WD	Water District
WUE	water use efficiency

Chapter 1 Introduction

This report describes the alternatives development process and proposed alternatives for the Long-Term Water Transfers Environmental Impact Statement/Environmental Impact Report (EIS/EIR).

1.1 Background

Hydrologic conditions, climatic variability, and regulatory requirements for operation of water projects commonly affect water supply availability in California, making advance planning for water shortages necessary and routine. This variability can strain water supplies in areas that are dependent on delivery of Central Valley Project (CVP) supplies to meet most, if not all, of the water demand. In the past decades, water entities have been implementing water transfers to supplement decreased water supplies and transfers have become a common tool in water resource planning.

The Bureau of Reclamation and the San Luis & Delta-Mendota Water Authority (SLDMWA) are completing a joint EIS/EIR to provide National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA) compliance for water transfers from 2015 through 2024. Reclamation is serving as the Lead Agency under NEPA and SLDMWA is the Lead Agency under CEQA. This report refers to Reclamation and SLDMWA jointly as the Lead Agencies.

The EIS/EIR will evaluate water transfers from willing sellers upstream from the Sacramento-San Joaquin Delta (Delta) to buyers that export water from the Delta. Alternatives in this document only analyze transfers of CVP water supplies that require use of CVP or State Water Project (SWP) facilities and transfers of non-CVP water supplies that require use of CVP facilities. The cumulative analysis will include all potential transfers including SWP transfers. The water would be transferred to water users that are at risk of experiencing water shortages and require supplemental water supplies to meet anticipated demands. Water transfers would only be used to help meet existing demands and would not serve any new demands in the buyers' service areas.

In addition to SLDMWA, several other agencies have identified interest in purchasing transfer water to reduce potential water shortages. These agencies have requested to be included in the EIS/EIR. Table 1-1 summarizes all purchasing agencies, further referred to as buyers in this report. Figure 1-1 on the next page shows the location of buyers (referred to as Buyer Service Area) and the sellers (referred to as Seller Service Area).

To make water available, the seller must take an action to reduce beneficial use. Water transfers must be consistent with Federal and State law. Transfers in the Sacramento and San Joaquin area are governed by existing water rights, Delta pumping capacity, and reservoir storage capacity. The following sections describe past water transfers and regulations applicable to implementing water transfers.

1.1.1 History

The Lead Agencies have participated in water transfers through various past programs or agreements. The Central Valley Project Improvement Act (CVPIA), signed into law in 1992, authorizes water transfers between willing parties as long as transferred water is to be used for project purposes or other beneficial uses recognized under State law (Section 3405). As a result, Reclamation has facilitated and implemented CVP-related water transfers between willing sellers and buyers in need of supplemental water supplies. Transfers have included both in-basin and through-Delta transfers.

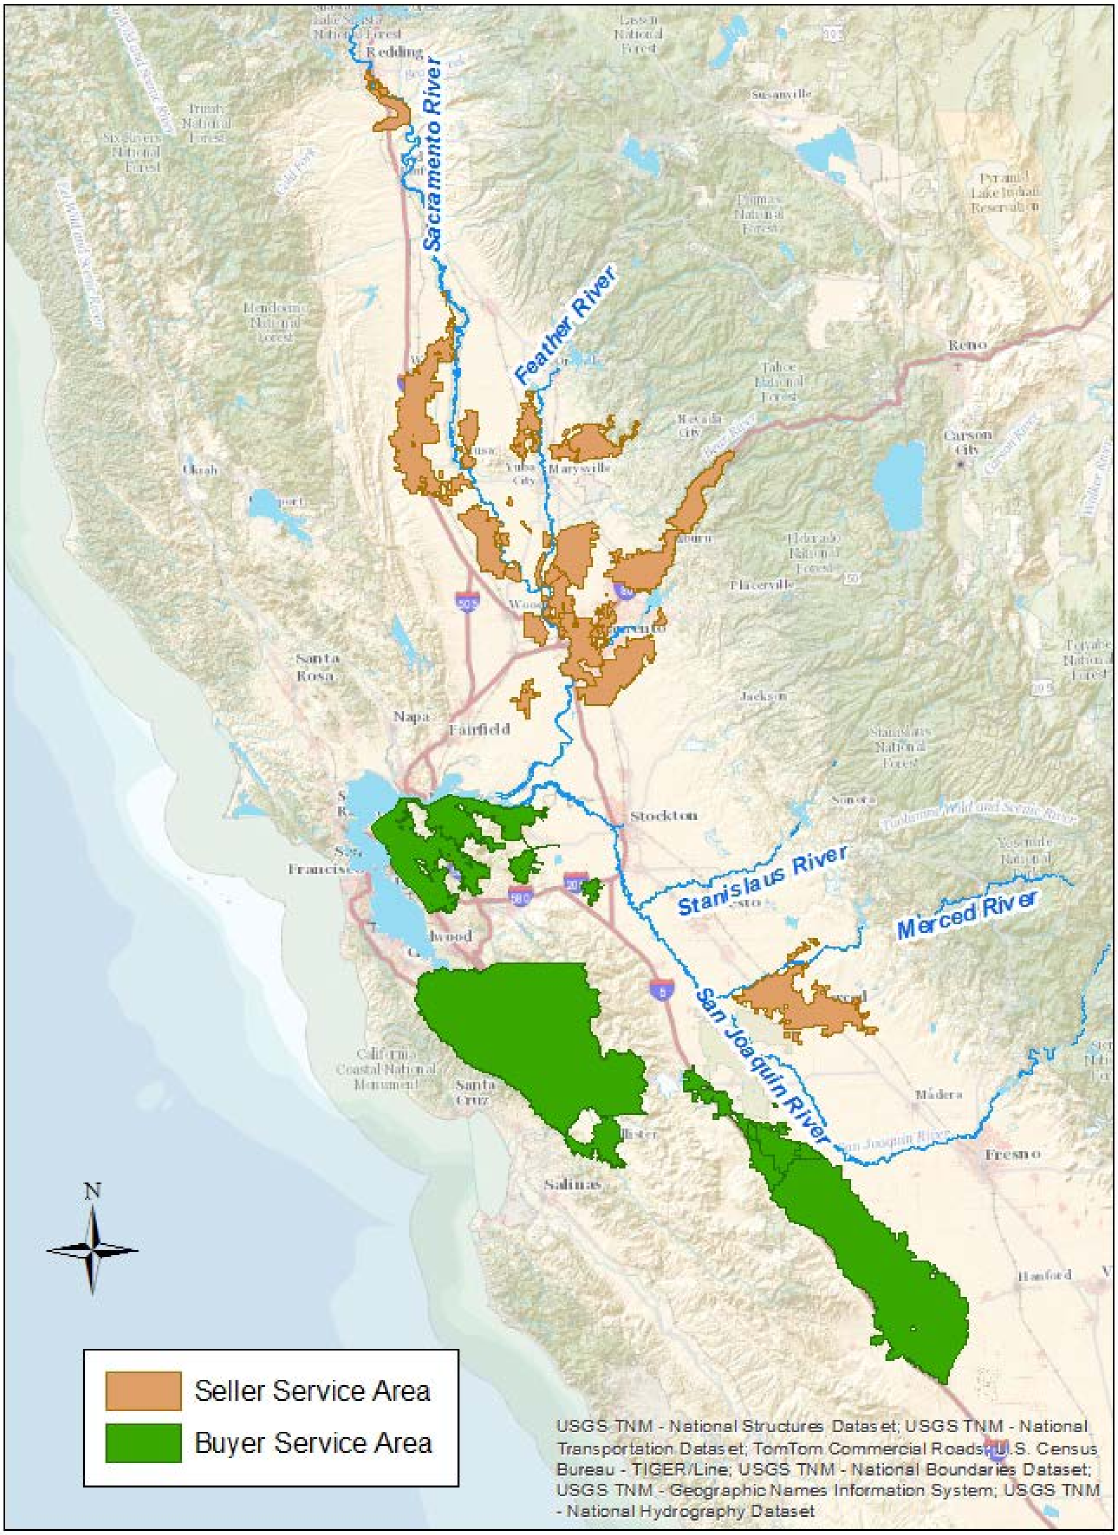

Figure 1-1. Buyer and Seller Service Areas

Reclamation is required to complete NEPA documentation for water transfers. NEPA compliance for transfers has varied in the past decade. Reclamation has developed the following NEPA documents to evaluate multiple through-Delta water transfers:

- Environmental Water Account EIS/EIR - evaluated water transfers from 2003 through 2007.
- Environmental Water Account Supplemental EIS/EIR - evaluated transfers for the 2008 transfer season.
- 2009 Drought Water Bank Environmental Assessment (EA) and Finding of No Significant Impact (FONSI) - evaluated CVP-related transfers that occurred under the 2009 Drought Water Bank.
- 2010-2011 Water Transfer Program EA and FONSI – evaluated through-Delta water transfers for 2010 and 2011 water years. Because of wetter hydrologic conditions, no transfers occurred in 2010 or 2011.
- 2013 Water Transfers EA and FONSI – evaluated through-Delta groundwater substitution transfers in 2013.
- 2014 SLDMWA Water Transfers EA and FONSI – evaluated through Delta transfers made available from groundwater substitution or cropland idling.

Reclamation has also completed multiple EAs that focus on in-basin transfers. In 2010, Reclamation signed two FONSIs for accelerated water transfers and exchanges from 2011 through 2015. One covered transfers between CVP South of Delta Contractors and the other covered transfers between Friant Division and Cross Valley CVP Contractors. Reclamation also worked with the Exchange Contractors, the CEQA lead agency, to complete an EIS/EIR to examine the environmental impacts of the transfer and exchange of the Exchange Contractors CVP water (up to 130,000 acre-feet [AF] per year for the next ten years) within the SLDMWA service area from 2005 through 2014. In 2014, Reclamation completed the 2014 Tehama-Colusa Canal Authority EA and FONSI to assess groundwater substitution and cropland idling transfers within from Sacramento Valley water users to the Tehama-Colusa Canal Authority. Other EAs have been completed for individual, in-basin and out-of-basin transfers.

Reclamation works cooperatively with the California Department of Water Resources (DWR) to develop the *Technical Information for Preparing Water Transfer Proposals* document that provides sellers and buyers with transfer information needed for Reclamation and DWR to facilitate transfers according to CVPIA and State law. Reclamation and DWR have published the paper each year since 2009 and plan to release it annually in the future with updated information on water transfers.

SLDMWA has negotiated water transfers in past years on behalf of the member agencies. SLDMWA member agencies have been identified as a potential buyer in all Reclamation's past transfer programs and many have purchased water in previous years.

While not the subject of this analysis except with regard to cumulative effects, transfers of SWP water have also occurred frequently in the past. DWR facilitates transfers for SWP contractors. DWR has operated several Drought Water Banks to support water transfers during drier hydrologic years, the most recent in 2009. For the 2009 Drought Water Bank, DWR solicited participants and helped connect buyers and sellers. DWR does not plan to implement banks in the future, but continues to facilitate water transfers for SWP contractors. SWP contractors currently identify and negotiate water transfers and submit transfer proposals to DWR.

1.1.2 Regulations Regarding Transfers

1.1.2.1 Federal

The Biological Opinions[1] on the Coordinated Operations of the CVP and SWP (U.S. Fish and Wildlife Service [USFWS] 2008; National Oceanic and Atmospheric Administration Fisheries Service [NOAA Fisheries] 2009) analyze transfers through the Delta from July to September that are up to 600,000 AF in critical and dry years. For all other year types, the maximum transfer amount is up to 360,000 AF. Transfers that exceed these amounts or are outside the transfer window would require new biological opinions. For this EIS/EIR, annual transfers would not reach this capacity and would likely stay in the range of up to 100,000 to 200,000 AF of water transferred annually to buyers.

Several lawsuits were filed challenging the validity of the 2008 USFWS and 2009 NOAA Fisheries Biological Opinions and Reclamation's acceptance of the Reasonable and Prudent Alternative (RPA) included with each (Consolidated Salmonid Cases, Delta Smelt Consolidated Cases). The District Court issued findings that concluded Reclamation had violated NEPA by failing to perform any NEPA analysis before provisionally adopting the 2008 USFWS RPA and 2009 NOAA Fisheries RPA. On December 14, 2010, the District Court found the 2008 USFWS Biological Opinion to be unlawful and remanded the Biological Opinion to USFWS. The District Court issued a similar ruling for the 2009 NOAA Fisheries Biological Opinion on September 20, 2011. On March 13, 2014, the United States Court of Appeals for the Ninth Circuit affirmed in part and reversed in part the finding from the District Court on the USFWS Biological Opinion. The Court of Appeals upheld the determination

[1] A written statement setting forth the opinion of the USFWS or the NOAA Fisheries Service as to whether a federal action is likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of a critical habitat. See 16 USCA 1536(b).

that Reclamation must complete NEPA analysis, but it reversed the finding that the scientific basis for the Biological Opinion was arbitrary and capricious. The NOAA Fisheries Biological Opinion is the subject of a future review from the Court of Appeals. Until the legal issues are resolved and new biological opinions are completed (if necessary), the 2008 USFWS and 2009 NOAA Fisheries biological opinions will guide operations of potential water transfers.

Reclamation approves transfers consistent with provisions of the CVPIA and State law that protect against injury to third parties as a result of water transfers. According to the CVPIA Section 3405(a), the following principles must be satisfied for any transfer:

- Transfer may not violate the provisions of Federal or state law;
- Transfer may not cause significant adverse effects on Reclamation's ability to deliver CVP water to its contractors;
- Transfer will be limited to water that would be consumptively used or irretrievably lost to beneficial use;
- Transfer will not have significant long-term adverse impact on groundwater conditions;
- Transfer will not adversely affect water supplies for fish and wildlife purposes. Reclamation will not approve any water transfer for which these basic principles have not been adequately addressed; and
- Transfer water must be made available in accordance with the seller's surface water monthly diversion schedule. For example, if the seller's monthly diversion for July is 10,000 AF, then only up to that amount can be transferred in July.

1.1.2.2 State

Several sections of the California Water Code provide authority to carry out transfers. Importantly, Section 1745.07 specifically indicates that transfers fitting within that portion of the Water Code are deemed to be a beneficial use of water and not to interfere with water rights. Section 1745 et seq. also defines types of transfers allowed and protections of water rights and third parties against water transfers. Water Code Section 1810 prohibits owners of conveyance facilities from denying use of unused capacity for transfers upon fair compensation and further specifies that "use of a water conveyance facility is to be made without injuring any legal user of water and without unreasonably affecting fish, wildlife, or other in-stream beneficial uses and without unreasonably affecting the overall economy or the environment of the county from which the water is being transferred."

1.1.2.3 Local

County governments also have requirements related to transferring water outside of the county, primarily related to groundwater extraction. Reclamation requires transfer participants to comply with local requirements (including ordinances relating to well drilling, well spacing, and groundwater extraction) and local groundwater management plans, as well as compliance with adjudications and with the overdraft protections in Water Code Section 1745 et seq.

1.2 Purpose of the Report

This Alternatives Development Report documents the process to develop the EIS/EIR alternatives. The Lead Agencies are using this structured planning process to delineate a reasonable range of alternatives for evaluation in the EIS/EIR in compliance with NEPA and CEQA.

This page intentionally left blank.

Chapter 2
Alternatives Development Process

Both NEPA and CEQA require EISs and EIRs, respectively, to identify a reasonable range of alternatives. To identify and screen alternatives, a structured, documented process was developed that included internal and public scoping (Figure 2-1).

Figure 2-1. Alternatives Development and Screening Process

2.1 NEPA Purpose of and Need for Action/CEQA Project Objectives

The purpose and need statement (under NEPA) and project objectives (under CEQA) describe the underlying need for and purpose of a proposed project. This statement is a critical part of the environmental review process because it helps to set the overall direction of an EIS/EIR, identify the range of reasonable alternatives, and focus the scope of analysis. The Lead Agencies developed the following purpose and need/basic project objectives statement.

2.1.1 Purpose and Need

The purpose of the Proposed Action is to facilitate and approve voluntary water transfers from willing sellers upstream of the Delta to water users south of the Delta and in the San Francisco Bay Area. Water users have the need for immediately implementable and flexible supplemental water supplies to alleviate shortages.

2.1.2 Project Objectives

As required by CEQA, a lead agency must identify the objectives sought by the proposed project. SLDMWA has developed the following objectives for long-term water transfers through 2024:

- Develop supplemental water supply for member agencies during times of CVP shortages to meet existing demands.

- Meet the need of member agencies for a water supply that is immediately implementable and flexible and can respond to changes in hydrologic conditions and CVP allocations.

Because shortages are expected due to hydrologic conditions, climatic variability, and regulatory requirements, transfers are needed in most, if not all years.

2.2 Measure Identification

The public provided comments on the scope of the EIS/EIR during the public scoping period. Some of these comments include suggestions for specific measures intended to address the purpose and need/basic project objectives. The Lead Agencies reviewed the purpose and need/basic project objectives, public scoping comments, scientific data, and previous studies in their initial effort to brainstorm measures. This resulted in an initial list of measures in Table 2-1 (described in more detail in Chapter 3).

Table 2-1. Initial Measures

Measures	Measure Description
Agricultural Water Use Efficiency (Buyer Service area)	Increase agricultural water use efficiency in buyer service area to reduce agricultural water use, including improvements to agricultural systems to increase recapture and reuse of irrigation water
Agricultural Water Use Efficiency (Upstream from Delta Region)	Increase agricultural water use efficiency in seller service area to reduce agricultural water use
Conservation – Municipal & Industrial	Increase water conservation for municipal and industrial uses in buyer service area to reduce water demands
Desalination - brackish	Desalinate brackish groundwater supplies and distribute to Buyer Service area to develop new supply
Desalination - seawater	Desalinate seawater and distribute to Buyer Service area to develop new water supply
Reclamation - nonpotable reuse	Treat wastewater for agricultural water use in Buyer Service area
Reclamation - indirect potable reuse (IPR)	Advance treat wastewater and store in groundwater basins for future potable reuse
Cropland Idling Transfers-rice, field crops, and grains	Idle croplands and transfer irrigation water to buyers
Cropland Idling Transfers-pasture and alfalfa	Idle pasture and alfalfa fields and transfer irrigation water to buyers
Land retirement in San Joaquin Valley	Permanently retire lands in San Joaquin Valley and transfer irrigation water to other croplands
Groundwater substitution	Pump groundwater for irrigation rather than use surface water supplies, and transfer surface water to buyers
New surface storage	Build new surface storage facilities to store water for buyers
Groundwater storage	Build new facilities to recharge and extract groundwater for use in Buyer Service area, or expand existing groundwater storage programs by expanding recharge and extraction facilities
Water rights purchase	Purchase water rights for permanent transfer of water

Measures	Measure Description
Crop shifting	Shift from a higher water use crop to a lower water use crop and transfer incremental decrease in water use to buyers
Rice decomposition water	Use alternate method to decompose rice straw and transfer rice decomposition water to buyers
Reservoir release	Transfer available water stored in existing, non-CVP or SWP reservoirs
Transfers within the Buyer Service Area	Implement water transfers between buyers and sellers within the Buyer Service area
Groundwater development	Develop new groundwater supplies by constructing new wells and pumps in the Buyer Service area
Modify CVP and SWP contracts	Change CVP and SWP contracts to limit water use in the Buyer Service area
Change cropping patterns in San Joaquin Valley	Plant lower water use crops or increase fallowed land in the Buyer Service area
Limit dairy and cattle ranches in San Joaquin Valley	Limit dairy and cattle ranches in San Joaquin Valley to decrease water use
Enforce seniority system to manage deliveries	Deliver water supplies based on seniority of water rights
Implement policy of no net increase in water availability for expansion	Prohibit use of CVP supplies for newly developed urban or agricultural lands
Pipe water from Canada and northern states	Purchase water and build distribution system to deliver water from northern states to buyers
Fix Owens Valley	Increase water supply available from Owens Valley

2.3 Screening Methods

The Lead Agencies determined that they should screen the initial list of measures before combining the measure into alternatives. The agencies wanted to carry forward measures that had some potential to contribute to the purpose and need/basic project objectives. They based the measure evaluation and screening on NEPA and CEQA guidance:

- NEPA requires that agencies shall “rigorously explore and objectively evaluate all the reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated” (40 Code of Federal Regulations [CFR] Part 1502.14(a)). The Department of the Interior NEPA procedures (43 CFR Part 46.420(b)) define reasonable alternatives as “alternatives that are technically and economically practical or feasible and meet the purpose and need of the proposed action.”

- CEQA Guidelines section §15126.6(a) states, “An EIR shall describe a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project…” An EIR need not consider every conceivable alternative to a project or alternatives that are infeasible. (CEQA Guidelines, §15126.6(a).) State CEQA Guidelines section 15364

> defines feasible as "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors."

Both NEPA and CEQA include provisions that alternatives meet (or meet most of) the purpose and need/basic project objectives, and be potentially feasible. Some alternatives do not fully meet the purpose and need/project objectives, but may be carried forward for additional analysis because they have potential to minimize some types of environmental effects or help create a reasonable range of alternatives for consideration by decision-makers.

The Lead Agencies determined that they would screen the alternatives based on their ability to meet key elements of the purpose and need/basic project objectives:

- Immediate: the term proposed for this EIS/EIR is 2015 through 2024. This period is relatively short, and measures need to be able to provide some measurable benefit within this time period.
- Flexible: project participants need water in some years, but not in others. They need measures that have the flexibility to be used only when needed.
- Provide Water: project participants need measures that have the capability of providing additional water to regions that are experiencing shortages.

Measures need to meet these three criteria to move forward for further evaluation.

2.4 Alternatives Development

The Lead Agencies screened the measures by applying the screening criteria to each measure based on available information and best professional judgment. The measures that will move forward for more detailed analysis in the EIS/EIR are those that best meet the NEPA purpose and need and CEQA basic project objectives, minimize negative effects, are feasible, and represent a range of reasonable alternatives. Chapter 4 describes the screening results in more detail.

The Lead Agencies combined the remaining measures into alternatives. The remaining measures represent potential methods to transfer water. The alternatives examine different combinations of transfer types, with different potential maximum quantities of transfers.

Chapter 3 Measures

This chapter describes measures identified for the alternatives development process. As described in Section 2.2, these measures were developed based on existing studies, past water transfer actions, and public comments received during the scoping period. Chapter 4 includes an evaluation of the measures relative to the purpose and need for long-term water transfers.

3.1 Agricultural Water Use Efficiency (Buyer Service Area)

For the agricultural water use efficiency (WUE) measure in the Buyer Service Area, districts or farmers would increase irrigation efficiency by implementing best management practices (BMPs) to reduce applied water on crops. This measure would also include improvements to agricultural systems to increase recapture and reuse of irrigation water. Reclamation requires CVP contractors to implement cost-effective, BMPs to manage water use. The CVPIA of 1992 and Section 210(b) of the Reclamation Reform Act of 1982 requires the preparation and submittal of a Water Management Plan from certain entities that enter into a repayment contract or water service contract with the Reclamation. Each plan is required to be updated every five years. Reclamation develops criteria to evaluate plans prepared by CVP contractors to meet the water conservation requirements. Criteria require contractors to identify BMPs for efficient water use and an implementation plan.

This measure would increase WUE above current and proposed practices identified in the water management plans. Districts and farmers would need to identify and invest in additional district-level or on-farm practices to improve irrigation efficiencies.

3.2 Agricultural Water Use Efficiency (Upstream from Delta)

Under this measure, districts or farmers could implement agricultural WUE practices and transfer water savings to the Buyer Service Area. Water savings would be transferrable only if it is considered irrecoverable. Irrecoverable losses include water that currently flows to a salt sink, the ocean, an inaccessible or degraded aquifer, or the atmosphere (CALFED 2000). If the water saving is recoverable, the water can be reused and is not a true savings. Water can only be transferred if there is a reduction in beneficial use; therefore, recoverable losses do not qualify for a transfer. Sellers must prove that the water savings is irrecoverable in order to sell the water for transfer. This measure would also include improvements to agricultural systems to increase recapture and reuse of irrigation water. This measure would increase WUE above the current practices, and for CVP contractors, above the current and proposed practices identified in the water management plans (see Section 3.1).

3.3 Conservation - Municipal and Industrial

Under this measure, agencies in the Buyer Service Area would implement municipal and industrial (M&I) conservation actions to reduce water demands above those that are ongoing or proposed. Santa Clara Valley Water District (WD), East Bay Municipal Utility District (MUD), and Contra Costa WD serve large urban areas in the San Francisco Bay Area and currently implement M&I conservation programs and include demand reduction measures in long-term planning documents:

- In its *2009 Water Use Efficiency Strategic Plan*, Santa Clara Valley WD set numeric targets for water conservation by year 2030 (Santa Clara Valley WD 2008). To achieve conservation targets, Santa Clara Valley WD launched several programs to encourage conservation in homes, businesses, and for landscaping, including a rebate program. Details can be found on the Water Conservation website (www.scvwd.dst.ca.us/programs/waterconservation.aspx).

- East Bay MUD summarized conservation efforts in the *East Bay Water 2010-A Status report on Local Water Use and Water Supplies* (East Bay MUD 2010). To meet the state-wide goal for a 20 percent reduction in water use by 2040, East Bay MUD has implemented the WaterSmart Center (East Bay MUD 2011a). The WaterSmart Center serves as a platform for residential and commercial rebates and programs focused on conservation.

- Contra Costa WD offers several programs for the water consumer to encourage water conservation practices, including rebates for water-smart appliances, lawn & landscaping schedules, and a home water survey. Water conservation program details can be found on the Contra Costa WD conservation website (www.ccwater.com/conserve).

These agencies have determined that they have a demand for transfers in addition to the actions that they are already undertaking related to conservation. For conservation to address potential shortages, it would need to be above the conservation efforts already planned by each agency.

3.4 Desalination

Desalination would create additional water supply through the treatment of seawater or brackish groundwater. Desalination would require water agencies to either construct a new facility or expand an existing facility. Buyers would use the desalinated water to make up for reduced deliveries of CVP water.

3.4.1 Desalination - Brackish

A brackish groundwater desalination facility would require new wells and a reverse osmosis treatment plant to pump and treat brackish groundwater from a basin within the Buyer Service Area. The treated water then would need to be conveyed to water users through new or existing distribution systems. The desalination facility would need to dispose of brine left over from the treatment process. Brine is typically discharged into the ocean; however, alternative inland brine disposal processes may be available such as evaporation ponds, deep well injection, or disposal to a salt sink.

3.4.2 Desalination - Seawater

Seawater desalination is fundamentally similar to brackish groundwater desalination but utilizes a coastal treatment plant that draws nearby seawater as the source. The Bay Area Regional Desalination Project (BARDP) is currently being developed by the Contra Costa WD, East Bay MUD, San Francisco Public Utilities Commission, and Santa Clara Valley WD. The BARDP evaluation selected three potential locations for desalination. The highest ranking plant would be co-located with the existing Mirant Power Plant near the confluence of the Sacramento River, New York Slough, and the San Joaquin River. A pilot study was conducted at Mallard Slough from October 2008 through April 2009, to evaluate potential treatment types for the BARDP. Results from the study indicated that desalination is feasible in the region and that site selection is an important part of the design process (MWH 2010). Three potential transfer buyers are participating in the BARDP.

3.5 Water Recycling and Reuse

Water recycling creates new water supply through either the treatment of wastewater for non-potable uses or by recharging groundwater aquifers with advanced treated wastewater for future extraction for potable uses (indirect potable reuse [IPR]). Both recycling and reuse options require a wastewater source, treatment, and distribution facilities.

3.5.1 Reclamation - Nonpotable Reuse

This measure would provide recycled water for irrigation, landscaping, or other suitable uses. A new or expanded existing tertiary treatment plant would be needed to treat wastewater. This measure would also require construction of pipelines to convey recycled water to new users. Most of the urban districts in the Buyer Service Area have existing wastewater treatment plants and use recycled water within their service area. Plans also exist to increase recycled water use. East Bay MUD developed the Water Supply Management Program 2040 long-term plan to meet future water supply needs, which includes the goal of increasing recycled water use to 11 million gallons per day (East Bay MUD 2011b). Santa Clara Valley WD works with wastewater authorities that operate four wastewater treatment plants in Santa Clara County. Santa Clara Valley WD also has plans to expand recycled water use in the coming years, including working with the City of San Jose to build an advanced water treatment facility that will produce up to ten million gallons per day (Santa Clara Valley WD 2011).

3.5.2 Reclamation - Indirect Potable Reuse

In an IPR project, wastewater that has undergone advanced treatment is stored in a groundwater basin for future potable use. This measure would require construction of an advanced wastewater treatment plant, groundwater recharge and extraction facilities, and a transmission system to connect the facilities. The term “indirect” implies that the highly-treated recycled water does not enter the potable distribution system directly. The treated wastewater would be injected into the groundwater basin through wells or placed in spreading basins to percolate into an aquifer. With adequate residence time, the treated water and groundwater would blend, undergo natural settling/treatment, and then be extracted for potable water supply. Extracted water quality must meet Regional Water Quality Control Board standards.

3.6 Cropland Idling Transfers

This measure involves idling cropland and transferring the irrigation water to the Buyer Service Area. Cropland idling water would be available on the same pattern throughout the growing season as it would have been consumed had a crop been planted. The quantity of water made available from cropland idling is determined based on the evapotranspiration of applied water (ETAW). ETAW is the portion of applied surface water that is utilized by the crop and evaporated from the soil and plant surfaces.

For this alternatives development process, cropland idling measures are separated into two categories based on type of crops eligible for transfers. The first crop idling measure includes rice, field crops, and grain crops, which have been idled in past transfer programs. The second crop idling measure includes pasture and alfalfa, which Reclamation has generally not allowed to participate in transfers in the past because of water accounting challenges.

3.6.1 Cropland Idling Transfers - Rice, Field Crops, and Grains

Table 3-1 shows ETAW values for rice, field, and grain crops that are eligible for idling. The ETAW value, less carriage water losses, would be transferred to the buyer. The irrigation season generally extends from April through September; surface water could be made available during the entire irrigation period. However, because of the regulated transfer period, water can only be moved through the Delta during July through September. Reclamation does not guarantee water prior to July can be stored in CVP reservoirs; therefore, the buyer may only receive a portion of the cropland idling transfer water (ETAW from July through September).

Table 3-1. Estimated ETAW Values (in AF/acre) For Various Crops Suitable for Idling

Crop	ETAW
Bean	1.5
Corn	1.8
Cotton	2.3
Melon	1.1
Milo	1.6
Onion	1.1
Pumpkin	1.1
Rice	3.3
Sudan Grass	3.0
Sugar Beets	2.5
Sunflower	1.4
Tomato	1.8
Vine Seed/ Cucurbits	1.1
Wild Rice	2.0

Source: DWR and Reclamation 2013

3.6.2 Cropland Idling Transfers - Pasture and Alfalfa

Alfalfa and pasture idling have been excluded from past transfer programs due to regional variation in ETAW values. Alfalfa is a perennial crop, and is typically grown for three to four years until yields decline. An alfalfa transfer program would require managers to follow typical harvest and growing practices in spring and early summer. Fields must then be completely disced by July 1 to prevent deep roots from using groundwater during summer months. Water that would have been used to irrigate in July through September would then be made available for transfer. Alfalfa has an ETAW of 1.7 AF/acre from July through September, but only alfalfa grown in the Sacramento Valley floor north of the American River would be allowed for transfers.

Pasture is also a multi-year crop, but the type and quality of pasture may vary significantly. This makes it difficult to assign a specific ETAW value for pasture idling. Like with alfalfa idling, pasture managers would irrigate through spring and early summer, disc fields by July 1, and then generate transfer water July through September. Pasture ETAW would need to be determined on a case-by-case basis.

3.7 Land Retirement in San Joaquin Valley

Land retirement in San Joaquin Valley involves permanently retiring lands from agricultural production and transferring the irrigation water to the buyer. Reclamation is implementing a land retirement program through the San Luis Unit Drainage Program, which retires land in drainage impaired areas of the San Joaquin Valley. The program aims to retire 194,000 acres of farmland (Reclamation 2006). This measure would retire land in addition to that proposed for the existing program.

3.8 Groundwater Substitution

This measure involves North of Delta sellers pumping groundwater for irrigation in lieu of using their surface water supply. Surface water would then be transferred to the buyer. Transfer water from groundwater substitution would be made available during the irrigation season from April through October. If Reclamation cannot store water prior to the transfer season, irrigators could use surface water from April through June and switch to groundwater in July when surface water can be transferred.

3.9 New Surface Storage

This measure includes building new surface storage facilities to store additional CVP water that could increase CVP deliveries to the Buyer Service Area and reduce potential shortages. Reclamation and DWR are partnering on five surface storage projects that were identified in the CALFED Record of Decision. One project (Los Vaqueros Reservoir Expansion) is already complete and fully utilized; therefore, it does not have available capacity to meet the purpose and need for this effort. The remaining project studies are in various phases of environmental review and feasibility study.

Shasta Lake Water Resources Investigation. This project proposes to raise Shasta Dam to increase water storage for agricultural, M&I, and environmental purposes and encourage Sacramento River salmon population growth. Reclamation has released a public draft EIS/EIR and feasibility report and is working to address comments and finalize these documents (Reclamation 2012).

North-of-the-Delta Offstream Storage. This project proposes to build Sites Reservoir, a new off-stream reservoir in Glenn County, to store additional CVP and SWP water supplies. Reclamation and DWR released a Preliminary Administrative Draft EIS/EIR and Preliminary Engineering Design Report in May 2014 (DWR 2014). The agencies are continuing work towards public draft documents.

In-Delta Storage Project. This project would construct new storage in the Delta region provided by two storage islands and two habitat islands. DWR and Reclamation completed the In-Delta Storage Program State Feasibility Study in 2004 and Draft Supplemental Feasibility Report in 2006. Further work on the In-Delta Storage Project has been suspended since July 2006 (DWR 2013).

Upper San Joaquin River Basin Storage Investigation. This project would construct new storage in the Upper San Joaquin River watershed to expand water storage capacity, increase reliability, and contribute to restoration efforts. Current efforts are focused on a new dam and reservoir between Friant and Kerckhoff dams (Reclamation 2014). Reclamation released a Draft Feasibility Report in February 2014 and is scheduled to complete a Draft EIS/EIR later in 2014 (Reclamation 2014).

3.10 Groundwater Storage

Groundwater storage could include construction of new groundwater storage facilities or becoming a banking partner with an existing groundwater bank. Groundwater banking is defined as the intentional storage of supplies in subsurface aquifers with the expectation of a subsequent retrieval for beneficial use by the depositor (Reclamation 2008). Groundwater storage would allow buyers to acquire and store water throughout the year and carry water over from a wet year to a subsequent dry year when they may experience shortages.

New groundwater storage includes the construction of new facilities to recharge and extract groundwater for use in Buyer Service Area. Groundwater storage requires the ability to recharge water into a groundwater basin and extract it later to return water to the banking partner. Buyers could also increase participation in existing groundwater banks, which would involve negotiating a lease agreement with an entity that operates a groundwater banking program. The agreement would require payment for use of recharge and extraction facilities, as well as charges for occupying or reserving the storage space.

3.11 Water Rights Purchase

A water rights purchase would involve the purchase of an appropriative water right from a private party for the permanent transfer of water to the buyer. The quantity and terms of the water right would become transferrable water. Water rights could either be purchased within the Buyer Service Area or upstream from the Delta. The water rights holder would cease use of the water, which could result in retired agricultural lands. A water rights purchase would require a legal contract and conveyance infrastructure to move water to the Buyer Service Area, if existing infrastructure or exchange agreement is not available. Few water rights purchases have occurred in the region.

3.12 Delta Conveyance

New Delta conveyance includes changes to the existing through Delta CVP and SWP conveyance system to improve water supply deliveries to south of Delta contractors. New conveyance facilities could address restrictions on Delta exports and help reduce associated shortages. The Bay Delta Conservation Plan (BDCP) is investigating potential options for Delta conveyance, including facilities that would divert water from the north Delta and move water it through tunnels to the south Delta. The Draft BDCP and associated Draft EIS/EIR are available for public review.

3.13 Crop Shifting in the Seller Service Area

Crop shifting is the practice of substituting a low water use crop for a high water use crop. The difference in water use from the shift would be available for transfer. Farmers generally rotate between several crops to maintain soil quality, and it may be difficult to predict what would have been planted absent a transfer. To calculate the amount of water made available from crop shifting, agencies would compare the change in consumptive water use (see ETAW values, Table 3.1) during the transfer year to the average water use during a five-year baseline period.

3.14 Rice Decomposition Water

Traditional management practices for rice straw decomposition require surface water diversions in the fall and winter months to flood harvested fields. Under this measure, farmers would use alternate methods to decompose rice straw, such as mechanical chopping and discing or bailing, and would transfer the water that would have been used for flooding to the buyer. About one AF per acre is used for flooding fields. Rice decomposition water is used in the fall and winter after the July-September transfer window. If a transfer occurs, water would need to be stored until the following July, which would put it at risk of spill. The consumptive use of rice decomposition available for transfer is not yet determined.

3.15 Reservoir Release

Reservoir release transfers involve the transfer of available water stored in existing non-CVP or -SWP reservoirs. Transferred water would be limited to the quantity that would not have otherwise been released downstream.

When the willing seller releases stored reservoir water for transfer, these reservoirs are drawn down to levels lower than without the water transfer. To refill the reservoir, a seller must prevent some flow from going downstream.

Sellers must refill the storage at a time when downstream users would not have otherwise captured the water, either in downstream Project reservoirs or with Project pumps in the Delta. Typically, refill can only occur during Delta excess conditions when there is more water than the Projects can pump. Additionally, if the non-Project reservoir has a Project reservoir downstream, refill must occur at a time when the Project reservoir cannot capture the water because of flood storage requirements in the reservoir.

3.16 Transfers within the Buyer Service Area

This measure would transfer water from water users within the Buyer Service Area. Transfer participants would shift CVP water supplies to meet irrigation demand or M&I requirements. Transfers occur frequently within the Buyer Service Area. Reclamation has developed EAs to facilitate implementation of in-basin transfers without additional environmental analysis. The first EA covered transfers from 2006 through 2010 for CVP contractors south of the Delta and in the Friant Division. Reclamation has completed two new EAs to continue in-basin transfers from 2011 through 2015:

- 2011-2015 Accelerated Water Transfers and Exchanges between South of Delta Contractors for Contract Years 2011to 2015 as outlined in 2010 EA (Reclamation 2010a).

- Accelerated Water Transfer Program for Friant Division and Cross Valley CVP Contractors from 2011to 2015 as outlined in 2010 EA (Reclamation 2010b).

Reclamation also worked with the Exchange Contractors, the CEQA lead agency, to complete an EIS/EIR to examine the environmental impacts of the transfer and exchange of the Exchange Contractors CVP water (up to 130,000 AF per year for the next ten years) within the SLDMWA service area from 2005 through 2014. Other EAs have been completed for individual, in-basin transfers.

This measure contemplates transfers above those that are already implemented under existing programs.

3.17 Groundwater Development

Under this measure, additional groundwater development would be used to offset CVP delivery reductions. Groundwater development would require the construction of new wells and pumps in the Buyer Service Area to increase groundwater production.

Much of the groundwater resources in the region are already managed through ongoing activities such as the Westlands Water District Groundwater Management Plan (Westlands Water District 1996) and the Santa Clara Valley WD Groundwater Management Plan (Santa Clara Valley WD 2013). Generally, in the Buyer Service Area, groundwater levels fluctuate over time. Monitoring shows substantial drawdown in drier years when more users turn to groundwater supplies because surface water supplies are limited (Westlands Water District 2012, DWR 2006, Santa Clara Valley WD 2013). This action would include groundwater extraction in addition to what is already occurring under existing conditions.

3.18 Modify CVP Contracts

This measure would change CVP contracts to limit water use in the buyer service area. CVP contract modifications would focus on reducing demands in the Buyer Service Area to reduce potential shortages in the future. Such reduction would likely result in land retirement and reduced agricultural production.

3.19 Change Cropping Patterns in San Joaquin Valley

This measure would encourage farmers to plant lower water use crops or increase fallowed land to reduce water demands in the Buyer Service Area. San Joaquin Valley farmers would alter cropping patterns to reduce water deliveries during shortage periods. Such changes would be in addition to those implemented annually by farmers who select crops in response to both water and market conditions. The number of acres now improved with permanent crops either limits cropping pattern change flexibility in the short term or must consider the economic effects of sacrificing investments in the permanent crops.

3.20 Limit Dairies in San Joaquin Valley

This measure would limit the number of dairies in the Buyer Service Area to decrease water demand. Dairy operations would need to relocate to areas outside of the Buyer Service Area. The land could not be used for a different purpose that would involve consumptive use of water to allow the action to produce water to help address shortages.

3.21 Enforce Seniority System to Manage Deliveries

This measure would enforce seniority systems to manage deliveries and water supply would be delivered based on seniority of water rights. CVP deliveries are based on a seniority system where settlement contractors receive waters first and M&I contractors typically receive a higher allocation than agricultural users when supplies are limited.

3.22 Implement Policy of No Net Increase in Water Availability for Urban or Agricultural Expansion

This measure proposes implementing a policy of no net increase in CVP water availability for urban or agricultural expansion. CVP water could not be used to support new urban development or increase the amount of irrigated land in production. This measure would limit CVP water use to existing urban and agricultural uses.

3.23 Pipe Water from Canada and Northern States

This measure would involve the purchase of water from Washington, Oregon, and Canada. A new water source would need to be identified and a purchase contract would need to be implemented that involves crossing state and/or Federal boundaries. Construction of new distribution facilities would be required to deliver purchased water to the Buyer Service Area.

3.24 Fix Owens Valley

The Owens Valley is a main water source for the City of Los Angeles. The city diverts most of the surface water in the valley into the Owens River–Los Angeles Aqueduct system. Additionally, ground water is pumped or flows from wells to supplement the surface-water diversions to the river–aqueduct system. Increased exports caused water levels in the valley to decline and resulted in substantial losses of native vegetation and habitat degradation. The Los Angeles Department of Water and Power is working with local agencies and stakeholders in Inyo County to restore vegetation and improve water management, including conjunctive use of groundwater and surface water supplies. Under this measure, the city would implement identified restoration programs to maintain water supplies from Owens Valley to serve city demands.

Chapter 4
Measures Screening Evaluation

4.1 Screening Evaluation

The screening process described in Chapter 2 was applied to all measures. As described in Section 2.3, the Lead Agencies developed three criteria to address the purpose and need statement and basic project objectives:

- Immediate: the term proposed for this EIS/EIR is 2015 through 2024. This period is relatively short, and measures need to be able to provide some measurable benefit within this time period.

- Flexible: project participants need water in some years, but not in others. They need measures that have the flexibility to be used only when needed.

- Provide Substantial Water: project participants need measures that have the capability of providing additional water to regions that are experiencing shortages.

If a measure did not meet a criterion, it was considered a fatal flaw and screened out from further consideration. Measures that met all purpose and need criteria move forward to the alternatives formulation phase. The following sections present the evaluation of each measure relative to the above screening criteria. Chapter 3 defines each measure.

4.1.1 Agricultural Water Use Efficiency (Buyer Service Area)

Immediate: no
Flexible: yes
Provide Substantial Water: no

As described in Section 3.2, CVP contractors currently implement WUE BMPs, as required by CVPIA Section 3405(e). Reclamation also supports WUE through the WaterSMART program. This measure proposes additional WUE to existing and proposed plans. As part of the existing plans, CVP contractors have already implemented (or are currently implementing) WUE measures. Additional measures would generally require substantial infrastructure and investment and would not be immediately implementable. Flexibility depends on how the measures are implemented; WUE could be flexible, but the flexibility decreases when the measures are implemented for permanent crops.

The purpose and need for water transfers is to provide additional water to reduce shortages. Buyers are taking actions to address shortages, such as WUE measures, within the No Action/No Project, and these measures would help users accommodate shortages but would not provide any additional supply. Implementing agricultural WUE in the Buyer Service Area would not provide water to users with existing demands affected by CVP shortages.

4.1.2 Agricultural Water Use Efficiency (Upstream from Delta)

Immediate: yes
Flexible: yes
Provide Substantial Water: yes

This measure would be both immediate and flexible upstream from the Delta for measures such as weed control. Agricultural WUE practices can be implemented relatively quickly. Sellers would need to prove that water saved is irrecoverable and reduces a beneficial use. Water could then be sold to buyers. Buyers could call on the transfer annually as needed. Transfer water would provide water to existing demands in the Buyer Service Area to reduce potential shortages.

4.1.3 Conservation – M&I

Immediate: yes
Flexible: yes
Provide Substantial Water: no

Buyers serving urban demands currently implement M&I conservation measures and have incorporated additional measures in long-range plans to meet conservation goals. Measures could generally be implemented within the project timeframe. Conservation could occur year round and implemented in any year. Similar to agricultural WUE, implementing additional M&I conservation in the Buyer Service Area would not provide water to meet existing demands affected by CVP shortages. Additionally, implementing conservation measures in addition to existing planned measures would be challenging because M&I conservation goals are very high under existing conditions.

4.1.4 Desalination – Brackish

Immediate: no
Flexible: yes
Provide Substantial Water: yes

This measure would not be immediate to provide water to reduce shortages from 2015 to 2024. Planning, pilot testing, design, permitting, and construction of a brackish water desalination plant and distribution system take many years. Brackish water desalination would be flexible if the basin is influenced by seawater and water is available year-round for extraction and treatment. This measure could provide enough water to reduce CVP shortages.

4.1.5 Desalination - Seawater

Immediate: no
Flexible: yes
Provide Substantial Water: yes

Planning, pilot testing, design, permitting, and construction of an ocean water desalination plant and distribution system takes many years. The BARDP is still in the planning process. Therefore, operation of ocean water desalination plant would not occur in time to provide substantial benefits during the 2015 to 2024 timeframe. Ocean water desalination would be flexible as water is available year round and could provide enough water to reduce CVP shortages.

4.1.6 Reclamation - Nonpotable Reuse

Immediate: no
Flexible: yes
Provide Substantial Water: yes

Non-potable reuse requires identifying a wastewater source, planning, design, and construction of a wastewater treatment plant, and conveyance to agricultural distribution systems. This measure would not be implemented to provide benefits during the entire 2015 to 2024 timeframe. This measure would be flexible because recycled water would be available year round. Assuming an adequate wastewater source can be identified, this measure would provide water to reduce shortages.

4.1.7 Reclamation - Indirect Potable Reuse

Immediate: no
Flexible: yes
Provide Substantial Water: yes

An IPR project would provide a new potable water source. IPR projects require feasibility studies, pilot studies, design, construction and often a lengthy public education and outreach program. An IPR project would not be implemented in time to provide benefits during the entire 2015 to 2024 timeframe. Water provided by an IPR project would be flexible because it would be pumped from the groundwater basin as needed. Assuming an adequate wastewater source can be identified, this measure would provide water to reduce shortages.

4.1.8 Cropland Idling Transfers - Rice, Field, Grain Crops

Immediate: yes
Flexible: yes
Provide Substantial Water: yes

Cropland idling transfers can occur immediately in that farmers can choose to idle land generally up to the time of planting. Water would be transferred the starting in July of the same year. Cropland idling transfers are also flexible because buyers can use rainfall in the winter months to help predict CVP water needs for the irrigation season. If the transfer water is no longer needed or export capacity appears to be restrictive, buyers could opt out of the transfer without a very large investment. Multi-year contracts would likely include an option fee, but it would not be as large as if infrastructure were developed and no longer needed. Cropland idling can also provide a substantial amount of water for transfer. The Sacramento Valley has extensive irrigated crop acreage and past transfers actions have shown that farmers are willing to idle land and sell irrigation water.

4.1.9 Cropland Idling Transfers - Pasture and Alfalfa

Immediate: yes
Flexible: yes
Provide Substantial Water: yes

Similar to cropland idling for rice, field, and grain crops, pasture and alfalfa idling would also be immediate, flexible and provide water to reduce CVP shortages. Some areas of alfalfa, including the Delta Region and the Sacramento River area south of the American River confluence, would not be allowed for idling because groundwater levels in these regions are relatively high and fields intended for idling may consume groundwater. In these instances, alfalfa idling would not result in a reduction of consumptive use. Because of water accounting issues, Reclamation must evaluate alfalfa idling transfers on an individual basis.

Pasture idling would have less certainty than alfalfa, and would be difficult to verify that consumptive use has been reduced to make water available for transfer. For this reason, pasture transfers are screened out.

4.1.10 Land Retirement in the San Joaquin Valley

Immediate: no
Flexible: no
Provide Substantial Water: no

Under the San Luis Drainage Feature Re-evaluation, Reclamation is working to retire 194,000 acres of drainage impaired farmland. Irrigation water for retired lands will be distributed to other lands in the San Luis Unit. This measure proposes to retire additional land above the 194,000 acres. Identifying and negotiating land retirement agreements with willing landowners would take several years to implement. This measure is not flexible because land would go out of irrigated agricultural production permanently. Further, land retirement does not provide additional water to address basin-wide CVP shortages, but rather provides a way for users to address shortages in the No Action/No Project Alternative.

4.1.11 Groundwater Substitution

Immediate: yes
Flexible: yes
Provide Substantial Water: yes

Under this measure, sellers in the Upstream from Delta Region would use groundwater in lieu of surface water supplies. Surface water would be transferred to the Buyer Service Area. Groundwater substitution transfers would be both immediate and flexible. Farmers can turn on and off groundwater pumps and switch between surface and groundwater supplies at any time. Similar to cropland idling transfers, buyers can negotiate groundwater substitution transfers in the year of the transfer and have flexibility to opt of out the transfer if water is not needed. Groundwater basins in the Upstream from Delta Region can provide substantial amounts of water for local irrigators and allow for CVP water to be transferred to the Buyer Service Area to reduce potential shortages.

4.1.12 New Surface Storage

Immediate: no
Flexible: yes
Provide Substantial Water: yes

Reclamation is investigating new storage opportunities that could increase CVP deliveries. The studies are in the planning phases and projects would not likely be implemented to provide benefits from 2015 through 2024. Once implemented, storage projects would provide water and be flexible.

4.1.13 Groundwater Storage

Immediate: yes
Flexible: yes
Provide Substantial Water: no

This measure would be implemented in the Buyer Service Area. Developing new groundwater storage would require construction of recharge, extraction, and conveyance facilities and could not occur immediately. Participation in existing banks, however, could move forward immediately with existing facilities. Once fully implemented, the measure could be flexible because farmers can pump groundwater for irrigation when needed. The success of groundwater storage, however, depends on having an available source of water to recharge and withdraw later during shortages. Agencies in the Buyer Service Area face water shortages in most years and would not have additional water available for recharge. Without an adequate source of recharge water, this measure would not provide sufficient water to reduce CVP shortages.

4.1.14 Water Rights Purchase

Immediate: no
Flexible: yes
Provide Substantial Water: no

This measure would require identifying and negotiating water right purchases with interested sellers. Few water rights sales have occurred in past years. It may take several years to identify sellers and provide enough water to provide benefits to CVP contractors and undertake the legal process to purchase the water right. Therefore, this measure would not be immediate or provide water.

4.1.15 Delta Conveyance

Immediate: no
Flexible: yes
Provide Substantial Water: yes

Reclamation is studying Delta conveyance measures through the BDCP process. The BDCP is in the early stages of the planning process. It is not likely that a measure would provide be implemented during the 2015 though 2024 timeframe. New Delta conveyance would be flexible and provide water to south of Delta contractors because it would not have the same pumping restrictions that currently exist at Jones and Banks pumping plants.

4.1.16 Crop Shifting in Seller Service Area

Immediate: yes
Flexible: yes
Provide Substantial Water: yes

Similar to cropland idling, crop shifting would also be immediate and flexible. Crop shifting would generally provide less water than a crop idling transfer on a per acre basis; however, because of the extensive irrigated acreage and crop variability in the Sacramento Valley, crop shifting transfer could potentially provide a substantial amount of water to reduce CVP shortages.

4.1.17 Rice Decomposition Water

Immediate: yes
Flexible: yes
Provide Substantial Water: no

Rice water decomposition transfers would be immediate and flexible. Buyers can negotiate with sellers on an annual basis prior to fall flooding. The transfers would be flexible because buyers could opt out if transfer water is not needed. The Sacramento Valley has extensive rice acreage that is flooded during the fall. The schedule of when this water is available, however, means that it cannot provide substantial water when it is needed. Water would be available in the fall after the irrigation season in which it is needed.

4.1.18 Reservoir Release

Immediate: yes
Flexible: yes
Provide Substantial Water: yes

Some agencies in the Upstream from Delta Region have local (non-CVP) reservoirs that could provide water for transfer. Under this measure, sellers would release water stored in local reservoirs for transfer through the Delta to the Buyer Service Area. Water eligible for transfer would not have otherwise been released downstream. Reservoir release transfers are both immediate and flexible. Water would be released from an existing reservoir and conveyed using existing infrastructure. Buyers would have the option of calling on transfers annually prior to the irrigation season and can opt out if needed. This measure could provide water to reduce potential CVP shortages.

4.1.19 Transfers within Buyer Service Area

Immediate: yes
Flexible: yes
Provide Substantial Water: no

Buyers currently transfer water within the basin to help reduce the effects of CVP delivery reductions. Additional transfers could be immediate and flexible to assist water users in selecting where limited water will be applied but would not provide substantial water to reduce CVP shortages. Even after in-basin transfers occur, CVP contractors continue to face shortages.

4.1.20 Groundwater Development

Immediate: no
Flexible: yes
Provide Substantial Water: no

This measure would be implemented in the Buyer Service Area. Groundwater development would require planning, locating, and installing new wells and conveyance to on-farm systems. Planning and construction of the new system would not likely be developed prior to 2015. Once installed, groundwater use is flexible because farmers can turn pumps on or off as needed. New groundwater development in the Buyer Service Area would not provide a substantial supply to water users to reduce CVP shortages. In response to the previous dry years and reduced CVP water supplies, users have pumped additional groundwater for irrigation. As a result, groundwater levels have reduced and typically do not recover without additional recharge. Therefore, new groundwater development would not provide enough water annually to reduce CVP shortages.

4.1.21 Modify CVP Contracts

Immediate: no
Flexible: no
Provide Substantial Water: no

Reclamation has long-term contracts with CVP contractors and cannot modify contracts to reduce contract water supplies. This measure would not provide any water or flexibility to CVP contractors to meet a potential shortage.

4.1.22 Change Cropping Patterns in San Joaquin Valley

Immediate: yes
Flexible: yes
Provide Substantial Water: no

Changing cropping patterns would not reduce potential CVP shortages. Farmers commonly change cropping patterns as normal farm practices and to respond to reduced water supplies or market prices. In the San Joaquin Valley, many farmers have planted lower water use crops to reduce irrigation needs during a particular year. At the same time, in order to support their investments in WUE equipment and higher priced supplemental supplies, many farmers have now planted permanent crops that create the same demand in all years. This measure would not provide enough benefits to farmers experiencing shortages.

4.1.23 Limit Dairies in San Joaquin Valley

Immediate: no
Flexible: yes
Provide Substantial Water: no

This measure would limit new dairies in the Buyer Service Area. There are not many existing dairies in the Buyer Service Area. In addition, Reclamation would need to work with counties or cities to enforce relocation or a policy to restrict new farms. Furthermore, to the extent such farms have an allocation of irrigation water, removing those uses would not necessarily change the need for water to irrigate the same acres. This measure would not provide much, if any, water to alleviate shortages.

4.1.24 Enforce Seniority System to Manage Deliveries

Immediate: no
Flexible: no
Provide Substantial Water: no

Modifying deliveries would need to occur after long-term contracts have expired. Under current contracts, CVP contractors do receive water based on seniority. Settlement and exchange contractors receive water before other CVP contractors. Regardless of seniority, modifying contracts would not provide any additional water. CVP contractors in the Buyer Service Area would continue to face shortage in dry years and due to regulatory restrictions.

4.1.25 Implement Policy of No Net Increase in Water Availability for Agricultural and Urban Expansion

Immediate: no
Flexible: no
Provide Substantial Water: no

This measure would not be immediate or flexible. Agricultural land in the San Joaquin Valley is considered to be fully developed; therefore, a no net increase policy would not be effective for agricultural water supplies. Buyers have also stated they plan to use water for existing demands and transfers would not be used to meet new demands. This measure would also not provide any water to CVP contractors to meet existing demands during a shortage.

4.1.26 Pipe Water from Canada and Northern States

Immediate: no
Flexible: yes
Provide Substantial Water: yes

This measure requires purchasing a water source from Canada or northern states, including Oregon, Washington, or Idaho, and transporting the water to the Buyer Service Area. Infrastructure would be required to move water. This measure would take years to negotiate and implement and would not provide benefits during the 2015 to 2024 timeframe. This measure would be flexible if the water can be called on when needed. This measure would provide water to reduce CVP shortages in the Buyer Service Area.

4.1.27 Fix Owens Valley

Immediate: no
Flexible: no
Provide Substantial Water: no

CVP contractors do not receive water from Owens Valley; therefore, this measure would not be flexible or provide water to reduce CVP shortages.

4.2 Screening Results

Table 4-1 summarizes the screening evaluation results. An “x” indicates that the measure met the criterion. A “-” indicates the criterion was not met and the measure was screened out for further analysis.

Table 4-1. Screening Evaluation Results

Transfer Measures	Purpose and Need Criteria		
	Immediate	Flexible	Provides water
Agricultural water use efficiency (Buyer Service Area)	-	X	-
Agricultural water use efficiency (Upstream from Delta)	X	X	X
Conservation – municipal & industrial	X	X	-
Desalination - brackish	-	X	X

4.3 Measures Carried Forward to Alternatives Formulation

The following measures met all purpose and need criteria and will be combined into alternatives to be analyzed in the EIS/EIR:

- Agricultural WUE (Upstream from Delta)
- Cropland Idling Transfers - rice, field crops, grains
- Cropland Idling Transfers - alfalfa
- Groundwater Substitution
- Crop Shifting
- Reservoir Release

This page left blank intentionally.

Chapter 5 Alternatives

This chapter presents alternatives developed based on the evaluation described in Chapter 4. Alternatives for the EIS/EIR include different combinations of potential measures and a No Action/No Project Alternative. Transfers would only be implemented through agreements between willing sellers and buyers. The alternatives propose a menu of measures that buyers and sellers can select from to implement a transfer. Some measures in an alternative may not be implemented if there are no willing sellers or buyers interested in that particular measure. The next steps in alternative development will identify willing sellers, proposed transfer measures, and potential quantities for transfer. The Lead Agencies have identified preliminary sellers and transfer quantities for each alternative.

Reclamation's role would be to facilitate transfers that comply with Federal and state law and would not include negotiating transfer measures among buyers and sellers. SLDMWA, on behalf of its member agencies, and other interested buyers would negotiate transfers with willing sellers, including agreeing upon transfer measures and quantities included in the proposed alternatives.

5.1 Alternative 1 – No Action/No Project

CEQA requires an EIR to include a No Project Alternative. CEQA Guidelines Section 15126.6(e)(2) states that "the "no project" analysis shall discuss the existing conditions at the time the notice of preparation is published, or if no notice of preparation is published, at the time environmental analysis is commenced, as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services." NEPA requires an EIS to "include the alternative of no action" (40 CFR Part 1502.14(d)).

The No Action/No Project Alternative represents the state of the environment without the Proposed Action or any of the alternatives. Under the No Action/No Project Alternative, some agricultural and urban water users may face potential shortages in the absence of water transfers. To the extent transfer water is not available; there will be demand will go unmet by surface water. Demand may be met by increasing groundwater pumping, idling cropland, reducing landscape irrigation, or rationing water.

5.2 Alternative 2 – Full Range of Transfers

This alternative combines all potential transfer measures that met the purpose and need and were carried forward through the screening process, as identified in Chapter 4. Measures in the Full Range of Transfers Alternative include:

- Agricultural WUE (Upstream from Delta Region)
- Cropland idling transfers – rice, field, grains
- Cropland idling transfers – alfalfa
- Groundwater substitution
- Crop shifting
- Reservoir release

Table 5-1 identifies preliminary sellers and transfers under this alternative. The quantities represent the upper limit for transfer. Because of the uncertainty of hydrologic and operating conditions in the future, it is likely that only a portion of the potential transfers identified in Table 5-1 would occur. Additionally, many agencies are uncertain about whether they would participate through groundwater substitution or cropland idling/crop shifting transfers. They have included their potential upper limit for both types of transfers, but they would not sell the maximum amount of both types in the same year. Entities requiring Reclamation approval that are not listed in this table may decide that they are interested in selling water, but those transfers may require supplemental NEPA and Endangered Species Act analysis to allow Reclamation to complete the evaluation of the transfers. This alternative would be the least restrictive for buyers and sellers and provides the most potential water by offering the whole range of transfer measures. No sellers for rice water decomposition transfers have been identified at this time, but could potentially occur in the future under this alternative.

Table 5-1. Alternative 2 Potential Sellers (Upper Limits)

Total[1]	124,171	61,369	0	0	166,324	115,993	97,000	3,100

Note:

[1] These totals cannot be added together. Agencies could make water available through groundwater substitution, cropland idling, or a combination of the two; however, they will not make the full quantity available through both methods. Table 5-1 reflects the total upper limit for each agency.

5.3 Alternative 3 – No Cropland Modifications

The No Cropland Modifications Alternative includes the following measures:

- Agricultural WUE (Upstream from Delta Region)
- Reservoir release
- Groundwater substitution

The Lead Agencies developed this alternative because buyers are not certain they are interested in cropland idling and crop shifting transfers due to operational restrictions. Buyers would need to purchase the entire ETAW for a cropland idling or shifting transfer; however, they may only receive the portion of ETAW during the July through September transfer period.

Table 5-2 identifies preliminary sellers and transfers under Alternative 3. Similar to Table 5-1, the quantities in Table 5-2 are maximum amounts and would not likely be transferred each year. Alternative 3 includes less water to be transferred than Alternative 2.

5.4 Alternative 4 – No Groundwater Substitution

The No Groundwater Substitution Alternative includes the following measures:

- Agricultural WUE (Upstream from Delta Region)
- Cropland idling transfers– rice, field and grains
- Cropland idling transfers– alfalfa
- Crop shifting
- Reservoir release

Public comment received during the scoping period included many concerns regarding groundwater impacts associated with groundwater substitution transfers. The Lead Agencies have developed this alternative to address these comments and create an alternative that could reduce potential environmental effects of the Proposed Action. Table 5-3 identifies preliminary sellers and transfers under Alternative 3. The quantities in Table 5-3 are maximum amounts and would not likely be transferred each year. This alternative has the smallest quantity of water transferred.

Appendix B

Water Operations Assessment

This page left blank intentionally.

Appendix B
Water Operations Assessment

B.1 Background

Hydrologic conditions, climatic variability, and regulatory requirements for operation of water projects commonly affect water supply availability in California. This variability strains water supplies, making advance planning for water shortages necessary and routine. In the past decades, water entities have been implementing water transfers to supplement available water supplies to serve existing demands and transfers have become a common tool in water resource planning.

The U.S. Department of the Interior, Bureau of Reclamation (Reclamation) manages the Central Valley Project (CVP), which includes storage in reservoirs (such as Shasta, Folsom, and Trinity reservoirs) and diversion pumps in the Sacramento-San Joaquin Delta (Delta) to deliver water to users in the San Joaquin Valley and San Francisco Bay area. When these users experience water shortages, they may look to water transfers to help reduce potential impacts of those shortages.

A water transfer involves an agreement between a willing seller and a willing buyer. To make water available for transfer, the willing seller must take an action to reduce the consumptive use of water or reduce reservoir storage. This water would be conveyed to the buyers' service area for beneficial use. Water transfers would only be used to help meet existing demands and would not serve any new demands in the buyers' service areas.

Reclamation and the San Luis & Delta-Mendota Water Authority (SLDMWA) are completing a joint Environmental Impact Statement/Environmental Impact Report (EIS/EIR), in compliance with the National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA), for water transfers from 2015 through 2024. Reclamation is serving as the Lead Agency under NEPA and SLDWMA is the Lead Agency under CEQA. Reclamation would facilitate transfers proposed by buyers and sellers. The SLDMWA, consisting of federal and exchange water service contractors in western San Joaquin Valley, San Benito, Santa Clara, and Stanislaus counties, helps negotiate transfers in years when the member agencies could experience shortages.

This EIS/EIR evaluates water transfers that originate from entities located upstream of the Delta. Purchasing agencies are in areas south of the Delta or in the San Francisco Bay Area. Water transfers are subject to federal and state law.

The transfers included in this EIS/EIR are only those involving CVP supplies or CVP facilities. These transfers require approval from Reclamation, which necessitates compliance with NEPA. Other transfers not involving CVP supplies or use of CVP facilities could occur during the same time period, subject to their own environmental review (as necessary). Non-CVP transfers are analyzed in combination with the potential alternatives in the cumulative analysis.

B.2 Purpose of Water Operations Analysis

An analysis of water operations is necessary to assist in evaluation of potential environmental impacts associated with the Long-Term Water Transfer Project (the Project). Water transfers have the potential to affect both the natural system and operation of the CVP and State Water Project (SWP). The purpose of this analysis is to simulate water made available by various sellers included in the Project, how that water moves through the system and potentially effects operations, and how and where transfer water is diverted by buyers. Output from the water operations analysis for parameters such as stream flow, reservoir storage, Delta outflow, and CVP and SWP Delta exports provides a basis for environmental assessment.

B.3 Analytical Approach

Water transfer analysis is performed with several analytical tools. Separate tools are used to evaluate the surface water and groundwater systems with information and results passed between the tools. Analysis relies on the use and interaction of three different models: CalSim II, the Sacramento Valley Finite Element Groundwater Model (SACFEM2013), and Transfer Operations Model (TOM). Model results of a baseline condition, the No Action/No Project Alternative, without proposed water transfers are compared to model results with proposed water transfers under each Project alternative to determine the extent and significance of any differences resulting from the Project.

CalSim II serves as the basis for simulating the surface water system. A baseline model of CVP/SWP operations for the Sacramento and San Joaquin river systems and the Delta was developed and provided by Reclamation. This model baseline represented the best available model assumptions developed by Reclamation as of January 2014.

Estimated groundwater pumping associated with groundwater substitution transfers was added to baseline groundwater pumping under existing conditions and input to SACFEM2013 to simulate the effects of groundwater substitution transfers on Sacramento Valley aquifers. SACFEM2013 also simulates interaction between groundwater and surface water systems at the streambed interface. Groundwater pumping can affect the surface water system because a hydraulic connection exists between the groundwater and surface water systems in the Sacramento Valley. SACFEM2013 was used to simulate effects on the groundwater system and the change in stream-aquifer interaction. SACFEM2013 model results for the change in stream-aquifer interaction were incorporated into the water operations analysis.

A separate model, TOM, was developed to simulate changes in the surface water system. TOM is a spreadsheet model developed by MBK Engineers to assess how water made available for transfer moves through the river system and is diverted by buyers. Additionally, TOM analyzes how changes in stream-aquifer interaction due to groundwater substitution transfers affect the CVP and SWP. TOM was developed to quickly and effectively assess changes from a variety of transfer sources and mechanisms to a variety of different buyers.

TOM relies on the CalSim II baseline simulation of CVP and SWP operations and then layers on operational changes of water transfers. Post-processing CalSim II results allows for simulation of specific water transfers and their associated constraints while maintaining compliance with the regulatory requirements simulated in CalSim II. TOM uses output from both CalSim II and SACFEM2013 to simulate the operational changes that result from water transfers.

Figure B-1 illustrates the models, input information, and output flow used to in the water operations analysis.

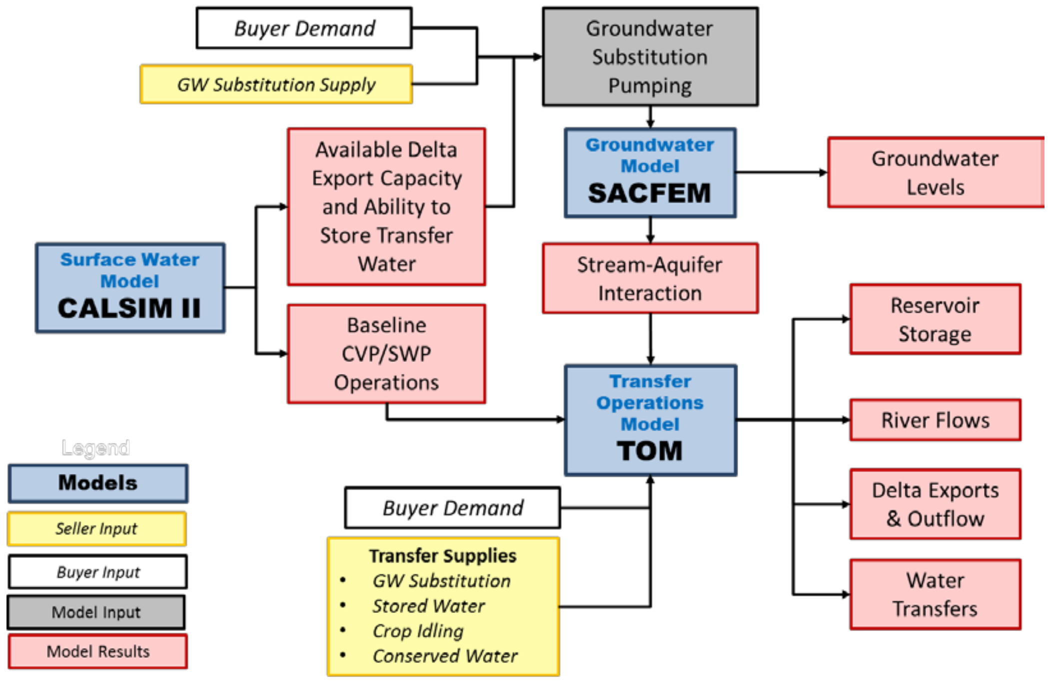

Figure B-1. Analytical Process and Modeling

B.4 Model Descriptions

A description of models used in water operations analysis, primarily CalSim II and TOM, and their underlying assumptions are outlined in more detail in the following sections. A brief description of SACFEM2013 is also provided. Additional documentation and results from SACFEM2013 are presented in Appendix D.

B.4.1 CalSim II

CalSim II is a planning model designed to simulate operations of CVP and SWP reservoirs and water delivery systems. CalSim II simulates flood control operating criteria, water delivery policies, in-stream flow requirements, Delta outflow requirements, and CVP/SWP (Project) Delta export operations. CalSim II is the best available tool for modeling CVP and SWP operations and is the primary system-wide hydrologic model used by Reclamation and the California Department of Water Resources (DWR) to conduct planning and impact analyses of potential projects.

CalSim II is a simulation by optimization model. CalSim II simulates operations by solving a mixed-integer linear program to maximize an objective function for each month of the simulation. CalSim II was developed to simulate operation of the CVP and SWP for defined physical conditions and a set of regulatory requirements. CalSim II simulates these conditions using 82 years of historical hydrology from water year 1922 through 2003.

CalSim II modeling conducted for the Long Term Water Transfer Project is built upon the Common Assumption model package, developed jointly by Reclamation and DWR. This model package has been revised and updated to reflect the operational requirements contained in the U.S. Fish and Wildlife Service (USFWS) 2008 Biological Opinion (BO) on delta smelt and the National Oceanic and Atmospheric Administration Fisheries Service (NOAA Fisheries) 2009 BO on Chinook salmon. Regulatory requirements included in baseline CalSim II simulation, including those specified in the BOs, are summarized in Attachment 1.

Reclamation provided the project team the CalSim II baseline studies in January 2014. The Reclamation study was at a projected future level of development and was consistent with Reclamation's operating assumptions at that time. The project team worked collaboratively with Reclamation modelers to revise the baseline study for an existing level of development, requirements, and projects. This existing level study is used as the baseline and the basis for TOM.

B.4.2 SACFEM2013

SACFEM2013 is a full water budget based, transient groundwater flow model that incorporates all groundwater and surface water budget components on a monthly time-step over the period of simulation. SACFEM2013 provides very high resolution estimates of groundwater levels and stream flow effects due to groundwater pumping within the Sacramento Valley. SACFEM2013 is an application of the MicroFEM© groundwater modeling package. SACFEM2013 simulates a 41-year period, corresponding to historical hydrology from water year 1970 through 2010, on a monthly time-step. Additional information and description of SACFEM2013 can be found in Appendix D.

B.4.3 TOM

TOM was developed to analyze effects of the Long-Term Water Transfer Project on the CVP, SWP, major rivers, and the Delta. TOM was developed to quickly and effectively simulate water made available from various sellers as it moves through the system, the effects on CVP and SWP operations, and diversion of transfer water by buyers. TOM simulates operations on a monthly time-step for the 34-year period, water year 1970 through 2003, common to both CalSim II and SACFEM2013. TOM relies on output from both SACFEM2013 and CalSim II.

Facilitating water transfers in actual operations presents numerous challenges. In real-time operations, transfer water cannot be tracked separately as it moves through the system in the same way it can be tracked and accounted for in a model. Water made available for transfer is released into the system, or not diverted from the system, and managed as part of the total available water within the system at any given time. This requires an increased level of coordination between CVP and SWP operators. When facilitating actual water transfers, CVP and SWP operators identify the volume of transfer water to be made available in advance of the actual transfer. This volume of water is considered when determining operations before, during, and after the transfer period. Transfer water becomes co-mingled with CVP/SWP water and unregulated flows in the system and re-diverted at downstream locations such as CVP and SWP pumping facilities in the south Delta. Transfer water affects accounting under the Coordinated Operation Agreement (COA) between the CVP and SWP, and can require COA accounting adjustments. Transfer water can also change the timing of when CVP and SWP Project water is moved. A portion of transfer water is typically used as carriage water to maintain Delta water quality when transfer water is moved through the Delta. This requires initial estimates for carriage water that must later be verified and adjusted. All the additional accounting and adjustments for transfers are layered onto the already complex task of operating the CVP and SWP for numerous in-stream flow, water temperature, water quality, and water supply constraints.

TOM was developed in consultation with Reclamation and with an understanding of both actual operations and CalSim II model assumptions. Rules used in TOM to simulate operational responses to water transfers and changes in stream-aquifer interaction were reviewed with CVP operations staff. Assumptions and logic used in TOM are described in the following sections.

B.4.3.1 TOM Operations and Assumptions

TOM begins with a baseline CalSim II simulation of the CVP/SWP system and Delta operations, and then layers on water transfer operations. TOM uses information on the timing and volume of transfer water to be made available from various transfer sources as input and simulates the effects of those transfers.

B.4.3.1.1 Buyer Demands and Seller Supplies

The Project team developed estimates of both buyer’s demand for transfer water and seller’s supplies of transfer water. CVP contractors identified as buyers include East Bay Municipal Utility District (MUD), Contra Costa Water District (WD), and the SLDMWA. Annual transfer demands for East Bay MUD were provided directly by the agency. The volume of annual transfer demand for Contra Costa WD was provided the district and the years when demand for transfer water were identified and discussed with the district.

SLDMWA demand for transfer water often exceeds the available capacity to move the water through the Delta. Therefore, an estimate of annual available Delta export capacity was developed from baseline CalSim II output. Available Delta export capacity was used as a surrogate for SLDMWA demand for transfer water from Sacramento Valley sellers. Additionally, water made available by Merced Irrigation District (ID) can be moved to SLDMWA through a variety of facilities that connect the lower San Joaquin River with the Delta-Mendota Canal (DMC) without going through CVP or SWP Delta export facilities. Therefore, additional demands were assumed for SLDMWA in years when CVP south-of-Delta agricultural water service contract allocations were less than 65 percent. In these years, SLDMWA demand for transfer water exceeded Merced ID's available transfer supply and was assumed to be all of the available supply.

Figure B-2 illustrates the annual demands simulated in TOM for each potential buyer with demands for SLDMWA limited by available Delta export capacity and available supply.

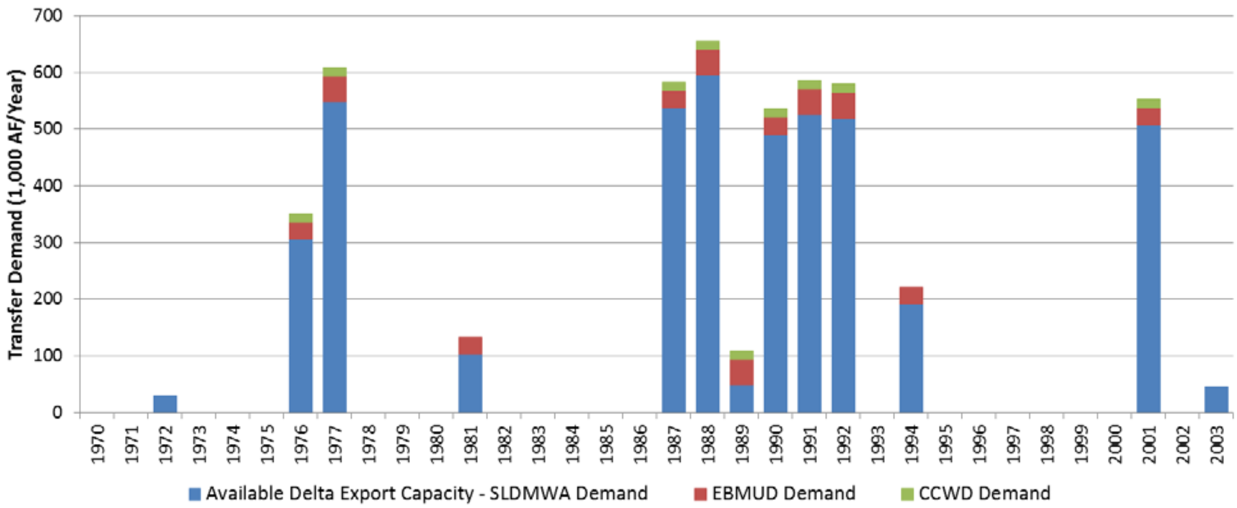

Figure B-2. Annual Demand for Transfer Water by CVP Buyers

The Project team also developed estimates of water supplies that can be made available for transfer from willing sellers interested in participating in the Project. Estimates of available supply were developed in consultation with potential sellers. Sellers include CVP contractors and non-CVP contractors with the ability to provide water to the buyer's points of diversion. Sellers can make water available through several different transfer mechanisms including groundwater substitution, crop idling, conserved water, and reservoir release. Available water transfer supply is typically less than demand for transfer water, and can be less than the available capacity to move the water from seller to buyer. Therefore, the volume of water transferred on an annual basis is typically limited by available water transfer supply. Different alternatives were developed to analyze effects of making transfer water available with different mechanisms. Figure B-3 illustrates annual available supplies for the alternative that includes all transfer mechanisms.

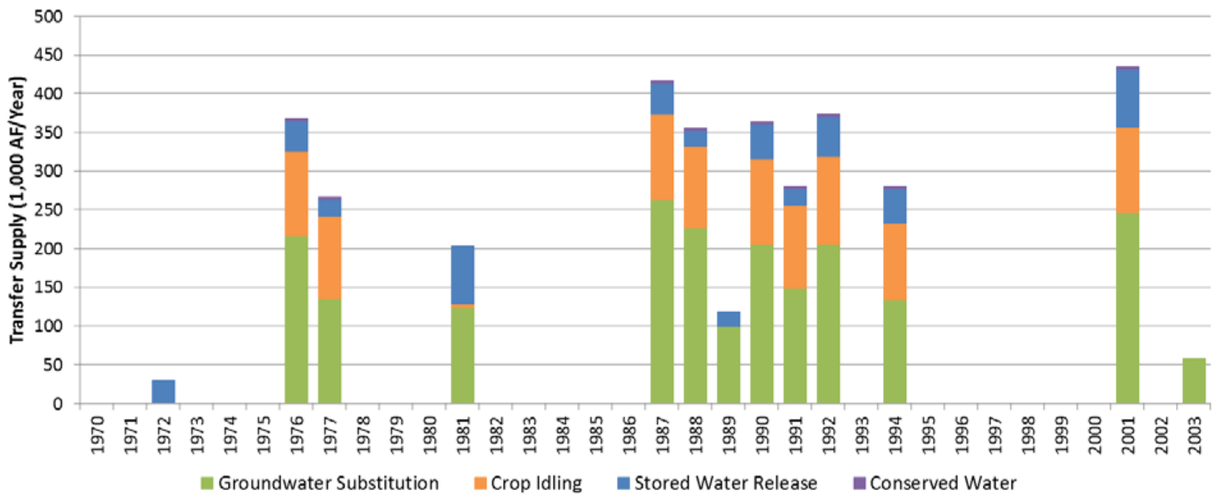

Figure B-3. Annual Available Water Transfer Supply

Comparison of Figure B-2 and Figure B-3 shows demand for transfer water frequently exceeds the available water transfer supply.

