Santa Ana Region

September 26, 2001

ITEM: 16

SUBJECT: Toxics Total Maximum Daily Loads (TMDLs) for the San Diego
Creek/Newport Bay Watershed

Discussion

Pursuant to the requirements of Section 303(d) of the Clean Water Act, the Regional Board listed Newport Bay and San Diego Creek as impaired due to toxic substances. The 303(d) listing triggered the requirement that TMDLs be developed for those toxics causing impairment. Regional Board and US Environmental Protection Agency (USEPA) staff are coordinating efforts to develop these TMDLs. USEPA is required by a consent decree to complete toxics TMDLs in Upper and Lower Newport Bay and San Diego Creek by April 15, 2002.

The 303(d) listing was general, identifying pesticides, metals, priority organics, and unknown toxicity as the sources of impairment. Consequently, the first step in the TMDL process was the analysis of available data to identify the specific constituents of concern. Board staff reviewed available data on water column chemistry, sediment chemistry, fish and shellfish tissue concentrations (reflecting bioaccumulation), and toxicity. These data were compared to appropriate criteria and guidelines to determine what substances appeared to be causing violations of the narrative and numeric toxics objectives specified in the Basin Plan. The data reviewed and the results of the evaluation are described in the Problem Statement for the Total Maximum Daily Load (TMDL) For Toxic Substances in Newport Bay and San Diego Creek. This report was presented to the Regional Board at the January 19, 2001 Board meeting.

More recently, the USEPA conducted an independent analysis of the data, emphasizing the last five years of water quality, sediment, and fish tissue data, to identify the chemicals USEPA believes cause impairment. USEPA also reviewed new data and updates to existing data sets that became available after the completion of Board staff's Problem Statement. USEPA has formulated a list of toxicants for which TMDLs will be developed. USEPA's list is in general agreement with the Regional Board's toxics TMDL list.

The development of the TMDLs is a cooperative effort between the USEPA and Regional Board staff. To assure that the consent decree deadline of April 15, 2002 is met, the approach being employed to develop the toxics TMDLs differs from that used for the prior Newport TMDLs. For the prior TMDLs, the requisite components, including source analysis, numeric target(s), wasteload and load allocations, and total

maximum daily load (the so-called "technical TMDL"), were developed together with an implementation plan and schedules. The technical TMDL and implementation plan were presented to and adopted by the Regional Board as a Basin Plan amendment (BPA). For the toxics TMDLs, however, there is not sufficient time to complete the implementation plan and Basin Plan Amendment process by April 15, 2002. Therefore, Board staff and USEPA are developing technical TMDLs that will be promulgated by USEPA on or before April 15, 2002. Board staff will subsequently prepare implementation plans and Basin Plan Amendment packages for consideration by the Regional Board.

Board staff are working on the TMDLs for diazinon, chlorpyrifos, and selenium, while USEPA will complete the technical TMDLs for the other toxicants. A letter from David Smith (attached), USEPA TMDL Team Leader, describes the process by which USEPA will combine the Regional Board and USEPA staff reports into two separate documents: a toxics TMDL (for all toxicants) and the technical support documents. It is expected that the documents will be available for comment by January 2002. USEPA will then proceed with toxics TMDL promulgation by April 15, 2002.

Once the TMDLs are promulgated, Regional Board staff will develop implementation plans and Basin Plan amendments for the TMDLs to be incorporated into the Basin Plan. A copy of the draft diazinon and chlorpyrifos TMDLs is attached for your review. Substantial work has also been accomplished on the selenium TMDL. Board staff expects to present an overview of both TMDLs to the Regional Board at the September 26 Board meeting.

9/7/01 Letter from David Smith, US EPA
Draft Diazinon and Chlorpyrifos TMDLs

**UNITED STATES ENVIRONMENTAL PROTECTION AGENCY****REGION IX****75 Hawthorne Street****San Francisco, CA 94105-3901**

September 7, 2001

Mr. Gerard J. Thibeault
Executive Officer
Santa Ana Regional Water Quality Control Board
3737 Main Street, Suite 500
Riverside, CA 92501

Dear Mr. Thibeault,

The U.S. Environmental Protection Agency (EPA) continues to develop TMDLs for toxic substances in Newport Bay and San Diego Creek. I write to provide a progress report and to introduce Peter Kozelka, EPA Region 9 Water Division. Dr. Kozelka is our designated TMDL liaison to the Santa Ana Regional Board, and he has been actively involved with this project.

As you know, the scope of these TMDLs is to address water quality impairment due to a group of "toxic" chemicals, more specifically PCBs, metals and pesticides. Potential water bodies include: Santa Ana/Delhi Channel, San Diego Creek and its freshwater tributaries, Upper and Lower Newport Bay, and Rhine Channel. Whereas we view these TMDLs as a cooperative effort between EPA and Regional Board staff—and we greatly appreciate your staff's commitment to support TMDL development—let me reiterate that EPA (alone) is under consent decree to complete toxics TMDLs by April 15, 2002.

In December 2000, Ken Theisen, Regional Board staff, provided a "problem statement" describing which chemicals were probable cause of impairment with respect to each waterbody. EPA staff has completed an independent assessment of water column, sediment and fish tissue monitoring data (emphasis on last five years) to identify the chemicals we believe cause impairment. For our assessment, we included several new data sets and updated results for existing data sets, and EPA's assessment shows fairly good agreement with chemicals identified by RWQCB staff as to chemicals of primary concern.

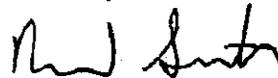

We will approach these TMDLs as follows:

Regional Board staff will develop TMDLs for Chlorpyrifos, Diazinon and Selenium.

EPA Region 9 staff will develop TMDLs for organochlorine compounds (including legacy pesticides such as DDT) and metals. Some toxicants will be addressed for all water bodies, whereas others will address impairment within specific water bodies. For example, we may write TMDLs for certain toxicant(s) in San Diego Creek only, or we may write TMDLs for toxicant(s) in Rhine Channel as a water body separate from Lower Newport Bay.

We anticipate combining all staff reports into two documents: the toxics TMDL (for all toxicants) and the technical support documents (with additional scientific details regarding source analysis per toxicant, modeling results and other relevant information). These documents will be available for public comment in January 2002. Notification will likely include addressees of Santa Ana RWQCB Basin Plan and Newport Bay Watershed Management Committee mailing lists, as well as public announcement. We expect a 30 to 60 day comment period. To ensure our commitment to Toxics TMDL consent decree, EPA will establish these TMDLs by April 15, 2002.

Sincerely,

David Smith
TMDL Team Leader

1.0 PROBLEM STATEMENT

1.1 INTRODUCTION

An investigation of stormwater runoff in tributaries to Newport Bay in 1992 and 1993 demonstrated the existence of aquatic life toxicity (Bailey et al, 1993). A toxicity identification evaluation (TIE) performed on several of the samples collected during the study, indicated that one or more pesticides were responsible for the observed toxicity, and that diazinon was likely one of these pesticides.

Separate sampling programs, the Toxic Substances Monitoring (TSM) program, and the State Mussel Watch (SMW), demonstrated that chlorpyrifos and diazinon were present in fish and mussel tissue. The TSM and SMW were conducted in upper and lower Newport Bay as well as in the drainage channels in the Newport Bay watershed, with diazinon and chlorpyrifos data available from 1983 onwards.

As a result of these investigations, pesticides were included on the 1998 California 303d list for upper and lower Newport Bay, and for Reach 1 of San Diego Creek. Reach 2 of San Diego Creek was listed for unknown toxicity.

Supplemental studies to determine the sources of the toxicity observed during the 1992-93 investigation were carried out from 1996 to 2000 (Lee and Taylor, 1999, 2001). These studies further documented the occurrence of aquatic life toxicity in the Newport Bay watershed, and concluded that diazinon and chlorpyrifos were causing a large portion of the observed toxicity in San Diego Creek. An investigation of Upper Newport Bay indicated the presence of toxicity attributable to chlorpyrifos in stormwater runoff entering the upper bay from San Diego Creek. There were no samples collected from lower Newport Bay.

Based on these findings, TMDL development for diazinon and chlorpyrifos in San Diego Creek, and chlorpyrifos in upper Newport Bay was initiated (Santa Ana Regional Water Quality Control Board [SARWQCB], January 2001). Diazinon and chlorpyrifos are widely used organophosphate pesticides, and are among the pesticides detected most frequently in urban waterways. Further details on diazinon and chlorpyrifos usage in the Newport Bay watershed can be found in **Section 3**.

The remainder of this problem statement summarizes previous investigations in the Newport Bay watershed and describes the impairment of water quality standards caused by pesticide-derived aquatic life toxicity.

1.2 PREVIOUS INVESTIGATIONS/AVAILABLE DATA

This TMDL is based on analysis of data collected in the Newport Bay watershed over the past five years. The available data were generated by state and local agencies as part of various investigative or monitoring programs. These programs are briefly described below.

1. Toxic Substances Monitoring (TSM) and State Mussel Watch (SMW): The TSM and SMW are statewide screening programs designed to identify areas where toxic substances are bioaccumulating in fish and mussel tissue. The TSM program includes four locations in the

Newport Bay watershed, one location in Upper Newport Bay, and one location in Lower Newport Bay. Samples analyzed for diazinon and chlorpyrifos have been collected beginning in 1983, and has continued at irregular intervals through 2000. The SMW program has collected samples for diazinon and chlorpyrifos analysis from 19 locations, mostly within Upper and Lower Newport Bay. Although some of the locations were sampled only once or twice since 1982, annual samples have been collected at several locations for over ten years.

2. Aquatic Life Toxicity Investigations; 319(h) and 205(j) studies: Studies of stormwater runoff in tributaries to Newport Bay in 1992 and 1993 demonstrated the existence of aquatic life toxicity. As a result, supplemental studies to determine the sources of the observed toxicity were carried out from 1996 to 2000. These studies were funded under the USEPA Clean Water Act Section 205j and 319h grant programs. The first study, (under the 205j program) was carried out from 1996-1999. Eighty-five samples were collected from seven stormwater runoff events and four dry-weather sampling events. The second study (under the 319h program) was carried out during 1999 and 2000. Three stormwater runoff events, and two dry weather events were monitored, and a total of 31 samples were analyzed for diazinon and chlorpyrifos. Further details on these studies can be found in the respective reports (Lee and Taylor, 1999; 2001).

3. Orange County Public Facilities and Resources Department (OCPRD): Orange County has been implementing a water quality monitoring program since 1991 as part of its NPDES permit. Although no diazinon and chlorpyrifos analyses are currently required under this permit, the OCPRD has collected semi-annual sediment data for diazinon analysis.

3. California Department of Pesticide Regulation (CDPR) Pesticide Use Reports: Beginning in January 1990, California required growers to report all pesticides used on all crops. All pesticides applied on golf courses, parks, cemeteries, rangeland, pasture, and along roadside and railroad rights-of-way were also subject to the expanded reporting requirements. Pesticide dealers also faced expanded reporting and record keeping requirements. Structural fumigators, professional gardeners and other nonagricultural Pest Control Operators continued to report all pesticide use. Home-use pesticides are exempt from the regulations.

