMPs and structural controls that also benefit storm water quality. Typical measures and controls for controlling pollutants for facilities in this subsection are presented in Part XI.N.3.a.(3)(b).

(1) Waste Material Handling and Storage. Given the nature and type of materials stored and handled at these facilities, the potential exists for accidental spills and leaks. Consequently, the types of activities that occur at these facilities which could potentially result in contamination of storm water runoff is also of concern to EPA. The following table is a list of activities which may result in a release of pollutants.

TABLE N-8. TYPES OF POTENTIAL POLLUTANT-CAUSING ACTIVITIES AT WASTE RECYCLING FACILITIES THAT HANDLE LIQUID RECYCLABLE WASTES

Activity	Potential sources of pollutants	Pollutants of concern
Drum/Individual Container Storage and Handling.	Leaks or spills due to faulty container/drum integrity, e.g., leaking seals or ports. Container materials incompatible with waste material. Improper stacking and storage of containers.	Mineral spirits, industrial solvents, immersion cleaners, dry cleaner solvents, paint solvents, spent antifreeze.
Return and Fill Stations	Leaks, spills, or overflows from tanker truck transfer of wastes and hose drainage. Leaking pipes, valves, pumps, worn or deteriorated gaskets or seals.	Mineral spirits, industrial solvents, immersion cleaners, dry cleaner solvents, paint solvents, spent antifreeze.
Individual Container/Drum Storage Improper Stacking and Storage of Containers.	Leaks or spills due to faulty container/drum integrity, e.g., leaking seals or ports.	Mineral spirits, industrial solvents, immersion cleaners, dry cleaner solvents, paint solvents, spent antifreeze.
Storage Tank Operations	Overfill of storage tanks, leaking pipes, valves, worn or deteriorated pumps seals. Leaking underground storage tanks.	Mineral spirits, industrial solvents, immersion cleaners, dry cleaner solvents, paint solvents, spent antifreeze.
Material Handling Equipment	Leaking fuel lines, worn gaskets, leaking hydraulic lines and connections.	Fuel, hydraulic fluid, oil and grease.

(2). Other Activities of Concern. The following table highlights other types of activities that are potential sources of storm water contamination.

TABLE N-9. OTHER POTENTIAL SOURCES OF STORM WATER CONTAMINATION

Activity	Potential sources of pollutants	Pollutants of concern
Vehicle and Equipment Maintenance (if applicable).	Replacement of fluids such as transmission and brake fluids, antifreeze, oil and other lubricants, washdown of maintenance areas, dumping fluids down floor drains connected to storm sewer system, outside storage of fluids and oily rags and waste material.	Oil and grease, fuel, accumulated particulate matter, antifreeze.
Vehicle or Equipment Washing (if applicable)	Wash water or steam cleaning	Oil, detergents, chlorinated solvents, suspended solids and accumulated particulate matter.

(3). Pollutants Found in Storm Water Discharges. Based on data provided in group application sampling information, pollutants that were most frequently reported included TSS, BOD, COD, nitrite plus nitrate, oil and grease. The following table provides a statistical summary of data.

TABLE N-10. SUMMARY STATISTICS FOR WASTE RECYCLING FACILITIES[1] (SIC 5093)—(RECYCLABLE LIQUID WASTES). ALL VALUES IN MG/L

[2] Composite samples.

c. *Recycling Facilities.* This particular group of recycling facilities is distinguished from scrap recycling facilities and waste recycling facilities that accept a mixed wastestream of non-recyclable and recyclable wastes. Facilities included in this sub-sector would include only those facilities that receive source-separated, recyclable materials primarily from non-industrial and residential sources. This includes source-separated material recovery facilities (MRF). EPA Group Applications 274, 647, 828, and 1145 included significant numbers of facilities that would fall within this sub-sector. The recyclable materials in this sub-sector can be characterized as common consumer products such as paper, newspaper, cardboard, plastic containers, glass bottles, aluminum and tin cans. These facilities commonly accept a mix of recyclable materials and reject non-recyclable materials at the source.

(1) *Pollutant-Causing Activities Associated with Recycling Facilities.* There are basically four areas associated with these facilities that are potential sources of pollutants, they include: (1) inbound recyclable materials; (2) outdoor material storage; (3) indoor storage and material processing; and (4) vehicle maintenance. The potential exists that recycling facilities may unknowingly accept nonrecyclable materials and/or small quantities of household hazardous wastes (HHW). If these materials are not handled, stored or disposed of properly, they could become potential pollutant sources. Recycling facilities are already aware of this issue and have commonly instituted practices to minimize accepting such materials. These practices include public education brochures, training of curbside pick-up drivers, and rejecting non-recyclable materials at the source.

Outdoor material storage is another issue of concern given the practice of storing degradable, recyclable products outdoors such as bales of wastepaper and various types of recyclable containers containing residual fluids, e.g., beverage containers. Wastepaper exposed to weather will deteriorate and can be a source of oxygen-demanding substances. For example, biochemical oxygen demand (BOD) concentrations as high as 152 mg/l were measured at facilities that store wastepaper outdoors. Similarly, recycling facilities that stored unprocessed aluminum beverage containers outdoors can be a contaminant source of oxygen-demanding substances. BOD concentrations as high as 460 mg/l were measured at recycling facilities that store unprocessed recyclable containers outdoors.

The third area of concern is indoor processing and storage. EPA is primarily concerned with the potential for illicit connections or improper dumping to floor drains that discharge to a storm sewer system. Another potential source of contamination is the practice of washing down tipping floor areas and allowing the washwater to drain to the storm sewer system. EPA believes that these issues can be readily addressed by disconnecting floor drains to the storm sewer, good housekeeping practices and providing routine employee training. The practice of allowing tipping floor washwaters to discharge to a storm sewer system is prohibited under this permit.

The last area of concern is vehicle maintenance. Onsite vehicle maintenance was infrequently reported in group permit applications. Although vehicle maintenance frequently occurs indoors, the following specific activities could contribute pollutants to storm water: washdown of vehicle maintenance areas, leaks or spills of fuel, hydraulic fluids, lubricants, and other fluids, and exposed oils and oily rags. Fueling areas may lack roof cover, consequently, topping off fuel tanks or overfilling storage tanks (without high-level alarms) could contribute to contamination of surface runoff. Vehicle washing can result in accumulated residue material being discharged to a storm sewer system. The following tables identify significant materials that are exposed to precipitation or runoff based on information from two group applications (274 and 647).

TABLE N–11.—SIGNIFICANT MATERIALS REPORTED IN GROUP APPLICATION NO. 274

Significant materials	Percent of facilities[1]	Pollutant-causing activities
Paper Stock	43	Outdoor exposure could result in deterioration of paper.
Wood Pallets	83	Residual materials on pallets.
Recyclable Waste Paper in Bales	83	Outdoor exposure could result in deterioration of paper.
Recyclables Plastic, Glass, and Aluminum	30	Residual fluids from containers.
Gasoline/Diesel Fuel (outside pumps)	28	Leaks or spills. Overtopping during fueling.

[1] Column totals greater than 100% because many facilities have one or more of these significant materials exposed.

R0016237

TABLE N-12.—Significant Materials Reported in Group Application No. 826

Significant materials	Percent of facilities[1]	Pollutant-causing activity
Wood Pallets	64	Residual materials on pallets.
Waste Paper	27	Outdoor exposure could result in deterioration of paper.
Recyclable Waste Paper in Bales	41	Outdoor exposure could result in deterioration of paper.
Gasoline/Diesel Fuel (outside pumps)	55	Leaks or spills. Overtopping during fueling.
Lubricating Fluids	14	Leaks or spills.

[1] Column totals greater than 100% because many facilities have one or more of these significant materials exposed.

EPA has established special pollution prevention plan requirements for recycling facilities that receive only source-separated recyclable materials. Specific requirements are discussed in Part XI.N.3.a.(3)(c) of the permit.

(2) Pollutants Found in Storm Water Discharges.

Based on data provided in group applications 274, 647, 826, and 1145, pollutants that were most frequently reported included TSS, BOD, COD, nitrite plus nitrate, TKN, total phosphorus, oil and grease, and total aluminum (group 1145 only). The table N-13 provides a statistical summary of data.

TABLE N-13.—SUMMARY STATISTICS FOR SELECTED RECYCLING FACILITIES[i] (SIC 5093) (GROUP APPLICATIONS 247, 647, 826, AND 1145) ALL UNITS IN mg/L UNLESS OTHERWISE NOTED

3. Options for Controlling Pollutants

a. Scrap and Waste Recycling Facilities (SIC 5093) (Nonliquid recyclable waste materials). This section addresses source control measures, BMPs and structural controls that are specifically applicable to the scrap recycling facilities (SIC 5093) and waste recycling facilities (SIC 5093) and which are engaged in the reclaiming and recycling of solid materials such as ferrous and nonferrous metals, plastics, paper, glass and cardboard and automotive parts.

The BMPs described in this subsection are specifically applicable to scrap recycling and waste recycling facilities. Scrap recycling and waste recycling facilities applying for coverage under Part XI.N. of today's permit shall employ a broad and comprehensive range of BMPs and source control measures to minimize and/or eliminate the diversity of pollutants associated with scrap processing operations. In instances where facilities conduct certain operations indoors or under cover, a determination will be made by the owner/operator of the facility as to the applicability of these BMPs and source control measures to these particular activities.

The following table summarizes alternative source control measures, nonstructural BMPs (BMPs), and structural controls that are associated with and applicable to scrap and waste processing facilities (SIC 5093) (nonliquid recyclable materials).

TABLE N-14.— SUMMARY OF ALTERNATIVE BMP OPTIONS FOR SCRAP AND WASTE RECYCLING PROCESSING FACILITIES

Activity	BMP alternatives
Inbound Recyclable and Waste Material Control.	Establish program to encourage suppliers of scrap, waste and other salvageable materials to drain residual fluids prior to arrival at the facility.
	Establish acceptance program for handling, storage and disposal of lead-acid batteries.
	Establish procedures for rejecting or handling, storing and disposal of hazardous wastes and other nonhazardous residual fluids.
	Establish procedures to properly handle industrial turnings and cuttings and prohibiting cutting oils and metallic fines from coming in contact with runoff.
	Identify inspector training requirements.
Outside Scrap Material Storage: (liquids)	Conduct inspections for fluids, e.g., oils, transmission fluids, antifreeze, brake fluid, and fuels. Establish handling/ storage/disposal procedures for these materials.