B.4.3.1.2 Transfer Operations and Priorities

TOM uses an assumed priority for transfer mechanisms used to make water available under Project alternatives. Transfer mechanisms are prioritized based on the likelihood of the mechanism being utilized and the operational flexibility inherent in the mechanism. For example, groundwater substitution and reservoir release are more likely transfer mechanisms than crop idling and are therefore a higher priority. Groundwater substitution has less operational flexibility than reservoir releases and is given a higher priority. TOM simulates the four transfer mechanisms in the following order:

- Groundwater substitution – for alternatives that include this mechanism
- Reservoir release
- Conserved water
- Crop idling – for alternatives that include this mechanism

Priorities for transfer mechanisms are necessary to develop groundwater pumping inputs to SACFEM2013 and simulate all transfers in TOM. Priorities were developed solely for this purpose.

TOM simulates water made available under each transfer mechanism, subject to various constraints. The following sections describe each transfer mechanism and associated constraints and operational considerations.

B.4.3.1.3 Groundwater Substitution Transfers

Groundwater substitution transfers involve pumping groundwater to meet a demand for water that would otherwise be met from surface water diversion. Surface water not diverted is then available for transfer. The volume of water made available for transfer is the volume of groundwater pumped during the transfer period. Groundwater substitution transfers allow a limited degree of flexibility in the timing of transfer because the transfer period starts and ends based on when groundwater pumping occurs. The Project includes groundwater substitution transfers in the Sacramento Valley. Figure B-4 illustrates annual groundwater substitution transfer supply identified by the sellers for years with available export capacity/transfer demand.

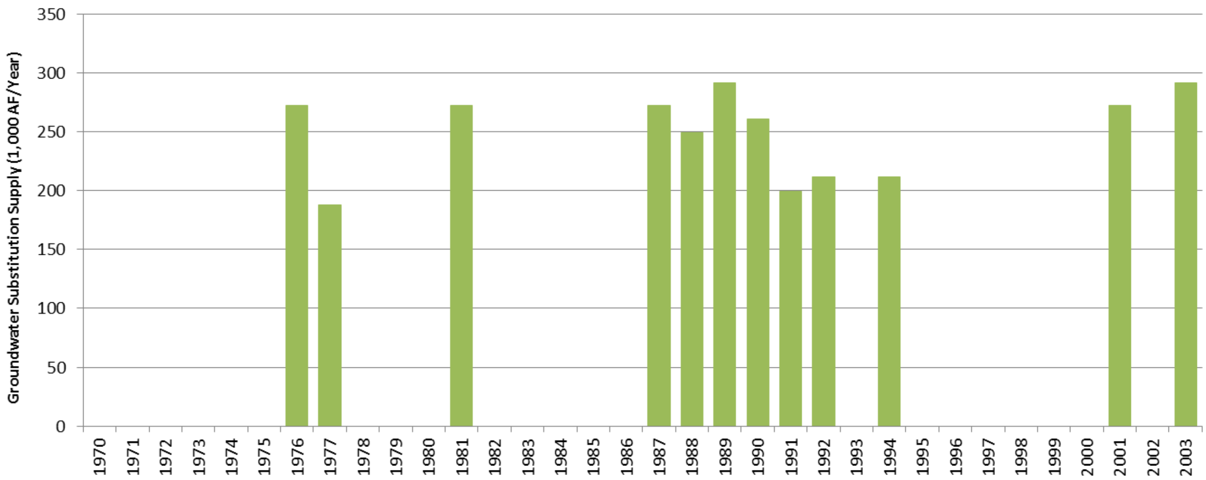

Figure B-4. Annual Groundwater Substitution Transfer Supply

Groundwater substitution transfers included in the analysis were developed based on input from sellers, buyer demand, capacity to convey the water, and an analysis of the ability to potentially store water pumped from April through June in upstream CVP/SWP reservoirs. The ability to store water pumped April through June is described in greater detail in a subsequent section. The result of this analysis is a time-series of pumping that varies by month and year and is significantly less than the volumes illustrated in Figure B-4. Figure B-5 illustrates the range of monthly pumping simulated, and the average monthly pumping for the 12 years when groundwater substitution transfers are simulated. Additional detail on the monthly volume of groundwater substitution transfer simulated for each seller is provided in Attachment 2.

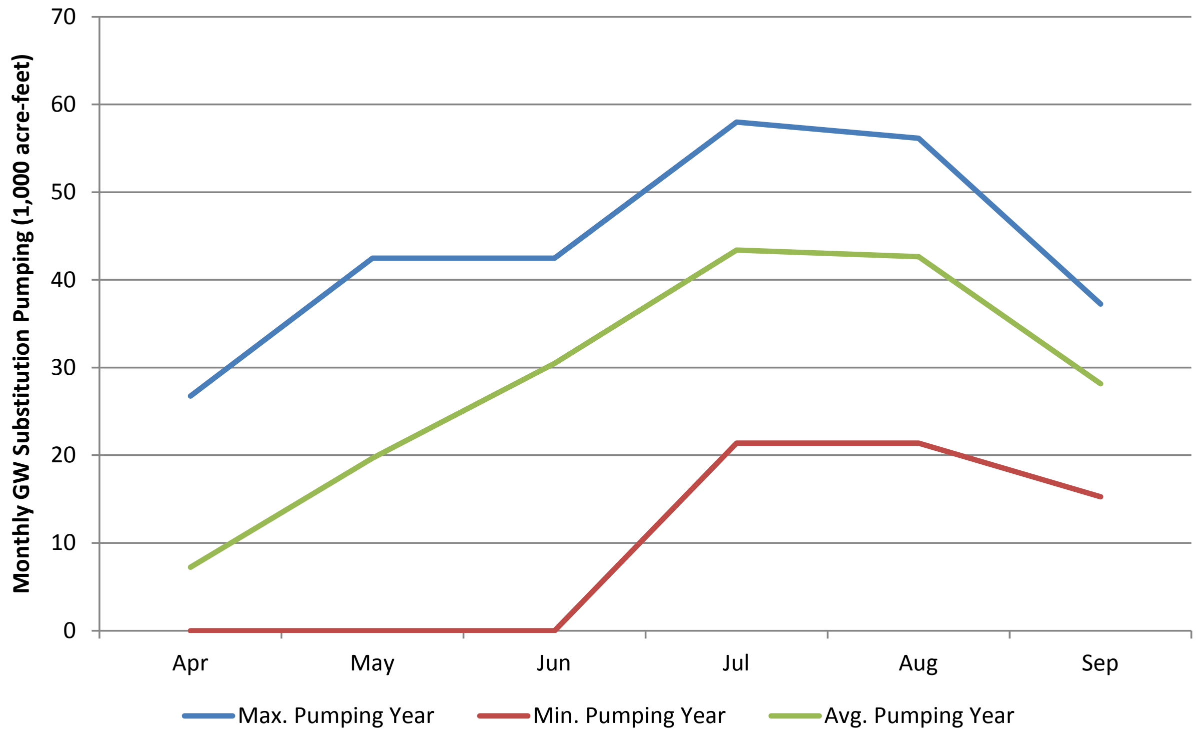

Figure B-5. Range of Monthly Groundwater Substitution Transfers Analyzed

Groundwater substitution transfers from the Sacramento Valley have the potential to create changes in stream-aquifer interaction that affect other parts of the water delivery system. Change in stream-aquifer interaction can be determined by comparing SACFEM2013 results from a baseline, without-transfer simulation to a with-transfer simulation that includes groundwater substitution pumping. Change in stream-aquifer interaction is calculated at each stream node for rivers and streams explicitly modeled in SACFEM2013. Changes are aggregated for nodes above specific locations that affect CVP/SWP operations, such as Wilkins Slough on the Sacramento River or total Delta inflow. Changes in stream-aquifer interaction due to groundwater substitution transfers include increased stream loss to the aquifer and decreased aquifer contribution to stream flow.

Figure B-5 illustrates the time-series of total change in stream-aquifer interaction in the Sacramento Valley (at the Delta) that result from groundwater substitution transfers proposed in the Project. Change in stream-aquifer interaction illustrated in Figure B-~~5~~ 6 is a reduction in Delta inflow.

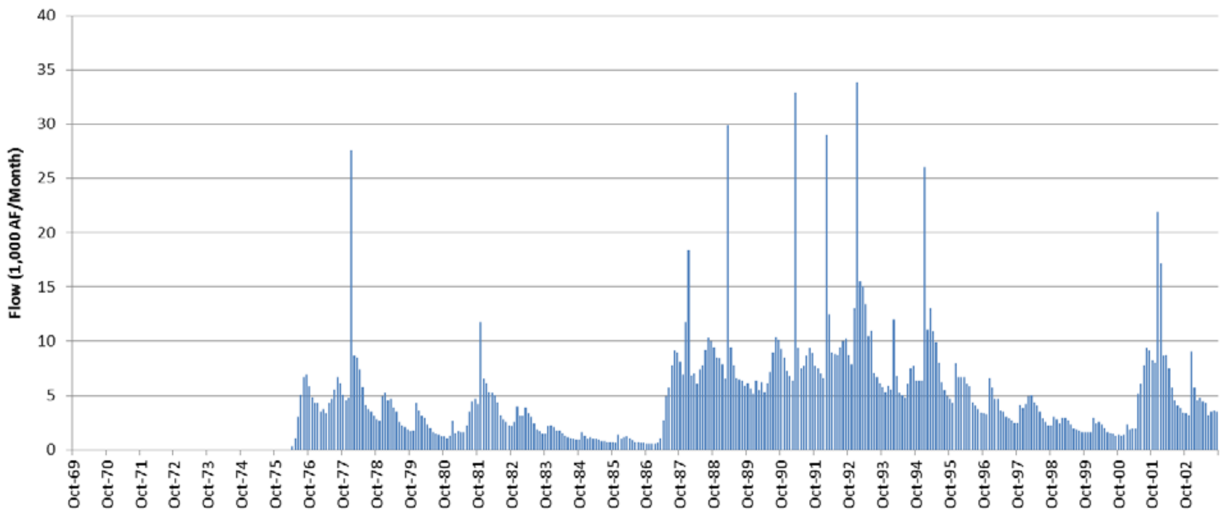

Figure B-~~5~~6. Total Change in Stream-Aquifer Interaction due to Groundwater Substitution Transfers

The timing of when changes in stream-aquifer interaction reduce stream flow is the key to understanding and simulating how changes may affect CVP/SWP operations. CVP/SWP operations will change in response to reduced stream flows under two conditions:

- When stream flow at minimum flow compliance locations (such as the Sacramento River at Wilkins Slough, the lower Feather River, or the American River at H Street) is at minimum levels and controlling upstream reservoir release.
- When the Delta is in balanced conditions.

The Delta can be in either a balanced or surplus condition. Balanced conditions, as defined in COA, are those periods when DWR and Reclamation agree that releases from upstream reservoirs plus unregulated flow approximately equals the water needed to meet Sacramento Valley in-basin uses plus exports. Conversely, excess or surplus conditions are periods when it is agreed that releases from upstream reservoirs plus unregulated flow exceed Sacramento Valley in-basin uses plus exports. Sacramento Valley in-basin uses include Delta water quality.

TOM simulates how changes in stream-aquifer interaction affect CVP and SWP operations. Time-series of the change in stream-aquifer interaction calculated from SACFEM2013 results for specific locations that affect CVP/SWP operations are input to TOM. Logic in TOM simulates changes in CVP/SWP operations that occur as a result of these changes in stream flow.

Stream flow reductions when the Delta is in surplus and river flows exceed minimum flow requirements will not affect CVP/SWP operations. During these periods TOM simulates the reduction in stream flow in the major river systems and Delta outflow. Surplus conditions occur approximately half of the time. Figure B-~~6~~ 7 illustrates changes in stream-aquifer interaction that occur during Delta balanced and surplus conditions.

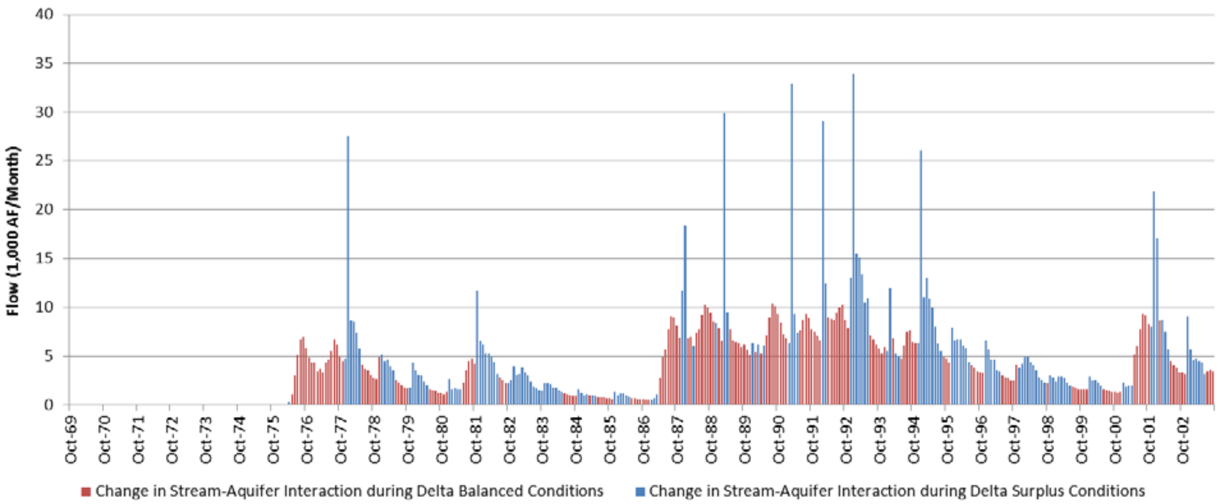

Figure B-~~6~~7. Change in Stream-Aquifer Interaction during Delta Balanced and Surplus Conditions

During periods when the Delta is in balanced conditions and/or flows on affected rivers and streams are at minimum flow requirements the CVP/SWP would respond to stream flow reductions that result from groundwater substitution transfers. TOM assumes the CVP/SWP will fully compensate for changes during these periods to maintain compliance with regulatory requirements. TOM includes logic to simulate the CVP/SWP operational response based on the location of the change in stream flow and CVP/SWP conditions. For example, the CVP would respond to reductions in Sacramento River flow at Wilkins Slough by increasing release from Shasta to comply with minimum flow requirements at that location. TOM simulates these types of operational responses.

There can be a variety of operational responses to changes in Delta inflow. TOM uses assumptions based reservoir storage conditions, minimum flow requirements, the portion of CVP and SWP water in the Delta, COA accounting, and Delta exports to simulate these operational responses by the CVP and SWP. Operational responses include increased release from upstream reservoirs and decreased Delta exports.

Changes in Delta inflow affect the CVP and SWP differently based on system conditions at the time and COA accounting. The obligation of each project to respond to reductions in Delta inflow is generally governed by the accounting split illustrated below in Figure B.~~7~~-8. However, during some periods the CVP may already be providing water in excess of the COA obligation and the CVP's ability to export CVP water at Jones. In these instances, the effects of reductions in Delta inflow as a result of groundwater substitution transfers primarily affect the SWP.

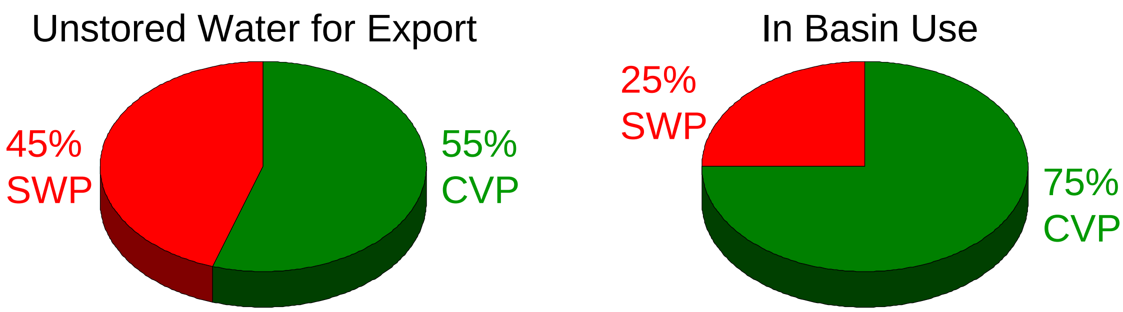

Figure B-~~7~~8. COA Accounting

B.4.3.1.4 Reservoir Release

The Long-Term Water Transfer Project includes reservoir release transfers from four water districts who own and operate reservoirs that can provide water to CVP buyers. These agencies and associated reservoirs are Placer County Water Agency and the Middle Fork Project (MFP) reservoirs of French Meadows and Hell Hole on the American River upstream of Folsom Reservoir, South Sutter WD and Camp Far West Reservoir on the Bear River, Browns Valley ID and Merle Collins Reservoir on French Dry Creek a tributary to the Yuba River, and Merced ID and Lake McClure on the Merced River.

In most instances, reservoir release transfers offer a higher degree of flexibility than other transfer mechanisms. Reservoir releases can be timed to coincide with available capacity and modified to accommodate other regulatory restrictions.

Annual volumes of water available through reservoir release transfers were developed and provided by the sellers. Annual time-series were input to TOM. TOM simulates operation of the seller's reservoirs to analyze the effects on reservoir storage, flow downstream, and reservoir refill. Figure B-~~8~~ 9 illustrates the annual volume of reservoir release water available from each seller in years with available export capacity/transfer demand.

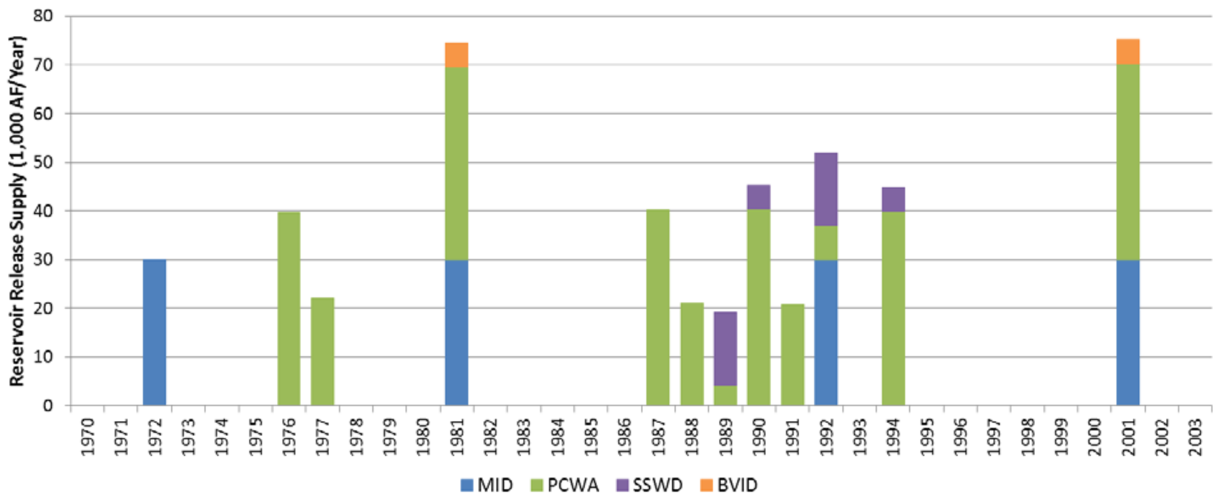

Figure B-~~8~~9. Annual Reservoir Release Transfer Supply

Transfer water released from Placer County Water Agency's MFP reservoirs flows into and through Folsom Reservoir. Transfer water made available from Placer County Water Agency must be in Folsom before being released for transfer, or moved through Folsom during the transfer, i.e. transfer water is not released from Folsom before being released from Placer County Water Agency reservoirs. Placer County Water Agency provided output from their MFP model for both a baseline and with-transfer scenario. Output included reservoir storage in French Meadows and Hell Hole and North Fork American River flow into Folsom. This model output was used to determine when transfer water flowed into Folsom and when MFP reservoirs refilled. Logic in TOM releases transfer water out of Folsom without bypassing hydropower generation.

Transfer water released from South Sutter WD's Camp Far West Reservoir flows down the Bear River, into the Feather River and eventually the Delta. There are no operational constraints that limit South Sutter WD's ability to release transfer water and therefore TOM assumes these transfers occur when there is demand, available capacity to divert the water, and the Delta is in balanced conditions. Logic in TOM for the operation of Camp Far West is based on a CalSim II module of the Bear River and is used to determine when Camp Far West refills.

Reservoir release transfers from Browns Valley ID's Merle Collins Reservoir are simulated in TOM. Browns Valley ID provided a baseline operation of Merle Collins Reservoir from a spreadsheet model owned by the district. Browns Valley ID also provided guidance on the years and conditions when the district would consider making a reservoir release transfer. This information was incorporated into TOM and logic developed to simulate the operation of Merle Collins Reservoir for a with-transfer scenario.

A reservoir release transfer from Merced ID's Lake McClure flows down the Merced River and is conveyed to SLDMWA. There are a variety of potential conveyance options to move transfer water from the Merced River to SLDMWA. Conveyance options include:

- Diversion at Merced ID's Crocker-Huffman Diversion Dam on the Merced River, conveyance through Merced ID's canals and distribution system to the Eastside Canal, through new conveyance facilities and into Turner Island WD and San Luis Canal Company, SLDMWA member agencies.

- Release down the Merced River to the lower San Joaquin River and diversion into facilities that connect the lower San Joaquin River and the Delta-Medota Canal. Three different facilities exist across the following districts: Patterson ID, West Stanislaus ID, and Banta Carbona ID. Connections through Patterson ID and West Stanislaus ID are located off the San Joaquin River upstream of the confluence with the Tuolumne River. The connection through Banta Carbona ID is located on the San Joaquin River downstream from Vernalis.

- Release down the Merced River, into the San Joaquin River for diversion at CVP, SWP, or Contra Costa WD's diversion facilities.

Assumptions input to TOM prioritize utilizing these conveyance options on an upstream to downstream priority, subject to physical capacities. A greater degree of flexibility exists for transfers from Merced ID because transfers can be scheduled based on available capacity to convey the water, and because there are multiple options for conveying transfer water without going through CVP/SWP facilities in the south Delta. However, transfers that affect water quality in the San Joaquin River are limited to periods when New Melones Reservoir is not releasing to meet water quality requirements at Vernalis.

B.4.3.1.5 Conserved Water

Conserved water is made available by Browns Valley ID from their pre-1914 Yuba River water rights. In 1990, Browns Valley ID implemented the Upper Main Water Conservation Project for the purpose of conserving water. Details of this project and documentation of the 3,100 acre-feet of annual conserved water are contained in the report *Analysis of Water Conserved Under the Upper Main Water Conservation Project* (MBK Engineers, 2002). Browns Valley ID's conserved water is available for transfer every year, but is only simulated as transferred in years with demand and available Delta export capacity (see Figure B-3). Conserved water is stored in Yuba County Water Agency's New Bullards Bar Reservoir and released for transfer in years with demand and capacity.

TOM simulates operation of New Bullards Bar Reservoir and Yuba River flow below New Bullards Bar to analyze effects on reservoir storage, Yuba River flow, and reservoir refill.

B.4.3.1.6 Crop Idling

Water can be made available through crop idling by not growing and irrigating a crop with available surface water and instead making that water available for transfer. The volume of water that may be transferred with a crop idling transfer is limited to the evapotranspiration of applied water (ETAW) that would have been consumed by the crop. The ETAW limit is intended to help protect third parties in the area of the seller. Crop idling transfers analyzed for the Project are from the Sacramento Valley only.

Annual volumes of crop idling water to be made available were provided by individual sellers. The volume of crop idling water to be made available can vary between Project alternatives. Figure B-~~9~~ 10 illustrates the maximum annual volumes identified by sellers in the Sacramento Valley for years with available export capacity/transfer demand.

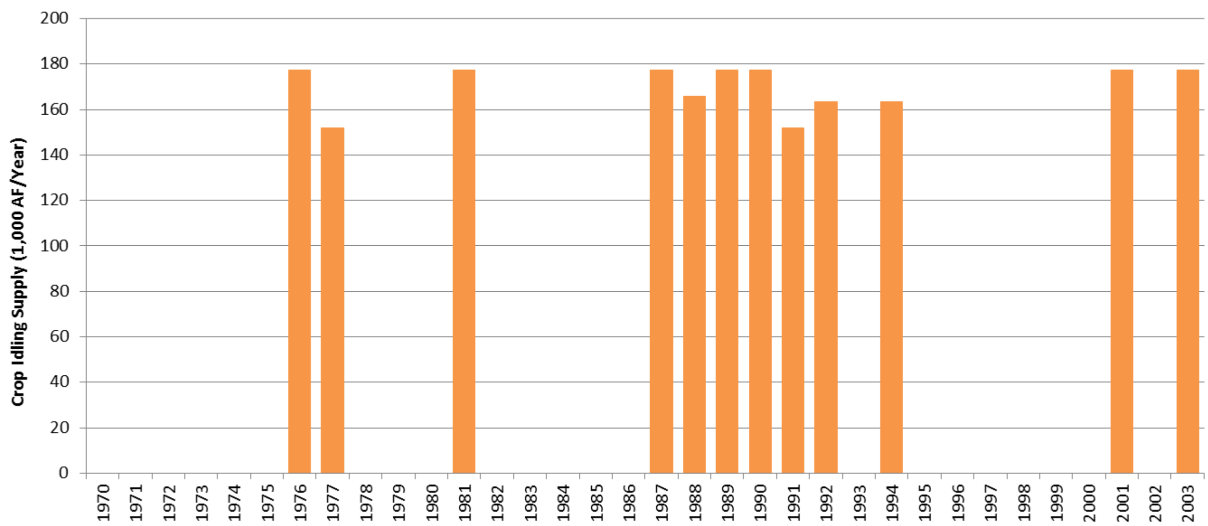

Figure B-~~9~~10. Maximum Annual Crop Idling Transfer Supply

Annual volumes were assumed to be made available on a monthly pattern based on the ETAW of rice, the assumed crop to be idled. Figure B-~~10~~ 11 illustrates the monthly ETAW pattern for rice. This monthly ETAW pattern has been used in the execution of water transfers for numerous years and is referenced in "Cropland Idling, Issue No. 1 – DRAFT Rice Water Transfer Pattern" (Reclamation 2009).

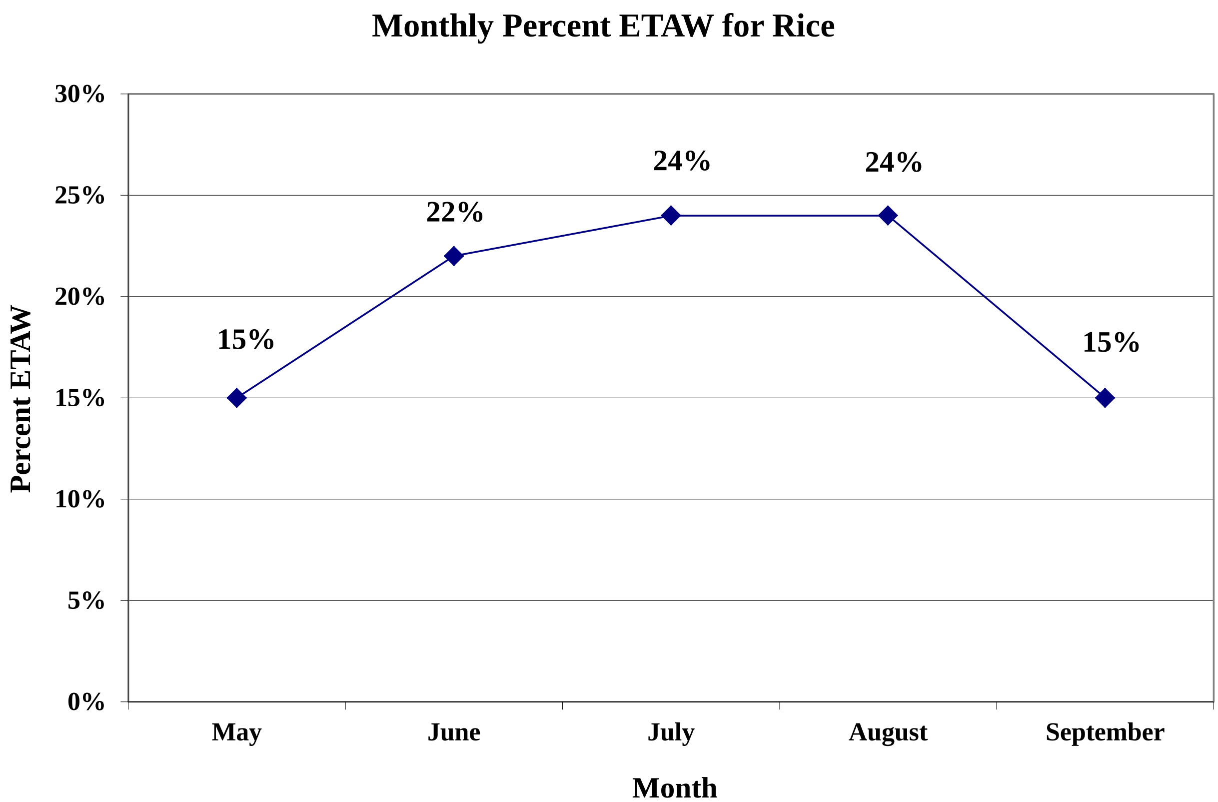

Figure B-~~10~~11. Monthly ETAW Pattern for Rice

Crop idling transfers offer the least flexibility of all transfer mechanisms. The decision to enter into crop idling transfers is typically made in spring months when there is still considerable uncertainty in the water supply forecast and the ability to convey water through the Delta. Crop idling transfers make water available on the fixed schedule illustrated in Figure B-~~10~~11. Therefore, transfer water made available in May and June, a total of 37 percent of the annual volume, can be lost or not diverted by the seller because there is rarely available export capacity at CVP or SWP pumping plants in those months and it may not be held in upstream storage.

B.4.3.1.7 Storing Transfer Water in CVP/SWP Reservoirs Upstream of the Delta

The BOs limit the season for water transfers through the Delta for export at CVP/SWP pumping facilities to July through September (NOAA Fisheries 2009, USFWS 2008). However, it may be possible to make water available prior to July and that water may be stored temporarily in CVP/SWP reservoirs upstream of the Delta. Transfer water stored prior to July would be released and moved through the Delta from July through September. It is difficult to predict when these conditions may occur, and therefore it is not possible to guarantee the ability to store water in every year.

In order for transfer water to be stored in upstream reservoirs two conditions must be met: 1) there must be surplus flow (flow in excess of minimum requirements for flow and temperature) upstream from where the transfer water is made available (the point of non-diversion), and 2) the CVP/SWP reservoir where the water will be stored must be operated to meet a requirement downstream from the point of non-diversion. Under these conditions it may be possible to temporarily store transfer water in CVP or SWP reservoirs. Transfer water would be stored in upstream reservoirs by reducing releases from those reservoirs when transfer water is made available.

Analysis of the baseline CalSim II simulation of CVP and SWP operations was performed to identify potential opportunities to store both groundwater substitution and crop idling transfer water made available from April through June in upstream CVP and SWP reservoirs. This information was used to determine months when groundwater substitution pumping was simulated in SACFEM2013. These same assumptions were incorporated into TOM to simulate the resulting changes in river flows, reservoir levels, and operations. These assumptions are made only for the purpose of analysis conducted for the environmental document to provide a conservative estimate of potential environmental impacts and may not be appropriate or applicable under actual operations in a particular year.

B.4.3.1.8 Shift in CVP/SWP Exports to Facilitate Transfers

As previously described, there are numerous considerations and adjustments made by Project operators to facilitate water transfers through CVP and SWP export facilities. One such adjustment can be to shift the timing of when Project water is moved from north-of-Delta reservoirs through the Delta. The timing of Project water movement can shift to assist in making export capacity for transfers available on a pattern that better matches the period of transfer. These shifts are more common at SWP facilities because the larger capacity at Banks provides greater flexibility.

TOM simulates shifts in timing of Project water movement at SWP facilities by adjusting baseline Oroville releases and Banks pumping from July through September of some years. Logic in TOM adjusts Oroville releases and Banks pumping to create a more regular monthly pattern of available export capacity.

B.4.3.1.9 Diversion of Transfer Water by Sellers

Water made available by sellers is conveyed through the system and diverted by CVP buyers. Diversions by buyers are made at existing points of diversion. A buyer's ability to divert transfer water is subject to available capacity and regulatory constraints as described in the following section.

B.4.3.1.9.1 East Bay MUD

East Bay MUD diverts both CVP Project water and transfer water at the Freeport Regional Water Project on the Sacramento River near Freeport. The location of these diversion facilities may provide additional flexibility for when transfer water may be diverted to East Bay MUD. Diversions at Freeport do not affect the Delta in the same way as CVP/SWP diversions in the southern Delta. Therefore, it may be possible for East Bay MUD to divert transfer water in months when there is typically no available export capacity at CVP/SWP facilities. East Bay MUD's Freeport diversions are limited to 155 cubic feet per second (cfs) capacity, East Bay MUD's share of the total Freeport Regional Water Project capacity.

Additionally, East Bay MUD diversions at Freeport are not subject to a "carriage water" adjustment to the volume of water made available for transfer. Carriage water is defined as the extra water needed to carry a unit of water across the Delta to CVP/SWP export facilities while maintaining a constant salinity. Because the transfer water is made available and diverted at the upstream edge of the Delta it is assumed that there is no change in Delta salinity associated with the transfer.

B.4.3.1.9.2 Contra Costa WD

Contra Costa WD diverts water under existing water rights, a CVP water service contract, and transfer water from multiple points of diversion in the Delta. The baseline CalSim II simulation includes diversions under Contra Costa WD's water rights and CVP contract. Diversion of transfer water is simulated in TOM to occur at three locations: Rock Slough, Old River, and Victoria Canal. Transfer diversions are simulated to occur at the location with the best water quality and available capacity after diversions under Contra Costa WD's water rights and CVP contract. Assumptions on the specific location of transfer diversions are necessary for analysis of Delta water quality performed in the Delta Salinity Model 2. Transfers to Contra Costa WD assume a 20 percent carriage water adjustment to maintain Delta salinity.

B.4.3.1.9.2 SLDMWA

SLDMWA member agencies receive water diverted at CVP/SWP export facilities in the southern Delta. Transfer water purchased by SLDMWA is conveyed through available export capacity at Jones and Banks pumping plants. Transfers from the Sacramento River assume a 20 percent carriage water adjustment to maintain Delta salinity. Transfers from Merced ID that enter the Delta from the San Joaquin River assume a ten percent carriage water adjustment.

Additionally, water made available by Merced ID can be conveyed directly to SLDMWA member agencies through facilities that connect to Merced ID's internal conveyance system and facilities that join the lower San Joaquin River and the DMC without going through CVP/SWP export facilities.

B.4.4 Level of Development

The Long Term Water Transfer Project is intended to provide environmental assessment for water transfers over a ten-year period. Therefore, analysis conducted to support environmental assessments was conducted at an existing level of development with consideration of reasonably foreseeable projects that may be constructed over the next ten years.

CalSim II simulations at a projected Level of Development (LOD) are used to depict how the modeled water system might operate with an assumed physical and institutional configuration imposed on a long-term hydrologic sequence. An existing LOD study assumes that current land use, facilities, and operational objectives are in place for each year of simulation (water year 1922 through 2003). The results are a depiction of the current environment which provides a basis for comparison of project effects for the impact analysis under CEQA. A future LOD study is needed to explore how the system may perform under an assumed future set of physical and institutional conditions and is used for the Future No Action Condition for NEPA analysis. The Project's ten-year period allows simulation of a single level of development under the assumptions that conditions are not likely to change significantly over such a short time horizon.

B.5 Model and Analysis Limitations

There are limitations in the ability of models to accurately address all of the intricacies of complex water management operations. Professional judgment is required to interpret results and determine benefits and impacts. Analysis for the Long Term Water Transfer Project is based on three primary models: CalSim II, SACFEM2013, and TOM. The overall analysis is therefore subject to the individual and combined limitations of all three models. While it is important to recognize and acknowledge the limitations of models as they are applied for this analysis, collectively these three models represent the best available tools for performing the analysis to serve as the basis for determining environmental impacts.

Model limitations and uncertainty for SACFEM2013 is described in Appendix D. Model limitations in CalSim II and TOM stem primarily from challenges of using computer models and fixed algorithms to simulate human decision-making processes. CVP/SWP operations are based on numerous regulatory requirements, a multitude of real-time data, and some degree of discretion on the part of operators. Numerous simplifying assumptions are necessary to simulate these complex operations. Computer models are capable of simulating many, but not all, regulatory requirements. Computer models are typically based on a more limited set of available data and use generalized rules that attempt to represent typical operator decisions. Computer models are far from perfect. However, these imperfections and simplifications do not render models useless. The regular and continued use of CalSim II for planning studies and environmental assessment by Reclamation, DWR, and others indicates the model is adequate for these purposes.

B.6 Project Alternatives and Results

B.6.1 Alternative 1: No Action/No Project Alternative

CEQA requires an EIR to include a No Project Alternative. The No Project Alternative allows for a comparison between the impacts of the proposed project with future conditions of not approving the proposed project. The No Project Alternative may include some reasonably foreseeable changes in existing conditions and changes that would be reasonably expected to occur in the foreseeable future if the project were not approved.

Under the No Action/No Project Alternative CVP related water transfers through the Delta would not occur from 2015-2024. However, other transfers that do not involve the CVP could occur under the No Action/No Project Alternative. Additionally, CVP transfers within basins could continue and would still require Reclamation's approval. Some CVP entities may decide that they are interested in selling water to buyers in export areas under the No Action/No Project Alternative; however, they would need to complete individual NEPA and Endangered Species Act compliance for each transfer to allow Reclamation to complete the evaluation of the transfers for approval.

Alternative 1 is simulated with the baseline CalSim II model provided by Reclamation and other information and model results provided by buyers and sellers. These results represent reasonably foreseeable conditions for the 2015-2024 period and are used for comparison with results from each of the project alternatives.

B.6.2 Alternative 2: Full Range of Transfer Measures

Alternative 2 would involve transfers from potential sellers upstream from the Delta to buyers in the Central Valley and Bay Area. Alternative 2 includes transfers under all potential transfer measures: groundwater substitution, reservoir release, conserved water, and crop idling/crop shifting. The order in which transfer measures are prioritized and simulated to occur is described in previous sections. The following section summarizes the results of Alternative 2 with comparisons to and changes from the No Project Alternative.

Figure B-~~11~~ 12 is a summary of the quantity of transfer water made available (Transfer Supply) under Alternative 2 on an annual basis and illustrates where the water is diverted or used (Transfer Use). A percentage of water to be transferred through the Delta becomes carriage water to maintain Delta water quality. Unused transfer water is from two different sources/transfer measures. In some years there can be unused crop idling water during May and June because there is no ability to store it upstream or available capacity at the export pumps. A second source is reservoir release transfers from Placer County Water Agency that are held in Folsom but spill prior to being delivered to East Bay MUD. Results are summarized by water year and show small amounts of water in wetter years such as 1978, 1982, 1993, etc. These are transfers from Placer County Water Agency to East Bay MUD that extend past September of the year when the transfer begins. East Bay MUD may begin taking delivery of transfer water from Placer County Water Agency as early as March and extend into February of the following year.

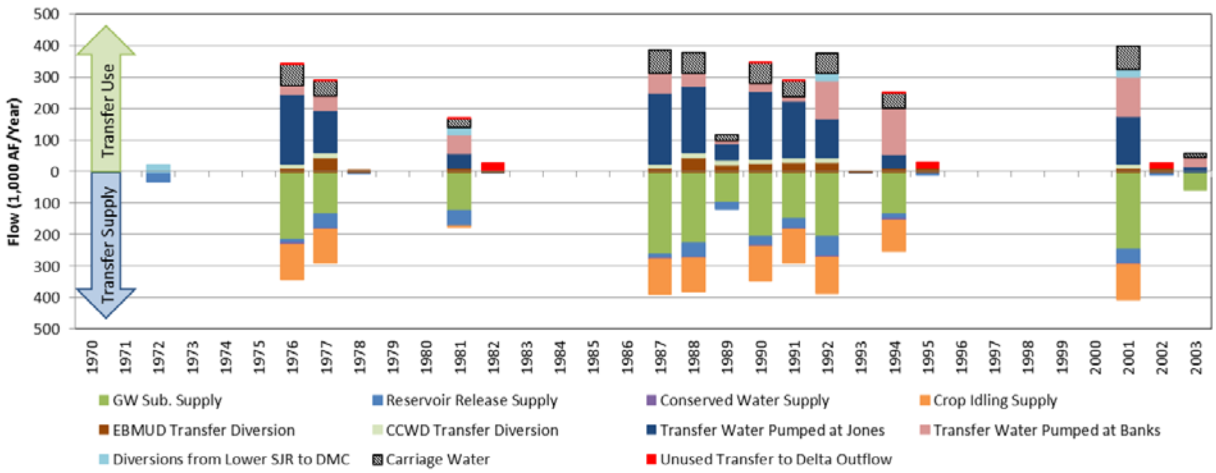

Figure B-~~11~~12. Annual Transfer Summary for Alternative 2

TOM simulates transfer water made available and moved through the system and produces results under each Project alternative for comparison with baseline, without transfers, results. TOM simulates the effects of transfers on reservoir storage, river flows, Delta outflow and exports, and diversions by Contra Costa WD and East Bay MUD. The following sections describe and illustrate these effects for Alternative 2.

B.6.2.1 Storage

Figure B-~~12~~ 13 illustrates the change in operations at Shasta with the Project. Under Alternative 2 release from Shasta can increase or decrease. Decreased releases occur when transfer water is stored in Shasta during the April through June period and create higher storage conditions than under Alternative 1 (Baseline). Releases increase during the July through September period when stored transfer water is released for delivery. These releases bring storage back to Baseline levels. Releases also increase because groundwater substitution transfers reduce stream flow on the Sacramento River, and during times of low-flow, stored water must be released from the reservoir to meet minimum flow requirements at Wilkins Slough.

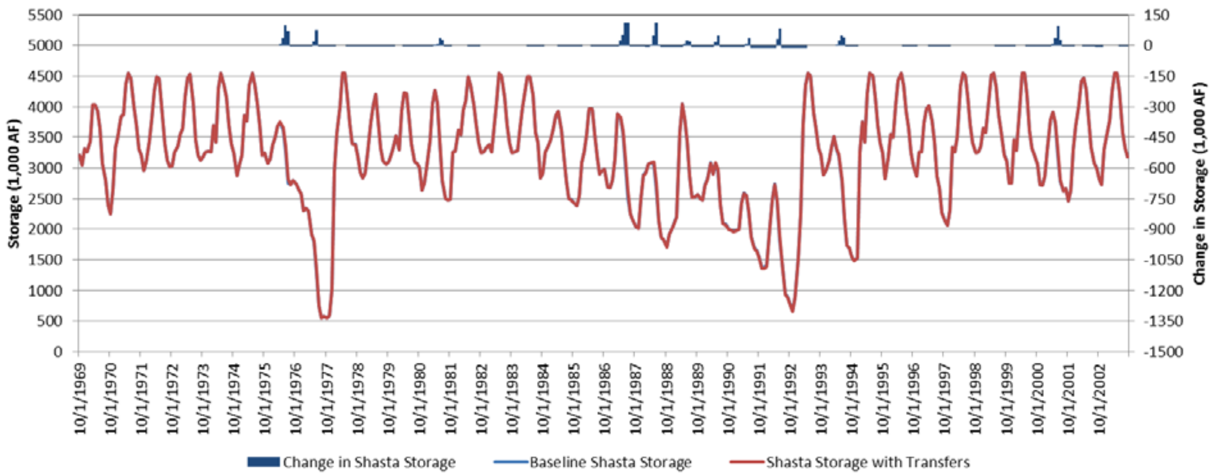

Figure B-~~12~~13. Shasta Operations with and without Alternative 2 Transfers

Operations at Folsom are illustrated below in Figure B-~~13~~14. Transfer water can be temporarily stored in Folsom for release and delivery in subsequent months. This includes transfers from groundwater substitution in the American River Basin, crop idling in the Sacramento Valley, and reservoir release from upstream Placer County Water Agency reservoirs. Releases from Folsom can increase to maintain minimum flow requirements downstream on the American River at H Street.

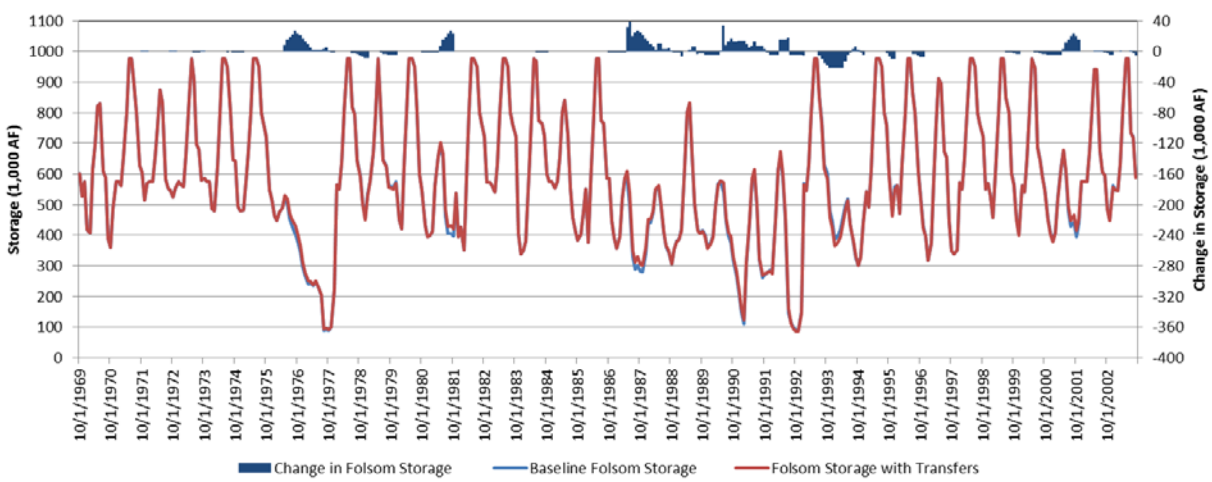

Figure B-~~13~~14. Folsom Operations with and without Alternative 2 Transfers

Figure B-~~14~~ 15 illustrates changes in Oroville storage with and without the Project. Larger changes in Oroville storage result from shifting the timing of delivery of SWP water to accommodate transfers. There are also decreases in storage when additional water is released to maintain minimum flow requirements on the Lower Feather River. These additional releases from

Oroville are made to account for reductions in Feather River flows due to groundwater substitution transfers.

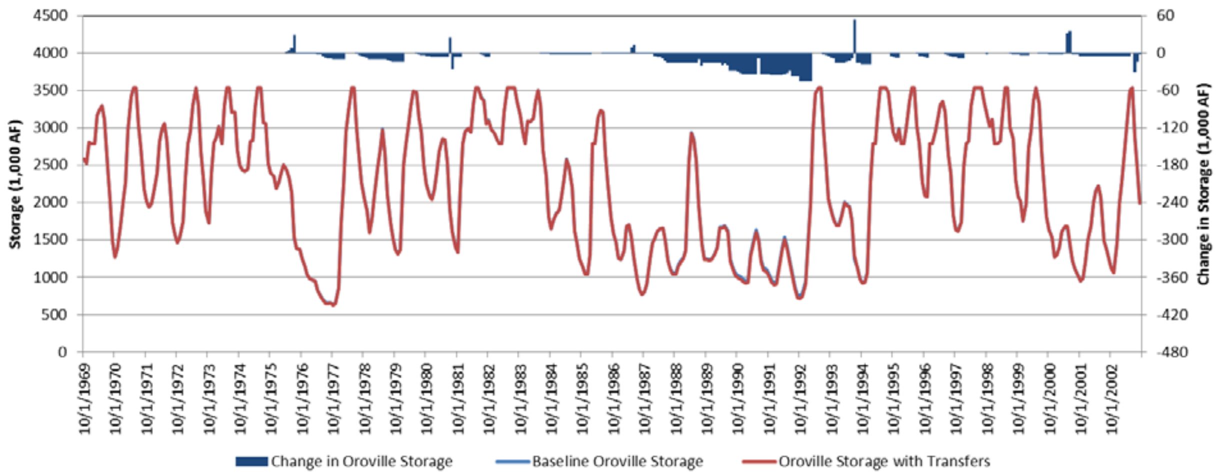

Figure B-~~14~~15. Oroville Operations with and without Project

South Sutter WD releases water from Camp Far West Reservoir to participate in reservoir release transfers. Figure B-~~15~~ 16 illustrates the only change in reservoir storage from baseline conditions as the quantity released for transfer, a volume of five or 15 thousand acre-feet (TAF). Camp Far West Reservoir storage returns to baseline levels when the reservoir refills.

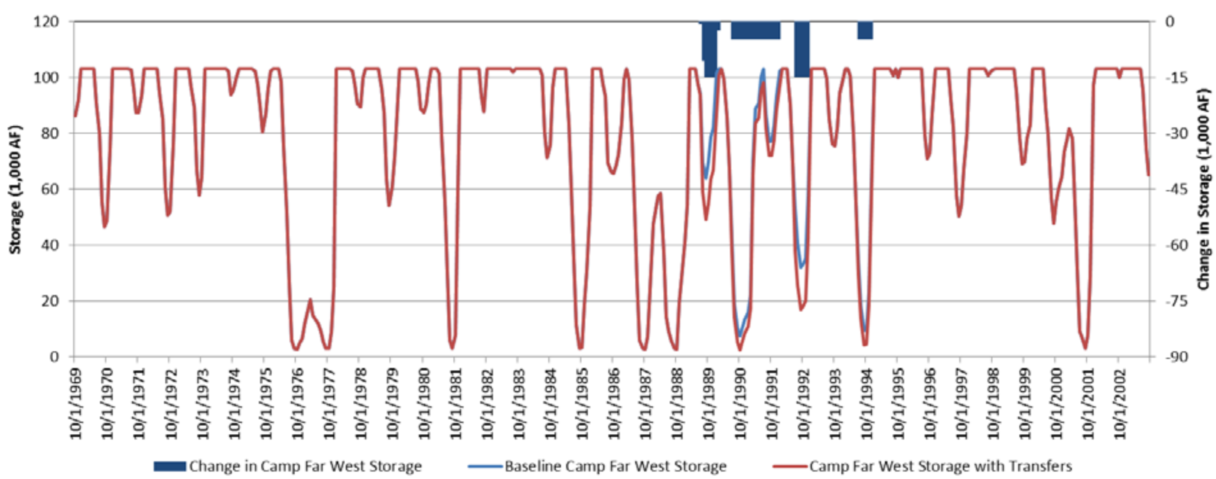

Figure B-~~15~~16. Camp Far West Operations with and without Alternative 2 Transfers

Browns Valley ID releases water from Merle Collins Reservoir to participate in reservoir release transfers. Figure B-~~16~~ 17 illustrates the only change in reservoir storage from baseline conditions as the quantity released for transfer, up to five TAF in any year. Merle Collins Reservoir storage returns to baseline levels when the reservoir refills.

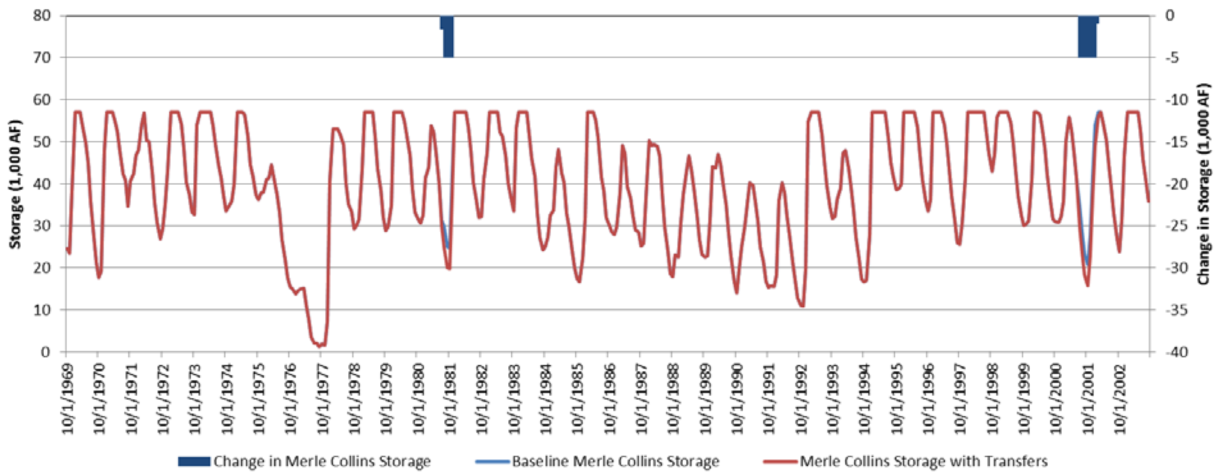

Figure B-~~16~~17. Merle Collins Reservoir Operations with and without Alternative 2 Transfers

Placer County Water Agency releases water from MFP reservoirs of French Meadows and Hell Hole to participate in reservoir release transfers. Figure B-~~17~~ 18 illustrates the combined storage in these two reservoirs under both baseline and with Project operations. MFP reservoir storage returns to baseline levels when the reservoirs refill.

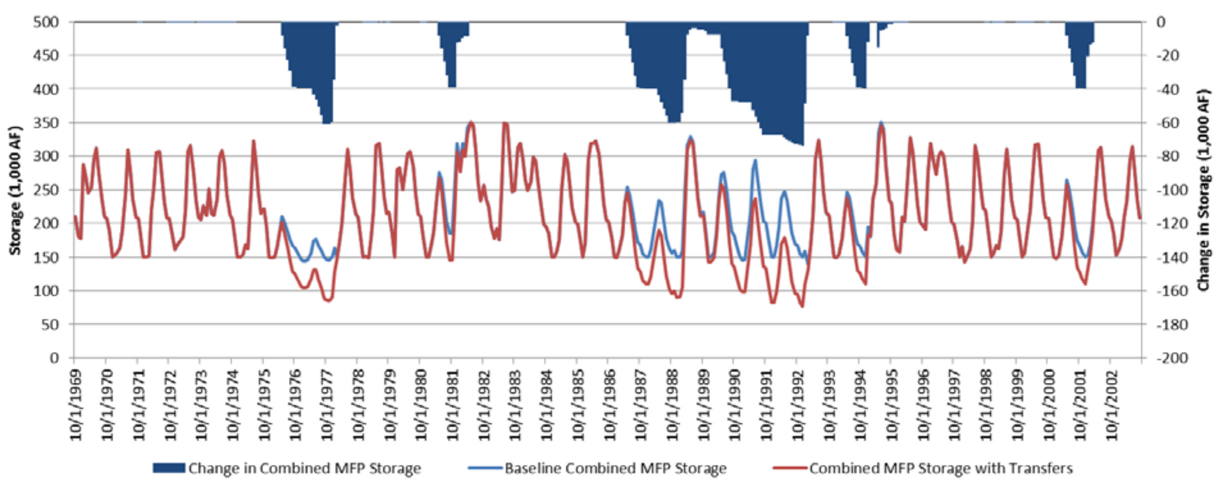

Figure B-~~17~~18. MFP Operations with and without Alternative 2 Transfers

Figure B-~~18~~ 19 illustrates Merced ID operations of Lake McClure with and without reservoir release transfers. Reservoir release transfers of up to 30 TAF reduce reservoir storage until the reservoir refills in subsequent wet years.

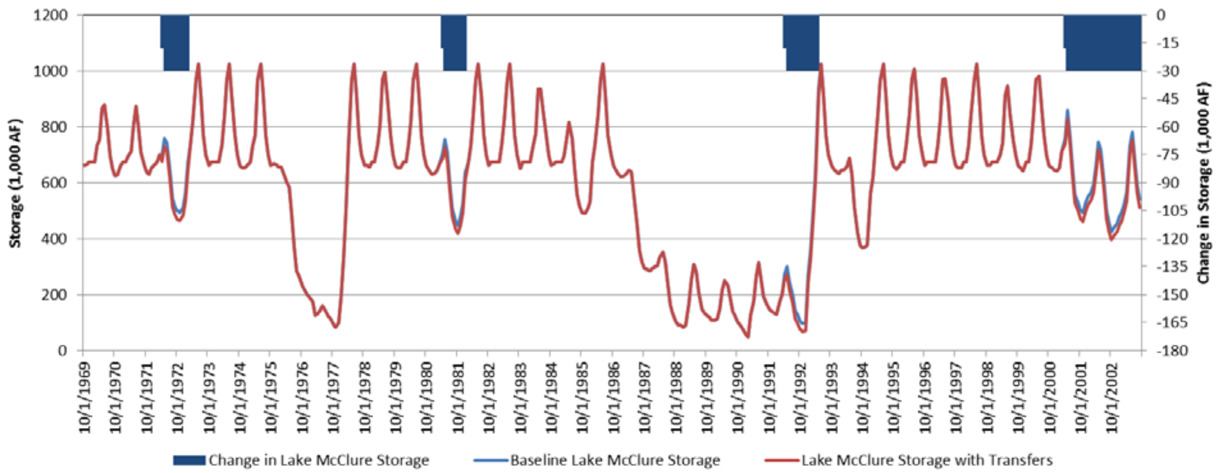

Figure B-~~18~~19. Lake McClure Operations with and without Alternative 2 Transfers

Conserved water is stored in Yuba County Water Agency's New Bullards Bar Reservoir and released for transfer in years with demand and capacity. The effect of these releases is illustrated below in Figure B-~~19~~20. New Bullards Bar Reservoir storage returns to baseline levels when the reservoir refills.

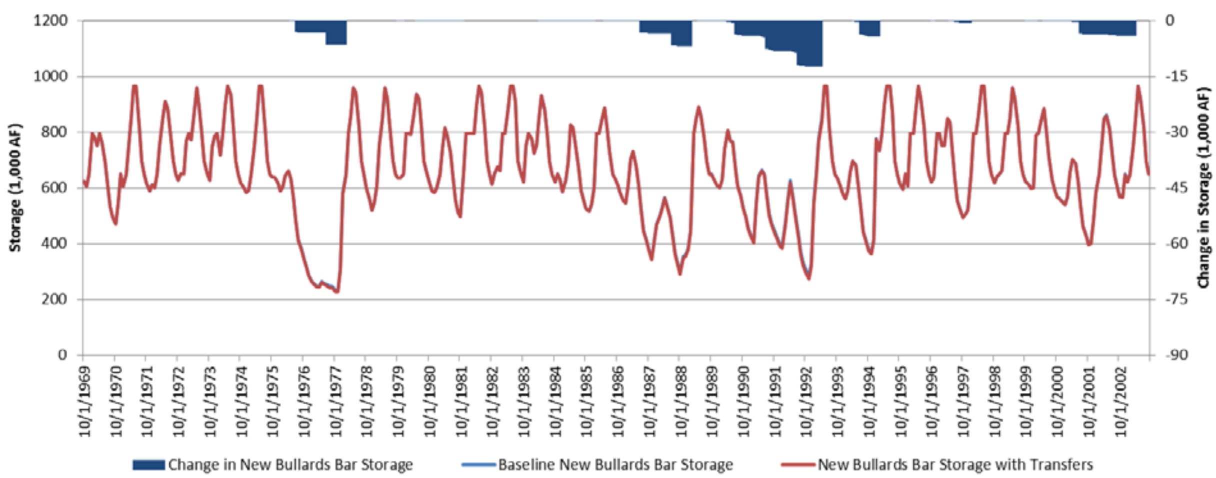

Figure B-~~19~~20. New Bullards Bar Operations with and without Alternative 2 Transfers

B.6.2.2 Stream Flow

Releases from Keswick Dam, as illustrated below in Figure B-~~20~~21, reflect the changes in Shasta storage seen in Figure B-~~12~~13. A reduction in release corresponds to an increase in Shasta storage. Reduced releases typically occur in the April through June period when it may be possible to store transfer water made available downstream in Shasta. Months of reduced releases are followed by increased releases as transfer water is released to be moved through the Delta during the July through September period.

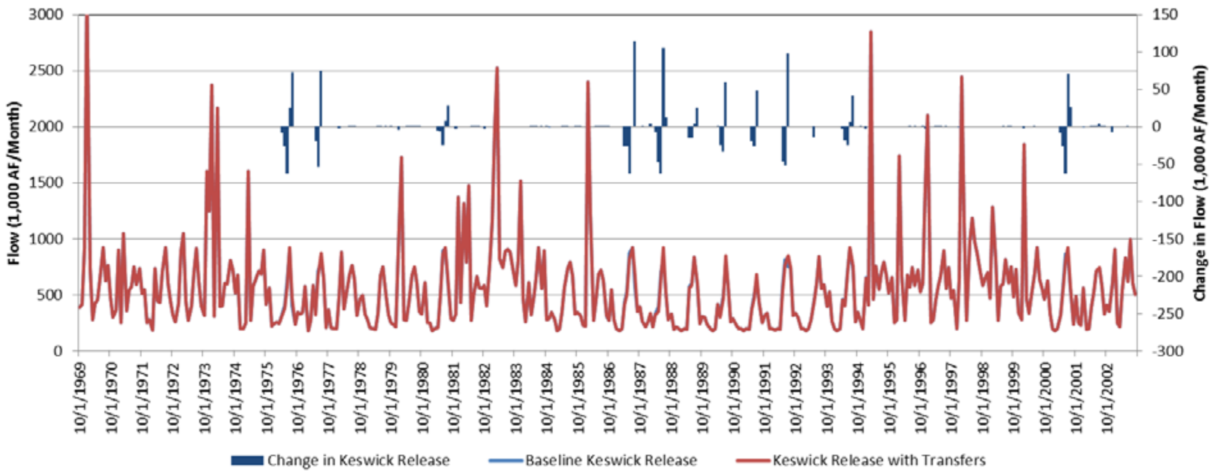

Figure B-~~20~~21. Keswick Dam Release with and without Alternative 2 Transfers

Figure B-~~21~~ 22 illustrates the effect of Alternative 2 transfers to the Sacramento River at Wilkins Slough. Increased flows result from changes in Keswick release, plus water made available by groundwater substitution and crop idling transfers upstream of Wilkins Slough. Decreases occur when transfer water is stored upstream in Shasta.

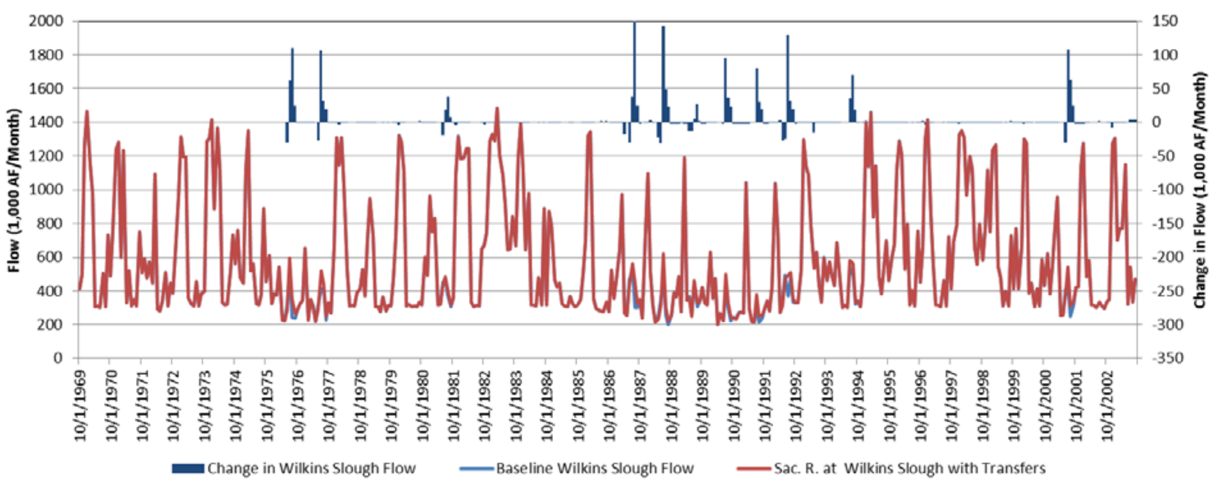

Figure B-~~21~~22. Sacramento River at Wilkins Slough with and without Alternative 2 Transfers

Figure B-~~22~~ 23 illustrates Nimbus Dam releases. Nimbus releases reflect CVP operations of Folsom Reservoir. Increases in release of approximately five TAF are water made available by Placer County Water Agency being released for re-diversion by East Bay MUD. Larger increases are typically preceded by decreases as transfer water made available downstream is stored in Folsom. Large releases occur when stored transfer water is release to be conveyed through the Delta. Decreases also occur when Placer County Water Agency's upstream reservoirs refill, typically during times when Folsom is also spilling water to maintain flood space requirements.

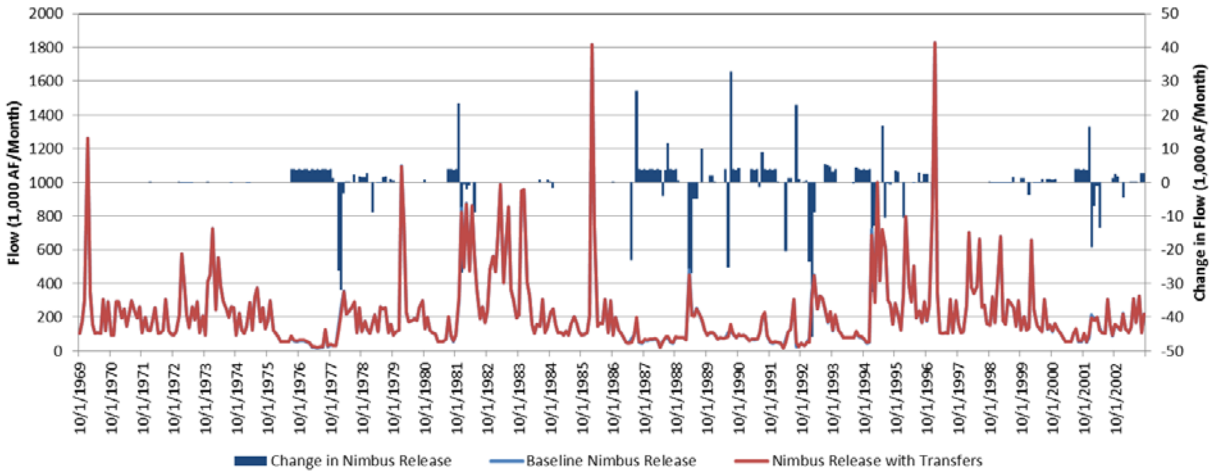

Figure B-~~22~~23. Nimbus Dam Release with and without Alternative 2 Transfers

Flows on the American River at H Street, illustrated in Figure B-~~23~~24, show similar changes as flows at Nimbus. Flow at H Street also increases from water made available by groundwater substitution transfers by Sacramento Suburban WD and the City of Sacramento.

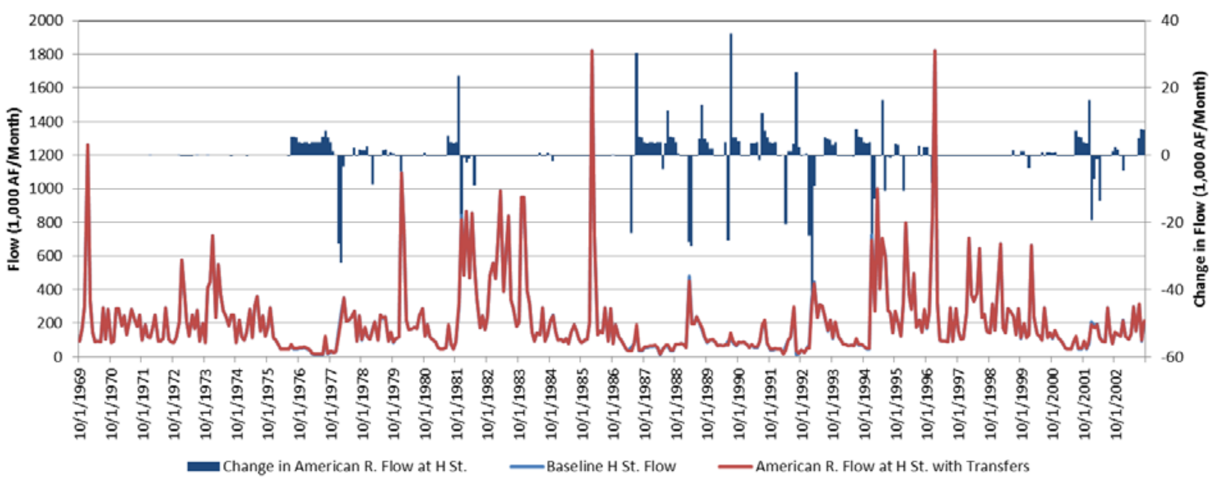

Figure B-~~23~~24. American River at H Street with and without Alternative 2 Transfers

Figure B-~~24~~ 25 illustrates change in Feather River flow below Thermalito. Flow in the Feather River below Thermalito changes due to changes in the operation of Oroville. Transfer water made available on the Feather River downstream from Thermalito can be temporarily stored in Oroville for release and transfer during the July through September period. Water stored prior to

July reduces Feather River flow. Increases and decreases in flow on the Feather River below Thermalito also occur from shifts in timing of SWP water to accommodate transfers. The magnitude of some of these differences is affected by model nuances within CalSim II that can create variations from month-to-month in release of SWP water from Oroville for movement through the Delta.

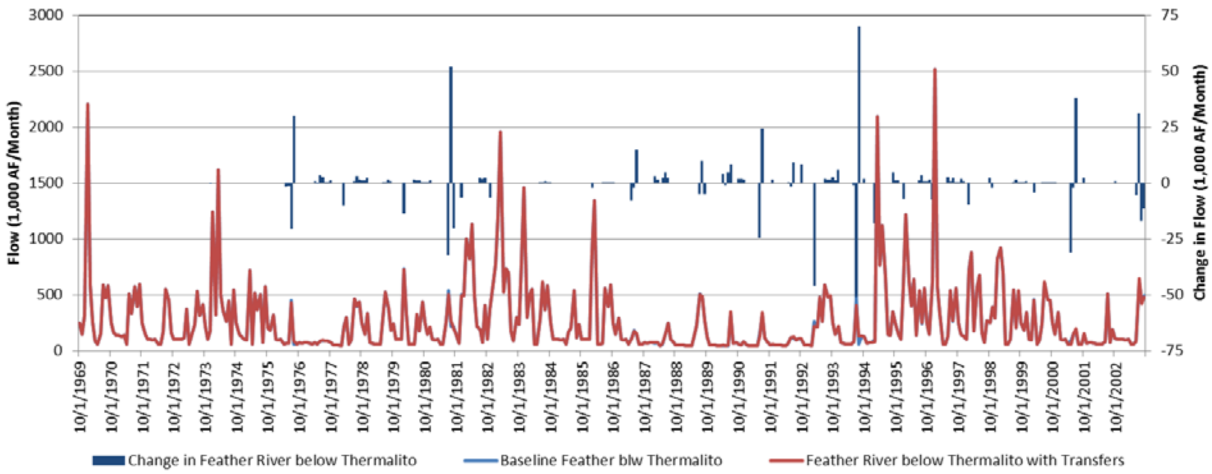

Figure B-~~24~~25. Feather River below Thermalito with and without Alternative 2 Transfers

Figure B-~~25~~ 26 illustrates changes in flow on the Yuba River at Marysville as a result of Browns Valley ID's transfers of conserved water from New Bullards Bar Reservoir and reservoir release from Merle Collins Reservoir. Increases indicate transfer water moving downstream for re-diversion and decreases indicate upstream reservoir refill.

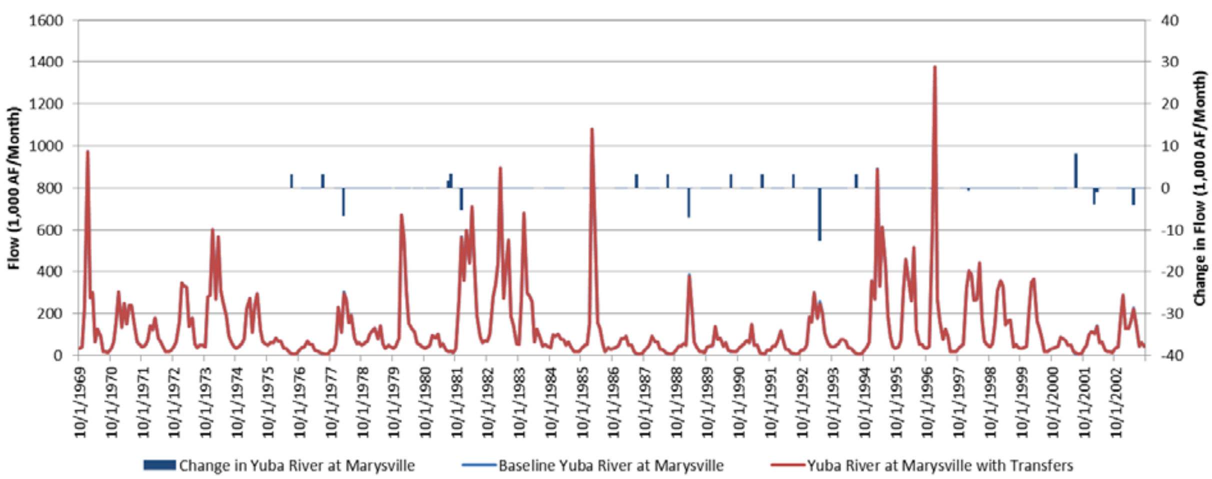

Figure B-~~25~~26. Yuba River at Marysville with and without Alternative 2 Transfers

Figure B-~~26~~ 27 illustrates the response of Bear River flows into the Feather River as a result of South Sutter WD reservoir release transfers from Camp Far

West Reservoir. Flows increase when water is released for transfer and decrease when Camp Far West refills.

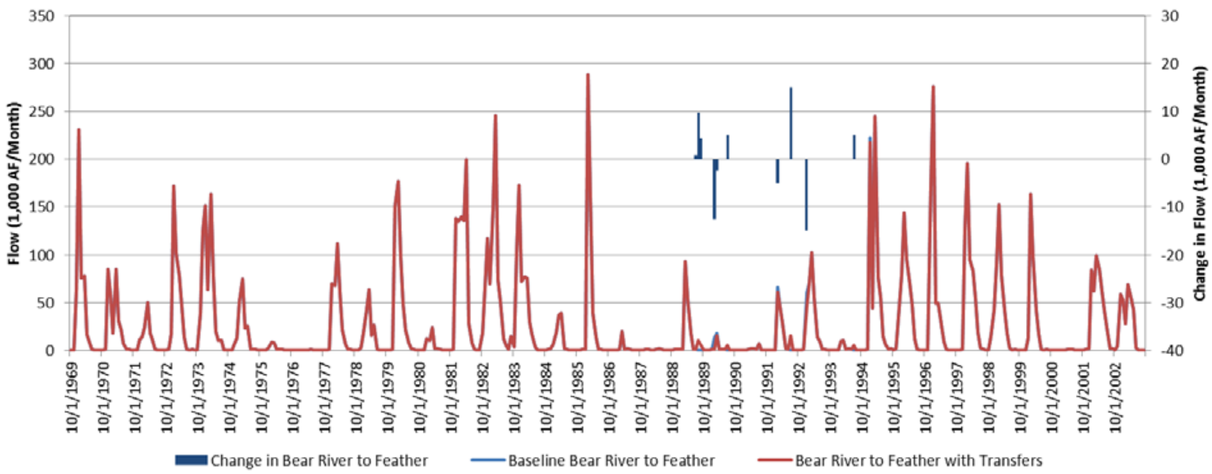

Figure B-~~26~~<u>27</u>. Bear River to the Feather River with and without Alternative 2 Transfers

The flow on the Lower Feather River represents an aggregation of flows on the Yuba River, Bear River, and upper portions of the Feather River. There are also increases due to water made available by groundwater substitution transfers along the Feather River between Thermalito and the confluence with the Sacramento. Figure B-~~27~~ <u>28</u> illustrates the effect to the Feather River.

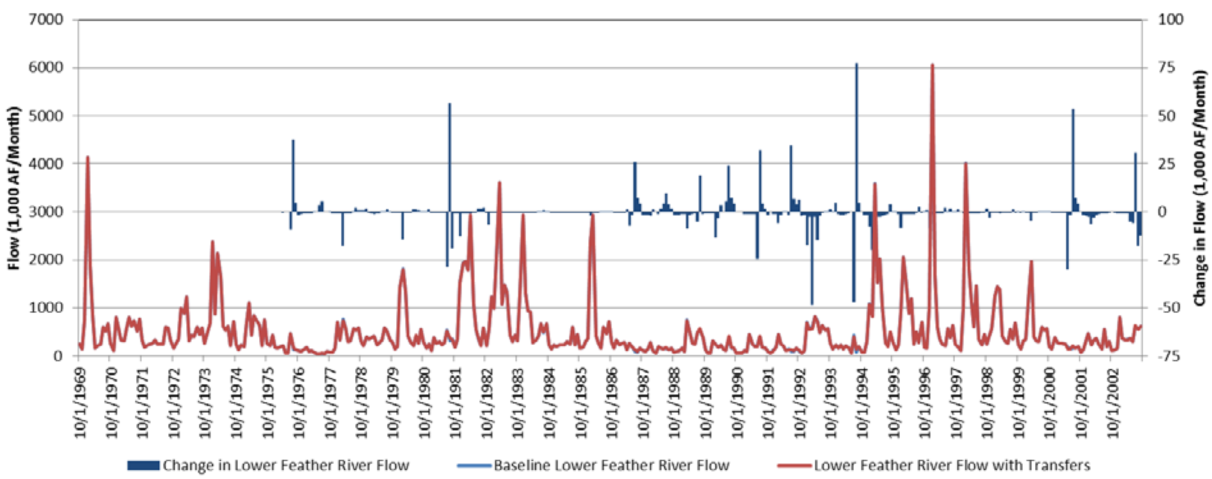

Figure B-~~27~~<u>28</u>. Lower Feather River with and without Alternative 2 Transfers

Figure B-~~28~~ <u>29</u> illustrates the flow of the Sacramento River at Freeport. This location is an aggregation of all changes on the Sacramento River at Wilkins Slough, the Lower Feather River, the American River at H Street, and changes between those locations and Freeport. Changes between those locations and Freeport include increases in flow due to water made available through groundwater substitution and crop idling transfers and decreases due to stream-aquifer interaction. Reductions in flow of approximately 50 TAF or more are a result of changes in stream and flood bypass flows during surplus conditions after one or more years of groundwater substation transfers. These changes are also illustrated above in Figure B-~~6~~7.

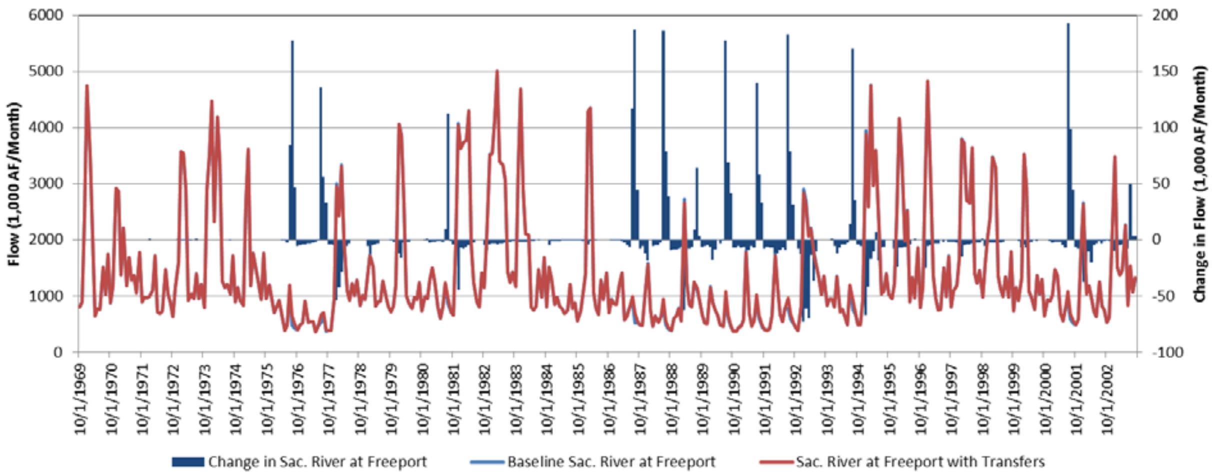

Figure B-~~28~~29. Sacramento River at Freeport with and without Alternative 2 Transfers

Figure B-~~29~~ 30 illustrates the changes on the Merced River at the confluence with the San Joaquin River. Increases in Merced River flow represent transfer water made available by reservoir releases at Lake McClure; decreases occur when Lake McClure refills.