4. CDPR Red Imported Fire Ant (RIFA) Monitoring: The RIFA is an aggressive, exotic insect that was first discovered in Southern California in October 1998. In response, the California Department of Food and Agriculture (CDFA) designed a RIFA eradication/control plan to deal with the infestations (CDFA, March 1999). Part of the plan required treatment of targeted areas with a suite of pesticides that included diazinon and chlorpyrifos.

To monitor the environmental impact of the RIFA plan, a surface water sampling program was initiated in Orange County, conducted by the CDPR. Over 100 samples were collected and analyzed for pesticides during the period March/April 1999 to January 2001. These included 22 rounds of monthly sampling and one rainfall runoff sampling event. Data from the sampling events are summarized in monthly monitoring memos (CDPR, 1999-2000).

5. CDPR Sales and Use Survey: The CDPR and the University of California conducted a residential pesticide survey to better document the residential use occurring in the Newport Bay watershed. Preliminary results from the survey are available, however, the project is not scheduled for completion until December 2001.

1.3 WATER QUALITY STANDARDS

Beneficial Uses: Beneficial Uses for San Diego Creek are designated in the Basin Plan (SARWQCB, 1995). San Diego Creek Reach 1 has the designated beneficial uses of water contact recreation (REC1), non-contact water recreation (REC2), warm freshwater habitat (WARM), and wildlife habitat (WILD). Reach 2 is listed for the same uses but is deemed to possess these beneficial uses only intermittently. In addition, Reach 2 has the intermittent groundwater recharge (GWR) beneficial use designation (SARWQCB, 1995).

Upper Newport Bay has the REC1, REC2, and WILD designated beneficial uses, as well as the following seven additional beneficial uses:

- Preservation of Biological Habitats of Special Significance (BIOL)
- Commercial and Sport Fishing (COMM)
- Estuarine Habitat (EST)
- Marine Habitat (MAR)
- Rare, Threatened, or Endangered Species (RARE)
- Spawning, Reproduction, and Development (SPWN)
- Shellfish Harvesting (SHEL)

Numeric Water Quality Objectives: The Regional Board has not adopted numeric water quality objectives for diazinon and chlorpyrifos. The USEPA has promulgated numeric water quality criteria for California for priority toxic pollutants, but diazinon and chlorpyrifos are not included in this list.

Narrative Water Quality Objectives: The Basin Plan specifies two narrative water quality objectives for toxic substances. These are:

- (1) *Toxic substance shall not be discharged at levels that will bioaccumulate in aquatic resources to levels which are harmful to human health, and*
- (2) *The concentration of toxic substances in the water column, sediment or biota shall not adversely affect beneficial uses.*

Antidegradation Standard: As diazinon and chlorpyrifos are man-made chemicals that do not naturally occur in the environment, it can be argued that their presence in a surface water constitutes a lowering of the water quality of that surface water. This is permissible only if beneficial uses are protected, and the lowering of water quality is consistent with the maximum benefit to the people of the state of California.

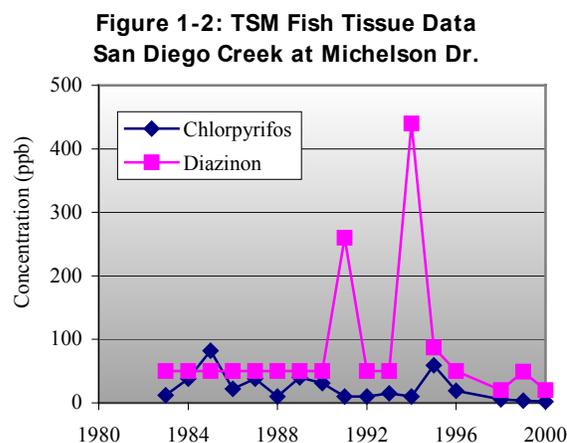

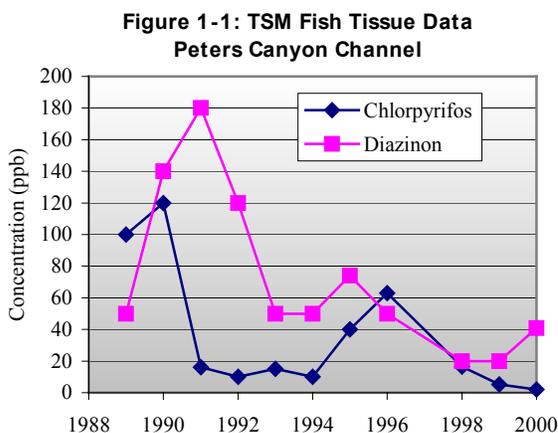

1.4 IMPAIRMENT ASSESSMENT

1.4.1 Bioaccumulation and Food Consumption Guidelines/Limits

The TSM and SMW programs have collected fish, mussel, and tissue samples from the Newport Bay watershed. Samples have been collected from within both Upper and Lower Newport Bay, and from San Diego Creek and its tributaries.

TSM data: Chlorpyrifos concentrations have consistently remained orders-of-magnitude below the OEHHA screening value (10,000 ppb) for fish consumption. Diazinon concentrations have exceeded the OEHHA screening value of 300 ppb only once (440 ug/kg) during the programs

history. **Figures 1-1 and 1-2** show the TSM results for the two stations where the longest record of data is available (Peters Canyon Channel and San Diego Creek at Michelson), and where the highest diazinon concentration was observed.

(OEHHA Screening Values: Diazinon = 300 ppb; Chlorpyrifos = 10,000 ppb)

SMW data: Diazinon and chlorpyrifos concentrations in mussel tissue have never exceeded the OEHHA guidelines. The observed concentrations were only detected intermittently and there is no trend apparent in the data. Detection frequencies were 40% and less than 10% for chlorpyrifos and diazinon respectively.

Bioaccumulation

Diazinon and chlorpyrifos are not known to bioaccumulate to levels of concern in the environment. The bioaccumulation factor (BAF) for diazinon in fish is generally less than 100 (L/kg). Although diazinon and chlorpyrifos are detected intermittently in the TSM and SMW programs, the concentrations observed in the Newport Bay watershed do not provide evidence of bioaccumulation. Rough bioaccumulation factors calculated using the TSM fish data and water column concentration data collected in the Newport Bay watershed from 1996-2001, are about 54 for diazinon and 32 for chlorpyrifos (L/kg). Bioaccumulative chemicals of concern are generally those that have BAFs greater than 1,000.

1.4.2 Aquatic Life Toxicity

San Diego Creek and Upper Newport Bay were listed as impaired due in part to pesticide-derived toxicity (303d). Although a mixture of pesticides was associated with the toxicity, the primary sources of toxicity were identified as diazinon and chlorpyrifos. The impairment was documented through over 300 acute toxicity tests conducted on 123 water samples from 1996 to 2001. The toxicity tests were performed as part of the 205j and 319h programs, and as part of the DPR-RIFA water quality investigation. In addition, nurseries in the Newport Bay watershed that have waste discharge permits began conducting bimonthly chronic toxicity tests in 2000.

Figures 1-3 and 1-4 summarize the toxicity test results using *Ceriodaphnia dubia*, (the most sensitive of the test species). Eighty-one toxicity tests were conducted on baseflow samples collected in the Newport Bay watershed. Toxicity to *Ceriodaphnia* was not present in 20% of

these tests, while 80% of the tests resulted in at least partial mortality to *Ceriodaphnia* (**Figure 1-3**).

Figure 1-3: Ceriodaphnia Toxicity Tests in the Newport Bay Watershed Baseflow; 1996-2001

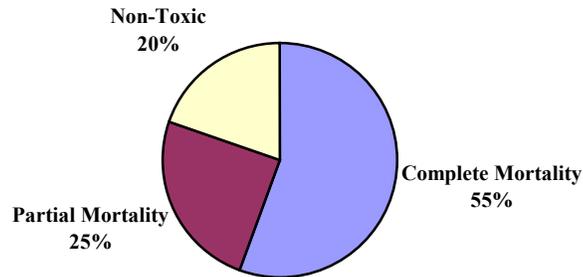

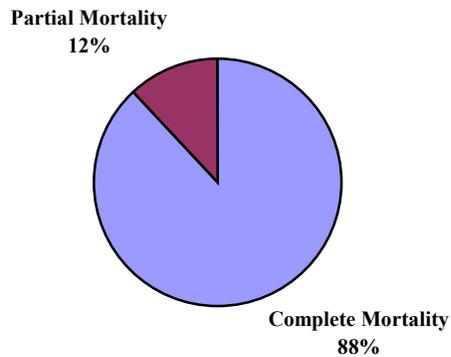

Figure 1-4 summarizes the stormwater toxicity data. Forty-two toxicity tests were conducted on stormwater samples collected from various locations in the Newport Bay watershed. All samples were toxic to *Ceriodaphnia*, with 88% of the samples causing complete mortality within a few days.

Figure 1-4: Ceriodaphnia Toxicity Tests in the Newport Bay Watershed Stormflow; 1996-2001

Aquatic Life Toxicity Investigations (319h and 205j Programs):

A total of 63 undiluted samples were collected for acute toxicity testing during the 205j and 319h investigations. Several additional samples required dilution prior to testing due to salinity levels that were high enough to cause mortality to one of the test organisms (*Ceriodaphnia dubia*). Serial dilutions and TIE procedures resulted in over 300 toxicity tests being conducted on the water samples.

Toxicity attributable to diazinon and chlorpyrifos occurred in San Diego Creek during virtually all monitored storm events. Dry weather toxicity was generally confined to the upper reaches of the watershed and diluted or otherwise ameliorated upstream of monitoring locations in San Diego Creek. (Lee and Taylor, 1999, 2001) In the 319h study, 100% *Ceriodaphnia* mortality was observed in virtually all storm samples, usually within 2 days. Stormwater runoff samples, with the salinity adjusted to that of seawater, were also toxic to the saltwater test species *Mysidopsis bahia*. The toxicity to *Mysidopsis* is attributable to the chlorpyrifos concentration in the samples.

Most of the toxicity tests performed under the 319h program were supplemented with serial dilutions to measure the acute toxic units present. TIEs were also performed in many cases to identify the specific constituents responsible for the observed toxicity.

Table 1-1 shows toxicity test data on samples collected in the Newport Bay watershed during the 319h investigation. The data are sorted by the expected toxicity based on the water column concentrations, and reference LC50s for diazinon and chlorpyrifos. The LC50 is the concentration of a toxic constituent that results in 50% mortality to the test organism. For **Table 1-1**, the reference LC50s are those published by the CDDFG (CDFG 2000a: diazinon = 440 ng/L and chlorpyrifos = 60 ng/L). Measured toxicity that exceeds the expected toxicity indicates the presence of additional compounds at toxic concentrations. Based on TIE work performed on these samples, the additional toxicity is mainly attributable to carbaryl, and potentially to some pyrethroid pesticides. Several samples still had significant toxicity that was due to unknown causes.