R0016238

TABLE N-14.— SUMMARY OF ALTERNATIVE BMP OPTIONS FOR SCRAP AND WASTE RECYCLING PROCESSING FACILITIES—Continued

Activity	BMP alternatives
	Drain and collect liquids in a designated area. Provide covered storage or impervious areas with curbing/berms or other appropriate containment. Stored liquid materials in covered areas or impervious areas with curbing/berms or other appropriate measure. Establish spill prevention procedures. Provide adequate supply of materials for dry clean up of spills or leaks. Prevent runoff into liquid storage areas. Store liquid wastes in materially compatible containers. Minimize/eliminate the accumulation of liquid wastes. Establish procedures if hazardous wastes are discovered after material accepted. Conduct periodic inspections of storage areas. Conduct preventative maintenance of BMPs as necessary.
Outside Scrap Material Storage: (bulk solid materials).	Minimize runoff from coming into areas where significant materials are stored, e.g., diversion structures such as curbing, berms, containment trenches, surface grading, and elevated concrete pads or other equivalent measure. Use adsorbents to collect leaking or spills of oil, fuel, transmission and brake fluids, e.g., dry absorbent, drip pans. Install media filters such as catch basin filters and sand filters. Install oil/water separator in storage areas with vehicle transmissions and engines. Locate spill plans under stored vehicles. Provide nonrecyclable waste storage bins and containers. Conduct periodic inspections. Conduct preventative maintenance as necessary. Provide equipment operator training to minimize damage to controls, e.g., curbing and berms.
Storage Other: (lightweight materials)	Identify/provide supplier training or information bulletins on requirements for acceptance of lightweight materials. Encourage supplier participation in program to minimize/eliminate, as practicable, volume of semi-solid and liquid residues in recyclable materials, e.g., residual fluids in aluminum and plastic containers. Provide covered storage, container bins or equivalent for lighter-weight materials such as glass, plastics, aluminum cans, paper, cardboard. Minimize/eliminate residue from bottles, containers, etc. from coming in contact with runoff. Establish dry clean up methods. Establish procedures and employee training for the handling, storage and disposal of residual fluids from small containers. Prohibit washdown of tipping floor areas. Provide good housekeeping to eliminate particulate and residual materials buildup. Establish cleaning schedule for high traffic areas. Provide covered disposal containers or equivalent for residual waste materials. Eliminate floor drains discharging to storm sewer.
Scrap Processing Operations:	Provide training to equipment operators on how to minimize exposure of runoff to scrap processing areas. Schedule frequent cleaning of accumulated fluids and particulate residue around all scrap processing equipment. Schedule frequent inspections of equipment for spills or leakage of fluids, oil, fuel, hydraulic fluids. Conduct routine preventive maintenance of equipment per original manufacturer's equipment (OME) recommendations. Replace worn or malfunctioning parts. Site process equipment on elevated concrete pads or provide runoff diversion structures around process equipment, berms, containment trenches or surface grading or other equivalent measure. Discharge runoff from within bermed areas to a sump, oil/water separator, media filter or discharge to sanitary sewer. Conduct periodic maintenance and clean out of all sumps, oil/water separators, media filters. Dispose of residual waste materials properly, e.g., according to RCRA. Provide curbing, dikes, and berms around scrap processing equipment to prevent contact with runoff. Where practicable, locate process equipment e.g., balers, briquetters, small compactors, under an appropriate cover. Provide cover over hydraulic equipment and combustion engines. Provide dry-clean up materials, e.g.; dry-adsorbents, drip pans, absorbent booms, etc. to prevent contact of hydraulic fluids, oils, fuels, etc., with storm water runoff. Provide alarm, pump shutoff, or sufficient containment for hydraulic reservoirs in the event of a line break. Stabilize high traffic areas, e.g., concrete pads, gravel, pavement, around processing equipment, where practicable. Provide site gages or overfill protection devices for all liquid and fuel storage reservoirs and tanks. Establish spill prevention and response procedures, including employee training. Provide containment bins or equivalent for shredded material, especially lightweight materials such as fluff (preferably at the discharge of these materials from the air classification system).
Supplies for Process Equipment	Locate storage drums containing liquids, including oils and lubricants indoors. Alternatively, site palletized drums and containers on an impervious surface and provide sufficient containment around the materials. Provide sumps, oil/water separators, if necessary.

R0016239

50962 Federal Register / Vol. 60, No. 189 / Friday, September 29, 1995 / Notices

TABLE N-14.—SUMMARY OF ALTERNATIVE BMP OPTIONS FOR SCRAP AND WASTE RECYCLING PROCESSING FACILITIES—Continued

Activity	BMP alternatives
	Conduct periodic inspections of containment areas and containers/drums for corrosion. Perform preventive maintenance of BMPs, as necessary. Instruct employees on proper material handling and storage procedures.
Scrap lead acid battery Program	Establish inspection and acceptance procedures for scrap lead-acid batteries. Provide supplier training on acceptance practices for scrap batteries. Provide employee training on the safe handling, storage and disposition of scrap batteries. Separate all scrap batteries from other scrap materials. Store scrap batteries under cover or equivalent. Establish procedures for the storage, handling, disposition of cracked or broken batteries in accordance with applicable Federal regulations, e.g., RCRA. Establish procedures to collect and dispose of leaking battery acid according to Federal regulations, e.g., RCRA. Provide covered storage or equivalent to prevent exposure to either precipitation or runoff.
Vehicle and Equipment Maintenance	Establish an inventory of materials used in the maintenance shop that could become a potential pollutant source with storm water runoff, e.g., fuels, solvents, oils, lubricants. Store and dispose of oily rags, filters (oil and air), batteries, engine coolant, transmission fluid, use oil, brake fluid, and solvents in a manner that minimizes potential contact with runoff and in compliance with State and Federal regulations. Label and track recycling of waste materials, e.g., batteries, solvent, used oil. Drain oil filters before disposal or recycling. Drain all fluids from all parts or components that will become scrap material or secondhand parts. Store liquid waste materials in compatible containers. Store and dispose used batteries in accordance with scrap lead acid battery program. Disconnect all floor drains connected to storm sewer system. Prohibit non-storm water discharges, e.g., dumping of used liquids down floor drains and washdown of maintenance areas. Provide employee training on appropriate storage and disposal of waste materials. Provide good housekeeping measures. Conduct inspections of work areas for compliance with BMPs.
Fueling	Use spill and overflow protection devices. Provide high level alarm on fuel storage tanks. Minimize/eliminate runoff onto fueling areas. Reduce exposure of fueling areas to precipitation by covering the fueling area. Provide dry adsorbents to clean up fuel spills. Conduct periodic inspections of fueling areas. Instruct personnel on proper fueling procedures. Provide curbing or posts around fuel pumps to prevent collisions during vehicle ingress and egress.
Vehicle and Equipment Washing	Avoid washing vehicles and equipment outdoors. Use biodegradable, phosphate free detergents. Recycle wash water. Provide vehicle wash rack with dedicated sediment trap. Use autoshut-off valves on washing equipment.
Outdoor vehicle parking and storage	Use drip pans under all equipment and vehicles waiting maintenance. Cover vehicle and equipment storage areas. Conduct inspections of storage and parking areas for leaks and filled drip pans. Provide employee training.
Vehicle and Equipment Painting (where applicable).	Keep paint and solvents away from traffic areas. Conduct sanding and painting in nonexposed areas, e.g., under cover, in accordance with OSHA standards. Cleanup accumulated particulate matter. Minimize overspraying parts. Dispose or recycle paint, solvents and thinner properly. Provide training to employees. Conduct periodic inspections of paint spraying areas.
Erosion and Sediment Control	Minimize runon from adjacent properties, e.g., diversion dikes, berms, or equivalent. Trap sediment at downgradient locations and outlets serving unstabilized areas. This may include filter fabric fences, gravel outlet protection, sediment traps, vegetated or riprap swales, vegetated strips, diversion structures, catch-basin filters, retention/detention basins or equivalent. Runoff containing oil and grease may include the use of absorbent booms or sand filters in front of outlet structures or other equivalent measures. Stabilize all high traffic areas, including all vehicle entrances and exit points. Conduct periodic sweeping of all traffic areas. Conduct inspections of BMPs. Perform preventative maintenance as needed on BMPs. Provide employee training on the proper installation and maintenance of erosion and sediment controls.

R0016240

b. Waste Recycling Facilities (SIC 5093)—(recyclable liquid wastes). This section addresses source control measures, BMPs, and structural controls that are specifically applicable to waste recycling facilities (SIC 5093) which are engaged in such activities as reclaiming and recycling of liquid wastes such as spent solvents, used oil, and used antifreeze (ethylene glycol). Waste recycling facilities applying for coverage under Part XI.N. of today's proposed permit will be required to employ a comprehensive range of BMPs and source control measures to minimize contact of pollutants with storm water runoff and precipitation. In instances where facilities conduct certain operations indoors or under cover, a determination will be made by the owner/operator of the facility as to the applicability of these BMPs and source control measures to their particular facility. The following table summarizes the percent breakdown of BMPs that were reported by applicants participating in group application number 195.

TABLE N-15.—TYPES OF BMPS REPORTED IN EPA GROUP APPLICATION NUMBER 195

BMP	Percent of facilities
Secondary Containment (includes tanks, piping, and return/fill stations)	70
Containment Trench (includes closed loop containment trenches with sumps, sloped floors, and/or berms)	91
Roof (includes canvass tank roofs and enclosed structures)	7
Contingency Plan (serves as Spill Prevention and Countermeasures Control Plan)	100
Prevention and Preparedness Plan (includes inspection information and general housekeeping procedures)	100

The following table summarizes types of BMPs, and structural control options that are applicable to liquid waste recycling facilities.