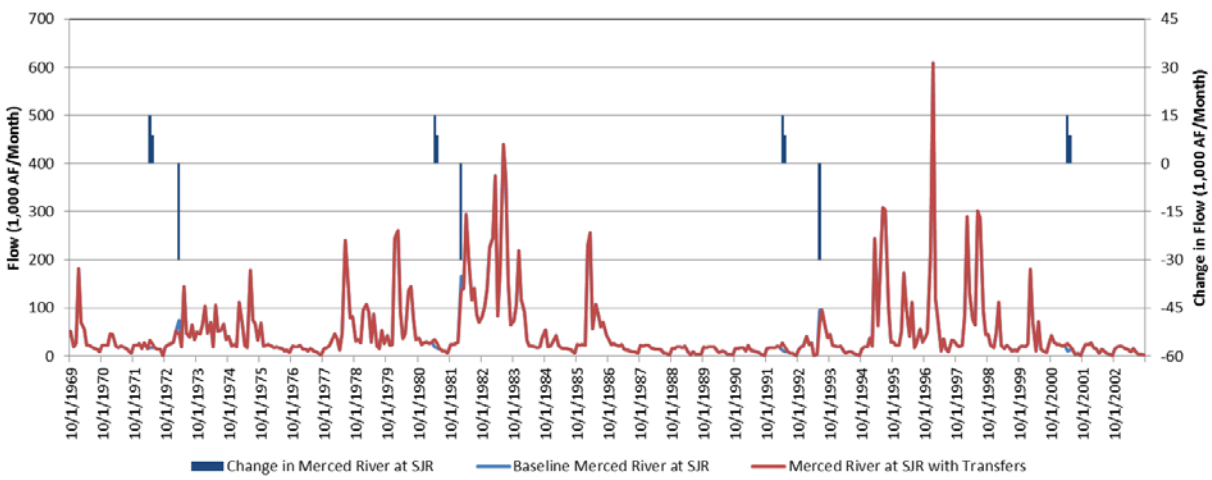

Figure B-~~29~~30. Merced River at the San Joaquin River with and without Alternative 2 Transfers

Figure B-~~30~~ 31 illustrates San Joaquin River flows at Vernalis. Increases in flow are Merced ID transfer water to be diverted at Banta Carbona ID and conveyed to the DMC. Decreases in flow occur when Lake McClure refills space vacated during reservoir release transfers.

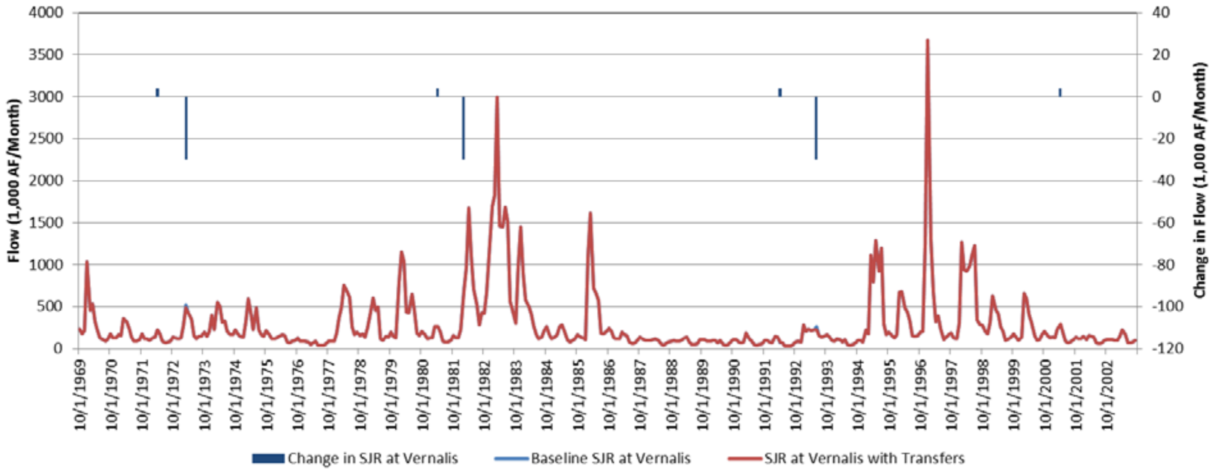

Figure B-~~30~~31. San Joaquin River at Vernalis with and without Alternative 2 Transfers

Changes to Delta outflow are illustrated below in Figure B-~~31~~32. Increases in Delta outflow are primarily due to carriage water to facilitate transfers through the Delta. Decreases in Delta outflow are attributed to reservoir refill upstream and changes in stream-aquifer interaction.

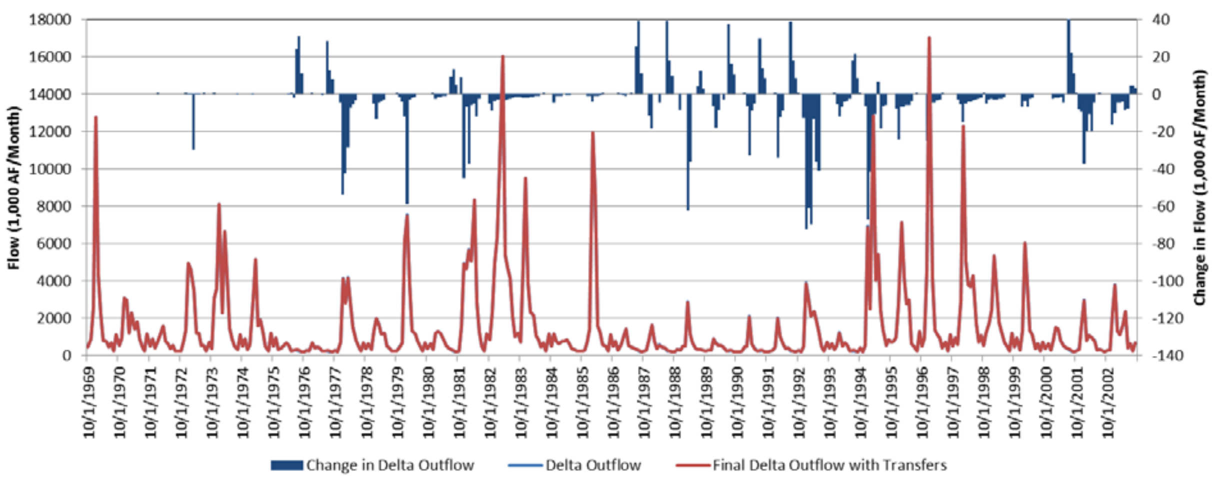

Figure B-~~31~~32. Delta Outflow with and without Alternative 2 Transfers

Table B-1 summarizes changes in Delta outflow on an average monthly basis. Average annual Delta outflow is decreased by approximately 31 TAF with decreases November through June and increases June through September.

Table B-1. Average Monthly Delta Outflow (TAF) for Alternative 2

Delta Outflow	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	393	867	1,490	3,260	3,312	3,278	1,753	1,381	816	546	297	638	18,031
With Transfers	393	867	1,485	3,250	3,300	3,268	1,748	1,378	813	554	303	641	18,000
Change	0	-1	-5	-10	-12	-10	-5	-3	-3	8	6	3	-31

B.6.2.3 Exports and Diversions

Figure B-~~32~~ 33 illustrates the change in exports at Jones Pumping Plant. Increases are generally due to export of transfer water for SLDMWA. Decreases in Jones exports are due to changes in Sacramento Valley stream-aquifer interaction that reduce Delta inflows.

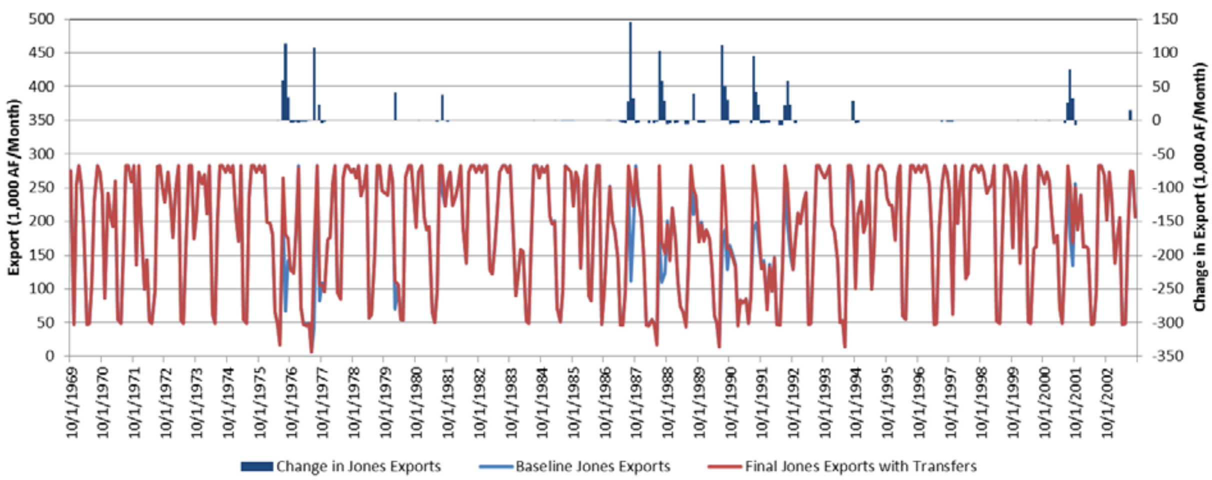

Figure B-~~32~~33. Exports at Jones Pumping Plant with and without Alternative 2 Transfers

Table B-2 summarizes the average monthly exports at Jones Pumping Plant for the baseline and with Project alternatives and the change. Increases occur during the transfer months of July, August, and September, with an average annual increase of 39 TAF.

Table B-2. Average Monthly Exports at Jones Pumping Plant (TAF) for Alternative 2

Jones Exports	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	222	212	235	197	186	198	69	65	153	256	252	223	2,268
With Transfers	221	211	235	197	187	198	69	65	152	272	270	231	2,306
Change	-1	-1	0	0	1	0	0	-1	-1	17	18	8	39

Transfer water can also be exported at Banks Pumping Plant. Banks exports also can be reduced when changes in stream-aquifer interaction affect the SWP. This is illustrated below in Figure B-~~33~~34.

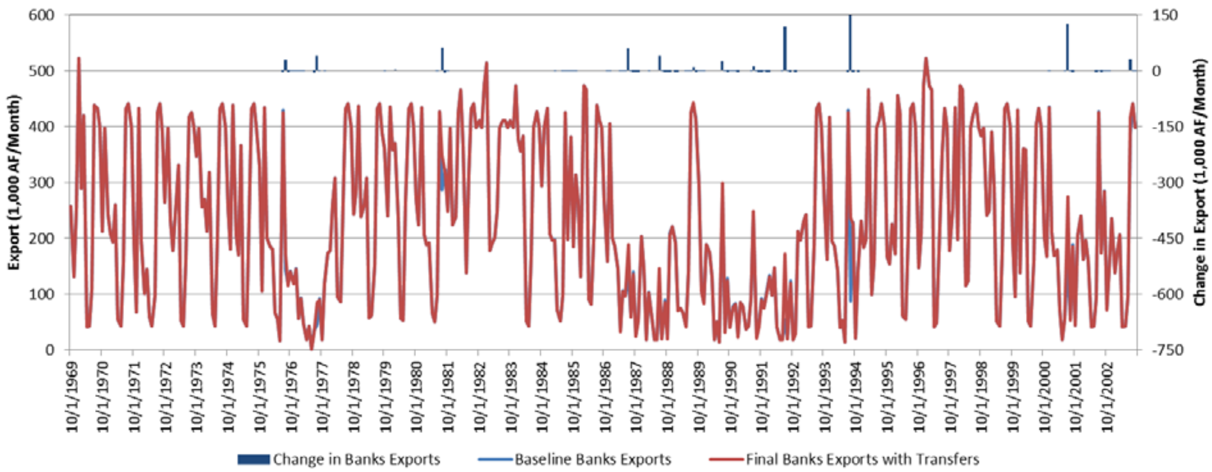

Figure B-~~33~~34. Exports at Banks Pumping Plant with and without Alternative 2 Transfers

Table B-3 summarizes the average monthly exports at Banks Pumping Plant for the baseline and with Project alternatives and the change. The average annual change is an increase of approximately 15 TAF.

Table B-3. Average Monthly Exports at Banks Pumping Plant (TAF) for Alternative 2

Banks Exports	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	202	212	307	222	239	261	70	62	156	363	316	320	2,731
With Transfers	201	211	307	221	239	261	70	62	156	375	324	319	2,746
Change	-1	-1	0	0	0	0	0	0	0	11	8	-1	15

Total CVP/SWP exports, the sum of exports at Jones and Banks Pumping Plants, are illustrated in Figure B-~~34~~35.

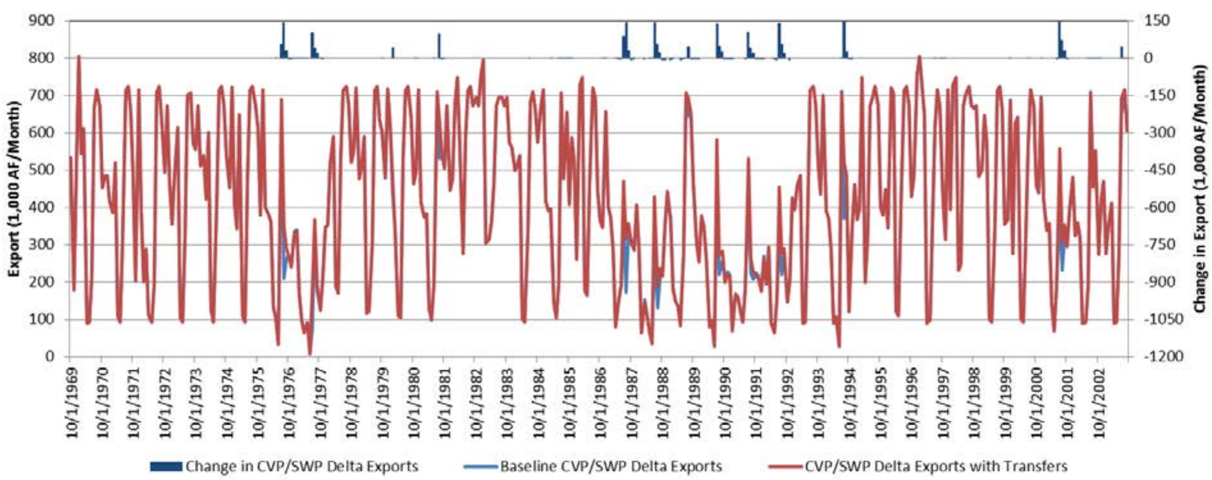

Figure B-~~34~~36. Total CVP/SWP Exports from the Delta with and without Alternative 2 Transfers

Table B-4 summarizes the average monthly combined CVP/SWP exports. The average annual change under Alternative 2 is approximately 54 TAF.

Table B-4. Average Monthly Combined CVP/SWP Exports (TAF) for Alternative 2

CVP/SWP Exports	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	424	424	543	419	425	459	138	128	309	619	568	543	4,998
With Transfers	422	422	542	418	426	459	138	127	308	647	594	549	5,052
Change	-2	-2	-1	-1	1	0	0	-1	-1	28	26	6	54

Transfer water is also diverted by East Bay MUD at the Freeport Regional Water Project (Freeport) and by Contra Costa WD at their diversion facilities on Rock Slough, Old River, and Victoria Canal. Figure B-35 36 illustrates changes in diversions by East Bay MUD at Freeport. Baseline East Bay MUD diversions represent diversion of CVP project water under East Bay MUD's existing contract. Diversion of transfer water occurs during months when East Bay MUD is also diverting CVP project water and increases the total East Bay MUD Freeport diversion up to the available capacity.

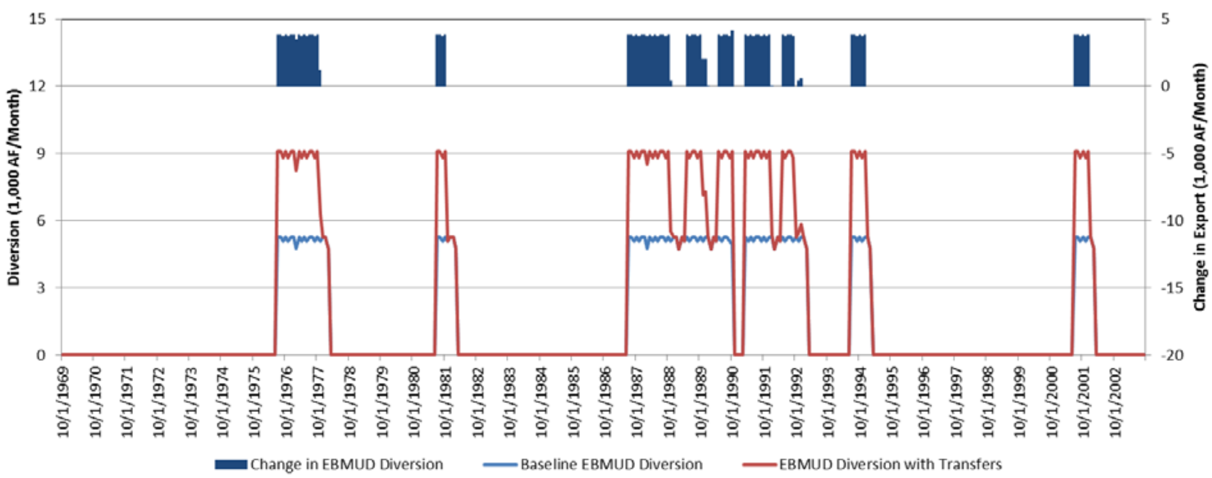

Figure B-3536. East Bay MUD Diversions with and without Alternative 2 Transfers

Contra Costa WD diversions increase to take delivery of transfer water as illustrated below in Figure B-3637. Contra Costa WD identified an annual transfer demand of up to 15 TAF and this volume of water diverted at a rate of five TAF per month during the July through September period. Contra Costa WD diversions of transfer water are assumed to occur at the point of diversion with the best water quality and available capacity.

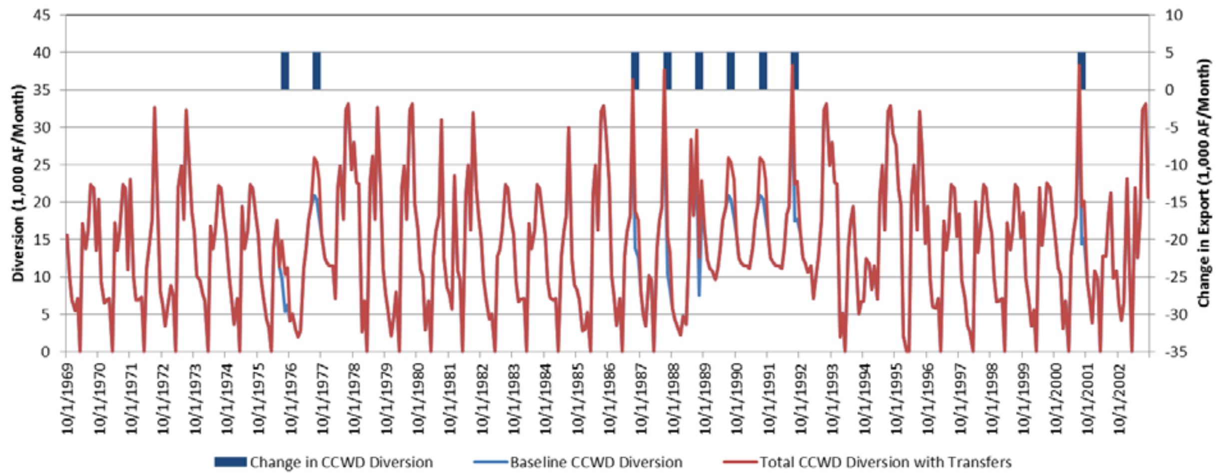

Figure B-~~36~~37. Contra Costa WD Diversions with and without Alternative 2 Transfers

B.6.3 Alternative 3: No Cropland Modifications

Alternative 3 would include transfers through groundwater substitution, stored reservoir release, and conservation. It would not include any cropland idling transfers.

Figure B-~~37~~ 38 summarizes the quantity of transfer water made available (Transfer Supply) under Alternative 3 on an annual basis, and illustrates where the water is diverted (Transfer Use). As in Alternative 2, a percentage of water to be transferred through the Delta becomes carriage water to maintain Delta water quality. Alternative 3 does not include crop idling transfer so there are no transfer supplies from that measure. Unused transfer water under this alternative is from the spill of Placer County Water Agency reservoir release water from Folsom before it can be released and re-diverted by East Bay MUD.

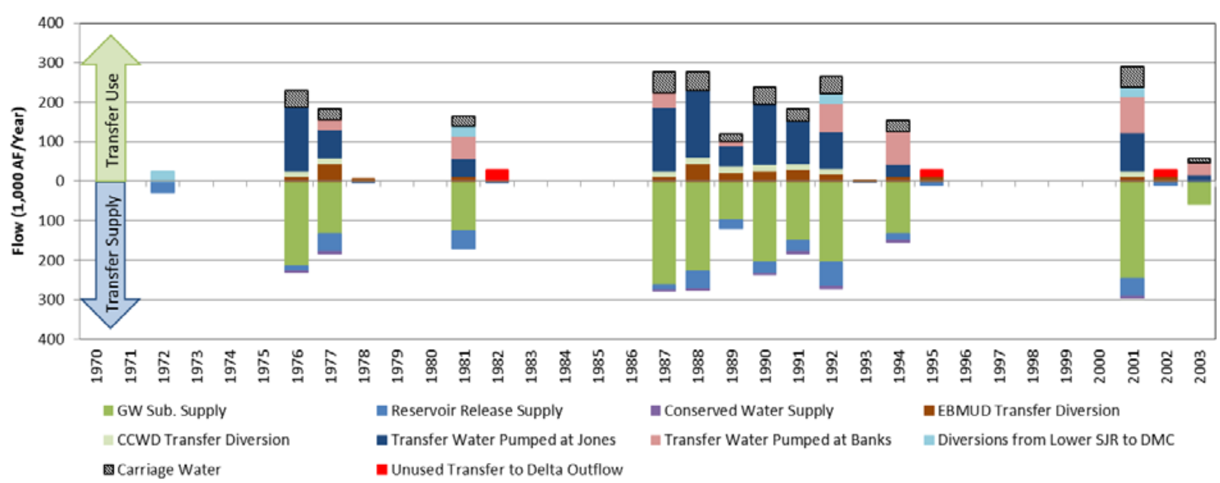

Figure B-~~37~~38. Annual Transfer Summary for Alternative 3

B.6.3.1 Storage

Changes in the operation of Shasta under Alternative 3 are similar to changes under Alternative 2 (see Figure B-~~38~~39). Increases in storage under Alternative 3 occur when groundwater substitution transfers start prior to July and transfer water is stored upstream. There are also small reductions in storage when additional releases are made to account for changes in Sacramento River flow as a result of groundwater substitution transfers.

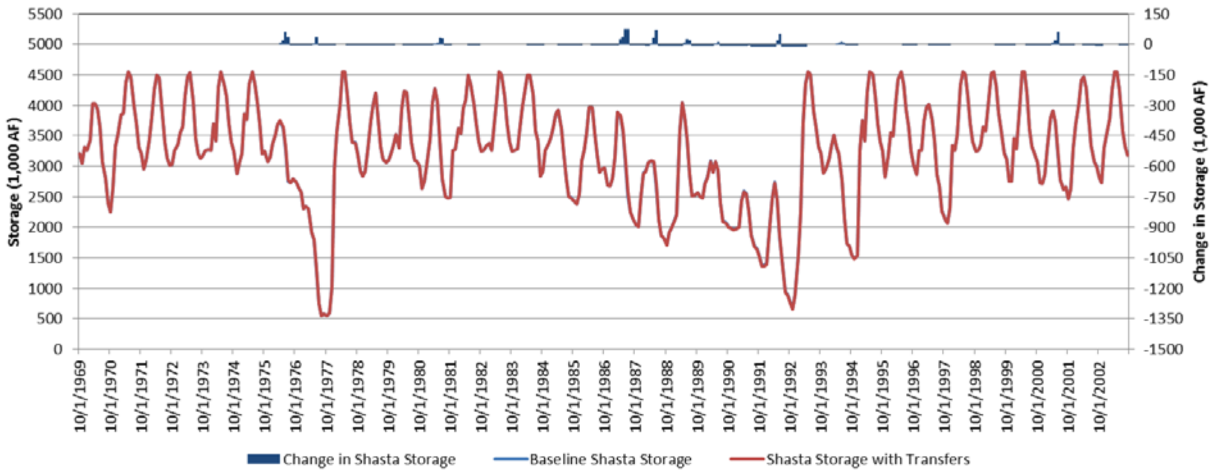

Figure B-~~38~~39. Shasta Operations with and without Alternative 3 Transfers

Folsom is used to regulate reservoir release transfers from Placer County Water Agency's upstream reservoirs before delivery to East Bay MUD. This operation can result in temporary changes in storage, as illustrated in Figure B-~~39~~40. Additional releases are also made out of Folsom to account for changes in river flows as a result of groundwater substitution transfers.

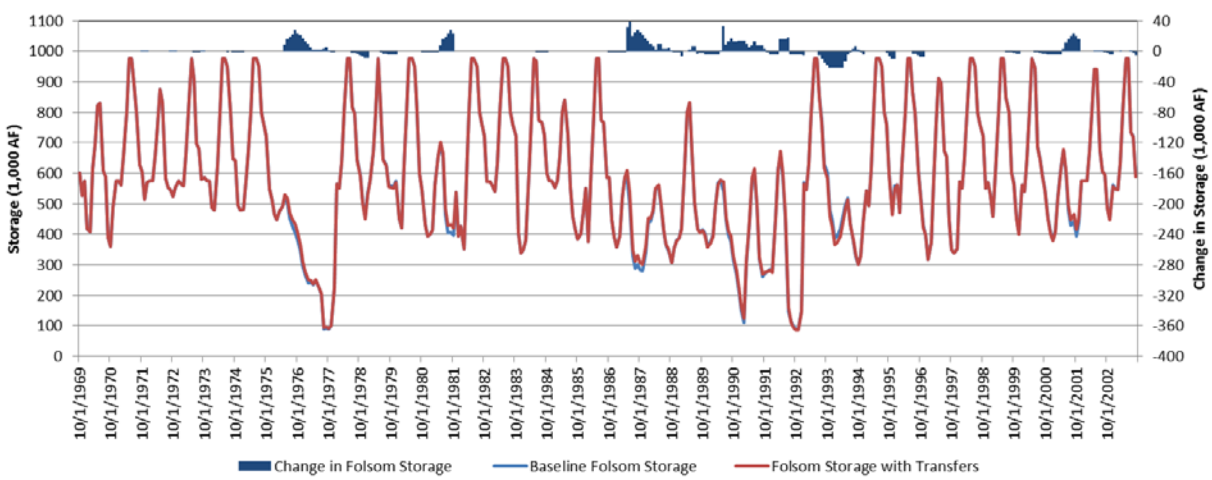

Figure B-~~39~~40. Folsom Operations with and without Alternative 3 Transfers

Figure B-~~40~~ 41 illustrates the change in operations at Oroville. Changes in Oroville operations result from shifting the timing of delivery of SWP water to accommodate transfers. There are also decreases in storage when additional water is released to maintain minimum flow requirements on the Lower Feather River. These additional releases from Oroville are made to account for reductions in Feather River flows due to groundwater substitution transfers.

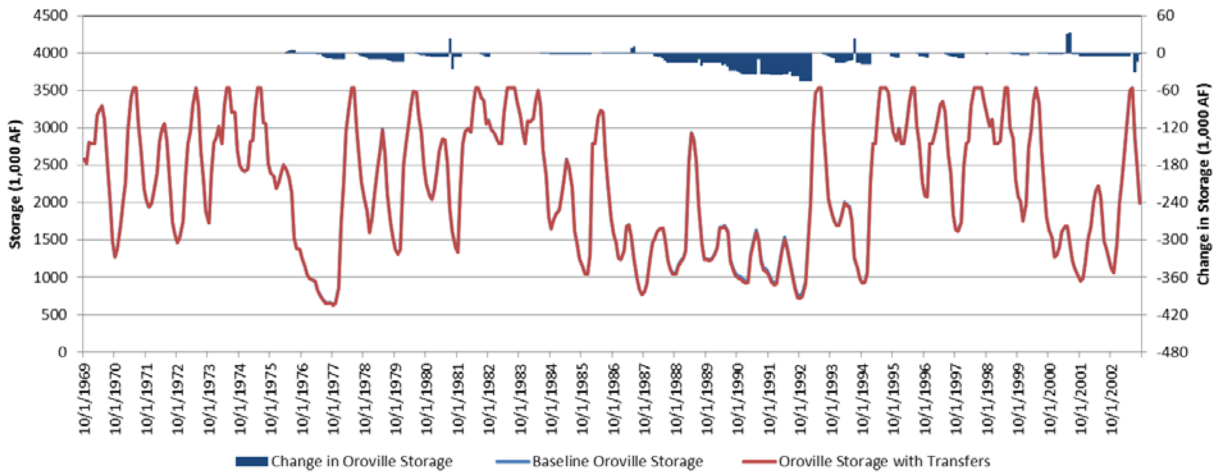

Figure B-~~40~~41. Oroville Operations with and without Alternative 3 Transfers

South Sutter WD releases water from Camp Far West Reservoir to participate in reservoir release transfers. Figure B-~~41~~ 42 illustrates the only change in reservoir storage from baseline conditions as the quantity released for transfer. Camp Far West Reservoir storage returns to baseline levels when the reservoir refills.

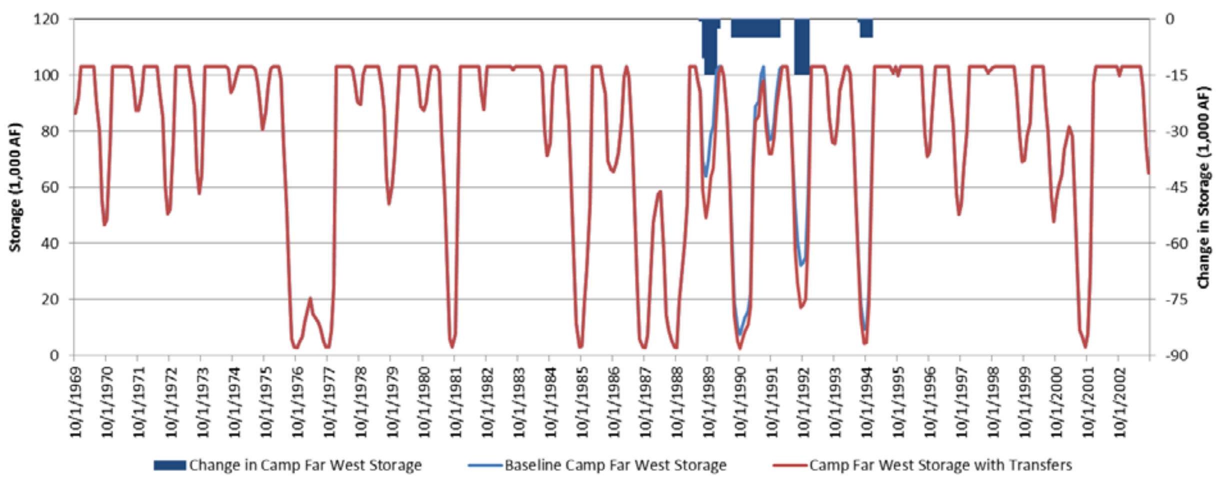

Figure B-~~41~~42. Camp Far West Operations with and without Alternative 3 Transfers

Browns Valley ID releases water from Merle Collins Reservoir to participate in reservoir release transfers. Figure B-~~42~~ 43 illustrates the only change in reservoir storage from baseline conditions as the quantity released for transfer, up to five TAF in any year. Merle Collins Reservoir storage returns to baseline levels when the reservoir refills.

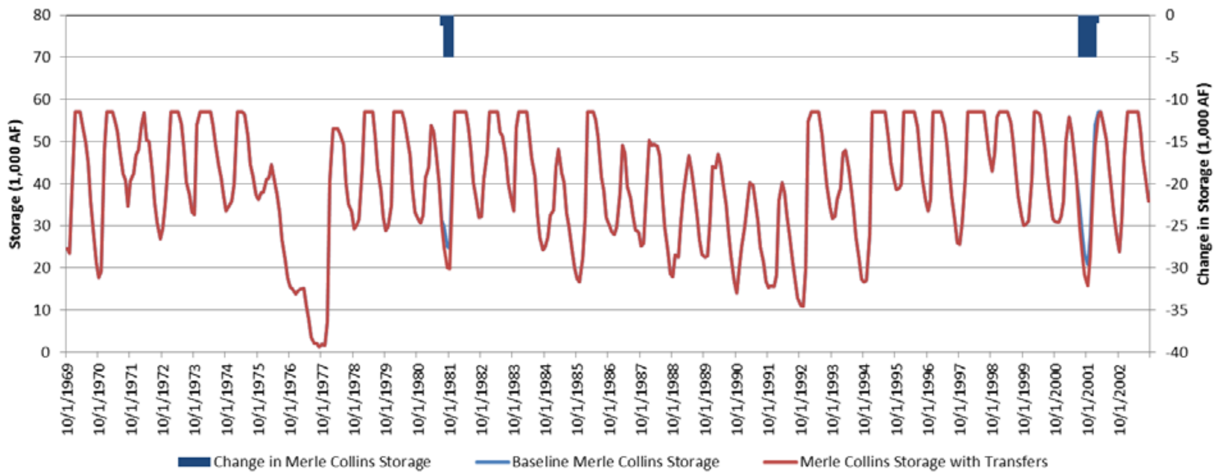

Figure B-~~42~~43. Merle Collins Operations with and without Alternative 3 Transfers

Placer County Water Agency releases water from MFP reservoirs of French Meadows and Hell Hole to participate in reservoir release transfers. Figure B-~~43~~ 44 illustrates the combined storage in these two reservoirs under both baseline and with Project operations. MFP reservoir storage returns to baseline levels when the reservoirs refill.

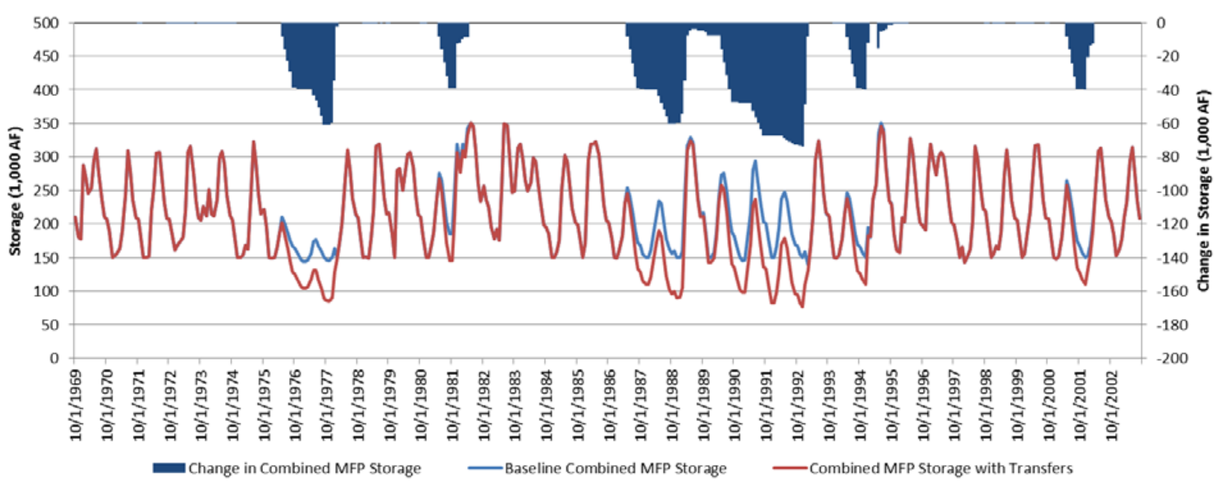

Figure B-~~43~~44. MFP Operations with and without Alternative 3 Transfers

Figure B-~~44~~ 45 illustrates change in storage of Lake McClure due to reservoir release transfers. Storage in Lake McClure can be lower by up to 30 TAF, the volume of reservoir release transfer, and returns to baseline levels when the reservoir refills with water that would otherwise have been released to maintain flood space requirements.

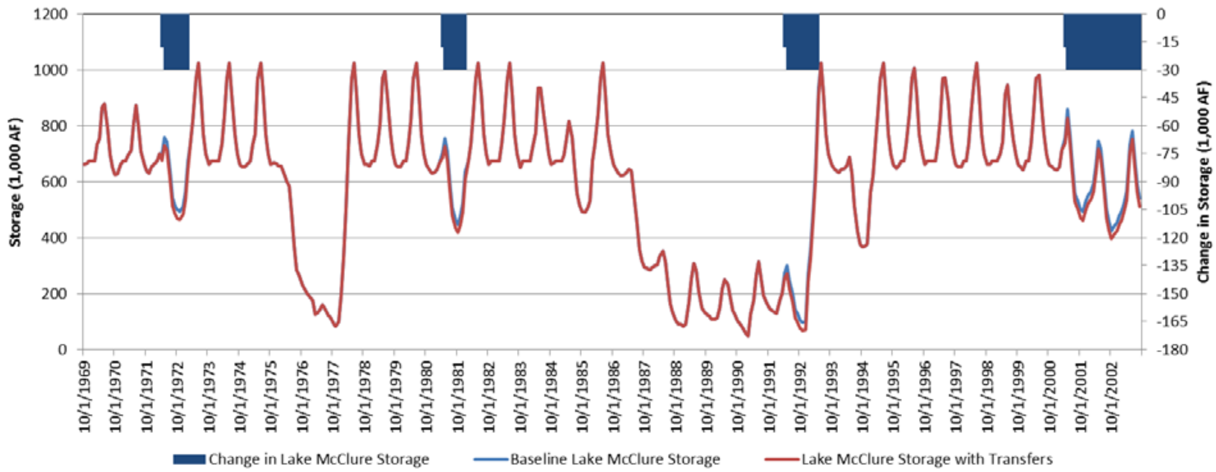

Figure B-~~44~~45. Lake McClure Operations with and without Alternative 3 Transfers

Conserved water from Browns Valley ID is stored in Yuba County Water Agency's New Bullards Bar Reservoir and released for transfer in years with demand and capacity. These releases of stored water are the primary effect to New Bullards Bar Reservoir as illustrated below in Figure B-~~45~~46.

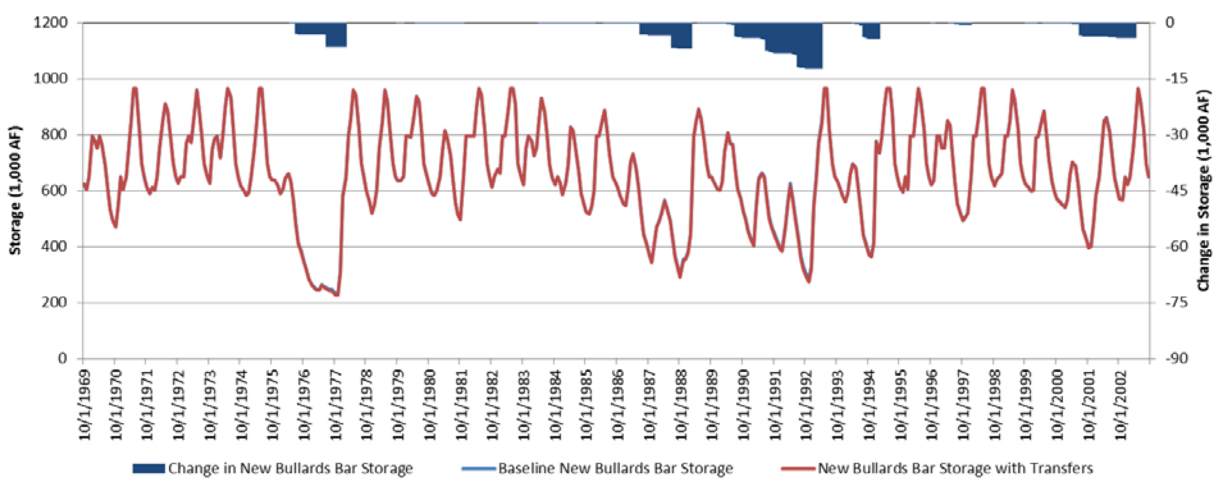

Figure B-~~45~~46. New Bullards Bar Operations with and without Alternative 3 Transfers

B.6.3.2 Stream Flow

Releases from Keswick Dam, as illustrated below in Figure B-~~46~~47, reflect changes in Shasta storage seen in Figure B-~~38~~39. A reduction in release corresponds to an increase in Shasta storage. Reduced releases typically occur in the April through June period when it may be possible to store transfer water made available downstream. Months of reduced releases are followed by increased releases as transfer water is released to be moved through the Delta during the July through September period.

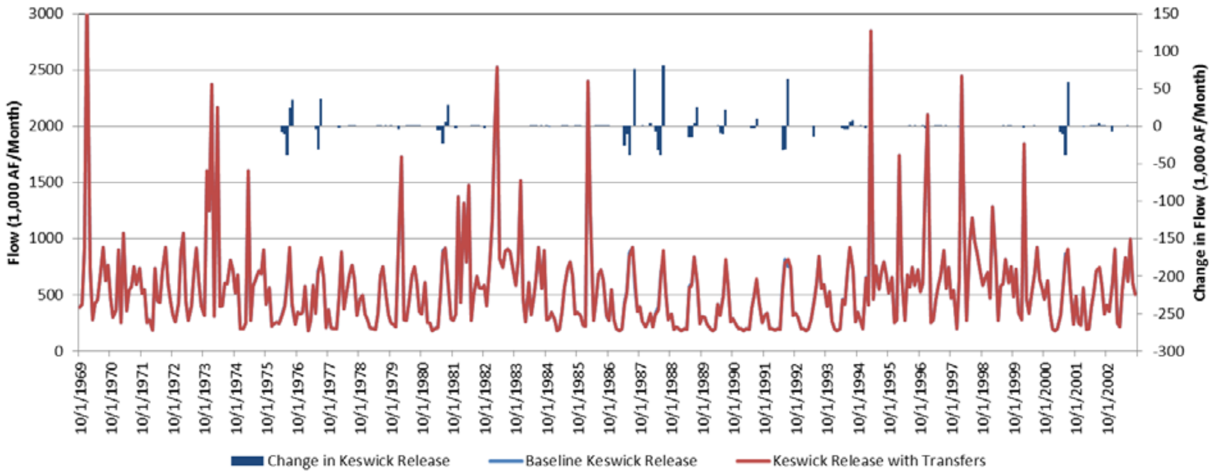

Figure B-~~46~~47. Keswick Dam Release with and without Alternative 3 Transfers

Figure B-~~47~~ 48 illustrates the effect to flows on the Sacramento River at Wilkins Slough. Flows are reduced when groundwater substitution transfers commence prior to July and are simulated as stored upstream in Shasta. Flows are increased in the July through September period when previously stored transfer water is released for delivery through the Delta, and additional groundwater substitution transfers occur upstream of Wilkins Slough.

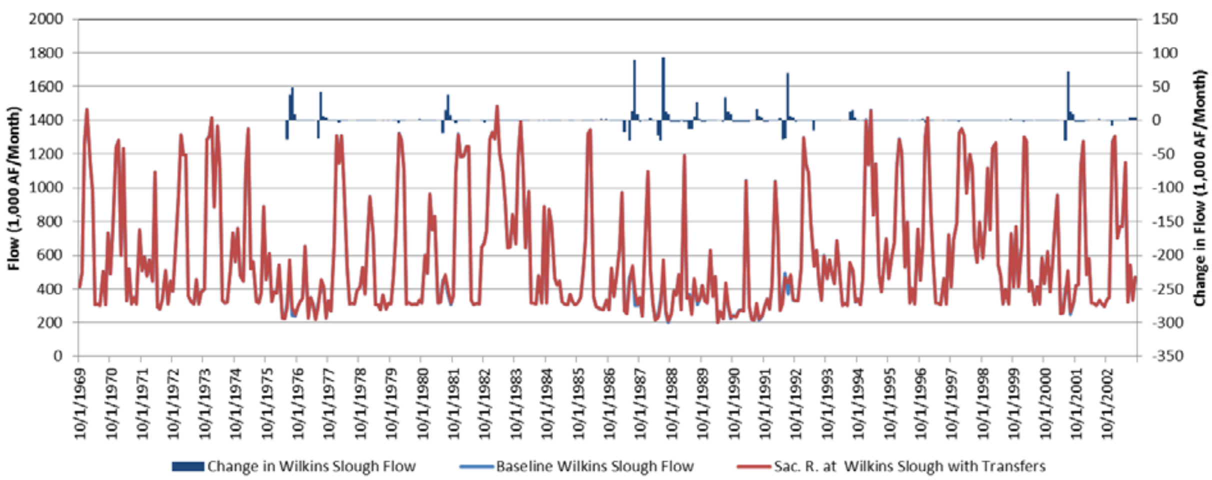

Figure B-~~47~~48. Sacramento River at Wilkins Slough with and without Alternative 3 Transfers

Figure B-~~48~~ 49 illustrates Nimbus Dam releases under baseline and with Alternate 3 transfers. Nimbus releases reflect CVP operations of Folsom

Reservoir. Increases in release of approximately five TAF are water made available by Placer County Water Agency and released from Folsom for re-diversion by East Bay MUD. Larger increases are typically preceded by decreases as transfer water made available downstream is stored in Folsom. Large releases occur when stored transfer water is release to be conveyed through the Delta. Decreases also occur when Placer County Water Agency's upstream reservoirs refill, typically during times when Folsom is also spilling water to maintain flood space requirements.

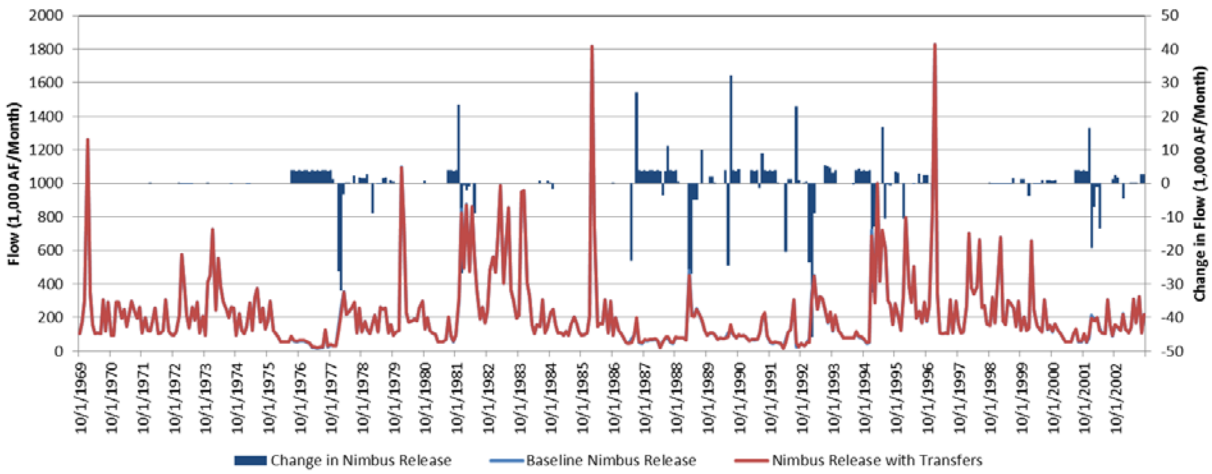

Figure B-4849. Nimbus Dam Release with and without Alternative 3 Transfers

The change in flow on the American River at H Street is similar as the change in release from Nimbus. Increases in flow are larger from July through September by the volume of groundwater substitution transfer made available by Sacramento Suburban WD and the City of Sacramento. Figure B-49 50 is a comparison of flows under baseline and Alternative 3.

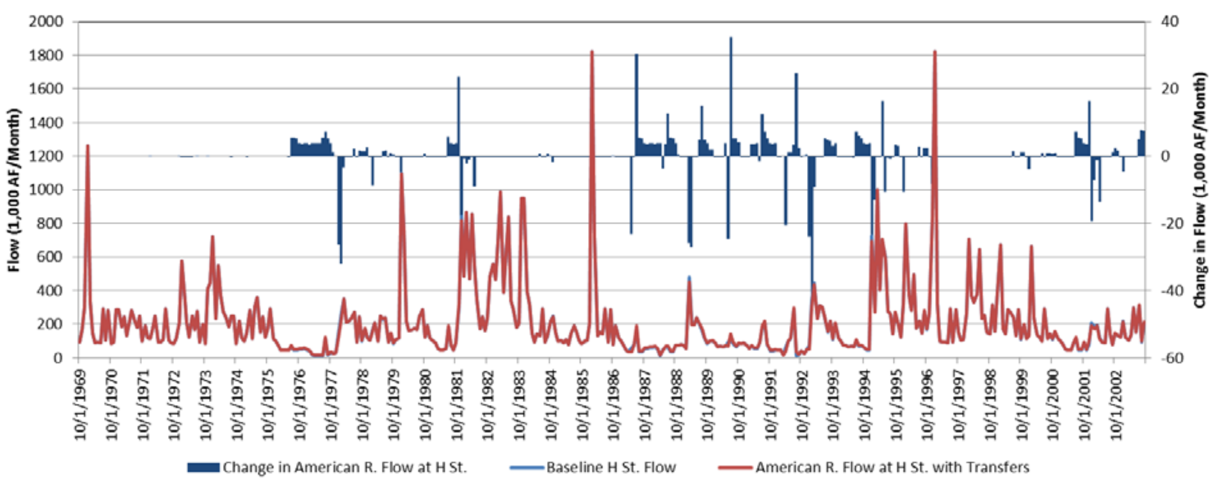

Figure B-4950. American River at H Street with and without Alternative 3 Transfers

Figure B-~~50~~ 51 illustrates changes in Feather River flow downstream from Thermalito. Flow in the Feather River below Thermalito changes due to changes in the operation of Oroville. Transfer water made available on the Feather River downstream from Thermalito can be temporarily stored in Oroville for release and transfer during the July through September period. Water stored prior to July reduces Feather River flow. Increases and decreases in flow on the Feather River below Thermalito also occur from shifts in timing of SWP water to accommodate transfers. The magnitude of some of these differences is affected by model nuances within CalSim II that can create variations from month-to-month in release of SWP water from Oroville for movement through the Delta.

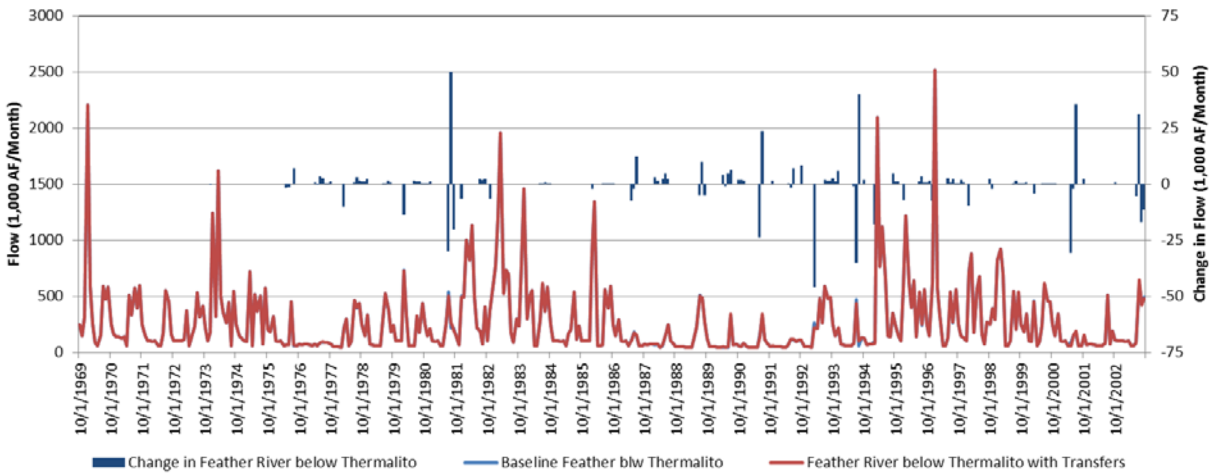

Figure B-~~50~~51. Feather River below Thermalito with and without Alternative 3 Transfers

Figure B-~~51~~ 52 illustrates changes in flow on the Yuba River as a result of New Bullards Bar Reservoir release of Browns Valley ID conserved water (increases) and reservoir refill (decreases).

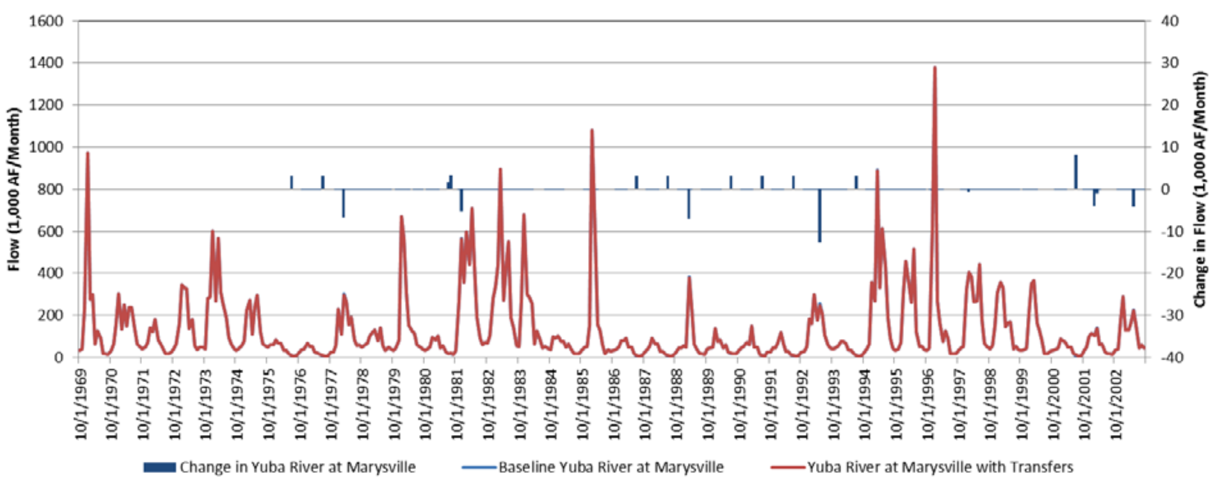

Figure B-~~51~~52. Yuba River at Marysville with and without Alternative 3 Transfers

Figure B-~~52~~ 53 illustrates the monthly flow of the Bear River at the confluence with the Feather River. Bear River flow changes as a result of South Sutter WD reservoir release transfers from Camp Far West Reservoir. Flows increase when water is released for transfer and decrease when Camp Far West refills.

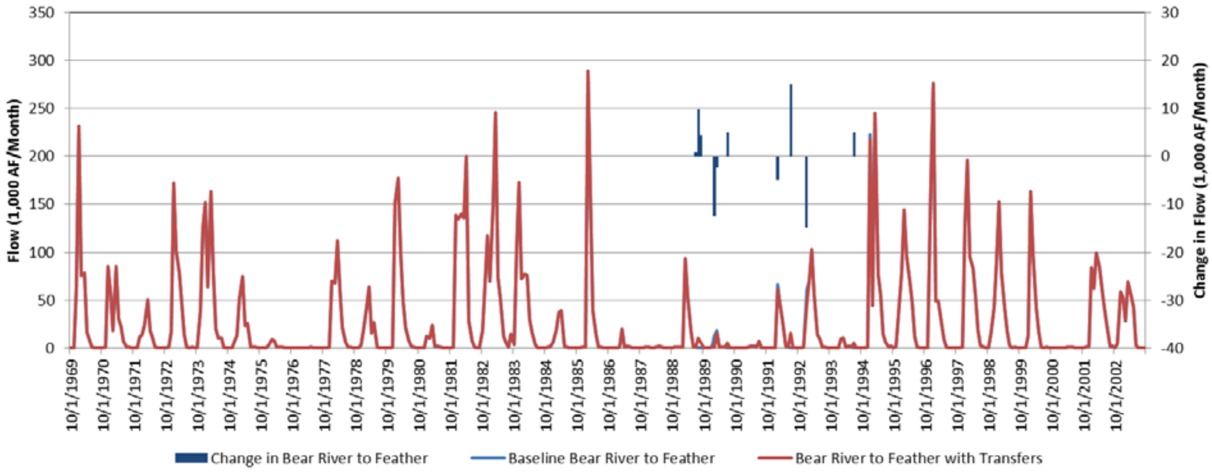

Figure B-~~52~~53. Bear River to the Feather River with and without Alternative 3 Transfers

The flow on the Lower Feather River represents an aggregation of flows on the Yuba River, Bear River, and upper portions of the Feather River. There are also increases due to water made available by groundwater substitution transfers along the Feather River between Thermalito and the confluence with the Sacramento. Figure B-~~53~~ 54 illustrates flows and changes in flows for the baseline and Alternative 3.

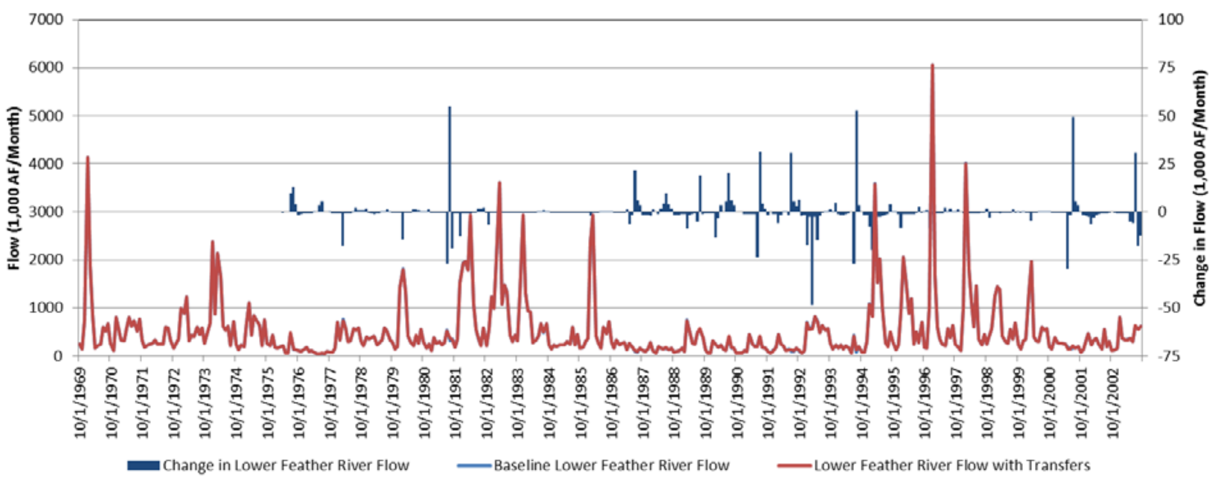

Figure B-~~53~~54. Lower Feather River with and without Alternative 3 Transfers

Figure B-~~54~~ 55 illustrates Sacramento River at Freeport under baseline and Alternative 3 transfers. This location is an aggregation of all changes on the

Sacramento River at Wilkins Slough, the Lower Feather River, and the American River at H Street, and changes between those locations and Freeport. Changes between those locations and Freeport include increases in flow due to water made available through groundwater substitution transfers and decreases due to stream-aquifer interaction. Reductions in flow of approximately 50 TAF or more are a result of changes in stream and flood bypass flows during surplus conditions after one or more years of groundwater substation transfers. These changes are also illustrated above in Figure B-~~6~~7.

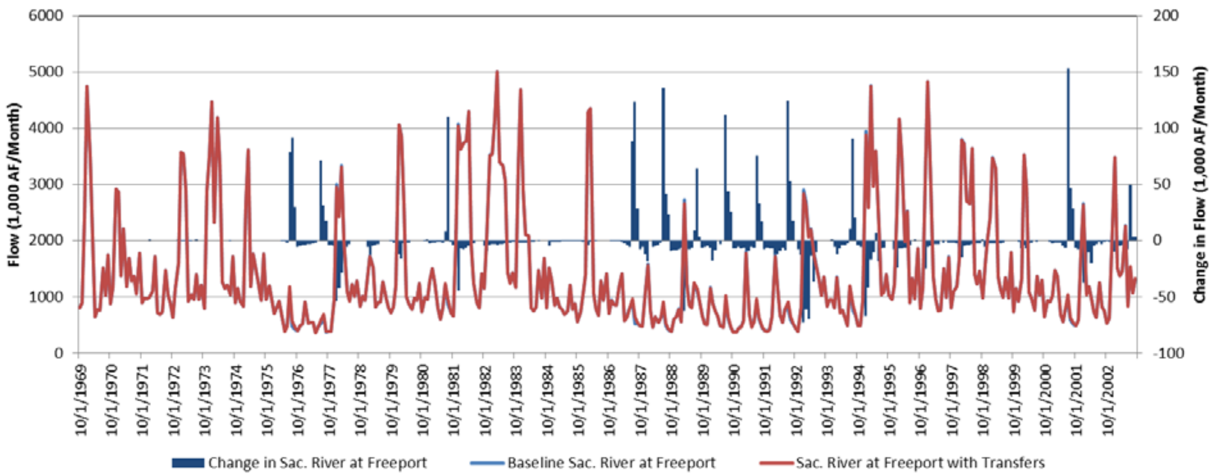

Figure B-~~54~~55. Sacramento River at Freeport with and without Alternative 3 Transfers

Figure B-~~55~~ 56 illustrates changes on the Merced River at the confluence with the San Joaquin River. Change in flow corresponds to storage change at Lake McClure; increases represent transfer water made available by reservoir releases at Lake McClure while decreases result from reservoir refill.

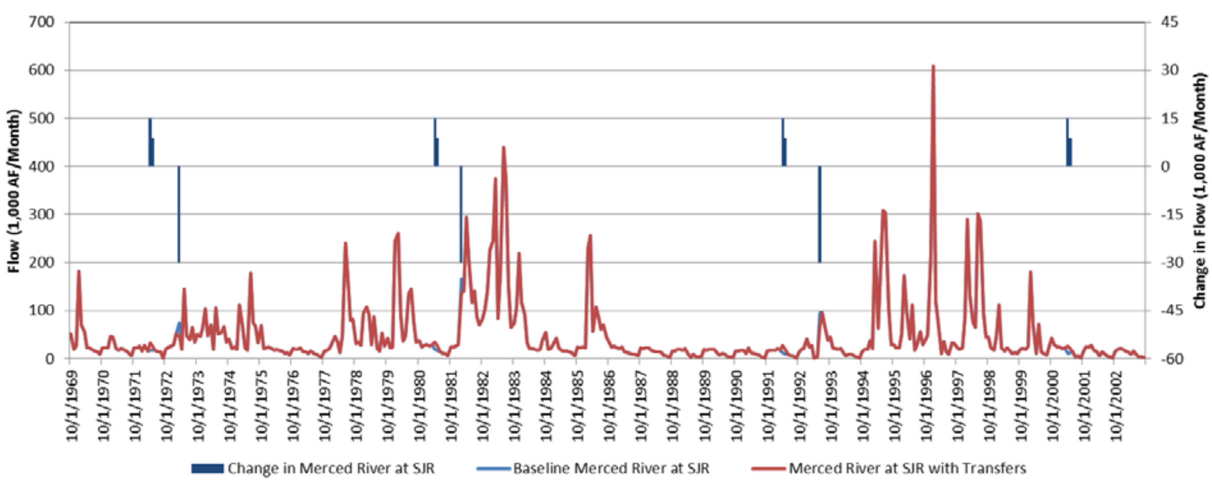

Figure B-~~55~~56. Merced River at the San Joaquin River with and without Alternative 3 Transfers

Figure B-~~56~~ 57 illustrates San Joaquin River flows at Vernalis. Increases in flow are Merced ID transfer water to be diverted at Banta Carbona ID and conveyed to the DMC prior to reaching the head of Old River. Decreases in flow occur when Lake McClure refills space vacated by reservoir release transfers and also reduce Delta outflow.

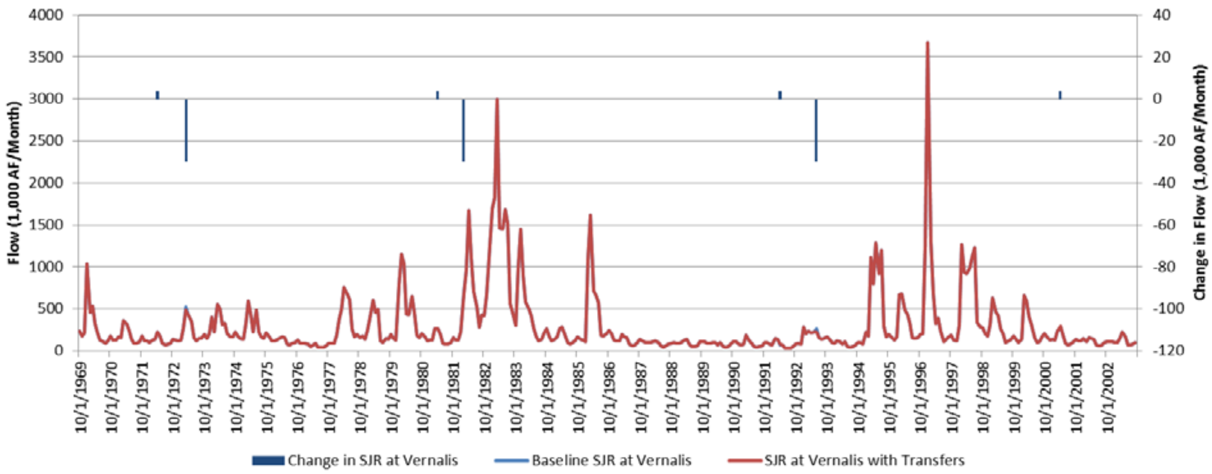

Figure B-~~56~~57. San Joaquin River at Vernalis with and without Alternative 3 Transfers

Changes to Delta outflow are illustrated below in Figure B-~~57~~58. Increases in Delta outflow are primarily due to carriage water to facilitate transfers. Decreases in Delta outflow are attributed to reservoir refill upstream and changes in stream-aquifer interaction during surplus conditions.

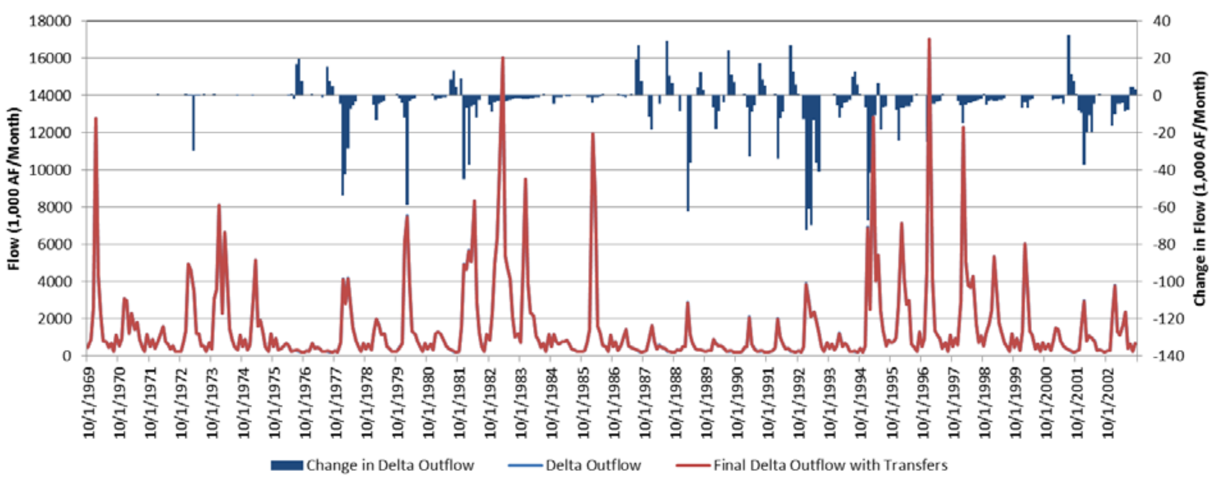

Figure B-~~57~~58. Delta Outflow with and without Alternative 3 Transfers

Table B-5 summarizes changes in Delta outflow on a monthly average basis. Average annual Delta outflow is reduced by approximately 31 TAF. Delta outflow increases from July through September due to carriage water for transfers through the Delta. Delta outflow is reduced from November through June when reservoirs refill and from changes in stream-groundwater interaction during surplus conditions.

Table B-5. Average Monthly Delta Outflow in (TAF) for Alternative 3

Delta Outflow	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	393	867	1,490	3,260	3,312	3,278	1,753	1,381	816	546	297	638	18,031
With Transfers	393	867	1,485	3,250	3,300	3,268	1,748	1,378	813	552	301	640	17,995
Change	0	-1	-5	-10	-12	-10	-5	-3	-3	6	4	2	-37

B.6.3.3 Exports and Diversions

Figure B-~~58~~ 59 illustrates the change in exports at Jones Pumping Plant. Increases are primarily transfer water exported to SLDMWA. Decreases in exports at Jones occur as a result of changes in stream-groundwater interaction that reduce Delta inflow during balanced conditions.

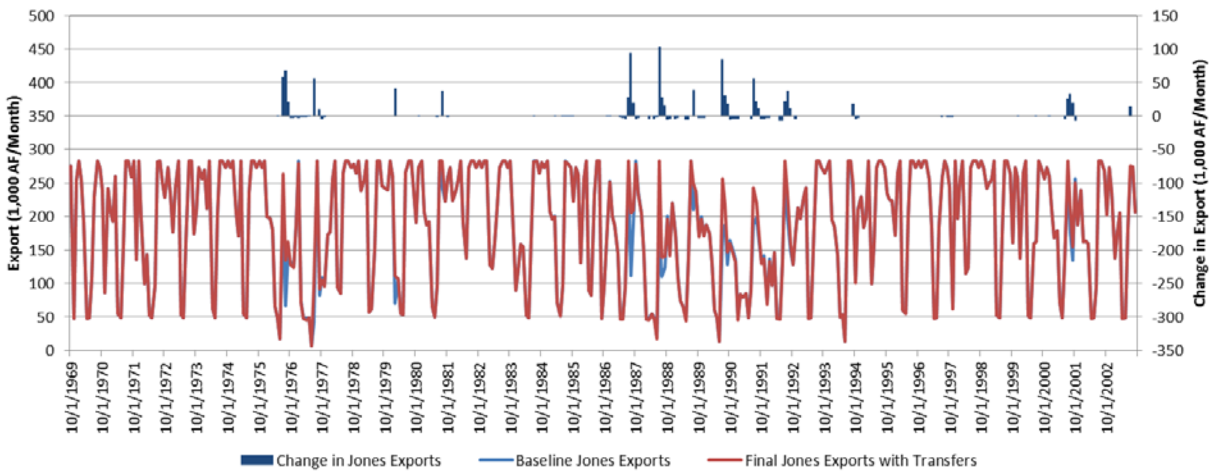

Figure B-~~58~~59. Exports at Jones Pumping Plant with and without Alternative 3 Transfers

Table B-6 summarizes the average monthly exports at Jones Pumping Plant. Increases occur during the transfer months of July, August, and September, with an average annual increase of 25 TAF. There are small decreases in most other months.

Table B-6. Average Monthly Exports at Jones Pumping Plant (TAF) for Alternative 3

Jones Exports	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	222	212	235	197	186	198	69	65	153	256	252	223	2,268
With Transfers	221	211	235	197	187	198	69	65	152	269	263	227	2,292
Change	-1	-1	0	0	1	0	0	-1	-1	13	11	4	25

Increases in exports at Banks Pumping Plant occur when Banks is used to export transfer water. This is illustrated below in Figure B-~~59~~60.

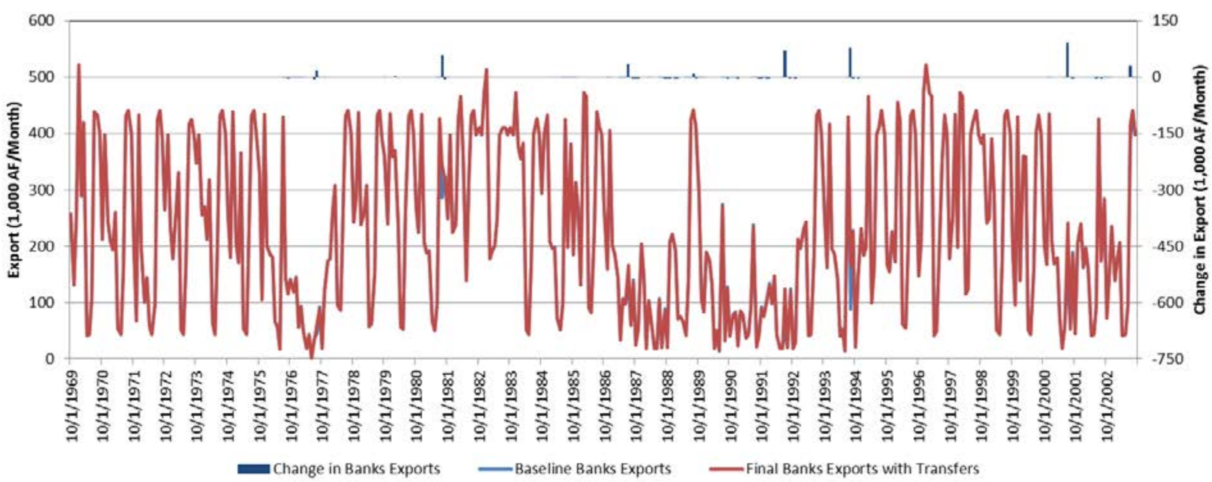

Figure B-~~59~~60. Exports at Banks Pumping Plant with and without Alternative 3 Transfers

Table B-7 summarizes the average monthly exports at Banks Pumping Plant. Pumping increases in the months of July, August, and September with an average annual increase of 8.3 TAF.

Table B-7. Average Monthly Exports at Banks Pumping Plant (TAF) for Alternative 3

Banks Exports	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	202	212	307	222	239	261	70	62	156	363	316	320	2,731
With Transfers	201	211	307	221	239	261	70	62	156	370	320	319	2,737
Change	-1	-1	0	0	0	0	0	0	0	6	4	-1	6

Total CVP/SWP exports, the sum of exports at Jones and Banks Pumping Plants, are illustrated in Figure B-~~60~~61.

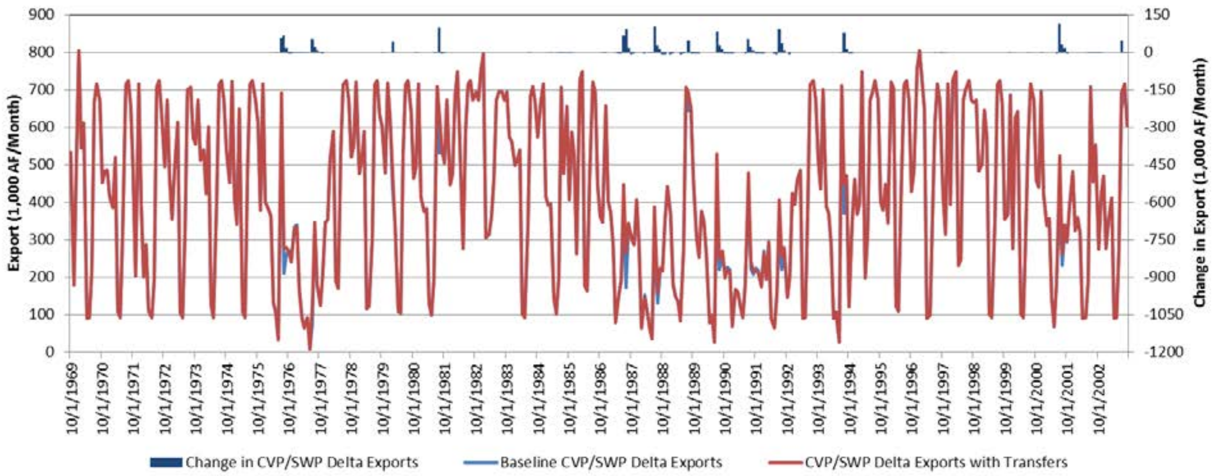

Figure B-~~60~~61. Total CVP/SWP Exports from the Delta with and without Alternative 3 Transfers

Table B-8 summarizes the average monthly combined CVP/SWP exports. The average annual change under Alternative 3 is approximately 31 TAF. Exports increase in the July through September period and decrease in most other months.

Table B-8. Average Monthly Combined CVP/SWP Exports (TAF) for Alternative 3

CVP/SWP Exports	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	424	424	543	419	425	459	138	128	309	619	568	543	4,998
With Transfers	422	422	542	418	426	459	138	127	308	638	583	546	5,030
Change	-2	-2	-1	-1	1	0	0	-1	-1	19	16	3	31

Figure B-~~61~~ 62 illustrates baseline, Alternative 3, and the change in East Bay MUD diversions at Freeport. The changes are an increase in diversions during months when East Bay MUD would be taking CVP Project water.

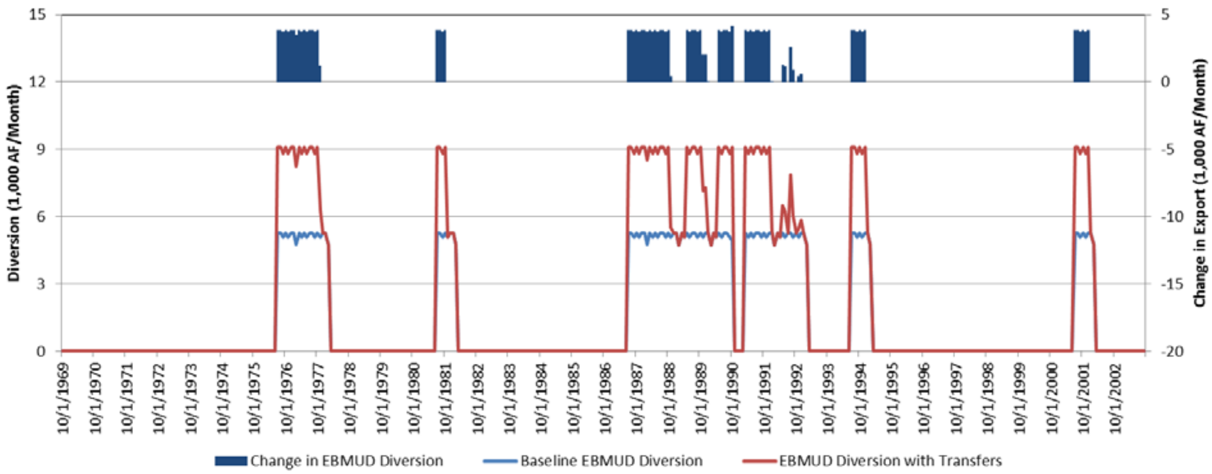

Figure B-~~61~~62. East Bay MUD Diversions with and without Alternative 3 Transfers

Contra Costa WD diversions increase to take delivery of transfer water as illustrated below in Figure B-~~62~~63. Contra Costa WD identified an annual transfer demand of up to 15 TAF and this volume of water diverted at a rate of five TAF per month during the July through September period. Contra Costa WD diversions of transfer water are assumed to occur at the point of diversion with the best water quality and available capacity.

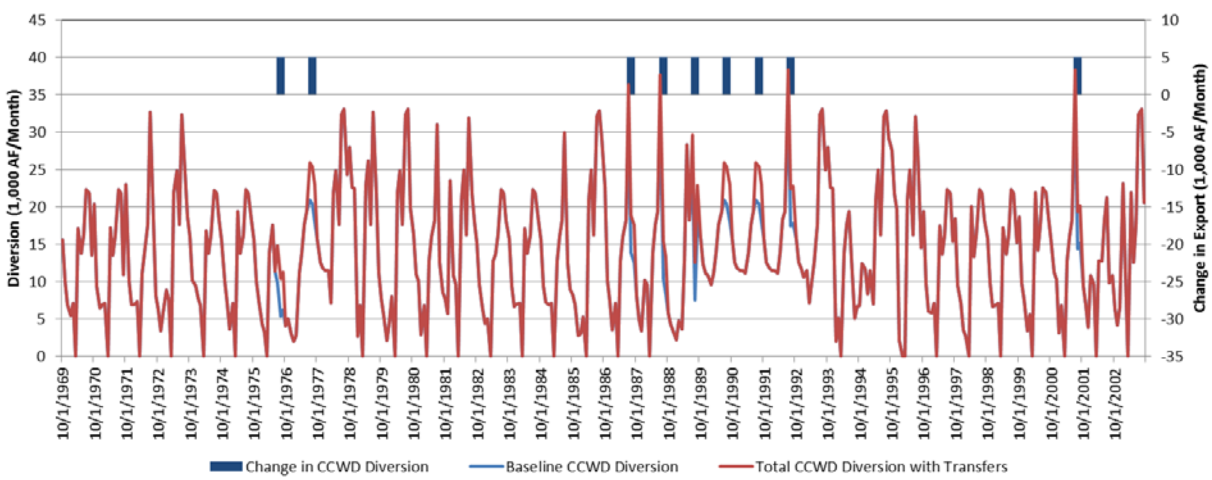

Figure B-~~62~~63. Contra Costa WD Diversions with and without Alternative 3 Transfers

B.6.4 Alternative 4: No Groundwater Substitution

Alternative 4 would include transfers through cropland idling, crop shifting, stored reservoir release, and conservation. It would not include any groundwater substitution transfers.