**Table 1-1: Results of 319h *Ceriodaphnia* Acute Toxicity Tests

(Adapted from Lee and Taylor, 2001)

DPR-RIFA: Acute Toxicity Tests

The DPR has completed 22 sampling rounds in the Newport Bay watershed. Sixty acute toxicity tests have been performed using *Ceriodaphnia dubia*. The DPR-RIFA tests were not accompanied by serial dilutions or TIEs, and identification of the toxic constituents was based on expected toxicity derived from reference LC50 data.

The DPR has not completed detailed data analysis for the RIFA monitoring project, however, preliminary data indicate that chlorpyrifos and diazinon are responsible for most of the observed toxicity in San Diego Creek. At the nursery discharge monitoring locations, bifenthrin appears to

account for a significant portion of the toxicity in addition to diazinon, and chlorpyrifos. However, bifenthrin is relatively immobile compared to diazinon and chlorpyrifos, and has been detected in only one of 22 DPR monthly sampling events in San Diego Creek (CDPR, 1999-2001).

Nurseries: Chronic Toxicity Tests

The nurseries in the Newport Bay watershed began performing chronic toxicity tests on their effluent in 2000 to comply with new Waste Discharge Requirements that were being implemented for the nutrient TMDL. As of January 2001, Hines Nurseries had completed seven chronic toxicity tests, and El Modeno Gardens had completed two chronic toxicity tests. Bordiers Nursery had not yet conducted chronic toxicity tests.

Test results were generally 2 chronic toxic units (TUc) for reproduction and 1-2 TUc for survival. Constituents responsible for the observed chronic toxicity are not currently identified through additional sampling and analysis. DPR data show that the mix of pesticides causing toxicity in nursery discharge typically includes diazinon, chlorpyrifos, and bifenthrin (CDPR, 1999-2001).

1.5 SUMMARY

Over 300 toxicity tests have been performed on 123 water samples collected from the Newport Bay watershed. These tests have demonstrated the persistent occurrence of aquatic life toxicity in San Diego Creek and its tributaries, and in Upper Newport Bay, particularly during storm events. Based on water column chemistry data and TIEs, there is conclusive evidence that diazinon and chlorpyrifos are causing acute and chronic toxicity in San Diego Creek and Upper Newport Bay (chlorpyrifos). There is no compelling evidence of bioaccumulation of these substances to levels of concern.

The persistent occurrence of aquatic life toxicity in San Diego Creek and Upper Newport Bay is a threat to the established beneficial uses of these waterbodies. Adverse impacts to these beneficial uses is a violation of the second narrative objective specified in the Basin Plan (SARWQCB, 1995).

2.0 NUMERIC TARGET

2.1 POTENTIAL NUMERIC TARGETS

Two methods have been proposed for setting numeric targets in the upper Newport Bay watershed. These are:

- (1) The CDFG water quality criteria for diazinon and chlorpyrifos derived using USEPA guidelines (USEPA, 1985). Note these criteria have not been formally adopted, but are the best scientifically-derived guidance available.
- (2) A Probabilistic Ecological Risk Assessment (PERA) for diazinon implemented by Novartis (Hall and Anderson, 2000). This method could also be applied for chlorpyrifos.

Tables 2-1 and **2-2** show potential diazinon and chlorpyrifos concentration targets, along with several reference concentrations for comparison.

**Table 2-1 Potential Diazinon Target Concentrations and Reference Values
(Freshwater)**

Source	Concentration (ng/L)
California Department of Fish and Game (CDFG): CCC	50
CDFG: CMC	80
Probabilistic Ecological Risk Assessment (PERA): Arthropods 5th percentile	144
Reference :	
Ceriodaphnia LC50 (CDFG)	440
San Diego Creek stormwater average	445
San Diego Creek maximum	960

CCC=Criterion Continuous Concentration (chronic); CMC=Criterion Maximum Concentration (acute)

Table 2-2 Potential Chlorpyrifos Concentration Limits and Reference Values

Source	Concentration (ng/L)	
	Freshwater	Saltwater
California Department of Fish and Game (CDFG): CCC	14	9
CDFG: CMC	20	20

San Diego Creek Stormwater Average	87	---
San Diego Creek Maximum	580	---
Upper Newport Bay Average	---	43.3
Upper Newport Bay Maximum	---	132

CCC=Criterion Continuous Concentration (chronic); CMC=Criterion Maximum Concentration (acute)

USEPA Method as Applied by CDFG: The USEPA method provides for development of an acute and a chronic concentration criterion. The acute criterion is referred to as the Criterion

Maximum Concentration (CMC), and the chronic criterion is referred to as the Criterion Continuous Concentration. The use of two limits is intended to be less restrictive than “a one-number criterion would have to be in order to provide the same degree of protection” (USEPA, 1985).

The CMC is designed to “estimate the highest one-hour average concentration that should not result in unacceptable effects on aquatic organisms and their uses.” The CCC is designed to “estimate the highest four-day average concentration that should not cause unacceptable toxicity during a long-term exposure” (USEPA, 1985).

The frequency of allowed exceedance for both the CCC and CMC is set as once in three years; an interval deemed sufficient to allow ecosystems to recover from the stress caused by the exceedance. The CCC and CMC are intended to provide protection to 95% of the species in the data set, and are derived by using acceptable toxicity tests from a representative set of species.

The methodology includes provisions to account for bioaccumulation, and for toxicity to plant species if warranted. As discussed in **Section 1.4.1**, bioaccumulation is not a concern for diazinon and chlorpyrifos. Toxicity to aquatic plants is also not a significant concern, based on toxicity test results in the Newport Bay watershed using the algae *Selenastrum capricornatum*.

PERA Method: The PERA is a risk assessment, and is more comprehensive in scope. The PERA approach characterizes risk to aquatic species by comparing distributions of environmental exposure data with distributions of species response data (toxicity data) from laboratory studies. The overlap of these distributions is a measure of potential risk to aquatic life.

The numeric target for the PERA is derived by pooling available toxicity tests to form a cumulative frequency distribution. The desired level of protection is then selected by choosing appropriate percentiles from the distribution (usually the 5th or 10th percentiles). In the Newport Bay watershed PERA, performed by Novartis (Hall and Anderson, September 2000) the 5th and 10th percentiles were determined separately for the entire toxicity data set (all species) and for arthropods (the most sensitive phylum to diazinon). The 5th percentile for arthropods corresponds to protection of 95% of arthropod species, and is similar to the USEPA acute criterion, which is designed to be protective of 95% of the species included in the representative data set.

Differences between the USEPA method and the PERA as implemented by Novartis include differing statistical methods for grouping and averaging the data, and the additional requirement in the USEPA method for selection of a representative set of taxa.

However, the major difference between the USEPA method and the PERA is the inclusion of a safety margin in the USEPA method. Although both methodologies are based on statistically determining the 5th percentile of the toxicity test data, the USEPA method includes a final step to divide the 5th percentile value by a factor of two. The rationale for this safety margin is that the toxicity test data are based on LC50s. Using the LC50 without the safety margin implies a numeric target that allows 50% mortality (or greater) at the selected level of protection (5th percentile). But as stated by USEPA, “a concentration that would severely harm 50% of the 5th percentile cannot be considered to be protective of that percentile or that species” (USEPA, 1985). Noting this point, USEPA Region IX has stated that the PERA method as implemented by Novartis, is not considered protective under the Clean Water Act (USEPA, August 2000a).

2.2 SELECTED TARGET

The CDFG applied the USEPA methodology by assembling a database of available toxicity tests and evaluating each test for inclusion in the set of tests used for calculating the acute and chronic recommended criteria. The selected numeric targets are the recommended acute and chronic criteria derived by the CDFG (CDFG 2000a). These concentrations are shown in **Table 2-3**. Setting numeric targets at the CDFG-derived criteria will ensure that aquatic organisms and their uses should not be affected unacceptably if the four-day average concentrations do not exceed the chronic numeric targets (**Table 2-3**), more than once every three years on the average, and if the one-hour average concentrations do not exceed the acute numeric targets (**Table 2-3**) more than once every three years on the average.

Table 2-3 Selected Numeric Targets

Pesticide	Criterion	Concentration (ng/L)	
		Freshwater	Saltwater
Diazinon	Chronic (CCC)	50	---
Diazinon	Acute (CMC)	80	---
Chlorpyrifos	Chronic (CCC)	14	9
Chlorpyrifos	Acute (CMC)	20	20

*CCC=Criterion Continuous Concentration;
CMC=Criterion Maximum Concentration*

3.0 SOURCE ANALYSIS

3.1 INTRODUCTION

This section of the TMDL presents an analysis of the major sources of diazinon and chlorpyrifos to San Diego Creek and Upper Newport Bay. The source analysis focuses on water column concentrations, as these were associated with aquatic life toxicity and impairment of beneficial uses in San Diego Creek and Upper Newport Bay. Several investigations have been conducted in the watershed targeting aquatic life toxicity associated with pesticides. These studies were not detailed enough to identify discrete sources, but it is largely recognized that diazinon and chlorpyrifos are nonpoint source problems, and characterization of discrete sources throughout the watershed is impractical.

A source analysis approach based on correlating land use types with diazinon and chlorpyrifos export rates was employed in the 319h study (Lee and Taylor, 2001), however, this approach was hampered by the mixed land use patterns upstream of many of the sampling locations, and the limited number of samples. A study conducted by Scanlin and Feng (1997), suggested that diazinon loads could not be predicted on the basis of general land cover variables. Nevertheless, by pooling data from the various studies conducted in the watershed, estimates of chlorpyrifos and diazinon runoff concentrations and loads can be made according to broad land use categories.

The following sections analyze usage of chlorpyrifos and diazinon (Section 3.2). Environmental fate and transport parameters are discussed in Section 3.3. Section 3.4 presents a summary of the chlorpyrifos and diazinon data collected in the Newport Bay watershed and discusses the potential sources. Calculated load estimates are presented in Section 3.5. Conclusions are summarized in Section 3.6.

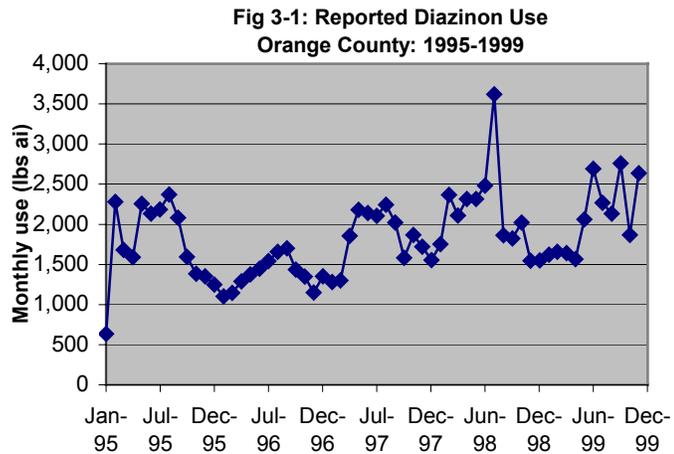

3.2 USAGE

The CDPR requires records of all pesticide applications except for residential use by homeowners. These records are compiled and reported on a county-by-county basis. The Newport Bay watershed occupies 20% of Orange County, and it is assumed here that 20% of the pesticide use reported for Orange County occurred within the Newport Bay watershed.