TABLE N-16.—TYPES OF BMP OPTIONS APPLICABLE TO LIQUID WASTE RECYCLING FACILITIES

Activity	BMP alternatives
Individual Drum/Container Storage	Ensure container/drums are in good condition. Store waste materials in materially compatible drums. Use containers that meet National Fire Protection Association (NFPA) guidelines.
	Put individual containers on pallets. Limit stack height of individual containers/drums. Provide straps, plastic wrap, or equivalent around stacked containers to provided stability.
	Label/mark drums. Segregate hazardous and flammable wastes. Comply with NFPA guidelines for segregation of flammable wastes.
	Provide adequate clearance to allow material movement and access by material handling equipment.
	Provide semipermanent or permanent cover over wastes.
	Provide adequate clearance between stored materials to allow movement and handling.
	Establish clean up procedures, including the use of dry adsorbents, in the event of spills or leaks.
	Prohibit washing down of material storage areas. Disconnect or seal all floor drains from storm sewer system.
	Develop spill prevention, countermeasures and control (SPCC) procedures for all liquid container storage areas. Ensure employees are familiar with SPCC procedures. Schedule/conduct periodic employee training.
	Provide secondary containment, dikes, berms, containment trench, sumps, or other equivalent measure, in all storage areas.
Bulk Liquid Storage	Use welded pipe connections versus flange connections. Inspect all flange gaskets for deterioration.
	Apply corrosion inhibitors to exposed metal surfaces.
	Provide high level alarms for storage tanks.
	Provide redundant piping, valves, pumps, motors, as necessary, at all pumping stations. Provide manually activated shutoff valves in the event of spill. Install visible and/or audible alarms in the event of a spill.
	Install manually activated drainage values, or equivalent, versus flapper-type drain values. Provide adequate security against vandalism and tampering.
	Provide secondary containment around all bulk storage tanks, including berms, dikes, surface impoundments or equivalent. Ensure surfaces of secondary containment areas are adequately sealed to prevent leaks.
	Provide stationary boxes around all return and fill stations to eliminate/minimize hose drainage and minor waste transfer spills.
Waste Transfer Areas	Provide secondary containment or equivalent measures around all liquid waste transfer facilities.
	Provide cover over liquid waste transfer areas.
	Establish clean up procedures for minor spills including the use of dry adsorbents.
Inspections	Conduct inspections of all material storage, handling and transfer areas.
	Document signs of corrosion, worn parts or components on pumps and motors, leaking seals and gaskets.
	Conduct periodic nondestructive testing (NDT) of all bulk storage tanks for signs of deteriorating structural integrity.
Preventive Maintenance	Conduct periodic preventive maintenance of all structural controls, replace worn parts on components on valves, pumps, motors per manufacturer's recommendations.
Vehicle Maintenance (if applicable)	Establish an inventory of materials used in the maintenance shop that could become a potential pollutant source with storm water runoff, e.g., fuels, solvents, oils, lubricants.

R0016241

TABLE N-16.—TYPES OF BMP OPTIONS APPLICABLE TO LIQUID WASTE RECYCLING FACILITIES—Continued

Activity	BMP alternatives
	Store and dispose of oily rags, filters (oil and air), batteries, engine coolant, transmission fluid, use oil, brake fluid, and solvents in a manner that minimizes potential contact with runoff and in compliance with State and Federal regulations. Label and track recycling of waste materials, e.g., batteries, solvent, used oil. Drain oil filters before disposal or recycling. Drain all fluids from all parts or components that will become scrap material or secondhand parts. Store liquid waste materials in compatible containers. Store and dispose used batteries in accordance with scrap lead acid battery program. Disconnect all floor drains connected to storm sewer system. Prohibit non-storm water discharges, e.g., dumping of used liquids down floor drains and washdown of maintenance areas. Provide employee training on appropriate storage and disposal of waste materials. Provide good housekeeping measures. Conduct inspections of work areas for compliance with BMPs.
Vehicle Cleaning (if applicable)	Avoid washing vehicles and equipment outdoors. Use biodegradable, phosphate free detergents. Recycle wash water. Provide vehicle wash rack with dedicated sediment trap. Use autoshut-off valves on washing equipment.
Training	Provide employee training on proper material handling and storage procedures. Require familiarization with applicable SPCC measures.

c. Recycling Facilities (SIC 5093). This section addresses best management practices that have been employed by one or more facilities within group applications 274, 647, 826, and 1145. The following table provides examples of BMPs used by the recycling facilities within this sub-section:

TABLE N-17.—Types of BMP Options Applicable to Recycling Facilities

Activity	BMP options and alternatives
Inbound Recyclable Materials Control	Provide public education brochures on acceptable recyclable materials. Educate curbside pick-up drivers on acceptable materials. Reject unacceptable materials at the source. Employee training. Provide totally-enclosed drop-off containers for public.
Indoor Storage	Store equivalent of the average daily volume of recyclable materials indoors. Provide good housekeeping. Disconnect all floor drains from storm sewer system. Prohibit illicit discharges and illegal dumping to floor drains that are connected to the storm sewer. Direct tipping floor washwaters to sanitary sewer system if permitted by local sanitary authority.
Recyclable Material Processing	Conduct processing operations indoors. Clean up residual fluids. Conduct routine preventive maintenance on all processing equipment. Schedule frequent good housekeeping to minimize particulate and residual materials buildup.
Outdoor Storage	Store only processed materials, i.e., baled plastic and aluminum and glass cullet. Provide containment pits with sumps pumps that discharge to sanitary sewer system. Prevent discharge of residual fluids to storm sewer. Provide dikes and curbs around bales of waste paper. Use tarpaulins or covers over bales of wastepaper. Conduct regularly scheduled sweeping of storage areas to minimize particulate buildup.
Residual Non-recyclable Materials	Store residual non-recyclable materials in covered containers for transport to a proper disposal facility. Bale residual non-recyclable materials and cover with tarpaulin or equivalent.
Vehicle Maintenance	Avoid washing equipment and vehicles outdoors. Eliminate outdoor maintenance areas.
Fueling	Establish spill prevention and clean-up procedures. Provide dry-absorbent materials or equivalent. Provide employee training, i.e., avoid topping off fuel tanks. Divert runoff from fueling areas.
Lubricant Storage	Eliminate or minimize outside storage. Provide employee training on proper, handling, storage. Divert runoff from storage areas.

4. Discharges Covered under this Section

The requirements listed under this section are applicable to storm water discharges from facilities typically identified in SIC 5093 (except for battery reclaimers and auto salvage yards). This includes facilities that are engaged in the processing, reclaiming and wholesale distribution of scrap and waste materials such as ferrous and nonferrous metals, paper, plastic,

R0016242

cardboard, glass. For purposes of this permit, the term waste recycling facility applies to those facilities within SIC 5093 that receive a mixed wastestream of recyclable and non-recyclable wastes. Facilities that are engaged in reclaiming and recycling liquid wastes such as used oil, antifreeze, mineral spirits and industrial solvents and which are classified SIC 5093 are also covered under this section. The term recycling facility is used in this permit to those facilities that only receive source-separated recyclable materials primarily from non-industrial and residential sources, e.g., common consumer products including paper, newspaper, glass, cardboard, plastic containers, aluminum and tin cans.

5. Special Conditions

The following section identifies special conditions that are applicable to permittees applying for coverage under Part XI.N. of today's permit.

a. Prohibition of Non-storm Water Discharges. This section requires scrap and waste recycling facilities that are typically classified in SIC 5093 to certify that certain non-storm water discharges are not occurring at their facilities. A list of non-storm water discharges that are not authorized by this section has been identified. These discharges are prohibited due to the likelihood these discharges will contain substantial pollutant concentrations. The following non-storm water discharges are not authorized by this section: waste discharges to floor drains or sinks connected to the facilities storm sewer or storm drainage system; water originating from vehicle and equipment washing; steam cleaning wastewater; process wastewaters; washwater originating from cleaning tipping floor areas or material receiving areas that discharge to any portion of a storm sewer system; wastewater from wet scrubbers; boiler blowdown; noncontact and contact cooling water; discharges originating from dust control spray water; discharges from oil/water separators and sumps in the absence of a storm event; discharges originating from the cleaning out of oil/water separators or sumps; and non-storm water discharges from turnings containment areas.

The operators of non-storm water discharges must seek coverage for these discharges under a separate National Pollutant Discharge Elimination System (NPDES) permit if discharging to either a municipal separate storm sewer system or to waters of the United States. If such a permit has been issued, the plan shall identify the NPDES permit number and a copy of the NPDES permit shall be located at the facility and shall be readily accessible. If a permit application has been submitted for a non-storm water discharge, the plan shall be annotated accordingly and a copy of the application shall be located at the facility and shall be readily accessible.

For facilities that have prohibited discharges identified under this section and which discharge to a sanitary sewer system, the facility operator is required to take the appropriate notification actions as may be required by the operator of the sanitary sewer system. Any relevant documentation, i.e., notification letters and approvals, shall be kept with the plan. For facilities that have been issued an industrial user permit under the pretreatment program for discharges prohibited under this section, the plan shall identify the appropriate NPDES permit number and a copy of the permit shall be kept at the facility and shall be readily accessible. EPA strongly recommends that operators keep copies of relevant documentation concerning non-storm water discharges and NPDES permits with the plan.

6. Storm Water Pollution Prevention Plan Requirements

a. Contents of the Plan. In addition to the supplemental information requirements identified in Part VI.C., scrap and waste recycling facilities in SIC 5093 are required to provide the additional information applicable to their industrial sector. The storm water pollution prevention plan is broken out into three subcategories; scrap recycling and waste recycling facilities (nonliquid materials); waste recycling facilities (liquid materials); and recycling facilities.

(1) Description of Potential Pollutant Sources

(a) Scrap Recycling and Waste Recycling Facilities (nonliquid recyclable wastes)—This section establishes that scrap recycling and waste recycling facilities shall provide the following information in their pollution prevention plan.

(i) Inbound Recyclable and Waste Material Control Program—The plan shall include a recyclable and waste material inspection program to minimize the likelihood of receiving non-recyclable materials (e.g., hazardous materials) that may be significant pollutant sources to storm water discharges. At a minimum, the plan shall address the following:

Information/education measures to encourage major suppliers of scrap and recyclable waste materials to drain residual fluids, whenever applicable, prior to its arrival at the facility. This includes vehicles and equipment engines, radiators, and transmissions, oil-filled transformers, white goods (appliances) and individual containers or drums;

Activities which accept scrap and materials that may contain residual fluids, e.g., automotive engines containing used oil, transmission fluids, etc., shall describe procedures to minimize the potential for these fluids from coming in contact with either precipitation or runoff. The description shall also identify measures or procedures to properly store, handle, dispose and/or recycle these residual fluids;

Procedures pertaining to the acceptance of scrap lead-acid batteries. Additional requirements for the handling, storage and disposal or recycling of batteries shall be in conformance with conditions for a scrap lead-acid battery program, see below;

A description of training requirements for those personnel engaged in the inspection and acceptance of inbound recyclable materials; and

Liquid wastes, including used oil, shall be stored in materially compatible and nonleaking containers and disposed or recycled in accordance with all requirements under the Resource Recovery and Conservation Act (RCRA), and other State or local requirements.