Figure B-~~63~~ 64 summarizes the quantity of transfer water made available under Alternative 4 on an annual basis and illustrates where the water is diverted or used. As in the other alternatives, a percentage of water to be transferred through the Delta goes to carriage water to maintain Delta water quality with increased exports under the transfer alternative. The volume of crop idling water available under Alternative 4 is greater than under Alternative 2 because some sellers may choose to expand crop idling transfers if groundwater substitution transfers are not used.

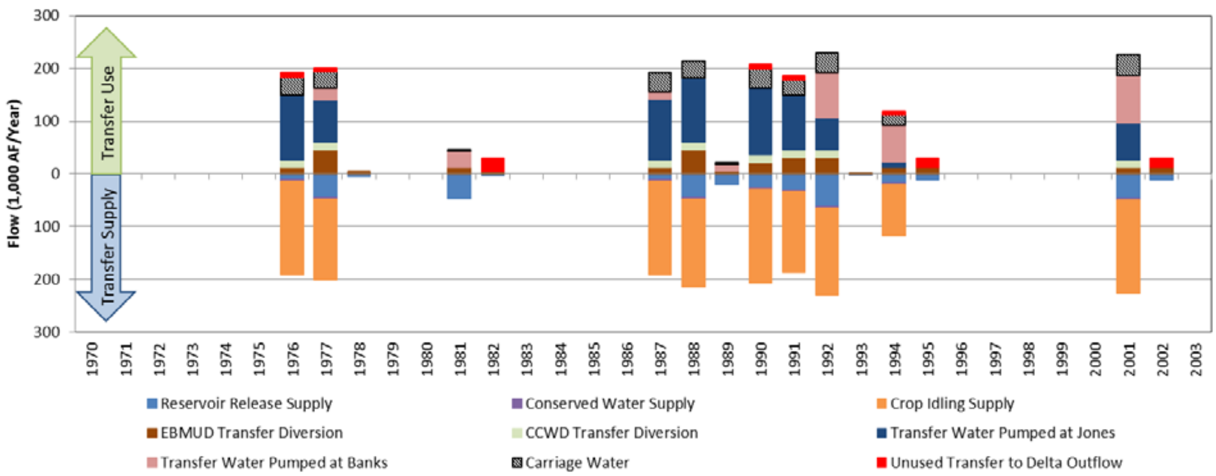

Figure B-~~63~~64. Annual Transfers Summary for Alternative 4

B.6.4.1 Storage

Figure B-~~64~~ 65 illustrates the change in operations at Shasta with the Project. Under Alternative 4 Shasta storage increases in some month when transfer water made available in May and June from crop idling can be stored for transfer in July, August, and September. There are no reductions in Shasta storage under this alternative because there are no releases in excess of baseline releases to account for changes in stream-aquifer interaction.

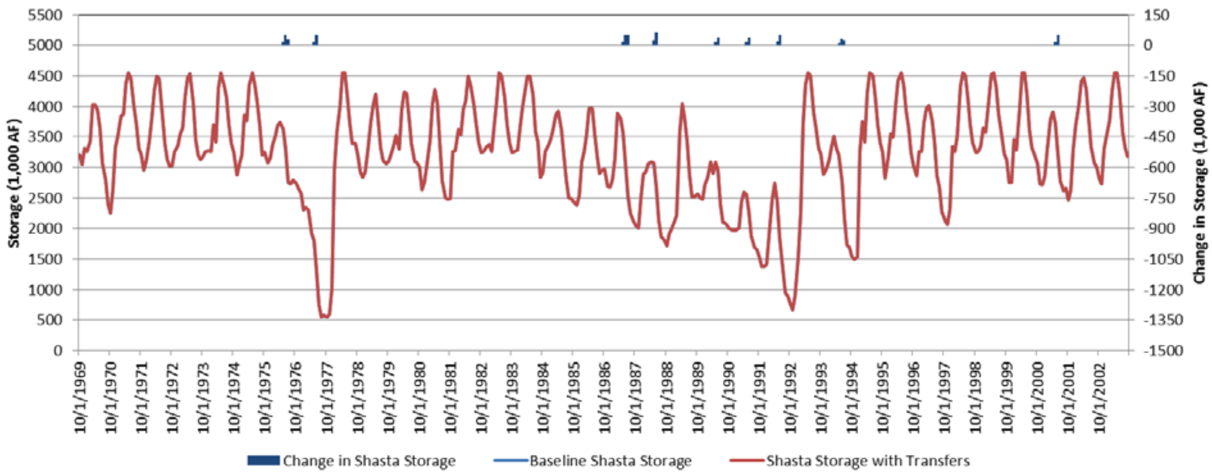

Figure B-~~64~~65. Shasta Operations with and without Alternative 4 Transfers

Operations at Folsom under Alternative 4 are illustrated below in Figure B-~~65~~66. Transfer water can be temporarily stored in Folsom for release and delivery in subsequent months. This includes transfers from crop idling in the Sacramento Valley, and reservoir release from upstream Placer County Water Agency reservoirs.

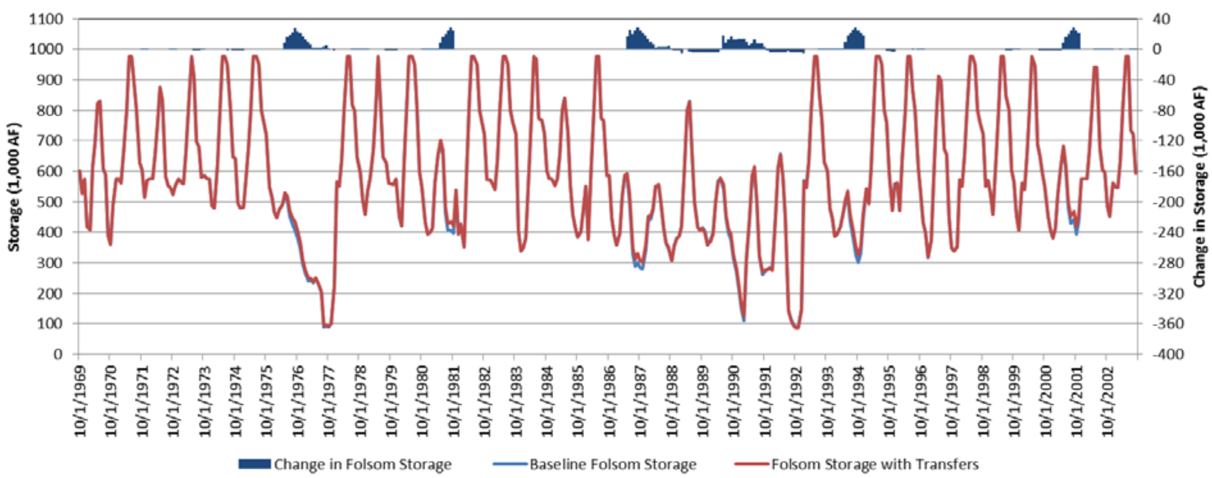

Figure B-~~65~~66. Folsom Operations with and without Alternative 4 Transfers

Figure B-~~66~~ 67 illustrates the change in SWP operations at Oroville. Changes in Oroville storage occur from shifts in the timing of delivery of SWP water to accommodate transfers and temporary storage of crop idling water.

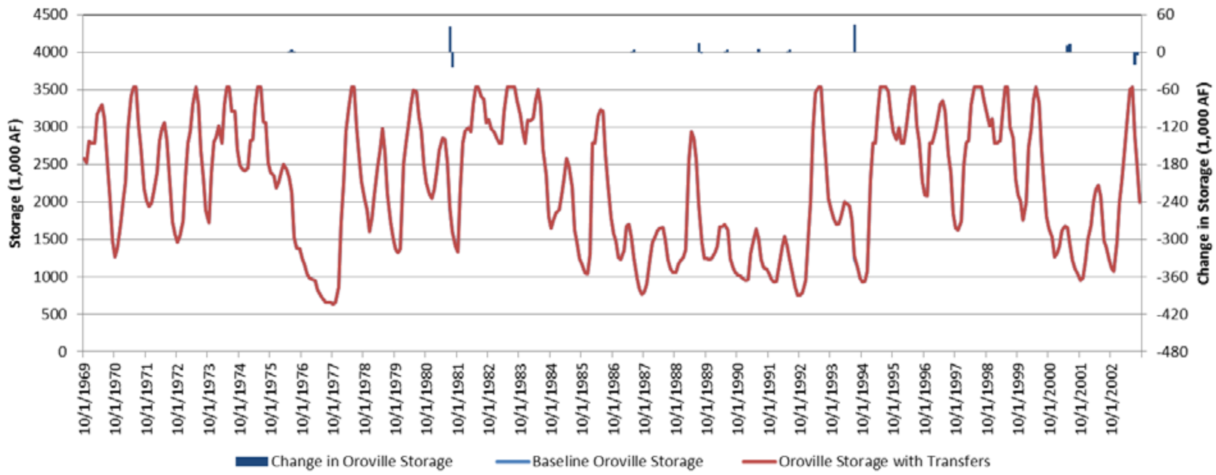

Figure B-~~66~~67. Oroville Operations with and without Alternative 4 Transfers

South Sutter WD releases water from Camp Far West Reservoir to participate in reservoir release transfers. Figure B-~~67~~ 68 illustrates the only change in reservoir storage from baseline conditions as the quantity released for transfer. Camp Far West Reservoir storage returns to baseline levels when the reservoir refills.

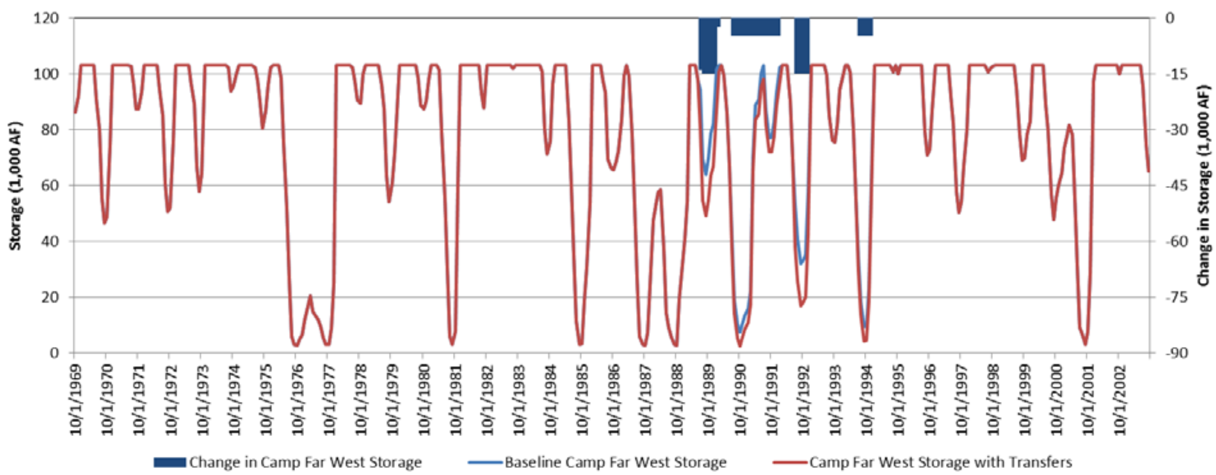

Figure B-~~67~~68. Camp Far West Operations with and without Alternative 4 Transfers

Browns Valley ID releases up to five TAF of water from Merle Collins Reservoir for transfer. Changes in Merle Collins storage are the same for Alternatives 2, 3, and 4 because all alternatives include reservoir release transfer measures. Figure B-~~68~~ 69 illustrates Browns Valley ID operations of Merle Collins when making reservoir release transfers of up to five TAF.

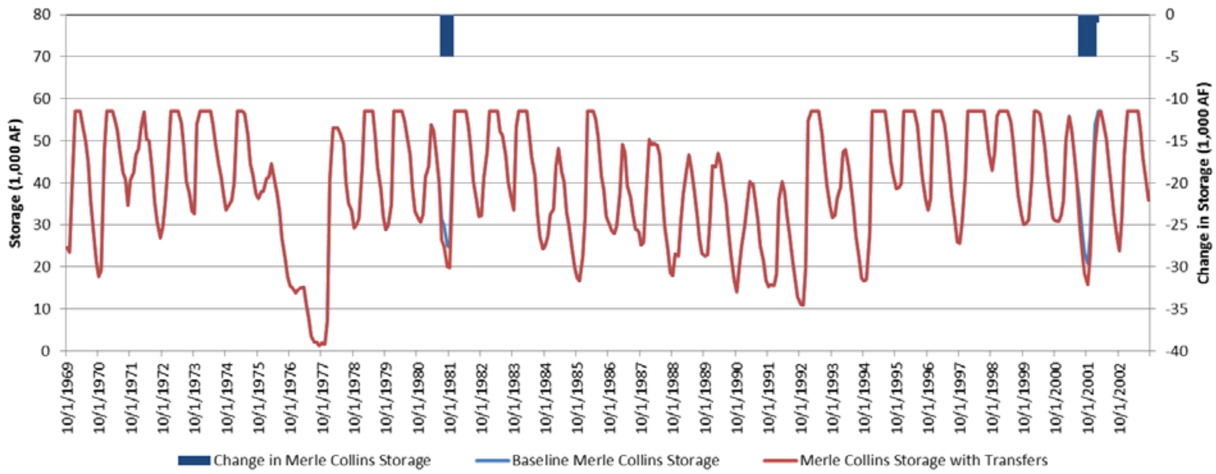

Figure B-~~68~~69. Merle Collins Operations with and without Alternative 4 Transfers

Placer County Water Agency releases water from MFP reservoirs for transfer to East Bay MUD. Changes in MFP storage are the same for Alternatives 2, 3, and 4 because all alternatives include reservoir release transfer measures (see Figure B-~~69~~70).

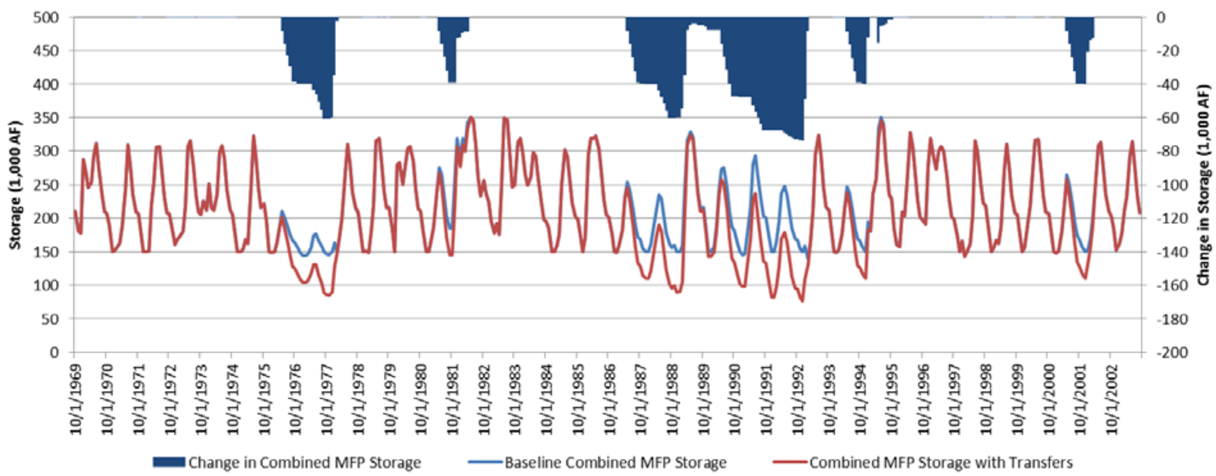

Figure B-~~69~~70. MFP Operations with and without Alternative 4 Transfers

Figure B-~~70~~ 71 illustrates Merced ID operations of Lake McClure when making reservoir release transfers of up to 30 TAF.

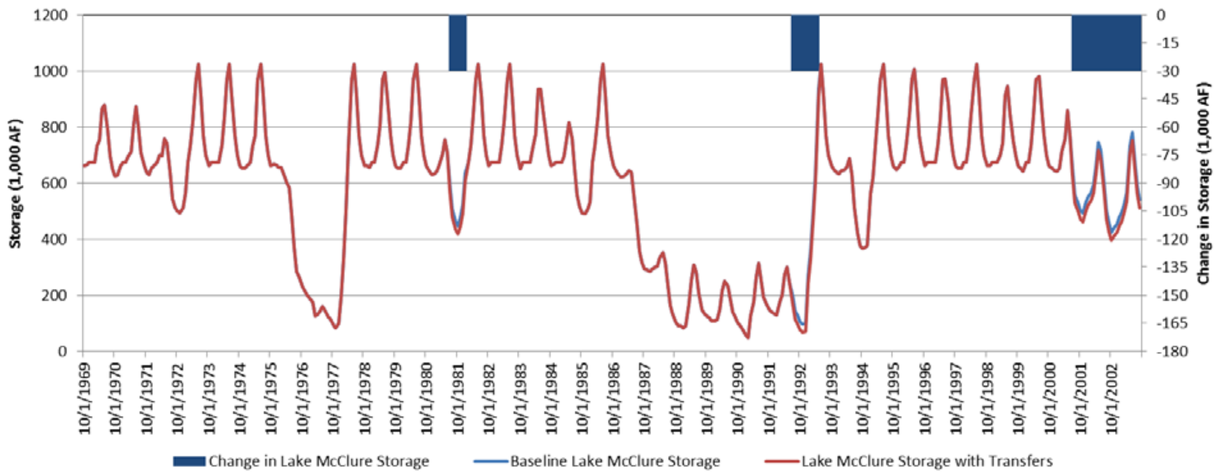

Figure B-~~70~~71. Lake McClure Operations with and without Alternative 4 Transfers

Browns Valley ID's conserved water is stored in Yuba County Water Agency's New Bullards Bar Reservoir and released for transfer in years with demand and available export capacity. These releases of conserved water are the only effect to New Bullards Bar Reservoir as illustrated below in Figure B-~~71~~72. New Bullards Bar Reservoir storage returns to baseline levels when the reservoir refills.

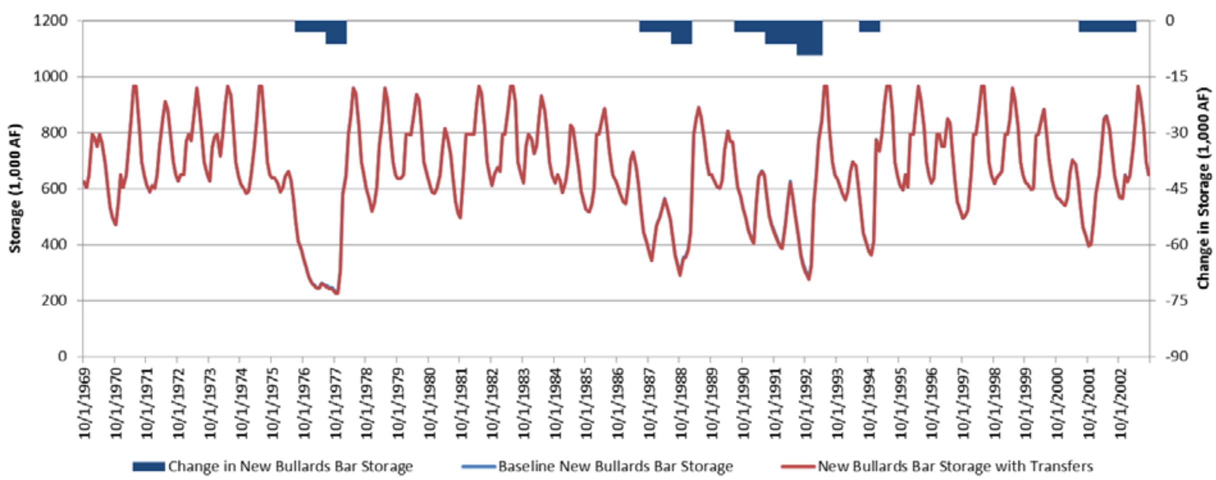

Figure B-~~71~~72. New Bullards Bar Operations with and without Alternative 4 Transfers

B.6.4.2 Stream Flow

Releases from Keswick Dam correspond with Shasta operations as illustrated below in Figure B-~~72~~73. Decreases in release occur when crop idling transfers are stored in Shasta and precede increases as stored transfer water is released for transfer through the Delta. There are no releases in response to changes in stream-groundwater interaction because there are no groundwater substitution transfers in Alternative 4.

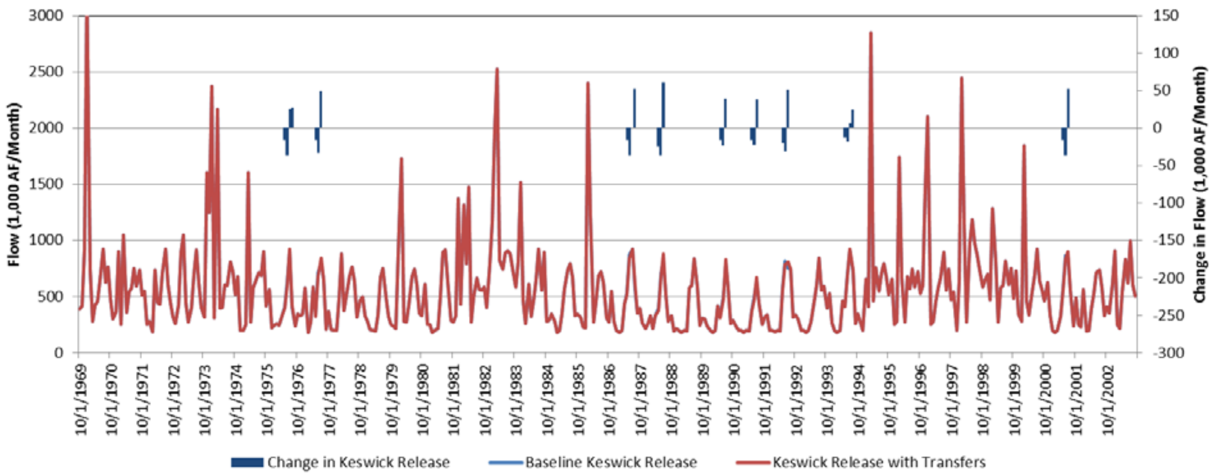

Figure B-~~72~~73. Keswick Dam Release with and without Alternative 4 Transfers

Figure B-~~73~~ 74 illustrates the effect of Alternative 4 transfers to the Sacramento River at Wilkins Slough. Increased flows result from changes in Keswick release, plus water made available by crop idling transfers upstream of Wilkins Slough. Decreases occur when transfer water is stored upstream in Shasta.

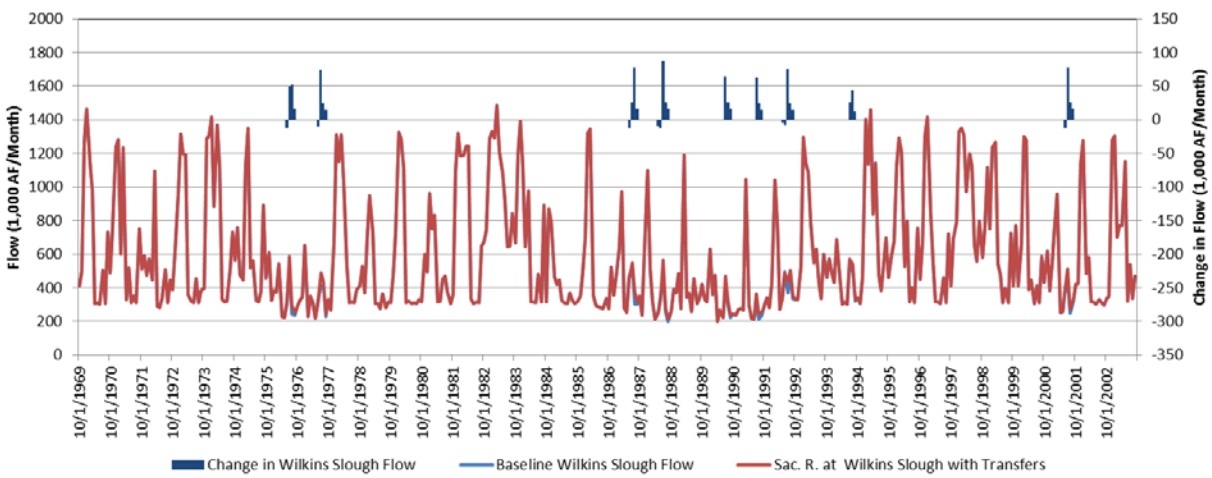

Figure B-~~73~~74. Sacramento River at Wilkins Slough with and without Alternative 4 Transfers

Figure B-~~74~~ 75 illustrates Nimbus Dam releases. Nimbus releases reflect CVP operations of Folsom Reservoir. Increases in release occur when Placer County Water Agency transfer water is released from Folsom for diversion at Freeport by East Bay MUD. Decreases can occur if transfer water made available downstream from Folsom is stored in Folsom and when Placer County Water Agency's upstream reservoirs refill.

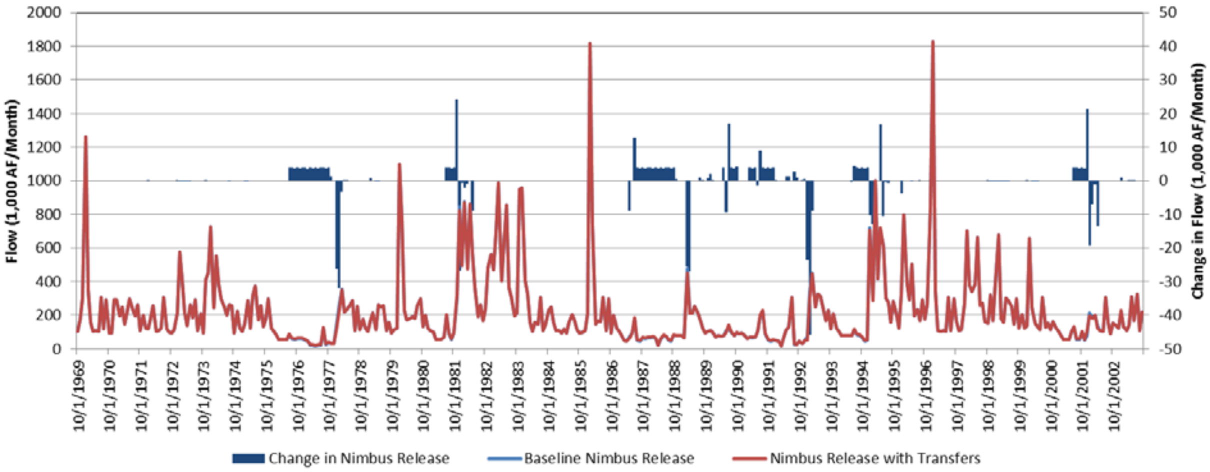

Figure B-~~74~~75. Nimbus Dam Release with and without Alternative 4 Transfers

Flows on the American River at H Street, illustrated below in Figure B-~~75~~76, reflect the same changes in flow under Alternative 4 as illustrated above at Nimbus.

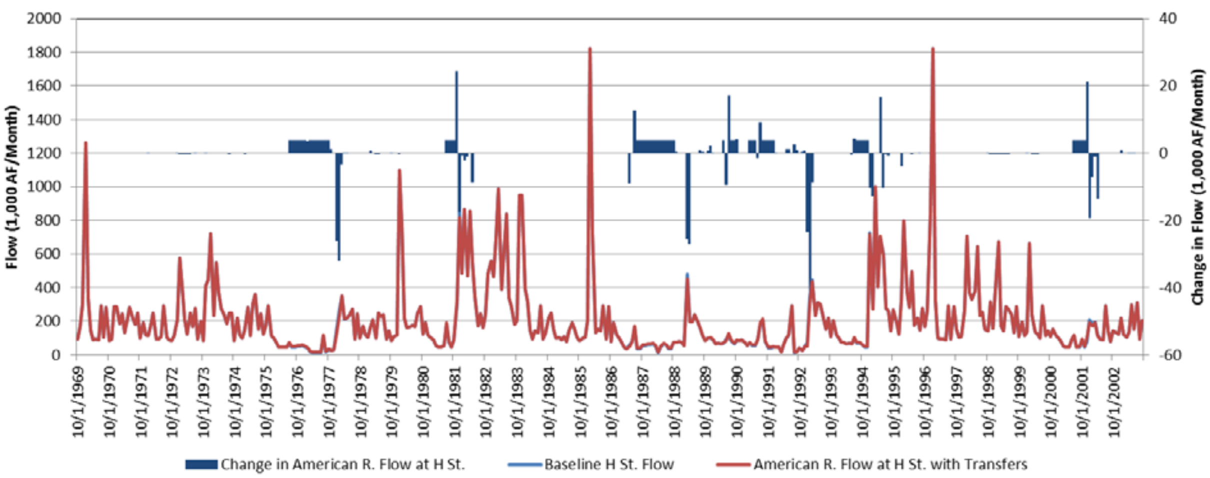

Figure B-~~75~~76. American River at H Street with and without Alternative 4 Transfers

Figure B-~~76~~-77 illustrates change in Feather River flow below Thermalito. Feather River flows change due to changes in operations at Oroville. Increases and decreases in flow on the Feather River below Thermalito are primarily a result of shifting the timing of delivery of SWP water to accommodate transfers. Changes also occur when crop idling water, stored in previous months, is released down the Feather River for delivery through the Delta.

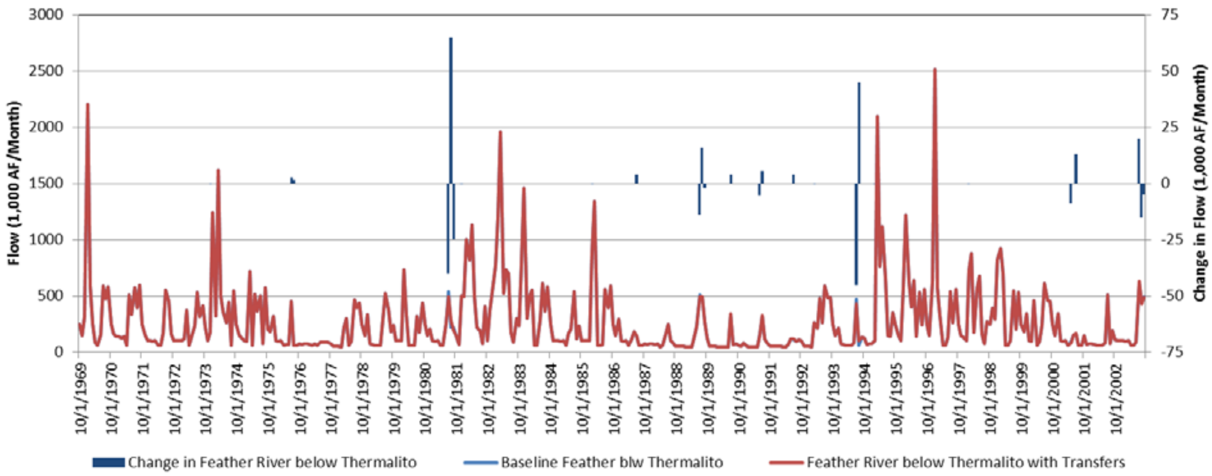

Figure B-~~76~~77. Feather River below Thermalito with and without Alternative 4 Transfers

Figure B-~~77~~ 78 illustrates changes in flow on the Yuba River as a result of Browns Valley ID's reservoir release transfers from Merle Collins Reservoir and release of Browns Valley ID's conserved water from New Bullards Bar Reservoir. Decreases occur when these reservoirs refill.

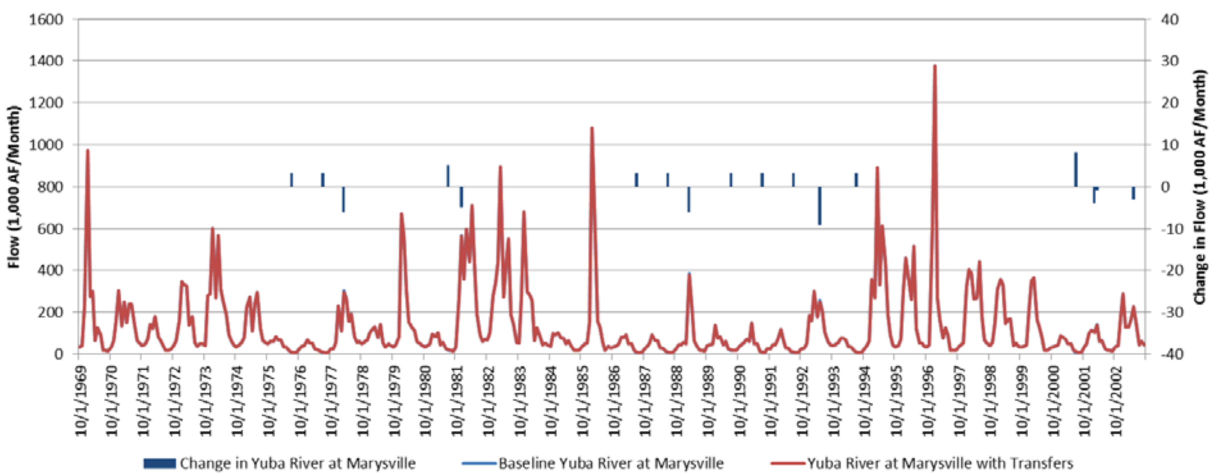

Figure B-~~77~~78. Yuba River at Marysville with and without Alternative 4 Transfers

Figure B-~~78~~ 79 illustrates the response of Bear River flows into the Feather River as a result of South Sutter WD reservoir release transfers from Camp Far West Reservoir. Flows increase when water is released for transfer and decrease when Camp Far West refills.

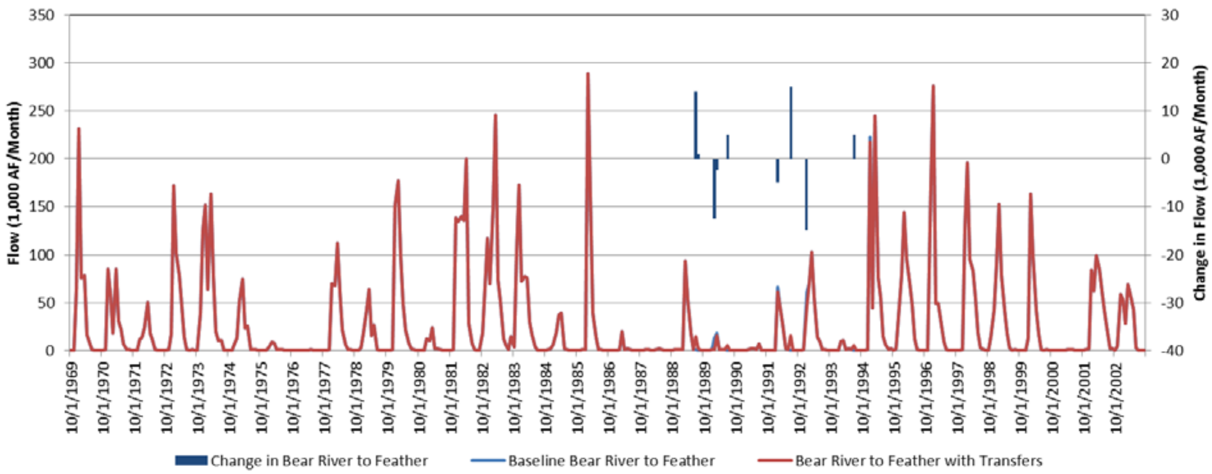

Figure B-~~78~~79. Bear River to the Feather River with and without Alternative 4 Transfers

The flow on the Lower Feather River represents an aggregation of flows on the Yuba River, Bear River, and upper portions of the Feather River. There are also increases due to water made available by crop idling transfers. Figure B-~~79~~ 80 represents the effect to the Feather River system.

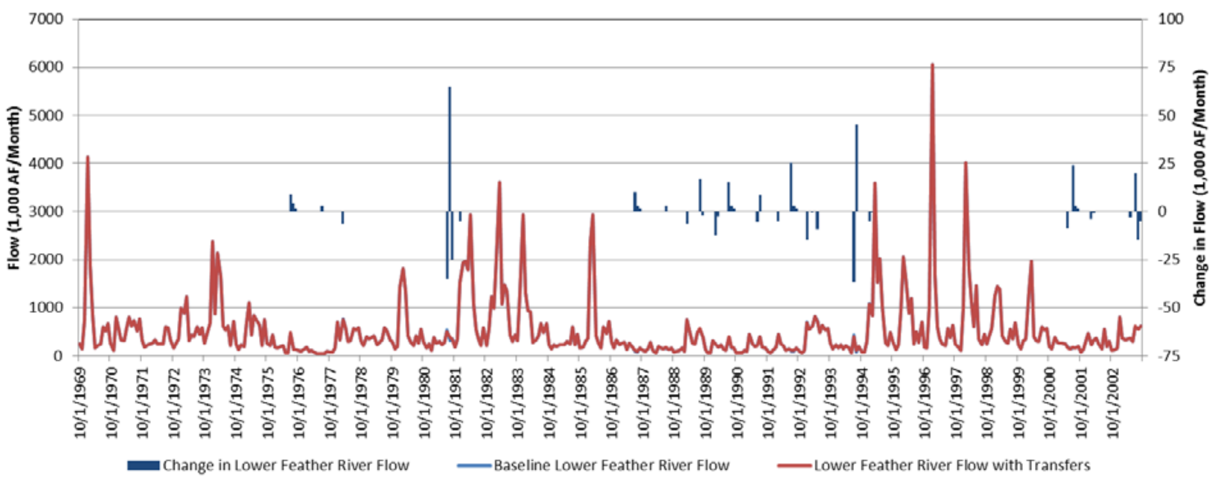

Figure B-~~79~~80. Lower Feather River with and without Alternative 4 Transfers

Figure B-~~80~~ 81 illustrates the flow of the Sacramento River at Freeport. This location is an aggregation of all changes on the Sacramento River at Wilkins Slough, the Lower Feather River, and the American River at H Street, and changes between those locations and Freeport. Changes between those locations and Freeport include increases in flow due to water made available through crop idling transfers.

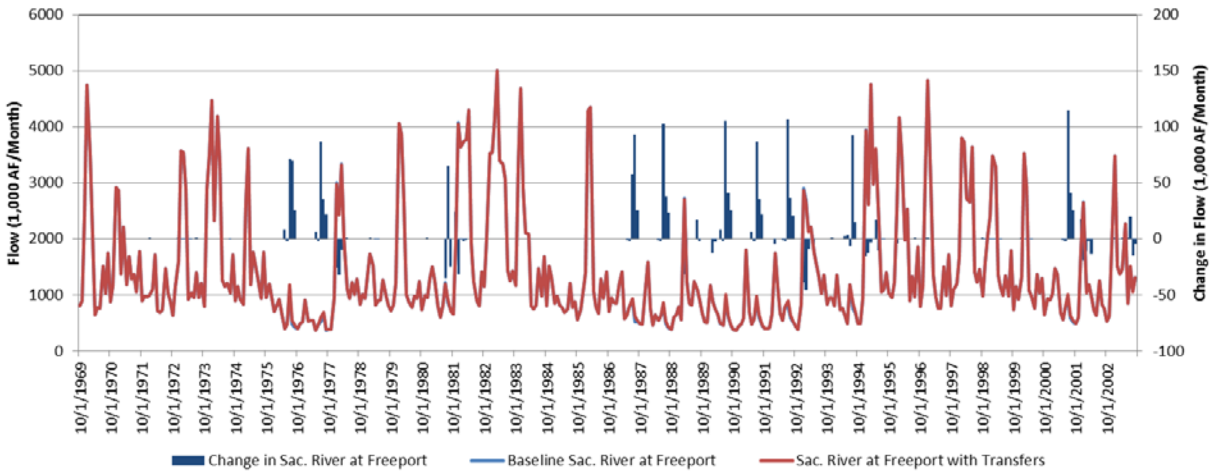

Figure B-~~80~~81. Sacramento River at Freeport with and without Alternative 4 Transfers

Figure B-~~81~~ 82 illustrates changes on the Merced River at the confluence with the San Joaquin River. Increases in Merced River flow are transfer water made available by reservoir releases at Lake McClure; decreases are a result of reservoir refill.

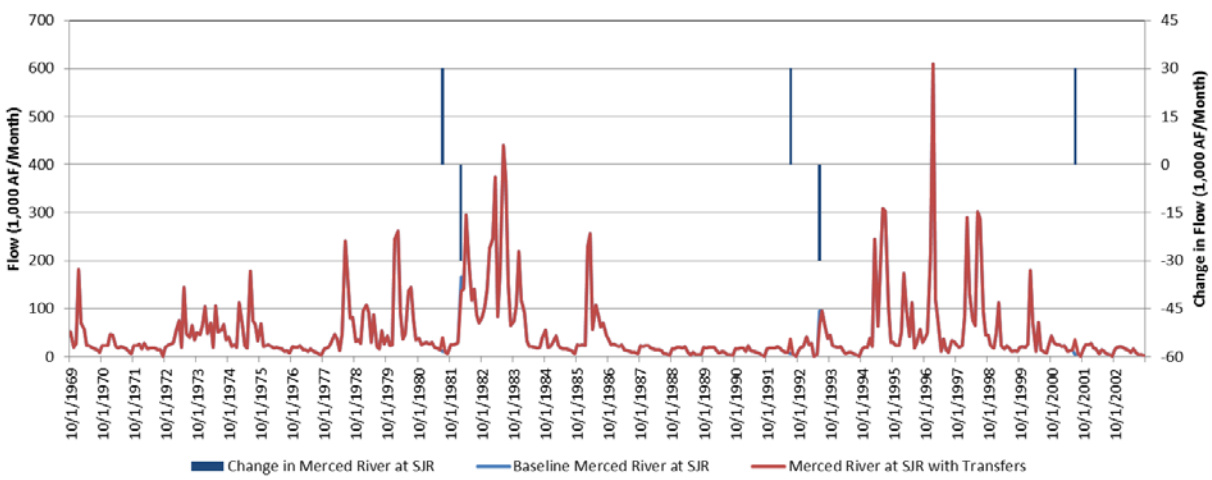

Figure B-~~81~~82. Merced River at the San Joaquin River with and without Alternative 4 Transfers

Figure B-~~82~~ 83 illustrates San Joaquin River flows at Vernalis. Increases in flow result from Merced ID transfers. Under Alternative 4, transfer water made available by Merced ID is diverted at CVP/SWP export facilities in the south Delta. Therefore, changes at Vernalis equal changes in Merced River flows at the confluence with the San Joaquin River.

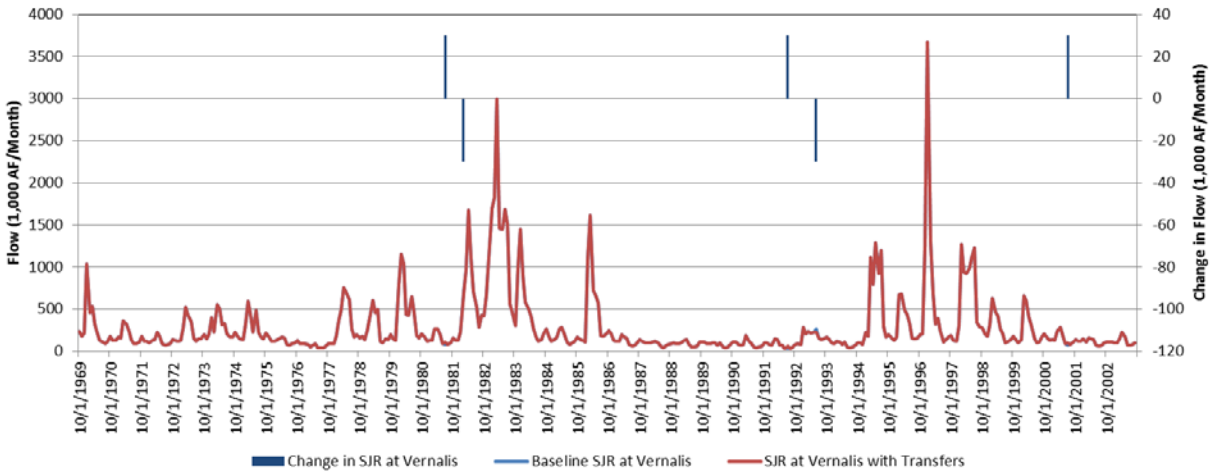

Figure B-~~82~~83. San Joaquin River at Vernalis with and without Alternative 4 Transfers

Changes to Delta outflow are illustrated below in Figure B-~~83~~84. Increases in Delta outflow are primarily due to carriage water to facilitate transfers through the Delta. Decreases in Delta outflow are attributed to reservoir refill upstream.

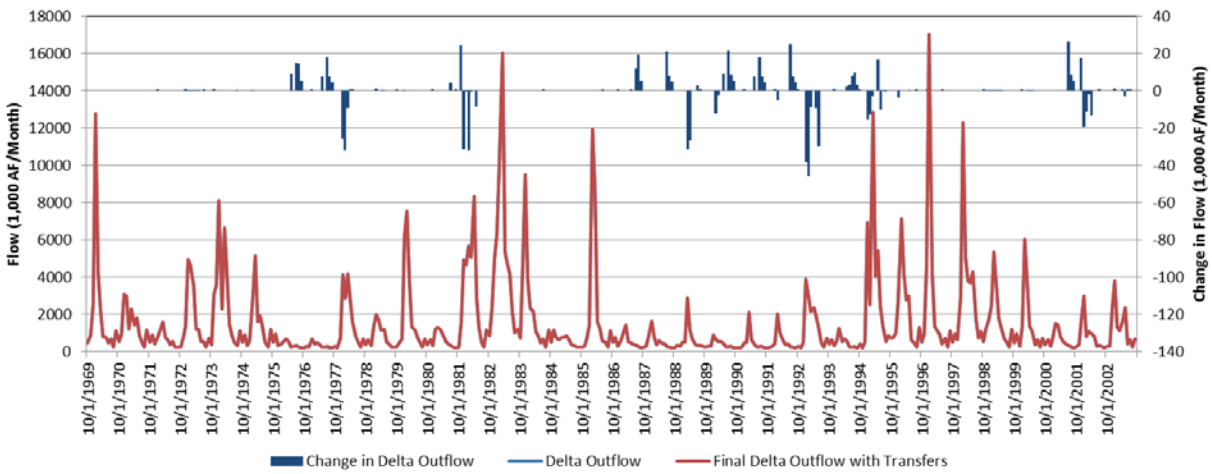

Figure B-~~83~~84. Delta Outflow with and without Alternative 4 Transfers

Table B-9 summarizes these changes on an average monthly and annual basis. Average annual Delta outflow is reduced by one TAF with increases primarily from July through September for carriage water and decreases primarily from January through March as reservoirs that made transfer releases refill.

Table B-9. Average Monthly Delta Outflow (TAF) for Alternative 4

Delta Outflow	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	393	867	1,490	3,260	3,312	3,278	1,753	1,381	816	546	297	638	18,031
With Transfers	393	868	1,489	3,257	3,307	3,277	1,751	1,382	815	551	300	640	18,030
Change	0	1	0	-3	-4	-2	-1	1	-1	5	3	1	-1

B.6.4.3 Exports and Diversions

Figure B-~~84~~ 85 illustrates the change in exports at Jones Pumping Plant. Under Alternative 4 there are only increases in exports.

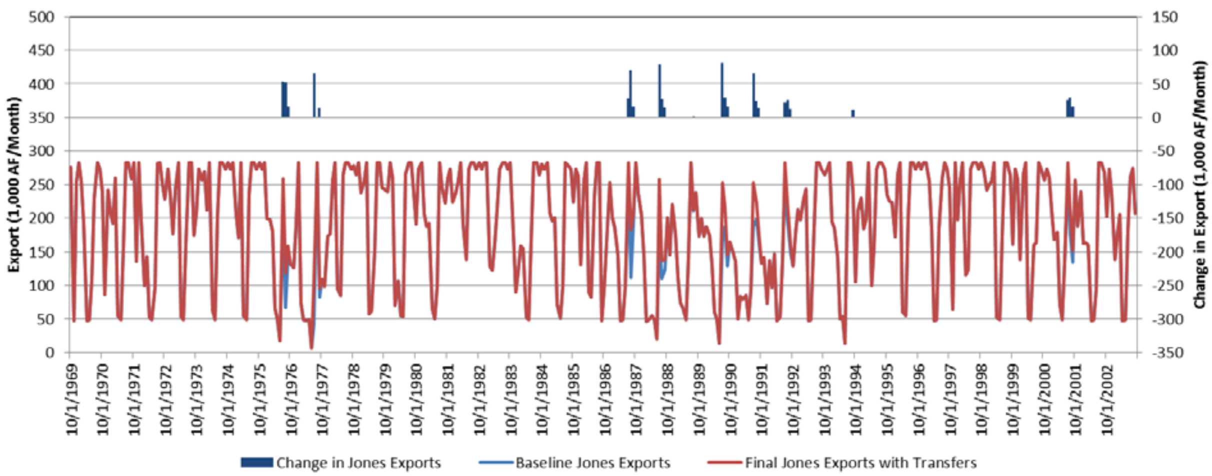

Figure B-~~84~~85. Exports at Jones Pumping Plant with and without Alternative 4 Transfers

Table B-10 summarizes the average monthly exports at Jones Pumping Plant. Increases occur during the transfer months of July, August, and September, with an average annual increase of 24 TAF.

Table B-10. Average Monthly Exports at Jones Pumping Plant (TAF) for Alternative 4

Jones Exports	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	222	212	235	197	186	198	69	65	153	256	252	223	2,268
With Transfers	222	212	235	197	186	198	69	65	153	268	259	227	2,291
Change	0	0	0	0	0	0	0	0	0	12	8	4	24

Increases in Banks Pumping Plant exports occur when Banks is used to export transfer water. Decreases occur when the timing of SWP water as simulated in the CalSim II baseline is shifted to help facilitate transfers. These changes are illustrated below in Figure B-~~85~~86.

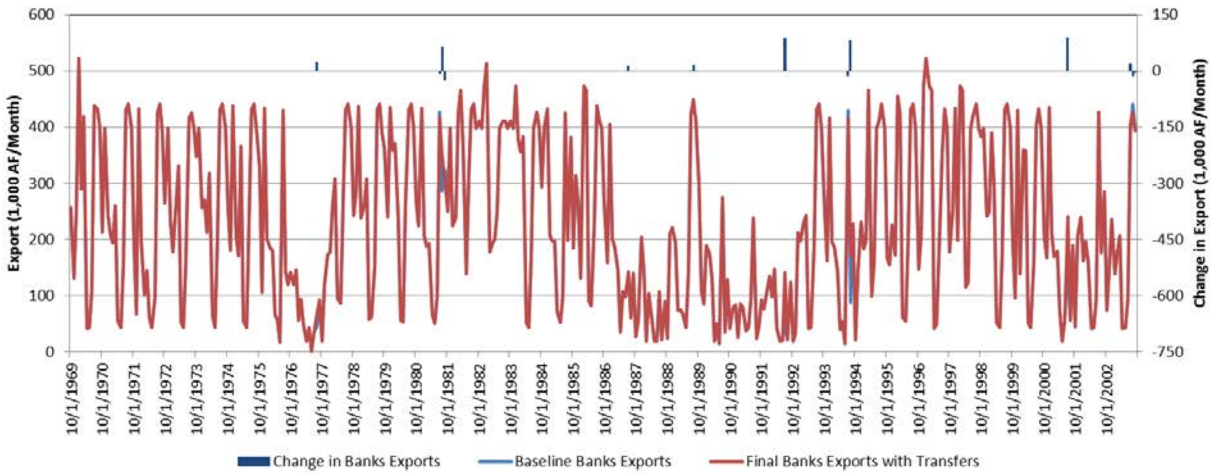

Figure B-~~85~~86. Exports at Banks Pumping Plant with and without Alternative 4 Transfers

Table B-11 summarizes average monthly exports at Banks Pumping Plant. Average annual Banks exports increase by ten TAF.

Table B-11. Average Monthly Exports at Banks Pumping Plant (TAF) for Alternative 4

Banks Exports	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	202	212	307	222	239	261	70	62	156	363	316	320	2,731
With Transfers	202	212	307	222	239	261	70	62	156	369	321	319	2,740
Change	0	0	0	0	0	0	0	0	0	5	5	-1	10

Total CVP/SWP exports, the sum of exports at Jones and Banks Pumping Plants, are illustrated in Figure B-~~86~~87.

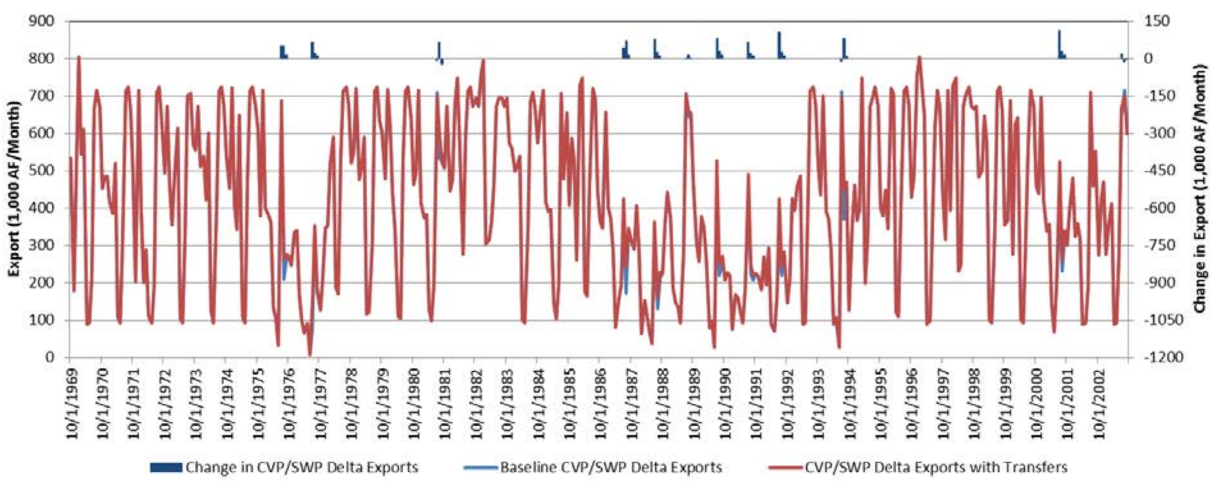

Figure B-~~86~~87. Total CVP/SWP Exports from the Delta with and without Alternative 4 Transfers

Table B-12 summarizes average monthly combined CVP/SWP exports. Average annual combined exports increase by 33 TAF with changes in the July through September period only.

Table B-12. Average Monthly Combined CVP/SWP Exports (TAF) for Alternative 4

CVP/SWP Exports	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Total
Baseline	424	424	543	419	425	459	138	128	309	619	568	543	4,998
With Transfers	424	424	543	419	425	459	138	128	309	637	580	546	5,032
Change	0	0	0	0	0	0	0	0	0	18	13	3	33

Figure B-~~87~~ 88 illustrates diversions made by East Bay MUD at Freeport under both the baseline and with Project scenarios. Baseline diversions represent East Bay MUD taking delivery of CVP Project water under their existing water service contract.

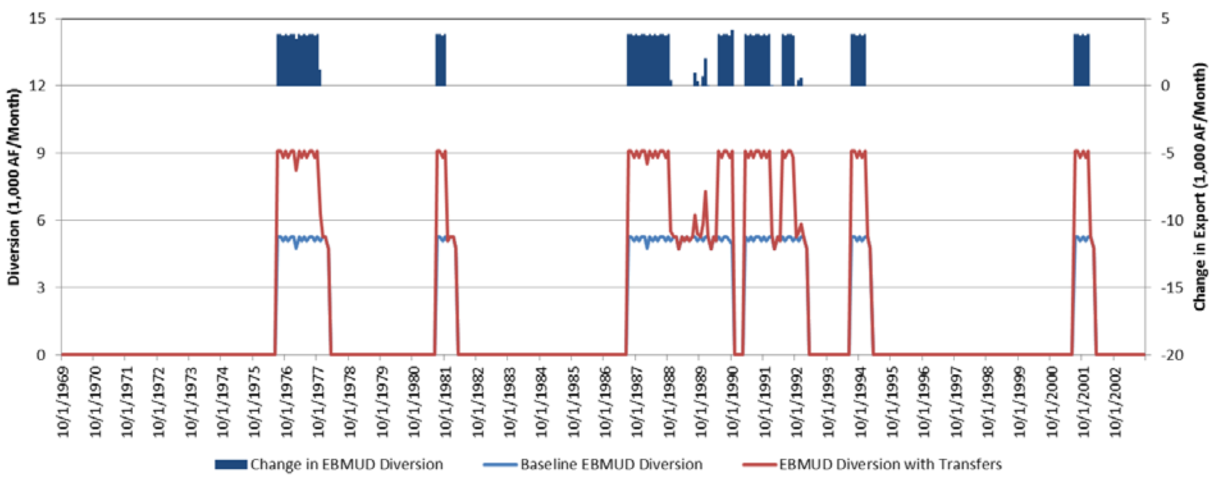

Figure B-~~87~~88. East Bay MUD Diversions with and without Alternative 4 Transfers

Contra Costa WD diversions increase to take delivery of transfer water as is illustrated below in Figure B-~~88~~89.

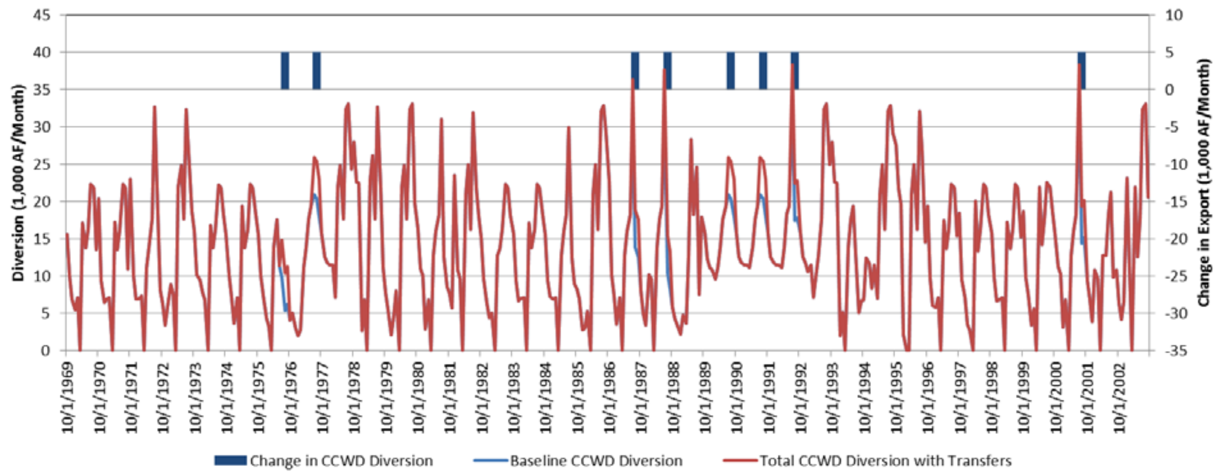

Figure B-~~88~~89. Contra Costa WD Diversions with and without Alternative 4 Transfers

Attachment 1: CalSim II Assumptions for Baseline Operations

	Existing Condition[1]
Planning Horizon	2014
Period of Simulation	82 years (1922-2003)
HYDROLOGY	
Level of Development (land use)	2005 Level[3]
DEMANDS	
North of Delta (excluding the American River)	
CVP	Land-use based, limited by contract amounts[4]
SWP (FRSA)	Land-use based, limited by contract amounts[5]
Non-project	Land-use based, limited by water rights and SWRCB Decisions for Existing Facilities
Antioch Water Works	Pre-1914 water right
Federal refuges	Recent historical Level 2 water needs[6]
American River Basin	
Water rights	Year 2005, full water rights[7]
CVP	Year 2005 plus Freeport Regional Water Project[7]
San Joaquin River Basin[9]	
Friant Unit	Limited by contract amounts, based on current allocation policy
Lower basin	Land-use based, based on district level operations and constraints
Stanislaus River basin[10 19]	Land-use based, based on New Melones Interim Operations Plan, up to full CVP Contractor deliveries (155 TAF per year) depending on New Melones Index
South of Delta	
CVP	Demand based on contract amounts[4]
Federal refuges	Firm Level 2 water needs[6]
Contra Costa WD	195 TAF per year CVP contract supply and water rights[11]
SWP[5 12]	Demand based on full Table A amounts (4.13 MAF per year)
Article 56	Based on 2001-2008 contractor requests
Article 21	MWD demand up to 200 TAF per month (December-March) subject to conveyance capacity, KCWA demand up to 180 TAF per month, and other contractor demands up to 34 TAF per month, subject to conveyance capacity
North Bay Aqueduct	77 TAF per year demand under SWP contracts, up to 43.7 cfs of excess flow under Fairfield, Vacaville and Benicia Settlement Agreement
FACILITIES	
System-wide	Existing facilities
Sacramento Valley	
Shasta Reservoir	Existing, 4,552 TAF capacity
Red Bluff Diversion Dam	Diversion dam operated with gates out all year, NOAA Fisheries BO (Jun 2009) Action I.3.1[19]; assume permanent facilities in place

	Existing Condition[1]
Colusa Basin	Existing conveyance and storage facilities
Upper American River	Placer County Water Agency American River pump station
Lower Sacramento River	Freeport Regional Water Project
Fremont Weir	Existing (un-notched) Weir
Delta Export Conveyance	
SWP Banks Pumping Plant (South Delta)	Physical capacity is 10,300 cfs, permitted capacity is 6,680 cfs in all months and up to 8,500 cfs during Dec 15th - Mar 15th depending on Vernalis flow conditions[20];additional capacity of 500 cfs (up to 7,180 cfs) allowed Jul–Sep for reducing impact of NOAA Fisheries BO (Jun 2009) Action IV.2.1[19] on SWP[21]
CVP C.W. “Bill” Jones Pumping Plant (formerly Tracy PP)	Permit capacity is 4,600 cfs in all months (allowed for by the DMC-California Aqueduct Intertie)
Upper DMC Capacity	Exports limited to 4,200 cfs plus diversion upstream from DMC constriction plus 400 cfs DMC-California Aqueduct Intertie
Los Vaqueros Reservoir	Enlarged storage capacity (160 TAF), existing pump location, Alternate Intake project included[14]
San Joaquin River	
Millerton Lake (Friant Dam)	Existing, 520 TAF capacity
South of Delta (CVP/SWP project facilities)	
South Bay Aqueduct	SBA rehabilitation, 430 cfs capacity from junction with California Aqueduct to Alameda County FC&WSD Zone 7 point
California Aqueduct East Branch	Existing capacity
REGULATORY STANDARDS	
Trinity River	
Minimum Flow below Lewiston Dam	Trinity EIS Preferred Alternative (369-815 TAF per year)
Trinity Reservoir end-of-September minimum storage	Trinity EIS Preferred Alternative (600 TAF as able)
Clear Creek	
Minimum flow below Whiskeytown Dam	Downstream water rights, 1963 Reclamation proposal to USFWS and NPS, predetermined Central Valley Protection Improvement Act 3406(b)(2) flows[22], and NOAA Fisheries BO (Jun 2009) Action I.1.1[19]
Upper Sacramento River	
Shasta Reservoir end-of-September minimum storage	NOAA Fisheries 2004 Winter-run Biological Opinion (1,900 TAF in non-critical dry years), and NOAA Fisheries BO (Jun 2009) Action I.2.1[19]
Minimum flow below Keswick Dam	Flows for the SWRCB Water Rights Order 90-5, predetermined Central Valley Protection Improvement Act 3406(b)(2) flows, and NOAA Fisheries BO (Jun 2009) Action I.2.2[19]
Feather River	
Minimum flow below Thermalito Diversion Dam	2006 Settlement Agreement (700 / 800 cfs).
Minimum flow below Thermalito Afterbay outlet	1983 DWR, CDFW agreement (750 – 1,700 cfs)
Yuba River	
Minimum flow below Daguerre Point Dam	D-1644 Operations (Lower Yuba River Accord)[15]

	Existing Condition[1]
American River	
Minimum flow below Nimbus Dam	American River Flow Management as required by NOAA Fisheries BO (Jun 2009) Action II.1[19]
Minimum flow at H Street Bridge	SWRCB D-893
Lower Sacramento River	
Minimum flow near Rio Vista	SWRCB D-1641
Mokelumne River	
Minimum flow below Camanche Dam	Federal Energy Regulatory Commission 2916-029[13], 1996 (Joint Settlement Agreement)
Minimum flow below Woodbridge Diversion Dam	Federal Energy Regulatory Commission 2916-029[13], 1996 (Joint Settlement Agreement)
Stanislaus River	
Minimum flow below Goodwin Dam	1987 Reclamation, CDFW agreement, and flows required for NOAA Fisheries BO (Jun 2009) Action III.1.2 and III.1.3[19]
Minimum dissolved oxygen	SWRCB D-1422
Merced River	
Minimum flow below Crocker-Huffman Diversion Dam	Davis-Grunsky (180 – 220 cfs, Nov – Mar) and Cowell Agreement
Minimum flow at Shaffer Bridge	Federal Energy Regulatory Commission 2179 (25 – 100 cfs)
Tuolumne River	
Minimum flow at Lagrange Bridge	Federal Energy Regulatory Commission 2299-024, 1995 (Settlement Agreement) (94 – 301 TAF per year)
San Joaquin River	
San Joaquin River below Friant Dam/Mendota Pool	Interim San Joaquin River Restoration flows limited by existing channel capacities
Maximum salinity near Vernalis	SWRCB D-1641
Minimum flow near Vernalis	SWRCB D-1641 and NOAA Fisheries BO (Jun 2009) Action IV.2.1 Phase II flows not provided due to lack of agreement for purchasing water.
Sacramento-San Joaquin Delta	
Delta Outflow Index (flow and salinity)	SWRCB D-1641 and USFWS BO (Dec 2008) Action 4[19]
Delta Cross Channel gate operation	SWRCB D-1641 with additional days closed from Oct 1-Jan 31 based on NOAA Fisheries BO (Jun 2009) Action IV.1.2[19] (closed during flushing flows from Oct 1-Dec 14 unless adverse water quality conditions)
South Delta exports (Jones PP and Banks PP)	SWRCB D-1641 export limits and Vernalis flow-based export limits in Apr -May as required by NOAA Fisheries BO (June 2009) Action IV.2.1 Phase II[19] (additional 500 cfs allowed for Jul-Sep for reducing impact on SWP)[21]
Combined Flow in Old and Middle River	USFWS BO (Dec 2008) Actions 1-3 and NOAA Fisheries BO (Jun 2009) Action IV.2.3[19]
OPERATIONS CRITERIA: RIVER-SPECIFIC	
Upper Sacramento River	
Flow objective for navigation at Wilkins Slough	NOAA Fisheries BO (Jun 2009) Action I.4[19]; 3,250 – 5,000 cfs based on CVP water supply condition

	Existing Condition[1]
American River	
Folsom Dam flood control	Variable 400/670 flood control diagram (without outlet modifications)
Feather River	
Flow at mouth of Feather River (above Verona)	Maintain the CDFW/DWR flow target of 2,800 cfs for Apr - Sep dependent on Oroville inflow and FRSA allocation
Stanislaus River	
Flow below Goodwin Dam	Revised Operations Plan and NOAA Fisheries BO (Jun 2009) Action III.1.2 and III.1.3[19]
San Joaquin River	
Salinity at Vernalis	Grasslands Bypass Project (partial implementation)
OPERATIONS CRITERIA: SYSTEMWIDE	
CVP Water Allocation	
CVP settlement and exchange	100% (75% in Shasta critical years)
CVP refuges	100% (75% in Shasta critical years)
CVP agriculture	100% - 0% based on supply. South-of-Delta allocations are additionally limited due to D-1641, USFWS BO (Dec 2008), and NOAA Fisheries BO (Jun 2009) export restrictions[19]
CVP municipal & industrial	100% - 50% based on supply. South-of-Delta allocations are additionally limited due to D-1641, USFWS BO (Dec 2008), and NOAA Fisheries BO (Jun 2009) export restrictions[19]
SWP Water Allocation	
North of Delta (FRSA)	Contract-specific
South of Delta (including North Bay Aqueduct)	Based on supply; equal prioritization between Ag and M&I based on Monterey Agreement; allocations are limited due to D-1641, USFWS BO (Dec 2008), and NOAA Fisheries BO (Jun 2009) export restrictions[19]
CVP/SWP Coordinated Operations	
Sharing of responsibility for in-basin use	1986 Coordinated Operations Agreement (East Bay MUD FRWP and 2/3 of the North Bay Aqueduct diversions are considered as Delta export, 1/3 of the North Bay Aqueduct diversion is considered as in-basin use)
Sharing of surplus flows	1986 Coordinated Operations Agreement
Sharing of restricted export capacity for project-specific priority pumping	Equal sharing of export capacity under SWRCB D-1641, USFWS BO (Dec 2008), and NOAA Fisheries BO (Jun 2009) export restrictions[19]
Water transfers	Acquisitions by SWP contractors are wheeled at priority in Banks Pumping Plant over non- SWP users; LYRA included for SWP contractors[21]
Sharing of export capacity for lesser priority and wheeling-related pumping	Cross Valley Canal wheeling (max of 128 TAF per year), CALFED ROD defined Joint Point of Diversion
San Luis Reservoir	San Luis Reservoir is allowed to operate to a minimum storage of 100 TAF
CVPIA 3406(b)(2)	
Policy decision	Per May 2003 Department of Interior decision
Allocation	800 TAF per year, 700 TAF per year in 40-30-30 dry years, and 600 TAF per year in 40-30-30 critical years

	Existing Condition[1]
Actions	Pre-determined non-discretionary USFWS BO (Dec 2008) upstream fish flow objectives (Oct- Jan) for Clear Creek and Keswick Dam, non-discretionary NOAA Fisheries BO (Jun 2009) actions for the American and Stanislaus Rivers, and NOAA Fisheries BO (Jun 2009) actions leading to export restrictions[19]
Accounting adjustments	No discretion assumed under USFWS BO (Dec 2008) and NOAA Fisheries BO (Jun 2009)[19], no accounting
WATER MANAGEMENT ACTIONS	
Water Transfer Supplies	
Lower Yuba River Accord[21]	Yuba River acquisitions for reducing impact of NOAA Fisheries BO export restrictions[19] on SWP

Notes:

1 These assumptions were developed under the direction of the DWR and Reclamation management team for the Bay Delta Conservation Plan (BDCP) Habitat Conservation Plan and EIR/EIS. Additional modifications were made by Reclamation and the Long-Term Water Transfer Project team and coordinated with Reclamation.

2 Footnote removed.

3 The Sacramento Valley hydrology used in the Existing Condition CalSim II model reflects nominal 2005 land use assumptions. The nominal 2005 land use was determined by interpolation between the 1995 and projected 2020 land use assumptions associated with Bulletin 160-98. The San Joaquin Valley hydrology reflects 2005 land use assumptions developed by Reclamation to support Reclamation studies.

4 CVP contract amounts have been reviewed and updated according to existing and amended contracts, as appropriate. Assumptions regarding CVP agricultural and municipal and industrial (M&I) service contracts and Settlement Contract amounts are documented in the Delivery Specifications attachments to the BDCP CalSim II assumptions document.

5 SWP contract amounts have been updated as appropriate based on recent Table A transfers/agreements. Assumptions regarding SWP agricultural and M&I contract amounts are documented in the Delivery Specifications attachments to the BDCP CalSim II assumptions document.

6 Water needs for Federal refuges have been reviewed and updated and are documented in the Delivery Specifications attachments to the BDCP CalSim II assumptions document.

7 Assumptions regarding American River water rights and CVP contracts are documented in the Delivery Specifications attachments to the BDCP CalSim II assumptions document. The Sacramento Area Water Forum agreement, its dry year diversion reductions, MFP operations and “mitigation” water is not included.

8 Footnote removed.

9 The new CalSim II representation of the San Joaquin River has been included in this model package (CalSim II San Joaquin River Model, Reclamation, 2005). Updates to the San Joaquin River have been included since the preliminary model release in August 2005.

10 The CalSim II model representation for the Stanislaus River does not necessarily represent Reclamation’s current or future operational policies. A suitable plan for supporting flows has not been developed for NOAA Fisheries BO (Jun 2009) Action III.1.3.

11 The actual amount diverted is reduced because of supplies from the Los Vaqueros project. The existing Los Vaqueros storage capacity is 160 TAF. Associated water rights for Delta excess flows are included.

12 Under Existing Conditions it is assumed that SWP Contractors can take delivery of all Table A allocations and Article 21 supplies. Article 56 provisions are assumed and allow for SWP Contractors to manage storage and delivery conditions such that full Table A allocations can be delivered. Article 21 deliveries are limited in wet years under the assumption that demand is decreased in these conditions. Article 21 deliveries for the NBA are dependent on excess conditions only, all other Article 21 deliveries also require that San Luis Reservoir be at capacity and that Banks PP and the California Aqueduct have available capacity to divert from the Delta for direct delivery.

13 Mokelumne River flows reflect East Bay MUD operations in consideration of supplies associated with the Freeport Regional Water Project.

14 The Contra Costa WD Alternate Intake Project, an intake at Victoria Canal, that operates as an alternate Delta diversion for Los Vaqueros Reservoir.

15 D-1644 and the Lower Yuba River Accord are assumed to be implemented for the Existing Conditions baselines. The Yuba River is not dynamically modeled in CalSim II. Yuba River hydrology and availability of water acquisitions under the Lower Yuba River Accord are based on modeling performed and provided by the Lower Yuba River Accord EIS/EIR study team.

16 Footnote removed.

17 Footnote removed.

18 Footnote removed.

19 In cooperation with Reclamation, NOAA Fisheries, USFWS, and California Department of Fish and Wildlife, DWR has developed assumptions for implementation of the USFWS BO (Dec 15th 2008) and NOAA Fisheries BO (June 4th 2009) in CalSim II.

[20] Current U.S. Army Corps of Engineering permit for Banks PP allows for an average diversion rate of 6,680 cfs in all months. Diversion rate can increase up to 1/3 of the rate of San Joaquin River flow at Vernalis during Dec 15th – Mar 15th up to a maximum diversion of 8,500 cfs, if Vernalis flow exceeds 1,000 cfs.

[21] Acquisitions of Component 1 water under the Lower Yuba River Accord, and use of 500 cfs dedicated capacity at Banks PP during Jul– Sep, are assumed to be used to reduce as much of the impact of the Apr-May Delta export actions on SWP contractors as possible.

[22] Delta actions, under USFWS discretionary use of CVPIA 3406(b)(2) allocations, are no longer dynamically operated and accounted for in the CalSim II model. The Combined Old and Middle River Flow and Delta Export restrictions under the USFWS BO (Dec 15th 2008) and the NOAA Fisheries BO (June 4th 2009) severely limit any discretion that would have been otherwise assumed in selecting Delta actions under the CVPIA 3406(b)(2) accounting criteria. Therefore, it is anticipated that CVPIA 3406(b)(2) account availability for upstream river flows below Whiskeytown, Keswick and Nimbus Dams would be very limited. It appears the integration of BO Reasonable and Prudent Alternative actions will likely exceed the 3406(b)(2) allocation in all water year types. Upstream flows on Clear Creek and the Sacramento River are pre-determined based on CVPIA 3406(b)(2) based operations from the Aug 2008 BA Study 7.0 and Study 8.0 for Existing Conditions baselines. The procedures for dynamic operation and accounting of CVPIA 3406(b)(2) are not included in CalSim II.

[23] Only acquisitions of Lower Yuba River Accord Component 1 water are included.

Key:

CVP = Central Valley Project
FRSA = Feather River Service Area
TAF = thousand acre-feet
MAF = million acre-feet
KCWA = Kern County Water Agency
BO = biological opinion
DMC = Delta-Mendota Cana
NBA = North Bay Aqueduct
EIS = Environmental Impact Statement
NPS = National Park Service
CDFW = California Department of Fish and Wildlife
LYRA = Lower Yuba River Accord
SWP = State Water Project
SWRCB = State Water Resources Control Board
WD = Water District
MWD = Metropolitan Water District of Southern California
cfs = cubic feet per second
PP = Pumping Plant
SBA = South Bay Aqueduct
FC&WSD = Flood Control and Water Service District
USFWS = U.S. Fish and Wildlife Service
DWR = Department of Water Resources
FRWP = Freeport Regional Water Project
ROD = Record of Decision
CALFED = State (CAL) and Federal (FED) agencies participating in the Bay-Delta Accord
CVPIA = Central Valley Project Improvement Act
NOAA Fisheries = National Oceanic and Atmospheric Administration Fisheries Service

Attachment 2: Monthly Simulated Transfers by Seller for each Alternative

The following tables show the volume of water simulated as transferred by each seller for each alternative. A separate table is included for each type of transfer: groundwater substitution, reservoir release, conserved water, and crop idling.

Table B1. Simulated Groundwater Substitution Transfers for Alternatives 2 & 3 (1,000 acre-feet)

Table B4: Simulated Reservoir Release Transfers for Specified Alternatives (1,000 acre-feet)

WY	Apr	May	Jun	Jul	Aug	Sep	Total
South Sutter Water District: Alts. 2, 3, & 4							
1989	0	0	0	14	1	0	15
1990	0	0	0	5	0	0	5
1992	0	0	0	15	0	0	15
1994	0	0	0	5	0	0	5
Browns Valley Irrigation District: Alts. 2, 3, & 4							
1981	0	0	0	5	0	0	5
2001	0	0	0	5	0	0	5

Additionally, Browns Valley ID is simulated to make a conserved water transfer of 3,100 acre-feet in July of the following years: 1976, 1977, 1987, 1988, 1990, 1991, 1992, 1994, and 2001. This conserved water transfer operates similar to a reservoir release transfer from New Bullards Bar Reservoir.

WY	Apr	May	Jun	Jul	Aug	Sep	Total
Placer County Water Agency: Alts. 2, 3, & 4							
1976 1977	0	8.2	7.5	6.8	7.2	9.0	38.7
1977	0	4.1	3.2	4.3	4.9	5.5	22.0
1981	0	8.2	7.8	7.9	8.1	7.4	39.4
1987	0	8.2	7.6	8.2	8.3	7.2	39.5
1988	0	4.1	3.8	4.0	4.5	4.6	21.0
1990	0	8.2	8.0	7.7	8.2	7.7	39.8
1991	0	5.2	3.9	3.5	4.1	3.8	20.5
1992	0	1.2	1.2	1.3	1.3	0.9	5.9
1994	0	8.4	7.9	8.2	7.9	6.7	39.0
2001	0	8.2	7.6	8.2	8.3	7.3	39.5

Values shown are releases from PCWA reservoirs into Folsom Reservoir. Water is released from Folsom for rediversion at Freeport by EBMUD at approximately 3,800 acre-feet per month from July through February.

WY	Apr	May	Jun	Jul	Aug	Sep	Total
Merced Irrigation District: Alts. 2 & 3							
1972	18	12	0	0	0	0	30
1981	18	12	0	0	0	0	30
1992	18	12	0	0	0	0	30
2001	18	12	0	0	0	0	30

In Alts. 2 & 3 transfers from Merced ID are diverted from facilities on the lower San Joaquin River.

WY	Apr	May	Jun	Jul	Aug	Sep	Total
Merced Irrigation District: Alt. 4							
1981	0	0	0	30	0	0	30
1992	0	0	0	30	0	0	30
2001	0	0	0	30	0	0	30

In Alt. 4 transfers from Merced ID are diverted from CVP/SWP facilities in the south Delta.

Delta Conditions Assessment

This page left blank intentionally.

Appendix C
Delta Conditions Assessment

C.1 Background

Hydrologic conditions, climatic variability, and regulatory requirements for operation of water projects commonly affect water supply availability in California. This variability strains water supplies, making advance planning for water shortages necessary and routine. In the past decades, water transfers have become a common tool in water resource planning to supplement available water supplies to serve existing demands.