3.2.1 Diazinon

As shown in **Figure 3-1**, reported diazinon use in Orange County has remained fairly steady over the past five years. Seasonally-correlated increases in diazinon use are apparent in the summer months in response to increased pest activity.

As noted above, residential use by homeowners is not reported in the CDPR database. Information on national pesticide usage by homeowners is available from the USEPA Pesticide Industry Sales and Usage Market Estimates report. On a national basis, 75% of the diazinon used in the US each year is for non-agricultural purposes, with 39% used by homeowners outdoors and 3% used by homeowners indoors (USEPA, November 1999). Total homeowner use is therefore about 42% on a national basis.

In Orange County, the total agricultural use is likely less than the national average due to urbanization of the watershed. Thus homeowner uses probably account for more than the 42% reported nationally. A more specific estimate of the unreported homeowner use can be obtained by assuming the national ratio of homeowner use to total non-agricultural use (42/75, or 56%) is applicable to Orange County. Since data on the total non-agricultural diazinon use in Orange County is reported to the CDPR on a yearly basis, the national ratio can be used to estimate the unreported homeowner use in Orange County. Estimating the unreported homeowner use at 56% of total non-agricultural use results in a figure of 29,119 lbs active ingredient (ai) for 1999. This would amount to 54% of total use (including agricultural use) in Orange County; somewhat higher than the national figure of 42% reported by USEPA.

Tables 3-1 and 3-2 present the reported and estimated unreported diazinon use in Orange County. For 1999, the total diazinon use in the Newport Bay watershed would be one-fifth of the Orange County total, or approximately 10,714 lbs ai, while the estimated residential use would be about 5,824 lbs ai.

Table 3-2 indicates that urban uses accounted for over 97% of diazinon use, while agricultural uses (including nurseries) accounted for the remainder. Preliminary data from the Sales and Use Survey in the Newport Bay watershed (Wilén, forthcoming) indicate that unreported residential diazinon use in 2000 was about 7,864 lbs ai; about 32% larger than the estimate of 5,919 lbs presented above using separate national data. This would suggest that total urban uses account for more than the 97% indicated in **Table 3-2**.

**Table 3-1: Reported and Estimated Unreported Diazinon Use
Orange County: 1995-1999 (lbs ai)**

Use	1995	1996	1997	1998	1999
Structural	17,463	14,046	18,892	23,076	22,085
Nursery	1,037	839	803	1,212	1,144
Agriculture	2,004	746	1,363	865	429
Landscape	1,030	762	595	612	789
Other non-residential	9.8	46.2	1.6	1.7	5.3
Reported subtotal	21,543	16,439	21,655	25,766	24,452
Estimated Unreported Residential Use	23,548	18,905	24,804	30,150	29,119
Total	45,092	35,344	46,458	55,915	53,571

ai = active ingredient

Tables 3-1 and 3-2 show a decline in agriculture use from 1995 to 1999, both in absolute and percentage terms. The land use data also show a similar pattern, and the decline in agricultural diazinon usage may be a reflection of the continuing conversion of agricultural land to urban uses in Orange County and the Newport Bay watershed.

**Table 3-2: Reported and Estimated Diazinon Use
Orange County: 1995-1999 (percent)**

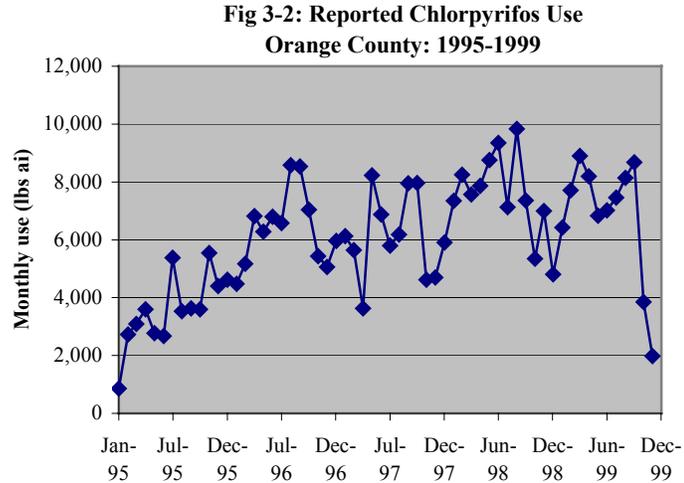

Use	1995	1996	1997	1998	1999
Structural	38.7%	39.7%	40.7%	41.3%	41.2%
Nursery	2.3%	2.4%	1.7%	2.2%	2.1%
Agriculture	4.4%	2.1%	2.9%	1.5%	0.8%
Landscape	2.3%	2.2%	1.3%	1.1%	1.5%
Other non-residential	0.0%	0.1%	0.0%	0.0%	0.0%
Estimated Residential	52%	53%	53%	54%	54%
Total	100%	100%	100%	100%	100%

USEPA Phaseout of Certain Diazinon Uses: In January 2001, USEPA released a revised risk assessment and an agreement with registrants to phase out most diazinon uses (USEPA, January 2001). Under the agreement, all indoor uses will be terminated, and all outdoor non-agricultural uses will be phased out over the next few years. Retail sales will be banned after December 31, 2002. The EPA expects that these actions will end about 75% of the current use of diazinon. In addition, about one-third of the agricultural crop uses will be removed.

The usage data in **Table 3-2** show that non-agricultural and non-nursery uses account for over 90% of the diazinon use in Orange County. It is thus likely that the EPA agreement will result in the cessation of most diazinon use in the Newport Bay watershed soon after the outdoor non-agricultural use registration expires on December 31, 2004.

3.2.2 Chlorpyrifos

Figure 3-2 shows the reported Chlorpyrifos use in Orange County from 1995 to 1999. As with diazinon, higher use tends to occur in the dry season, and is likely correlated with increased pest activity during warmer weather. An increasing trend from 1995 to 1998 is apparent followed by a sharp drop in 1999. This drop may be due to the agreement between EPA and the manufacturers to begin phasing out certain uses of chlorpyrifos (see below).

Tables 3-3 and 3-4 show the reported and estimated unreported chlorpyrifos use in Orange County. While overall chlorpyrifos use declined in 1999, nursery use increased by 300 percent. The significant increase in chlorpyrifos use by nurseries is likely due to the requirements imposed by the CDFA under the RIFA program. Runoff of the solution from the treatment area is not permitted (CDFA, March 1999).

**Table 3-3: Reported and Estimated Unreported Chlorpyrifos Use
Orange County: 1995-1999 (lbs ai)**

Use	1995	1996	1997	1998	1999
Structural	38,263	72,174	69,865	88,985	74,904
Nursery	652	772	971	994	2,913
Agriculture	1,414	952	1,450	645	1,132
Landscape	1,446	1,230	1,374	1,082	1,005
Other non-residential	7	268.5	1.6	1.6	35.3
Reported subtotal	41,782	75,396	73,662	91,707	79,990
Estimated Unreported Residential Use	21,663	40,185	38,859	49,128	41,424
Total	63,445	115,580	112,520	140,835	121,414

ai = active ingredient

Unreported (residential) chlorpyrifos use can be estimated by determining the national ratio of unreported home use to licensed (non-agricultural) use as reported in the USEPA Market Estimates Report (USEPA November 1999). Nationally, in 1995/96, the residential use was estimated at 2-4 million lbs ai, while the licensed (non-agricultural) use was estimated at 4-7 million lbs ai. Using the midpoints of these ranges, the ratio of residential use to licensed non-agricultural use is 0.545 on a national basis. Applying this ratio to the licensed non-agricultural use in Orange County reported to the CDPR for 1999 (75,944 lbs ai) yields an estimate of 41,424 lbs ai unreported residential use (**Table 3-3**). This indicates that the unreported residential use was roughly 34% of the total use in 1999 (**Table 3-4**). Total chlorpyrifos use in the Newport Bay watershed for 1999 would be approximately 24,300 lbs ai (one-fifth of the Orange County total).

Preliminary data from the Sales and Use Survey (Wilens, forthcoming) indicates that retail sales of chlorpyrifos in the Newport Bay watershed may have declined to as little as 546 lbs ai on an

annual basis in 2000. This compares to the estimated residential use of 8,285 lbs ai (one-fifth of the Orange County total) presented in **Table 3-3** for 1999. The decline in chlorpyrifos use appears to be a continuation of the trend shown in **Figure 3-2** toward the end of 1999, and is likely related to the re-registration agreement for chlorpyrifos (see below).

**Table 3-4: Reported and Estimated Unreported Chlorpyrifos Use
Orange County: 1995-1999 (percent)**

Use	1995	1996	1997	1998	1999
Structural	59.2%	61.9%	61.3%	62.7%	60.6%
Nursery	1.0%	0.7%	0.9%	0.7%	2.4%
Agriculture	2.2%	0.8%	1.3%	0.5%	0.9%
Landscape	2.2%	1.1%	1.2%	0.8%	0.8%
Other non-residential	0.0%	0.2%	0.0%	0.0%	0.0%
Reported subtotal	66%	65%	65%	65%	66%
Estimated Unreported Residential Use	34%	35%	35%	35%	34%
Total	100%	100%	100%	100%	100%

An analysis of chlorpyrifos sales data provided by Dow AgroSciences indicates that treatment for wood protection accounts for 70% of urban use (Giesy et al, October 1998). Typical applications involve subsurface injection of chlorpyrifos at relatively high concentrations. Another 14% of urban use was categorized as home use (indoor pests, pet collars, lawns and gardens, building foundations, and other structural applications), while non-residential turf applications accounted for 7% of urban use.

USEPA Phaseout of Certain Chlorpyrifos Uses: In June 2000, the EPA published its revised risk assessment and agreement with registrants for chlorpyrifos (USEPA, June 2000). The agreement imposes new restrictions on chlorpyrifos use in agriculture, cancels or phases out nearly all indoor and outdoor residential uses, and also cancels non-residential uses where children may be exposed. Application rates for non-residential areas where children will not be exposed (golf courses, road medians, industrial plant sites) will be reduced. Public health use for fire ant eradication and mosquito control will be restricted to professionals. Non-structural wood treatments will continue at current rates. Since the EPA estimates that about 50% of the chlorpyrifos use (both licensed and unreported) takes place at residential sites, the agreement is likely to result in at least a 50% decrease in chlorpyrifos use.

In Orange County, residential use (reported and unreported) likely accounts for over 90% of total chlorpyrifos use (most of the reported use is for structural protection applied in and around homes). Thus, it appears that over 90% of the current chlorpyrifos use in the Newport Bay watershed will be eliminated by the EPA agreement. Retail sales are scheduled to stop by December 31, 2001, and structural uses will be phased out by December 31, 2005.

As noted above, the CDPR data, and the preliminary Sales and Use Survey data indicate that chlorpyrifos use has been declining sharply within the last two years. This is likely due to the warning from EPA that retailers should not purchase stock unless they were able to sell it by December 31, 2001. A survey conducted in northern California in late 2000 noted, "Chlorpyrifos products have become increasingly difficult to find" (TDC Environmental, May 2001). It should be noted that the available water-quality data for the Newport Bay watershed, is largely from 1996-2000, and not directly correlated to the latest usage data from 2000-2001.