(ii) Scrap and Waste Material Stockpiles (outdoors)—The plan shall address areas where significant materials are exposed to either storm water runoff or precipitation. The plan must describe those measures and controls used to minimize contact of storm water runoff with stockpiled materials. The plan should include measures to minimize the extent of storm water contamination from these areas. The operator shall consider (within the plan) the use of the following BMPs (either individually or in combination) or their equivalent to minimize contact with storm water runoff:

Diversion devices or structures such as dikes, berms, containment trenches, culverts and/or surface grading;

Media filtration such as catch basin filters and sand filters;

Silt fencing; and,

Oil/water separators, sumps and dry adsorbents in stockpile areas that are potential sources of residual fluids, e.g., automotive engine storage areas.

The operator may consider the use of permanent or semipermanent covers, or other similar forms of protection over stockpiled materials where the operator determines that such measures are reasonable and appropriate.

R0016243

The operator may consider the use of sediment traps, vegetated swales and/or vegetated strips to facilitate settling or filtering out of pollutants and sediment.

(iii) Stockpiling of Turnings Previously Exposed to Cutting Fluids (outdoors)—The plan shall address all areas where stockpiling of industrial turnings (previously exposed to cutting fluids) occurs. The plan shall implement those measures necessary to minimize contact of surface runoff with residual cutting fluids. The operator shall consider implementation of either of the following two alternatives or a combination of both or equivalent measures:

Alternative 1: Storage of all turnings previously exposed to cutting fluids under some form of permanent or semi-permanent cover. Discharges of residual fluids from these areas to the storm sewer system in the absence of a storm event is prohibited. Discharges to the storm sewer system as a consequence of a storm event is permitted provided the discharge is first directed through an oil/water separator or its equivalent. Procedures to collect, handle, and dispose or recycle residual fluids that may be present shall be identified in the plan.

Alternative 2: Establish dedicated containment areas for all turnings that have been exposed to cutting fluids where runoff from these areas is directed to a storm sewer system, providing the following:

Containment areas constructed of either concrete, asphalt or other equivalent type of impermeable material;

A perimeter around containment areas to prevent runoff from moving across these areas. This would include the use of shallow berms, curbing, or constructing an elevated pad or other equivalent measure;

A suitable drainage collection system to collect all runoff generated from within containment areas. At a minimum, the drainage system shall include a plate-type oil/water separator or its equivalent. The oil/water separator or its equivalent shall be installed according to the manufacturer's recommended specifications, whenever available, specifications will be kept with the plan;

A schedule to maintain the oil/water separator (or its equivalent) to prevent the accumulation of appreciable amounts of fluids. In the absence of a storm event, no discharge from containment areas to the storm sewer system are permitted unless the discharge is covered by a separate NPDES permit; and

Identify procedures for the proper disposal or recycling of collected residual fluids.

(iv) Scrap and Waste Material Stockpiles (covered or indoors)—The plan shall address, at a minimum, measures and controls to minimize and, whenever feasible, eliminate residual liquids and particulate matter from materials stored indoors from coming in contact with surface runoff. The operator shall consider including in their plan: good housekeeping measures to collect residual liquids from aluminum, glass and plastic containers and prohibiting the practice of allowing washwater from tipping floors or other indoor processing areas from discharging to a storm sewer system, inspections to ensure that material stockpile areas with existing floor drains are not connected to the storm sewer system or any portion of the storm sewer system, and the disconnection of any floor drains to the storm drainage system.

(v) Scrap and Recyclable Waste Processing Areas—The plan shall address areas where scrap and recyclable waste processing equipment are sited. This includes measures and controls to minimize surface runoff from coming in contact with scrap processing equipment. In the case of processing equipment that generate visible amounts of particulate residue, e.g., shredding facilities, the plan shall describe good housekeeping and preventive maintenance measures to minimize contact of runoff with residual fluids and accumulated particulate matter. At a minimum, the operator shall consider including the following:

A schedule of periodic inspections of equipment for leaks, spills, malfunctioning, worn or corroded parts or equipment; preventive maintenance program to repair and/or maintain processing equipment; measures to minimize shredder fluff from coming in contact with surface runoff; use of dry-absorbents or other cleanup practices to collect and to dispose or recycle spilled or leaking fluids; and installation of low-level alarms or other equivalent protection devices on unattended hydraulic reservoirs over 150 gallons in capacity. Alternatively, provide secondary containment with sufficient volume to contain the entire volume of the reservoir.

The operator shall consider using the following types of BMPs:

(a) Diversion structures such as dikes, berms, culverts, containment trenches, elevated concrete pads, grading to minimize contact of storm water runoff with outdoor processing equipment;

(b) Oil/water separators or sumps in processing areas that are potential sources of residual fluids and grease;

(c) Permanent or semipermanent covers, or other similar measures;

(d) Retention and detention basins or ponds, sediment traps or vegetated swales and strips, to facilitate settling or filtering out of pollutants in runoff from processing areas; or

(e) Media filtration such as catch basin filters and sand filters.

(vi) Scrap Lead-acid Battery Program—The plan shall address measures and controls for the proper receipt, handling, storage and disposition of scrap lead-acid batteries (battery reclaiming is not eligible for coverage under this permit). The operator shall consider including: procedures for accepting scrap batteries and describing how they will be segregated from other scrap materials; procedures for managing battery casings that may be cracked or leaking, including the proper handling and disposal of residual fluids; measures to minimize and, whenever possible, eliminate exposure of scrap batteries to either runoff or precipitation; the schedule for conducting periodic inspections of scrap battery storage areas and applicable source control measures; and measures to provide employee training on the management of scrap batteries.

(vii) Erosion and Sediment Control—The plan shall identify all areas associated with industrial activity that have a high potential for soil erosion and suspended solids loadings, i.e., areas that tend to accumulate significant particulate matter. Appropriate source control, stabilization measures, nonstructural, structural controls, or an equivalent shall be provided in these areas. The plan shall also contain a narrative discussion of the reason(s) for selected erosion and sediment controls. At a minimum, the operator shall consider in the plan, either individually or in combination, the following erosion and sediment control measures:

Filtering or diversion practices, such as filter fabric, sediment filter boom, earthen or gravel berms, curbing or other equivalent measure;

Catch basin filters, filter fabric, or equivalent measure, placed in or around inlets or catch basins that receive runoff from scrap and waste storage areas, and processing equipment; and

Sediment traps, vegetative buffer strips, or equivalent, that effectively trap or remove sediment prior to discharge through an inlet or catch basin.

In instances where significant erosion and suspended solids loadings continue after implementation of source control

R0016244

measures and nonstructural controls, the operator shall consider providing in the plan for a detention or retention basin or other equivalent structural control. All structural controls shall be designed using good engineering practice. All structural controls and outlets that are likely to receive discharges containing oil and grease must include appropriate measures to minimize the discharge of oil and grease through the outlet. This may include the use of an absorbent boom or other equivalent measure.

Where space limitations (e.g., obstructions caused by permanent structures such as buildings and permanently-sited processing equipment and limitations caused by a restrictive property boundary) prevent the siting of a structural control, i.e., retention basin, such a determination will be noted in the plan. The operator will identify in the plan what existing practices shall be modified or additional measures shall be undertaken to minimize erosion and suspended sediment loadings in lieu of a structural BMP.

(*viii*) *Spill Prevention and Response Procedures*—To prevent or minimize storm water contamination at loading and unloading areas, and from equipment or container failures, the operator shall consider including in the plan the following practices:

Description of spill prevention and response measures to address areas that are potential sources of leaks or spills of fluids;

All significant leaks and spills should be contained and cleaned up as soon as possible. If malfunctioning equipment is responsible for the spill or leak, repairs should also be conducted as soon as possible;

Cleanup procedures should be identified in the plan, including the use of dry absorbent materials or other cleanup methods. Where dry absorbent cleanup methods are used, an adequate supply of dry absorbent material should be maintained onsite. Used absorbent material should be disposed of properly;

Drums containing liquids, including oil and lubricants, should be stored indoors; or in a bermed area; or in overpack containers or spill pallets; or in similar containment devices;

Overfill prevention devices should be installed on all fuel pumps or tanks;

Drip pans or equivalent measures should be placed under any leaking piece of stationary equipment until the leak is repaired. The drip pans should be inspected for leaks and checked for potential overflow, and be emptied regularly to prevent overflow and all liquids will be disposed of in accordance with all requirements under RCRA; and

An alarm and/or pump shut off system should be installed and maintained on all outside equipment with hydraulic reservoirs exceeding 150 gallons (only those reservoirs not directly visible by the operator of the equipment) in order to prevent draining the tank contents in the event of a line break. Alternatively, the equipment may have a secondary containment system capable of containing the contents of the hydraulic reservoir plus adequate freeboard for precipitation. Leaking hydraulic fluids should be disposed of in accordance with all requirements under RCRA.

(*ix*) *Quarterly Inspections*—A quarterly inspection shall include all designated areas of the facility and equipment identified in the plan. The inspection shall include a means of tracking and conducting follow up actions based on the results of the inspection. The inspections shall be conducted by members of the Storm Water Pollution Prevention team. At a minimum, quarterly inspections shall include the following areas:

All outdoor scrap processing areas;

All material unloading and loading areas (including rail sidings) that are exposed to either precipitation or storm water runoff;

Areas where structural BMPs have been installed;

All erosion and sediment BMPs;

Outdoor vehicle and equipment maintenance areas;

Vehicle and equipment fueling areas; and

All areas where waste is generated, received, stored, treated, or disposed and which are exposed to either precipitation or storm water runoff.

If exposed to precipitation or storm water runoff, the inspection shall attempt to identify any corroded or leaking containers, corroded or leaking pipes, leaking or improperly closed valves and valve fittings, leaking pumps and/or hose connections, and deterioration in diversionary or containment structures. Spills or leaks shall be immediately addressed according to the facilities. A record of inspections shall be maintained with the plan.

The BMPs identified above have been employed by scrap recycling and waste recycling facilities are believed to be appropriate given the types of pollutants found in storm water discharges from these facilities. In addition, the diversity of options allows permittees to select those BMPs that are most applicable to the extent of the risk that exists at a particular facility. In instances where nonstructural measures are not sufficient, the conditions direct the permittee to more stringent requirements such as structural controls.

(*b*) *Waste Recycling Facilities (Recyclable liquid wastes)*—This section establishes that waste recycling facilities (recyclable liquid wastes) shall provide the following information.

(*i*) *Waste Material Storage (Indoors)*—The operator shall consider including in the plan measures and controls to minimize residual liquids from waste materials stored indoors from coming in contact with surface runoff and provisions to maintain a sufficient supply of dry-absorbent materials or a wet vacuum system or other equivalent measure to promptly respond to minor leaks or spills. Measures for secondary containment or its equivalent and procedures for proper material handling (including labeling and marking) and storage of containerized materials should be considered. Drainage from bermed areas should be discharged to an appropriate treatment facility or sanitary sewer system. Discharges from bermed areas should be covered by a separate NPDES permit or industrial user permit under the pretreatment program. The drainage system, where applicable, should include appropriate appurtenances such as pumps or ejectors and manually-operated valves of the open-and-close design.