The United States Department of the Interior, Bureau of Reclamation (Reclamation) manages the Central Valley Project (CVP), which includes storage in reservoirs (such as Shasta, Folsom, and Trinity reservoirs) and diversion pumps in the Sacramento-San Joaquin Delta (Delta) to deliver water to users in the San Joaquin Valley and San Francisco Bay area. When these users experience water shortages, they may look to water transfers to help reduce potential impacts of those shortages.

A water transfer involves an agreement between a willing seller and a willing buyer. To make water available for transfer and conveyance to the Buyer Service Area for beneficial use, the willing seller must take an action to reduce the consumptive use of water or reduce reservoir storage. Water transfers would only be used to help meet existing demands and would not serve any new demands in the Buyer Service Area.

Reclamation and the San Luis & Delta-Mendota Water Authority (SLDMWA) are completing a joint Environmental Impact Statement/Environmental Impact Report (EIS/EIR), in compliance with the National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA), for water transfers from 2015 through 2024. Reclamation is serving as the Lead Agency under NEPA and SLDWMA is the Lead Agency under CEQA. Reclamation would facilitate transfers proposed by buyers and sellers. The SLDMWA, consisting of federal and exchange water service contractors in western San Joaquin Valley, San Benito, and Santa Clara counties, helps negotiate transfers in years when the member agencies could experience shortages.

This EIS/EIR evaluates water transfers that originate from entities located upstream of the Delta. Purchasing agencies are in areas south of the Delta or in the San Francisco Bay Area. Water transfers are subject to federal and state law.

This EIS/EIR analyzes transfers to CVP contractors, using CVP or SWP facilities to deliver these transfers.

C.2 Purpose of Delta Conditions Analysis

An analysis of Delta conditions is necessary to assist in evaluation of potential environmental impacts associated with Long-Term Water Transfers within the Delta. Water transfers have the potential to affect both the natural system and operation of the CVP and State Water Project (SWP). The purpose of this analysis is to simulate the hydrodynamics and water quality within the Delta when transfer water is made available by various sellers to determine how and where within the Delta the effects are likely to occur under the alternatives. Output from the Delta conditions analysis for parameters such as water level (stage), water quality, and environmental flows under D-1641 and the biological opinions (BOs) provides a basis for environmental assessment.

C.3 Analytical Approach

The Delta Conditions analysis is performed with the Delta Simulation Model 2 (DSM2). DSM2 setup relies on the output of three additional tools for this Project: CalSim II, the Transfer Operations Model (TOM), and the Delta Island Consumptive Use model (DICU model). CalSim II outputs simulating California’s water delivery system to the Delta are used to supply inflow and export boundary conditions to DSM2. Within DSM2, agricultural influences and the effect of meteorological conditions are modeled by boundary conditions supplied by the DICU, model. DSM2 boundary conditions affected by the assumptions under the alternatives are supplied by TOM.

DSM2 model results of a baseline (Base) alternative, the No Action/No Project Alternative without proposed water transfers, as developed in CALSIM II, are compared to model results with proposed water transfers under each alternative supplied by TOM to determine the extent and significance of any differences resulting from the transfers.

A distinction needs to be made between the uses of models for *absolute* versus *comparative* analyses. In an *absolute analysis,* the model is run once to predict an outcome – for example, the outcome could be the concentration of EC at one of the Delta water intakes. In a *comparative analysis*, the model is run twice, once with conditions representing a baseline and another run with an alternative representing some specific changes to Delta operations and/or bathymetry in order to assess the change in modeled outcome due to the given change in model configuration. The assumption is that while the model might not produce results reflecting these changes with absolute certainty, it does produce a reasonably reliable estimate of the relative change in outcome.

For the long-term water transfers analysis, as is customary in most projects using CalSim II planning models combined with DSM2, the analysis is a comparative analysis approach[1]. The Base alternative represents a condition that approximates an operational and regulatory framework that is assumed to determine the hydrodynamics and water quality in the Delta at an Existing Condition time frame. DSM2 was used to determine changes from due to the Alternatives in: EC patterns in the Delta; water level changes in the south Delta; changes in X2, the location of the 2 ppt salinity isohaline; and, changes in the magnitude of the combined flow in Old and Middle Rivers (OMR flow).

C.4 Model Descriptions

Models used in the Delta conditions analysis are described briefly in the following sections – DSM2, CALSIM II, the TOM and the DICU model. Appendix B supplies detail on the assumptions and logic used in CalSim II and TOM. For these studies, the modeled time frame is restricted to water years 1970 – 2003.

C.4.1 DSM2

DSM2 is a one-dimensional (1-D) hydrodynamic and water quality simulation model used to represent conditions in the Sacramento-San Joaquin Delta. The model was developed by the Delta Modeling Section (DMS) of the Department of Water Resources (DWR) and is used to model impacts associated with projects in the Delta. DSM2 has been used extensively to model hydrodynamics and salinity in the Delta, as well as Dissolved Organic Carbon (DOC). Salinity is modeled as electrical conductivity (EC), which is assumed to behave as a conservative constituent. DOC was not modeled in the current study.

DSM2 contains three separate modules, a hydrodynamic module (HYDRO), a water quality module (QUAL), and a particle tracking module (PTM). QUAL uses the hydrodynamics simulated in HYDRO as the basis for its transport calculations. PTM was not used in the current study. Detailed descriptions of the mathematical formulation implemented in the hydrodynamic module, DSM2-HYDRO and for EC in the water quality module, DSM2-QUAL, the data required for simulation, and the calibration of HYDRO and QUAL are documented in a series of reports available at: http://baydeltaoffice.water.ca.gov/modeling/deltamodeling/annualreports.cfm .

The calibration of DSM2 has primarily focused on hydrodynamics and the conservative transport of salinity (EC). The DSM2 network used for the HYDRO hydrodynamic and QUAL water quality simulations in this study was updated in 2009 (Chilmakuri, 2009), The version of the model (V 8.1.2) used in

[1] 2003, http://sacramentoriverportal.org/modeling/CALSIM-Review.pdf

this study implements the NAVD88 datum in the formulation of the grid and the development of boundary conditions, a change from previous versions of the model.

C.4.2 DICU

The Delta Island Consumptive Use Model, or DICU[2] model, was developed by the Planning Division of DWR to estimate agricultural diversions and return flows to Delta channels. The DICU model is used in DSM2 to estimate historical agricultural flows and to estimate project planning model agricultural volumes and the salinity of return flows. These volumes and the associated concentration of water quality parameters are assigned to numerous DSM2 nodes. In this report, the term "DICU" is used to refer both to the conceptual model and to the associated computer program.

The values calculated for consumptive use in the conceptual model include the following parameters:

- Evapotranspiration – includes climatic conditions, soil type and plant type and associated acreage
- Precipitation – spatially distributed using Delta weather station values
- Surface runoff
- Soil moisture
- Irrigation – water diverted from channels, estimated by season
- Seepage – water used by plants flows from channels to Delta islands
- Drainage – return flows from irrigation and leaching to channels from Delta islands
- Leach water – heavy applications of water in winter months used to leach salts from soils.

The DICU model as a whole is most sensitive to changes in irrigation efficiency (a constant factor applied to irrigation withdrawals) and to leaching water estimates. Calculations for water diversions and returns are most sensitive to changes in efficiency of irrigation and in evapotranspiration. Changes in seepage values can cause changes in irrigation demands and in return flows, although they only have a small impact on return flows. Studies have indicated that DICU seepage estimates are probably low.

---

[2] http://modeling.water.ca.gov/delta/reports/misc/EstDICU.pdf

The DICU model provides time series of values that are applied as boundary conditions on a monthly average basis[3],[4] (DWR, 1995a; DWR 2002) in DSM2 at 257[5] locations throughout the Delta – these locations are subdivided into 142 regions. There are three components to DICU flows – diversion, drainage and seepage. The total monthly diversions incorporate agricultural use, evaporation and precipitation, drains incorporate agricultural returns, and seeps incorporate channel depletions. These flows are distributed as boundary conditions that vary by region and by Water Year Type. Acreages for land use categories and crop type are varied by two categories of water year type, critical and non-critical. The critical years in the DICU model include the D-1485 (same as D-1641) water year classification types of Critical and Dry; non-critical years include the remaining Water Year classification types.

The concentration of EC in agricultural return flows, the Drain flows in DSM2, are also applied on a monthly average basis using the same monthly averages in every year regardless of water year type. The estimation of water quality concentrations in return flows in the DICU model is documented in DWR publications available online[6].

C.4.3 CALSIM II

CalSim is a model that was developed by the California Department of Water Resources to simulate California State Water Project (SWP) and Central Valley Project (CVP) operations in planning studies. CalSim II is the latest version of CalSim available for general use. It represents the Central Valley with a node and link structure to simulate natural and managed flows in rivers and canals. It generates monthly flows showing the effect of land use, potential climate change, and water operations on flows throughout the Central Valley.

CalSim II is a simulation by optimization model which simulates operations by solving a mixed-integer linear program to maximize an objective function for each month of the simulation. CalSim II simulates the operation of the CVP and SWP systems for defined physical conditions and a set of regulatory requirements. The model simulates these conditions using up to 82 years of historical hydrology from Water Year (WY) 1922 through WY 2003.

The system objectives and constraints are specified as input to the model, and CalSim II then utilizes optimization techniques to route water through a network representing the California water system given user-defined priority weights. A linear programming (LP)/mixed integer linear programming (MILP) solver determines an optimal set of decisions for each time period given this set

[3] http://baydeltaoffice.water.ca.gov/modeling/deltamodeling/models/dicu/dicu.cfm

[4] http://www.iep.ca.gov/dsm2pwt/reports/DSM2FinalReport_v07-19-02.pdf, http://baydeltaoffice.water.ca.gov/modeling/deltamodeling/models/dicu/DICU_Dec2000.pdf

[5] note that Byron-Bethany irrigation district is included as a DICU flow in Clifton Court Forebay, so there are actually 258 DICU nodes

[6] http://baydeltaoffice.water.ca.gov/modeling/deltamodeling/models/dicu/DICU_Dec2000.pdf

of weights and system constraints. The CalSim II model has been designed to separate the physical and operational criteria from the actual process of determining the allocations of water to competing interests. Thus, CalSim II provides quantitative hydrologic-based information to those responsible for planning, managing and operating the SWP and CVP. As the official model of those projects, CalSim II is the default system model for the analysis of water in the Central Valley of California.[7]

C.4.4 Transfer Operations Model (TOM)

TOM was developed to analyze effects of Long-Term Water Transfers on the CVP, SWP, major rivers, and the Delta by tracking: the water made available from various sellers as it moves through the system; the effects on CVP and SWP operations; and, the diversion of transfer water by buyers. TOM simulates operations on a monthly time-step for the same 34-year period as CalSim II, and its output is used is supply a subset of the boundary conditions used in DSM2 to model the Alternatives. (See Appendix B for more details.)

In real-time operations, tracking transfer water requires an increased level of coordination between CVP and SWP operators as it affects accounting under the Coordinated Operation Agreement (COA) between the CVP and SWP, and can require COA accounting adjustments. Transfer water can change the timing of when CVP and SWP Project water is moved. A portion of transfer water is typically used as carriage water to maintain Delta water quality when transfer water is moved through the Delta. This requires initial estimates for carriage water that must later be verified and adjusted. TOM was developed in consultation with Reclamation and with an understanding of both actual operations and CalSim II model assumptions. Rules used in TOM to simulate operational responses to water transfers and changes in stream-aquifer interaction were reviewed with CVP operations staff.

C.4.5 Level of Development

The Long-Term Water Transfers EIS/EIR is intended to provide environmental assessment for water transfers occurring over a ten-year period. Because of the relatively short horizon, it is anticipated that the existing Level of Development (LOD) would not substantially change, although reasonably foreseeable projects that may be constructed over the next ten years have been incorporated into the model. CalSim II existing LOD simulations depict how the modeled water system might operate with an assumed physical and institutional configuration imposed on a long-term hydrologic sequence, assuming that current land use, facilities, and operational objectives are in place for each year of simulation (water years 1970 through 2003). The results are a depiction of the current environment which provides a basis for comparison of alternatives effects for the impact analysis under CEQA. The ten-year period allows simulation of a

[7] http://sacramentoriverportal.org/modeling/CALSIM-Review.pdf, Section 6.1

single level of development under the assumptions that conditions are not likely to change significantly over such a short time horizon.

C.5 Modeling Methodology and Analysis Limitations

C.5.1 DSM2 Scenario Development

DWR-DMS has developed a series of computer applications, called preprocessors, to automate the generation of DSM2 model inputs and boundary conditions. These applications produce input time series for DSM2 flows from CalSim II output, as well as time series for the timing of operations for certain gates and barriers, for example, the gates at the entry of Clifton Court Forebay (CCFB) and the gates in the Delta Cross Channel (DCC). The time series, as well as the time series for DICU flows and EC concentrations, are copied into a single input file in the DSS data format that is read directly into DSM2. Boundary conditions for the Base case come solely from CalSim II output, while boundary conditions defining the alternatives come from TOM. As mentioned previously, these alternatives depict an Existing, or Current Conditions, LOD.

C.5.2 Inflow, Export and EC Boundary Conditions

Boundaries that define the movement of water into and out of the Delta, and thus also the transport of water quality constituents, consist of inflow boundaries, outflow boundaries and a stage boundary set at Martinez. In Figure C-1 (left), the main inflow boundary locations are denoted by blue dots as is the stage boundary at Martinez. The inflow boundaries are found at the each of the major rivers (Sacramento, San Joaquin, Calaveras, Mokelumne and Cosumnes), and at the Yolo Bypass. The stage boundary at Martinez is also an outflow boundary. In Figure C-1 (right), the approximate positions of Delta export/ diversion locations (water intakes) are shown.

CalSim II and EXCEL files were converted to DSM2 input. CalSim II output was developed as boundary conditions by running the preprocessors for DSM2. Time series in EXCEL files representing TOM model output were transferred to DSS format using the CalSim II file as a template, and then run through the DSM2 preprocessors. Similarly, the stage boundary at Martinez was obtained from a standardized time series under direction of the preprocessor logic. The EC boundary condition at Martinez is calculated in a DSM2 preprocessor using the NDO (Net Delta Outflow) value from CalSim II DSS file output and an equation defining an NDO-EC relationship at Martinez. The EC time series at the San Joaquin River location at Vernalis was supplied by MBK staff, either in the original CalSim II DSS file or in the EXCEL file with TOM model output. EC values at the other major inflow boundaries are set as standard constants for use in QUAL.

C.5.3 Limitations of the Analysis

There are limitations in the ability of models to accurately address all of the intricacies of complex water management operations. Professional judgment is required to interpret results and determine benefits and impacts. Analysis of Delta Conditions for the Long-Term Water Transfers is based on several models each with their own simplifications, idiosyncrasies and limitations. The overall analysis is therefore subject to the individual and combined limitations of these models. While it is important to recognize and acknowledge the limitations of models as they are applied for this analysis, these three models represent the best available tools for performing the analysis to serve as the basis for determining environmental impacts. The regular and continued use of DSM2, in particular, for planning studies and environmental assessment by Reclamation, DWR, and others indicates DSM2 is adequate for the purposes of this EIS/EIR.

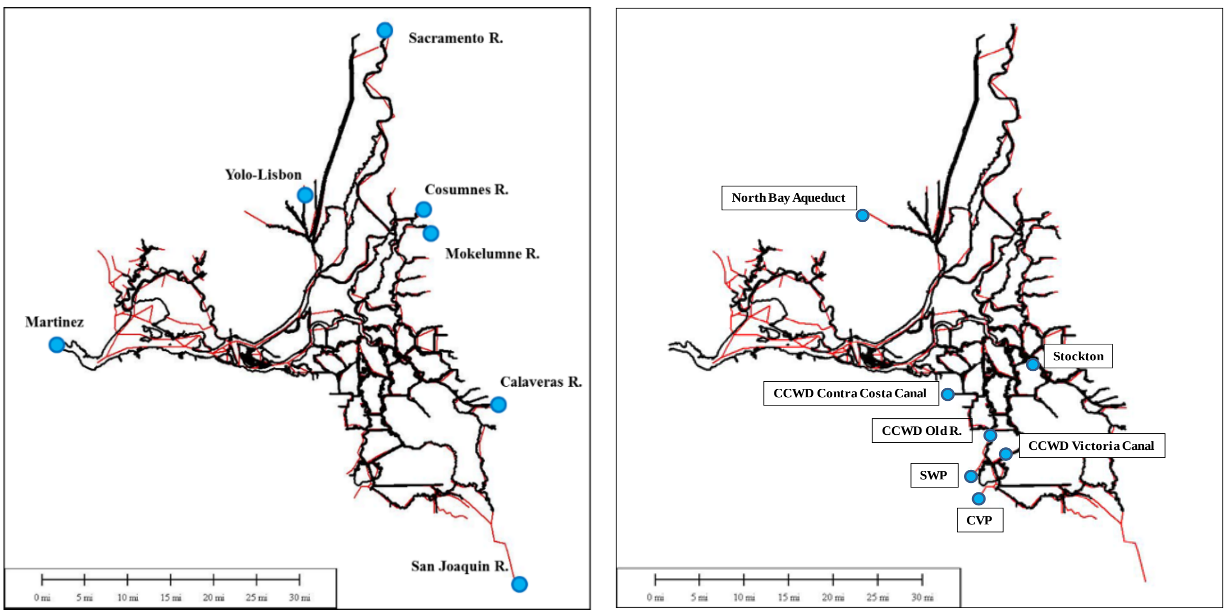

Figure C-1. Approximate Location (Blue Circles) Of: (Left) the Main Model Inflow Boundaries and the Stage Boundary At Martinez; and, (Right) the Water Intakes (Export Locations).

C.6 Description of Project Alternatives

C.6.1 Alternative 1: No Action/No Project Alternative

CEQA requires an EIR to include a No Action/No Project Alternative which allows for a comparison between the impacts of the action alternatives with Base case conditions. The No Action/No Project Alternative may include some reasonably foreseeable changes in existing conditions and changes that would be reasonably expected to occur in the foreseeable future if transfers were not approved.

Under the No Action/No Project Alternative, CVP related water transfers through the Delta would not occur from 2015-2024. However, other transfers that do not involve the CVP could occur under the No Action/No Project Alternative. Additionally, CVP transfers within basins could continue and would still require Reclamation's approval. Some CVP entities may decide that they are interested in selling water to buyers in export areas under the No Action/No Project Alternative; however, they would need to complete individual NEPA and Endangered Species Act (ESA) compliance for each transfer to allow Reclamation to complete the evaluation of the transfers for approval.

C.6.2 Alternative 2/Proposed Action: Full Range of Transfers

Alternative 2 would involve transfers from potential sellers upstream from the Delta to buyers in the Central Valley and Bay Area. Alternative 2 includes transfers under all potential transfer measures: groundwater substitution, reservoir release, conserved water, and cropland idling and crop shifting.

C.6.3 Alternative 3: No Cropland Modifications

Alternative 3 would include transfers through groundwater substitution, stored reservoir release, and conservation. It would not include any cropland idling or shifting transfers.

C.6.4 Alternative 4: No Groundwater Substitution

Alternative 4 would include transfers through cropland idling, crop shifting, stored reservoir release, and conservation. It would not include any groundwater substitution transfers.

C.6.5 Nomenclature Used in the DSM2 Analysis of Delta Conditions

The following descriptive nomenclature was used in headings and/or captions for Tables and Plots depicting model results for the Alternatives, and in the text of this document:

- Alternative 1 = (Existing Condition) Base
- Alternative 2 = All Transfers
- Alternative 3 = No Crop Idle
- Alternative 4 = No Groundwater Substitution

C.7 Comparison of Boundary Conditions for the Alternatives

Alternative 1, the Base condition, was simulated in DSM2 with the conditions defined by the baseline CalSim II output. These results represent reasonably foreseeable conditions for the 2015-2024 period and are used for comparison with results from each of the project alternatives. Selected boundary conditions for Alternatives 2 – 4 differed from CalSim II baseline conditions – the Base conditions and the monthly average differences are depicted in Figure C-2 through Figure C-10. Tables show computations of monthly average differences, average monthly differences and average monthly percent differences – the Attachment to this Appendix contain the full set of tabular results. In general, the Proposed Action has the greatest change from Base among the Alternatives.

Conditions for all other boundary conditions (not shown), including DICU flows and EC concentrations, were used by all four Alternatives. For the All Transfers and No Crop Idle alternatives, diversions of water for Banta Carbona Water District were specified downstream of Vernalis. These diversions were incorporated in the San Joaquin River inflow boundary instead of at their geographic location as they were small in volume, totaling 54 cfs in increments of 4 cfs over the simulation period (water years 1970 through 2003), and the diversion location would not affect any of parameters tracked for the Delta conditions analysis.

Table C-1 document the change from Base for Sacramento River inflow as shown in Figure C-2, while Table C-2 through Table C-4 show computation of the average monthly percent difference results. These tables show that the period July to September in Dry and Critical water years account for the increases in Sacramento River inflow for each of the water transfer alternatives, and that most other months and years have variable levels of decrease in inflow. The timing of the increases in inflow are in line with the release of transfer water from storage in upstream dams discussed in Appendix B. Percent decreases in inflow are less than 2% in all other months and year types.

Table C-1~~1~~. Monthly Average Difference in Sacramento River Inflow (c~~C~~fs) between the All Transfers and Base Alternatives, (All Transfers – Base). The Lower Table Computes Average Monthly Differences.

The East Bay Municipal Utility District (EBMUD) transfer water occur as exports on the upper Sacramento River near Freeport. Table C-5, Table C-6 and Figure C-3 illustrate these results. The flow volumes are small in comparison with Sacramento River flows. The exports of transfer water occur mainly in Critical and Dry water years, although some transfer also occurs in a few Above Normal or Wet water years.

Table C-55. Monthly Average Difference in EBMUD Export (cfs) for the All Transfers Alternative, (All Transfers – Base). The Lower Table Computes Average Monthly Differences.

On the San Joaquin River (Figure C-4), Table C-7 shows that the average monthly percent change from Base inflow is less than +/- 2% for all months, water year types and alternatives except for July in Dry and Critical water years in the No Groundwater Substitution alternative, Alternative 3, whose results for average monthly percent difference results are shown in Table C-7. As can be seen in Figure C-3, the increased flow of approximately 500 cfs in this alternative occurred in exactly three water years (1981, 1992 and 2001). Figure C-5, San Joaquin River inflow EC for Base and change from Base for the Alternatives, illustrates that the upstream changes on the San Joaquin make little difference to inflow EC, as increases and decreases were infrequent and small in magnitude. Thus, the changes in San Joaquin River inflow and EC in Alternatives 2 through 4 have very little influence on the model results in the Delta.

South Delta exports at the SWP-Banks and CVP-Jones locations, Figure C-6 and Figure C-7 respectively, show a similar pattern to Sacramento R. inflow in monthly average percent difference increases and decreases, shown in Table C-8 and Table C-9 for Alternative 2. Increases in export flow occur July and August in Dry and Critical years at SWP, and July – September in Dry and Critical years at CVP. The patterns of percent increases and decreases of exports at these locations are similar for Alternatives 3 and 4, but the percentages are smaller (see the Attachment Section on Export Boundary Conditions for monthly average table details).

The export volumes are much smaller at each of the three Contra Costa Water District (CCWD) export locations, shown in Figure C-10 through Figure C-8. For each of these transfer water buyers, all changes in exports are increases for each of the alternatives, unlike the SWP and CVP which also experience decreases in export flow in the Alternatives. The three locations have different patterns of increases in the export of transfer water – although all exports occur in Critical and Dry water years, the Old River location (Table C-10) only exports transfer water in August and September, while the other two locations also export water in July (Table C-11 and Table C-12).

Table C-13 illustrates the percent change from Base Net Delta Outflow (NDO) for the alternatives – NDO is the sum of all inflow and outflows set as boundary conditions in DSM2 as calculated in CalSim II. NDO percent changes in the table reflect the changes in Sacramento inflow with the largest increases occurring July through September in Critical and Dry water years for all alternatives in comparison with Base With a few exceptions, the rest of the differences from Base are relatively small percent decreases. Figure C-11 illustrates the plot of Base NDO and the change from Base NDO for the alternatives. The Martinez EC boundary condition, illustrated in Figure C-12 as a monthly average, is calculated in a preprocessor from NDO for each of the Alternatives.

C.8 Comparison of Salinity (EC) Results

The change in EC for Alternatives 2 – 4 in large part reflects the changes in flow for the Sacramento River and the SWP and CVP exports as these volumes were by far the largest in magnitude in comparison with the Base, Alternative 1. The largest changes in EC should reflect the balance between these two flows for the alternatives, as Sacramento inflow increases tend to reduce EC in the Delta while SWP+CVP export increases tend to increase EC. If export increases dominate locally, EC increases due to increased intrusion of Martinez EC, and if Sacramento inflow increases dominate locally, EC will decrease. In addition, when the Delta Cross Channel is open, low EC Sacramento River water reaches the central Delta, mainly through Middle River – increases in this flow are facilitated by increases in SWP and CVP export pumping. Table C-14 illustrates that on average, flow through the DCC was greater than Base flow July - September in Critical and Dry water years for all alternatives while in almost all other months and water year types, Base flow through the DCC was greater.

In this section, modeled EC results are presented at selected D-1641 locations that showed a change from Base EC (illustrated in figures) and/or average monthly percent change from Base EC (illustrated in tables) values that differed notably from Base monthly average or average monthly values. At most locations, the change or percent change from base EC was negligible. Plots and tables for locations not covered in this section are found in the Attachment.

Sacramento River (inflow) and SWP and CVP (export) increases in volume occurred mainly July – September in Critical and Dry water years, with the largest increases in the All Transfers alternative, with decreases in volume occurring in most other months with few exceptions. Of the three alternatives, the All Transfers alternative had the greatest changes and percent changes in comparison with the Base alternative.

Figure C-13 and Table C-15 illustrate that the largest changes in modeled EC at the intake to Clifton Court Forebay (for SWP exports) occur in the All Transfers alternative. For all alternatives, the largest EC percent increases occur in July and August of Critical and Dry water years, and the largest decreases occur in September and October of Critical water years. The No Groundwater Substitution alternative has a different pattern for EC percent decreases in Dry water years than the other two alternatives, as the percent differences are smaller in magnitude in September and October for this alternative.

Figure C-14 and Table C-16 illustrate the changes in modeled EC for CVP exports for the three alternatives. The pattern of EC increases and decreases is the same as those for the SWP exports, but the magnitudes are smaller at the CVP location.

Figure C-15. SWP and CVP Monthly Average Chloride for the Alternatives.

D-1641 standards require that all export locations maintain chloride concentration less than 250 mg/L. Figure C-15 shows chloride concentration at SWP and CVP, and Figure C-16 shows chloride at CCWD’s Old River and Victoria Canal locations. Each location used the following conversion (DWR, 2001) calculated from monthly average EC:

$$\textit{Chloride (mg/L)} = (EC - 160.6)/3.66$$

Figure C-16. CCWD's Old River (OR) and Victoria Canal (VC) monthly Average Chloride for the Alternatives.

At CCWD's intake in the Contra Costa Canal, denoted in this document as the Rock Slough Intake, a different conversion is used to calculate chloride from EC:

$$\text{Chloride (mg/L)} = (EC - 89.6)/3.73$$

The D-1641 criteria at this location specifies the minimum number of days that mean daily chloride should be less than 150 mg/L. For Critical water years this is 155 days, and for Dry water years this is 165 days. Results in Table C-17 indicate that several Critical and one Dry water year have greater percent differences (bold font).

Table C-17~~17~~. Monthly Average Percent Change from Base EC at CCWD Rock Slough Location for the All Transfers Alternative.

For these years, mean daily chloride was calculated from EC model output for the four Alternatives, and the number of days that chloride was greater than 150.5 mg/L was tabulated – results are shown in Table C-18. Although D-1641 specifies 14-day durations for mean daily chloride concentration, since most DSM2 boundary conditions are specified as monthly values, it is not sensible to account for this constraint herein.

Table C-18~~18~~. Check on D-1641 Chloride Standard at the CCWD Rock Slough Intake Location – Number Days Mean Daily Chloride < 150 mg/L.

Water Year	Base	All Transfers	No Crop Idle	No GW Sub
1988 (Crit)	272	264	278	275
1990 (Crit)	201	193	195	195
1991 (Crit)	180	176	177	177
1992 (Crit)	194	183	185	186
2001 (Crit)	338	338	338	338

The model results for the three CCWD intake locations are also presented by comparing the monthly average percent difference tables by alternative. Table C-19 through Table C-21 illustrates the results for all three locations for the All Transfers, No Groundwater Substitution and No Crop Idle alternatives, respectively. For each alternative, the CCWD-Victoria Canal intake location has a different pattern of monthly average percent increases and decreases than the other two alternatives (not shown), as the path for much of the water exported is through Middle River which is more heavily influenced by the operations of the DCC than the other two locations. In August of Critical water years, Victoria Canal sees a decrease in EC while the other locations saw an increase – this is likely due to the increased flow through the DCC (Table C-14) combined with the increased exports (Table C-8 and Table C-9) in comparison with the Base alternative.

The pattern of EC changes at CCWD's Rock Slough and Old River intake locations is similar to the pattern at the SWP location, with the largest EC increases occurring in July and August of Critical and Dry water years, with Rock Slough showing greater increases than Old River as it receives a greater proportion of higher EC water from the Martinez boundary than the Old River location.

Table C-19~~19~~. CCWD Intakes –Average Monthly Percent Change from Base EC for the All Transfers Alternative.

Table C-22 illustrates results for average monthly percent change from Base EC at Collinsville, RSAC081, on the Sacramento River. The increases and decreases in percent change from Base EC at RSAC081 reflect the boundary conditions changes in NDO (Figure C-11). EC results at locations in Suisun Marsh show a similar pattern.

Table C-23 and Table C-24 illustrate EC results as percent change from Base at RSAN007, near Antioch, and RSAN018, Jersey Point, respectively, on the San Joaquin River. The model results for EC at RSAN007 are similar to those at RSAC081, as they are both strongly influenced by the increases in Sacramento River outflow, as reflected in the changes in NDO flow in comparison with Base. The results at RSAN018 (Table C-24), Jersey Point, are somewhat different than those at RSAN007 (Table C-23). The Jersey Point location has a more complicated set of influences on EC, as local antecedent conditions, such as the EC in Franks Tract, of higher or lower EC waters can serve as reservoirs that mix locally near RSAN018. However, the largest increases (June – July) and decreases (August – November) in EC occur in Critical water years for all alternatives.

Both RSAN018 and RSAC092 on the Sacramento River at Emmaton have D-1641 have constraints for EC specified by water year type. Examining the average monthly percent change from Base at RSAN018 in Table C-24, large changes in EC are seen in Critical (Cr) June and July periods and in Above Normal (AN) July's (i.e., the values indicate individual years may be influencing results). Monthly average Tables (not shown, see the Attachment) indicate that for RSAN018 the AN water year 2003 and the Cr water years 1990 and 1991 can serve as indicators for adherence to D-1641 criteria for RSAN018, and that water years 2003 (AN) and 1976, 1977 and 1991 (Cr) can serve as indicators for RSAC092.

Using the maximum EC constraints at RSAC092 for AN and Cr water years (the plotted constants), Figure C-17 shows that there are only minor differences between the Base Alternative 1 and the other Alternatives (2-4) . Similarly, for RSAN018 (Figure C-18) the difference in Base alternative in increase in EC amounts to a shift in EC increases of a few days. These differences could be accounted for in real operations by delaying exports and/or reservoir releases by a few days to adhere more closely to D-1641 standards.

Figure C-17. Comparison of 14-Day Running Average EC at RSAC092 for Selected Time Frames Pertinent to D-1641.

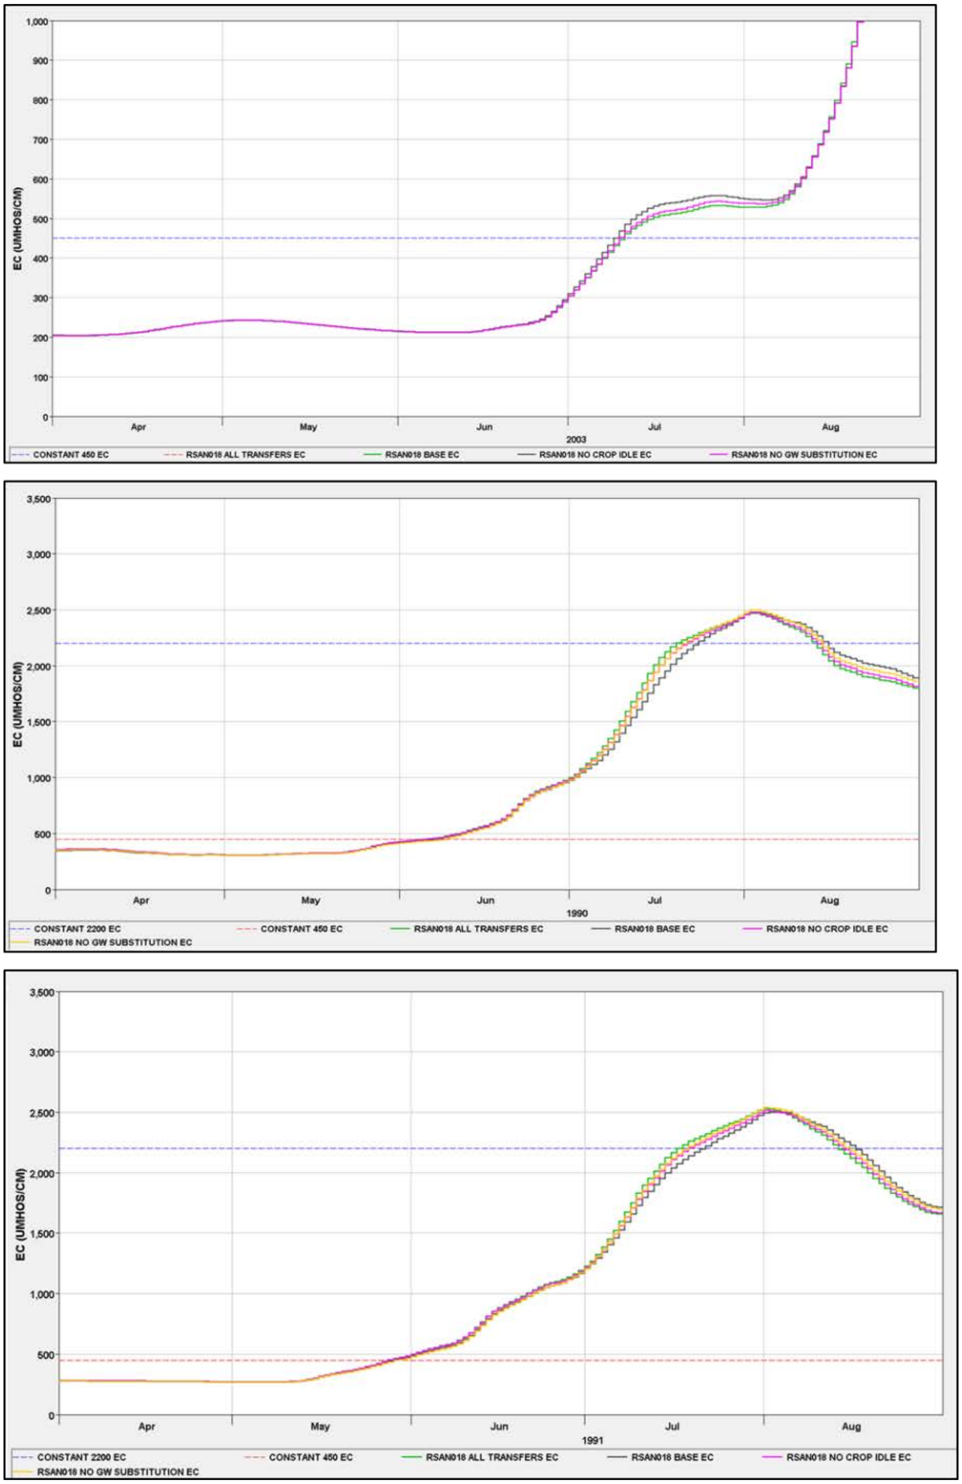

Figure C-18. Comparison of 14-Day Running Average EC at RSAN018 for Selected Time Frames Pertinent to D-1641.

C.9 Comparison of Stage Results

The potential exists for decreases in water level elevation due operational changes in the three Alternative that might affect agricultural withdrawals of water in the south Delta, a conservative estimate of stage changes was calculated as follows at each relevant D-1641 location in HEC DSSVue:

1. the daily minimum stage was calculated for all the Base and three Alternative from the 15-minute model output

2. daily change from Base stage was calculated (Daily Alternative Min Stage – Daily Base Min Stage)

3. monthly average stage was calculated from the results at step 2.

3.4. overall monthly averages and averages by Water Year type were calculated

Step 2, the difference in daily minimum stage is a conservative estimate of potential decreases in stage since changes in exports and/or inflows can shift the timing of stage potentially resulting in overly optimistic or pessimistic stage differences when calculated with 15-minute output data. As CalSim II model outputs are calculated on a monthly time step and input as boundary conditions for DSM2, the final calculation of stage changes as a monthly average is appropriate.

In addition, there is the potential for stage increases which would be considered a benefit during low flow conditions or during the summer particularly in dry or critical years. To this end, an additional calculation was made in which a conservative estimate of increase in stage was similarly made as:

1. the daily maximum stage was calculated for all the Base and three Alternative from the 15-minute model output

2. daily change from Base stage was calculated (Daily Alternative Max Stage – Daily Base Max Stage)

3. monthly average stage was calculated from the results at step 2.

4. overall monthly maximum and monthly maximum by Water Year type were calculated.

Stage changes were calculated upstream and downstream of agricultural barrier locations in Old and Middle Rivers, in Grant Line Canal, and in three additional locations: Old River near Middle River, Old River near Tracy, and RMID040 in Middle River. Results are shown as monthly average tables of difference in stage (Alternative – Base), with Average monthly results separated by water year type at the bottom of each Table.

A selection of results for ~~three~~ several of these locations ~~are~~ is shown in this section to illustrate the general results. T~~t~~he complete set of stage results is found in the Attachment. The largest differences for stage decrease from Base ~~stage~~ occurred for the All Transfers alternative, as this alternative had the greatest increases over Base exports for SWP and CVP in the south Delta. Figure C-19 shows the monthly averaged minimum daily Base stage calculation and change from minimum Base stage for each the alternatives downstream of the Old River agricultural barrier. This location was chosen for the All Transfers alternative as it had the largest decreases in monthly average of daily minimum stage difference, -0.2 ft., of any of the agricultural barrier locations, as shown in Table C-25. All seven of these occur in July or August of Dry or Critical water years. For the No Crop Idle Alternative, June 1993 had a difference of -0.2 ft. upstream of the barrier in Old River as did July 1987 downstream of this barrier. All other decreases in monthly average of daily minimum stage were -0.1 ft. or less at both the upstream and downstream locations of the Grant Line Canal and Middle River agricultural barrier locations for all of the alternative. The stage difference results in Grant Line Canal upstream of the agricultural barrier are plotted in Figure C-20 for all of the alternatives, and the monthly average results for the All Transfers alternative are shown in Table C-26. Each of Old River near Middle River, Old River near Tracy, and RMID040 in Middle River had exactly one stage decrease of -0.2 ft., occurring in June 1993, an Above Normal water year, for all three of the alternative. These results are shown for the Old River near Middle River location in Figure C-21, and monthly average calculation for the All Transfers alternative in Table C-27.

The results for stage increases highlighted the “No Groundwater Substitution” alternative in both the minimum and maximum stage difference calculations. This Alternative was the only one in which either maximum or minimum stage increased. Table C-28 shows increases maximum stage difference for the location in Middle River (RMID040) in July for several Dry (1981, 2001) and Critical (1992) Water Years. Table C-29 shows an increase in the minimum stage difference for the location at Old River near Middle River (RMID040) in July of 1981, 2001. Note that stage increases for the No Groundwater substitution Alternative are among the smallest of the all the Alternatives, so it is not surprising that stage increases also occur at several locations.

Table C-25~~25~~. Difference in Minimum Stage (ft) at Old River Downstream of Barrier for All Transfers minus Base Alternatives.

C.10 Comparison OF X2 Results

Figure C-22 and Table C-30 illustrate the monthly average and average monthly, respectively, model results for the alternatives for the location of X2 in kilometers (km) from the Golden Gate. Westward changes, negative values, are considered beneficial as higher outflow is thought to expand the volume of habitat region available to fish species. Specification of X2 is part of the D-1641 compliance standards February – June. Changes in inflow and export operations will result in a change in X2 location. According to criteria specified in (SWRCB, 1999), eastward changes in monthly average X2 position (positive values in our analysis) of 1.1 km are not significant in general, and in Critically

Dry years an eastward movement of 3.0 km is not significant. It can be seen in Figure C-22 that changes in X2 are insignificant for each of the alternative, as all monthly average differences are less than 1.1 km. Alternative 3, No Groundwater Substitution, has the smallest differences in comparison with the Base X2 location.

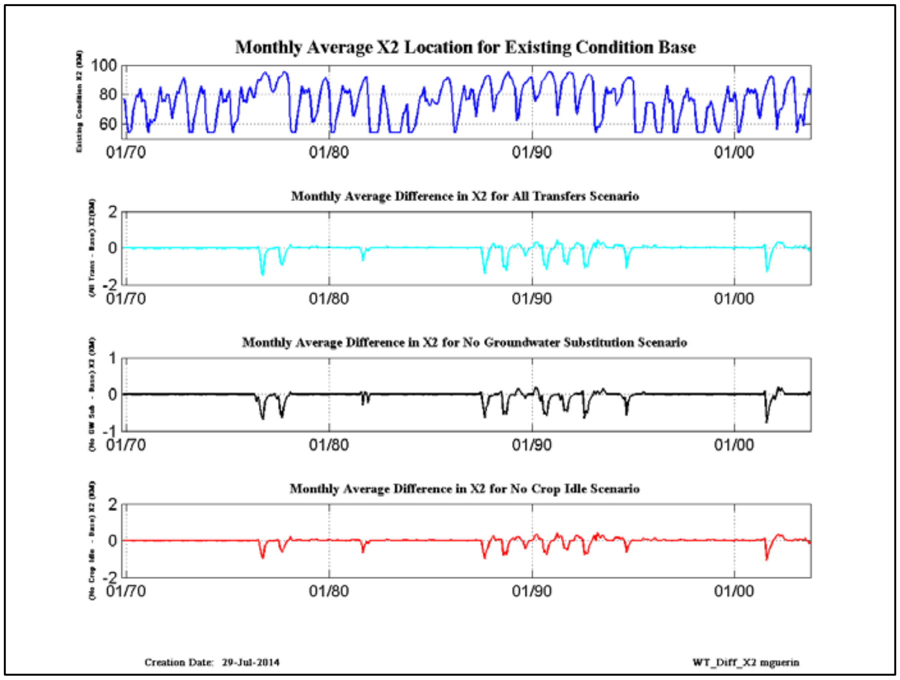

Figure C-22. Monthly Average X2 Location for Existing Condition Base and the Differences Alternative – Base.

Table C-30~~28~~. X2 Monthly Average Change from Base Location (km).

C.11 Comparison of OMR results

Under National Marine Fisheries Service and California Fish and Wildlife Service Biological Opinions (BOs), CVP and SWP operations are mandated to maintain exports at levels to minimize entrainment of delta smelt, steelhead, and winter-run salmon between December and June. Entrainment protection is currently met via prescriptions for OMR flow using measurements supplied by the US Geological Survey (USGS). This prescription is called into play when delta smelt are found in locations believed to put them at risk for entrainment. Restrictions to OMR flow, and therefore to export levels, are considered to be an “adaptive management” process in which decisions on changes in Delta operations are made after assessing current conditions and data. The period December – March is used to protect pre-spawning delta smelt adults along with turbidity or export salvage triggers, and the period through June is used to protect larval smelt along with water temperature triggers.

The 15-minute DSM2 flow results at ROLD024 and at RMID015 were daily averaged, added together then smoothed with a 14-day running average – the final step was to monthly average the running average results and then calculate change from Base and percent change between each alternative and the Base alternative. Percent change from Base of the monthly averaged OMR flow for the alternatives was then used to gauge the effect of alternative Delta operations found in the alternatives. Note that negative percent difference numbers indicate that a negative OMR flow in the alternative was smaller in magnitude than the Base.

The change from Base results (Figure C-23) show that all alternative tend to increase the magnitude of negative OMR flow. The December – June percent change from Base values (Table C-31) of OMR flow are similar for the All Transfers and No Crop Idle alternatives, with positive percent changes in April and June of Above Normal water years, while the No Groundwater Substitution alternative has a positive percent change in June of Above Normal water years.

The Biological Opinions (FWS, 2008; NOAA, 2009) prescribing OMR flow values for the protection of delta smelt are complicated by additional triggers used to specify the “adaptive” actions to restrict negative OMR flows, such as turbidity, water temperature, and the presence of delta smelt at certain locations or times.

C.12 Summary of Results

The Delta Conditions analysis of DSM2 alternatives examined regulated parameters to determine the magnitude of changes to these parameters that could occur if the system operations defined by any of the Alternatives were implemented instead of Base operations. The pertinent parameters are:

- salinity (EC) changes at D-1641 locations
- changes in south Delta stage heights identified in D-1641, as decreases in stage might affect agricultural diversion operations
- changes in the location of X2, the 2 ppt salinity isohaline, as regulated by D-1641
- changes in the magnitude in the combined Old River plus Middle River flow (OMR) December – June as regulated by the NMFS and FWS BOs

Alternative 1 is the Base condition, and all analyses of the regulated parameters for the Alternatives are defined *via* a change from the Base conditions using the “comparative analysis” approach discussed above. The model time span is 09/1969 – 10/2003, i.e., water years 1970 through 2003. As DSM2 boundary conditions are specified as monthly values, defined either by CalSim II or TOM model output, all comparisons are made using either monthly average (one value per month modeled) or average monthly (one value per month, averaged over the modeled years) calculations.

The Proposed Project, Alternative 2 or the “All Transfers” alternative, has boundary conditions with the greatest changes to Base conditions among the alternatives. Although both the Sacramento and San Joaquin Rivers change under the alternatives, increases in Sacramento River inflow in the months July – September of Critical and Dry water years dominate the changes and are greatest in the All Transfers alternative and smallest in the No Groundwater Substitution alternative, Alternative 3. Export changes are the greatest at the SWP and CVP export locations, as expected, and the increases generally mirror the increases in Sacramento River inflow, although increases in SWP exports end in August while increases in CVP exports end in September. In the other months, exports generally decrease as average monthly values. These results reflect the changes discussed in Appendix B (Water Operations Assessment).

Changes in the EC regime were calculated for each Alternative in comparison with Base at all D-1641 locations, and the entire set of results are compiled in the Attachment to this Appendix. It was found that results at many locations were either small (had average monthly percent differences around +/- 1% or less) or were characteristic of a region (e.g., Suisun Marsh), so they are not discussed in this document. Instead, only those results that reflect general trends or occur at export locations were included herein.

As expected, the All Transfers alternative, the Proposed Project, exhibits the largest increases in EC in July – August of Critical and Dry water years at SWP and CVP export locations, with the No Groundwater Substitution alternative showing the smallest average monthly EC increases over all water years. At these locations, EC decreases in Critical and Dry water years September - December even though exports have increased over Base in September. Note that the EBMUD exports were not covered herein for EC, as only low EC Sacramento River water is exported at this location.

The model results for the three CCWD intake locations are differ by location. The CCWD-Victoria Canal intake location has a different pattern of increases and decreases than the other two locations. In August of Critical water years, Victoria Canal sees a decrease in EC while the other locations saw an increase – this is likely due to the increased flow of low EC Sacramento River water through the DCC and then through Middle River as Victoria Canal is more heavily influenced by DCC operations than the other two locations. The pattern of EC changes at CCWD’s Rock Slough and Old River intake locations is similar to the pattern at the SWP location, with the largest EC increases occurring in July and August of Critical and Dry water years, with Rock Slough showing greater increases than Old River as it receives a greater proportion of water from the Martinez boundary than the Old River location.

In general, the All Transfers alternative sees the largest increases in EC when exports are the greatest, with Critical water years in July seeing the largest percent difference of 4.2% at the SWP location and 3.3 % at the CVP location. In terms of D-1641 criteria for chloride concentration, all export locations regulated by the 250 mg/L standard were in compliance on a monthly average basis – spot checks at SWP showed the compliance was also maintained with daily average chloride. At the Contra Costa Canal location (CCWD's intake modeled at Rock Slough), the chloride standard was in compliance for the requisite number of days for all alternatives.

At locations RSAN007 and RSAC081, near the confluence of the Sacramento and San Joaquin Rivers, the influence of Sacramento River increases result in EC decreases during the increased export periods. The increases in EC during other periods are less than 2% on an average monthly. RSAN018, Jersey Point, and RSAC092, Emmaton were checked for D-1641 EC compliance and it was found that only in June/July of one Above Normal (2003) and a selection of Critical water years had the potential to violate standards. In comparison with the Base, the potential exists for the Critical water year standards to be exceeded in the Alternatives by EC increases occurring a few days sooner than in the Base, which could be changed with a minor variation in export timing.

Changes in the south Delta stage were calculated for each Alternative in comparison with Base at all D-1641 locations, and discussed only at representative locations - the entire set of results are compiled in the Attachment to this Appendix. Stage changes were assessed via a conservative calculation that compared the monthly average of differences in daily minimum stage. The analyses consider a stage difference of -0.2 ft. to indicate a potentially significant result. Stage decreases were greatest for the Proposed Project/All Transfers alternative at the Old River downstream of agricultural barrier location, but changes of this magnitude only occurred in seven of the 408 months simulated. These decreases occurred in July and August of Dry or Critical water years, when south Delta exports increased in comparison with Base. Monthly average decreases in stage were sparse in all other locations and alternatives, with few instances when stage changes reached -0.2 ft. (e.g., in June 1993 in several locations for each of the alternatives).

Changes in X2 were evaluated as the change from monthly average Base values. The No Groundwater Substitution alternative, Alternative 3, had the smallest changes in X2. According to the criteria specified in (SWRCB, 1999), none of the changes in X2 are considered significant.

The Biological Opinions (FWS, 2008; NOAA, 2009) prescribing December – June OMR flow values for the protection of delta smelt are complicated by additional triggers used to specify the "adaptive" actions to restrict the magnitude of negative OMR flows, such as turbidity, water temperature, and the presence of delta smelt at certain locations or times. These adaptive constraints make it difficult to assess the significance of a change in OMR flow due to the alternatives. However, all of the Alternatives tend to increase the magnitude of negative OMR flow (positive percent values indicate a result to be avoided). The December – June average monthly percent change from Base values of OMR flow are similar for the All Transfers and No Crop Idle alternatives, with positive percent changes in April and June of Above Normal water years, while the No Groundwater Substitution alternative has a positive percent change in June of Above Normal water years.

Attachment C.1: DSM2 Detailed Model Output and Boundary Conditions

C.1.1 Salinity (EC) Model Output

Model output for EC at each location was calculated for water years 1970 – 200. It is presented here in two basic forms – as Tables and as Figures showing monthly average EC for the Base scenario and change from Base EC, (Scenario – Base). The Tables have several subtypes: monthly average results for water years 1970 – 2003, average monthly results for the average over all water year types and results split by water year type. For each location, the Tables show Base salinity as EC, change from Base EC and percent change from Base EC for each of the three alternative scenarios (i.e., seven tables per location).

Table 1-1. Martinez Base salinity (EC).

C.1.2 Stage Model Output

Model output for each location is presented here in two basic forms – as Tables and as Figures showing monthly average of daily minimum stage for the Base scenario and change from Base for monthly average of daily minimum stage, (Scenario – Base). The Tables have several subtypes, although all of them show results for water years 1970 – 2003, including average monthly results for the average over all water year types and results split by water year type. For each location, the Tables show Base monthly average of daily minimum stage, change from Base of Monthly Average of daily minimum stage and percent change from Base of monthly average of daily minimum stage for each of the three alternative scenarios (i.e., seven tables per location).

Results were calculated upstream and downstream of agricultural barrier locations in Old River, Middle River and Grant Line Canal, as well as at three additional locations: Old River near Middle River, Old River near Tracy, and RMID040 in Middle River.

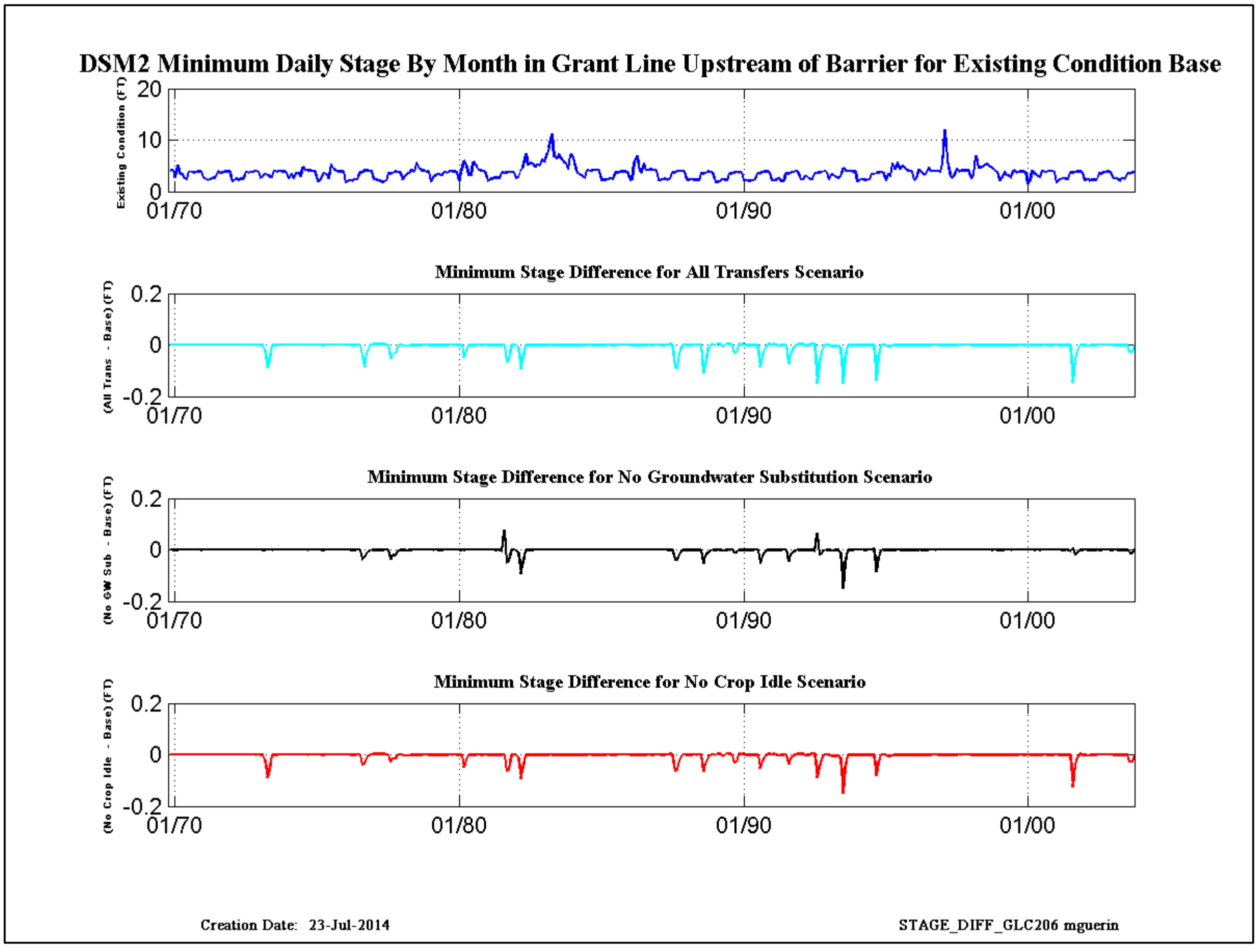

Figure 2-1. Minimum stage at Grant Line barrier and minimum stage differences Scenario – Base.

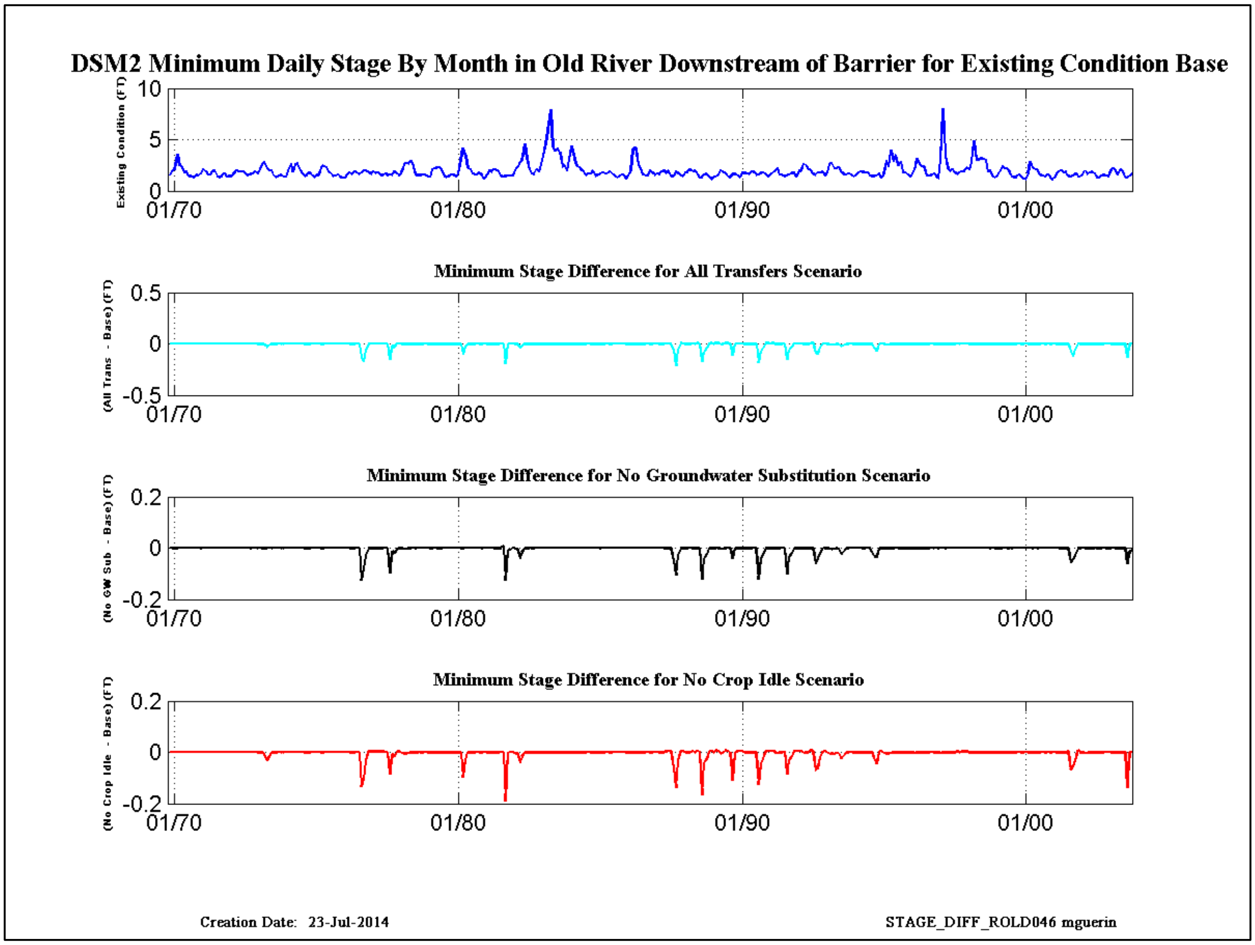

Figure 2-2. Minimum stage at Old River Downstream barrier and minimum stage differences Scenario – Base.

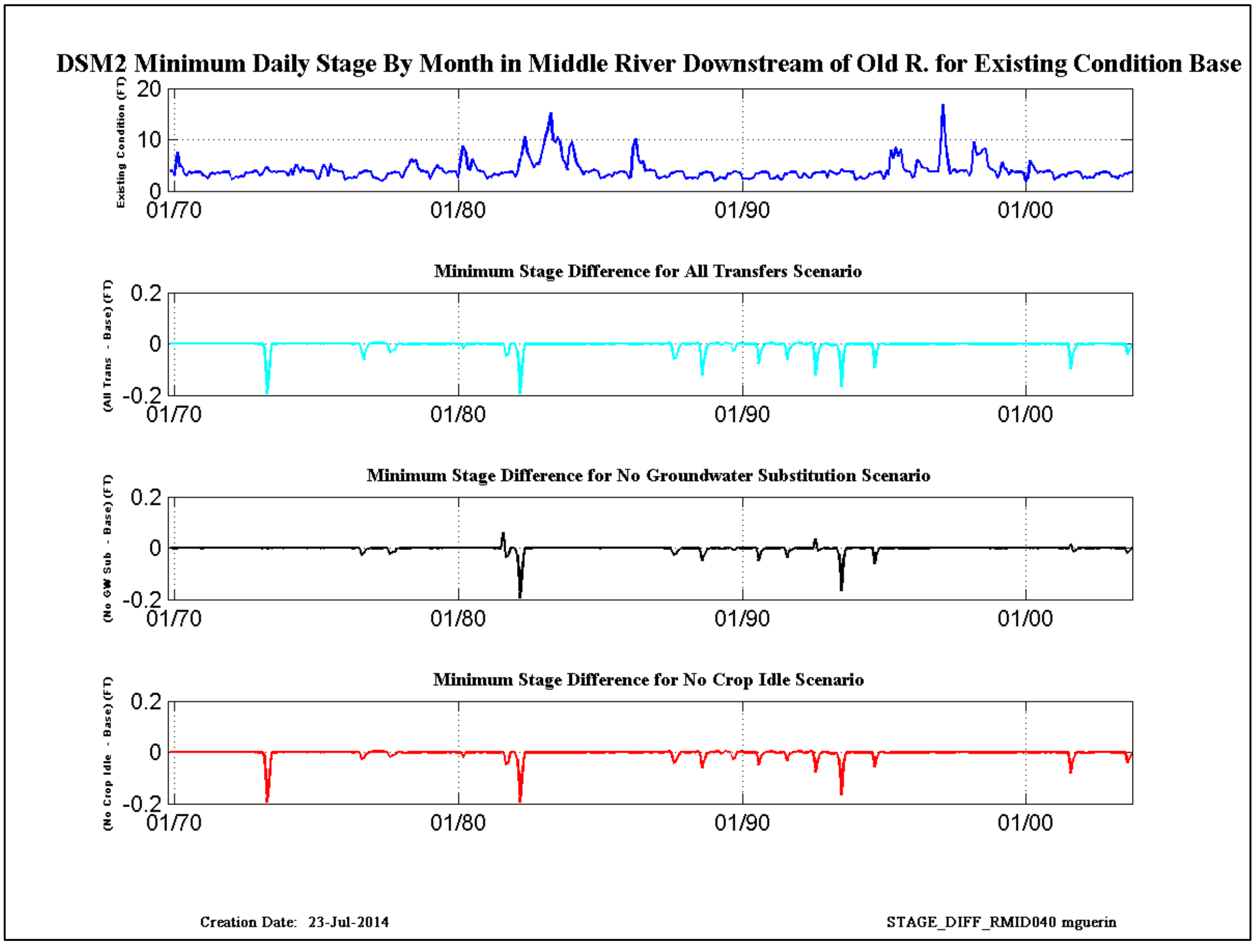

Figure 2-3. Minimum stage at Middle River Downstream of Old R. barrier and minimum stage differences Scenario – Base.

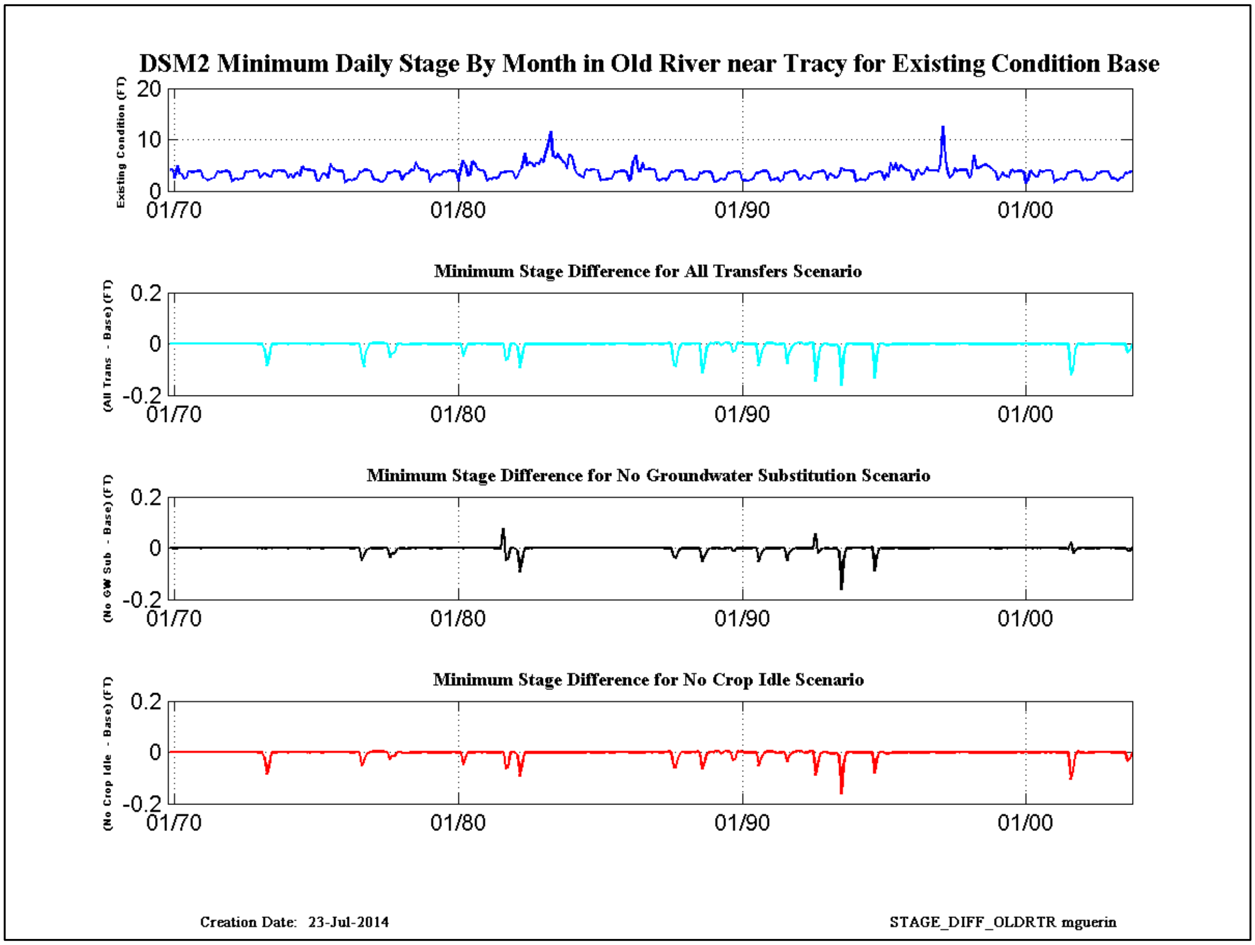

Figure 2-4. Minimum stage at Old River near Tracy barrier and minimum stage differences Scenario – Base.

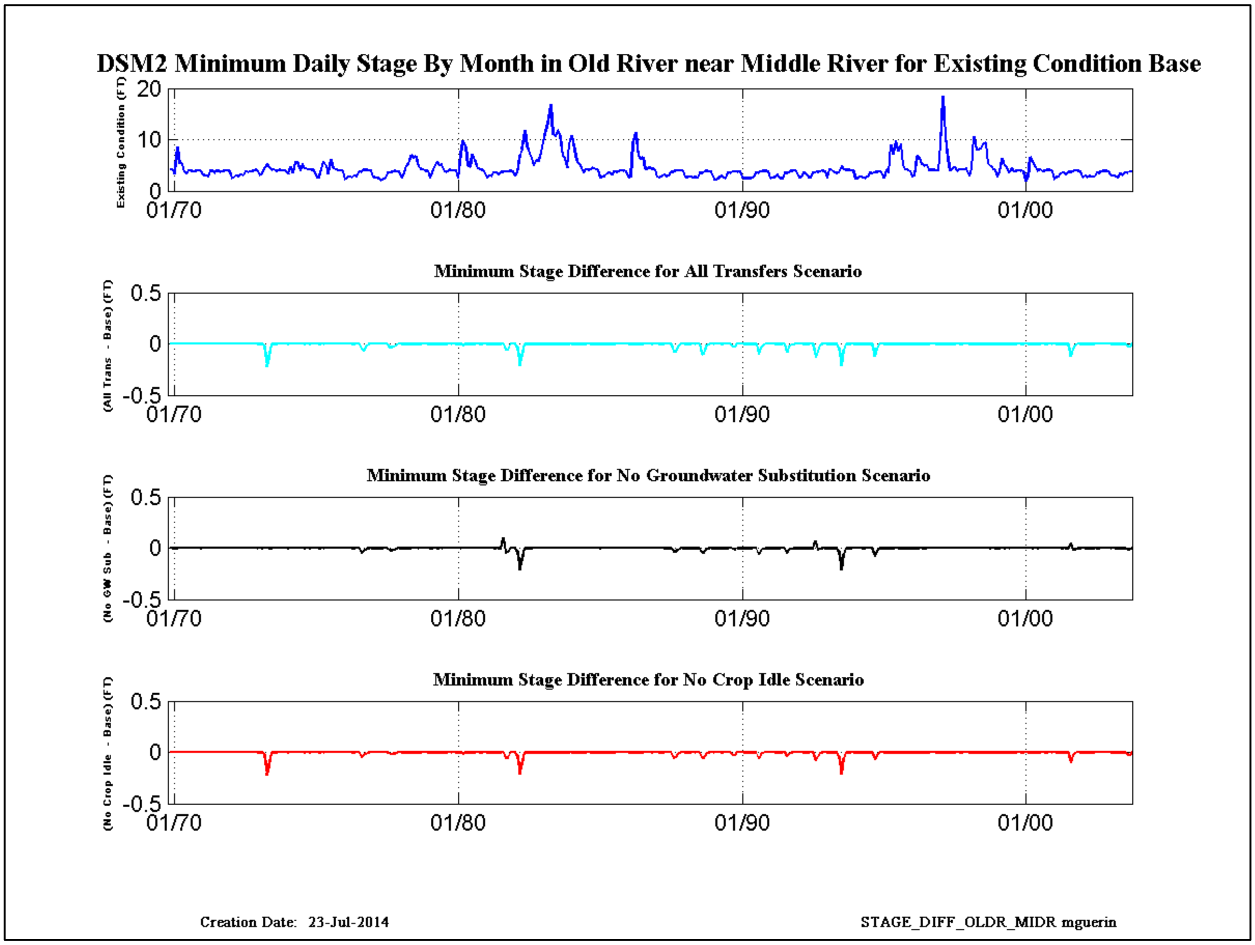

Figure 2-5. Minimum stage at Old River near Middle River barrier and minimum stage differences Scenario – Base.

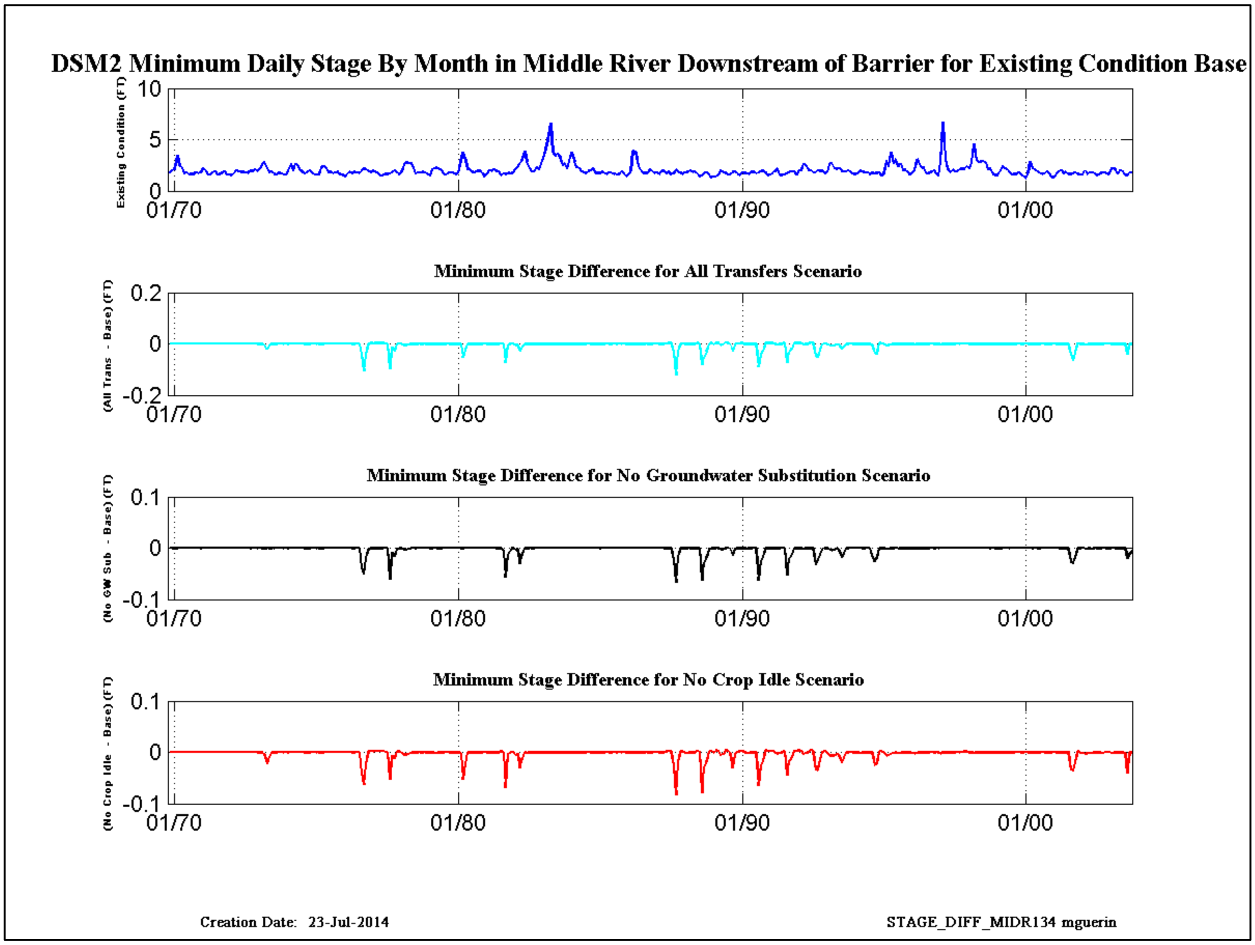

Figure 2-6. Minimum stage at Middle River barrier and minimum stage differences Scenario – Base.

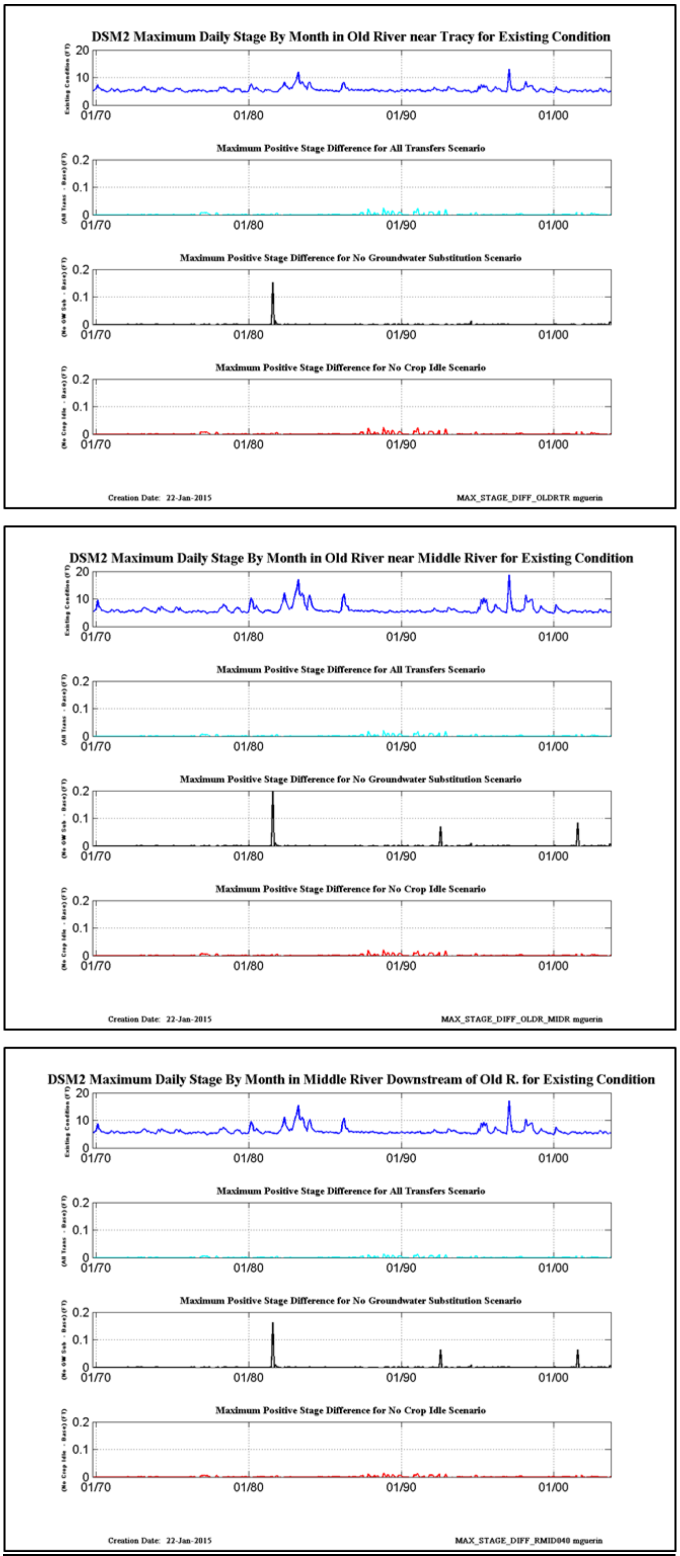

Figure 2-11. Figures show the maximum positive stage difference at three locations.

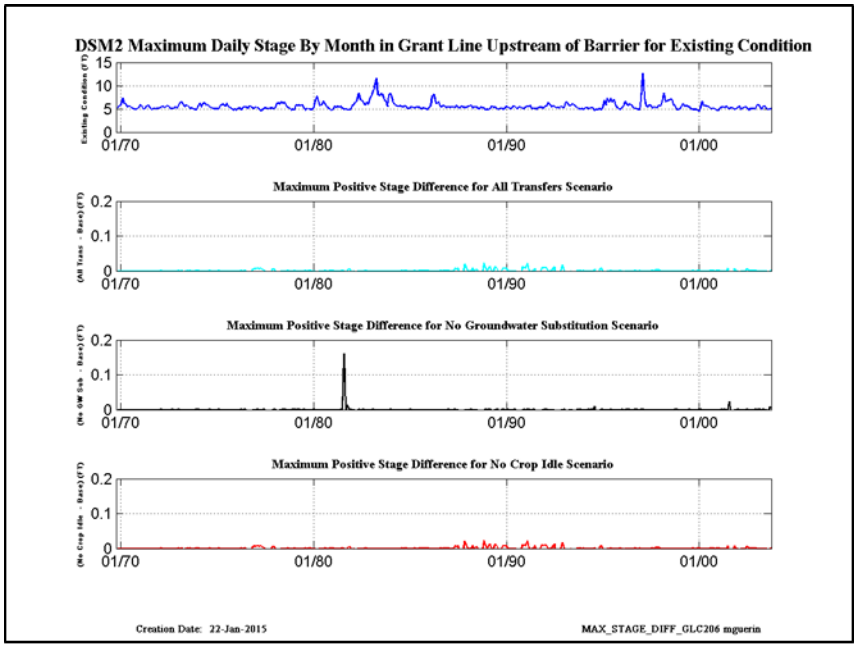

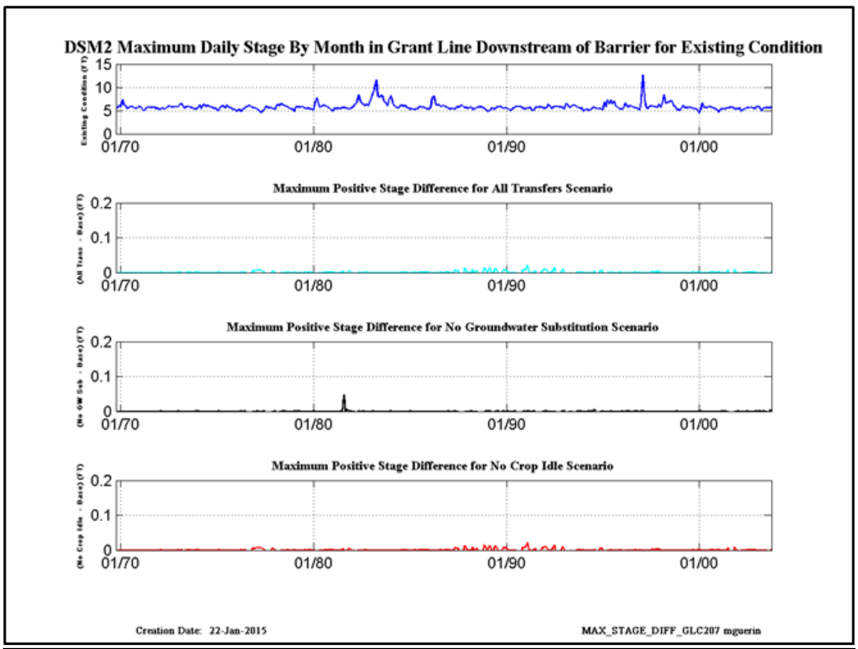

Figure 2-12. Figures show the maximum positive stage difference upstream and downstream of the barrier in Grant Line Canal.