3.3 ENVIRONMENTAL FATE

The environmental fate of chlorpyrifos and diazinon can be inferred from their physical properties. **Table 3-5** presents properties for diazinon and chlorpyrifos along with several other pesticides that occasionally contribute to the aquatic life toxicity in San Diego Creek. In general, diazinon and chlorpyrifos are a more significant water quality threat because of the combined properties of higher toxicity, mobility, and persistence. Carbaryl for example, is mobile but less toxic and less persistent than diazinon and chlorpyrifos.

Table 3-5: Pesticide Properties

Pesticide	Ceriodaphnia	Solubility	Adsorption		
	LC50 (ng/L)	(mg/L)	Coefficient	Soil Half-Life	Water Half-Life
Bifenthrin	78	0.1	1,000,000	7 days to 8 months	n/a
Carbaryl	3,380	40	300	7-28 days	10 days
Chlorpyrifos	60	2	6070	2-4 months	1-2.5 months
Diazinon	440	40	1000	2-4 weeks	6 months
DDT	4,700	<1	100,000	2-15 years	1-2 months
Malathion	1,140	130	2.75	1-25 days	< 1 week

*source: EXTOXNET Pesticide Information Profiles; CDFG(2000)
n/a=not available*

Relative to most pesticides, diazinon is fairly soluble and mobile in aquatic systems. It is only weakly bound by sediment. In contrast, chlorpyrifos is much less soluble and has a much higher potential to adsorb to soil and sediment.

In general, diazinon is relatively persistent in aquatic environments with a half-life of about six-months under neutral pH conditions. The pH of the channel network in the Newport Bay watershed is generally between 7.5 and 8, a range that would maintain the stability of diazinon. In soil, the diazinon half life is shorter owing to greater microbial degradation.

For diazinon, the major routes for dissipation appear to be biodegradation, volatilization, and photolysis (USEPA, May 1999). Degradation is fastest from bare soil, followed by vegetation, and aquatic environments. Biodegradation from impervious urban areas (walkways, pavement) would be slowest due to the relative absence of microbes. This indicates that diazinon may accumulate in residential areas until rainfall runoff carries it into the drainage channel network. In a residential runoff survey conducted in the Castro Valley Creek watershed, diazinon was found in all samples as long as seven weeks after application.

Diazinon dissipation half-lives did not appear to be correlated with formulation type (granular, wettable powder, or emulsifiable concentrate).

The reported diazinon formulations in Orange County for 1999 are listed in **Table 3-6**. The liquid formulations are likely to be the most mobile as they are already in soluble form. The granules would likely remain available until a storm event washed the remaining active ingredient into the storm drains.

Table 3-6: Diazinon Formulations for Reported Uses in Orange County, 1999

Formulation	Use (lbs ai)	Percent
Emulsifiable Concentrate	14,776	60.4%
Granular/Flake	4,675	19.1%
Wettable Powder	2,720	11.1%
Flowable Concentrate	1,969	8.1%
Liquid Concentrate	275	1.1%
Dust/Powder	36.8	0.2%
Pressurized Liquid/Sprays/Foggers	0.465	0.0%
Solution/Liquid (Ready-To-Use)	0.184	0.0%
Total	24,452	100%

Regardless of the formulation used, runoff is likely to occur only after significant rainfall or irrigation. Aside from runoff, a potentially significant discharge could occur through improper disposal of old or leftover material. The degree of knowledge concerning proper disposal varies considerably and it is unlikely that homeowners are able to purchase the exact amount needed.

Large-scale aerial spray applications may drift and result in significant offsite migration. These are generally applied to orchard crops in the Central Valley and, as **Table 3-6** shows, they are not a significant application in Orange County.

There is evidence that the amount of diazinon that reaches the drainage channel network is generally less than one percent of that applied (Scanlin and Feng, 1997). Thus, relatively limited instances of improper use (e.g. inappropriate disposal, excess outdoor application) could account for a large portion of the observed concentrations in the drainage channels.

Compared to diazinon, chlorpyrifos has a shorter half-life in water, but a longer half-life in soil. This is due in part to its higher adsorption coefficient, which results in chlorpyrifos partitioning out of the aquatic phase as it is bound by sediment and soil.

Table 3-7 shows the chlorpyrifos formulations used in Orange County in 1999. As with diazinon, concentrates, powders, and granular/flake formulations account for over 99% of the uses. These formulations require mixing/preparation prior to use.

Table 3-7: Chlorpyrifos Formulations used in Orange County, 1999

Formulation	Use (lbs ai)	Percent
Emulsifiable Concentrate	70,067	87.6%
Wettable Powder	6,571	8.2%
Liquid Concentrate	2,281	2.9%
Granular/Flake	996	1.2%
Pressurized Liquid/Sprays/Foggers	38.1	0.0%
Paint/Coatings	35.1	0.0%
Suspension	1.58	0.0%
Solution/Liquid (Ready-To-Use)	0.103	0.0%
Total	79,990	100%

Of the top four formulations used in Orange County, only the granular/flake formulation would act to slowly release the active ingredient into the water, while the other formulations would enhance mobility. The lower release rate would result in lower concentrations over time.

Dissipation of chlorpyrifos from water takes place through sorption, volatilization, and photolysis. Chemical breakdown (hydrolysis) rates increase with increasing temperature and pH. Adsorbed chlorpyrifos is subject to degradation by UV light, chemical hydrolysis, and biodegradation.

3.4 SOURCES OF DIAZINON AND CHLORPYRIFOS

This section presents an analysis of the sources of diazinon and chlorpyrifos in the Newport Bay Watershed. A summary of the diazinon data is presented in Section 3.5.1, followed by a discussion of diazinon sources categorized by land use in Section 3.5.2. The chlorpyrifos data is summarized in Section 3.5.3, and chlorpyrifos sources categorized by land use are discussed in Section 3.5.4. Point sources (wastewater dischargers) are discussed in Section 3.5.5. Secondary non-point sources, (sediment remobilization, groundwater, and atmospheric deposition) are discussed separately in Sections 3.5.6, 3.5.7, and 3.5.8.

3.4.1 Diazinon Data Summary

Table 3-8 summarizes the results of diazinon sampling in the Newport Bay watershed. The sampling programs are described in **Section 2**. The table shows the high diazinon detection frequency, particularly during stormflow. The observed diazinon concentrations are similar to those observed in urban watersheds elsewhere in California. The median values for both baseflow and stormflow exceed the reference Criterion Chronic Concentration (CCC) and the Criterion Maximum Concentration (CMC). Approximately 98% of the diazinon results collected within the drainage channels exceeded the CDFG CCC of 50 ng/L.

Table 3-8: Summary of Diazinon Sampling Results

Source	Count	No. of Detects	Detection Frequency	Results			
				Min	Max	Average	Median
Water (ng/L)							
Drainage Channels	198	185	93%	<40	10,000	471	220
Baseflow	104	93	89%	<40	10,000	473	160
Stormflow	94	92	98%	<50	7,990	451	357
Upper Newport Bay	26	26	100%	197	720	386	357
Rainfall	1	1	100%	13	13	13	13
Sediment (ug/kg)							
Drainage Channels	98	2	2%	<10	49	---	---
Newport Bay	64	2	3%	<0.4	60	---	---

Numeric Target (ng/L)	
Freshwater	CDFG
CCC	50
CMC	80

Source: CDFG, 2000a

For comparison, the median diazinon concentration in the Santa Ana River downstream of Prado dam was 100 ng/L (USGS, 2000), and the detection frequency was 99% (72 of 73 samples). The USGS also reported stormflow concentrations as significantly elevated relative to baseflow concentrations.

The low detection frequency for the sediment samples is in accordance with the moderately low diazinon adsorption coefficient, and its relatively high solubility. All the sediment detections were reported from samples collected in 1994, and diazinon has not been detected in subsequent semi-annual sediment sampling.

Table 3-9: Diazinon Results by Waterbody Group

Waterbody Group	Count	Results (ng/L)				Percent Exceeding	
		Min	Max	Avg.	Median	CCC	CMC
Trib. SDC-R2	24	40	7,990	817	256	96%	92%
Trib. SDC-R1	21	49	628	226	134	86%	67%
Trib.-PCC	41	40	10,000	791	271	83%	78%
PCC	15	170	820	390	367	100%	100%
SDC - R1	59	50	960	301	215	95%	92%
Trib. UNB	35	40	2,250	357	202	94%	91%

Trib. = Tributary; SDC= San Diego Creek; PCC=Peters Canyon Channel
R1, R2 = Reach 1, Reach 2; UNB=Upper Newport Bay

Table 3-9 presents the data summarized by waterbody group. Highest concentrations occur in the upstream tributary channels to San Diego Creek. The maximum concentrations in Hines Channel (which drains into Peters Canyon Channel) were three baseflow samples collected in 1998 with concentrations ranging from 2,500 ng/L to 10,000 ng/L.

The maximum concentration of six baseflow samples collected in Hines channel during 2000, was 323 ng/L, indicating a decrease in usage, or more effective runoff control.

The similarity in median concentrations indicates that there are no clearly dominant areas of the watershed with regard to diazinon loading to San Diego Creek and Upper Newport Bay. Concentrations in Peters Canyon Channel are somewhat elevated relative to the other segments of the drainage network. This was also a conclusion of the 319h study (Lee and Taylor, 2001)

San Diego Creek Reach 2: There were no sampling stations within Reach 2 of San Diego Creek. However, 24 samples were collected from tributary channels (Bee Canyon and Marshburn Slough). These samples were collected several miles upstream of where these channels joined San Diego Creek and were mainly targeted at monitoring nursery discharges. The median concentration for these samples was 256 ng/L, with maximum concentrations of 7,990 ng/L during stormflow and 2,320 ng/L during baseflow. Over 95% of the samples collected exceeded the CCC, while 92% exceeded the CMC.

San Diego Creek Reach 1: The main tributary to San Diego Creek Reach 1, (aside from Reach 2), is Peters Canyon Channel. Median diazinon concentrations in Peters Canyon Channel (367 ng/L) were higher than in San Diego Creek (208 ng/L). The median concentration for other tributaries to San Diego Creek was 143 ng/L. All 15 samples collected within PCC exceeded both the CCC and CMC, while in the tributary channels to the PCC, the percentages exceeding the CCC and CMC were lower, 83% and 78% respectively. For samples collected within Reach 1 itself, 95% exceeded the CCC and 92% exceeded the CMC.

Upper Newport Bay: The median concentration for drainage channels discharging directly to Upper Newport Bay (East Costa Mesa, Westcliff Park, Santa Ana Delhi) was 202 ng/L. The CDFG has not recommended a CCC or CMC for diazinon in saltwater, however, the LC-50 for the commonly used test species (*Mysidopsis bahia*) is 4,200 ng/L, and the observed diazinon concentrations were all below this level, with a maximum of 720 ng/L. The USEPA (USEPA, August 2000b) has published draft recommended acute and chronic criteria for diazinon in saltwater (820 ng/L and 400 ng/L respectively). The maximum and average results from Upper Newport Bay were below the respective draft USEPA saltwater CMC and CCC.