(*ii*) *Waste Material Storage (outdoors)*—The plan will address areas where waste materials are exposed to either storm water runoff or precipitation. The plan must include measures to provide appropriate containment, drainage control and/or other appropriate diversionary structures. The plan must describe those measures and controls used to minimize contact of storm water runoff with stored materials. The operator shall consider including in the plan the following preventative measures or an equivalent:

An appropriate containment structure such as dikes, berms, curbing or pits, or other equivalent measure. The containment should be sufficient to store the volume of the largest single tank and should include sufficient freeboard for precipitation;

A sufficient supply of dry-absorbent materials or a wet vacuum system to collect liquids from minor spills and leaks in contained areas; and

Discharges of precipitation from containment areas containing used oil shall be in accordance with applicable sections of 40 CFR Part 112.

(*iii*) *Truck and Rail Car Waste Transfer Areas*—The plan will describe

R0016245

measures and controls for truck and rail car loading and unloading areas. This includes appropriate containment and diversionary structures to minimize contact with precipitation and/or storm water runoff. The plan will also address measures to clean up minor spills and/or leaks originating from the transfer of liquid wastes. This may include dry-clean up methods, roof coverings, and other runoff controls.

(iv) Erosion and Sediment Control—The plan shall identify all areas associated with industrial activity that have a high potential for soil erosion. Appropriate stabilization measures, nonstructural and structural controls shall be provided in these areas. The plan shall contain a narrative consideration of the appropriateness for selected erosion and sediment controls. Where applicable, the facility shall consider the use of the following types of preventive measures: sediment traps; vegetative buffer strips; filter fabric fence; sediment filtering boom; gravel outlet protection; or other equivalent measures that effectively trap or remove sediment prior to discharge through an inlet or catch basin.

(v) Spill Prevention and Response Procedures—The plan will address measures and procedures to address potential spill scenarios that could occur at the facility. This includes all applicable handling and storage procedures, containment, diversion controls and clean-up procedures. The plan will specifically address all outdoor and indoor storage areas, waste transfer areas, material receiving areas (loading and unloading), and waste disposal areas.

(vi) Quarterly Inspections—Quarterly visual inspections shall be conducted by a member, or members, of the storm water pollution prevention team. The quarterly inspection shall include all designated areas of the facility and equipment identified in the plan. The inspection shall include a means of tracking and conducting follow up actions based on the results of the inspection. At a minimum, the inspections shall include the following areas:

Material storage areas;

Material unloading and loading areas (including rail sidings) that are exposed to either precipitation or storm water runoff;

Areas where structural BMPs have been installed;

All erosion and sediment BMPs;

Outdoor vehicle and equipment maintenance areas (if applicable);

Vehicle and equipment fueling areas (if applicable); and

All areas where waste is generated, received, stored, treated, or disposed and which are exposed to either precipitation or storm water runoff.

If exposed to precipitation or storm water runoff, the inspection shall identify the presence of any corroded or leaking containers, corroded or leaking pipes, leaking or improperly closed valves and valve fittings, leaking pumps and/or hose connections, and deterioration in diversionary or containment structures. Spills or leaks shall be immediately addressed according to the facility's spill prevention and response procedures.

(c) Recycling Facilities.—This section establishes that recycling facilities (including MRFs) that receive only source-separated recyclable materials primarily from non-industrial and residential sources shall provide the following information in their pollution prevention plan.

(i) Inbound Recyclable Material Control Program. The plan shall include a recyclable material inspection program to minimize the likelihood of receiving non-recyclable materials (e.g., hazardous materials) that may be significant source of pollutants in surface runoff. At a minimum, the operator shall consider addressing in the plan the following:

A description of information and education measures to educate the appropriate suppliers of recyclable materials on the types of recyclable materials that are acceptable and those that are not acceptable, e.g., household hazardous wastes;

A description of training requirements for drivers responsible for pickup of recyclable materials;

Clearly mark public drop-off containers as to what materials can be accepted;

Rejecting non-recyclable wastes or household hazardous wastes at the source; and

A description of procedures for the handling and disposal of nonrecyclable materials.

(ii) Outdoor Storage. The plan shall include BMPs to minimize or reduce the exposure of recyclable materials to surface runoff and precipitation. The plan, at a minimum, shall include good housekeeping measures to prevent the accumulation of visible quantities of residual particulate matter and fluids, particularly in high traffic areas. The plan shall consider tarpaulins or their equivalent to be used to cover exposed bales of recyclable waste paper. The operator shall consider within the plan the use of the following types of BMPs (individually or in combination) or their equivalent:

Provide totally-enclosed drop-off containers for public.

Provide a sump and sump pump with each containment pit. Prevent the discharge of residual fluids to storm sewer system. Prevent discharging to the storm sewer system;

Provide dikes and curbs around bales of recyclable waste paper;

Divert surface runoff away from outside material storage areas;

Provide covers over containment bins, dumpsters, roll-off boxes; and,

Store the equivalent one day's volume of recyclable materials indoors.

(iii) Indoor Storage and Material Processing. The plan shall address BMPs to minimize the release of pollutants from indoor storage and processing areas to the storm sewer system. The plan shall establish specific measures to ensure that all floor drains do not discharge to the storm sewer system. The following BMPs shall be considered for inclusion in the plan:

Schedule routine good housekeeping measures for all storage and processing areas;

Prohibit the practice of allowing tipping floor washwaters from draining to any portion of a storm sewer system;

Provide employee training on pollution prevention practices;

(iv) Vehicle and Equipment Maintenance. The plan shall also provide for BMPs in those areas where vehicle and equipment maintenance is occurring outdoors. At a minimum, the following BMPs shall be considered for inclusion in the plan:

Prohibit vehicle and equipment washwater from discharging to the storm sewer system;

Minimize or eliminate outdoor maintenance areas, wherever possible;

Establish spill prevention and clean-up procedures in fueling areas;

Provide employee training on avoiding topping off fuel tanks;

Divert runoff from fueling areas;

Store lubricants and hydraulic fluids indoors;

Provide employee training on proper, handling, storage of hydraulic fluids and lubricants.

Monitoring and Reporting Requirements

Analytical Monitoring Requirements. EPA believes that scrap recycling and waste recycling facilities (nonsource-separated facilities only) may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. In order to provide a tool for evaluating the effectiveness of the pollution prevention

R0016246

plan and to characterize the discharge for potential environmental impacts, the permit requires scrap recycling and waste recycling facilities to collect and analyze samples of their storm water discharges for the pollutants listed in Table N–18. The pollutants listed in Table N–18 were found to be above benchmark levels for a significant portion of scrap and waste recycling facilities that submitted quantitative data in the group application process, or are believed to be present based upon the description of industrial activities and significant materials exposed. Because these pollutants have been reported above benchmark levels, EPA is requiring monitoring after the pollution prevention plan has been implemented to assess the effectiveness of the pollution prevention plan and to help ensure that a reduction of pollutants is realized.

At a minimum, storm water discharges from scrap recycling and waste recycling facilities must be monitored quarterly during the second year of permit coverage. Samples must be collected at least once in each of the following periods: January through March; April through June; July through September; and October through December. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Table N–18. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE N–18.—INDUSTRY MONITORING REQUIREMENTS

Pollutants of concern [1]	Cut-off concentration
Chemical Oxygen Demand (COD).	120 mg/L
Total Suspended Solids (TSS).	100 mg/L
Total Recoverable Aluminum.	0.75 mg/L
Total Recoverable Copper.	0.0636 mg/L
Total Recoverable Iron ...	1.0 mg/L
Total Recoverable Lead .	0.0816 mg/L
Total Recoverable Zinc ...	0.117 mg/L

[1] Several congeners of PCBs (PCB–1016, –1221, –1242, –1248, –1260) were above established benchmarks, however, EPA believes that these constituents will readily bound up with sediment and particulate matter. Therefore, EPA feels that monitoring for TSS will serve as an adequate indicator for the control of PCBs.

If the average concentration for a parameter is less than or equal to the value listed in Table N–18, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration listed in Table N–18, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit.

TABLE N–19.—SCHEDULE OF MONITORING

2nd Year of Permit Coverage	• Conduct quarterly monitoring. • Calculate the average concentration for all parameters analyzed during this period. • If average concentration is greater than the value listed in Table N–18, then quarterly sampling is required during the fourth year of the permit. • If average concentration is less than or equal to the value listed in Table N–18, then no further sampling is required for that parameter.
4th Year of Permit Coverage	• Conduct quarterly monitoring for any parameter where the average concentration in year 2 of the permit is greater than the value listed in Table N–18. • If industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will reassess the effectiveness of the adjusted pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly chemical sampling.

b. Alternative Certification. Throughout today's permit, EPA has proposed monitoring requirements for facilities which the Agency believes have the potential for contributing significant levels of pollutants to storm water discharges. The alternative described below is necessary to ensure that monitoring requirements are only imposed on those facilities that do, in fact, have storm water discharges containing pollutants at concentrations of concern. EPA has determined that if materials and activities are not exposed to storm water at the site, then the potential for pollutants to contaminate storm water discharges does not warrant monitoring.