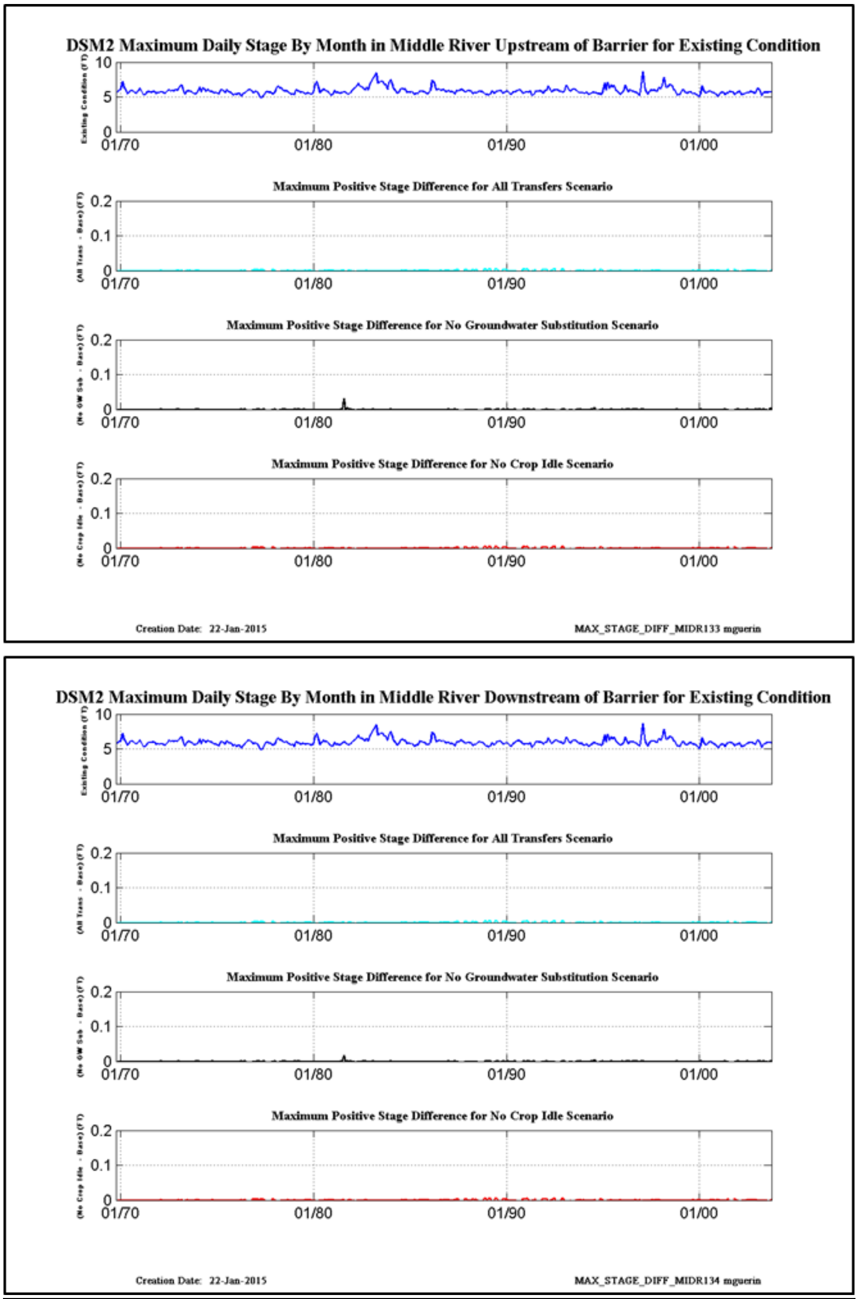

Figure 2-13. Figures show the maximum positive stage difference upstream and downstream of the barrier in Middle River.

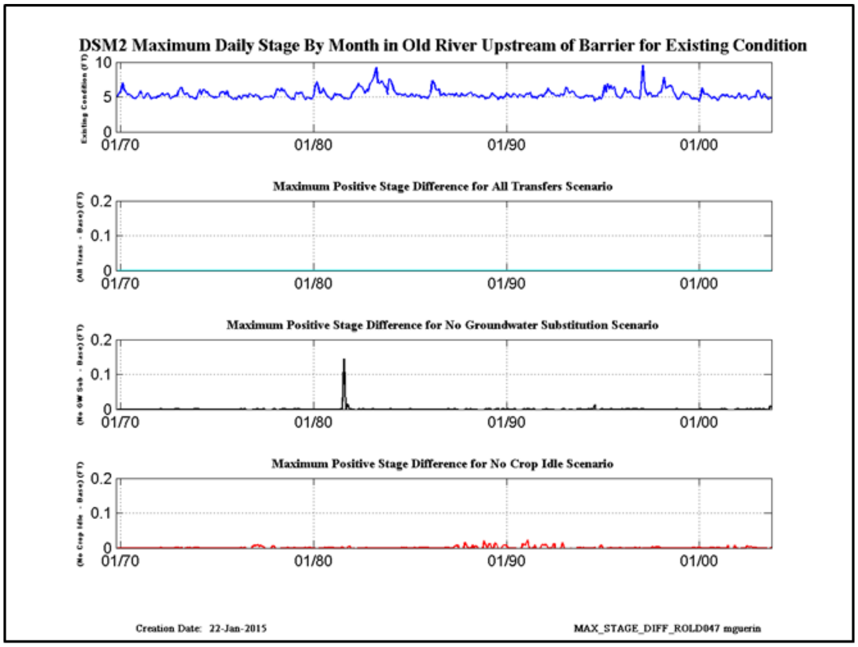

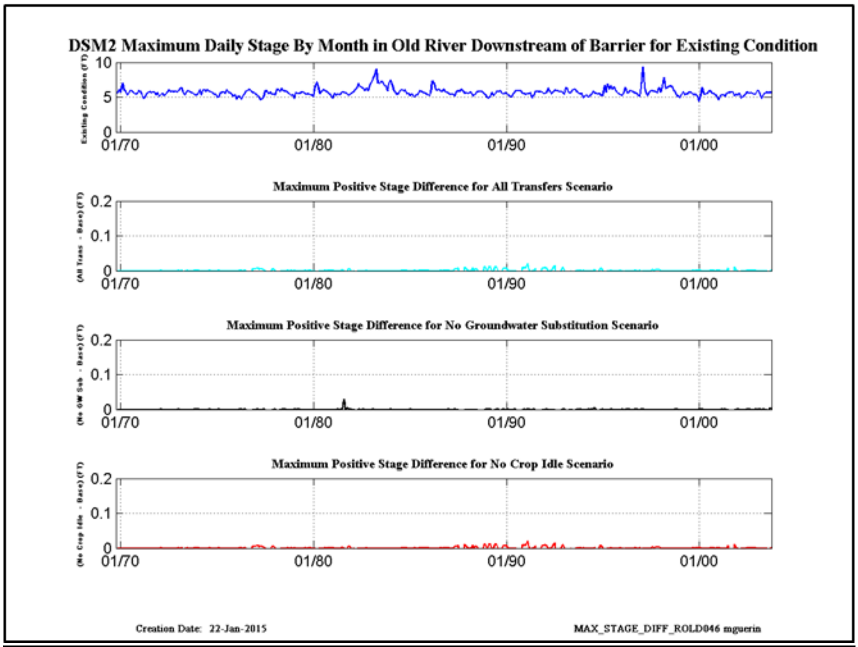

Figure 2-14. Figures show the maximum positive stage difference upstream and downstream of the barrier in Old River.

C.1.3 X2 Model Output

X2 is defined as the distance in km from Golden Gate to the position of 2.0 ppt (parts per thousand) bottom salinity. Using EC data analysis at stations throughout the Delta, regression relationships were developed relating Net Delta Outflow (NDO) to EC measurements (Jassby *et.al.*, 1995). Using these data, it was also found that 2.0 ppt corresponds to 2640 µS cm^{-1} surface EC and to 3000 µS cm^{-1} bottom EC.

The position of X2 is regulated from February to June each year by the 1995 Bay/Delta Plan (SWRCB, 1995). The compliance standard for the position of X2 can be met either with flow objectives specified by the Net Delta Outflow Index (NDOI) or as an equivalent EC standard, each of which vary with the Sacramento Water Year Type[1]. Compliance is met by a 3-day NDOI for an X2 location at Collinsville (81 km, NDOI=7100 cfs), Chipps (75 km, NDOI=11,400 cfs) or at Port Chicago (64 km, NDOI=29,200 cfs). Equivalently, compliance can also be met at these locations using surface EC of 2640 µmhos cm^{-1}on a daily basis or on a 14-day running average basis.

DSM2 is depth-averaged EC, so as a proxy for X2, the methodology developed to use DSM2 EC output for the calculation of X2 assumed that the average of the top and bottom EC values for X2, 2820 µmhos cm^{-1} was the *de facto* location of X2. Using this estimate, the monthly average DSM2 EC output at six RKI[2] locations in the western Delta – RSAC054, RSAC064, RSAC075, RSAC077, RSAC081, RSAC084, RSAC092 and RSAC101 – were used to calculate X2 (see **Error! Reference source not found.**). Eastward movement of X2 is less desirable from a fish habitat standpoint.

Linear interpolation was used to estimate the location of X2 between successive points. Two exceptions occurred: if EC at RSAC054 (Martinez boundary) EC was less than 2820 µmhos cm^{-1}, X2 was set to be 54 km, or if EC at RSAC101was greater than 2820 µmhos cm^{-1}, X2 was set to be101 km – the latter case did not occur. When 2820 µmhos cm^{-1} occurred between two adjacent RKI locations, RKI_1 and RKI_2 (in km), the average change in EC per km between the points, delta_X2, was used to calculate the position of X2 as follows, where EC(RKI_1) is the EC at RKI_1:

$$X2 = RKI_1 + (2820 – EC (RKI_1))/delta\_X2$$

[1]Sacramento R. Water Year Index = 0.4 * Current Apr-Jul Runoff Forecast (MAF) + 0.3 * Current Oct-Mar Runoff (MAF) + 0.3 * Previous Water Year's Index (if it exceeds 10.0, then 10.0 is used)

[2]RKI is River Kilometer Index, the distance from the Golden Gate in km.

For each scenario, the position of X2 was calculated using the linear interpolation method. Plots of monthly average of X2 position are presented below, with Figure 3-3 also showing the change in X2, (Scenario minus Base), for all three alternative scenarios.

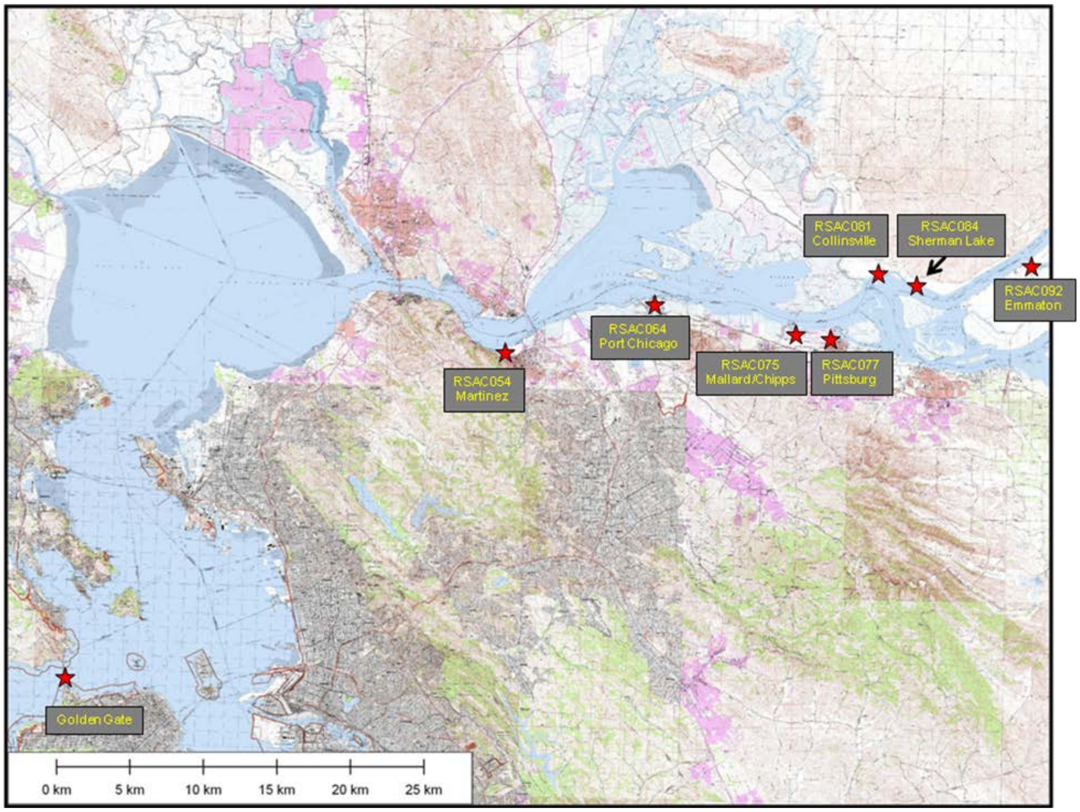

Figure 3-1. DSM2 Output locations used in the calculation of X2 are on the Sacramento River from Rio Vista (upstream of Emmaton) to Martinez

C.1.5 Boundary Conditions: Sacramento and San Joaquin River Inflows, Net Delta Outflow (NDO) and San Joaquin River Salinity (EC)

See the text in Appendix C for details on the boundary conditions for the Base and the Alternatives 2- 4.

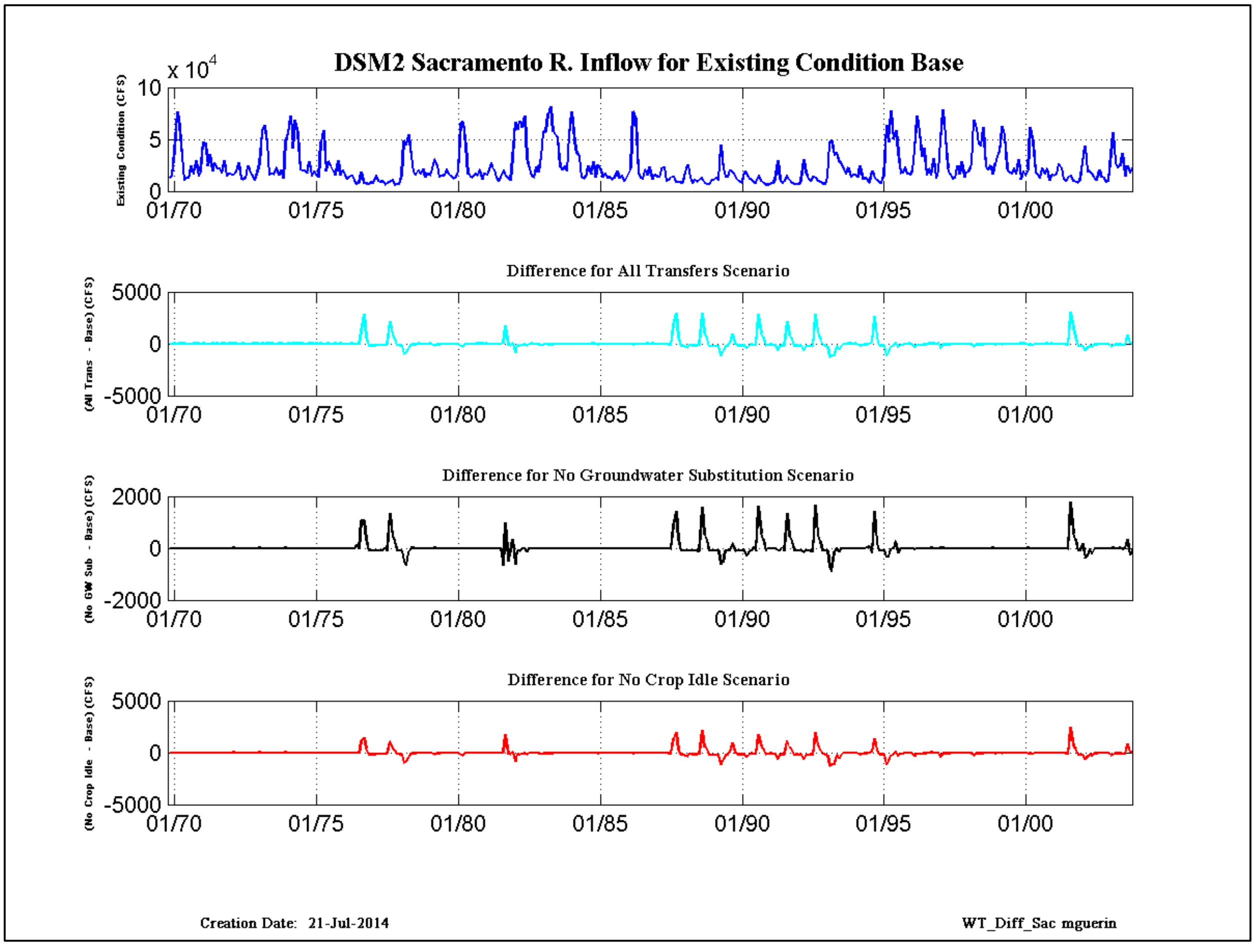

Figure 5-1. Sacramento R. Inflow for the Base condition and change from Base for the scenarios.

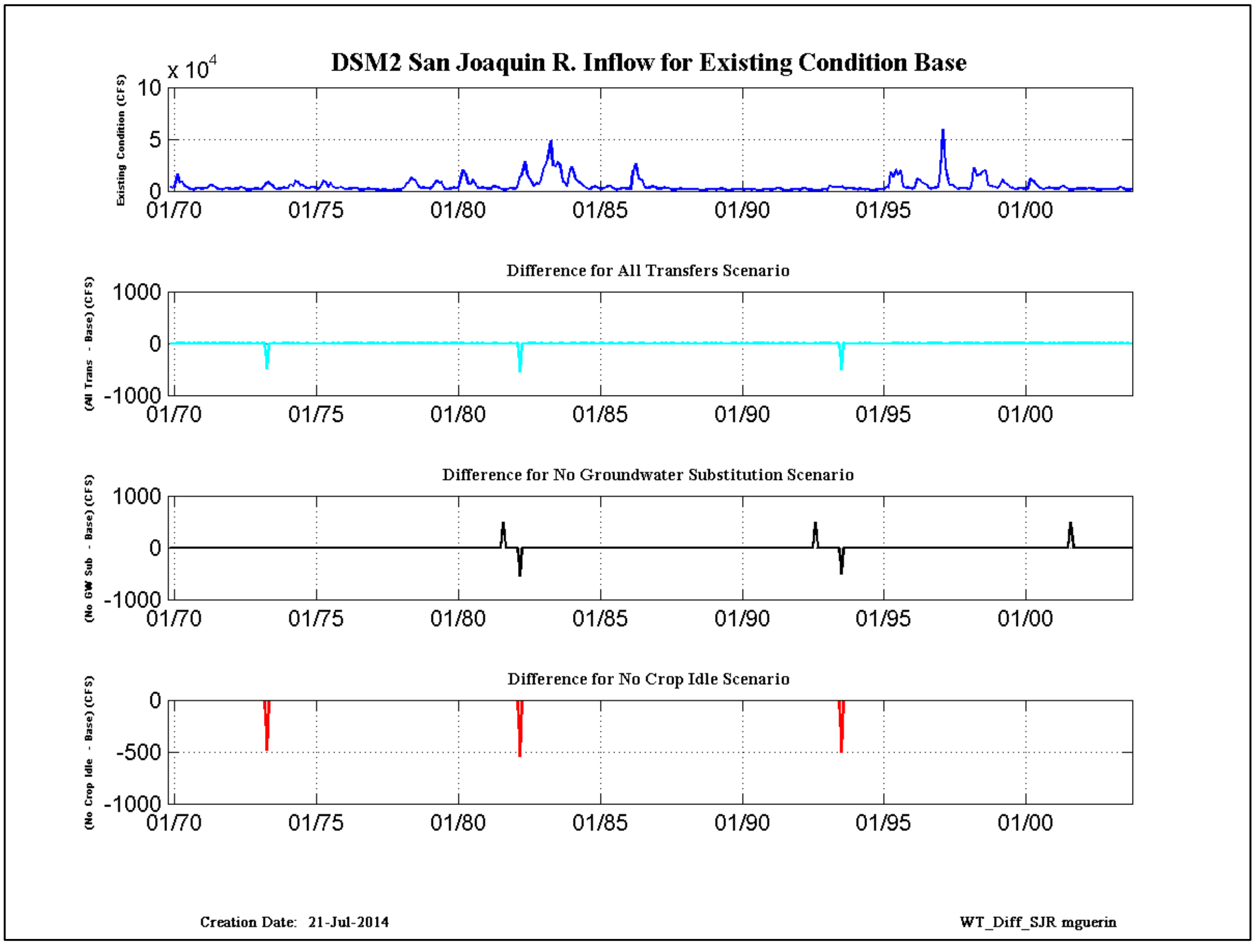

Figure 5-2. San Joaquin R. Inflow for Existing Base condition and change from Base for the scenarios.

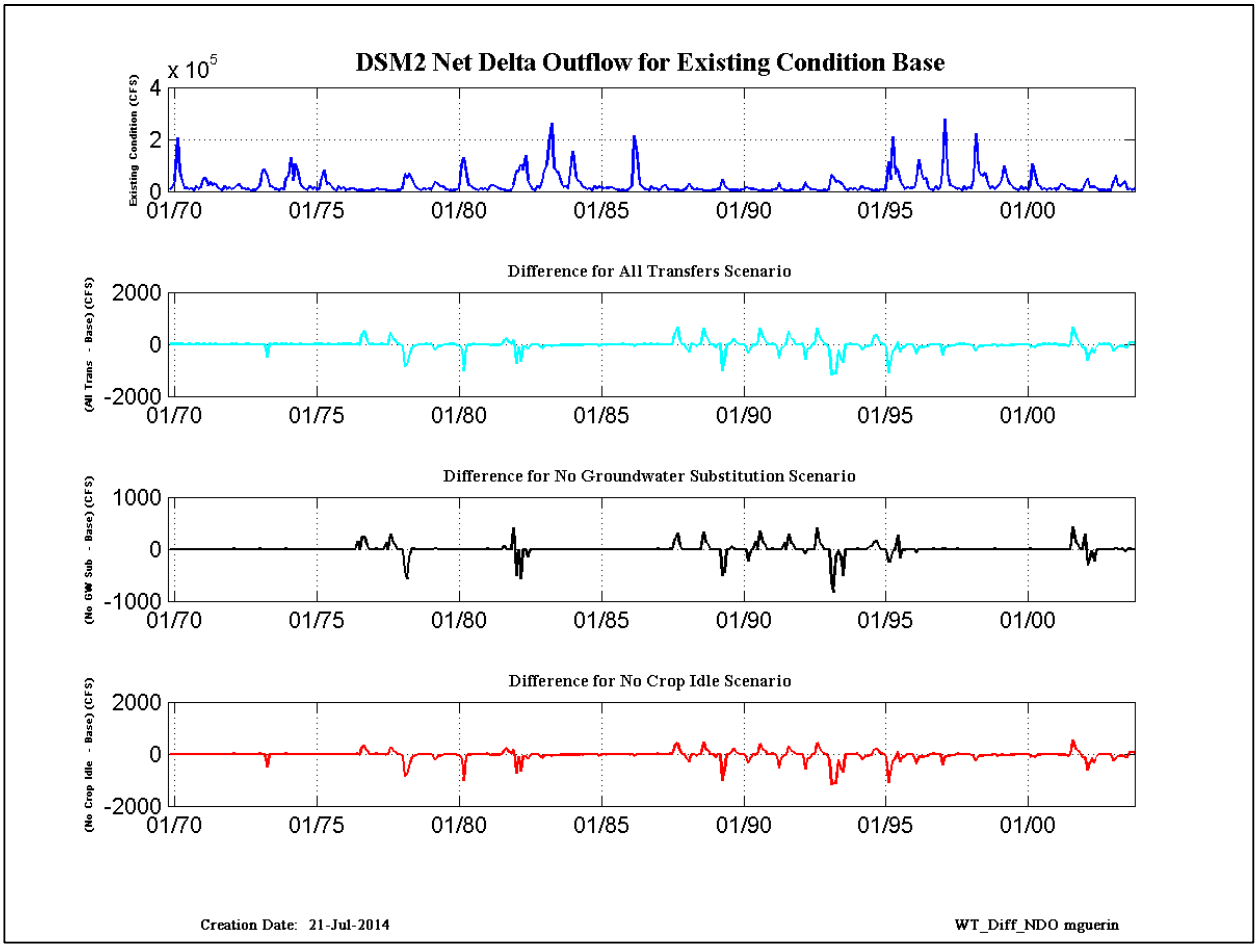

Figure 5-3. Net Delta Outflow for the Base condition and change from Base for the scenarios.

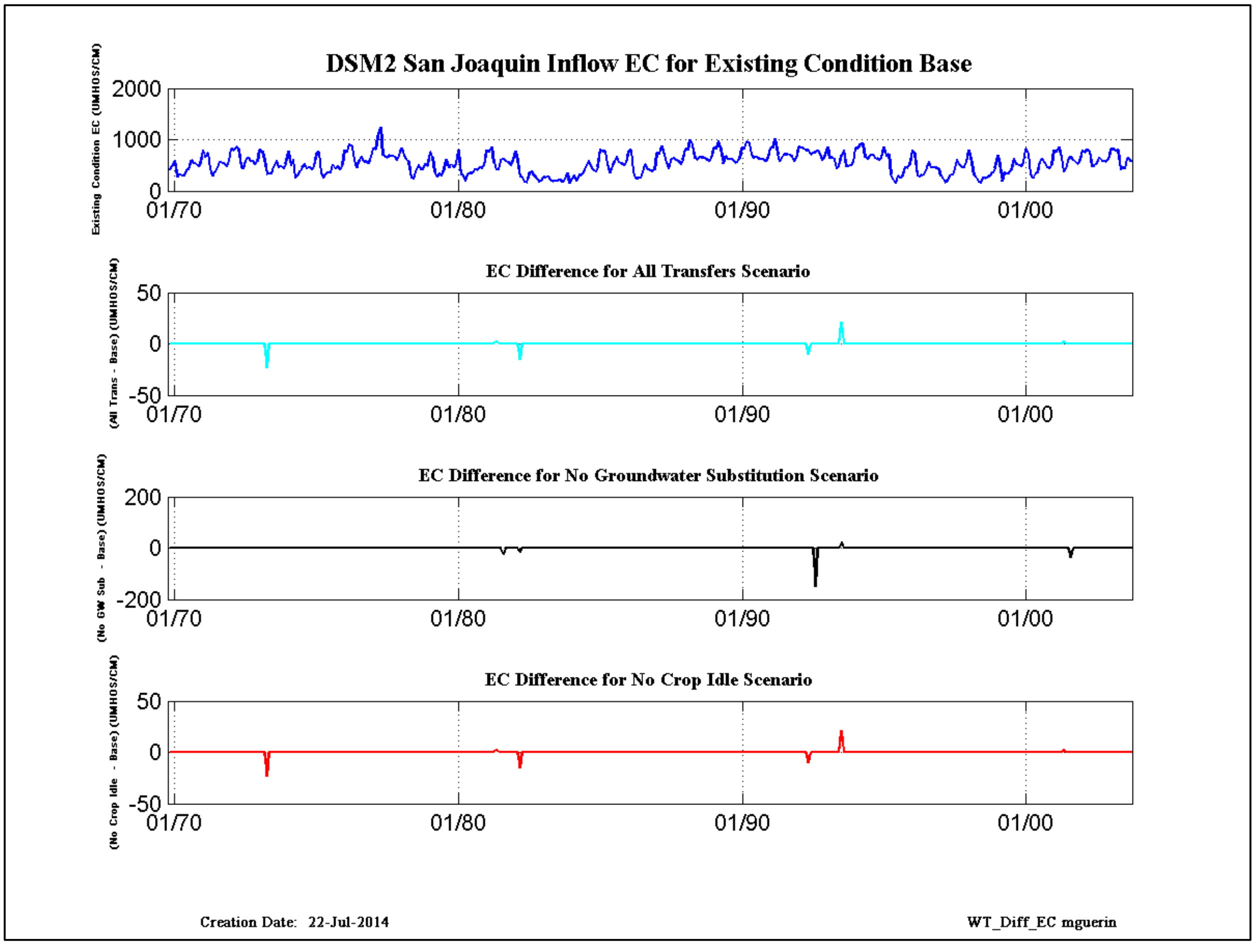

Figure 5-4. San Joaquin Inflow EC for Existing Base condition and change from Base for the scenarios.

Table 5-1. Sacramento River Base inflow (cfs).

Groundwater Model Documentation

This page left blank intentionally.

Appendix D Groundwater Model Documentation

Implementation of conjunctive water management within the Sacramento Valley is one strategy being used to enhance the reliability of the existing water supply, as well as potentially improve water quality, within the San Francisco Bay-Delta. However, the operation of conjunctive water management, or groundwater substitution projects, can result in adverse impacts on water resources within the valley. The two most critical potential impacts of additional groundwater production are depression of local groundwater levels, with associated impacts on well yields from nearby water supply wells, and changes in the hydraulic relationship between the surface water and groundwater systems in the area. To support the evaluation of these potential impacts, a high-resolution, numerical groundwater modeling tool was developed to estimate the impacts of potential future conjunctive water management projects on surface water and groundwater resources within the Sacramento Valley. This model, known as the Sacramento Valley Finite Element Groundwater Model (SACFEM2013), is described herein.

In 2011, prior to selecting the SACFEM model for use in this EIS/EIR analysis, a model evaluation process was undertaken to select the best fitting tool for the groundwater analysis in the EIS/EIR. Each model evaluated, including the selected SACFEM model, has undergone changes and updates over the past few years since the model evaluation. Where appropriate, the text below includes notes as to the more recent model updates/additions.

D.1 Model Evaluation

D.1.1 Introduction

This EIS/EIR analyzes the environmental effects of a variety of types of transfers, including groundwater substitution transfers. For groundwater substitution transfers, a willing seller would pump additional groundwater for irrigation in lieu of a surface water supply. The surface water would then be transferred to the buyer. Additional groundwater pumping could affect the groundwater system through: (1) a decline in groundwater levels (resulting in potential water quality and subsidence concerns) and (2) a change in the groundwater/surface water interaction flows.

A quantitative model can help analyze these impacts by simulating groundwater conditions with the additional groundwater pumping. The distinction between the model code (the computational “engine” behind the simulation) and the model application (the use of the code to simulate conditions in a certain area) should be noted. The process evaluated several available groundwater models against criteria that were deemed relevant to the required EIS/EIR analysis.

D.1.2 Evaluation Criteria

The following criteria were used to evaluate the potential use of several available groundwater models.

- **Numerical Code.** The numerical modeling code must be available for use by others. The code should also have sufficient technical review and/or benchmarking tests to illustrate the model computationally performs in accordance with established solution techniques.
- **Spatial Extent.** The model must encompass most of the Sacramento Valley where potential sellers are located.
- **Grid.** The model's grid should be sufficiently refined such that accurate results (e.g., groundwater levels, changes to groundwater/surface water interaction flows) are simulated. Grid sizes that are too large will not provide accurate results at the scale needed for this study. If the grid is not acceptably discretized, the grid must be able to be refined relatively easily to accommodate the needs of this work.
- **Transient Calibration.** The model application should have been calibrated over transient conditions. A steady-state calibration is, likely, not sufficient for this study because groundwater substitution transfers have the potential to occur over varying hydrologic year types. Therefore, the model should be calibrated over a transient period long enough to encompass multiple hydrologic conditions.
- **Technical Review.** The model application has been thoroughly reviewed and deemed adequate for use in this type of modeling study.
- **Availability.** The model application must be available for public use in the time frame of this study.

D.1.3 Available Models

The majority of potential sellers that would be transferring water through groundwater substitution are in the Sacramento Valley. There are several groundwater models that encompass some or all of the Sacramento Valley. These models are briefly described below. The evaluation criteria from the previous section are included along with a brief discussion of the adequacy of the model to meet the criteria.

D.1.3.1 C2VSIM

The California Central Valley Groundwater-Surface Water Simulation Model (C2VSIM) was developed by the California Department of Water Resources (DWR) and uses the Integrated Water Flow Model (IWFM) numerical code. IWFM is a finite-element code that simulates groundwater flow and groundwater/surface water interaction. The model is capable of estimating the amount of historical and future groundwater pumping based on input data such as cropping, evapotranspiration, and surface water delivery patterns. At the time of the model selection, C2VSIM simulated conditions in the entire Central Valley over the period of Water Years[1] (WY) 1921 through 2003 on a monthly basis. The model grid was relatively coarse in both the horizontal and vertical directions (three layers, 1,393 nodes, and 1,392 elements). The model simulates 72 stream reaches, two lakes, and eight bypass canals. There are 97 surface water diversion points simulated in model. Water accounting is carried out over 21 subregions that use four land use types (agriculture, urban, native, and riparian).

- **Numerical Code.** The IWFM code used by C2VSIM is available for use. This code and many of its components have been tested by DWR.
- **Spatial Extent.** C2VSIM covers the entire Central Valley.
- **Grid.** C2VSIM's grid spacing varies throughout the model. In general, node spacing is on the order of miles. This node spacing is not adequate for simulation of potential impacts at the scale needed (see note below).
- **Transient Calibration.** C2VSIM is calibrated for WY 1921 through 2003 (see note below).
- **Technical Review.** The code has been tested and used.
- **Availability.** This model would be available for use.

Note: Since the model selection was completed, C2VSIM has been updated to include simulation through WY 2009. A "fine grid" version of C2VSIM has recently been developed and would be available for use. However, this version was not available at the time this study began.

D.1.3.2 CVHM

The Central Valley Hydrologic Model (CVHM) was developed by the U.S. Geologic Survey (USGS) to aid in making water management decisions throughout the Central Valley (Faunt 2009). The model focuses on groundwater availability and changes in storage. CVHM uses the MODFLOW-2000 finite-difference numerical model code. MODFLOW, developed and maintained by the USGS, is commonly believed to be the most widely accepted

[1] A water year runs from October 1 of the previous calendar year through September 30 of the current calendar year (for example, water year 1970 includes the period of October 1, 1969 through September 30, 1970).

numerical modeling code in use. To develop CVHM, the USGS conducted a "texture analysis" of 8,500 drillers' logs to describe the sediment characteristics of aquifer materials. These characteristics were used to assign hydraulic conductivities to the model. CVHM uses the Farm Management Process to estimate groundwater pumping based on land use patterns and applied surface water, similar to IWFM.

CVHM uses a uniform 1-mile square grid to simulate conditions from WY 1962 through WY 2003 over the entire Central Valley. Similar to IWFM, water budgets are developed over 21 regions that use urban, native, and crop land use categories. The model simulates 43 inflows to streams in the valley and 66 diversions from streams.

- **Numerical Code.** The MODFLOW-2000 code used by CVHM is available for use. MODFLOW is an industry standard modeling platform.
- **Spatial Extent.** CVHM covers the entire Central Valley.
- **Grid.** CVHM's grid has uniform 1-mile by 1-mile square cells. The 1-mile spacing is not adequate for simulation of potential impacts at the scale needed. Several post-processing routines exist that allow the subdivision of all model cells and the extraction of boundary conditions. For example, each 1-mile cell could be divided into four sections yielding 0.5-mile cell spacing. Further subdivision is also possible (e.g. 16 sections would yield 0.25-mile (1,320 ft) cell spacing). Model runtime will increase as the number of cells is increased.
- **Transient Calibration.** CVHM is calibrated for WY 1962 through 2003.
- **Technical Review.** CVHM has been peer reviewed and published by the USGS as Professional Paper 1766.
- **Availability.** CVHM is available for public use.

D.1.3.3 SACFEM

The SACFEM model was developed to simulate groundwater conditions in the Sacramento Valley using the MicroFEM© finite-element numerical code. This model is capable of simulating groundwater conditions and groundwater/surface water interactions in the valley. The model contains 88,992 nodes and 177,095 elements and covers the entire Sacramento Valley groundwater basin from the Cosumnes River in the south to just north of Red Bluff. The model does not include the Redding or San Joaquin Valley groundwater basins as C2VSIM and CVHM do. The node spacing varies from 500 ft to 5,800 ft depending on the location in the model. The areas of fine node discretization exist where detailed groundwater and groundwater/surface water results were required during the development of the model.

SACFEM uses input from the Integrated Demand Calculator (IDC) as guidance to assign deep percolation and groundwater pumping data. The IDC performs the water demand calculations (i.e., land use demand, surface water deliveries, and groundwater pumping) that IWFM and CVHM also conduct. The output from IDC is assigned as input to SACFEM.

- **Numerical Code.** The MicroFEM code used by SACFEM is available for purchase. MicroFEM has been reviewed by the National Groundwater Association's (NGWA) Ground Water Journal (Diodato 2000).

- **Spatial Extent.** SACFEM covers the entire Sacramento Valley groundwater basin.

- **Grid.** SACFEM's grid spacing varies from 500 to 5,800 ft. The current version of the model has already been sufficiently refined in the areas near potential groundwater substitution sellers. However, additional grid refinement may be necessary depending on the locations of potential substitution sellers. Several pre- and post-processing tools can be used to facilitate this process (see note below).

- **Transient Calibration.** SACFEM is calibrated for years 1982 through 2003 (also see note below).

- **Technical Review.** The SACFEM model was peer reviewed in late 2010. The peer review identified several items that could be improved. The review listed seven items as Tier 1 (requires attention and revision/modification), three items as Tier 2 (strengthen model defensibility), and two items as Tier 3 (improve model features/capabilities) [see note below].

- **Availability.** The current version of SACFEM is available for use.

Note: Several updates have been made to the SACFEM model since its initial selection for use in this analysis. The highest priority ("Tier 1") items identified during the peer review process were addressed to improve the technical accuracy of the model. The model's calibration period was extended through WY 2010. The grid of the model was also refined to include smaller node spacing in the areas surrounding the potential sellers and in the areas of the flood bypasses in the valley. After updating the model and incorporating the technical feedback, the model was renamed from SACFEM to SACFEM2013. Further information on SACFEM2013 is provided in the sections below.

D.1.3.4 HydroGeoSphere

The HydroGeoSphere (HGS) model code is being applied to the Sacramento Valley. HGS is likely the most computationally comprehensive of the models discussed here. The code simultaneously solves the groundwater and surface water flow equation and is capable of using sub-gridding (i.e., localized grid refinement) and sub-timing (i.e., varying time steps to improve accuracy) routines. The sub-gridding process would be valuable to improve the accuracy of simulated results near pumping centers, for example. At this time, little additional information regarding the Sacramento Valley application of HydroGeoSphere is known (e.g., number of nodes, elements, rivers, etc.). The construction and calibration of this model are understood to be on-going.

- **Numerical Code.** The HGS code is available for purchase. The extent of testing is unknown.
- **Spatial Extent.** The Sacramento Valley application of HGS covers the entire groundwater basin.
- **Grid.** Work on HGS is underway to allow for sub-gridding. The sub-gridding functionality may not be complete at this time.
- **Transient Calibration.** The transient calibration in the Sacramento Valley application of HGS is not complete at this point.
- **Technical Review.** The Sacramento Valley application of the HGS model is not complete and, therefore, has not had technical review.
- **Availability.** The Sacramento Valley application of the HGS model is not complete.

D.1.3.5 Local Models

In addition to the larger-scale models listed above which cover the Sacramento and/or Central Valleys, several smaller, local groundwater models also exist. These models include applications to the Butte County, Stony Creek Fan, Lower Colusa basin, North American River, Sacramento County, Yolo, and Yuba County areas. The combined extent of each of these models covers much of the Sacramento Valley. Many of the models have been developed in either IWFM or its predecessor, the Integrated Groundwater-Surface Water Model (IGSM). For the most part, each of these local models occupies a separate area and does not overlap extensively with another local model. Therefore, where adjoining models abut, separate boundary conditions have been established for each model. It is possible that the boundary conditions do not fully agree with each other. Additionally, each model may have differing interpretations of hydraulic conductivity and layering. Each model was developed separately and each may not have the most up-to date data included.

- **Numerical Code.** The majority of the local models were developed in either IWFM or IGSM. These codes would be available for use.

- **Spatial Extent.** The combined extent of the local models covers most of the Sacramento Valley. The areas east and west of Red Bluff are not covered by one of the local models. Even though the models cover most of the Sacramento Valley, the simulation of potential impacts may be difficult if the impacts exceed each of the separate model's areas.

- **Grid.** The grid spacing in some of the local models is likely sufficient, but grid spacing for some models is unknown. Revisions to the grid(s) and input data may be required if the grid spacing is deemed too large.

- **Transient Calibration.** Several of the local models (Stony Creek Fan, Butte County, Yuba County, and Yolo County) have been calibrated over an approximate 30-year period. The Lower Colusa model is calibrated for a 19-year period. The calibration period for the other models is not known at this point.

- **Technical Review.** The status of technical reviews of these models is not known. Most of the models have, likely, not undergone significant technical or peer reviews.

- **Availability.** The availability of each of the models would need to be determined by the model's owner. Because most of the models were developed for public agencies they should be available. However, the exact availability for each of the local models is not known.

D.1.4 Selection

Based on the evaluation criteria described above, the SACFEM model was selected for use in the analysis for this EIS/EIR. The model was updated to the SACFEM2013 version as part of this EIS/EIR to address the peer review comments. SACFEM2013 was used for this EIS/EIR.

D.2 SACFEM2013

This section provides a more detailed description of SACFEM2013. Appendix M is the SACFEM User's Manual.

D.2.1 Model Code Description

MicroFEM (Hemker 1997), a finite-element based, three-dimensional, integrated groundwater modeling package developed in The Netherlands, was chosen to simulate the groundwater flow systems in the Sacramento Valley Groundwater Basin. The current version of the program (4.10) has the ability to simulate up to 25 layers and 250,000 surface nodes. MicroFEM is capable of modeling saturated, single-density groundwater flow in layered systems.

Horizontal flow is assumed in each layer, as is vertical flow between adjacent layers.

MicroFEM was the chosen modeling platform for the following reasons:

- The finite-element scheme allowed the construction of a model grid covering large geographic areas (over 5,960 square miles in the Sacramento Valley Groundwater Basin) with coarse node spacing outside of the simulated project areas and finer node spacing in areas of interest (e.g., near potential project areas). The finer node spacing near simulated production wells provides greater resolution of simulated groundwater levels and stream impacts.

- The graphical interface allows rapid assignment of aquifer parameters and allows proofing of these values by graphical means.

- The flexible post-processing tools allow for rapid evaluation of transient water budgets for model simulations and identification of changes to stream discharges and other water fluxes across the model domain.

D.2.2 Sacramento Valley Groundwater Basin

The following briefly summarizes the geology and hydrology of the Sacramento Valley Groundwater Basin.

D.2.2.1 Geologic Setting

The Sacramento Valley Groundwater Basin is a north-northwestern trending asymmetrical trough filled with as much as ten miles of both marine and continental rocks and sediment (Page 1986). On the eastern side, the basin overlies basement bedrock that rises relatively gently to form the Sierra Nevada; and on the western side, the underlying basement bedrock rises more steeply to form the Coast Ranges. Marine sandstone, shale, and conglomerate rocks that generally contain brackish or saline water overlie the basement bedrock. The more recent continental deposits, overlying the marine sediments, contain fresh water. These continental deposits are generally 2,000 to 3,000 feet thick (Page 1986). The depth (below ground surface) to the base of fresh water typically ranges from 1,000 to 3,000 feet (Bertoldi et al. 1991).

In the Sacramento Valley Groundwater Basin, groundwater users pump primarily from deeper continental deposits. Groundwater is recharged by deep percolation of applied water and rainfall, infiltration from streambeds, and lateral inflow along the basin boundaries. The quantity and timing of snowpack melt are the predominant factors affecting the surface water and groundwater hydrology, and peak runoff in the basin typically lags peak precipitation by one to two months (Bertoldi et al. 1991).

D.2.2.2 Hydrology

The Sacramento River is the main surface water feature in the Sacramento Valley Groundwater Basin. It has several major tributaries draining the Sierra Nevada, including the Feather, Yuba, and American Rivers. The flow in these tributaries depends heavily on the precipitation in the Sierra Nevada. Stony, Cache, and Putah Creeks drain the Coast Range and are the main west side tributaries to the Sacramento River. The west side tributaries contribute significantly less streamflow than those on the eastside tributaries. The Sacramento River flows south through the center of the valley before heading west to flow out Suisun Bay.

Streamflow data for streams throughout the Sacramento Valley are collected at gaging stations operated by ~~the California Department of Water Resources~~DWR[2] ~~(DWR)~~ and the ~~U.S. Geological Survey~~USGS[3] ~~(USGS)~~.

D.2.3 Model Construction

This section discusses the development of the groundwater model grid and layering, the assignment of groundwater flux boundary conditions, and the basis for assignment of material properties to the aquifers within the model domain.

D.2.3.1 Spatial Grid

The SACFEM2013 grid used for the groundwater substitution transfer simulations consists of 153,812 nodes and 306,813 elements (see Figure D-1). The current grid was configured to support evaluation of potential conjunctive water management projects associated with the Long-Term Water Transfer Program; however, the SACFEM2013 model was designed to be grid independent, and geographic information system (GIS)-based tools have been developed to build a similar model of the valley on any grid developed to support a particular application. The nodal spacing of the current grid varies from as large as approximately 3,300 feet (1,000 meters) near the model boundary and in areas where long-term water transfer projects are not being evaluated, to as small as 410 feet (125 meters) in areas where long-term water transfer groundwater production is being evaluated. Nodal spacing of approximately 1,640 feet (500 meters) is included along streams and flood bypasses included in SACFEM2013. The finer node spacing near proposed project areas allows for more refined estimates of the effects of groundwater pumping on groundwater levels and groundwater/surface water interaction in the potential project areas. The model domain boundary coincides with the lateral extent of the freshwater aquifer within the Sacramento Valley Groundwater Basin.

D.2.3.2 Vertical Layering

The total model thickness is defined by the thickness of the freshwater aquifer (less than 3,000 micromhos), as defined by Berkstresser (1973) and

[2] http://cdec.water.ca.gov/
[3] http://waterdata.usgs.gov/nwis

subsequently refined in the northern portion of the valley by DWR (DWR ~~2002~~2005). For the southern portion of the model area, defined by Berkstresser data, elevation contour lines of the base of fresh water, along with information from boring locations (point measurements of the elevation of the base of fresh water), were digitized and used to generate a three-dimensional surface defining the elevation of the base of fresh groundwater. For the northern portion of the model area, the locations of geologic cross sections developed by DWR Northern District staff were plotted, along with the estimated base of freshwater elevations obtained from the cross section information; and a base of freshwater elevation contour map was constructed. These data sets were then merged to yield a single interpretation of the structural contour map of the base of freshwater across the Sacramento Valley (see Figure D-2).

Total Aquifer Thickness

The uppermost boundary of the SACFEM2013 model is defined at the water table. To develop a total saturated aquifer thickness distribution and, therefore, a total model thickness distribution, it was necessary to construct a groundwater elevation contour map and then subtract the depth to the base of freshwater from that groundwater elevation contour map. Average calendar year groundwater elevation measurements were obtained from the DWR Water Data Library. These measurements were primarily collected biannually, during the spring and fall periods; and these values were averaged at each well location to compute an average water level for each location. These values were then contoured, considering streambed elevations for the gaining reaches of the major streams included in the model, to develop a target groundwater elevation contour map for the year 2000. As described above, the distribution of the elevation of the base of freshwater was subtracted from this groundwater elevation contour map to provide an estimate of the distribution of the total saturated aquifer thickness across the model domain.

Model Layer Thickness

The strategy used to develop the overall layering of the SACFEM2013 model was to develop a tool that provided sufficient layers to assess the effects of groundwater pumping on shallow features such as wetlands and streams, but also to provide sufficient vertical resolution to allow assignment of pumping stresses to appropriate depths within the aquifer that reflect the major producing zones within the aquifer system. Additionally, to facilitate investigation of potential future conjunctive water management projects using the lower Tuscan aquifer, the layering strategy also provided for two layers explicitly representing this deep aquifer system.

Layer one of the SACFEM2013 model was assigned a maximum thickness of approximately 65 feet (20 meters). The thickness of this layer was limited to provide more accurate shallow groundwater elevations with which to support evaluations of the effects of changing groundwater levels on surface streams and wetland/riparian areas. Layers two through five represent the more regional groundwater-producing zones within the valley. The thicknesses of these layers were assigned using a specified percentage of the available aquifer thickness at a given location, to provide multiple-depth zones within which to assign regional pumping. The assumed layer thicknesses for layers two through five were also selected to reflect typical screened intervals of production wells in the Sacramento Valley. The thicknesses of layers two through four each represent approximately ten percent of the total aquifer thickness (one to 107 meters, three to 350 feet), and the thickness of layer five represents approximately 15 percent of the total aquifer thickness on average (one to 193 meters, three feet to 633 feet).

Where the lower Tuscan aquifer is present (the northeastern and central portions of the valley), the elevation of the top of layer six was defined by the structural contour surface of the top of the lower Tuscan aquifer. Two layers were assigned to represent this unit because in many areas of the model, the depth to the base of fresh water (the base of the model) is as much as 900 feet below the upper surface of the lower Tuscan. Groundwater production wells drilled into the lower Tuscan would almost certainly be screened over a much smaller depth interval. To allow representation of this condition in the model, layer six was assigned a thickness of between 250 to 360 feet (75 to 110 meters) in the central portion of the northern Sacramento Valley Groundwater Basin. The total range in layer six thickness is approximately three to 580 feet (one to 177 meters). The remaining lower Tuscan thickness not apportioned to layer six was assigned to layer 7. The exception to this convention is in the northeastern portion of the model near the City of Chico. The lower Tuscan outcrops in the foothills above Chico; thus, in these areas, all layers of the model represent the lower Tuscan aquifer. Moving west from Chico, a transition zone exists where a decreasing number of layers represent the lower Tuscan until it is limited to layers six and seven, as discussed above. In areas where the lower Tuscan is not present, the thicknesses of layers six and seven represent 18 and 27 percent of the total aquifer thickness, respectively. A contour map of the total saturated aquifer thickness is presented on Figure D-3.

D.2.3.3 Model Time Discretization

Time is continuous in the physical system, but a numerical model must describe the field problem at discrete time intervals. SACFEM2013 was set up to simulate transient flow conditions between Water Years[4] 1970 and 2010 with monthly stress periods. As such, model stresses (such as stream stage, groundwater pumping, deep percolation, etc.) and model output are assigned/evaluated on a monthly basis.

D.2.3.4 Boundary Conditions

A combination of no-flow, specified-flux, and head-dependent boundary conditions were used to simulate the groundwater flow system within the

[4] ~~A water year runs from October 1 of the previous calendar year through September 30 of the current calendar year (for example, water year 1970 includes the period of October 1, 1969 through September 30, 1970).~~

Sacramento Valley. Each of these boundary conditions is discussed in more detail below.

Head-dependent Boundaries

Surface Water Bodies. A head-dependent boundary condition was chosen to simulate the major streams, flood bypasses, and reservoirs within the Sacramento Valley. The MicroFEM wadi system was used to implement streams within the model domain. MicroFEM's wadi package is a two-way head-dependent boundary condition (that is, it can act as a source of groundwater recharge or as a groundwater sink) that calculates the magnitude and direction of nodal fluxes by using the relative values of the user-specified stream stage (wh1) and the calculated head in the upper aquifer (h1), but is limited by a critical depth (wl1). When calculated groundwater elevations fall below this critical depth, it is assumed that the water table de-couples from the river system, and the leakage rate from the river to the aquifer becomes constant. The equations that govern operation of the wadi package are as follows:

Groundwater discharge to a stream is simulated if h1 > wh1:

$$Q_{outflow} = a * (h1 - wh1) / | wc1 | \quad (1)$$

In coupled streams (groundwater elevation is above the stream bottom elevation), groundwater recharge from a stream is simulated if h1 < wh1:

$$Q_{inflow} = a * (wh1 - h1) / | wc1 | \quad (2)$$

In decoupled streams (groundwater elevation is below the stream bottom elevation), groundwater recharge from a stream is simulated if:

$$Q_{inflow} = a * (wh1 - wl1) / | wc1 | \quad (3)$$

Where:

Q = volumetric flux

a = nodal area

h1 = simulated groundwater elevation in layer 1

wh1 = simulated stream stage

wl1 = stream bottom elevation

wc1 = resistance across the streambed

Nodal area is a grid-dependent parameter that can be automatically calculated within MicroFEM. In general, the nodal area around a node that represents a discrete reach of a stream is greater than the surface area of that stream along the reach in the field. The effective resistance term (wc1) incorporates an areal correction factor to account for this discrepancy the wadi resistance term (wc1) is a measure of the resistivity of the streambed sediments. The resistances are calculated as follows:

$$wc1 = Dr/Kv\ ))^{*}\ (a/LW) \qquad (4)$$

Where:

Dr = thickness of streambed sediments

Kv = vertical hydraulic conductivity of streambed sediments

L = stream length represented by the model node

W = field width of the wetted river channel within the stream reach represented by L. Fifty individual streams are simulated with MicroFEM's wadi package in the current version of SACFEM2013.

Stream locations were digitized from existing base maps and USGS topographic quadrangle sheets, and imported into the model domain. Stream length within a given node is a grid-dependent variable calculated by MicroFEM at each river node. The stream-length term is generally overestimated by MicroFEM at stream confluences. Manual corrections of this term were made where necessary. Streambed thickness was assumed to be 3.28 feet (one meter) for all river nodes. Assumptions of streambed Kv were based on the type of streambed deposits expected given stream size. Streams draining the Sierra Nevada were generally assigned lower streambed Kv's, with all streams except the Bear River and Big Chico Creek having values of two meters per day (m/d) (0.0023 centimeters per second [cm/s]) or less. Westside streams were assigned higher values, with most being at or above five m/d (0.0058 cm/s). Wetted stream width was calculated from aerial photographs at two locations along each stream. Few streams showed greater variability in width such that it was necessary to develop a continuously variable distribution along the stream length. This was accomplished by estimating wetted stream width at several points via examination of aerial photographs and fitting a polynomial to the data points.

Streambed elevations (wl1) were estimated using data from 10-meter Digital Elevation Model (DEM) data. It was assumed that the minimum DEM elevation that at/near a given stream node represented the streambed elevation at that location. Polynomials were fitted to the distribution of streambed elevations and cumulative distance along each stream. These polynomials provided relationships that were used to both "smooth" the distribution of streambed elevations and populate values for nodes where the SACFEM2013 nodal resolution was finer than the DEM spacing.

As previously discussed, SACFEM2013 simulates transient conditions from water years 1970 through 2010 on a monthly basis. Monthly varying distributions of stream stage were developed for all streams included in SACFEM2013. Further historical measured stream stage data for model streams was analyzed to determine the timing and location of streams that experience seasonal drying. During months where a given stream is interpreted as experiencing no surface water flow, the SACFEM2013 nodes are converted from a MicroFEM wadi boundary condition to a MicroFEM drainage boundary condition, discussed in more detail below.

The current version of SACFEM2013 incorporates additional recharge from the major flood bypasses in the Sacramento Valley during wet periods. These include the Butte Bypass, the Sutter Bypass, and the Yolo Bypass. Historical weir data were evaluated to determine the timing and location of flood bypass inundation. During periods of bypass flow, the interpreted water surface elevation was compared to the DEM data to determine the spatial distribution of bypass inundation. Active flood bypass nodes were simulated using MicroFEM's wadi boundary condition. The wh1 value for each active flood node was assigned the interpreted water surface elevation (which varied on a monthly basis). The wc1 value was assumed to be ten for all active bypass nodes. During dry periods (and non-inundated bypass nodes), flood bypasses were simulated as groundwater sinks using MicroFEM's drainage package.

The final surface water bodies simulated in SACFEM2013 using MicroFEM's wadi package are the major reservoirs located within the interior of the Sacramento Valley Groundwater Basin, Black Butte Reservoir and Thermalito Afterbay. The lake bottom elevations were assumed to be constant for both reservoirs, and were simulated as 100 feet below the average DEM elevation (assumed to represent lake stage) for Black Butte reservoir and 40 feet below the average DEM elevation for Thermalito Afterbay. The wc1 values were assumed to be one for both reservoirs. The lake stage elevation was assumed to be constant spatially across each reservoir; however, historical data were evaluated to develop monthly-variable lake stage datasets for the SACFEM2013 simulation period.

Drains. MicroFEM's drainage package was used to simulate boundary conditions across the top surface of the model, excluding nodes where wadi boundaries exist. Drainage boundary conditions are one-way head-dependent boundaries that allow the transfer of water out of the model domain only. The elevation of the drain boundaries were set at the land surface. The drain boundaries were included in the model to represent a combination of surficial processes that occur in areas of shallow groundwater, including evapotranspiration and groundwater discharge to the surface. Additionally, as discussed above, specific streams and flood bypasses were converted from wadi boundary conditions to drain boundary conditions during periods when a given surface water body was interpreted as being dry.

Groundwater discharge to a drain is simulated if h1 > dh1:

$$Q_{outflow} = a * (h1 - dh1) / | dc1 | \text{ (where a = nodal area)} \quad (5)$$

Groundwater discharge to a drain is simulated if h1 < dh1:

$$Q_{outflow} = 0 \quad (6)$$

The parameter dc1 represents the drain conductance and is a measure of the resistance to flow across the drain boundary. The dc1 was assumed to be 500 throughout the model domain.

Specified-flux Boundaries. Three sets of specified-flux boundary conditions were implemented in the SACFEM2013 model. These conditions are as follows: (1) deep percolation of applied water and precipitation along with agricultural pumping, (2) mountain-front recharge, and (3) urban pumping. Each is discussed in more detail below.

Deep Percolation of Applied Water, and Precipitation and Agricultural Pumping. The first set of specified-flux boundary conditions reflects the deep percolation of precipitation and applied water across the valley, as well as the regional agricultural pumping. The deep percolation flux values were applied to every surface node in the model. The pumping stresses due to agricultural pumping were applied at selected locations in model layers two through four (the depths of the regional producing zones across the valley). The spatial distribution and magnitudes of these fluxes were derived from the surface water budget calculations described in full detail in the Surface Water Budget section below.

Mountain-front Recharge. The second set of specified-flux boundary conditions represents the subsurface inflow of precipitation falling within the Sacramento River watershed but outside the extent of the model domain. To estimate these flux values, the USGS 10-meter DEM along with GIS-based hydrography coverages for the Sacramento Valley were used to delineate the drainage areas that are tributary to the model domain but fall outside of the watersheds of the rivers explicitly represented in the model. It is these areas that can contribute water to the model domain but are not accounted for in the wadi boundary conditions defined in the model. After the extents of these watershed areas were defined, they were intersected with monthly Parameter – elevation Relationships on Independent Slopes Model (PRISM)[5] rainfall datasets using GIS tools, and the volume of precipitation falling on the watershed was computed. On the basis of the computed total volume of precipitation, the deep percolation to the groundwater system was calculated using the following empirical relationship developed by Turner (1991):

[5] http://prism.oregonstate.edu/

$$DP = (PPT-2.32)*(PPT)^{0.66} \quad (7)$$

Where:

DP = average annual deep percolation of precipitation (inches per year)
PPT = annual precipitation (inches per year)

A summary of the process that was used to estimate the quantity of subsurface inflow, otherwise known as mountain-front recharge, is as follows:

1. The area of each drainage basin tributary to the model domain that is not represented by streams explicitly simulated in SACFEM2013 was computed using a GIS-based analysis of the land surface topography. The extent of these smaller watersheds is shown on Figure D-1.

2. Each drainage area polygon was then intersected with a GIS coverage of annual total rainfall estimated using the PRISM model for each year of the simulation period. This distribution of annual average rainfall was then used to calculate the total volume of rainfall falling on the small watershed areas, and an overall average rainfall rate was computed (inches per year).

3. The total annual rainfall rate was then used to compute a deep percolation quantity using the relationship between annual rainfall and deep percolation rate developed by Turner (1991) and described above.

4. The annual volume of deep percolation computed in Step three was then converted into monthly values that were based on the monthly distribution of streamflow measured in ungauged sections of Deer Creek. These monthly deep percolation quantities were then introduced at the model domain boundary of each small watershed polygon using injection wells into layer one. The quantity applied to each model boundary node was proportional to boundary length of each element divided by the total boundary length of the drainage polygon.

5. The deep percolation rates for individual drainage basins were adjusted during SACFEM2013 calibration to improve the match between simulated and measured groundwater elevations. Final factors applied to the deep percolation rates range from 0.5 to 1.5.

Urban Pumping. The final set of specified-flux boundary conditions applied in the SACFEM2013 model reflects urban pumping within the model domain. The distribution of agricultural pumping that was developed using the surface water budgeting methodologies described below do not include urban pumping. As a first step to estimate the quantity of urban pumping to apply to the model, the year 2010 U.S. Census data were evaluated. Each municipal area with a population greater than 5,000 that used groundwater as a source of municipal supply was further assessed. For municipalities where urban water management plans were available, the reported annual groundwater use was simulated in SACFEM2013. For cities that do not have a current water management plan, a pumping volume that was based on an annual average per capita value of 271 gallons/capita/day was simulated. Further, municipalities in the northern Sacramento area pumping rates were assigned consistent with the Sacramento County Integrated Groundwater and Surface Water Model (SacIGSM) model. Urban pumping was assigned spatially to all SACFEM2013 nodes within a given city area and was apportioned equally to model layers two through four. The monthly variability in urban pumping quantity was distributed on the basis of typical seasonal trends for municipal water use.

No-flow Boundaries
A no-flow boundary was specified across the bottom boundary of the model, representing the freshwater/brackish water interface.

D.2.3.5 Surface Water Budget

Approach
One of the most critical components to the successful operation of ~~the~~ SACFEM2013 is computation of transient surface water budget components. These water budget components were estimated by using a variety of spatial information including land use, cropping patterns, source of irrigation water, surface water availability in different year types and locations, and the spatial distribution of precipitation. Surface water budget components include deep percolation of applied water, deep percolation of precipitation, and agricultural pumping.

Surface water budgets were developed by intersecting existing GIS data developed by DWR with the groundwater model grid to develop land use for each groundwater model node. Additionally, GIS data on water districts and surrounding areas were used to identify district and non-district areas. The resulting intersection provided land use, water district, and water source information for each of the over 150,000 groundwater model nodes.

Methodology
A semi-physically based soil moisture accounting model and historical precipitation data were used to simulate the root zone processes and calculate applied water demand and deep percolation past the root zone for each node. Calculated deep percolation was split between applied water and precipitation depending on the season and the availability of water from each source.

Calculated values for deep percolation were compared to estimated values prepared by DWR's Northern District for the year 2000. Northern District staff calculated detailed water budgets in 2000, which included some of the best available estimates of regional deep percolation. In some areas, soil parameters in the root zone model were adjusted to provide similar volumes of deep percolation. However, considerable uncertainty still exists in any estimate of regional deep percolation because soil conditions vary widely, and it is not possible to measure deep percolation on a regional basis.

The total demand for applied water was used in conjunction with the water source and water district attributes from the GIS intersection to estimate agricultural groundwater pumping. Some areas are supplied solely from groundwater, and calculated total applied water demand represents groundwater pumping. Other areas are supplied by a mix of groundwater and surface water. For these areas, estimates of the availability of surface water each year were made to determine the fraction of applied water demand met from surface water and groundwater. In these areas, additional information on the overlying water district was combined with district water rights and contracts to estimate available surface water. For example, districts within the Tehama-Colusa Canal Authority have water contracts with the Bureau of Reclamation that receive different allocations each year. An estimate of those allocations from an existing level of development simulation of Central Valley Project operations was used to calculate the availability of surface water for groundwater model elements within those districts. Any remaining applied water demand, after consideration of available surface water, is assumed to be met by groundwater pumping.

D.2.3.6 Aquifer Properties

The distribution of aquifer properties across the Sacramento Valley is poorly understood. In certain areas with significant levels of groundwater production, the collection of aquifer test data and the measurement of historical groundwater-level trends in response to known groundwater production rates have provided valuable information on aquifer properties. However, in the majority of the valley, these data are not available.

To estimate the spatial distribution of aquifer properties across the model domain for this numerical modeling effort, a database of well productivity information was used. In consultation with DWR staff, a database was obtained that included all of the specific capacity yield data that were available from well log records. These data were compiled along with well construction information for each production well to yield a representative data set of well productivity across the valley. Wells that did not have available construction data were omitted from further consideration. To protect owner privacy, the exact location of each well was modified by DWR staff to reflect the center of the section in which each well was located. This modification in well location did not adversely affect the use of the data to estimate the spatial distribution of aquifer properties, given the extremely large area encompassed by the model domain. Approximately 1,000 wells in the database within the model domain were used in this analysis.

The intent of the modeling analysis described herein is to simulate the effects of the operation of high-productivity irrigation wells screened within the major producing zones in the valley to support conjunctive water management projects. Therefore, the aquifer properties that are of primary interest are those of the major aquifer zones tapped by large-diameter irrigation wells. The well database described above was filtered to remove data obtained from tests on low-yield and shallow, domestic-type wells. All test data from wells that reported a well yield below 100 gallons per minute were eliminated from consideration, as were the test data from wells with a total depth of less than 100 feet. The only exception to this second consideration was for wells that were located along the basin margins – where aquifers are thin – that reported what appeared to be valid test results. Data from these wells were considered because they were often the only data available in the basin margin areas.

After the data set for consideration was finalized, the reported specific capacity data for each well were used to estimate an aquifer transmissivity for that location. The relationship used to estimate aquifer transmissivity was the following form of a simplified version of the Jacob non-equilibrium equation:

$$Sc = T/2000 \quad (8)$$

Where:

Sc = specific capacity of an operating production well (gallons per minute per foot of drawdown)

T = aquifer transmissivity (gallons per day per foot)

After a transmissivity estimate was computed for each location, the transmissivity value was then divided by the screen length of the production well to yield an estimate of the aquifer horizontal hydraulic conductivity (Kh). The final step in the process was to smooth the Kh field to provide regional-scale information. Individual well tests produce aquifer productivity estimates that are local in nature, and might reflect small-scale aquifer heterogeneity that is not necessarily representative of the basin as a whole. To average these smaller scale variations present in the data set, a FORTRAN program was developed that evaluated each independent Kh estimate in terms of the available surrounding estimates. When this program is executed, each Kh value is considered in conjunction with all others present within a user-specified critical radius, and the geometric mean of the available Kh values is calculated. This geometric mean value is then assigned as the representative regional hydraulic conductivity value for that location. The critical radius used in this analysis was 10,000 meters, or about six miles. The point values obtained by this process were then gridded using the kriging algorithm to develop a Kh distribution across the model domain. The aquifer transmissivity at each model node within each model layer was then computed using the geometric mean Kh values at that node times the thickness of the model layer. Insufficient data were available to attempt to subdivide the data set into depth-varying Kh distributions, and it was, therefore, assumed that the computed mean Kh values were representative of the major aquifer units in all model layers. The distribution of K used throughout most of the SACFEM2013 model layers is shown in Figure D-4. During model calibration, minor adjustments were made to the Kh of model layer one east of Dunnigan Hills and in model layers six and seven in the northern Sacramento Valley based on qualitative assessment of Lower Tuscan aquifer test data in this area.

MicroFEM computes vertical flow between adjacent model layers based on the simulated head difference between adjacent model layers and the vertical resistance term. The vertical resistance term in MicroFEM is calculated as follows:

$$V = \frac{\left(b_i / Kv_i + b_{i+1} / Kv_{i+1} \right)}{2} \qquad (9)$$

Where:

V = Vertical resistance to flow between an upper model layer (i) and adjacent lower model layer (i+1) ($days^{-1}$)

b_i = Saturated thickness of model layer i (meters)

b_{i+1} = Saturated thickness of model layer i+1 (meters)

Kv_i = Vertical hydraulic conductivity of model layer i (m/d)

Kv_{i+1} = Vertical hydraulic conductivity of model layer i+1 (m/d)

The ratio of Kh to vertical hydraulic conductivity (Kv) were assumed to be 500:1 in layers two through seven and 50:1 in layer one at all model nodes except those representing bedrock areas. The Kh:Kv in areas of bedrock outcrop (such as the Sutter Buttes, Black Butte, and Dunnigan Hills) was assumed to be 1:1 in all model layers.

The specific yield of model layer one was assumed to be 12 percent throughout the SACFEM2013 model domain. The aquifer storativity of model layers two through seven is 6.5×10^{-5} multiplied by model layer thickness throughout the majority of the model domain, with variations along small portions of the model boundary.

D.3 Sensitivity

To test the sensitivity of the SACFEM2013 model to various hydrologic parameters, several sensitivity simulations have been run to-date. Each of these sensitivity simulations varied specific sets of hydraulic parameters. The following parameters were varied in simulations performed to-date.

1. Basin Deposits: The hydraulic conductivity of the Basin deposits (geologic terms Qb, Qm, and Qp) were decreased. Basin deposits are generally surficial deposits of fine grain nature. Decreasing the hydraulic conductivity of the basin deposits would have the tendency to slow the flow of water from the surface to the groundwater.

2. Stream Deposits: The hydraulic conductivity of the Stream deposits (geologic terms Qsc, Qa, and Qal) were increased. Stream deposits are located along the historic channel of the river and represent a coarser grained material. Increasing the hydraulic conductivity of these deposits can allow faster movement of water through this area.

3. Basin and Stream Deposits: The hydraulic conductivity of the Basin deposits (geologic terms Qb, Qm, and Qp) were decreased, and the hydraulic conductivity of the Stream deposits (Qsc, Qa, and Qal) were increased. This simulation combines the changes made in the previous two simulations.

4. Horizontal Hydraulic Conductivity: The horizontal hydraulic conductivity throughout the model was decreased by one order of magnitude (i.e., all values were multiplied by 0.1). A decrease in hydraulic conductivity slows the movement of water through the aquifer.

5. Anisotropy Ratio: The anisotropy ratio (the ratio of horizontal hydraulic conductivity to vertical hydraulic conductivity) was changed across the entire model from 500:1 to 1000:1. Increasing this ratio from 500:1 to 1000:1 increases the resistance to flow in the vertical direction by decreasing the vertical hydraulic conductivity of the aquifer.

6. Storage Coefficients: The values of the storage coefficients were increased. The specific yield was increased from 0.12 to 0.2. The storativity value was increased by a factor of 10 across the entire model. Changes to storage coefficients also result in a change in the velocity of groundwater movement within the aquifer.

7. Streambed Hydraulic Conductivity. The hydraulic conductivity of each streambed was decreased by a factor of 10. Decreasing the hydraulic conductivity of the streambeds would slow movement of water between the surface water and groundwater systems.

The SACFEM2013 model has been calibrated (as previously described). It should be noted that model was not recalibrated for each of the parameters sets listed above. The purpose of the sensitivity simulations is to determine which parameters the model results may or may not be sensitive to.

The sensitivity simulations were run with approximately 153,000 acre-feet of water pumped in a single year. This volume of water is roughly equivalent to the average of all pumping in transfer years under the Proposed Action.

Pumping was specified at the locations and depths of the wells used in the Proposed Action. The change in groundwater level (i.e., drawdown) between simulations with and without the 153,000 acre-feet of pumping was plotted at three locations. Locations 6, 21, and 30 were selected as they are spread across the area where drawdown due to the Proposed Action is simulated (Figures 3.3-28a through 3.3-33c). Simulated drawdown has been plotted at each location for the water table and at the depth of pumping in the area surrounding that location.

Figures D-5 and D-6 show the simulated drawdown at Location 6. Figure D-5 shows the drawdown at the water table (model layer 1). Figure D-6 shows the drawdown in model layer 7. At the water table (Figure D-5), each of the simulations show similar or less drawdown as compared to the calibrated model. Three of the sensitivity simulations (stream bed conductivity, anisotropy ratio, hydraulic conductivity) show recovery period that is longer than the calibrated model. In the pumping zone (Figure D-6), two simulations (hydraulic conductivity, anisotropy ratio) show more drawdown than the calibrated model. Three of the simulations show a longer recovery period following the pumping. The increase anisotropy simulation has a similar, but slower recovery, than the calibrated model. The higher storage coefficient and lower streambed conductivity simulations take additional years for the groundwater levels to recover from the pumping.

Figures D-7 and D-8 show similar results at Location 21. Figure D-7 shows the simulated drawdown in model layer 1. Figure D-8 shows the results in model layer 6, where pumping occurs in this area. The results at the water table (Figure D-7) are very similar to those shown for Location 6 (Figure D-5). In the pumping zone (Figure D-8), two simulations show an increase in the total drawdown (hydraulic conductivity, anisotropy ratio). The hydraulic conductivity simulation also shows a longer period to recover from the pumping. The simulation with altered storage coefficients also requires a longer period to recover, although drawdown in this simulation is significantly lower.

Figures D-9 and D-10 show the simulated drawdown at Location 30 in Layers 1 and 3, respectively. Similar to the other locations, the drawdown and recovery period at the water table (Figure D-9) show similar trends to those described for Location 6 (Figure D-5) and Location 21 (Figure D-7). At the depth of pumping (Figure D-10), two simulations (anisotropy ratio, hydraulic conductivity) show an increase in the amount of drawdown that is simulated as compared to the calibrated model. Two of the simulations (storage coefficients, hydraulic conductivity) require a longer period for groundwater levels to recover than the calibrated model.

Appendix F

Air Quality Emission Calculations

This page left blank intentionally.

Table F-1. General Conformity Applicability Evaluation (Unmitigated Emissions)

County/ Nonattainment Area	Emissions (tons per year)							
	VOC	NOx	CO	SOx		PM10	PM2.5	
	Sacramento Metro[1,5]	Sacramento Metro[1,5]	Sacramento Area[2]	Sacramento[3,4]	Yuba City-Marysville[6]	Sacramento Co.	Sacramento[4]	Yuba City-Marysville[6]
Colusa	--	--	--	--	--	--	--	--
Glenn	--	--	--	--	--	--	--	--
Sacramento	2.1	71.9	5.6	0.010	--	0.2	0.2	--
Shasta	--	--	--	--	--	--	--	--
Solano	0.0	0.0	--	--	--	--	--	--
Sutter	2.3	19.5	--	--	3.1	--	--	0.8
Tehama	--	--	--	--	--	--	--	--
Yolo	0.7	7.9	--	--	--	--	--	--
Yuba	--	--	--	--	0.0	--	--	0.0
Total	5.1	99.3	5.6	0.010	3.1	0.2	0.2	0.8
Classification	Severe	Severe	Maintenance	PM2.5 Precursor	PM2.5 Precursor	Maintenance	Nonattainment	Nonattainment
De Minimis Threshold (tpy)	25	25	100	100	100	100	100	100
Exceed?	No	Yes	No	No	No	No	No	No

Note:

[1]The Sacramento Metro 8-hour O3 nonattainment area consists of Sacramento and Yolo Counties and parts of El Dorado, Placer, Solano, and Sutter Counties. Emissions occurring within the attainment area of these counties are excluded from the total emissions.

[2]The Sacramento Area CO maintenance area is based on the Census Bureau Urbanized Area and consists of parts of Placer, Sacramento, and Yolo Counties. The general conformity applicability evaluation is based on emissions that would occur within the entire county to be conservative.

[3]All counties are designated as attainment areas for SO2; however, since SO2 is a precursor to PM2.5, its emissions must be evaluated under general conformity.

[4]The 24-hour PM2.5 nonattainment area for Sacramento includes Sacramento County and parts of El Dorado, Placer, Solano, and Yolo Counties. The general conformity applicability analysis assumes that all emissions that could occur within each county would occur within the Sacramento nonattainment area to be conservative.

[5]VOC and NOx emissions are excluded from Sutter County for Cranmore Farms, Garden Highway Mutual Water Company, Gilsizer Slough Ranch, Pelger Mutual Water Company, Reclamation District 1004, and Tule Basin Farms because they are located in areas designated as attainment for the federal 8-hour O3 NAAQS.

[6]The Yuba City-Marysville PM2.5 nonattainment area contains all of Sutter County and a part of Yuba County.

Table F-2. Emissions Outside of 8-Hour Ozone Nonattainment Area (tons per year)

Water Agency	County	VOC	NOx
Cranmore Farms	Sutter	Electric	Electric
Garden Highway Mutual Water Company	Sutter	Electric	Electric
Gilsizer Slough Ranch	Sutter	0.7	8.8
Pelger Mutual Water Company	Sutter	0.1	1.2
Reclamation District 1004	Sutter	n/a	n/a
Tule Basin Farms	Sutter	0.3	9.4
Total		1.0	19.3

Notes:
If a specific HP and emission tier combination has an emission standard of NMHC+NOx, then 95% of emissions assumed to be NOx and 5% of emissions assumed to be VOC (see CARB Carl Moyer Program Guidelines).
AP-42 emission factors used for SOx in all cases.
If an emission standard is not available for a given pollutant, then AP-42 emission factors used.
PM2.5 assumed to be 98% of PM10 emissions based on size fractions for stationary internal combustion diesel engines.

Legend
- (purple) Assumed to be electric (similar to 32W-2)
- (green) Engine power rating not provided; assumed to be equal to maximum horsepower for all engines operating at the water agency with the same fuel type
- (blue) Emission factor based on NMHC+NOx emission standard

						n/a	**3,800**	**100%**	**465**	**2,230**	**22**	**3,187**	**38,441**							**1.55**	**29.38**	**27.06**	**9.63**	**1.55**	**1.55**	**0.11**	**2.14**	**1.97**	**0.70**	**0.11**	**0.11**

Notes:

If a specific HP and emission tier combination has an emission standard of NMHC+NOx, then 95% of emissions assumed to be NOx and 5% of emissions assumed to be VOC (see CARB Carl Moyer Program Guidelines).

AP-42 emission factors used for SOx in all cases.

If an emission standard is not available for a given pollutant, then AP-42 emission factors used.

PM2.5 assumed to be 98% of PM10 emissions based on size fractions for stationary internal combustion diesel engines.

Legend

[shaded] Emission factor based on NMHC+NOx emission standard

Conversion Factors

1 lb =	453.6 g
1 ton =	2,000 lbs
1 month =	30.4 days
1 hour =	60 minutes
1 acre-foot =	325,851 gallons

Notes:
If a specific HP and emission tier combination has an emission standard of NMHC+NOx, then 95% of emissions assumed to be NOx and 5% of emissions assumed to be VOC (see CARB Carl Moyer Program Guidelines).
AP-42 emission factors used for SOx in all cases.
If an emission standard is not available for a given pollutant, then AP-42 emission factors used.
PM2.5 assumed to be 98% of PM10 emissions based on size fractions for stationary internal combustion diesel engines.

CARB Airborne Toxic Control Measure (ATCM) for Stationary Compression Ignition Engines

Table F-39. Summary of the Emission Standards for New Stationary Diesel-Fueled CI Engines > 50 BHP used in Agricultural Operations

Horsepower Range	Diesel PM [1] (g/bhp-hr)	HC (g/bhp-hr)	NOx (g/bhp-hr)	NMHC+NOx (g/bhp-hr)	CO (g/bhp-hr)
50<HP<100	0.3				
100<=HP<175	0.22				
175<=HP	0.15				

Source: See Section 93115.8(a)

Notes:

[1] Less than or equal to the emission standard OR Off-Road CI Engine Certification Standard for an off-road engine of the maximum rated power, whichever is more stringent.