3.4.2 Diazinon Sources Categorized by Land Use

Tables 3-10a and 3-10b present the diazinon results by sampling location along with the land use pattern in the monitored sub-watershed. The locations in **Table 3-10a** are sorted according to

median stormwater runoff concentration, while in **Table 3-10b**, they are sorted according to median baseflow concentration. Several of the locations were sampled for only baseflow or only stormflow conditions.

**Table 3-10a: Land Use and Diazinon Stormflow Concentrations
Newport Bay Watershed: 1996-2000**

Station	Land Use	Count	Stormflow Results (ng/L)			
			Min	Max	Avg.	Median
Westcliff Park	residential	7	174	1,079	692	678

San Joaquin Creek - Univ Dr.	agricultural-open	2	<50	<50	<50	<50

At virtually all the locations, the median stormflow concentration is significantly higher than the median baseflow concentration. Since stormwater runoff constitutes about 80% of the volume of water discharged to Newport Bay on an annual basis, this would indicate that the overwhelming majority of the pesticide load would derive from stormflow rather than baseflow. The average concentration is actually higher for baseflow, but this is biased by a few very high detections from 1998 near nurseries. These results have not been observed in later sampling and the nurseries have subsequently instituted measures targeted at reducing pesticide runoff.

Although the sampling network is not detailed enough to identify individual sources (aside from nurseries), two conclusions are apparent:

- (1) Stormflow concentrations are virtually always higher than baseflow concentrations. This is particularly the case in the non-agricultural areas.
- (2) Residential areas tend to yield the highest stormwater runoff concentrations while the nursery areas tend to yield the higher baseflow concentrations.

These conclusions were also evident in the 319h study (Lee and Taylor, 2001). The 319h study monitored pesticide concentrations in runoff and correlated this with land use in the sub-watershed.

Studies reported in the literature indicate that residential hotspots (individual homes) can account for most of the diazinon runoff from a neighborhood. Samples collected from the near vicinity of these residential hotspots (prior to dilution in the storm drain), showed concentrations above 10,000 ng/L (Scanlin and Feng, 1997). Such detailed sampling and analysis for pesticides has not been conducted in residential areas of the Newport Bay watershed.

3.4.3 Chlorpyrifos Data Summary

Table 3-11 summarizes the chlorpyrifos results. The detection frequency is lower than for diazinon. This is due in part, to the lower solubility of chlorpyrifos, and its greater affinity for sediment (**Table 3-5**). As discussed in **Section 3-4**, the lower mobility of chlorpyrifos results in lower concentrations in the drainage channels, despite the fact that over twice as much chlorpyrifos is applied as compared to diazinon (lbs ai) (**Tables 3-1 and 3-3**),

The average values for stormflow and baseflow exceed the numeric target Criterion Chronic Concentration (CCC). Within the drainage channels, 44% of the chlorpyrifos results exceeded the CCC of 14 ng/L, while 92% of the samples collected in Upper Newport Bay were above the saltwater CCC of 9 ng/L.

Table 3-11: Summary of Chlorpyrifos Sampling Results

Source	Count	No. of Detects	Detection Frequency	Results

CMC	20

Source: CDFG, 2000a

The sediment data for chlorpyrifos is reflective of the higher soil adsorption coefficient relative to diazinon. Although chlorpyrifos analyses were not presented in the OCPFRD data, chlorpyrifos was detected in both sediment samples collected by the CDFG.

Table 3-12: Chlorpyrifos Results by Waterbody Group

Waterbody Group	Count	Results (ng/L)			Detection Frequency
		Max	Avg.	Median

UNB	24	132	43.3	41.5	100%

Trib. = Tributary; SDC= San Diego Creek; PCC=Peters Canyon Channel; R1, R2 = Reach 1, Reach 2; UNB=Upper Newport Bay

Table 3-12 presents the data summarized by waterbody group. Detection frequencies were low, particularly in the upper reaches of the watershed. Detection frequencies were higher in Peters Canyon Channel and its tributaries, where a large proportion of the samples were from undiluted nursery discharges. Comparison to the CCC and CMC is difficult because they are set at levels below the analytical reporting limit used for most of the sampling programs.

San Diego Creek Reach 2: There were no samples collected from within Reach 2, however, samples collected from tributary channels discharging into Reach 2 had a low detection frequency (33%) and a maximum concentration of 121 ng/L.

San Diego Creek Reach 1: Samples collected from locations in Reach 1 of San Diego Creek (at Campus, Coronado, and Harvard streets) had a relatively high detection frequency and the highest median concentration, along with Peters Canyon Channel. This may indicate that the greater part of the chlorpyrifos loading is derived from Peters Canyon Channel and its sampled tributaries (Hines, Central Irvine). However, the maximum chlorpyrifos concentrations occurred in two samples collected from San Joaquin Creek, which discharges directly into Reach 1 of San Diego Creek.

Upper Newport Bay: Chlorpyrifos was detected in all samples collected in Upper Newport Bay, where a lower detection limit was employed. The samples were collected over several days during a storm event in January 1999. The chlorpyrifos concentration that saltwater organisms are exposed to is largely dependent on the degree of mixing between saltwater and freshwater in the upper bay. In the case of the storm sampled in January 1999, a freshwater lens persisted for several days in the upper bay. Chlorpyrifos concentrations were inversely correlated with salinity. Overall, the observed concentrations were lower in Upper Newport Bay than in San Diego Creek.

3.4.4 Chlorpyrifos Sources Categorized by Land Use

Tables 3-13a and 3-13b present the chlorpyrifos results by sampling location along with the land use pattern in the monitored sub-watershed. The locations in **Table 3-13a** are sorted according to median stormwater runoff concentration, while in **Table 3-13b**, they are sorted according to median baseflow concentration.

Stations sampling runoff derived from mixed land use areas tended to have the highest chlorpyrifos concentrations under both baseflow and stormflow conditions. A major exception was the data from San Joaquin Creek. This creek was sampled during two separate storm events in February, 2000. (Baseflow samples were not collected). The results were the two highest chlorpyrifos concentrations (770 ng/L and 470 ng/L) in the entire dataset.

This sample was also associated with very high concentrations of carbaryl that were determined to originate from agricultural fields planted with strawberries that were treated with pesticides immediately prior to a rainfall event.

Chlorpyrifos was not detected in the two stormflow samples collected at the second non-nursery agricultural location (Sand Canyon Ave - NE corner Irvine Blvd). Therefore, assigning a median concentration to the entire watershed for non-nursery agriculture based on this limited data may be unwarranted.

It is difficult to draw strong conclusions from the data in **Tables 3-13a and 3-13b** due to the limited number of samples at most of the locations, and the large number of non-detect results. The chlorpyrifos results also do not correlate well with the diazinon results; the locations with the higher diazinon concentrations do not generally yield the higher chlorpyrifos concentrations. The sampling locations at Westcliff Park and the Central Irvine Channel at Monroe were the only locations among the top seven stormflow results for both chlorpyrifos and diazinon. The baseflow results had a somewhat better correlation, but overall the data suggest differing usage patterns for chlorpyrifos and diazinon.

Sample locations monitoring residential areas tended to have lower chlorpyrifos concentrations. Chlorpyrifos was not detected at three of the residential locations under either baseflow or stormflow conditions. The detection frequency, and maximum concentrations detected at another partly residential location (Santa Ana Delhi Channel) were low. The only residential site with relatively high chlorpyrifos concentrations was Westcliff Park (stormflow), but the baseflow concentrations were relatively low.

Although it appears that some of the nursery/agricultural locations yield higher chlorpyrifos concentrations than the residential areas, it should be noted that the nursery monitoring locations are selected to monitor undiluted nursery discharge, very close to where the chlorpyrifos is used. In contrast, runoff from individual homes where chlorpyrifos is applied is not monitored, since the monitoring location is within a channel collecting mixed/diluted runoff from many homes. In addition, because of the relative immobility of chlorpyrifos, and its tendency to adsorb to sediment, higher chlorpyrifos concentrations are most likely to be encountered only near areas where it is applied, before it partitions out of the aqueous phase and settles out along with the sediment.

3.4.5 Point Sources (Wastewater Dischargers)

There are over fifteen waste discharge requirement (WDR) and NPDES permit holders in the Newport Bay watershed. Some of these permits are in the process of being rescinded.

NPDES

Five of the NPDES permits are minor permits for discharge of extracted groundwater. These are not expected to be sources of diazinon and chlorpyrifos loads to the watershed (groundwater is discussed further below), and the dischargers are not required to monitor for OP pesticides. The other two NPDES permits are classified as major permits and are discussed below.

NPDES - Stormwater Runoff:

Stormwater runoff in the Newport Bay watershed is regulated by an NPDES permit for Orange County. As discussed in Section 2, the OCPFRD monitoring program does not include analysis for organophosphate pesticides. However, considerable data have been collected from stormwater runoff channels as part of the 205j, 319h, and CDPR investigations.

NPDES - Sewage Treatment Plants:

Diazinon has been found in effluent from STPs (USEPA, May 1999). Presumably, the diazinon results from improper disposal of surplus pesticides into sewer drains. The Newport Bay Watershed residential use survey has indicated a lack of knowledge among homeowners concerning proper disposal procedures (Wilén, forthcoming). The only STP in the Newport Bay Watershed (IRWD STP), does not discharge effluent to the drainage channels or Newport Bay.

WDR

Nursery WDRs:

There are three commercial nurseries in the Newport Bay watershed that are regulated under WDRs. WDRs are being prepared for an additional two nurseries. Together, these nurseries account for less than two percent of the area in the Newport Bay Watershed. As part of the nutrient TMDL for Newport Bay (1999) nurseries greater than five acres and discharging to tributaries that enter Newport Bay were required to institute a regular monitoring program. The monitoring program includes bi-monthly monitoring for toxicity, however, there is no requirement for analysis of OP pesticides. Several of the sampling locations for the 205j, 319h and DPR-RIFA studies were chosen to monitor discharges from nurseries to the drainage channel network. The highest diazinon results occurred in Hines channel and the Drain at Bee Canyon and Portola Parkway sampling station. These results reflect relatively undiluted discharge from agricultural (mostly nursery) areas.

Other WDRs:

Several other facilities (including three landfills) have WDRs but none are required to monitor for OP pesticides, and they are not considered to be significant sources of OP pesticide loads.

3.4.6 Groundwater

Although there are no currently available groundwater data for diazinon and chlorpyrifos in the Newport Bay watershed, groundwater does not appear to be contributing diazinon and chlorpyrifos loads to the drainage system. Diazinon and chlorpyrifos concentrations are lower downstream of areas where groundwater seeps into the drainage channels. This indicates that the groundwater serves to dilute the concentrations.

In general, diazinon and chlorpyrifos tend to dissipate from the ground surface or in the upper soil layers before percolating to groundwater. Diazinon and chlorpyrifos have not been detected in groundwater sampling conducted by the USGS in the lower Santa Ana River Basin.