Therefore, a discharger is not subject to the monitoring requirements of this Part provided the discharger makes a certification for a given outfall, or on a pollutant-by-pollutant basis in lieu of monitoring reports required, under penalty of law, signed in accordance with Part VII.G. (Signatory Requirements), that material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, industrial machinery or operations, significant materials from past industrial activity that are located in areas of the facility that are within the drainage area of the outfall are not presently exposed to storm water and will not be exposed to storm water for the certification period. Such certification must be retained in the storm water pollution prevention plan and submitted to EPA in the case of certifying that a pollutant is not present, the permittee must submit the certification along with the monitoring

R0016247

reports required under paragraph (c) below. If the permittee cannot certify for an entire period, they must submit the date exposure was eliminated and any monitoring required up until that date. This certification option is not applicable to compliance monitoring requirements associated with effluent limitations. EPA does not expect facilities to be able to exercise this certification for indicator parameters, such as TSS and BOD.

c. Reporting Requirements. Permittees are required to submit all monitoring results obtained during the second and fourth year of permit coverage within 3 months of the conclusion of each year. For each outfall, one signed Discharge Monitoring Report form must be submitted to the Director per storm event sampled. For facilities conducting monitoring beyond the minimum quarterly requirements an additional Discharge Monitoring Report Form must be filed for each analysis.

d. Sample Type. All discharge data shall be reported for grab samples. All such samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches in magnitude and that occurs at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. The required 72-hour storm event interval is waived where the preceding measurable storm event did not result in a measurable discharge from the facility. The required 72-hour storm event interval may also be waived where the permittee documents that less than a 72-hour interval is representative for local storm events during the season when sampling is being conducted. The grab sample shall be taken during the first 30 minutes of the discharge. If the collection of a grab sample during the first 30 minutes is impracticable, a grab sample can be taken during the first hour of the discharge, and the discharger shall submit with the monitoring report a description of why a grab sample during the first 30 minutes was impracticable. If storm water discharges associated with industrial activity commingle with process or nonprocess water, then where practicable permittees must attempt to sample the storm water discharge before it mixes with the non-storm water discharge.

e. Representative Discharge. When a facility has two or more outfalls that, based on a consideration of industrial activity, significant materials, and management practices and activities within the area drained by the outfall, the permittee reasonably believes discharge substantially identical effluents, the permittee may test the effluent of one of such outfalls and report that the quantitative data also applies to the substantially identical outfall(s) provided that the permittee includes in the storm water pollution prevention plan a description of the location of the outfalls and explains in detail why the outfalls are expected to discharge substantially identical effluent. In addition, for each outfall that the permittee believes is representative, an estimate of the size of the drainage area (in square feet) and an estimate of the runoff coefficient of the drainage area [e.g., low (under 40 percent), medium (40 to 65 percent), or high (above 65 percent)] shall be provided in the plan.

f. Quarterly Visual Examination of Storm Water Quality. Quarterly visual examinations of storm water discharges from each outfall are required. The examination must be of a grab sample collected from each storm water outfall. The examination of storm water grab samples shall include any observations of color, odor, clarity, floating solids, settled solids, suspended solids, foam, oil sheen, or other obvious indicators of storm water pollution. The examination must be conducted in a well lit area. No analytical tests are required to be performed on these samples. The examination must be conducted at least once in each of the following periods: January through March; April through June; July through September; and October through December.

The examination must be made at least once in each quarter of the permit during daylight unless there is insufficient rainfall or snow-melt to generate runoff. Where practicable, the same individual should carry out the collection and examination of discharges throughout the life of the permit to ensure the greatest degree of consistency possible. Grab samples shall be collected within the first 30 minutes (or as soon thereafter as practical, but not to exceed 60 minutes) of when the runoff begins discharging. Reports of the visual examination include: the examination date and time, examination personnel, visual quality of the storm water discharge, and probable sources of any observed storm water contamination. The visual examination reports must be maintained onsite with the pollution prevention plan.

EPA realizes that if a facility is inactive and unstaffed it may be difficult to collect storm water discharge samples when a qualifying event occurs. Today's final permit has been revised so that inactive, unstaffed facilities can exercise a waiver of the requirement to conduct quarterly visual examination.

EPA believes that this quick and simple assessment will allow the permittee to approximate the effectiveness of his/her plan on a regular basis at very little cost. Although the visual examination cannot assess the chemical properties of the storm water discharged from the site, the examination will provide meaningful results upon which the facility may act quickly. The frequency of this visual examination will also allow for timely adjustments to be made to the plan. If BMPs are performing ineffectively, corrective action must be implemented. A set of tracking or follow-up procedures must be used to ensure that appropriate actions are taken in response to the inspections. The visual examination is intended to be performed by members of the pollution prevention team. This hands-on examination will enhance the staff's understanding of the storm water problems on that site and effects on the management practices that are included in the plan.

When a discharger is unable to collect samples over the course of the visual examination period as a result of adverse climatic conditions, the discharger must document the reason for not performing the visual examination and retain this documentation on-site with the records of the visual examination. Adverse weather conditions which may prohibit the collection of samples include weather conditions that create dangerous conditions for personnel (such as local flooding, high winds, hurricane, tornadoes, electrical storms, etc.) or otherwise make the collection of a sample impracticable (drought, extended frozen conditions, etc.).

g. Retention of Records

(1) The permittee shall retain records of all inspections and monitoring information, including certification reports, noncompliance reports, calibration and maintenance records and all original strip chart recordings for continuous monitoring instrumentation, copies of all reports, and supporting data, requested by the permitting authority for at least 3 years after the date of the sampling event or inspection.

O. Storm Water Discharges Associated With Industrial Activity From Steam Electric Power Generating Facilities, Including Coal Handling Areas

1. Industrial Profile

The conditions in this section apply to storm water discharges from steam electric power generating facilities. The steam electric power generating category includes facilities which are coal, oil, gas, or nuclear fired. Heat captured co-generation facilities are not covered under the definition of storm water discharge associated with industrial activity, however, dual fuel co-generation facilities are included in the definition. When an industrial facility, described by the above coverage provisions of this section, has industrial activities being conducted onsite that meet the description(s) of industrial activities in another section(s), that industrial facility shall comply with any and all applicable monitoring and pollution prevention plan requirements of the other section(s) in addition to all applicable requirements in this section. The monitoring and pollution prevention plan terms and conditions of this multi-sector permit are additive for industrial activities being conducted at the same industrial facility (co-located industrial activities). The operator of the facility shall determine which other monitoring and pollution prevention plan section(s) of this permit (if any) are applicable to the facility.

Storm water discharges from coal piles are eligible for coverage under this permit, where these discharges are not already subject to an existing NPDES permit.

The production of electrical energy always involves the conversion of some other form of energy. The two most important sources of energy which are converted to steam electric energy are the chemical energy of fossil fuels and the atomic energy of nuclear fuels. Current uses of fossil fuels are based on a combustion process, followed by steam generation to convert the heat first into mechanical energy and then to convert the mechanical energy into electrical energy. Nuclear power plants utilize a cycle similar to that used in fossil fueled power plants except that the source of heat is atomic interactions rather than the combustion of fossil fuel.

The steam electric power generating process for fossil fuel systems are typically enclosed and subject to effluent limitations guidelines [40 Code of Federal Regulations (CFR) Part 423], as is coal pile runoff. However, the unloading and transport of coal within the facility is subject to the conditions set forth in this section of today's permit. Likewise, the unloading and storage areas for liquid fuels and chemicals are subject to the conditions in this section of today's permit.

Industrial activities occurring at steam electric power generating facilities that pertain to the storm water rule include, "* * * but [are] not limited to, storm water discharges from industrial plant yards; material handling sites; refuse sites; sites used for the application or disposal of process wastewaters (as defined at 40 CFR Part 401); sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage, or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials and intermediate and finished materials; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water" (40 CFR 122.26(b)(14)). Common industrial activities at steam electric power generating facilities include the unloading, transport, and storage of raw materials, and the disposal of waste materials.

Significant materials include, "* * * but [are] not limited to: raw materials; fuels; materials such as solvents, detergents, and plastic pellets; finished materials such as metallic products; * * * hazardous substances designated under Section 101(14) of CERCLA; any chemical facilities required to report pursuant to Section 313 of Title III of SARA; fertilizers; pesticides; and waste products such as ashes, slag, and sludge that have the potential to be released with storm water discharges" (40 CFR 122.26(b)(12)). Significant materials commonly found at steam electric power generating facilities include: coal; diesel fuel; and waste materials.

Historically, steam electric power generating facilities were categorized in accordance with the type of fuel they burned. Recently, however, steam electric power generating facilities have modified their equipment to enable them to use more than one fuel. Presented below are brief descriptions of the industrial activities and significant materials associated with the production of steam electric power. Due to the increase in facilities burning multiple fuels the industrial activities and significant materials are discussed together. However, the industrial activities and significant materials for nuclear powered facilities are discussed separately. Unique practices are noted.

a. Industrial Activities: Fossil Fuel Powered Plants. Steam electric power generation can be divided into four stages. In the first operation, fossil fuel (coal, oil, or natural gas) is burned in a boiler furnace. The evolving heat is used to produce pressurized and superheated steam. This steam is conveyed to the second stage, the turbine, where it gives energy to the rotating blades and, in the process, loses pressure and increases in volume. The rotating blades of the turbine act to drive an electric generator or alternator to convert the imparted mechanical energy into electrical energy. The steam leaving the turbine enters the third state, the condenser, where it is condensed to water. The liberated heat is transferred to a cooling medium which is normally water. Finally, the condensed steam is reintroduced into the boiler by a pump to complete the cycle.

Features unique to coal-fired plants include coal storage and preparation (transport, beneficiation, pulverization, drying), coal-fired boiler, ash handling and disposal systems, and flue gas cleaning, and desulfurization.

b. Significant Materials: Fossil Fuel Powered Plants. The type of fuel (coal, oil, gas, nuclear) used to fire power plant boilers most directly influences the number of waste streams. The influence comes principally from the effect of fuel on the volume of ash generated. Stations using heavy or residual oils generate fly ash in large quantities and may generate some bottom ash. Stations which burn coal create both fly ash and bottom ash. Bottom ash is the residue which accumulates on the furnace bottom, and fly ash is the lighter material which is carried over in the flue gas stream.

c. Industrial Activities: Nuclear Powered Plants. Nuclear power plants utilize a cycle similar to that used in fossil fueled power plants except that the source of heat is atomic interactions rather than the combustion of fossil fuel. Water serves as both moderator and coolant as it passes through the nuclear reactor core. In a pressurized water reactor, the heated water then passes through a separate heat exchanger where steam is produced on the secondary side. This steam, which contains radioactive materials, drives the turbines. In a boiling water reactor, steam is generated directly in the reactor core and is then piped directly to the turbine. This arrangement produces some radioactivity in the steam and therefore requires some shielding of the turbine and condenser.

d. Significant Materials: Nuclear Powered Plants. Few if any significant materials are exposed to storm water at nuclear powered steam electric facilities. Materials that are potentially exposed do not involve steam electric generating equipment, raw materials, or waste products. The materials that are exposed to storm water are office wastes and ground maintenance equipment and tools.

2. Pollutants in Storm Water Discharges Associated With Steam Electric Power Generating Facilities

Steam electric generating facilities are subject to effluent limitations guidelines that limit the number and variety of industrial activities that are included in the storm water program. Pollutants may be present in storm water as a result of outdoor activities associated with steam electric power generating facilities such as: material handling and transport operations; waste disposal; and deposition of airborne particulate matter. In addition, sources of pollutants other than storm water, such as illicit connections,[92] spills, and other improperly dumped materials, may increase the pollutant loadings discharged into waters of the United States.