[2] Off-Road CI Engine Certification Standard for an off-road engine of the model year and maximum rated power of the engine installed to meet the applicable PM standard, or Tier 1 standards.

[3] Prior to January 1, 2008, these limits shall not apply to engines sold from one agricultural operation to another and funded under State or federal incentive.

Table F-40. Emission Standards for Noncertified Greater than 50 BHP In-Use Stationary Diesel-Fueled Engines Used in Agricultural Operations

Horsepower (HP) Range	Compliance Date [1]	PM (g/bhp-hr)	HC [2,3] (g/bhp-hr)	NOx [2,3] (g/bhp-hr)	NMHC+NOx [2,3] (g/bhp-hr)	CO [2,3] (g/bhp-hr)
50<HP<75	2011	0.3				
75<=HP<100	2011	0.3				
100<=HP<175	2010	0.22				
175<=HP<=750	2010	0.15				
750<HP	2014	0.075				

Source: See Sections 93115.8(b) (2) and (4)

Note:

[1] Compliance date on or after December 31

[2] Engine Certification Standards for off-road engine of the model year and maximum rated power of the engine installed to meet the applicable PM standard.

[3] If no limits have been established for an off-road engine of the same model year and maximum rated power, then the in-use stationary diesel-fueled engine used in an agricultural operation shall not exceed Tier 1 standards in Title 13.

Table F-41. Emission Standards Tier 1- and Tier 2-Certified Greater than 50 BHP In-Use Stationary Diesel-Fueled Engines Used in Agricultural Operations

Horsepower Range (hp)	Compliance Date	PM (g/bhp-hr)	HC [2,3] (g/bhp-hr)	NOx [2,3] (g/bhp-hr)	NMHC+NOx [2,3] (g/bhp-hr)	CO [2,3] (g/bhp-hr)
50<HP<75	2015	0.02				
75<=HP<175	2015	0.01				
175<=hp<=750	2014	0.01				
750<HP	2014	0.075				

Source: See Sections 93115.8(b)(3) and (4)

Notes:

[1] Compliance date on or after December 31 or 12 years after the date of initial installation, whichever is later.

[2] Off-Road CI Engine Certification Standards for an off-road engine of the model year and maximum rated power of the engine installed to meet the applicable PM standard.

[3] If no limits have been established for an off-road engine of the same model year and maximum rated power, then the in-use stationary diesel-fueled engine used in agricultural operation shall not exceed Tier 1 standards in Tier 13, CCR, section 2423 for an off-road engine of the same maximum rated power irrespective of model year.

Table F-42. Tier 1, Tier 2, and Tier 3 Exhaust Emission Standards

Maximum Rated Power	Tier	Model Year	(g/kW-hr)					(g/hp-hr)

Evaporative	6.61E-04	0.09	0.00	0.00	E	
Crankcase	4.85E-03	0.69	4.41E-05	0.01	E	
Refueling	1.08E-03	0.15	0.00	0.00	E	

Source: U.S. Environmental Protection Agency. 1996. Compilation of Air Pollutant Emission Factors (AP-42). Chapter 3.3: Gasoline and Diesel Industrial Engines.

Notes:

[a] References 2,5-6,9-14. When necessary, an average brake-specific fuel consumption (BSFC) of 7,000 Btu/hp-hr was used to convert from lb/MMBtu to lb/hp-hr. To convert from lb/hp-hr to kg/kwhr, multiply by 0.608. To convert from lb/MMBtu to ng/J, multiply by 430. SCC = Source Classification Code. TOC = total organic compounds.

[b] PM-10 = particulate matter less than or equal to 10 :m aerodynamic diameter. All particulate is assumed to be 10 µm in size.

[c] Assumes 99% conversion of carbon in fuel to CO2 with 87 weight % carbon in diesel, 86 weight % carbon in gasoline, average BSFC of 7,000 Btu/hp-hr, diesel heating value of 19,300 Btu/lb, and gasoline heating value of 20,300 Btu/lb.

[d] Instead of 0.439 lb/hp-hr (power output) and 62.7 lb/mmBtu (fuel input), the correct emissions factors values are 6.96 E-03 lb/hp-hr (power output) and 0.99 lb/mmBtu (fuel input), respectively. This is an editorial correction. March 24, 2009

For large stationary diesel engines (greater than 600 horsepower [hp]) see Chapter 3.4: Large Stationary Diesel and All Stationary Dual-Fuel Engines.

Table F-46. Uncontrolled Emission Factors for 4-Stroke Lean-Burn Engines [a]

Pollutant	Emission Factor (lb/MMBtu) [b] (fuel input)	Emission Factor Rating
NOx [c] 90 - 105% Load	4.08E+00	B
NOx [c] <90% Load	8.47E-01	B
CO [c] 90 - 105% Load	3.17E-01	C
CO [c] <90% Load	5.57E-01	B
CO2 [d]	1.10E+02	A
SO2 [e]	5.88E-04	A
TOC [f]	1.47E+00	A
Methane[g]	1.25E+00	C
VOC [h]	1.18E-01	C
PM10 (filterable) [i]	7.71E-05	D
PM2.5 (filterable) [i]	7.71E-05	D
PM Condensable [j]	9.91E-03	D

Source: U.S. Environmental Protection Agency. 2000. Compilation of Air Pollutant Emission Factors (AP-42). Chapter 3.2: Natural Gas-Fired Reciprocating Engines. July.

Notes:

[a] Reference 7. Factors represent uncontrolled levels. For NOx, CO, and PM10, “uncontrolled” means no combustion or add-on controls; however, the factor may include turbocharged units. For all other pollutants, the data set may include units with control techniques used for NOx control, such as PCC“uncontrolled” means no oxidation control; and SCR for lean burn engines, and PSC for rich burn engines. Factors are based on large population of engines. Factors are for engines at all loads, except as indicated. SCC = Source Classification Code. TOC = Total Organic Compounds. PM-10 = Particulate Matter ≤ 10 microns (μ) aerodynamic diameter. A “<“ sign in front of a factor means that the corresponding emission factor is based on one-half of the method detection limit.

[b] Emission factors were calculated in units of (lb/MMBtu) based on procedures in EPA Method 19. To convert from (lb/MMBtu) to (lb/10^6 scf), multiply by the heat content of the fuel. If the heat content is not available, use 1020 Btu/scf. To convert from (lb/MMBtu) to (lb/hp-hr) use the following equation:

lb/hp-hr = (lb/MMBtu) (heat input, MMBtu/hr) (1/operating HP, 1/hp)

[c] Emission tests with unreported load conditions were not included in the data set.

[d] Based on 99.5% conversion of the fuel carbon to CO2. CO2 [lb/MMBtu] = (3.67)(%CON)(C)(D)(1/h), where %CON = percent conversion of fuel carbon to CO2, C = carbon content of fuel by weight (0.75), D = density of fuel, 4.1 E+04 lb/10^6 scf, and h = heating value of natural gas (assume 1020 Btu/scf at 60EF).

[e] Based on 100% conversion of fuel sulfur to SO2. Assumes sulfur content in natural gas of 2,000 gr/10^6scf.

[f] Emission factor for TOC is based on measured emission levels from 22 source tests.

[g] Emission factor for methane is determined by subtracting the VOC and ethane emission factors from the TOC emission factor. Measured emission factor for methane compares well with the calculated emission factor, 1.31 lb/MMBtu vs. 1.25 lb/MMBtu, respectively.

[h] VOC emission factor is based on the sum of the emission factors for all speciated organic compounds less ethane and methane.

[i] Considered ≤ 1 μ in aerodynamic diameter. Therefore, for filterable PM emissions, PM10(filterable) = PM2.5(filterable).

[j] PM Condensable = PM Condensable Inorganic + PM-Condensable Organic

Engine Size Summary

Classification	Severe	Severe	Maintenance	PM2.5 Precursor	PM2.5 Precursor	Maintenance	Nonattainment	Nonattainment
De Minimis Threshold (tpy)	25	25	100	100	100	100	100	100
Exceed?	No	No	No	No	No	No	No	No

Note:

[1]The Sacramento Metro 8-hour O3 nonattainment area consists of Sacramento and Yolo Counties and parts of El Dorado, Placer, Solano, and Sutter Counties. Emissions occurring within the attainment area of these counties are excluded from the total emissions.

[2]The Sacramento Area CO maintenance area is based on the Census Bureau Urbanized Area and consists of parts of Placer, Sacramento, and Yolo Counties. The general conformity applicability evaluation is based on emissions that would occur within the entire county to be conservative.

[3]All counties are designated as attainment areas for SO2; however, since SO2 is a precursor to PM2.5, its emissions must be evaluated under general conformity.

[4]The 24-hour PM2.5 nonattainment area for Sacramento includes Sacramento County and parts of El Dorado, Placer, Solano, and Yolo Counties. The general conformity applicability analysis assumes that all emissions that could occur within each county would occur within the Sacramento nonattainment area to be conservative.

[5]VOC and NOx emissions are excluded from Sutter County for Cranmore Farms, Garden Highway Mutual Water Company, Gilsizer Slough Ranch, Pelger Mutual Water Company, Reclamation District 1004, and Tule Basin Farms because they are located in areas designated as attainment for the federal 8-hour O3 NAAQS.

[6]The Yuba City-Marysville PM2.5 nonattainment area contains all of Sutter County and a part of Yuba County.

Table F-51. Emissions Outside of 8-Hour Ozone Nonattainment Area (tons per year)

Water Agency	County	VOC	NOx
Cranmore Farms	Sutter	Electric	Electric
Garden Highway Mutual Water Company	Sutter	Electric	Electric

Conversion Factors

1 MMBtu =	1,000,000 Btu
1 ton =	2,000 lbs
1 month =	30.4 days
1 hour =	60 minutes
1 acre-foot =	325,851 gallons

http://www.water.ca.gov/pubs/dwrnews/california_water_facts_card/waterfactscard.pdf

Natural Gas Engine Fuel Consumption

Estimated BSFC =	7,000 Btu/bhp-hr	(Estimated from Waukesha engine specifications)
Higher Heating Value	1,020 Btu/scf	(AP-42, Chapter 3.2: Natural Gas-fired Reciprocating Engines)

SCR control efficiency	85%

Notes:
Pelger Mutual Water Company used to estimate emissions for other water agencies.
Engine power rating equal to 250 hp for Pelger Mutual Water Company engines.
The Byron Buck memo is based on diesel-fueled engines with sizes ranging from 121 to 225 hp; all engines are noncertified (Tier 0).
Pelger Mutual Water Company engines are therefore determined to be a sufficient proxy to estimate the difference in emissions between groundwater substitution and cropland idling.

1 acre-foot of groundwater pumped = 4.25 acre-feet produced by fallowing
Source: Byron Buck & Associates. 2009. "Comparison of Summertime Emission Credits from Land Fallowing Versus Groundwater Pumping."

Legend
- (purple) Assumed to be electric (similar to other wells operated by water agency)
- (green) Engine power rating not provided; assumed to be equal to maximum horsepower for all engines operating at the water agency with the same fuel type

Conversion Factors

1 lb =	453.6 g
1 tonne =	1,000 kg
1 tonne =	1,000,000 g
1 MWh =	1,000 kWh
1 GWh =	1,000,000 kWh
1 kW =	1.34 hp
1 hour =	60 minutes
1 acre-foot =	325,851 gallons

Notes:

Pelger Mutual Water Company used to estimate emissions for other water agencies.

Engine power rating equal to 250 hp for Pelger Mutual Water Company engines.

The Byron Buck memo is based on diesel-fueled engines with sizes ranging from 121 to 225 hp; all engines are noncertified (Tier 0).

Pelger Mutual Water Company engines are therefore determined to be a sufficient proxy to estimate the difference in emissions between groundwater substitution and cropland idling.

1 acre-foot of groundwater pumped = 4.25 acre-feet produced by fallowing

Source: Byron Buck & Associates. 2009. "Comparison of Summertime Emission Credits from Land Fallowing Versus Groundwater Pumping."

Appendix H

Biological Regulatory Setting

This page left blank intentionally.

Appendix H
Biological Resources Regulatory Setting

The following section describes laws, rules, regulations and policies that apply to the natural communities, common plants and wildlife, fisheries, and special-status species that occur within the area of analysis.

H.1 Federal

H.1.1 Endangered Species Act (ESA)

The Federal ESA defines "endangered" species as those in danger of extinction throughout all or a significant portion of their range. A "threatened" species is any species that is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range. Additional special-status species include "candidate" species and "species of concern." Candidate species are those for which the U.S. Fish and Wildlife Service (USFWS), or National Oceanic and Atmospheric Administration Fisheries Service (NOAA Fisheries) if applicable, has enough information on file to propose listing as endangered or threatened. A species that has been "delisted" is one whose population has met its recovery goal target and is no longer found to be in jeopardy of extinction. These agencies also may designate Critical Habitat for listed species.

Section 4 of the Federal ESA prohibits "take" of federally listed species without a permit that specifically authorizes that take. Take may be authorized through either a Section 10a1(a) permit for directed take of the species for scientific research, or through an incidental take permit, which allows an action to take of the species (under specifically prescribed conditions) where such take is incidental to the implementation of an otherwise lawful activity. Incidental take of a federally listed species may be addressed for a proposed project in one of two ways depending on whether the or not the project has a federal nexus. A federal nexus occurs when a project is authorized or funded by a federal agency. Projects without a federal nexus may address potential adverse impacts to species protected under Federal ESA Section 10, or (2) a federal lead agency regulates a proposed project in accordance with Federal ESA Section 7. As this project has a federal nexus, the Section 7 process will be followed. Section 7 defines a process for the federal lead agency to consult with the responsible federal resource agency (the USFWS or NOAA Fisheries), to determine whether proposed long-term water transfers are likely to adversely affect species that are listed or proposed for listing. The Section 7 process typically requires the preparation of a biological assessment (BA) by the federal lead agency followed by the preparation of biological opinion (BO) by the responsible federal resource agency.

H.1.2 Fish and Wildlife Coordination Act (FWCA)

The FWCA (16 U.S. Code [USC] 661 et seq.) requires Federal agencies to consult with USFWS, or, in some instances, with NOAA Fisheries and with State fish and wildlife resource agencies before undertaking or approving water projects that control or modify surface water. The purpose of this consultation is to ensure that wildlife concerns receive equal consideration water resource development projects and are coordinated with the features of these projects. The consultation is intended to promote the conservation of fish and wildlife resources by preventing their loss or damage and to provide for the development and improvement of fish and wildlife resources in connection with water projects. Federal agencies undertaking water projects are required to fully consider recommendations made by USFWS, NOAA Fisheries, and State fish and wildlife resource agencies in project reports and to include measures to reduce impacts on fish and wildlife in project plans.

The 1988 amendment to the Fish and Wildlife Conservation Act mandates USFWS to identify species, subspecies, and populations of all migratory nongame birds that, without additional conservation actions, are likely to become candidates for listing under the ESA of 1973. In 2008, USFWS issued the most recent version of the National list of *Bird Species of Conservation Concern.*

H.1.3 Magnuson-Stevens Fisheries Act of 2006

The Amended Magnuson-Stevens Fishery Conservation and Management Act, also known as the Sustainable Fisheries Act (Public Law 104-297) is the primary law governing the marine fisheries of the United States. The law establishes requirements to provide for the sustainable management of these fisheries and to promote the protection of essential fish habitat. This Act requires all Federal agencies to consult with the Secretary of Commerce on activities, or proposed activities, authorized, funded, or undertaken by that agency that may adversely affect Essential Fish Habitat. The Essential Fish Habitat provisions of the Sustainable Fisheries Act are designed to protect fisheries habitat from being lost due to disturbance and degradation.

H.1.4 Migratory Bird Treaty Act (MBTA)

The MBTA domestically implements a series of international treaties that provide for migratory bird protection. The MBTA authorizes the Secretary of the Interior to regulate the taking of migratory birds. The act further provides that it is unlawful, except as permitted by regulations, “to pursue, take, or kill any migratory bird, or any part, nest or egg of any such bird…” (16 USC 703). This prohibition includes both direct and indirect acts, although harassment and habitat modification are not included unless they result in direct loss of birds, nests, or eggs. The current list of species protected by the MBTA can be found in the March 1, 2010 Federal Register (75 FR 9281). This list comprises several hundred species, including essentially all native birds. Permits for take of nongame migratory birds can be issued only for specific activities, such as scientific collecting, rehabilitation, propagation, education, taxidermy, and protection of human health and safety and of personal property. USFWS publishes a list of birds of conservation concern (BCC) to identify migratory nongame birds that are likely to become candidates for listing under ESA without additional conservation actions. The BCC list is intended to stimulate coordinated and collaborative conservation efforts among federal, state, tribal, and private parties.

H.1.5 Executive Order 11990 (Protection of Wetlands)

Executive Order 11990 (Protection of Wetlands) requires Federal agencies to take actions to minimize the destruction, loss, or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands when undertaking Federal activities and programs. Any agency considering a proposal that might affect wetlands must evaluate factors affecting wetland quality and survival. These factors should include the proposal's effects on the public health, safety, and welfare due to modifications in water supply and water quality; maintenance of natural ecosystems and conservation of flora and fauna; and other recreational, scientific, and cultural uses.

H.2 State

H.2.1 California Endangered Species Act (CESA)

CESA (California Fish and Game Code Sections 2050–2116) was implemented in 1984 to prohibit the take of species that are listed as endangered and or threatened. CESA defines "endangered" species as those whose continued existence in California is jeopardized. State-listed "threatened" species are those not presently threatened with extinction, but which may become endangered if their environments change or deteriorate. Section 86 of the California Department of Fish and Game Code defines take as to "hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill." California Department of Fish and Wildlife (CDFW) administers CESA and authorizes incidental take through either California Fish and Game Code Section 2080.1 (consistency determination) or Section 2081 (Incidental Take Permit).

H.2.2 Fully Protected Species

Sections 3511, 3513, 4700, and 5050 of the California Fish and Game Code pertain to fully protected wildlife species (birds in Sections 3511 and 3513, mammals in Section 4700, and reptiles and amphibians in Section 5050) and strictly prohibit the take of these species. CDFW cannot issue a take permit for fully protected species, except under narrow conditions for scientific research or the protection of livestock, or if a Natural Community Conservation Plan (NCCP) has been adopted. Specifically, Section 3513 prohibits any take or possession of birds designated by the MBTA as migratory nongame birds except as allowed by federal rules and regulations pursuant to the MBTA.

H.2.3 Protection of Birds and Raptors

Section 3503 of the Fish and Game Code prohibits the killing of birds and/or the destruction of bird nests. Section 3503.5 prohibits the killing of raptor species and/or the destruction of raptor nests. Typical violations include destruction of active bird and raptor nests as a result of tree removal, and failure of nesting attempts (loss of eggs and/or young) as a result of disturbance of nesting pairs caused by nearby human activity.

H.2.4 California Native Plant Protection Act (CNPPA)

The CNPPA of 1977 prohibits importation of rare and endangered plants into California, take of rare and endangered plants, or sale of rare and endangered plants. CESA defers to the CNPPA, which ensures that state-listed plant species are protected when state agencies are involved in projects subject to California Environmental Quality Act.

H.2.5 Natural Community Conservation Planning Act (NCCPA)

The NCCPA, California Fish and Game Code, Section 2800, et seq., was enacted to form a basis for broad-based planning to provide for effective protection and conservation of the State's wildlife heritage, while continuing to allow appropriate development and growth. The purpose of natural community conservation planning is to sustain and restore those species and their habitat identified by CDFW that are necessary to maintain the continued viability of biological communities impacted by human changes to the landscape. A NCCP identifies and provides for those measures necessary to conserve and manage natural biological diversity within the plan area while allowing compatible use of the land. CDFW may authorize the take of any identified species, including listed and non-listed species, pursuant to Section 2835 of the NCCPA, if the conservation and management of such species is provided for in an NCCP approved by CDFW. NCCPs in the planning area are described in greater detail in Section 3.6.1.2.5 Regional/Local Requirements. The proposed water transfers occurring in NCCP planning areas will not require separate incidental take permits pursuant to CESA for covered species if the project adheres to the requirements of the relevant plans.

H.2.6 Requirements of the 1995 Bay Delta Plan Water Quality Control Plan (1995 Delta WQCP) and Decision 1641

The State Water Resources Control Board (SWRCB) adopted its WQCP for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary in May 1995 and incorporated several elements of U.S. Environmental Protection Agency (USEPA), NOAA Fisheries, and USFWS regulatory objectives for water salinity and endangered species protection. The WQCP identifies the beneficial uses of the Bay-Delta that are to be protected and includes flow and water quality objectives that are intended to protect the beneficial uses. The plan also includes an implementation program for achieving the water quality objectives.

Under the Clean Water Act, the water quality standards comprise the uses and the quality objectives established to protect them.

Features of the current WQCP affect the proposed water transfers because they require certain Delta outflows and regulate actions that may be used to protect fish and benefit the environment.

H.3 State and Federal Laws and Regulations Governing Water Transfers and Water Acquisitions

H.3.1 The Water Code

Both State and Federal laws contain provisions that authorize, acknowledge, or support water transfers. The Water Code protects legal users of water and fish and wildlife during water transfers through the "no injury rule," analyses of impacts to fish and wildlife, evaluation of third-party impacts, and the 1707 process.

Water Code Sections 1435, 1725, and 1736 require that the SWRCB make a finding that certain proposed transfers not result in unreasonable effects on fish and wildlife or other instream beneficial uses. These Code Sections apply to specific types of water transfers (urgent, temporary, and long-term transfers) related to post-1914 water rights. Pre-1914 water rights are not subject to the permit system, although a change in use for instream flow may be permitted under Section 1707 on petition to the SWRCB. The proposed water transfers were conceived in compliance with these codes.

In the context of the proposed water transfers "third parties" are any persons and resources other than the entities transferring or receiving water. Although the Water Code does not define "third party impacts," they traditionally include impacts related to downstream water rights; adjacent groundwater users; fish and wildlife; and recreation, economic, and social impacts. Most third-party impacts are evaluated under Water Code Sections that protect prior rights and fish and wildlife as discussed above. However, Water Code Sections 386 and 1810 require evaluation of other third-party impacts for some specific transfers and prohibit such transfers from affecting the overall economy of the area or county from which the water is being transferred. Water Code Section 1810 states that transferors can utilize public water conveyance facilities as long as "this use of a water conveyance facility is to be made without injuring any legal user of water and without unreasonably affecting fish, wildlife, or other instream beneficial uses and without unreasonably affecting the overall economy or the environment of the county from which the water is being transferred."

Section 1707 of the Water Code allows water rights holders, including riparian rights holders, to dedicate their rights to instream uses "for the purpose of preserving or enhancing wetlands, fish and wildlife resources, or recreation in, or on, the water." These transfers, from a consumptive use to a non-consumptive use with an identified need, may be temporary or permanent. The transfer must meet the following requirements for the SWRCB to consider approving the change in use:

- Will not increase the amount of water the person is entitled to use;
- Will not unreasonably affect any legal user of water; and
- Otherwise meets the requirements of Division 2 of the Water Code.

The petitioner can request that the water subject to transfer approval be in addition to water required for "Federal, State, or local regulatory requirements governing water quantity, water quality, instream flows, fish and wildlife, wetlands, recreation and other instream beneficial uses." If the petitioner does not submit this request to the SWRCB, then the water shall be used to meet any of the above requirements.

H.4 Other Pertinent Programs, Documents, Laws, and Agreements

Potential biological effects of water transfers in the project area have been previously addressed in documents.

H.4.1 Central Valley Project Improvement Act (CVPIA)

The CVPIA is a Federal statute passed in 1992 with the following purposes:

> *"To protect, restore, and enhance fish, wildlife, and associated habitats in the Central Valley and Trinity River basins of California; To address impacts of the Central Valley Project on fish, wildlife and associated habitats; To improve the operational flexibility of the Central Valley Project; To increase water-related benefits provided by the Central Valley Project to the State of California through expanded use of voluntary water transfers and improved water conservation; To contribute to the State of California's interim and long-term efforts to protect the San Francisco Bay/Sacramento-San Joaquin Delta Estuary; To achieve a reasonable balance among competing demands for use of Central Valley Project water, including the requirements of fish and wildlife, agricultural, municipal and industrial and power contractors."*

The CVPIA changed the relative priorities of the various project purposes of the Central Valley Project (CVP) by making fish and wildlife protection, as a project purpose, equal to water supply for agricultural and urban uses.

CVPIA Section 3406(b)(2) (CVPIA[b][2]) authorized and directed the Secretary to dedicate and manage 800,000 acre-feet (AF) of CVP yield annually for the primary purpose of implementing the fish, wildlife, and habitat restoration purposes and measures authorized in CVPIA, to assist the State of California in its efforts to protect the waters of the Bay-Delta Estuary, and to help meet obligations legally imposed on the CVP under State or Federal law following the date of enactment of the CVPIA. This dedicated 800,000 AF of water, known as (b)(2) water, was included as a component of the CALFED Programmatic Environmental Impact Statement/Environmental Impact Report (PEIS/EIR) existing regulatory baseline for fishery protection conditions for environmental and fisheries protection measures.

The operation of CVP and the State Water Project (SWP) facilities is subject to BOs issued by USFWS and the NOAA Fisheries. These BOs are subject to ongoing litigation and are currently under review by the two services:

- Biological Opinion on Implementation of the CVPIA and Continued Operation and Maintenance of the Central Valley Project (NOAA Fisheries 2000),
- Biological Opinion on the Effects of the Long-Term Central Valley Project and State Water Project Operations Criteria and Plan (NOAA Fisheries 2004),
- Consultation on Long-Term Renewal of Water Service Contracts in the Delta-Mendota Canal Unit (NOAA Fisheries 2005),
- Reinitiation of Formal and Early Section 7 Endangered Species Consultation on the Coordinated Operations of the Central Valley Project and State Water Project and the Operational Criteria and Plan to Address Potential Critical Habitat Issues (USFWS 2005a),
- Conclusion of Consultation on Long-Term Renewal of Water Service Contracts in the Delta-Mendota Canal Unit (USFWS 2005b),
- Formal Endangered Species Consultation on the Operations and Maintenance Program Occurring on Bureau of Reclamation Lands within the South-Central California Area Office: Biological Opinion (USFWS 2005c),
- Biological opinions for CVP Water contracts,
- Biological Opinion on the Coordinated Operations of the CVP and SWP in California. (USFWS 2008), and
- Biological Opinion on California's Central Valley Water Project (NOAA Fisheries 2009).

H.5 Regional/Local Requirements

Both the ESA and the NCCPA include provisions for the development of conservation plans to protect vegetation and wildlife resources.

A Habitat Conservation Plan (HCP) is a planning document that is required for issuance of an incidental take permit under section 10 of the ESA. The HCP process provides opportunities to conserve listed species, while streamlining permitting for participants' development projects within the planning area. HCP documents typically includes the following information: the anticipated take of the proposed project; measures to avoid, minimize or mitigate impacts to the maximum extent practicable, and a funding mechanism for acquiring and managing lands containing the habitats on which the covered species depend. Covered species may include both listed and non-listed species. This may provide an extra level of certainty for permittees, given that no amendments to the plan would be required if a covered species becomes listed under the ESA before the completion of project activities.

A NCCP is a similar process provided under state law, with some key differences. While the federal and state ESAs focus on protection and recovery of species that have already declined, NCCPs take a broader approach, seeking to anticipate and avoid future conflicts between preservation and development, as well as compliance with the CESA. NCCPs focus on regional-scale protection of ecosystems along with compatible development. A local agency oversees cooperative development of an NCCP by landowners, environmental groups, and other stakeholders, with support provided by CDFW and USFWS.

Project actions within the HCP/NCCP areas will comply with applicable requirements for covered activities within plan areas for existing HCPs/NCCPs. A separate Section 7 Consultation will also be undertaken for the long-term water transfers.

There are 11 HCPs or NCCPs that are either adopted or under development for areas that overlap with, or occur in the vicinity of, the long-term water transfers area of analysis (CDFW 2014a):

- Butte Regional Conservation Plan (BRCP) – The BRCP is a cooperative planning effort between the Cities of Biggs, Chico, Gridley, Oroville, County of Butte, and Butte County Association of Governments. The plan will provide streamlined ESA permitting for transportation projects, land development and covered activities such as construction and maintenance of facilities and infrastructure, residential construction, and recreational activity-related construction. The BRCP also aims to provide comprehensive conservation of species, wetlands and ecosystems, specifically contributing to the protection of 41 plant, fish, and wildlife species within the 564,270 acre plan area (CDFW 2014b). The BRCP covers nine of the focal species for the long-term water transfers including Red Bluff dwarf rush, Sacramento River winter-run Chinook salmon, and green sturgeon. This plan is under development.

- Bay-Delta Conservation Plan (BDCP) – The BDCP is a comprehensive conservation strategy for the Sacramento–San Joaquin River Delta (Delta) to protect ecosystem health, water quality, water supply, and California's economy, while permitting the operation of the CVP and State Water Project (SWP). The BDCP covers 56 species, including 11 of the focal species for the long-term water transfers including Central Valley Spring-run Chinook salmon, longfin smelt, and greater sandhill crane. This plan is under development. The draft BDCP and its corresponding draft EIS/EIR were published for public review and comment in December 2013 (Reclamation et al. 2013).

- East Contra Costa County HCP/NCCP – The East Contra Costa County HCP/NCCP was developed partially to address indirect and cumulative effects on terrestrial species from development supported by increases in water supply provided by Contra Costa Water District. Activities covered under the plan include public infrastructure projects, construction of residential and business development, and public infrastructure projects. The plan has been adopted by Contra Costa County, the Cities of Brentwood, Clayton, Pittsburg, and Oakley. The HCP/NCCP provides regional conservation and development guidelines to protect natural resources while improving the permit process for endangered species and wetland regulations. The plan will encompass a preserve system covering 30,300 acres of land that will be managed for the benefit of 28 species and the natural communities they depend upon (East Contra Costa County HCP Association 2006). The East Contra Costa County HCP covers 4 of the focal species for the long-term water transfers including giant garter snake, San Joaquin kit fox, and Western pond turtle.

- Natomas Basin HCP (NBHCP) - The NBHCP establishes a multi-species conservation program to mitigate the expected loss of habitat and incidental take and/or loss of covered species that would result from planned urban development. The plan covers 53,537 acres within the levees surrounding the Natomas Basin and 22 plant and wildlife species (The Natomas Basin Conservancy 2003). Covered activities under the plan include urban development, public and drainage improvements, water agency projects, and approved activities of the Natomas Basin Conservancy. Plan participants include the City of Sacramento, Sutter County, Sacramento County, and the acting regulatory agencies. The NBHCP covers four of the focal species for the long-term water transfers including giant garter snake, Western pond turtle, and white-faced ibis.

- Placer County Conservation Plan (PCCP) HCP/NCCP – The PCCP HCP/NCCP is intended to address the impacts associated primarily with unincorporated growth in western Placer County in addition to growth associated with the build-out of Lincoln's updated General Plan. The PCCP is intended to protect 31 special status species and federally regulated wetlands, as well as indirectly protect the habitat of hundreds of plant and wildlife species across approximately 201,000 acres of Western Placer County (Placer County Planning Services Division 2011). Covered activities include: urban development, in-stream projects, capital projects, operation and maintenance, rural development, conservation strategy implementation, and other Placer County conservation programs. Participants include the City of Lincoln, Placer County, Placer County Water Agency and South Placer Regional Transportation Authority. PCCP covers five of the focal species for the long-term water transfers including Ahart's dwarf rush, Red bluff dwarf rush, and Central Valley Steelhead. This plan is under development.

- San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) – The SJMSCP was developed to provide guidelines for converting open space to other land uses, preserving agriculture, and protecting plant and wildlife species. Activities covered under the plan include urban development, mining, non-agricultural activities occurring outside of urban boundaries, transportation projects, non-federal flood control projects, maintenance activities, and similar public agency projects. San Joaquin County, the Cities of Stockton, Lodi, Manteca, Tracy, Ripon, Escalon, and Lathrop are the plan participants. The plan addresses 97 special-status plant, fish and wildlife species in over 900,000 acres of the San Joaquin County (San Joaquin County 2000). The SJMSCP covers 12 of the focal species for the long-term water transfers including Sandford's arrowhead, Red Bluff dwarf rush, and Delta smelt.

- Santa Clara Valley (SCV) HCP/NCCP – The SCV HCP/NCCP is a regional partnership between the County of Santa Clara, Santa Clara Valley Transportation Authority, Santa Clara Valley Water District, and the Cities of San Jose, Gilroy and Morgan Hill, and regulatory agencies. The plan encompasses approximately 440,318 acres and will address impacts primarily associated with the future uses of land identified in the plan area (CDFW 2014c). Land preservation would mitigate for the environmental impacts of planned urban and rural development, instream activities, public infrastructure operations and maintenance activities (e.g. water, transportation, etc.) and would enhance the long term viability of 21 threatened or endangered plant and wildlife species (CDFW 2014c). SCV HCP/NCCP covers three of the focal species for the long-term water transfers including San Joaquin kit fox, Western pond turtle, and tricolored blackbird.

- Solano Multispecies HCP (SMSHCP) – The SMSHCP plan area covers 585,000 acres (Solano County Water Agency 2009). It was developed to address species conservation in conjunction with urban development, flood control/infrastructure improvement activities, and to support the issuance of an incidental take permit under the Federal ESA for the Bureau of Reclamation's Solano Project Contract Renewal. Activities covered under the plan include preservation, restoration, invasive species control, and water quality improvement. Covered species include federally and state-listed fish species and other wildlife species of concern. Plan participants include Solano County, a small portion of Yolo County, Solano County Water Agency's contract service area, including the Cities of Fairfield, Vacaville, Vallejo, Suisun City, Solano Irrigation District, and the Main Prairie Water District. The SMSHCP covers eight of the focal species for the long-term water transfers including winter-run Chinook salmon, Central Valley steelhead, and longfin smelt. This plan is still under development.

- South Sacramento HCP (SSHCP) – The proposed SSHCP would address issues related to species conservation, agricultural protection, and urban development in 341,000 acres of south Sacramento County. Activities covered under the plan include construction of residential, commercial, and industrial buildings, and associated infrastructure. The plan is being prepared by Sacramento County, the Cities of Sacramento, Elk Grove, and Galt, and Rancho Powers Authority. The plan would cover 40 plant and wildlife species, including ten species that are listed by the state or federal governments. The SSHCP covers five of the focal species for the long-term water transfers including Ahart's dwarf rush, Greater sandhill crane, and giant garter snake. This plan is still under development.

- Yolo Natural Heritage Program (YNHP) – This plan is still under development and the program released a draft plan on June 28, 2013 (Yolo Natural Heritage Program 2013). This 653,818-acre county-wide HCP/NCCP will provide for the conservation of 32 sensitive species in five habitat types: wetland, riparian, oak woodland, grassland, and agriculture (Yolo Natural Heritage Program 2013). No aquatic species will be addressed in the YNHP. The plan describes measures that local agencies will implement to conserve biological resources, obtain permits for urban growth and public infrastructure projects, maintain the agricultural heritage of the county, and acquire permanent conservation easements for sensitive plant and wildlife species in the plan area. Plan participants include Yolo County, the Cities of Davis, Woodland, West Sacramento, and Winters. The YNHP covers four of the focal species for the long-term water transfers including giant garter snake, Western pond turtle, and purple martin.

- Yuba-Sutter NCCP/HCP – This plan is still under development. The Yuba-Sutter NCCP/HCP is a cooperative planning effort initiated by Yuba and Sutter Counties in connection with improvements to Highways 99 and 70, as well as future development in the area surrounding those highways. The plan covers approximately 210,000 acres and provides for the regional protection and management of 31 listed and other special-status species and their habitats (CDFW 2014d). Plan participants include the Counties of Yuba and Sutter, Cities of Yuba, Live Oak, and Wheatland. The Yuba-Sutter HCP covers five of the focal species for the long-term water transfers including greater sandhill crane, Western pond turtle, and tricolored blackbird.

Special-Status Animals and Plants

This page left blank intentionally.

Appendix I
Special-Status Animals and Plants with Potential to Occur in the Area of Analysis

Table I-1. Special-Status Animals with Potential to Occur in the Area of Analysis

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Invertebrates						
Bay checkerspot butterfly *Euphydryas editha bayensis*	T	--	Historically occurred east, west, and south of SF bay, to Mt. Diablo south to Hollister. Currently, restricted to six core areas on the west and southern edges of the SF bay - SF peninsula, San Mateo County, and Santa Clara County, Any site with appropriate habitat within historic range should be considered potentially occupied (The Xerces Society 2012)	Restricted to native grasslands on outcrops of serpentine soil. The primary host plant for this butterfly is *Plantago erecta (*Dwarf plantain*)*. Secondary host plant include *Othocarpus densiflorou*s, *O.purpurscens,* and Purple owl's clover. Prefers shallow, serpentine-derived soils.	Adult present in spring. Flight season late February to early May.	None. Occurrences have been documented in the Buyer Service Area and suitable habitat may be present in the area of analysis. However, no impacts are expected to native grasslands.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Conservancy fairy shrimp *Branchinecta conservatio*	E	--	Northern two-thirds of the Central Valley. It ranges from Vina Plains of Tehama County; Sacramento NWR in Glenn County; Jepson Prairie Preserve and surrounding area east of Travis Air Force Base, Solano County; Mapes Ranch west of Modesto, Stanislaus County.	Inhabits the ephemeral water of swales and vernal pools. It is most commonly found in grass or mud bottomed swales, earth sump, or basalt flow depression pools in unplowed grasslands.	Has been collected from early December to early May.	None. Occurrences have been documented within the Seller Service Area. Suitable habitat occurs within the area of analysis. No impacts to vernal pool or other habitats occupied by this species are anticipated. The species is not likely to occur to occur in rice fields and canals due to predators (i.e. fish).
Lange's metalmark butterfly *Apodemia mormo langei*	E	--	Restricted to sand dunes along the southern bank of the Sacramento-San Joaquin River. Within Contra Costa County, it is currently found only at Antioch Sand Dunes.	Inhabits stabilized dunes along the San Joaquin river and is endemic to Antioch sand dunes, Contra Costa county. The butterfly's primary host plant is *Eriogonum nudum var. auriculatum*. It feeds on nectar of other wildflowers, as well as host plant.	Breeding season is August - September, Larvae hatch during rainy months.	None. CNDDB occurrences have been documented within the Buyer Service Area, however no impacts to sand dunes are anticipated.
Longhorn fairy shrimp *Branchinecta longiantenna*	E	--	Restricted to northern, central, and portions of southern California; populations along the eastern margin of the Central Coast Mountains from Concord, Contra Costa County south to Soda Lake in San Luis Obispo County; the Kellogg Creek watershed; the Altamont Pass area; the western and northern boundaries of Soda Lake on the Carrizo Plain; and Kesterson National Wildlife Refuge in the Central Valley.	Endemic to the eastern marring of the central coast mountains in seasonally astatic grassland vernal pools. Found in ephemeral freshwater habitats, such as vernal pools and swales.	Has been observed from late December until late April.	None. Occurrences have been documented within the Seller Service Area. Suitable habitat may occur within the area of analysis. The species is not likely to occur to occur in rice fields and canals due to predators (i.e. fish). Transfers are not expected to impact any suitable grassland vernal pools or swales.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
San Bruno elfin butterfly *Callophrys mossii bayensis*	E	--	Found in vicinity of San Bruno mountains, San Mateo County (ESSIG 2012b).	Found in coastal, mountainous areas with grassy ground cover. Colonies are located on steep, north-facing slopes within the fog belt. Larval host plant is *Sedum spathulifolium.*	Year round	None. Occurrences have been documented in the Buyer Service Area and suitable habitat is present in the area. No impacts are anticipated to mountainous areas near San Bruno. Therefore no impacts to the species are expected.
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	T	--	Occurs only in the Central Valley and surrounding foothills below 3,000 feet elevation (USFWS 1980).	Dependent on elderberry shrubs (host plant) as a food source. Potential habitat consists of shrubs with stems one inch in diameter within Central Valley.	Year round for host plant and exit holes; March to June for adults	None. Occurrences have been documented within the Seller Service Area. Suitable habitat may occur within the area. However, elderberry shrubs would not be impacted by transfers, therefore no impacts are anticipated to the species.
Vernal pool fairy shrimp *Branchinecta lynchi*	T	--	Endemic to the Central Valley, Central Coast Mountains, and South Coast Mountains of California. It ranges from the Vina Plains in Tehama County, through the Central Valley, and south along the Central Coast to northern Santa Barbara County.	Endemic to the grasslands of the Central Valley, central coast mountains, and south coast mountains. Inhabits the ephemeral water of swales and vernal pools. It is most commonly found in grassed or mud bottomed swales, earth sump, or basalt flow depression pools in unplowed grasslands.	Has been collected from early December to early May.	None. Occurrences have been documented in both the Buyer and the Seller Service areas. Rice fields and canals are not likely to support this species due to the presence of predators (i.e. fish), therefore no impacts are anticipated to the species. Transfers are not expected to impact vernal pools or natural wetlands.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Vernal pool tadpole shrimp *Lepidurus packardi*	E	--	Endemic to the northern portion of the Central Valley of California. This species occurs from the Millville Plains and Stillwater Plains in Shasta County south throughout the Central Valley to Merced County.	Found in a variety of natural and artificial seasonally ponded Sacramento valley habitat types including: vernal pools, swales, ephemeral drainages, stock ponds, reservoirs, ditches, backhoe pits, and ruts caused by vehicular activities.	Has been collected from early December to early May.	None. Occurrences have been documented in both the Buyer and the Seller Service area. Suitable habitat is present in the area. Rice fields and canals are not likely to support this species due to the presence of predators (i.e. fish), therefore there is a low potential for impacts to the species. Transfers are not expected to impact vernal pools or natural wetlands. No impacts to the species are expected.
Zayante band-winged grasshopper *Trimerotropis infantilis*	E	--	Known only from Santa Cruz County. Found in local Santa Cruz mountains (the Zayanite Sand Hills ecosystem) (Santa Cruz Public Libraries 2012).	Found in isolated sandstone deposits. Inhabits mostly sand parkland habitat, but also in areas with well-developed ground cover and in sparse chaparral with grass.	Flight season from late May - Oct.	None. Occurrences have been documented in the Buyer Service Area and suitable habitat is present in the area, however, no impacts to suitable habitat are anticipated.
Amphibians						
California red-legged frog *Rana aurora draytonii*	T	SSC	Northwestern California, from Mendocino County south to northwestern Baja California. May now be extirpated in the southern Sierra Nevada; other Sierra Nevada foothill populations are small and highly localized. Nearly all current Central Valley sites are on the Coast Range slope, usually below 1,200m (3,936 ft).	Usually found in or near quiet permanent water of streams, freshwater marshes, or (less often) ponds and other quiet bodies of water; also damp woods and meadows some distance from water. Occurs in sites with dense vegetation (e.g., willows) close to water.	Year round. Little movement away from streamside habitats. Occasionally found on roads at night during winter and spring rains.	None. Suitable habitat is present within the area and occurrences of this species have been previously documented in the Buyer Service Area. Environmental Commitments would cause potential impacts to California red-legged frog to beneglegible.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
California tiger salamander *Ambystoma californiense*	T[1], E[2]	T	Found in annual grassland habitat, grassy understories of valley-foothill hardwood habitats, and uncommonly along stream courses in valley-foothill riparian habitats. Occurs from near Petaluma, Sonoma County, and east through the Central Valley to Yolo and Sacramento Counties and south to Tulare County.; and from the vicinity of San Francisco Bay south to Santa Barbara County. Occurs at elevations from 3m - 1,054m (3200ft).	Lives in vacant or mammal-occupied burrows, occasionally other underground retreats, throughout most of the year, in grassland, savanna, or open woodland habitats. Lays eggs on submerged stems and leaves, usually in shallow ephemeral or semi permanent pools and ponds that fill during heavy winter rains, sometimes in permanent ponds; breeding takes place in fish free pools and ponds.	Migrates up to two km between terrestrial habitat and breeding pond. Migrations may occur from November through April.	None. Occurrences have been documented within both the Buyer and Seller Service Areas. Suitable habitat may occur within the area, but would not be impacted by transfers. This species is not expected to occur in rice fields due to predatory fish. Existing Environmental Commitments would maintain flow and temperature in streams.
Foothill yellow-legged frog *Rana boylii*	--	SSC	This species is known from the Pacific drainages from Oregon to the upper San Gabriel River, Los Angeles County, California, including the coast ranges (west pf Cascade crest) and Sierra Nevada foothills in the United States. Isolated populations in San Joaquin County on the floor of the Central Valley. Elevation range extends from near sea level to 1940m (6370ft).	This species inhabits partially shaded, rocky streams at low to moderate elevations, in areas of chaparral, open woodland, and forest. Rarely encountered far from permanent water.	Year round. Significant seasonal movements for migrations from breeding area have not been reported.	None. Occurrences have been documented within both the Buyer and Seller Service Areas. Suitable habitat is present within the area. However Transfers are not expected to impact any suitable rocky stream and woodland habitats. No impact to the species is expected.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Western spadefoot toad *Spea hammondii*	--	SSC	This species occurs in the Central Valley and bordering foothills of California and along the Coast Ranges into northwestern Baja California, Mexico. In the Coast Ranges it is found from Point Conception, Santa Barbara County, south to Mexican border. Elevation ranges from near sea level to 1,363m (4,460 ft).	Lowlands to foothills, grasslands, open chaparral, pine-oak woodlands. Prefers short grass plains, sandy or gravelly soil. It is fossorial and breeds in temporary rain pools and slow-moving streams that do not contain bullfrogs, fish, or crayfish.	Year round. Usually in underground burrows most of year, but will travel several meters on rainy nights. Movement is rarely extensive.	None. Occurrences have been documented from both the Buyer and Seller Service Areas. Suitable habitat is present in the area. Transfers would not impact suitable upland habitat types. The species is not likely to occur in rice fields due to the presence of predatory fish, bullfrogs etc. Environmental Commitments to maintain flows will protect Western spadefoot toad.
Reptiles						
Alameda whipsnake *Masticophis lateralis euryxanthus*	T	T	Seven populations (recovery units) are known from Alameda and Contra Costa Counties, including the Mt. Diablo area and other East Bay Regional Parks, south almost to the border of Alameda and Santa Clara Counties. Likely occurred historically within San Joaquin and northern Santa Clara Counties.	The species is typically found in chaparral and scrub habitats, but it will also use adjacent grassland, oak savanna and woodland habitats. It is mostly found on south-facing slopes & ravines, with rock outcrops, deep crevices or abundant rodent burrows.	Year round.	None. Occurrences have been documented within the Buyers and Sellers Service Areas. No impacts to suitable habitat for Alameda whipsnake are anticipated.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
blunt-nosed leopard lizard *Gambelia sila*	E	E	Currently known from undeveloped land within the San Joaquin Valley and the Coast Range foothills. Historically, the blunt-nosed leopard lizard ranged from the San Joaquin Valley and foothills from Stanislaus County south to northern Santa Barbara and Ventura Counties, with observations below 800m elevation.	This species is a resident of sparsely vegetated alkali and desert scrub habitats in areas of low topographic relief. The lizard seeks cover in mammal burrows, under shrubs or structures such as fence posts.	Year round. Hibernates during winter and active from late-March - July.	None. Occurrences have been documented within the Buyer Service Area and suitable habitat is present within the area of analysis. No impacts to suitable habitat for blunt-nosed leopard lizard are anticipated.
coast horned lizard *Phrynosoma blainvillii*	--	SSC	Occurs in the Sierra Nevada foothills from Butte County to Kern County and throughout the central and southern California coast. Its elevational range extends up to 1200m (4000ft) in the Sierra Nevada foothills and up to 1800m (6000ft) in the mountains of southern California.	The species frequents a wide variety of habitats and is most commonly found in lowlands along sandy washes with scattered low bushes. It inhabits open areas for sunning, bushes for cover, patches of loose soil for burial & abundant supply of ants and other insects.	Year round.	None. Occurrences have been documented within both the Buyer and Seller Service Areas. No potential impacts to suitable habitat are anticipated.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
giant garter snake *Thamnophis gigas*	T	T	Endemic to wetlands in the Sacramento and San Joaquin Valleys from Chico, south to the Mendota Wildlife Area in Fresno County.	Marshes, sloughs, ponds, small lakes, streams and other waterways. Typically occurs in areas that provide adequate water during the active season with emergent wetland vegetation. Basking habitat consists of grassy areas or openings adjacent to aquatic habitat, and upland areas are also used for refuge from flood conditions (USFWS 2006)	Year round	High. Suitable habitat is present within the Buyer and Seller Service Areas. Suitable habitat in the Seller Service Area is intermittent based on normal variation in cropping. Direct impacts may include reduction in suitable aquatic habitat within the Seller Service Area. The greatest impact would occur during the breeding season. Conservation measures are in place to maintain aquatic habitat corridors within irrigation ditches.
San Francisco garter snake *Thamnophis sirtalis tetrataenia*	E	E	Historically occurred from north of the San Francisco-San Mateo County line south to Ano Nuevo State Reserve, west of the Santa Cruz Mountains (USFWS 2006b).	The species is found in the vicinity of freshwater marshes, ponds and slow moving streams in San Mateo county and the extreme northern Santa Cruz county. The snake prefers dense cover and water depths of at least 1ft. Upland areas near water are also very important for this species.	Year round	None. Suitable habitat may be present in a small portion of the Buyer Service Area within San Mateo County. No impacts to suitable San Francisco garter snake habitat are anticipated in association with the proposed Transfers.
San Joaquin whipsnake *Masticophis flagellum ruddocki*	--	SSC	Known from as far north as Arbuckle, Colusa County through the San Joaquin Valley and Coast Ranges south into Kern and Santa Barbara Counties.	The species is found in open, dry habitats with little or no tree cover, generally at elevations 20 - 900m. It is also found in valley grassland and saltbush scrub in the San Joaquin valley. The snake requires mammal burrows for refuge and oviposition sites.	Year round.	None. Suitable habitat is present within the Buyer Service Area in the San Joaquin Valley. There is a very low potential that this species could occur in or adjacent to agriculture within the Buyer Service Area, but no conversion of suitable habitat would occur in association with the proposed Transfers.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Silvery legless lizard *Anniella pulchra pulchra*	--	SSC	The silvery legless lizard ranges from Antioch in Contra Costa County south through the Coast, Transverse, and Peninsular Ranges along the western edge of the Sierra Nevada Mountains. It occurs in the San Joaquin Valley and Mojave Desert down into Baja California. In the Sierra Nevada foothills it may occur at elevations up to 1,800m asl. (Contra Costa County 2006).	Sandy or loose loamy soil. May occur under sparse vegetation of beaches, chaparral, or pine-oak woodland, or near sycamores, cottonwoods, or oaks that grow on stream terraces. Often found under logs, rocks, old boards, or compacted debris of woodrat nests. Requires refugia with soil moisture during hot conditions. Agriculture and disturbed sites are not known to support the species (Contra Costa County 2006).	Year round	None. Suitable habitat is present within both the Buyer and Seller Service Areas, and previous records exist within the Buyer Service Area. Transfers are not expected to impact suitable habitat for the silvery legless lizard.
Pacific pond turtle *Actinemys marmorata*	--	SSC	Ranged from extreme western Washington and British Columbia to northern Baja California, mostly to the west of the Cascade-Sierra crest.	The western pond turtle occupies a wide variety of wetland habitats including rivers and streams (both permanent and intermittent), lakes, ponds, reservoirs, permanent and ephemeral shallow wetlands, abandoned gravel pits, stock ponds, and sewage treatment.	Year round	High. Suitable habitat occurs within the area of analysis. Pond turtles may occur in ditches, canals, rice fields, etc. Environmental Commitments would cause potential impacts to California red-legged frog to be negligible.
Birds[3]						
Alameda song sparrow *Melospiza melodia pusillula*	--	SSC	Endemic, restricted to fringes of south San Francisco Bay (east to El Cerrito, south to Alviso and west to San Francisco). Largest concentration near Dumbarton Point salt marsh, Alameda County.	The species is a resident of salt marshes. It inhabits salicornia marshes, nests low in grindelia bushes and in salicornia.	Year round, non-migratory. Breeds late-Feb to mid-August.	None. Occurrences have been documented within the Buyer Service Area. Suitable habitat may occur within the area of analysis. However, Transfers are not expected to impact any suitable habitat (i.e. salt marshes).

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
American peregrine falcon *Falco peregrinus anatum*	D	E, FP	Throughout California. Uncommon resident that breeds along coast north of Santa Barbara, in the Sierra Nevada, and other northern CA mountains. Migrant birds occur along the coast and the western Sierra Nevada.	Breeds in woodland, forest and coastal habitats on protected cliffs and ledges. Riparian areas and coastal and inland wetlands are important habitats yearlong especially during the non-breeding season.	Year round. Coastal migrants occur in Spring and Fall.	None. Rice fields may provide suitable foraging habitat for the species, but birds could relocate to other habitat areas in the vicinity. No nesting habitat would be affected by Transfers.
Bald eagle *Haliaeetus leucocephalus*	D	E	Throughout California. Breeding mostly in Butte, Lake, Lassen, Plumas, Shasta, Siskiyou, and Trinity counties. Winter migrant at inland waters.	Riparian areas near coasts, rivers, and lakes. Nesting generally occurs in large old-growth trees in areas with little disturbance. In flooded fields, occasionally hunts for small mammals.	Year round. Local winter movements.	None. Occurrences have been documented within both the Buyer and Seller Service Area and both areas provide suitable habitat. No impacts to suitable nesting habitat are anticipated. Rice fields represent marginal foraging habitat. Birds would be able to relocate to other suitable habitat areas in the vicinity if fields were fallowed. Environmental commitments limit the amount of land that can be fallowed in a given county.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Bank swallow *Riparia riparia*	--	T	A neotropical migrant found primarily in riparian and other lowland habitats in California west of the deserts during the spring-fall period. Breeding population in California occurs along banks of the Sacramento and Feather rivers in the northern Central Valley. Casual in southern California in winter. Other colonies along the central coast from Monterey to San Mateo counties.	Requires vertical banks and cliffs with fine-textured or sandy soils near streams, rivers, ponds, lakes, and the ocean for nesting. Feeds primarily over grassland, shrub land, savannah, and open riparian areas during breeding season and over grassland, brushland, wetlands, and cropland during migration.	March-mid-September	None. Known from both the Buyer and Seller Service Areas. No suitable nesting habitat (i.e. cliffs) would be affected. There is potential that Transfers would reduce the area of cropland habitat used for foraging during migration (wetlands and croplands) due to changes in water application. However, fallow cropland would still providing suitable foraging habitat, and birds could forage at other croplands in the vicinity. Environmental commitments limit the amount of cropland idling that would occur.
black swift *Cypseloides niger*	--	SSC	Breeds locally in Sierra Nevada and Cascade range, San Gabriel, San Bernardino and San Jacinto Mts. Also in coastal bluffs and mountains from San Mateo County to San Luis Obispo County.	The bird breeds in small colonies on cliffs behind or adjacent to waterfalls in deep canyons and sea-bluffs above the surf. Found in moist crevice or cave on sea cliffs above the surf. Forage widely over many habitats. Avoids arid regions such as Great Basin, southern deserts and Central Valley.	Absent from October - April.	None. Occurrences have been documented within the Buyer Service Area. Suitable habitat may occur within the area of analysis. Habitat within the Buyers Service Area would not be affected, as water in excess of their CVP contract amount could not be procured, nor could this water be used to grow permanent crops. Therefore any change in habitat would fall within the normal range expected under their existing contracts.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Black tern *Chlidonias niger*	--	SSC	Common spring and summer visitor to fresh emergent wetlands of California.	Uses fresh emergent wetlands, lakes, ponds, moist grasslands, and agricultural fields. In migration, some take coastal routes and forage offshore.	April-September	High. No occurrences have been documented within either the Buyer or Seller Service Areas. However, suitable habitat (i.e. rice fields) is present, and the area of analysis is within the known range for the species. Therefore it has moderate potential to occur Water transfers could reduce suitable habitat for the species within the Seller Service Area. Conservation strategies are in place that would make potential impacts to this species to negligible.
Black-crowned night heron *Nycticorax nycticorax* (rookeries)	--	--	Year round resident and common in lowlands and foothills throughout most of California, including the Salton Sea and Colorado River areas, and very common locally in large nesting colonies. Uncommon in northwestern and rare in northeastern CA in midwinter. Uncommon in winter in southern deserts.	Feeds along the margins of lacustrine, large riverine, and fresh and saline emergent habitats. Nests and roosts in dense-foliaged trees and dense emergent wetlands.	Year round. Common nesting species from April -August.	None. No occurrences of black-crowned night heron have been documented within either the Buyer or Seller Service Areas. Suitable habitat is present in the area of analysis; however, no nesting or roosting habitats would be affected.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
cackling (=Aleutian Canada) goose *Branta hutchinsii leucopareia*	D	--	The species is found in during the winter in Del Norte County, San Francisco Bay-Delta, and South Central Valley.	Forages on natural pasture or pastures that are cultivated to grain. The species occurs on lakes, reservoirs and ponds. Preferred habitats include lacustrine, fresh emergent wetlands, moist grasslands, croplands, pastures, and meadows.	Year-round in northeastern California, except when water freezes. Wintering population in California migrates north and east to northeastern California. Winters on lakes and inland prairies.	None. Occurrences have been documented within both the Buyer and Seller Service Areas. The species distribution does not overlap with the major area where fallowing would occur. Transfers are not expected to impact breeding habitat (i.e. prefers islands in lakes).
California clapper rail *Rallus longirostris obsoletus*	E	E	Common locally around San Francisco, Monterey, and Morro bay.	Found in salt-water and brackish marshes traversed by tidal sloughs. The bird is associated with abundant growths of pickle weed, but feeds on mud-bottomed sloughs.	Year round. Non-migratory in coastal wetlands. Juveniles may disperse to freshwater wetlands late summer and autumn.	None. Occurrences have been documented within the Buyer Service Area. Suitable habitat may occur within the area of analysis. However, Transfers are not expected to impact any suitable habitat (i.e. salt-water marshes).
California horned lark *Eremophila alpestris actia*	--	WL	Found on coastal regions, chiefly from Sonoma to San Diego county, but also found in the main parts of San Joaquin Valley and east to the foothills.	Prefers short-grass prairie, mountain meadows, open coastal plains, alkali flats, "bald" hills, and fallow grain fields.	Year round in California. Some movement along the coast. May leave mountains in winter.	None. Occurrences have been documented within the Buyer Service Area. Suitable habitat occurs within the area of analysis. No impacts to breeding or foraging habitat are anticipated within the Buyer Service Area.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
California least tern *Sternula antillarum browni*	E	E	Nests along the coast from San Francisco Bay south to northern Baja California. Migratory in California. Breeding colonies in Southern California near marine and estuarine shores. In SF Bay found near salt ponds and estuarine shores.	Breeds on bare or sparsely vegetated, flat substrates, sand beaches, alkali flats, landfills or paved areas. Feeds in shallow, estuarine waters.	Late April in southern California to mid-May in northern California. Winters south of California. Absent from mid-October to late April.	None. Occurrences have been documented in the Buyer Service Area. Suitable habitat may occur within the area of analysis. No impacts are expected to suitable foraging or breeding habitat (i.e. sand beaches, alkali flats).
California yellow warbler *Dendroica petechia brewsteri*	--	SSC	Throughout California. From coastal Del Norte County., east to Modoc, south along coast range to Santa Barbara and Ventura County. Also found along western slope of Sierra Nevada to Kern County.	Frequents open to medium-density woodlands and forests with a heavy brush understory in breeding season. In migration, found in a variety of sparse to dense woodland and forest habitats. Breeds in montane chaparral, ponderosa pine and mixed conifer habitats.	April-October.	None. No occurrences have been documented in the area of analysis. The species is not likely to occur in rice fields, and no suitable habitat would be impacted (i.e. dense woodland and forest habitats).
Cooper's hawk *Accipiter cooperii*	--	WL	Throughout California. Breeds in southern Sierra Nevada foothills, New York Mountains, Owens Valley and local areas in southern California.	Frequents landscapes where wooded areas occur in patches and groves- live oak, riparian deciduous, other forest habitat near water. Often uses patchy woodlands and edges with snags for perching. Dense stands with moderate crown-depths used for nesting.	Year round. Breeding resident throughout wooded portion of California.	None. Occurrences have been documented within both the Buyer and Seller Service Area. Suitable habitat occurs within the area of analysis. No potential impacts to preferred foraging or nesting habitat are anticipated.
Double-crested cormorant *Phalacrocorax pelagicus*	--	WL	Along the entire coast of California and on inland lakes, in fresh, salt and estuarine waters. Uncommon from San Luis Obispo County south and very rare to the north. Common on Colorado River reservoirs and common in the Central Valley.	Open water with offshore rocks, islands, steep cliffs, dead branches of trees, wharfs, jetties, or even transmission lines. Requires undisturbed nest-sites beside water, on islands or mainland. Uses wide rock ledges on cliffs; rugged slopes; and live or dead trees, especially tall ones. Found on inland lakes, fresh, and estuarine waters.	Year round along coastal regions. Winters inland.	None. No occurrences have been documented within the area of analysis, but the species could occur at reservoirs and inland ponds. No negative impacts to foraging or breeding habitat are expected.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
ferruginous hawk *Buteo regalis*	--	WL	Winter resident and migrant at lower elevations and open grasslands in Modoc Plateau, Central Valley, and Coast ranges. Common winter resident of grassland and agriculture areas in southwestern California. Casual in northeast in summer.	Found in open grasslands, sagebrush flats, desert scrub, low foothills and fringes of pinyon-juniper habitats.	Migratory. Present in CA from Sept. to mid-April.	None. Occurrences have been documented within both the Buyer and Seller Service Areas. Suitable habitat occurs within the area of analysis. No potential impacts to preferred habitat are anticipated.
Golden eagle *Aquila chrysaetos*	T	E	Throughout California. Uncommon permanent resident and migrant throughout California, except of Central Valley. More common in southern California.	Riparian areas near coasts, rivers, and lakes. Nesting generally occurs in large old-growth trees in areas with little disturbance. Also in foothills, mountain areas, sage-juniper flats and desert.	Year round. Mostly resident moves down slope for winter and upslope after breeding season.	None. Occurrences have been documented within both the Buyer and Seller Service Areas. Suitable habitat occurs within the area of analysis. No impacts to nesting habitat are expected.
grasshopper sparrow *Ammodramus savannarum*	--	SSC	Uncommon and local, summer resident and breeder in foothills and lowlands west of Cascade-Sierra Nevada crest from Mendocino and Trinity counties south to San Diego County Also found in Shasta Valley, Siskiyou County, coastal southern California.	Found in dense grasslands on rolling hills, lowland plains, in valleys and on hillsides on lower mountain slopes. Favors native grasslands with a mix of grasses, forbs and scattered shrubs.	Winters chiefly in southern California, in coastal areas. Summer resident March to May, migrates south in August and September. Fall migrants occur on the Farallon Islands in late September to early October.	None. Occurrences have been documented in the Seller Service Area. Suitable habitat may occur with the area of analysis. The species' habitat (i.e. dense grassland, lowland plain areas) would not be affect by Transfers.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Great blue heron *Ardea herodias* (rookeries)	--	--	Throughout California. Most rookeries are in southern California some scattered in northern California.	Found in shallow estuaries, fresh and saline emergent wetlands, along riverine and rocky marine shores, in croplands, pastures, salt ponds, and in mountains above foothills. Nests and roosts in large trees.	Year round. Near salt ponds from July to October. Near rookeries February to June or July.	None. Rookeries have been documented within the Buyer and Seller Service Areas. No impacts to rookeries are anticipated. Idling of cropland foraging habitat would be limited by the environmental commitments, and birds could use alternative suitable foraging areas in the vicinity.
Great egret *Ardea alba* (rookeries)	--	--	Throughout California, except for high mountains and deserts.	Feeds and rests in fresh, and saline emergent wetlands, along the margins of estuaries, lakes, and slow-moving streams, on mudflats and salt ponds, and in irrigated croplands and pastures. Nests roosts in large trees.	Year round	None. Occurrences have been documented in the Seller Service Area. No impacts to rookeries are anticipated. Idling of cropland foraging habitat would be limited by the environmental commitments, and birds could use alternative suitable foraging areas in the vicinity.
Greater sandhill crane *Grus canadensis tabida*	--	T, FP	Breeds only in Siskiyou, Modoc and Lassen counties and in Sierra Valley, Plumas and Sierra counties. Winters primarily in the Sacramento and San Joaquin valleys from Tehama south to Kings Counties.	In summer, this race occurs in and near wet meadow, shallow lacustrine, and fresh emergent wetland habitats. Frequents annual and perennial grassland habitats, moist croplands with rice or corn stubble, and open, emergent wetlands. It prefers relatively treeless plains.	Migration southward is September-October and northward is March-April.	High. No occurrences have been documented within the area of analysis, but occurrences have been recorded in Butte and Sutter Counties. Suitable foraging and winter roosting habitat is present within the area of analysis (i.e. rice fields). Conservation strategies are in place for this species and birds would have other suitable nesting sites available.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Least bell's vireo *Vireo bellii pusillus*	E	E	California to northern Baja. Rare, local, summer resident below about 600m (2000ft), mostly in San Benito and Monterey counties. Present in coastal southern CA from Santa Barbara County south.	Inhabits low, dense riparian growth along water or along dry parts of intermittent streams. Typically associated with willow, cottonwood, baccharis, wild blackberry, or mesquite in desert localities.	end of March to end of August	None. Occurrences have been documented in the Buyer Service Area. Suitable habitat may occur within the area of analysis. Transfers are not expected to impact any suitable willow or dense riparian habitat, therefore no impacts to the species are anticipated.
LeConte's thrasher *Toxostoma lecontei*	--	SSC	Uncommon to rare local resident of southern California deserts from southern Mono County south to Mexican border, western and southern San Joaquin Valley. Also in Joshua tree. Formerly north to Fresno County, rare north of Kern County.	A desert resident primarily of open desert wash, desert scrub, alkali desert scrub, and desert succulent scrub habitats. Nests in dense, spiny shrub or densely branched cactus in desert wash habitat.	Year round. Non migratory.	None. CNDDB occurrences have been documented in the Buyer Service Area. Suitable habitat is present in area of analysis. No impacts are anticipated to occur to suitable habitat (i.e. desert scrub).
Little willow flycatcher *Empidonax traillii brewsteri*	--	E	Migrant at lower elevations, primarily in riparian habitats throughout Sierra Nevada and Cascade Range. Not found in north coast.	Most numerous where extensive thickets of low, dense willows edge on wet meadows, ponds, or backwaters. Dense willow thicket required for nesting and roosting. Feeds in willow thickets or low perches adjacent to meadows.	Spring (mid-May to early June) and fall (mid-August to early September)	None. This species has not been documented within the area of analysis according to CNDDB. Suitable habitat may be present within the area of analysis (i.e. dense willows), but would not be impacted by Transfers.
Loggerhead shrike *Lanius ludovicianus*	--	SSC	Common resident and winter visitor in lowland and foothills throughout California,. Rare on coastal slopes north of Mendocino County, occurring only in winter.	Found in broken woodlands, savannah, pinyon-juniper, Joshua tree, riparian woodlands, desert oases, scrub and washes. Prefers open country with perches for hunting, and fairly dense shrubs and brush for nesting. Rarely found in urbanized areas, but often found in open cropland.	Year round. In Great Basin, south to Inyo County, pop declines Nov.-March. Winter pop. More widespread in winter than during breeding season.	None. CNDDB occurrences have been documented in the Buyer Service Area. Suitable habitat may be present within the area of analysis. No impacts are anticipated to breeding or foraging habitats.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Long-billed curlew *Numenius americanus*	--	WL	Along the California coast, and in the Central and Imperial valleys.	Upland short grass prairies and wet meadows are used for nesting; coastal estuaries, open grasslands, and croplands are used in winter.	Winter migrant from July-April	Low. No CNDDB occurrences have been documented within the area of analysis, but the species is known to occur within the action area during winter migration. There is potential for impacts to suitable foraging habitat (i.e. cropland), although this may be reduced by environmental commitments, which protect winter foraging habitat in Butte Sink, and other wildlife management areas downstream. Birds can relocate to other suitable habitats within the area.
Long-eared owl *Asio otus*	--	SSC	Throughout California, except for entire floor of the Central Valley and locally on the southern coast.	Frequents dense, riparian and live oak thickets near meadow edges, and nearby woodland and forest habitats. Also found in dense conifer stands at higher elevations.	Year round	None. Occurrences have been documented in the Buyer Service Area. Suitable habitat occurs within the area of analysis. Transfers are not expected to impact any suitable habitat (i.e. forest and woodland habitats).
Merlin *Falco columbarius*	--	WL	Occurs in most of the western half of California below 3,900 ft. Rare in Mojave Desert and Channel Islands.	Frequents coastlines, open grasslands, savannahs, woodlands, lakes, wetlands, edges, and early successional stages. Ranges from annual grasslands to ponderosa pine and montane hardwood-conifer habitats.	Winter migrant from September-May	None. CNDDB occurrences have been documented in the Buyer Service Area. Suitable habitat is present in area of analysis. Foraging habitat may be altered, but Transfers would not decrease suitability. No negative impacts are anticipated.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Mountain plover *Charadrius montanus*	--	SSC	Found in Central Valley from Sutter and Yuba counties southward, foothill valleys west of San Joaquin Valley, Imperial Valley, plowed fields of Los Angeles and western San Bernardino County, and central Colorado river valley. Does not breed in California.	Found in short grasslands, freshly plowed fields, newly sprouting grain fields, and sod farms. Prefers grazed areas and areas with burrowing rodents.	Winter resident Sept. - March.	None. Occurrences have been documented within both the Buyer and Seller Service Area. Suitable habitat occurs within the area of analysis. Foraging habitat may be affected, but Transfers would not reduce suitability. Can relocate to other habitats within the area.
Northern harrier *Circus cyaneus*	--	SSC	Throughout lowland California, concentrated in the Central Valley and coastal valleys.	Breeds in annual grasslands and wetlands. Prefers marshes and grasslands for foraging and nesting. Also uses agricultural fields for nesting and foraging, although nests may be destroyed by agricultural activities.	Year round, nomadic	None. CNDDB occurrences have been documented in the Buyer Service Area. Suitable habitat is present in area of analysis. Foraging and breeding habitat may be affected, but fallow fields would still represent suitable habitat. Birds can relocate to other habitats within the area.
Osprey *Pandion haliaetus*	--	WL	Northern California from Cascade Ranges south to Lake Tahoe, and along the coast south to Marin County.	Associated strictly with large, fish-bearing waters, primarily in ponderosa pine through mixed conifer habitats.	Year round	None. Occurrences have been documented within both the Buyer and Seller Service Area. Suitable habitat occurs within the area of analysis. Water transfers would be subject to flow requirements. Therefore no impacts to foraging area expected. No impacts to nesting sites are anticipated.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
prairie falcon *Falco mexicanus*	--	WL	Found from southeastern deserts northwest throughout Central Valley and inner Coast Ranges and Sierra Nevada. Mostly absent from northern coastal fog belt. Not found in upper elevation of Sierra Nevada.	Inhabits dry, open level or hilly terrain. Breeds on cliffs, forages far afield. Annual grassland to alpine meadows, but primarily perennial grasslands, rangeland, agricultural fields and desert scrub.	Permanent resident. Northern migrants winter in California. Upslope in summer, down slope in winter.	None. CNDDB occurrences have been documented in the Buyer Service Area. Suitable habitat is present within the area of analysis. Foraging habitat (i.e. agricultural fields) may be altered, but Transfers would not reduce suitability.
purple martin *Progne subis*	--	SSC	In south, found on the coast and interior mountain ranges. Absent from higher desert regions. In north, found on coast and inland to Modoc and Lassen counties. Absent from higher slopes of Sierra Nevada. Current breeding populations are known from western Santa Clara and Alameda counties, and western Placer County.	Inhabits woodlands, low elevation coniferous forest of Douglas-fir, ponderosa pine and Monterey pine. Uses open habitats during migration, including grassland, wet meadows, and fresh emergent wetlands.	Summer resident throughout California.	Low. CNDDB occurrences have been documented in the Seller Service Area. This species is restricted to fairly limited nesting sites with suitable cavities free of brood parasites. When wetlands are unavailable, rice fields may represent relatively high quality foraging habitat. This habitat may be slightly reduced by Transfers, but the species can relocate to other suitable habitat in the vicinity. Crop idling limitations are in place in the environmental commitments.
saltmarsh common yellowthroat *Geothlypis trichas sinuosa*	--	SSC	Resident and summer visitor in San Francisco Bay area. Winter south along coast to San Diego county. Found in No. CA in summer months.	Found in fresh and salt water marshes. Requires thick, continuous cover to water surface for foraging and tall grasses, tulle and willows for nesting.	Year-round in southern California and San Francisco Bay, Summer resident in northern California.	None. Occurrences have been documented in the Buyer Service area and suitable habitat may be present in the area of analysis. Not known from rice fields. Water transfers would not affect suitable breeding or foraging habitat.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
San Pablo song sparrow *Melospiza melodia samuelis*	--	SSC	Confined to emergent wetland along north side of San Francisco and San Pablo bay. Highest density at Petaluma River mouth.	A resident of salt marshes. The species inhabits tidal sloughs in salicornia marshes and nests in grindelia bordering slough channels.	Year round	None. Occurrences have been documented in the Buyer Service area and suitable habitat may be present in the area of analysis. However, no impacts are expected to salt water marshes.
Short-eared owl *Asio flammeus*	--	SSC	Endemic to marshes bordering the San Francisco, San Pablo Bays and Suisun Bay. Winter migrant in Central Valley, western Sierra Nevada foothills and coastline. Uncommon winter migrant in southern California. Breeding range includes: Del Norte, Humboldt, SF Bay Delta, northeastern Modoc plateau, south Lake Tahoe to Inyo County and San Joaquin valley.	Usually found in open areas with few trees, including grasslands, wet meadows, irrigated lands, saline and fresh emergent wetlands, and cleared forests. Occasionally in estuaries during breeding season. Ground nester in tall grasses, brush, ditches, and wetlands.	Year round. Migrants in CA from Sept. - April.	None. Occurrences have been documented in the Buyer Service Area. Suitable habitat occurs within the area of analysis. No impacts to breeding habitat would occur. Fallow rice fields would still represent suitable foraging habitat for the species.
Snowy egret *Egretta thula* (rookeries)	--	--	Throughout California.	Found along shores of coastal estuaries, fresh and saline emergent wetlands, ponds, slow-moving rivers, irrigation ditches, and wet fields.	Year round	None. Occurrences have been documented in the Buyer Service Area, however suitable habitat is present in both the Buyer and Seller Service area. No impacts to rookeries are anticipated. Idling of cropland foraging habitat would be limited by the environmental commitments, and birds could use alternative suitable foraging areas in the vicinity.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Suisun song sparrow *Melospiza melodia maxillaris*	--	SSC	Endemic, restrict to Suisun Marsh from Carquinez Strait east to the confluence of the Sacramento and San Joaquin rivers near Antioch. Highest numbers near Benicia State Park and Martinez shoreline.	Resident of brackish-water marshes. Inhabits cattails, tulles, sedges, and salicornia.	Year round. Non-migratory. Breeds early March to July.	None. Occurrences have been documented in the Buyer Service area and suitable habitat may be present in the area of analysis. However, no impacts are expected to brackish-water marshes.
Swainson's hawk *Buteo swainsoni*	--	T	Lower Sacramento and San Joaquin Valleys, the Klamath Basin, Northeastern plateau, Lassen County, and Mojave desert.	Nests in mature trees, including valley oaks or cottonwoods in or near riparian habitats; forages in grasslands, irrigated pastures, and grain and row crop fields.	Spring and summer resident; small wintering population in the Delta. Moves south to southern and interior CA Sept.-Oct. Moves north March-May.	None. CNDDB occurrences have been documented within both the Seller and Buyer Service Area. Suitable habitat is present within the area of analysis. Transfers may alter the composition of foraging habitat in the Buyer and Seller Service Areas, but these areas would still be suitable for the species, and additional habitats in the vicinity would be available. No impacts to breeding habitat are expected.
Tricolored blackbird *Agelaius tricolor*	--	SSC	A resident in California found throughout the Central Valley and in coastal districts from Sonoma County south. Found locally in northeastern California,. In winter, more widespread along central coast and San Francisco Bay area.	Breeds near fresh water, preferably in emergent wetlands with tall, dense cattails or tulles, but also in thickets of willow, blackberry, wild rose, tall herbs. Feeds in grassland and cropland habitats.	Year round. Leaves northeastern CA in fall and winter.	Low. CNDDB occurrences have been documented within both the Seller and Buyer Service Area. Suitable habitat is present within the area of analysis. Foraging habitat may be affected by Transfers. Environmental commitments limit cropland idling and birds can relocate to other adjacent foraging habitats within the area.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Western burrowing owl *Athene cunicularia hypugaea*	--	SSC	Central and southern coastal habitats, Central Valley, Great Basin, and deserts. Formerly common in appropriate habitat throughout the state, excluding humid northwest coastal forests and high mountains. Present on larger offshore islands.	Open annual grasslands or perennial grasslands, deserts, and scrublands characterized by low-growing vegetation. Dependent upon burrowing mammals (especially California ground squirrel) for burrows.	Year round	None. Occurrences have been documented within both the Buyer and Seller Service Area. Suitable habitat occurs within the area of analysis. Agricultural ditches may be suitable habitat for burrowing owl burrow and nesting activity. Water transfers would not affect the suitability of habitat for burrowing owl in the area of analysis.
Western snowy plover *Charadrius alexandrinus*	T	SSC	Along the west coast states, with inland nesting taking place at the Salton Sea, Mono Lake, and at isolated sites on the shores of alkali lakes in northeastern California, in the Central Valley, and southeastern deserts.	Nests, feeds, and takes cover on sandy or gravelly beaches along the coast, on estuarine salt ponds, alkali lakes, and at the Salton Sea.	Migration is from July-March (some year round populations).	None. Occurrences have been documented in the Buyer Service Area. There is a CNDDB occurrence in Yolo County, however this species is not likely to occur in rice fields. Suitable habitat may occur within the area of analysis. However Transfers are not expected to impact any suitable breeding or foraging habitat (i.e. sandy beaches or estuarine salt ponds).
Western yellow-billed cuckoo *Coccyzus americanus*	C,	E	Uncommon to rare summer resident in scattered locations throughout California. Breeding population along Colorado river, Sacramento and Owen Valley, along South Fork of Kern River, Santa Ana River and Amargosa River. May be present along San Luis Rey River.	Deciduous riparian thickets or forests with dense, low-level or understory foliage, and which abut on slow-moving watercourses, backwaters, or seeps. Willow almost always a dominant component of the vegetation. In Sacramento Valley, also utilizes adjacent orchards, especially of walnut. Nests in sites with some willows, dense low-level or understory foliage, high humidity, and wooded foraging spaces.	Summer migration is from June-September.	None. Occurrences have been documented in the Seller Service Area. Suitable habitat is present within the area of analysis. However this species is not likely to occur in rice fields due to lack of suitable foraging and roosting habitat (i.e. dense riparian thickets). No impacts are anticipated.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
White-faced ibis *Plegadis chihi*	--	WL	Uncommon summer resident in sections of southern California, a rare visitor in the Central Valley, and is more widespread in migration. Uncommon to common in small pockets.	Feeds in fresh emergent wetlands, shallow lacustrine waters, muddy grounds of wet meadows, and irrigated or flooded pastures and croplands. Nests in dense, fresh emergent wetlands.	Present from April-October.	Low. Occurrences have been documented in the Seller Service Area. Suitable habitat is present in area of analysis. Low potential impact to foraging habitat in the Seller Service Area. No potential impacts are expected to roosting habitat. Can relocate to other habitats within the area. Environmental commitments would limit acreage of allowable cropland idling.
White-tailed kite *Elanus leucurus*	--	FP	Central Valley, coastal valleys, San Francisco Bay area, and low foothills of Sierra Nevada.	Savanna, open woodlands, marshes, partially cleared lands and cultivated fields, mostly in lowland situations. Rarely found away from agricultural areas. Feeds in open grasslands, meadows, farmlands and emergent wetlands. Nests located near open foraging area and placed on top of dense oak, willow or tree stands.	Year round	None. CNDDB occurrences have been documented within both the Seller and Buyer Service Area. Suitable habitat is present within the area of analysis. Foraging habitat may be altered, but would still be suitable for the species. No potential impacts to breeding habitat are anticipated.
yellow warbler *Dendroica petechia brewsteri*	--	SSC	Breeding range from coastal Del Norte County, east to Modoc plateau & Inyo County, south to coastal Santa Barbara and Ventura County., west to Kern County. Winters in Imperial and Colorado river valleys. Found up to 2500m (8000ft) in Sierra Nevada.	Associates with riparian habitats and prefers willows, cottonwood, aspens, sycamores, and alders. Nests in montane shrubbery in open conifer forests.	Summer resident throughout California.	None. Occurrences have been documented in the Buyer Service Area and suitable habitat is present with the area of analysis. No potential impacts are anticipated to riparian habitats.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
yellow-headed blackbird *Xanthocephalus xanthocephalus*	--	SSC	Breeds east of Cascade range and Sierra Nevada, Imperial and Colorado River valley, in Central Valley and select locations in coast range west of Central Valley. Common in winter in Imperial Valley. Found as high as 2000m (6600ft) in San Bernardino Mountains.	Associated with freshwater emergent wetlands along lakes and ponds. Nesting timed with maximum emergence of aquatic insects. Feeds on cultivated grains, in emergent vegetation, and in nearby grasslands and croplands.	Year round, in parts of Central Valley. Summer range in eastern California, and parts of Central Valley. Present April through early May, and in September.	Low. Occurrences have been documented in the Buyer Service Area and suitable habitat is present within both the Buyer and Seller Service Area. Impacts to foraging habitat are expected in the Seller Service Area, but the birds can relocate to other habitat in the area. Environmental commitments would limit the amount of cropland idling in the area of analysis.
Mammals						
Alameda Island mole *Scapanus latimanus parvus*	--	WL	Only known from Alameda Island, Alameda County.	Found in a variety of habitats, especially annual and perennial grasslands. Prefers moist, friable soils and avoids flooded soils.	Year round	None. Occurrences have been documented in the Buyer Service Area. Transfers would not impact suitable habitat.
American badger *Taxidea taxus*	--	SSC	Throughout California.	Found in dry, open stages of most shrub, forest, and herbaceous habitats with friable soils.	Year round. Permanent resident except in North Coast area.	None. Occurrences have been documented in both the Buyer and Seller Service area and suitable habitat is present within the area of analysis. Suitable habitats are not expected to be impacted.
big free-tailed bat *Nyctinomops macrotis*	--	SSC	Rare in California. Vagrants found in San Diego County. and Alameda County (record is suspect).	Found in low-laying arid areas in Southern California and requires high cliffs or rocky outcrops for roosting sites.	Year round resident in San Diego County and Alameda County.	None. Occurrences have been documented in the Buyer Service Area and suitable habitat may be present in the area of analysis. Transfers would not impact suitable arid, rocky terrain habitat.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
California wolverine *Gulo gulo*	PT	T, FP	A scarce resident of North Coast mountains and Sierra Nevada. Sightings range from Del Norte and Trinity counties. east through Siskiyou and Shasta counties., and south through Tulare County. A few possible sightings occur in the north coastal region as far south as Lake County. Habitat distribution in California is poorly known for the North Coast and northern Sierra Nevada.	In north coastal areas, has been observed in Douglas-fir and mixed conifer habitats. In the northern Sierra Nevada, have been found in mixed conifer, red fir, and lodge pole habitats, and probably use subalpine conifer, alpine dwarf-shrub, wet meadow, and montane riparian habitats. In the southern Sierra Nevada occur in red fir, mixed conifer, lodge pole, subalpine conifer, alpine dwarf-shrub, barren, and probably wet meadows, montane chaparral, and Jeffrey pine.	Year round (largely nocturnal)	None. Suitable habitat may occur within the area of analysis, however no CNDDB occurrences have been documented in the Buyer or Seller Service area. The species is not likely to occur in agriculture fields. No impacts are anticipated.
Fresno kangaroo rat *Dipodomys nitratoides exilis*	E	E	Western Fresno County. on the Alkali Sink Ecological Reserve and adjacent privately owned land.	Found in alkali sink-open grassland habitats. Prefers bare alkaline clay-based soils subject to seasonal inundation with more friable soil mounds around shrubs and grasses.	Year round. Breeds largely from March - June.	None. Occurrences have been documented in the Buyer Service Area. Suitable habitat present in the area of analysis. Transfers would not impact suitable habitat for this species (i.e. alkali sink grasslands).
giant kangaroo rat *Dipodomys ingens*	E	E	Found along western side of San Joaquin Valley (e.g. Carrizo Plain, Panoche Valley)	Found in annual grasslands and on and marginal habitat in alkali scrub. The species requires level terrain and sandy loam soils for burrowing.	Year round	None. Occurrences have been documented in the Buyer Service Area. Suitable habitat may be present in the area of analysis. However, no impacts are expected to suitable habitat (i.e. alkali desert scrub and annual grasslands).