3.4.7 Sediment Remobilization

As discussed in the fate and transport section, diazinon has a relatively low potential to adsorb to sediment while chlorpyrifos has a greater adsorption coefficient (**Table 3-5**). Chlorpyrifos could accumulate in sediment and be gradually released into the water through desorption. This would require stability of the adsorbed chlorpyrifos, but adsorbed chlorpyrifos is still subject to chemical hydrolysis and biodegradation.

The available sediment data demonstrate that diazinon is not being bound to sediment. As shown in **Table 3-8**, the detection frequency for diazinon in sediment samples is less than two percent.

Two sediment samples were collected by the CDFG in July/August 2000. Chlorpyrifos was detected in sediment from Hines channel (29 ng/g) and in sediment collected nine miles downstream from the nurseries in San Diego Creek (17 ng/g) (CDFG, October 2000). Diazinon was not detected at either location (reporting limit of 10 ng/g dry weight)

As part of the semi-annual sampling program, the OCPFRD collected 96 sediment samples from the Newport Bay watershed and 54 sediment samples from the Bay itself from 1994-1999. Only four diazinon detections were reported. All the detections occurred in 1994, at concentrations of 40 ug/kg to 60 ug/kg. Reporting limits ranged from 35 ug/kg to 400 ug/kg. OCPFRD does not currently monitor sediment for chlorpyrifos.

3.4.8 Atmospheric Deposition

Diazinon is one of the most frequently detected pesticides in air, rain, and fog (USEPA, May 1999). In sampling conducted in California in 1988, diazinon was detected in approximately 90% of the sites sampled. Chlorpyrifos has a vapor pressure in the same range as diazinon, and can be expected to volatilize from treated areas. It is not as commonly detected in the atmosphere however.

A rainwater sample collected in the Newport Bay watershed during the 205j studies (December 1997) was reported to have a diazinon concentration of 13 ng/L and a chlorpyrifos concentration of 23 ng/L (Lee and Taylor, 1999).

For comparison, eight rainwater samples collected in the Castro Valley Creek watershed, an urban watershed in northern California, had a mean diazinon detected concentration of 58 ng/L with a maximum of concentration of 88 ng/L (Katznelson and Mumley, 1997).

Higher diazinon concentrations in rainwater have been detected in agricultural areas (over 5,000 ng/L in 1994-95, and ranging from 418 ng/L to 5,463 ng/L in 14 cities located in the Central Valley) but these are likely related to aerial spray applications to orchards – a type of use that is negligible in the Newport Bay Watershed. Rainfall collected in the winter of 1992-93 in the San Joaquin basin contained up to 1,900 ng/L diazinon. The source of this diazinon is “presumed to be droplets from dormant spray applications (not volatilization from treated crops)” (Novartis, 1997).

Indirect deposition: Assuming the measured rainfall concentration is representative for all storm events, and assuming no degradation during runoff, the annual diazinon load derived from rainfall would be approximately 0.72 lbs. This would be about 3.4% of the total annual load to Newport Bay. For chlorpyrifos, the load would be 1.27 lbs, which would be about 33% of the total annual load to Newport Bay. It is uncertain however whether this contribution is from volatilization from use within the watershed, or is from aerial transport from outside the watershed. If the origin is from within the watershed, then the contribution from rainfall is already taken into account by the runoff sampling. Origin from outside the watershed would be a significant source for chlorpyrifos. Further study of aerial transport and deposition of pesticides is required. A forthcoming study funded by the DPR will address this issue in the Southern California region.

Direct deposition: Direct deposition (rainfall falling directly onto Newport Bay) would be negligible since the area of the bay relative to the watershed is less than one percent. The diazinon load would be less than 0.0072 lbs, or less than 0.03% of the annual load to the Bay. For chlorpyrifos the load would be 0.0127 lbs or about 0.3% of the total annual load.

3.5 CURRENT LOADING

This section presents calculations of diazinon and chlorpyrifos loads to San Diego Creek and Upper Newport Bay.

3.5.1 Diazinon

The calculated runoff loading based on flow and concentration data from the Newport Bay watershed is about 32 lbs annually (**Table 3-14**). This amounts to 0.24% of the estimated 10,700 lbs of diazinon (ai) that was used within the watershed in 1999. This finding is similar to the result reported in a recent study in the Castro Valley watershed (an urban watershed). The study found that 0.3% of the applied diazinon (ai) was discharged into Castro Valley Creek and that 90% of this load was delivered by stormwater runoff (Scanlin and Feng, 1997).

Table 3-14: Diazinon Current Loads

Waterbody	Annual Flow (acre-ft)	Median Conc. (ng/L)	Load		
			(lbs)	(percent)	
S. D. Creek Reach 2	Baseflow	4,374	160	2.5	14%
	Stormflow	16,919	375	15.9	86%
Total:				18.4	100%
S. D. Creek Reach 1	Baseflow	7,674	160	4.4	14%
	Stormflow	29,682	375	27.8	86%
Total:				32.2	100%

Note: Samples have not been collected from Reach 2 of San Diego Creek. For the purposes of calculating current loads, the median concentration for Reach 2 of San Diego Creek is set equal to the median concentration for Reach 1.

Table 3-15 presents summary diazinon results categorized by land use, and estimates of the annual load for baseflow and stormflow. Only samples from locations where either urban or non-urban (agriculture, nursery) land use predominated were included in generating the table; about 40% of the samples in the data set were excluded.

Table 3-15: Diazinon Concentrations and Loads by Land Use

Land use data: Jan, 2000 Orange County Planning and Development Services Department, in (in Newport Bay/San Diego Creek Watershed Study; Feb 2001)

The total diazinon load estimated from **Table 3-15** is not directly comparable with the total load calculated using the average data from San Diego Creek (**Table 3-14**) because the data sets are different. The table is simply intended to compare export rates from urban and agricultural areas. On a per-acre basis, diazinon export rates appear to be slightly higher for urban areas than for agricultural areas.

The intensive residential investigation in the Castro Valley Creek watershed (Scanlin and Feng, 1997) revealed that a small number of individual residential hotspots (2% to 4% of the homes) produced the bulk of the diazinon loading to the Creek. Controlled experiments to evaluate diazinon runoff from individual homes demonstrated that even when diazinon was used properly, and the label directions scrupulously followed, very high levels of diazinon would still be produced in the runoff. Highest source areas were patios and driveways, followed by roof drains. These results are probably due to the lower rates of dissipation from these surfaces as compared to lawns or soil, where biodegradation would be much more significant.

3.5.2 Chlorpyrifos

Table 3-16 presents an estimate of the annual chlorpyrifos loading to San Diego Creek and Upper Newport Bay. The total annual mass of chlorpyrifos entering Upper Newport Bay is about 7.3 pounds. This is about 0.03% of the estimated 24,300 lbs ai of chlorpyrifos applied in the watershed (one-fifth of the Orange County total given in **Table 3-3**). This load is based on a conservative estimate of chlorpyrifos concentrations in tributaries to Upper Newport Bay. Actual concentrations in Upper Newport Bay would be reduced due to mixing and dilution.

Table 3-16: Chlorpyrifos Current Loads

Waterbody	Annual Flow (acre-ft)	Median Conc. (ng/L)	Load	
			(lbs)	(percent)
S. D. Creek Reach 2	Baseflow	4,374	56	0.89 24%
	Stormflow	16,919	57	2.75 76%
	Total:			3.6 100%
S. D. Creek Reach 1	Baseflow	7,674	56	1.6 24%
	Stormflow	29,682	57	4.8 76%
	Total:			6.4 100%
Upper Newport Bay	Baseflow	9,281	53	1.9 24%
	Stormflow	35,236	61	5.4 76%
	Total:			7.3 100%

Note: Because samples have not been collected from Reach 2 of San Diego Creek, the median concentration for Reach 2 is set equal to the median concentration for Reach 1. The total load entering Upper Newport Bay is estimated by adding flow data and median chlorpyrifos concentrations from the Santa Ana Delhi channel.

Table 3-17 presents chlorpyrifos concentrations and loads categorized by land use for the baseflow and stormflow conditions. Compared to diazinon, urban areas contribute a lesser percentage of the stormflow chlorpyrifos load. On a per-acre basis, export rates for urban and agricultural areas are similar. The total chlorpyrifos load estimated from **Table 3-17** is not directly comparable with the total load calculated using the data from San Diego Creek (**Table 3-16**). The discrepancy between the two methods results from the differing data sets.

Table 3-17: Chlorpyrifos Concentrations and Loads by Land Use

Condition	LandUse	Count	Results (ng/L)				Area		Load		Load
			Min	Max	Det Freq.	Median	(acres)	(%)	(lbs)	(%)	(lbs/acre)
Baseflow	urban	27	nd	129	14%	<40	66,507	68%	0.69	87.7%	1.03E-05

	Total						97,741	100%	3.06	100%	3.13E-05

3.6 SUMMARY AND CONCLUSIONS

1. Reported and unreported urban uses account for over 90% of total diazinon and chlorpyrifos use in Orange County and in the Newport Bay Watershed.
2. About 32 pounds of diazinon are discharged annually to San Diego Creek, mostly during storm events. This amounts to about 0.24% of the applied diazinon mass in the watershed. About 7 pounds of chlorpyrifos are annually discharged to Upper Newport Bay, with 76% of the load delivered during storm events. This amounts to about 0.03% of the applied chlorpyrifos mass.
3. Surface runoff is the source of virtually all the loadings. Contributions from atmospheric deposition, sediment remobilization, and groundwater are negligible. An exception would be atmospheric transport and deposition of diazinon and chlorpyrifos originating from outside of the Newport Bay watershed. Further investigation would be required to determine whether this is an important source of pesticide loading to San Diego Creek and Newport Bay.
4. On a per acre basis, different land uses contribute diazinon and chlorpyrifos runoff at fairly equal rates within the watershed.
5. Runoff derived from urban land uses accounts for about 88% of the diazinon baseflow load, and 96% of the stormflow load. Agricultural sources (including nurseries) account for the remainder of the load.
6. For chlorpyrifos, runoff derived from urban land uses accounts for about 85% to 88% of the baseflow and stormflow loads, while agriculture (including nurseries) accounts for about 12% to 15% of the load.
7. Average diazinon concentrations in San Diego Creek exceed the chronic numeric target (CCC) of 50 ng/L both during baseflow (200 ng/L) and during stormflow (445 ng/L).
8. Average chlorpyrifos concentrations in San Diego Creek exceed the CDFG CCC (14 ng/L) during baseflow (111 ng/L) and stormflow (87 ng/L). The average chlorpyrifos concentration in Upper Newport Bay (43.3 ng/L) exceeds the saltwater chronic numeric target (CCC) of 9 ng/L.
9. The diazinon re-registration agreement by EPA will likely end over 90% of current diazinon use in the Newport Bay watershed. If runoff concentrations show a corresponding decline, diazinon concentrations in San Diego Creek could decrease below the chronic numeric target (50 ng/L).
10. The chlorpyrifos re-registration agreement by EPA will likely end over 90% of current chlorpyrifos use in the Newport Bay watershed. If runoff concentrations show a corresponding decline, chlorpyrifos concentrations in San Diego Creek and Upper Newport Bay could decline below the respective chronic numeric targets for freshwater and saltwater.