Many of the part 2 group application data submittals did not identify individual site characteristics or sources of storm water pollutants which may be responsible for pollutant loadings. In addition, because the industry has been moving toward combined fuel generating facilities, the part 2 sampling data was reviewed in the aggregate.

Table O–1 lists potential pollutant source activities and related pollutants associated with steam electric power generating facilities. The primary and largest potential source of storm water pollutants from fossil-fueled steam electric generating facilities is ash refuse piles.

TABLE O–1.—INDUSTRIAL ACTIVITIES, POLLUTANT SOURCES, AND POLLUTANTS FOR STEAM ELECTRIC POWER GENERATING FACILITIES

Activity	Pollutant source	Pollutant
Above Ground Liquid Storage Tank.	External corrosion and structural failure	Fuel, oil, heavy metals, ammonia, chlorine, sulfuric acid, sodium hydroxide, and other materials being stored.
	Installation problems	Fuel, oil, heavy metals, ammonia, chlorine, sulfuric acid, sodium hydroxide, and other materials being stored.
	Spills due to operator error	Fuel, oil, heavy metals, ammonia, chlorine, sulfuric acid, sodium hydroxide, and other materials being stored.
	Failure of piping systems	Fuel, oil, heavy metals, ammonia, chlorine, sulfuric acid, sodium hydroxide, and other materials being stored.
	Leaks or spills during pumping of liquids from barges, trucks, rail cars to a storage facility.	Fuel, oil, heavy metals, ammonia, chlorine, sulfuric acid, sodium hydroxide, and other materials being stored.
Vehicle and Equipment Maintenance.	Parts cleaning	Oil, heavy metals, chlorinated solvents, acid/alkaline wastes, ethylene glycol.
	Spills of oil, degreasers, hydraulic fluids, transmission fluid, radiator fluids.	Oil, arsenic, heavy metals, organics, chlorinated solvents, ethylene glycol.
	Fluids replacement	Oil, arsenic, heavy metals, organics, fuel.
Fueling Operations	Spills & leaks during fuel delivery	Fuel, oil, heavy metals.
	Spills caused by "topping off" fuel tanks	Fuel, oil, heavy metals.
	Leaking storage tanks	Fuel, oil, heavy metals.
	Allowing rainfall on the fuel area or storm water to run onto the fuel area.	Fuel, oil, heavy metals.
Coal Handling Areas	Fugitive dust emissions from coal handling	Suspended solids, copper, iron, aluminum, nickel, and trace metals.
	Spills during delivery	Suspended solids, copper, iron, aluminum, nickel, and trace metals.
	Offsite tracking of coal dust	Suspended solids, copper, iron, aluminum, nickel, and trace metals.
Ash Handling Areas, Ash Landfills.	Spills during transfer of ash to landfills	Suspended solids, chromium, copper, iron, zinc, oil and grease, aluminum.
	Offsite tracking of ash	Suspended solids, chromium, copper, iron, zinc, oil and grease, aluminum.
Scrapyards, Refuse Sites	Discarded material	Fuel, oils, heavy metals.

The ash composition from oil, on a weight percent basis, is much lower than that of coal. Oil ash rarely exceeds 0.3 percent of the input oil whereas coal ash comprises from 3 to 30 percent of the coal. In general, the ash content increases with increasing asphaltic constituents in which the sulfur acts largely as a bridge between aromatic rings.

The many elements which may appear in oil ash deposits include vanadium, sodium, and sulfur. Compounds containing these elements are found in almost every deposit in boilers fired by residual fuel oil and often constitute the major portion of these deposits. Oil ash, especially from plants using Venezuelan and certain Middle Eastern oil can contain significant amounts of nickel.

Some of the ash-forming constituents in the crude oil had their origin in animal and vegetable matter from which the oil was derived. The remainder is extraneous material resulting from contact of the crude oil with rock structures and salt brines or picked up during refining processes, storage, and transportation. Vanadium, iron, sodium, nickel, and calcium in fuel oil are common in rock strata, but elements including vanadium, nickel, zinc, and copper are believed to come from organic matter from which the petroleum was created.

[92] Illicit connections are contributions of unpermitted non-storm water discharges to storm sewers from any of a number of sources including sanitary sewers, industrial facilities, commercial establishments, or residential dwellings. The probability of illicit connections at steam electric facilities is low yet it still may be applicable at some operations.

The ash residue resulting from the combustion of coal is primarily derived from the inorganic matter in the coal. The chemical composition of dry bottom ash and fly ash are quite similar. The major constituents present in coal ash are silica, alumina, ferric oxide, calcium oxide, magnesium oxide, and minor amounts of sodium and potassium oxides. Other parameters which may be present include sulfur trioxide, carbon, boron, phosphorus, uranium, and thorium. The concentration differences can vary considerably from one site to another.[93]

When conducting their data analysis for their 1980 Development Document, the U.S. Environmental Protection Agency (EPA) found that there was no correlation between arsenic, nickel, zinc, copper, and selenium and total suspended solids, whenever their value was 30 mg/L or less.[94]

The quality of storm water runoff from coal handling areas is dependent on pH, as pH influences the release of toxic and heavy metals. Suspended solids levels result when storm water suspends coal particulates. Most of the total dissolved solids concentrations are a consequence of enhanced pyritic oxidation.

Storm water runoff from exposed sources of coal tends to be of an acid nature, primarily as a result of the oxidation of iron sulfide in the presence of oxygen and water.[95] The presence of certain acidophilic, chemoautotrophic bacteria, and a pH of 2.0 to 4.5 generally indicates storm water runoff high in iron, manganese, and total dissolved solids.[96]

Based on the similarities of the facilities included in this sector in terms of industrial activities and significant materials, EPA believes it is appropriate to discuss the potential pollutants at steam electric power generating facilities as a whole and not subdivide this sector. Therefore, Table O–2 lists data for selected parameters from facilities in the steam electric power generating sector. These data include the eight pollutants that all facilities were required to monitor for under Form 2F, as well as the pollutants that EPA has determined may merit further monitoring.

TABLE O–2.—STATISTICS FOR SELECTED POLLUTANTS REPORTED BY STEAM ELECTRIC GENERATING FACILITIES SUBMITTING PART II SAMPLING DATA[i] (mg/L)

Pollutant, Sample type	# of Facilities		# of Samples		Mean		Minimum		Maximum		Median		95th Percentile		99th Percentile	
	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp	Grab	Comp

[i] Applications that did not report the units of measurement for the reported values of pollutants were not included in these statistics. Values reported as non-detect or below detection limit were assumed to be 0.

[ii] Composite samples.

3. Pollutant Control Measures Required Under Other EPA Programs.

The Agency recognizes that other EPA programs address pollution prevention at steam electric power generating facilities. The Oil Pollution Prevention Program (40 CFR Part 112) has established procedures to prevent the discharge of oil from nontransportation related onshore and offshore facilities. This program requires owners or operators of onshore and offshore facilities to prepare a Spill Prevention Control and Countermeasure Plan (SPCC Plan) for their facility if they could reasonably be expected to discharge oil, into or upon the navigable waters of the United States or adjoining shorelines, in quantities that violate applicable water quality standards, or cause a film or sheen upon or discoloration of the surface of the water or adjoining shorelines or cause a sludge or emulsion to be deposited beneath the surface of the water or upon adjoining shorelines. Guidelines for the preparation and implementation of a Spill Prevention Control and Countermeasure Plan can be found at 40 CFR 112.7.

Under the Resource Conservation and Recovery Act (RCRA) specific requirements have been established which address generators of hazardous wastes. Regulations have been developed which address the accumulation of hazardous waste onsite prior to transport to a hazardous waste disposal facility. These regulations address proper storage of hazardous wastes, emergency planning, and training personnel in proper handling procedures for hazardous wastes.

4. Storm Water Pollution Prevention Plan Requirements

The conditions that apply to steam electric power generating facilities are based on the requirements set forth in the common permit conditions for storm water discharges from industrial activities discussed in today's fact sheet. The discussion that follows only addresses conditions that differ from those common conditions. There are no additional pollution prevention requirements beyond the common conditions for nuclear powered steam electric generating facilities.

a. Description of Pollutant Sources. Under the description of pollutant sources in the storm water pollution prevention plan requirements, permittees are required to include a site map of the facility. The areas required to be identified on the site map now also include the following: landfills,

[93] EPA. Effluent Guidelines Division. "Development Document for Effluent Limitations Guidelines and Standards for the Steam Electric Point Source Category." September 1980. (EPA 440/1–80/029–b). Page 131.

[94] EPA. Effluent Guidelines Division. "Development Document for Effluent Limitations Guidelines and Standards for the Steam Electric Point Source Category." September 1980. (EPA 440/1–80/029–b). Page 138.

[95] EPA. Effluent Guidelines Division. "Development Document for Effluent Limitations Guidelines and Standards for the Steam Electric Point Source Category." September 1980. (EPA 440/1–80/029–b). Page 138.

[96] EPA. Effluent Guidelines Division. "Development Document for Effluent Limitations Guidelines and Standards for the Steam Electric Point Source Category." September 1980. (EPA 440/1–80/029–b). Page 138.

treatment ponds, scrap yards, general refuse areas, locations of short and long term storage of general materials, and the location of stock pile areas. EPA believes this is appropriate since these areas may potentially be significant sources of pollutants to storm water. In addition, the site map must also indicate the outfall locations and the types of discharges contained in the drainage areas of the outfalls (e.g., storm water and air conditioner condensate). In order to increase the readability of the map, the inventory of the types of discharges contained in each outfall may be kept as an attachment to the site map.

b. Measures and Controls. Under the description of measures and controls in the storm water pollution prevention plan requirements, this section requires that all areas that may contribute pollutants to storm water discharges shall be maintained in a clean, orderly manner. This section also requires that the following 15 areas must be specifically addressed:

(1) Fugitive Dust Emissions. The plan must describe measures that prevent or minimize fugitive dust emissions from coal handling areas. The permittee shall consider establishing procedures to minimize offsite tracking of coal dust. To prevent offsite tracking the facility may consider specially designed tires, or washing vehicles in a designated area before they leave the site, and controlling the wash water.

(2) Delivery Vehicles. The plan must describe measures that prevent or minimize contamination of storm water runoff from delivery vehicles arriving on the plant site. At a minimum the permittee should consider the following:

(a) Develop procedures for the inspection of delivery vehicles arriving on the plant site, and ensure overall integrity of the body or container.

(b) Develop procedures to control leakage or spillage from vehicles or containers, and ensure that proper protective measures are available for personnel and environment.

(3) Fuel Oil Unloading Areas. The plan must describe measures that prevent or minimize contamination of storm water runoff from fuel oil unloading areas. At a minimum the facility operator must consider using the following measures or an equivalent:

(a) Use containment curbs in unloading areas.

(b) During deliveries station personnel familiar with spill prevention and response procedures must be present to ensure that any leaks or spills are immediately contained and cleaned up.

(c) Use spill and overflow protection (drip pans, drip diapers, and/or other containment devices shall be placed beneath fuel oil connectors to contain any spillage that may occur during deliveries or due to leaks at such connectors).

(4) Chemical Loading/Unloading Areas. The plan must describe measures that prevent or minimize the contamination of storm water runoff from chemical loading/unloading areas. At a minimum the permittee must consider using the following measures or an equivalent:

(a) Use containment curbs at chemical loading/unloading areas to contain spills.

(b) During deliveries station personnel familiar with spill prevention and response procedures must be present to ensure that any leaks or spills are immediately contained and cleaned up.

Where practicable chemical loading/unloading areas should be covered, and chemicals should be stored indoors.

(5) Miscellaneous Loading/Unloading Areas. The plan must describe measures that prevent or minimize the contamination of storm water runoff from loading and unloading areas. The facility may consider covering the loading area, minimizing storm water runon to the loading area by grading, berming, or curbing the area around the loading area to direct storm water away from the area, or locate the loading/unloading equipment and vehicles so that leaks can be controlled in existing containment and flow diversion systems.

(6) Liquid Storage Tanks. The plan must describe measures that prevent or minimize contamination of storm water runoff from above ground liquid storage tanks. At a minimum the facility operator must consider employing the following measures or an equivalent:

(a) Use protective guards around tanks.

(b) Use containment curbs.

(c) Use spill and overflow protection (drip pans, drip diapers, and/or other containment devices shall be placed beneath chemical connectors to contain any spillage that may occur during deliveries or due to leaks at such connectors).

(d) Use dry cleanup methods.

(7) Large Bulk Fuel Storage Tanks. The plan must describe measures that prevent or minimize contamination of storm water runoff from liquid storage tanks. At a minimum the facility operator must consider employing the following measures or an equivalent:

(a) Comply with applicable State and Federal laws, including Spill Prevention Control and Countermeasures (SPCC)

(b) Containment berms.

(8) The plan must describe measures to reduce the potential for an oil or chemical spill, or reference the appropriate section of their SPCC plan. At a minimum the structural integrity of all above ground tanks, pipelines, pumps and other related equipment shall be visually inspected on a weekly basis. All repairs deemed necessary based on the findings of the inspections shall be completed immediately to reduce the incidence of spills and leaks occurring from such faulty equipment.

(9) Oil Bearing Equipment in Switchyards. The plan must describe measures to reduce the potential for storm water contamination from oil bearing equipment in switchyard areas. The facility may consider level grades and gravel surfaces to retard flows and limit the spread of spills; collection of storm water runoff in perimeter ditches.

(10) Residue Hauling Vehicles. All residue hauling vehicles shall be inspected for proper covering over the load, adequate gate sealing and overall integrity of the body or container. Vehicles without load covers or adequate gate sealing, or with poor body or container conditions must be repaired as soon as practicable.

(11) Ash Loading Areas. Plant procedures shall be established to reduce and/or control the tracking of ash or residue from ash loading areas including, where practicable, requirements to clear the ash building floor and immediately adjacent roadways of spillage, debris and excess water before each loaded vehicle departs.

(12) Areas Adjacent to Disposal Ponds or Landfills. The plan must describe measures that prevent or minimize contamination of storm water runoff from areas adjacent to disposal ponds or landfills. The facility must develop procedures to:

(a) Reduce ash residue which may be tracked on to access roads traveled by residue trucks or residue handling vehicles.

(b) Reduce ash residue on exit roads leading into and out of residue handling areas.

(13) Landfills, Scrapyards, and General Refuse Sites. The plan must address landfills, scrapyards, and general refuse sites. The permittee is referred to Parts XI.L. and XI.N. of today's permit (Storm Water Discharges From Landfills and Land Application Sites and Scrap and Waste Material Processing and Recycling Facilities, respectively) for applicable Best Management Practices.

(14) Maintenance Activities. For vehicle maintenance activities

R0016252

performed on the plant site, the permittee shall consider the applicable Best Management Practices outlined in Part XI.P. of today's permit (Storm Water Discharges From Vehicle Maintenance or Equipment Cleaning Operations at Motor Freight Transportation Facilities, Passenger Transportation Facilities, Petroleum Bulk Oil Stations and Terminals, or the United States Postal Service).

(15) Material Storage Areas. The plan must describe measures that prevent or minimize contamination of storm water from material storage areas (including areas used for temporary storage of miscellaneous products and construction materials stored in lay down areas). The facility operator may consider flat yard grades, runoff collection in graded swales or ditches, erosion protection measures at steep outfall sites (e.g., concrete chutes, riprap, stilling basins), covering lay down areas, storing the materials indoors, covering the material with a temporary covering made of polyethylene, polyurethane, polypropylene, or hypalon. Storm water runon may be minimized by constructing an enclosure or building a berm around the area.

Based on information provided in part 1 of the group application process, the management practices applicable to the 15 areas listed above are commonly used at many steam electric power generating facilities. EPA believes that the incorporation of management practices to accomplish the objectives described above, in conjunction with the baseline requirements, will substantially reduce the potential for these activities and areas to significantly contribute to the pollution of storm water discharges. EPA believes that these requirements provide the necessary flexibility to address the variable risk for pollutants in storm water discharges associated with different facilities.

(c) Inspections. Under the inspection requirements of the storm water pollution prevention plan elements, this section requires that in addition to the comprehensive site evaluation required under Part VIII.C.4. of today's permit, qualified facility personnel shall be identified to inspect designated equipment and areas of the facility on a monthly basis. The following areas shall be included in the inspection: coal handling areas, fueling areas, loading/unloading areas, switchyards, bulk storage areas, ash handling areas, areas adjacent to disposal ponds and landfills, maintenance areas, liquid storage tanks and long term and short term material storage areas. A set of tracking or follow-up procedures shall be used to ensure that appropriate actions are taken in response to the inspections. Records of inspections shall be maintained onsite.

The purpose of the inspections is to check on the implementation of the storm water pollution prevention plan. The inspections allow facility personnel to monitor the success or failure of elements of the plan on a regular basis.

d. Employee Training. Steam electric power generating facilities are required to identify periodic training dates in the pollution prevention plan, but in all cases training must be held at least annually. EPA believes that such a frequency is necessary due to the many areas with a high potential for contamination of storm water.

5. Numeric Effluent Limitations

Coal pile runoff is subject to the effluent guidelines described in Part V.B of today's permit. However, steam electric generating facilities must comply with the requirement of Part V.B immediately upon permit issuance. Steam electric generating facilities are not permitted to take 3 years to meet this requirement.

6. Monitoring and Reporting Requirements

a. Analytical Monitoring Requirements. EPA believes that steam electric power generating facilities may reduce the level of pollutants in storm water runoff from their sites through the development and proper implementation of the storm water pollution prevention plan requirements discussed in today's permit. In order to provide a tool for evaluating the effectiveness of the pollution prevention plan and to characterize the discharge for potential environmental impacts, the permit requires steam electric power generating facilities to collect and analyze samples of their storm water discharges for the pollutant listed in Table O–3. The pollutant listed in Table O–3 was found to be above levels of concern for a significant portion of steam electric power generating facilities that submitted quantitative data in the group application process. Because this pollutant has been reported at or above levels of concern from steam electric power generating facilities, EPA is requiring monitoring after the pollution prevention plan has been implemented to assess the effectiveness of the pollution prevention plan and to help ensure that a reduction of pollutants is realized.

Under the Storm Water Regulations at 40 CFR 122.26(b)(14), EPA defined "storm water discharge associated with industrial activity". The focus of today's permit is to address the presence of pollutants that are associated with the industrial activities identified in this definition and that might be found in storm water discharges. Under the methodology for determining analytical monitoring requirements, described in section VI.E.1 of this fact sheet, zinc is above the bench mark concentrations for the steam electric generating facilities sector. After a review of the nature of industrial activities and the significant materials exposed to storm water described by facilities in this sector, EPA has determined that the higher concentrations of zinc are not likely to be caused by the industrial activity, but may be primarily due to non-industrial activities on-site. Today's permit does not require steam electric generating facilities to conduct analytical monitoring for this parameter.

At a minimum, storm water discharges from steam electric power generating facilities must be monitored quarterly during the second year of permit coverage. Samples must be collected at least once in each of the following periods: January through March; April through June; July through September; and October through December. At the end of the second year of permit coverage, a facility must calculate the average concentration for each parameter listed in Table O–3. If the permittee collects more than four samples in this period, then they must calculate an average concentration for each pollutant of concern for all samples analyzed.

TABLE O–3.—MONITORING REQUIREMENTS FOR STEAM ELECTRIC POWER GENERATING FACILITIES

Pollutant of concern	Cut-Off concentration
Total Recoverable Iron ...	1.0 mg/L

If the average concentration for a parameter is less than or equal to the value listed in Table O–3, then the permittee is not required to conduct quantitative analysis for that parameter during the fourth year of the permit. If, however, the average concentration for a parameter is greater than the cut-off concentration listed in Table O–3, then the permittee is required to conduct quarterly monitoring for that parameter during the fourth year of permit coverage. Monitoring is not required during the first, third, and fifth year of the permit. The exclusion from monitoring in the fourth year of the permit is conditional on the facility maintaining industrial operations and BMPs that will ensure a quality of storm water discharges consistent with the average concentrations recorded during the second year of the permit.

TABLE O–5.—Schedule of Monitoring

2nd Year of Permit Coverage	• conduct quarterly monitoring. • calculate the average concentration for all parameters analyzed during this period. • if average concentration is greater than the value listed in Table O–3, then quarterly sampling is required during the fourth year of the permit. • if average concentration is less than or equal to the value listed in Table O–3, then no further sampling is required for that parameter.
4th Year of Permit Coverage	• conduct quarterly monitoring for any parameter where the average concentration in year two of the permit is greater than the value listed in Table O–3. • if industrial activities or the pollution prevention plan have been altered such that storm water discharges may be adversely affected, quarterly monitoring is required for all parameters of concern.

In cases where the average concentration of a parameter exceeds the cut-off concentration, EPA expects permittees to place special emphasis on methods for reducing the presence of those parameters in storm water discharges. Quarterly monitoring in the fourth year of the permit will reassess the effectiveness of the adjusted pollution prevention plan.