4.0 LOAD ALLOCATION

4.1 INTRODUCTION

TMDLs, while commonly expressed as loads, can also be expressed using other measures. The TMDL regulations state; “TMDLs can be expressed in terms of mass per time, toxicity, or other appropriate measure” [40 CFR 130.2(i)].

For the diazinon and chlorpyrifos TMDLs, the concentration is the most appropriate measure. This is because the beneficial use impairment is due to toxic concentration levels in the aquatic environment. The numeric target consists of an acute and chronic criterion averaged on a 1-hour and 4-day time period, respectively. Setting the TMDL based on daily or annual loads could subject aquatic organisms to unacceptable adverse effects. This is because short-term concentrations could exceed the acute or chronic numeric targets while the average concentration indicated by the mass load would suggest compliance with the numeric targets.

The TMDL is therefore expressed using the chronic and acute concentration limits derived by the CDFG for these pesticides for the protection of aquatic life. The TMDL numeric targets apply to Reach 1 and Reach 2 of San Diego Creek (chlorpyrifos and diazinon) and to Upper Newport Bay for chlorpyrifos.

These numeric targets can be expressed as loads (mass per time) by multiplying the concentrations by the flow rates in San Diego Creek. The mass loads can be used to analyze the relative contributions of different dischargers to the total load. However, the concentration criteria will be used to measure compliance with the TMDL, not the mass loads.

4.2 ASSIMILATIVE CAPACITY

The assimilative capacity for diazinon and chlorpyrifos is based on comparison of stormwater samples in San Diego Creek to the chronic numeric target, and comparison of maximum observed concentrations to the acute numeric target. The chronic numeric target identifies the maximum continuous concentration that could be tolerated without adverse impacts. Concentration fluctuations are taken into account through expression of the chronic criterion as a four-day average. The allowed frequency of exceedance is once every three years. This interval is judged sufficient to allow impaired populations to recover (USEPA, 1985).

Because the chronic criterion is a four-day average, available time-series stormwater data from San Diego Creek were averaged and the highest average concentration for diazinon and chlorpyrifos were selected. For diazinon, the highest average concentration in San Diego Creek was from a storm event in January 1999, with samples collected over a three-day period (**Table 4-1**). In the case of chlorpyrifos, the highest stormwater concentration was from a sampling event in February 2000, where only a single sample was available (**Tables 4-2**).

The chronic criterion is paired with an acute criterion, which serves as a maximum concentration. Similar to the chronic criterion, exceedance of this concentration (a one-hour average) is allowed once every three years. To illustrate the needed reduction required for compliance with the acute criterion, the single maximum concentrations in San Diego Creek (baseflow or stormflow) were compared to the respective diazinon and chlorpyrifos acute numeric targets.

**Table 4-1: Diazinon Stormwater
Sampling in San Diego Creek**

Dates	Average (ng/L)	No. Samples
Jan 25-27, 1999	848	4
Jan 25-26, 2000	595	6
12-Feb-00	460	1
Mar 25-26, 1998	301	4
May 12-13, 1998	294	5
21-Feb-00	220	1
06-Dec-97	216	4
24-Feb-00	135	1

**Table 4-2: Chlorpyrifos Stormwater
Sampling in San Diego Creek**

Date	Average (ng/L)	No. Samples
12-Feb-00	260	1
21-Feb-00	170	1
Jan 25-26, 2000	120	6
24-Feb-00	101	1
06-Dec-97	70	4
May 12-13, 1998	59	5
Mar 25-26, 1998	50	4
Jan 25-27, 1999	50	4

Table 4-3 shows the needed load (concentration) reductions for diazinon and chlorpyrifos in order to achieve the TMDL numeric targets in San Diego Creek. The difference between the assimilative capacity and the current load is the required reduction. Chlorpyrifos concentrations may have begun to decline in 2000 and 2001, based on indications of a reduction in usage from the DPR database as well as from the Sales and Use Survey (Wilén, forthcoming) conducted in late 2000. There are as yet no clear indications of declining trends in diazinon usage in the watershed.

Table 4-3: Needed Load (Concentration) Reductions

Constituent	San Diego Creek (1996-2001)		TMDL		Needed Reduction	
	Storm Average (ng/L)	Maximum (ng/L)	Chronic (ng/L)	Acute (ng/L)	Chronic (ng/L)	Acute (ng/L)
Chlorpyrifos	260	580	14	20	95%	97%
Diazinon	848	960	50	80	94%	92%

4.3 MARGIN OF SAFETY

The TMDL regulations (40 CFR 130.7) require that “TMDLs shall be established at levels necessary to attain and maintain the applicable narrative and numerical water quality standards with seasonal variations and a margin of safety which takes into account any lack of knowledge concerning the relationship between effluent limitations and water quality.”

As discussed in **Section 2.1** the chronic and acute concentration limits as derived by the CDFG, include a margin of safety. In addition, the following conservative assumptions have been used in developing the load allocation and analyzing the needed reductions.

1. No consideration of pesticide breakdown from point of discharge to San Diego Creek. The half-lives of diazinon and chlorpyrifos in water range from a few days up to six months, but faster biotic or abiotic degradation can occur depending on site-specific conditions.
2. No consideration of mixing and dilution within the drainage channels. In particular, the dilution capacity provided by groundwater seepage into the drainage channel network has not been factored into the TMDL.
3. Calculation of assimilative capacity was performed using arithmetic averages of the data set, with non-detect results set equal to the detection limit. This likely overestimates the current load as the detection frequency for chlorpyrifos in San Diego Creek was less than 60%.

4.4 LOAD and WASTE LOAD ALLOCATIONS

Table 4-4 presents interim and final TMDL allocations for diazinon and chlorpyrifos. The final allocations are based on the numeric target. The interim allocation schedule is intended to provide a reasonable period of adjustment commensurate with the EPA phaseout agreements. The interim allocation for diazinon is based on the draft EPA recommended water quality criteria for diazinon that was published in 2000 (USEPA, August 2000b) and calculated using the USEPA methodology established in 1985 (USEPA 1985). As both the acute and chronic criteria were equal to 100 ng/L in this draft document, the interim allocation for diazinon is expressed as a maximum.

The interim allocation for chlorpyrifos is equal to one-half the *Ceriodaphnia dubia* LC50 (60 ng/L). *Ceriodaphnia dubia* was the most sensitive species in the CDFG data set that used to derive the acute and chronic recommended criteria for chlorpyrifos. The interim allocation for chlorpyrifos is expressed as a maximum.

Table 4-4: Diazinon and Chlorpyrifos Freshwater Load Allocations

Category	Diazinon (ng/L)			Chlorpyrifos (ng/L)		
	Interim (2002-2004) Maximum	Final (2005)		Interim (2002-2005) Maximum	Final (2006)	
		Acute	Chronic		Acute	Chronic
Wasteload Allocation	100	80	50	30	20	14
Load Allocation	100	80	50	30	20	14
TMDL	100	80	50	30	20	14

The final load allocations will come into effect when the EPA phaseout schedules for diazinon and chlorpyrifos are completed. The final diazinon load allocation is based on 4-day average of 50 ng/L, with a maximum 1-hour average concentration of 80 ng/L. The final chlorpyrifos load allocation is based on 4-day average of 20 ng/L, with a maximum 1-hour average concentration of 20 ng/L.

Chlorpyrifos in Upper Newport Bay

Table 4-5 presents interim and final TMDL allocations for chlorpyrifos in Upper Newport Bay. The interim allocation is equal to one-half the LC50 of *Mysidopsis bahia* (40 ng/L). *Mysidopsis bahia* was the most sensitive species in the CDFG data set that used to derive the acute and chronic recommended saltwater criteria for chlorpyrifos. The interim allocation is expressed as a maximum.

The final allocation is based on the CDFG recommended saltwater criteria for chlorpyrifos. Although the CDFG-derived acute concentration limit for chlorpyrifos is the same in both saltwater and freshwater (20 ng/L), the chronic limit in saltwater (9 ng/L) is less than the chronic limit in freshwater (14 ng/L).

The chlorpyrifos concentration in Upper Newport Bay is a function of the input concentration from the freshwater tributaries, and the degree of mixing between freshwater and saltwater. There will be sufficient mixing such that chlorpyrifos concentrations in Upper Newport Bay should be less than the concentration in the freshwater tributary channels. This was indeed the case during the sampling event conducted in Upper Newport Bay in January 1999. Thus, TMDL load and waste load allocations set at freshwater chronic criteria are expected to assure compliance with the saltwater numeric target.

**Table 4-5: Chlorpyrifos Load Allocations
Upper Newport Bay (ng/L)**

Category	Interim (2002-2005) Maximum	Final (2006)	
		Acute	Chronic
Wasteload Allocation	20	20	9
Load Allocation	20	20	9
TMDL	20	20	9

Point Sources

The waste load allocation pertains to the point sources in the watershed that are NPDES and WDR permit holders. The permits will need to be revised to reflect the TMDL load allocation.

Non-Point Sources

The load allocation refers to the non-point sources in the watershed. Non-point sources are grouped into four categories:

- Agriculture
- Groundwater
- Atmospheric Deposition
- Sediment Remobilization

As discussed in the source analysis, except for agriculture, these sources are negligible contributors to the total load, and are not expected to contribute to pesticide-derived aquatic life toxicity.

Agricultural sources account for 2% to 12% of the diazinon load, and 12% to 15% of the chlorpyrifos load depending on the flow condition (**see Section 3.5**). The acute and chronic TMDL numeric targets will apply to discharges from agricultural land.

4.5 SEASONAL VARIATION

The climate of the Newport Bay watershed can be categorized into two seasons for water quality purposes: a dry season, and a wet season. Pesticide usage correlates roughly with the season, with increasing usage in the warmer months due to increased pest activity. However, runoff into the drainage channels is greatest during the wet season, and higher pesticide concentrations are observed during storm events. The higher pesticide concentrations account for the toxicity observed in stormwater samples collected in the watershed.

The chronic criterion is designed to ensure protection of aquatic life during all stages of life, including the most sensitive stages. As stated above, the concentration-based impairment requires that the TMDL apply during all seasons. There is no evidence of seasonal factors that increase or decrease toxicity, or render diazinon and chlorpyrifos more bioavailable or less bioavailable.

4.6 CRITICAL CONDITIONS

Because the TMDL is being expressed as a concentration, a detailed analysis of critical conditions is unnecessary. The same concentration limits will apply during all flow conditions and seasons.

During formulation of previous TMDLs, storm events greater than 50 cubic feet per second (cfs) were assumed to have enough momentum to convey the freshwater storm loads to the ocean in a short period of time. Thus these stormflows were not included in the load allocations. For the pesticide TMDL however, stormflow concentrations above the chronic or acute limits would cause unacceptable adverse impacts. Therefore the TMDL applies to the entire flow regime.