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Greater western mastiff bat *Eumops perotis californicus*	--	SSC	Uncommon resident in southeastern San Joaquin Valley and Coastal Ranges from Monterey County southward through southern California, from the coast eastward to the Colorado Desert.	Occurs in many open, semi-arid to arid habitats, including conifer and deciduous woodlands, coastal scrub, annual and perennial grasslands, palm oases, chaparral, desert scrub, and urban areas. Crevices in cliff faces, high buildings, trees, and tunnels are required for roosting.	Year round (nocturnal activity)	None. Occurrences have been documented in the Seller Service Area. Suitable habitat is present in the area of analysis, bur no impacts are anticipated.
Nelson's antelope squirrel *Ammospermophilus nelsoni*	--	T	Found in the western San Joaquin valley from 200-1,200 ft. elevation. Found from southern Merced County to Kern, Kings and Tulare counties. In eastern portions of San Luis Obispo and Santa Barbara counties.	Found on dry sparsely vegetated loam soils. Requires widely scattered shrubs, forbs and grasses in broken terrain with gullies and washes.	Year round.	None. Occurrences have been documented with the Buyer Service Area. Suitable habitat may occur within the area of analysis. No impacts are anticipated to suitable upland habitats.
Pacific fisher *Martes pennati (pacifica) DPS*	C	SSC	Northern California coastal ranges up to Oregon, and the Sierra Nevada's.	Found in mature, dense, coniferous or mixed coniferous hardwood forest with closed canopies.	Year round	None. Occurrences have been documented with the Seller Service Area. Suitable habitat may occur within the area of analysis. No potential impacts are anticipated to suitable habitat (i.e. mixed conifer habitats).
pallid bat *Antrozous pallidus*	--	SC	Throughout California,, except for high Sierra Nevada from Shasta to Kern counties, northwestern corner of state from Del Norte & western Siskiyou cos. To northern Mendocino County.	Found in deserts, grasslands, scrublands, woodlands and forests. Most common in open, dry habitats with rocky areas for roosting.	Year round.	None. Occurrences have been documented with the Buyer Service Area. Suitable habitat may occur within the area of analysis. No impacts would occur to suitable habitat.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Ring-tailed cat *Brassariscus astutus*	--	FP	Ringtails are found in a variety of habitats centered around the semi-arid to arid climates of the west and southwest. Little information available on distribution and relative abundance among habitats.	Occurs in various riparian habitats, and in brush stands of most forest and shrub habitats, at low to middle elevations. Uses hollow trees, logs, snags, cavities in talus and other rocky areas, and other recesses are for cover.	Year round (nocturnal)	None. No CNDDB records of this species have been documented in the area of analysis. Suitable habitat is present in the area of analysis, but the species is not likely to occur in rice fields. No potential impact to suitable habitat are expected.
Riparian brush rabbit *Sylvilagus bachmani riparius*	E	E	Isolated populations on Caswell Memorial State Park on the Stanislaus River and along an overflow channel of the San Joaquin River.	Riparian thickets	Year round	None. No CNDDB records of this species have been documented in the area of analysis. Suitable habitat is present in the area of analysis, however, no potential impacts are expected to suitable habitat (i.e. riparian thickets).
Riparian (San Joaquin Valley) woodrat *Neotoma fuscipes riparia*	E	SSC	Found along the lower portions of the San Joaquin and Stanislaus rivers in the northern San Joaquin Valley. Historical records for the riparian woodrat are distributed along the San Joaquin, Stanislaus, and Tuolumne rivers, and Corral Hollow, in San Joaquin, Stanislaus, and Merced Counties.	Most numerous where shrub cover is dense and least abundant in open areas. Dens are usually built in willow thickets with oak over story.	Year round (nocturnal activity)	None. Suitable habitat present (i.e. dense shrubs) in both the Buyer and Seller Service Areas, however no CNDDB occurrences have been documented. No potential impacts are expected.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
salt-marsh harvest mouse *Reithrodontomys raviventris*	E	E	Found in San Francisco Bay and its tributaries.	Found in saline emergent wetlands. Pickle weed is the primary habitat for the species. Requires higher grassland areas for flood escape.	Year round.	None. CNDDB occurrences have been documented in the Buyer Service Area and suitable habitat may be present in the area of analysis. Transfers would not impact saline wetlands and salt marshes.
salt-marsh wandering shrew *Sorex vagrans halicoetes*	--	SSC	Southern arm of the San Francisco Bay in San Mateo, Santa Clara, Alameda and Contra Costa counties (Bolster 1998).	Found in the salt marshes. Inhabits medium high marsh where abundant driftwood is scattered among salicornia.	Year round. Breeds February - June	None. CNDDB occurrences have been documented in the Buyer Service Area and suitable habitat may be present in the area of analysis. Transfers would not impact salt marshes.
San Francisco dusky-footed woodrat *Neotoma fuscipes annectens*	--	SSC	Oregon, California and northwestern Baja California. Within California it is known from Alameda, Contra Costa, San Mateo, and Santa Clara, and Santa Cruz Counties.	Found in forest habitats of moderate canopy and moderate to dense understory. The species may prefer chaparral and redwood habitats. Nest sites include tree cavities, logs, and talus slopes (Carraway and Verts 1991; NatureServe 2011).	December - September	None. Occurrences have been documented within the Buyer Service area and suitable habitat may be present in the area of analysis. Transfers would not impact forest, chaparral and redwood habitat.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
San Joaquin kit fox *Vulpes macrotis mutica*	E	T	Found only in the Central Valley area of California. Kit foxes currently inhabit suitable habitat in the San Joaquin valley and in surrounding foothills of the Coast Ranges, Sierra Nevada, and Tehachapi Mountains; from southern Kern County north to Contra Costa, Alameda, and San Joaquin counties on the west; and near La Grange, Stanislaus County on the east.	Found in annual grasslands or grassy open stages of vegetation dominated by scattered brush, shrubs, and scrub. Build dens for cover. Some agricultural areas may support these foxes.	Year round (mostly nocturnal, but often active during daytime in cool weather)	None. Occurrences have been documented within both the Buyer and Seller Service Area. Suitable habitat is present within the area of analysis. San Joaquin kit fox have the potential to occur in inland and southern portions of the area of analysis. Changes in crop type could alter foraging habitat conditions in the Buyer Service Area, however buyers would not be allowed to buy more water than they were entitled to under their CVP contract. Transfer water would not be used to plant permanent crops, so cropping patterns would be within normal range considered under the CVP contracts and would be covered by the pertinent B.O. Conservation strategies are in place for this species.
San Pablo vole *Microtus californicus sanpabloensis*	--	SSC	Found in salt marshes of San Pablo creek on the south shore of San Pablo Bay.	Annual grassland, saline emergent wetlands, salt marsh.	Year round.	None. CNDDB occurrences have been documented in the Buyer Service Area and suitable habitat may be present in the area of analysis. Transfers would not impact the wetlands and salt marshes of San Pablo Bay.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
short-nosed kangaroo rat *Dipodomys nitratoides brevinasus*	--	WL	Found in the western side of San Joaquin valley, near the mouth of Panoche Creek in western Fresno County, south to near the mouth of San Emigdio Creek, in southwestern Kern County, and to northeast of Bakersfield. Also occurs in eastern San Benito Valley and Cuyama Valley, and Santa Barbara County (Bolster 1998).	Found in grassland and desert shrub, especially a triplex. Inhabits highly alkaline soils around soda lake and prefers flat to gently sloping terrain.	Year round	None. CNDDB occurrences have been documented in the Buyer Service Area and suitable habitat may be present in the area of analysis. Transfers would not impact suitable habitat for this species.
Tipton kangaroo rat *Dipodomys nitratoides nitratoides*	E	E	Found in the Tulare Lake basin of southern San Joaquin Valley, from approximately Lemoore and Hanford in Kings County to Visalia, Tipton, Delano and Bakersfield on the east.	The species is found in saltbush scrub and sink scrub communities. Requires soft friable soils. Currently limited to uncultivated ground with alkaline soils.	Year round	None. CNDDB occurrences have been documented in the Buyer Service Area and suitable habitat may be present in the area of analysis. Transfers would not impact suitable habitat for this species.
Tulare grasshopper mouse *Onychomys torridus tularensis*	--	SSC	Foothill and floor of the southern San Joaquin Valley from western Merced and eastern San Benito counties, east to Madera County, and south to foothills of Tehachapi and San Emigdio Mts. Also found on Carrizo Plains, eastern San Luis Obispo County, Cuyama Valley, parts of Kern County, Tulare Basin and Panoche Valley (Bolster 1998).	Found in hot, arid valleys and scrub deserts. Favors compact soils with sparse growth of perennial grasses.	Year round.	None. CNDDB occurrences have been documented in the Buyer Service Area. Suitable habitat is present within the area of analysis. Transfers would not impact suitable habitat for this species.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
western mastiff bat *Eumops perotis californicus*	--	SSC	Found in southeastern San Joaquin Valley and Coastal ranges from Monterey County southward through southern California and from the coast eastward to Colorado Desert.	Found in open, semi-arid habitats, including conifer and deciduous woodlands, coastal scrub, grasslands, and chaparral. Roost in crevices in cliff faces, high buildings, trees and tunnels.	Year round	None. CNDDB occurrences have been documented in the Buyer Service Area and suitable habitat is present within the area of analysis. No impacts are anticipated to feeding or roosting habitat.
western red bat *Lasiurus blossevillii*	--	SSC	Occurs from Shasta County to Mexican border, west of Sierra Nevada/Cascade crest and deserts. Winters in western lowlands and coastal regions south of SF bay. Not found in desert areas.	Found in trees 2-40ft above ground, from sea level up through mixed conifer forests. Prefers habitat edges and mosaics with trees. Feeds over a wide variety of habitats including grasslands, scrublands and croplands.	Year round. Migrates in spring (March-May) and autumn (Sept.-Oct). Migrates between summer and winter range.	None. Occurrences have been documented in the Buyer and Seller Service Area and suitable habitat is present within the area of analysis. No impacts to roosting habitat are anticipated. Transfers could alter the configuration of foraging habitat, but would not reduce suitability.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Fish						
Sacramento River Winter-run Chinook Salmon *Oncorhynchus tshawytcha*	E	E	Occurs on the mainstem Sacramento River from Keswick Dam, Shasta County (RM 302) to Chipps Island (RM 0) at the westward margin of the Sacramento-San Joaquin Delta; and in the Bay-Delta system. The area downstream of Red Bluff Diversion Dam is principally a migration corridor, although some rearing may occur during emigration.	Migrate to upstream freshwater habitat to mature and spawn. Once juveniles emerge from the gravel they seek low velocity, shallow-water areas to finish absorbing their yolk sac. Some disperse downstream when high-flow events correspond with emergence. In general, there is a shift in microhabitat use by juvenile Chinook to deeper, faster water as they grow larger. For juveniles, positive growth occurs at temperatures between 5-19 C. Temperatures greater than 24 C, even for short periods, is lethal. Salmon fry tend to move downstream, and smolts emigrate to the ocean, under conditions of increased flow, increased turbidity, and decreased temperatures.	Upstream Migration: Dec-Jul. Spawning: late Apr to early Aug Fry remain in river for five to ten months, prior to emigration. Emigration Sep.-Jan.	None. Species not present in the area of Analysis during period when transfers would occur. Potential impacts would not occur on the mainstem Sacramento River where flows are regulated by the Biological Opinions.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Central Valley Spring-run Chinook Salmon *Oncorhynchus tshawytcha*	T	T	Designated critical habitat for spring-run Chinook salmon includes San Francisco, San Pablo, and Suisun Bays, the Sacramento-San Joaquin Delta, and the Sacramento River from the Delta to Keswick Dam and the Feather River upstream to Thermalito Afterbay Dam. Spawning occurs above the valley floor in streams that have deep, cold pools where adult fish can hold over the summer before they spawn. Tributaries to the Sacramento River with independent spawning populations are Butte, Deer and Mill Creeks. Spawning may also occur on several other streams in the Area of Analysis including Thomes, Big Chico, and Antelope creeks, and the Yuba and Bear rivers. Rearing occurs in these streams and other the downstream portions of other streams tributary to the Sacramento, as well as in the Sutter and Yolo Bypasses, and in the Delta during outmigration of the young fish.	See Sacramento River winter-run Chinook salmon.	Upstream Migration and holding: Mar-Sep. Spawning: late Aug to Oct. Fry remain in river for three to 15 months, prior to emigration. Emigration Jan-Apr.	Low. Suitable habitat for over summer holding and spawning in the species primary spawning and rearing habitat is located upstream of the areas that would be affected by water transfers. Rearing habitat could potentially be affected by groundwater withdrawals in the lower sections of some streams. The sections of these waterways on the valley floor, where water transfers would occur, are typically too warm to support this species during the summer months. Potential impacts would not occur on the mainstem Sacramento River or the Feather River where the operating requirements specified in the Biological Opinions and D1641 would be met.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Fall/Late-fall Chinook Salmon *Oncorhynchus tshawytcha*	SC	SSC	Occur in the ocean from Alaska to California. Freshwater habitat use in the Central Valley occurs in the Sacramento River and all major tributaries and many minor ones, as well as in tributaries to the major tributaries to San Joaquin River, including the Merced River. In the Sacramento River, most spawning occurs between the Red Bluff Diversion Dam and Keswick Dam, although some fish spawn downstream of Red Bluff Diversion Dam. Small numbers also spawn in Battle Creek, Cottonwood Creek, Clear Creek, Mill Creek, as well as the Yuba and Bear rivers.	See Sacramento River winter-run Chinook salmon.	Fall Run: Upstream Migration: Jun-Dec. Spawning: late Sep to Dec. Fry remain in river one to seven months Emigration Dec-Mar. Late fall run: Upstream Migration: Oct-Apr. Spawning: Jan-Apr Fry remain in river seven to 13 months Emigration Dec-Mar.	Low. Operating requirements for all of the mainstem rivers would meet existing flow and temperature requirements as specified by the NMFS and USFWS BOs for the Long-term Operations of the State and Federal Water Projects and State Water Board Decision 1641. Water transfers from sellers upstream of the Delta may still result in some flow changes that would overlap spatially and temporally with the distribution of fall-run Chinook salmon emigrants, but flows would continue to meet regulatory requirements protective of this species. Transfers would not overlap the Chinook upstream migration, spawning or incubation periods.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
California Central Valley DPS Steelhead *Oncorhynchus mykiss*	T	SSC	Designated critical habitat includes all waters tributary to the San Francisco Bay from confluence of the Sacramento and San Joaquin River to the lowest impassible barrier. Within these reaches it includes all areas within the ordinary high water mark of the water body. Found in all major rivers and tributaries and may use smaller tributaries, and ephemeral tributaries when available.	Immigration from the ocean into the Delta, the Sacramento and San Joaquin River watersheds occurs when large amounts of cold water is available from winter rains. Spawning occurs in mainstem rivers and their tributaries to. The first year or two of life is spent in cool, clear, fast-flowing permanent streams and rivers where riffles predominate over pools, where there is ample cover in the form of riparian vegetation of undercut banks, and where invertebrate prey is diverse and abundant. Habitat preferences depend on fish size/age, with fry concentrating in shallow water along stream edges with low water velocities, juveniles occurring in deeper, faster water among rocks or other cover, and larger fish seeking out a wide variety of deeper habitats close to fast water. Optimal temperatures for growth are approximately 15-18 C.	Central Valley steelhead are mainly winter-run steelhead, which mature in the ocean and arrive in freshwater nearly ready to spawn. Upstream Migration: Aug-Apr. Spawning: Dec to Apr. Fry generally remain in river for one to three years. Emigration Oct-Jul.	Moderate. Uses the upper Sacramento River above Red Bluff Diversion Dam and the portions of all accessible tributaries to the Sacramento and San Joaquin Rivers with suitable temperatures for spawning and rearing. The Sacramento River below RBDD is used primarily as a migratory corridor. Water transfers from July through September, from sellers upstream of the Delta could overlap spatially and temporally with California Central Valley steelhead rearing in this region where water temperatures are suitable. Stream sections on the valley floor, where transfers could affect stream flow, are generally too warm to support rearing during the summer months, but rearing may occur above the valley floor where suitable temperatures occur. Potential impacts would not occur on the mainstem Sacramento River or the Feather River where the operating requirements specified in the Biological Opinions and D1641 would be met.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
North American Green sturgeon *Acipenser medirostris*	T	SSC	Ranges from Mexico to Alaska. The southern DPS includes spawning population in the Sacramento River, fish living in the Sacramento River, the Sacramento-San Joaquin Delta, and the San Francisco estuary. Not known to occur in the San Joaquin River. Critical habitat include: coastal marine waters from Monterey Bay to the Washington/Canada boarder; coastal bays and estuaries in California, Oregon, and Washington; fresh water rivers in the Central Valley. Proposed inland critical habitat includes Sacramento River downstream of Keswick Dam, Feather River downstream of Thermalito Dam, Yuba River downstream of Daguerre Dam, portions of Sutter and Yolo Bypasses, and the legal Delta.	Southern DPS: Adults immigrate into the Delta from the ocean to begin spawning migration into the Sacramento River. Spawning occurs in the Sacramento River (upstream of Hamilton City and downstream of Keswick Dam), both downstream and upstream of RBDD; a small number have been observed spawning in the Feather River during high flow years. Moyle (2002). Preferred spawning habitat contain large cobble in deep and cool pools with turbulent water. Water temp in spawning and egg incubation are critical; temp greater than 19C are lethal. Rear in fresh and estuarine areas for one to four years before dispersing into salt water. Occur in shallow water and move to deeper more saline areas as they mature. Emigration occurs as larvae drift downriver from freshwater spawning/rearing areas of Sacramento River watershed through the Delta to the ocean. Subadults inhabit the Delta and bays during summer months, while adults are associated with seawater and mixing zones of bays and estuaries and found in lower stretches of some rivers. Adult and juvenile green sturgeon are thought to use the same migratory routes as Chinook salmon.	Immigration: late Feb. to Jun. Spawning: March to July. After spawning, adults over-summer in deep pools of the Sacramento River from June to Nov. and emigrate to the ocean in fall and early winter and flows increase and temperatures decrease. Rearing: year-round.	Low. Potential impacts would not occur on the mainstem Sacramento River or the Feather River where the operating requirements specified in the Biological Opinions and D1641 would be met.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Delta smelt *Hypomesus transpacificus*	T	E	Endemic to Bay-Delta estuary. Primarily distributed downstream of Isleton on the Sacramento River, downstream of Mossdale on the San Joaquin River, Suisun Bay and Suisun marsh, freshwater regions of the Delta. Designated critical habitat (59 FR 65256) extends throughout Suisun Bay, the length of Goodyear, Suisun, Cutoff, first Mallard and Montezuma sloughs, and the contiguous waters of the legal Delta.	Primarily inhabit low salinity waters of estuary prior to migrating into freshwater habitats to spawn. Spawning occurs in slough and shallow edge area in the Delta and Sacramento River; spawning can occur in the Sacramento River as far upstream as Sacramento and in the Cache Slough region, the Mokelumne River system, and the San Joaquin River upstream as far as Prisoner's Point. Spawning occurs at water temperatures ranging from approximately 7C to 22C. Rearing juveniles remain in spawning areas, near or just above the X2 region of the Delta. Adult delta smelt abundance in the fall has been in the northwestern Delta in the channel of the Sacramento River. Although delta smelt tolerate a wide range of temperatures (<6C to > 25C), warm water temperatures restrict their distribution more than colder water temperatures.	Delta and Suisun Bay – year round	Low. Potential impacts would not occur in the Delta as the operating requirements specified in the Biological Opinions and D1641 would be met. Minor changes in flow could occur in the Delta as a result of water transfers, but these flows would be small. Principal rearing areas during the summer and fall are in and around Suisun Bay and in the Cache Slough region.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Longfin smelt *Spirinchus thaleichthys*	C [4]	T	Occur along the Pacific coast of North America; widespread within the Bay-Delta estuary, in the lower Sacramento River (downstream of Rio Vista), in the San Joaquin River (downstream of Medford Island). Also common in nearshore coastal marine waters.	Spawns at the transition zone between freshwater and slightly brackish water over sandy or gravel substrates at temperatures from 7 C to 14.5 C. Spawning occurs in the Sacramento River mainstem, as far upstream as Rio Vista, the San Joaquin River as far upstream as Medford Island, and in other waterways within the Delta. Hatching coincides with annual peak Delta outflows, which coincide with high turbidity. Larval smelt concentrate in near-surface, fresh and brackish waters. Distribution of larval and juvenile smelt depends on freshwater outflows from the Delta during the late-spring, eventually inhabiting the bays as well as nearshore coastal marine habitats. Longfin smelt do not occupy areas with temperatures greater than 22 C in combination with salinities greater than 26 ppt.	Spawning: November to June. Fry and juveniles have generally left the Delta by May or June.	None. Potential impacts would not occur in the Delta as the operating requirements specified in the Biological Opinions and D1641 would be met. Minor changes in flow could occur in the Delta as a result of water transfers, but these flows would be small. Longfin smelt do not occur in the Delta during the transfer period.
Hardhead	--	SSC	Hardhead are widely distributed in low to mid elevation streams in the Main Sacramento-San Joaquin river drainage as well as the Russian River drainage. Their range extends from the Ken River, in Kern County to the Pit River south of the Goose Lake drainage but are absent in the valley reaches.	Hardhead are typically found in undisturbed areas of the larger middle- and low elevation streams. Elevational range of hardhead is 10-1,450 m. Most streams in which they occur have summer temperatures in excess of 20°C.	Year-round	Low. Hardhead are largely excluded from the valley floor reaches of the streams and rivers within the Area of Analysis due to warm summer temperatures and the abundance of introduced fish.

Common Name *Scientific Name*	**Federal Special Status***	**State Special Status***	**Distribution**	**Habitat Association**	**Seasonal Occurrence**	**Potential Impact**
Sacramento splittail	--	SSC	Endemic to the lakes and rivers of the Central Valley. Current distribution generally restricted to the Delta, Suisun Bay, Suisun Marsh, the lower portions of the Napa and Petaluma rivers, and other parts of the San Francisco estuary. They may occur in the Sacramento River upstream as far as Red Bluff Diversion Dam and on the San Joaquin as far upstream as Salt Slough in wet years. They may also occur in the lower Feather and American rivers during these wetter periods. The Sutter and Yolo bypasses are important spawning areas today.	Inhabit estuarine to fresh waters. Spawning occurs primarily on inundated floodplains. Tend to be found in slow-moving sections of rivers and sloughs, and in the Delta and Suisun Marsh. YOY splittail are commonly found between Rio Vista and Chipps island indicating that juveniles prefer more riverine habitat.	Year round in the Delta, Sacramento and San Joaquin Rivers.	Low. Operating requirements for all of the mainstem rivers would meet existing flow and temperature requirements as specified by the NMFS and USFWS BOs for the Long-term Operations of the State and Federal Water Projects and State Water Board Decision 1641.

[1] Central CA DPS

[2] Santa Barbara and Sonoma Counties

[3] All bird species listed below and many other birds are protected during the nesting season under the federal Migratory Bird Treaty Act.

[4] USFWS has found that the San Francisco Bay-Delta Distinct Population Segment (DPS) of longfin smelt warrants protection under the federal Endangered Species Act, but higher priority listing actions currently preclude their listing.

Table I-2. Special-Status Plants with Potential to Occur in the Area of Analysis

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
adobe sanicle *Sanicula maritima*	-/R/ 1B.1	Alameda, Monterey, San Francisco, and San Luis Obispo Counties.	Meadows and seeps, valley and foothill grassland, chaparral, coastal prairie. Moist clay or ultramafic soils from 30-240m asl.	February - May	**None.** Adobe sanicle has been previously documented in the Buyer Service Area. Water transfer may increase the area of marginal habitat for this species in the Buyer Service Area. No negative impacts are expected.
Ahart's dwarf rush *Juncus leiospermus* var. *ahartii*	-/-/ 1B	Butte, Calaveras, Placer, Sacramento, Tehama, and Yuba Counties.	Valley and foothill grassland (mesic). May occur in disturbed areas including agricultural fields and locations with gopher digging activity (CNDDB 2012).	March-May	**Low.** Suitable grassland habitat occurs within the area of analysis and this species has been previously documented within the Seller Service Area. There is a low potential that this species would occur in managed rice fields.
Alkali milk-vetch *Astragalus tener var. tener*	-/-/ 1B.2	Central western California including Yolo County.	Subalkaline flats and areas around vernal pools.	March-June	**None.** Not likely to occur in rice fields, no suitable habitat (i.e. subalkali flats) would be affected by Transfers.
Anderson's manzanita *Arctostaphylos andersonii*	-/-/ 1B.2	Santa Clara, Santa Cruz, and San Mateo Counties.	Broadleaved upland forest, chaparral, North coast coniferous forest. Open sites in redwood forest from 180 - 800m asl.	November - May	**None.** Previously documented within the Buyer Service Area. No suitable habitat would be affected by the proposed Transfers.
Antioch Dunes evening-primrose *Oenothera deltoides* ssp. *howellii*	E/E/ 1B.1	Found only in Contra Costa and Sacramento Counties.	Occurs in inland dunes.	March-September	**None.** CNDDB records for this species have been documented within the Buyer Service Area. Not likely to occur in rice fields, and no inland dune habitat should be affected by Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
arcuate bush-mallow *Malacothamnus arcuatus*	-/-/ 1B.2	Santa Clara, Santa Cruz, and San Mateo Counties.	Chaparral within gravelly alluvium from 80 - 335m asl.	April - September	**None.** Previously observed within the Buyer Service Area. No impacts to suitable habitat are anticipated in association with the proposed Transfers.
Baker's navarretia *Navarretia leucocephala* ssp. *bakeri*	-/-/ 1B.1	Colusa, Glenn, Lake, Lassen, Mendocino, Marin, Napa, Solano, Sonoma, Sutter, Tehama, and Yolo Counties.	Cismontane woodland, meadows and seeps, vernal pools, valley and foothill grassland, lower montane coniferous forest. Vernal pools and swales, adobe or alkaline soils from 5 - 950m.	April - July	**None.** The CNDDB contains records of this species within the Seller Service Area. It is very unlikely that Baker's navarretia would establish in rice fields, given the lack of adobe or alkaline soils.
bearded popcorn-flower *Plagiobothrys hystriculus*	-/-/ 1B.1	Napa, Solano, and Yolo Counties.	Vernal pools, valley and foothill grassland in wet sites from 10-50m. This species is only known from a few very limited occurrences at the edges of vernal pools, such as at Jepson Prairie and in the Montezuma Hills.	April - May	**None.** Previous records of bearded popcorn-flower exist within the Seller Service Area. This species is not expected to occur in rice fields. No vernal pools or grassland habitats would be affected by the proposed Transfers.
Ben Lomond buckwheat *Eriogonum nudum* var. *decurrens*	-/-/ 1B.1	Alameda, Santa Clara, and Santa Cruz Counties.	Chaparral, cismontane woodland, lower montane coniferous forest. Ponderosa pine sandhills in Santa Cruz County from 50 - 800m asl.	June - October	**None.** The CNDDB contains occurrences of this species in the Buyer Service Area. No chaparral or woodland habitats would be affected by the proposed Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
bent-flowered fiddleneck *Amsinckia lunaris*	-/-/ 1B.2	Alameda, Contra Costa, Colusa, Lake, Marin, Napa, San Benito, Santa Clara, Santa Cruz, San Mateo, Sonoma, and Yolo Counties.	Cismontane woodland, valley and foothill grassland from 50 - 500m.	March - June	**None.** Bent-flowered fiddleneck has been previously documented within the Buyer Service Area. Although suitable habitat occurs within the area of analysis, none would be affected by the proposed actions.
big-scale balsamroot *Balsamorhiza macrolepis* var. *macrolepis*	-/-/ 1B.2	Alameda, Butte, Colusa, El Dorado, Lake, Mariposa, Napa, Placer, Santa Clara, Solano, Sonoma, Tehama, and Tuolumne Counties.	Valley and foothill grassland, cismontane woodland. Sometimes on serpentine. 35 - 1000m	March - June	**None.** This species has been previously documented within both the Buyer and Seller Service Areas. However it is not expected to occur in rice fields due to lack of suitable habitat.
big tarplant *Blepharizonia plumosa*	-/-/ 1B.1	Alameda, Contra Costa, San Joaquin, Solano, and Stanislaus Counties.	Valley and foothill grassland. Dry hills and plains in annual grassland. Clay to clay-loam soils, usually on slopes and often in burned areas 15 - 455m asl.	July - October	**None.** Big tarplant has been observed within the Buyer Service Area. Transfers would not affect suitable habitat for this species.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Boggs Lake hedge-hyssop *Gratiola hetersepela*	-/E/1B	Dispersed throughout the Sacramento and Central Valley. Also in Oregon.	Marshes, swamps, and vernal pools (clay).	April - August	**None.** A CNDDB occurrence has been documented within the Seller Service Area. This species may withstand some disturbances, such as cattle. However, modifications of natural hydrology by agriculture or other activities are considered a threat to the species, and Boggs Lake hedge-hyssop is not expected to occur within planted rice fields. No marsh or vernal pool habitat would be affected by the proposed Transfers.
Bolander's water-hemlock *Cicuta maculata var. bolanderi*	-/-/ 2.1	Occurs within California, Arizona, New Mexico, and Washington. In California it is found in Contra Costa, Los Angeles, Marin, Sacramento, Santa Barbara, San Luis Obispo, and Solano Counties.	Marshes, fresh or brackish water 0 - 200m asl.	July - September	**None.** Bolander's water hemlock has been previously documented within the Buyer Service Area. No marsh, fresh or brackish water habitat would be affected by the proposed Transfers.
Brandegee's clarkia *Clarkia biloba* ssp. *brandegeeae*	-/-/ 1B.2	Butte, El Dorado, Nevada, Placer, Sacramento, Sierra, and Yuba Counties.	Chaparral, cismontane woodland, often in roadcuts 295 - 885m asl.	May - July	**None.** This species has been previously recorded within the Seller Service Area. No impacts to suitable habitat are expected.
Brandegee's eriastrum *Eriastrum brandegeeae*	-/-/ 1B.2	Contra Costa, Colusa, Glenn, Lake, Santa Clara, Shasta, San Mateo, Tehama, and Trinity Counties.	Chaparral, cismontane woodland. On barren volcanic soils, often in open areas from 345 - 1000m asl.	April - August	**None.** Records of Brandegee's eriastrum exist for the Buyer Service Area. Suitable habitat would not be affected by Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Brewer's western flax *Hesperolinon breweri*	-/-/ 1B.2	Contra Costa, Napa and Solano Counties.	Chaparral, cismontane woodland, valley and foothill grassland. Often in rocky serpentine soils in serpentine chaparral and serpentine grassland from 30 - 885m asl.	May - July	**None.** Brewer's western flax has been previously observed within the Buyer Service Area. Suitable habitat would not be affected by Transfers.
Brittlescale *Atriplex depressa*	-/-/1B.2	Western Central Valley and valleys of adjacent foothills.	Alkali grassland, alkali meadow, alkali scrub, and vernal pools. Usually in alkali scalds or alkaline clay in meadows or annual grassland. Rarely associated with riparian areas, marshes, or vernal pools 1 - 320m asl.	April-October	**None.** Occurrences of this species have been documented in both the Buyer and Seller Service Areas in the CNDDB. This species is not likely to occur in rice fields due to lack of suitable habitat (i.e. alkali and vernal pools).
Butte County fritillary *Fritillaria eastwoodiae*	-/-/3.2	Butte, El Dorado, Nevada, Placer, Placer, Shasta, Tehama and Yuba Counties.	Chaparral, cismontane woodland, lower montane coniferous forest. Usually on dry slopes but also found in wet places. Soils can be serpentine, red clay, or sandy loam 40 - 1500m asl.	March - June	**None.** Butte County fritillary has been previously observed within the Seller Service Area. Rice fields do not provide suitable habitat for this species, and it is therefore not expected to be impacted by Transfers.
California jewel-flower *Caulanthus californicus*	E/E/ 1B.1	Fresno, Kings, Kern, Santa Barbara, San Luis Obispo, and Tulare Counties.	Chenopod scrub, valley and foothill grassland, pinyon-juniper woodland. From various valley habitats in both the Central Valley and Carrizo Plain 65 - 900m asl.	February - May	**None.** CNDDB records of this species exist for the Buyer Service Area. Suitable habitat would not be affected by Transfers.
California seablite *Suaeda californica*	E/-/ 1B.1	Alameda, Contra Costa, Santa Clara, San Francisco, and San Luis Obispo Counties.	Marshes and swamps. Margins of coastal salt marshes 0 - 5m asl.	July - October	**None.** California seablite has been previously observed within the Buyer Service Area. No impacts to suitable habitat within the Buyer Service Area are expected to occur.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
caper-fruited tropidocarpum *Tropidocarpum capparideum*	-/-/ 1B.1	Alameda, Contra Costa, Fresno, Glenn, Monterey, Santa Clara, San Joaquin, and San Luis Obispo Counties.	Valley and foothill grassland in alkaline clay 0 - 455m asl.	March - April	**None.** CNDDB records exist for the Buyer Service Area. Transfers are not expected to impact suitable habitat for this species.
Carquinez goldenbush *Isocoma arguta*	-/-/ 1B.1	Occurs in Solano County.	Valley and foothill grassland. Alkaline soils, flats, lower hills. On low benches near drainages and on tops and sides of mounds in swale habitat 1 - 20m asl.	August - December	**None.** Previously documented within the Buyer Service Area. Transfers would not affect water levels in the Seller Service Area and would only increase the levels in the Buyer Service Area.
chaparral harebell *Campanula exigua*	-/-/ 1B.2	Alameda, Contra Costa, San Benito, Santa Clara, and Stanislaus Counties.	Chaparral on rocky sites, usually on serpentine soils 300 - 1250m asl.	May - June	**None.** Chaparral harebell has been observed within the Buyer Service Area. However, Transfers are not expected to affect suitable habitat for this species.
chaparral ragwort *Senecio aphanactis*	-/-/ 2.2	California and Baja California. Within California, the species occurs in Alameda, Contra Costa, Fresno, Los Angeles, Merced, Monterey, Orange, Riverside, Santa Barbara, Santa Clara, the Channel Islands, San Diego, San Luis Obispo, Solano and Ventura Counties.	Cismontane woodland, coastal scrub. Drying alkaline flats 20 - 575m asl.	January - April	**None.** Previous records of this species exist within the Buyer Service Area. Transfers are not expected to affect suitable habitat for chaparral ragwort.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Choris' popcorn-flower *Plagiobothrys chorisianus* var. *chorisianus*	-/-/ 1B.2	Alameda, Santa Cruz, San Francisco, and San Mateo Counties.	Chaparral, coastal scrub, coastal prairie (mesic sites) 15 - 100m asl.	March - June	**None.** Choris' popcorn flower has been documented within the Buyer Service Area. No impacts to suitable habitat are anticipated in association with the proposed Transfers.
Colusa grass *Neostapfia colusana*	T/E/1B.1	Southern Sacramento Valley, and northern San Joaquin Valley.	Vernal pools.	May-July	**None.** According to the CNDDB, this species has been previously documented in the Seller Service Area. However, this species is not likely to occur in rice fields due to lack of suitable habitat (i.e. vernal pools).
Colusa layia *Layia septentrionalis*	-/-/ 1B.2	Colusa, Glenn, Lake, Mendocino, Napa, Sonoma, Sutter, Tehama, and Yolo Counties.	Chaparral, cismontane woodland, valley and foothill grassland. Scattered colonies in fields and grassy slopes in sandy or serpentine soil 145 - 1095m asl.	April - May	**None.** CNDDB records exist for the Seller Service Area. Transfers are not expected to impact suitable habitat for this species given that rice fields do not provide appropriate conditions.
Congdon's tarplant *Centromadia parryi* ssp. *congdonii*	-/-/ 1B.2	Alameda, Contra Costa, Monterey, Santa Clara, Santa Cruz, San Luis Obispo, San Mateo, and Solano Counties.	Valley and foothill grassland. Alkaline soils, sometimes described as heavy white clay 1 - 230m asl.	May - November	**None.** Although this species has been documented within the Buyer Service Area (CNDDB), no impacts to suitable habitat are expected.
Contra Costa goldfields *Lasthenia conjugens*	E/-/1B.1	San Francisco Bay Delta Regions, and scattered coastal areas.	Cismontane woodlands, playas, valley and foothill grasslands, and vernal pools. Often occurs in vernal pools, swales, and low depressions in open grassy areas 1 - 445m asl.	March-June	**None.** According to the CNDDB, this species has been previously documented within the Buyer Service Area. No impacts to suitable habitat (i.e. vernal pools, playas) are expected.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Contra Costa manzanita *Arctostaphylos manzanita* ssp. *laevigata*	-/-/1B.2	Contra Costa County.	Chaparral on rocky slopes 500 - 1100m asl.	January - April	**None.** Contra Costa manzanita has been observed within the Buyer Service Area. No impacts to suitable habitat for this species are expected.
Contra Costa wallflower *Erysimum capitatum* var. *angustatum*	E/E/1B.1	Contra Costa County	Inland dunes. Stabilized dunes of sand and clay near Antioch along the San Joaquin River 3 - 20m asl.	March - July	**None.** Records of this species exist within the Buyer Service Area. Suitable habitat would not be affected by Transfers.
coyote ceanothus *Ceanothus ferrisiae*	E/-/1B.1	Santa Clara County	Chaparral, valley and foothill grassland, coastal scrub. Serpentine sites in the Mt. Hamilton Range 120 - 455m asl.	January - May	**None.** The CNDDB contains records of this species within the Buyer Service Area. No suitable habitat for coyote ceanothus is expected to be impacted by the proposed Transfers.
Crampton's tuctoria (Solano grass) *Tuctoria mucronata*	E/E/1B	Located only in Yolo and Solano Counties.	Valley and foothill grassland (mesic), and vernal pools.	April-August	**None.** Occurrences have been documented outside of the area of analysis. Not likely to occur in rice fields. Suitable habitat within the Seller Service Area would not be impacted by Transfers.
Delta coyote-thistle(button celery) *Eryngium racemosum*	-/E/1B	Calaveras, Contra Costa, Merced, San Joaquin, and Stanislaus Counties.	Riparian scrub and vernally mesic clay depressions.	June-October	**None.** No occurrences have been documented within the area of analysis, but the species is known from Contra Costa, Merced, San Joaquin and Stanislaus Counties. No suitable habitat would be impacted by the proposed Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Delta mudwort *Limosella subulata*	-/-/ 2.1	Contra Costa, Marin, Sacramento, San Joaquin, Solano Counties.	Riparian scrub, freshwater marsh, brackish marsh. Usually on intertidal flats and muddy banks of the Delta in marshy or scrubby riparian associations, often with Lilaeopsis masonii 0 - 3m asl. Typically occurs with other rare plant species.	May - August	**None.** Previous CNDDB records exist within the Buyer Service Area, and suitable habitat is also present within the Seller Service Area. This species is not expected to occur within rice fields given that it is sensitive to alteration of natural hydrology and other disturbances (SCWA 2007).
Delta tule pea *Lathyrus jepsonii* var. *jepsonii*	-/-/ 1B.2	Contra Costa, Napa, Sacramento, San Joaquin, Solano, Sonoma, Yolo Counties.	Coastal salt marsh. In coastal salt marsh with Distichlis, Salicornia, Frankenia, etc. from 0-3m asl.	May - September	**None.** Suitable habitat is present within the area of analysis, and CNDDB records exist for the Buyers Service Area. Transfers are not expected to impact suitable habitat for this species (i.e. coastal salt marshes).
Diablo helianthella *Helianthella castanea*	-/-/ 1B.2	Alameda, Contra Costa, Marin, San Francisco, San Mateo.	Broadleaved upland forest, chaparral, cismontane woodland, coastal scrub, riparian woodland, valley and foothill grassland. Usually in chaparral/oak woodland interface in rocky, azonal soils. Often in partial shade 25-1150m asl.	March - June	**None.** Diablo helianthella has been previously documented within the Buyer Service Area. No impacts to suitable habitat for this species are anticipated.
diamond-petaled California poppy *Eschscholzia rhombipetala*	-/-/ 1B.1	Alameda, Contra Costa, Colusa, San Joaquin, San Luis Obispo, Stanislaus Counties.	Valley and foothill grassland. Alkaline clay slopes and flats. 0 - 975m asl.	March - April	**None.** This species has been previously documented within the Buyer Service Area. No impacts to suitable habitat are anticipated.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
dubious pea *Lathyrus sulphureus* var. *argillaceus*	-/-/ 3	Calaveras, El Dorado, Nevada, Placer, Shasta, Tehama Counties.	Cismontane woodland, lower montane coniferous forest, upper montane coniferous forest 150-305m asl.	April - May	**None.** CNDDB records of dubious pea exist within the Seller Service Area. Transfers actions would not affect suitable habitat for this species.
dwarf downingia *Downingia pusilla*	-/-/ 2.2	Occurs in California and South America. Within California: Amador, Fresno, Merced, Napa, Placer, Sacramento, San Joaquin, Solano, Sonoma, Stanislaus, Tehama, Yuba.	Vernal pools. Many historical occurrences are extirpated. In beds of vernal pools 1 - 880m asl.	March - May	**None.** Previously observed within the Seller Service Area. Not likely to establish in rice fields, due to lack of suitable habitat (i.e., vernal pools).
elongate copper moss *Mielichhoferia elongata*	-/-/ 2.2	Occurs in California, Colorado and Oregon. Within California, occurs in Fresno, Humboldt, Lake, Mariposa, Marin, Nevada, Placer, Plumas, Santa Cruz, Trinity, and Tulare Counties.	Cismontane woodland on very acidic, metamorphic rock or substrate, usually in higher portions in fens.	--	**None.** CNDDB records exist for the Seller Service Area. Transfers are not expected to affect suitable habitat for this species.
Ferris' milk-vetch *Astragalus tener* var. *ferrisae*	-/-/1B.1	Sacramento Valley.	Subalkaline flats and areas around vernal pools.	March-June	**None.** The species has been previously documented within the Seller Service Area. Not likely to occur in rice fields, due to lack of suitable habitat.
fragrant fritillary *Fritillaria liliacea*	-/-/ 1B.2	Alameda, Contra Costa, Monterey, Marin, San Benito, Santa Clara, San Francisco, San Mateo, Solano, Sonoma Counties.	Cismontane woodland, valley and foothill grassland. Grassy areas from 635 - 855m asl.	February - April	**None.** Previous records exist within the Buyer Service Area. Transfers are not expected to impact suitable habitat for fragrant fritillary.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Franciscan onion *Allium peninsulare* var. *franciscanum*	-/-/ 1B.2	Mendocino, Santa Clara, San Mateo, Sonoma Counties.	Cismontane woodland, valley and foothill grassland. Clay soils, often on serpentine. Dry hillsides from 100 - 300m asl.	May - June	**None.** Previous records of franciscan onion exist for the Buyer Service Area. The proposed Transfers is not expected to impact suitable habitat for this species.
Franciscan thistle *Cirsium andrewsii*	-/-/ 1B.2	Contra Costa, Marin, San Francisco, San Mateo, Sonoma Counties.	Coastal bluff scrub, broadleaved upland forest, coastal scrub. Sometimes serpentine seeps 0 - 135m asl.	March - July	**None.** Has been observed within the Buyer Service Area. No impacts to suitable habitat for Franciscan thistle are anticipated.
Greene's tuctoria *Tuctoria greeni*	E/R/1B.1	Butte, Colusa, Fresno, Glenn, Madera, Merced, Modoc, Shasta, San Joaquin, Stanislaus, Tehama, and Tulare Counties.	Vernal pools.	May-July	**None.** There is a CNDDB occurrence within the Seller Service Area, however this species is not likely to occur in rice fields due to lack of suitable habitat (i.e. vernal pools).
hairless popcorn-flower *Plagiobothrys glaber*	-/-/ 1A	Alameda, Marin, San Benito, Santa Clara Counties.	Meadows and seeps, marshes and swamps. Coastal salt marshes and alkaline meadows 5-180m asl.	March - May	**None.** This species has been documented by CNDDB within the Buyer Service Area. Transfers are not expected to impact suitable habitat for this species within the Buyer Service Area.
hairy Orcutt grass *Orcuttia pilosa*	E/E/1B.1	Northern Sacramento Valley, Pit River Valley; isolated populations in Lake and Sacramento counties.	Vernal pools.	May - September	**None.** Hairy Orcutt grass has previously been documented by the CNDDB in the Seller Service Area. However this species is not likely to occur in rice fields due to lack of suitable habitat (i.e. vernal pools).

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Hall's bush-mallow *Malacothamnus hallii*	-/-/ 1B.2	Contra Costa, Lake, Mendocino, Merced, Santa Clara, San Mateo, Stanislaus Counties.	Chaparral. Some populations on serpentine 10 - 550m asl.	May - October	**None.** Previous records exist within the Buyer Service Area. Transfers are not expected to impact suitable habitat for Hall's bush-mallow.
Hall's tarplant *Deinandra halliana*	-/-/ 1B.1	Fresno, Monterey, San Benito, San Luis Obispo Counties.	Cismontane woodland, valley and foothill grassland, vernal pools. In grassland and not necessarily in vernal pools 200 - 1000m asl.	April - May	**None.** Hall's tarplant has been observed within the Buyer Service Area. Transfers are not expected to impact vernal pools or other suitable habitat for this species within the Buyer Service Area.
Hartweg's golden sunburst *Pseudobahia bahiifolia*	E/E/1B	Found in El Dorado, Fresno, Madera, Merced, Stanislaus, Tuolumne, and Yuba Counties.	Cismontane woodland, valley and foothill grassland, often acidic.	April - May	**None.** There are CNDDB occurrences within Yolo County outside of the area of analysis. This species is not likely to be affected by Transfers given that it is not likely to occur in rice fields.
Heartscale *Atriplex cordulata*	-/-/1B	Western Central Valley and valleys of adjacent foothills.	Alkali grasslands, alkali meadows, and alkali scrub.	May - October	**None.** CNDDB occurrences have been documented within the Seller Service Area (Butte, Colusa, Yolo, and Glenn Counties). However this species is not likely to occur in rice fields due to lack of suitable habitat (i.e. alkali areas).

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Heckard's pepper-grass *Lepidium latipes* var**.** *heckardii*	-/-/1B	Glenn, Solano, and Yolo Counties.	Valley and foothill grassland alkaline flats.	March-May	**None.** This species has been previously documented within the Seller Service Area. However it is not likely to occur in rice fields due to lack of suitable habitat (i.e. alkali flats).
Henderson's bent grass *Agrostis hendersonii*	- /-/ 3.2	Found in Butte, Calaveras, Merced, Placer, Shasta, and Tehama Counties. Also found in Oregon.	Vernal pools.	March- June	**None.** CNDDB records for this species occur within the Seller Service Area. Not likely to occur in rice fields due to lack of suitable habitat (i.e. vernal pools).
Hispid bird's beak *Cordylanthus mollis* ssp. *hispidus*	-/-/1B.1	Alameda, Kern, Fresno, Merced, Placer, and Solano Counties.	Meadows and seeps, playas, valley and foothill grasslands (alkali).	June-September	**None.** Previously observed within the Seller Service Area according to CNDDB records. Not likely to occur in rice fields, no suitable habitat present.
hooked popcorn-flower *Plagiobothrys uncinatus*	-/-/ 1B.2	Monterey, San Benito, Santa Clara, San Luis Obispo, and Stanislaus Counties.	Chaparral, cismontane woodland, valley and foothill grassland, coastal bluff scrub. Sandstone outcrops and canyon sides, often in burned or disturbed areas 300 - 820m asl.	April - May	**None.** Hooked popcorn-flower has been documented within the Buyer Service Area. No impacts to suitable habitat for this species are anticipated.
Hoover's button-celery *Eryngium aristulatum* var. *hooverii*	-/-/ 1B.1	Alameda, San Benito, Santa Clara, San Diego, San Luis Obispo Counties.	Vernal pools. Alkaline depressions, vernal pools, roadside ditches and other wet places near the coast 5 - 45m asl.	July - August	**None.** This species has been documented within the Buyer Service Area. Suitable habitat for the species is present (e.g. irrigated agriculture and ditches), but no impacts to suitable habitat are expected within the Buyer Service Area.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Hoover's cryptantha *Cryptantha hooveri*	-/-/ 1A	Contra Costa, Kern, Madera, Stanislaus Counties.	Valley and foothill grassland in coarse sand up to 150m asl.	April - May	**None.** Hoover's cryptantha has been observed within the Buyer Service Area. No impacts to suitable habitat for this species are anticipated.
Hoover's eriastrum *Eriastrum hooveri*	D/-/ 4.2	Contra Costa, Kern, Madera, Stanislaus Counties.	Chenopod scrub, valley and foothill grassland, pinyon-juniper woodland. On sparsely vegetated alkaline alluvial fans, also in the Temblor Range on sandy soils 50 - 915m asl.	April - May	**None.** This species has previously been documented within the Buyer Service Area. No suitable habitat for this species would be impacted by the proposed Transfers.
Hoover's spurge *Chamaesyce hooveri*	T/-/ 1B.2	Scattered in Glenn, Butte, Colusa, Merced, Stanislaus, Tehama, and Tulare Counties.	Vernal pools.	July-September	**None.** According to the CNDDB occurrences have been documented in the Seller Service Area. However, this species is not likely to occur in rice fields due to lack of suitable habitat (i.e. vernal pools).
Hospital Canyon larkspur *Delphinium californicum* ssp. *interius*	-/-/ 1B.2	Alameda, Contra Costa, Merced, Monterey, San Benito, Santa Clara, San Joaquin, and Stanislaus Counties.	Cismontane woodland, chaparral. In wet, boggy meadows, openings in chaparral and in canyons 225 - 1060m asl.	April - June	**None.** Hospital Canyon larkspur has been observed within the Buyer Service Area. There is suitable habitat for this species in the area of analysis, but the proposed actions are not expected to impact these habitat in the Buyer Service Area.
Indian valley brodiaea *Broiaea coronaria* ssp. *rosea*	-/E/1B	Scattered in Glenn, Lake, Colusa, and Tehama Counties.	Closed cone coniferous forest, chaparral, valley and foothill grasslands (serpentinite).	May-June	**None.** CNDDB occurrences have been documented outside of the area of analysis. This species is not likely to occur in rice fields due to lack of suitable habitat.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Indian Valley bush-mallow *Malacothamnus aboriginum*	-/-/ 1B.2	Alameda, Contra Costa, Merced, Monterey, San Benito, Santa Clara, San Joaquin, and Stanislaus Counties.	Cismontane woodland, chaparral. Granitic outcrops and sandy bare soil, often in disturbed soils 150 - 1700m asl.	April - June	**None.** Indian Valley bush-mallow has been observed within the Buyers Service Area. The proposed Transfers should not affect suitable habitat for this species.
Jepson's milk-vetch *Astragalus rattanii var. jepsonianus*	-/-/1B.2	Colusa, Glenn, Lake, Napa, Tehama, and Yolo Counties.	Chaparral, cismontane woodland, valley and foothill grassland, often serpentinite.	April-June	**None.** Although suitable habitat exists, no CNDDB records have been documented within the area of analysis. This species is not likely to be impacted as rice fields do not provide suitable habitat.
Keck's checkerbloom *Sidalcea keckii*	E/-/1B.1	Colusa, Fresno, Merced, Napa, Solano, Tulare, and Yolo Counties.	Cismontane woodlands, foothill and valley grasslands (serpentinite).	April-May	**None.** No CNDDB occurrences of this species are known for the area of analysis. Suitable habitat is present, but would not be impacted by the proposed Transfers.
Kellogg's horkelia *Horkelia cuneata* ssp*. sericea*	-/-/ 1B.1	Alameda, Monterey, Marin, Santa Barbara, Santa Cruz, San Francisco, San Luis Obispo, and San Mateo Counties.	Closed-cone coniferous forest, coastal scrub, chaparral. Within old dunes, coastal sandhills, openings from 10 - 200m asl.	April - September	**None.** Records of Kellog's horkelia exist in the Buyer Service Area. Transfers are not expected to affect suitable habitat for this species within the area of analysis.
Kings Mountain manzanita *Arctostaphylos regismontana*	-/-/ 1B.2	Santa Clara, Santa Cruz, and San Mateo Counties.	Broadleaved upland forest, chaparral, north coast coniferous forest. Granitic or sandstone outcrops 305 - 730m asl.	January - April	**None.** This species has been previously observed within the Buyer Service Area. Suitable habitat is presented but would not be impacted by the proposed Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
large-flowered fiddleneck *Amsinckia grandiflora*	E/E/ 1B.1	Alameda, Contra Costa, and San Joaquin Counties.	Cismontane woodland, valley and foothill grassland. Annual grassland in various soils 275 - 550m asl.	April - May	**None.** Large-flowered fiddleneck has been recorded by the CNDDB within the Buyer Service Area. No impacts would occur to suitable habitat.
Layne's ragwort *Packera layneae*	T/-/1B	Butte, El Dorado, Tuolumne, and Yuba Counties.	Chaparral and cismontane woodland, rocky and often serpentinite.	April-August	**None.** There is a CNDDB occurrence within Butte County, outside the area of analysis. Although suitable habitat is present within the area of analysis, it is not expected to be impacted by the proposed Transfers.
Legenere *Legenere limosa*	-/-/1B.1	Sacramento Valley and south of the North Coast Ranges.	Vernal pools from 1-880m asl.	April-June	**None.** Legenere has been documented within both the Buyer and Seller Service Areas. Not likely to occur in rice fields, no suitable habitat present (i.e. vernal pools).
Lesser saltscale *Atriplex minuscula*	-/-/1B	Found in Butte, Fresno, Kern, Madera, Merced, Stanislaus, and Tulare Counties.	Chenopod scrub, playas, valley and foothill grasslands (alkali and sandy).	May-October	**None.** No CNDDB records exist for the area of analysis, but it has been documented within some of the counties. Suitable habitat occurs within the Buyer Service Area, but would not be impacted by the proposed Transfers.
Lime Ridge navarretia *Navarretia gowenii*	-/-/ 1B.1	Occurs within Contra Costa and Stanislaus Counties in California.	Chaparral on calcium carbonate rich soil with high clay content, 180 - 305m asl.	May - June	**None.** Previously documented within the Buyer Service Area. No suitable habitat for Lime Ridge navarretia would be affected by the proposed Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Loma Prieta hoita *Hoita strobilina*	-/-/ 1B.1	Alameda, Contra Costa, Santa Clara, Santa Cruz Counties.	Chaparral, cismontane woodland, riparian woodland. Within serpentine at mesic sites.	May - October	**None.** CNDDB records of Loma Prieta hoita exist for the Buyer Service Area. No impacts are expected within suitable habitat for this species.
Lone buckwheat *Eriogonum apricum* var. *apricum*	E/E/1B	Found in Amador and Sacramento Counties.	Chaparral.	July-October	**None.** Although it has been documented, no CNDDB records exist within the area of analysis. This species is not likely to occur in rice fields due to lack of suitable habitat.
Lost Hills crownscale *Atriplex coronata* var. *vallicola*	-/-/ 1B.2	Fresno, Kings, Kern, Merced, and San Luis Obispo Counties.	Chenopod scrub, valley and foothill grassland, vernal pools. In powdery, alkaline soils that are vernally moist with Frankenia, Atriplex spp. And Distichlis. 0 - 605m asl.	April - August	**None.** This species has been documented within the Buyer Service Area. No impacts to suitable habitat are expected.
lost thistle *Cirsium praeteriens*	-/-/ 1A	Little information exists on this plant. San Mateo and Santa Clara Counties. Little information exists on this species. It was collected from the Palo Alto area at the turn of the 20th century. Not observed since 1901.	0 - 100m asl.	June - July	**None.** CNDDB records of lost thistle exist for the Buyer Service Area. Very limited information is available. Based on status information it is likely to be extirpated and would therefore be unlikely to occur within an area impacted by transfers.
maple-leaved checkerbloom *Sidalcea malachroides*	-/-/ 4.2	Occurs within California and Oregon. In California the species occurs in Del Norte, Humboldt, Mendocino, Monterey, Santa Clara, Santa Cruz, and Sonoma Counties.	Broadleafed upland forest, coastal prairie, coastal scrub, North Coast coniferous forest. Woodlands and clearings near coast, often in disturbed areas 2 - 760m asl.	March - August	**None.** This species has been previously documented within the Buyer Service Area. No impacts to areas of suitable habitat are anticipated.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Marsh checkerbloom *Sidalcea oregana* ssp. *hydrophila*	-/-/1B	Glenn, Lake, Mendocino, and Napa Counties.	Meadows and seeps, and riparian forest.	June-August	**None.** Suitable habitat present within Glenn County in the area of analysis. This species is not expected to establish in rice fields, and therefore no impacts are anticipated.
Mason's lilaeopsis *Lilaeopsis masonii*	-/R/ 1B.1	Alameda, Contra Costa, Marin, Napa, Sacramento, San Joaquin, Solano, and Yolo Counties.	Freshwater and brackish marshes, riparian scrub. Tidal zones, in muddy or silty soil formed through river deposition or river bank erosion 0 - 10m asl. Populations may be ephemeral, using freshly deposited or exposed sediments (SCWA 2007).	April - November	**None.** Previous records of this species exist within the Buyer Service Area. This species is not expected to establish within rice fields.
Merced phacelia *Phacelia ciliata var. opaca*	-/-/ 1B.2	Merced County.	Valley and foothill grassland. Adobe or clay soils of valley floors, open hills or alkaline flats 60 - 150m asl.	February - May	**None.** Merced phacelia has been documented within the Seller Service Area. Transfers are not expected to affect suitable habitat for this species.
Metcalf Canyon jewel-flower *Streptanthus albidus* ssp. *albidus*	E/-/ 1B.1	Santa Clara County.	Valley and foothill grassland. Relatively open areas in dry grassy meadows on serpentine soils 45 - 245m asl.	April - July	**None.** This species was previously observed within the Buyer Service Area according to CNDDB. No Transfers-related impacts to suitable habitat for Metcalf Canyon jewel-flower are anticipated.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Milo Baker's lupine *Lupinus milo-bakeri*	-/T/1B	Glenn and Mendocino Counties.	Cismontane woodlands, foothill and valley grasslands.	June-September	**None.** Although suitable habitat is present within the area of analysis, no CNDDB records have been documented in either the Buyer or Seller Service Areas. This species is not likely to occur in rice fields due to lack of suitable habitat.
most beautiful jewel-flower *Streptanthus albidus* ssp. *peramoenus*	-/-/ 1B.2	Alameda, Contra Costa, Monterey, Santa Clara, and San Luis Obispo Counties.	Chaparral, valley and foothill grassland, cismontane woodland, serpentine outcrops, on ridges and slopes 120 - 730m asl.	March - October	**None.** Most beautiful jewel-flower has been previously observed within the Buyer Service Area. No Transfers-related impacts to suitable habitat for this species are expected.
Mount Day rockcress *Boechera rubicundula*	-/-/ 1B.1	Santa Clara County.	Rocky slopes in chaparral at 1200m asl.	April - May	**None.** According to CNDDB, this species was documented within the Buyer Service Area. No suitable habitat for this species would be affected by Transfers.
Mt. Diablo buckwheat *Eriogonum truncatum*	-/-/ 1B.1	Alameda, Contra Costa, and Solano Counties.	Chaparral, coastal scrub, valley and foothill grassland. Dry, exposed clay or sandy substrates 100 - 600m asl.	April - December	**None.** This species has been observed within the Buyer Service Area. No suitable habitat would be affected by Transfers.
Mt. Diablo fairy-lantern *Calochortus pulchellus*	-/-/ 1B.2	Alameda, Contra Costa, and Solano Counties.	Chaparral, cismontane woodland, riparian woodland, valley and foothill grassland on wooded and brushy slopes 200 - 800m asl.	April - June	**None.** Mt. Diablo fairy-lantern has been documented within the Buyer Service Area. No impacts to suitable habitat for this species are expected.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Mt. Diablo jewel-flower *Streptanthus hispidus*	-/-/ 1B.3	Contra Costa County.	Valley and foothill grassland, chaparral, talus or rocky outcrops 275 - 970m asl.	March - June	**None.** The Mt. Diablo jewel-flower has been documented in the Buyer Service Area. No impacts to suitable habitat area anticipated.
Mt. Diablo manzanita *Arctostaphylos auriculata*	-/-/ 1B.3	Contra Costa County.	Chaparral in canyons and on slopes. On sandstone 120 - 500m asl.	January - March	**None.** This species was previously observed within the Buyer Service Area according to CNDDB. No Transfers-related impacts to suitable habitat for Mt. Diablo phacelia are anticipated.
Mt. Diablo phacelia *Phacelia phacelioides*	-/-/ 1B.2	Contra Costa, San Benito, Santa Clara, and Stanislaus Counties.	Chaparral, cismontane woodland. Adjacent to trails, on rock outcrops and talus slopes, sometimes on serpentine 500 - 1370m asl.	April - May	**None.** Mt. Diablo phacelia has been documented within the Buyer Service Area. No impacts to suitable habitat for this species are expected.
Mt. Hamilton coreopsis *Leptosyne hamiltonii*	-/-/ 1B.2	Alameda, Santa Clara, and Stanislaus Counties.	Cismontane woodland. On steep shale talus with open southwestern exposure 530 - 1300m asl.	March - May	**None.** CNDDB records of Mt. Hamilton coreopsis exist within the Buyer Service Area. Transfers would not affect suitable habitat for this species.
Mt. Hamilton fountain thistle *Cirsium fontinale* var. *campylon*	-/-/ 1B.2	Alameda, Santa Clara, and Stanislaus Counties.	Cismontane woodland, chaparral, valley and foothill grassland. In seasonal and perennial drainages on serpentine soil 95 - 890m asl.	February - October	**None.** This species has been documented within the Buyers Service Area. No impacts to suitable habitat within the area of analysis are anticipated.
Mt. Hamilton jewel-flower *Streptanthus callistus*	-/-/ 1B.3	Santa Clara County.	Chaparral, cismontane woodland. Open talus slopes on shale with grey pine and/or black oak 600 - 790m asl.	April - May	**None.** Mt. Hamilton jewel-flower has been documented within the Buyers Service Area by CNDDB. Transfers would not impact suitable habitat for this species.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Mt. Hamilton lomatium *Lomatium observatorium*	-/-/ 1B.2	Santa Clara and Stanislaus Counties.	Cismontane woodland. Open to partially shaded openings in Pinus coulteri - Oak woodland. Sedimentary Franciscan rocks and volcanic soils 1219 - 1330m asl.	March - May	**None.** Mt. Hamilton lomatium has been documented within the Buyers Service Area by CNDDB. Transfers would not impact suitable habitat for this species.
Munz's tidy-tips *Layia munzii*	-/-/ 1B.2	Fresno, Kern, and San Luis Obispo Counties.	Chenopod scrub, valley and foothill grassland. Hillsides in white-grey alkaline clay soils with grasses and chenopod scrub associates 45 - 760m asl.	March - April	**None.** This species has been observed within the Buyer Service Area. No suitable habitat would be affected by Transfers.
Norris' beard moss *Didymodon norrisii*	-/-/ 2.2	Butte, Contra Costa, Colusa, Humboldt, Lake, Los Angeles, Madera, Monterey, Mariposa, Nevada, Plumas, San Benito, Santa Cruz, Shasta, Sierra, Sonoma, Tehama, Tulare, and Tuolumne Counties.	Cismontane woodland, lower montane coniferous forest. Moss from seasonally wet sheet drainages on exposed rock slabs or terraces that completely dry in summer.	--	**None.** Records of Norris' beard moss exist for the Buyer Service Area. Transfers would not impact suitable habitat for this species.
Northern California black walnut *Juglans hindsii*	-/-/1B	Native stands reported in Napa and Contra Costa Counties.	Riparian woodland.	April-May	**None.** Previously documented within the Buyer Service Area. Transfers would not impact suitable habitat for this species.
Oregon meconella *Meconella oregana*	-/-/ 1B.1	Occurs in California, Oregon and Washington. Within California occurs in Contra Costa and Santa Clara Counties.	Coastal prairie and coastal scrub in open, moist places 250 - 500m asl.	March - April	**None.** Oregon meconella has been observed within the Buyer Service Area. Transfers would not affect suitable habitat for this species.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
oval-leaved viburnum *Viburnum ellipticum*	-/-/2.3	Occurs in California, Oregon and Washington. Within California occurs in Contra Costa, El Dorado, Fresno, Glenn, Humboldt, Mendocino, Napa, Placer, Shasta, Sonoma and Tehama Counties.	Chaparral, cismontane woodland, and lower montane coniferous forest 215 - 1400m asl.	May - June	**None.** This species has been previously documented within the Buyer Service Area. Suitable habitat for oval-leaved viburnum is not expected to be affected by Transfers.
pallid manzanita *Arctostaphylos pallida*	T/E/1B.1	Alameda and Contra Costa Counties.	Broadleafed upland forest, closed-cone coniferous forest, chaparral, cismontane woodland, coastal scrub. Grows on uplifted marine terraces on siliceous shale or thin chert at 185 - 465m asl. May require fire.	December - March	**None.** Pallid manzanita has been observed within the Buyer Service Area. No Transfers-related impacts to suitable habitat are anticipated.
Palmate-bracted bird's-beak *Cordylanthus palmatus*	E/E/1B.1	Found in Glenn and Colusa Counties and within the Central Valley.	Alkali meadow, alkali scrub, valley and grasslands.	May-October	**None.** CNDDB records of this species exist for the Seller Service Area. Not likely to occur in rice fields; no suitable habitat is present (i.e. alkali areas).
Panoche pepper-grass *Lepidium jaredii* ssp. *album*	-/-/ 1B.2	Fresno, San Benito, and San Luis Obispo Counties.	Valley and foothill grassland. White or grey clay lenses on steep slopes. Incidental in alluvial fans and washes. Clay and gypsum-rich soils 65 - 910m asl.	February - June	**None.** Panoche pepper-grass has previously been documented within the Buyer Service Area. The proposed Transfers would not impact suitable habitat for this species.
Peruvian dodder *Cuscuta obtusiflora* var. *glandulosa*	-/-/ 2.2	Known from California, Baja California, Sonora and Texas. Within California records exist from Butte, Los Angeles, Merced, Sacramento, San Bernardino, Sonoma and Sutter Counties.	Marshes and swamps (freshwater). Freshwater marsh 15 - 280m asl.	July - October	**None.** CNDDB records of this species exist for the Seller Service Area. Peruvian dodder is unlikely to become established within rice fields.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Pincushion navarretia *Navarretia myersii* ssp. *myersii*	-/-/1B.1	Alamdor, Calaveras, Merced, Placer, and Sacramento Counties.	Vernal pools (often acidic).	May	**None.** Previously documented in the Seller Service Area. No vernal pools would be affected by Transfers.
pink creamsacs *Castilleja rubicundula* ssp. *rubicundula*	-/-/ 1B.2	Butte, Contra Costa, Colusa, Glenn, Lake, Napa, Plumas, San Benito, Santa Clara, and Shasta Counties.	Chaparral, meadows and seeps, valley and foothill grassland. Openings in chaparral or grasslands. On serpentine 20 - 900m asl.	April - June	**None.** Pink creamsacs has been previously documented within the Buyer Service Area. No impacts to suitable habitat for this species are anticipated.
Point Reyes bird's-beak *Chloropyron maritimum* ssp. *palustre*	-/-/ 1B.2	California and Oregon. Within California it occurs in Alameda, Humboldt, Marin, Santa Clara, San Francisco, San Mateo, and Sonoma Counties.	Coastal salt marsh, usually in coastal salt marsh with Salicornia, Distichlis, Jaumea, Spartina, etc. 0 - 15m.	June - October	**None.** CNDDB records of this species exist for the Buyer Service Area. Suitable habitat for this species is not expected to be affected by Transfers.
Presidio clarkia *Clarkia franciscana*	E/E/1B.1	Alameda and San Francisco Counties	Coastal scrub, valley and foothill grassland. Serpentine outcrops in grassland or scrub 20 - 335m.	May - July	**None.** Presidio clarkia has been previously observed within the Buyer Service Area. Suitable habitat exists in the area of analysis, but would not be affected by the proposed Transfers.
Recurved larkspur *Delphinium recurvatum*	-/-/1B	Disbursed throughout the Sacramento and Central Valley.	Chenopod scrub, cismontane, valley and foothill grasslands (alkali).	March-June	**None.** According to the CNDDB this species has been previously recorded in the Buyer Service Area. Suitable habitat exists (i.e. alkali areas) in the area of analysis, but would not be affected by the proposed Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Red Bluff dwarf rush *Juncus leiospermus* var. *leiospermus*	-/-/1B.1	Butte, Placer, Shasta, and Tehama Counties.	Chaparral, valley and foothill grassland, cismontane woodlands, vernal pools. Vernally mesic sites. Sometimes on edges of vernal pools 30 - 1020m asl. The species has also been documented within intermittent drainages and in areas with pocket gopher and ground squirrel activity (BRCP 2011).	March - May	**Low.** Red Bluff dwarf rush has been previously documented within the Seller Service Area. Given that the species has some tolerance for disturbance, is a low potential for red bluff dwarf rush to establish within rice fields, which may represent marginal habitat.
Red Hills soaproot *Chlorogalum grandiflorum*	-/-/1B.2	Amador, Butte, Calaveras, El Dorado, Placer and Tuolumne Counties.	Cismontane woodland, chaparral, lower montane coniferous forest. Occurs frequently on serpentine or gabbro, but also on non-ultramafic substrates, often on historically disturbed sites.	May - June	**None.** CNDDB records of this species exist within the Seller Service Area. This species is not expected to occur within rice fields due to lack of suitable habitat (i.e., serpentine areas).
Red mountain catchfly *Silene campanulata* ssp. *campanulata*	-/E/1B	Found in Colusa, Glenn, Mendocino, Shasta, Tehama, and Trinity Counties.	Chaparral and lower montane coniferous forest, usually sepentinite and rocky.	April-July	**None.** There is a CNDDB occurrences in the vicinity, within counties in the area of analysis. However this species is not likely to occur in rice fields due to lack of suitable habitat.
robust spineflower *Chorizanthe robusta* var. *robusta*	E/-/1B.1	Alameda, Monterey, Marin, Santa Clara, Santa Cruz, San Francisco, and San Mateo Counties.	Cismontane woodland, coastal dunes, coastal scrub. Sandy terraces and bluffs or in loose sand 3 - 120m asl.	April - September	**None.** Robust spineflower has been documented within the Buyer Service Area. Transfers are not expected to affect suitable habitat for this species.
rock sanicle *Sanicula saxatilis*	-/-/ 1B.2	Contra Costa and Santa Clara Counties.	Broadleafed upland forest, chaparral, valley and foothill grassland. Bedrock outcrops and talus slopes in chaparral or oak woodland habitat 625 - 1215m asl.	April - May	**None.** CNDDB records of this species exist within the Buyer Service Area. Suitable habitat for rock sanicle is not expected to be affected by Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
round-leaved filaree *California macrophylla*	-/-/1B.1	California, Baja California, Oregon.	Cismontane woodland, valley and foothill grassland. Clay soils 15 - 1200m asl.	March - May	**None.** Round-leaved filaree has been previously documented within both the Buyer and Seller Service Areas. No Transfers-related impacts to suitable habitat for the species are anticipated.
Sacramento Orcutt grass *Orcuttia viscida*	E/E/1B.1	Valley grasslands and freshwater wetlands.	Vernal pools.	May-June	**None.** CNDDB records of this species exist for the Seller Service Area. Sacramento Orcutt grass is not likely to occur in rice fields due to lack of suitable habitat (i.e. vernal pools).
saline clover *Trifolium hydrophilum*	-/-/ 1B.2	California's Central coast and Bay Area.	Marshes and swamps, valley and foothill grassland, vernal pools. Mesic, alkaline sites 0 - 300m asl.	April - June	**Low.** Records of saline clover exist within both the Buyer and Seller Service Areas. Rice fields may represent marginally suitable habitat for this species. There is a low potential for impacts within the Seller Service Area (Colusa, Solano, and Yolo Counties).
San Benito pentachaeta *Pentachaeta exilis* ssp. *aeolica*	-/-/ 1B.2	Monterey, San Benito, and Santa Clara Counties.	Cismontane woodland, valley and foothill grassland. Grassy areas from 635 - 855m asl.	March - May	**None.** This species has previously been documented within the Buyer Service Area. No suitable habitat for this species would be impacted by the proposed Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
San Francisco Bay spineflower *Chorizanthe cuspidata* var. *cuspidata*	-/-/ 1B.2	Alameda, Marin, San Francisco, San Mateo, and Sonoma Counties.	Coastal bluff scrub, coastal dunes, coastal prairie, coastal scrub. Sandy soil on terraces and slopes 5 - 550m asl.	April - August	**None.** San Francisco Bay spineflower has been observed within the Buyer Service Area. No impacts to suitable habitat for this species are anticipated in association with the proposed Transfers.
San Francisco collinsia *Collinsia multicolor*	-/-/ 1B.2	Monterey, Marin, Santa Clara, Santa Cruz, San Francisco, and San Mateo Counties.	Closed-cone coniferous forest, coastal scrub. On decomposed shale (mudstone) mixed with humus 30 - 250m asl.	March - May	**None.** This species has been documented within the Buyer Service Area. No impacts to suitable habitat are expected.
San Francisco popcorn-flower *Plagiobothrys diffusus*	-/E/1B.1	Alameda, Santa Cruz, San Francisco, and San Mateo Counties.	Valley and foothill grassland, coastal prairie. Historically known from grassy slopes with marine influence 60 - 485m asl.	March - June	**None.** San Francisco popcorn-flower has been observed within the Buyer Service Area. No impacts to suitable habitat for this species are anticipated in association with the proposed Transfers.
San Joaquin spearscale *Atriplex joaquiniana*	-/-/1B.2	Western Central Valley and valleys of adjacent foothills.	Alkali grasslands, and alkali scrub.	April-September	**None.** Has been previously documented within both the Buyer and Seller Service Areas. Not likely to occur in rice fields, no suitable habitat present (i.e. alkali areas).
San Joaquin woollythreads *Monolopia congdonii*	E/-/1B.2	Fresno, Kings, Kern, Santa Barbara, San Benito, San Luis Obispo, and Tulare Counties.	Chenopod scrub and valley and foothill grassland. Alkaline or loamy plains, sandy soils 60 - 800m asl.	February - May	**None.** San Joaquin woollythreads was previously documented within the Buyer Service Area. No impacts to suitable habitat are anticipated.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Sanford's arrowhead *Sagittaria sanfordii*	-/-/1B	Central Valley.	Freshwater marshes, shallow streams, and ditches.	May-August	**Moderate.** Sanford's arrowhead has been previously documented within the Seller Service Area. Not likely to establish in rice fields, but ditches represent suitable habitat. There is a moderate potential that this species would be affected by the proposed Transfers.
Santa Clara red ribbons *Clarkia concinna ssp. automixa*	-/-/ 4.3	Alameda and Santa Clara Counties.	Cismontane woodland, chaparral on slopes and near drainages 90-970m asl.	April - July	**None.** CNDDB records for this species exist for the Buyer Service Area. No suitable habitat for this species should be affected by Transfers.
Santa Clara Valley dudleya *Dudleya abramsii* ssp. *setchellii*	E/-/ 1B.1	Santa Clara County.	Valley and foothill grassland, cismontane woodland. On rocky serpentine outcrops and on rocks within grassland or woodland 80 - 335m asl.	April - October	**None.** Santa Clara Valley dudleya has been previously documented within the Buyer Service Area. Suitable habitat for this species would not be impacted by the proposed Transfers.
Santa Cruz tarplant, *Holocarpha macradenia*	T/E/1B.1	Alameda, Contra Costa, Monterey, Marin, Santa Cruz, and Solano Counties.	Coastal prairie, valley and foothill grassland. Light, sandy soil or sandy clay, often with non-natives 10 - 260masl.	June - October	**None.** Santa Cruz tarplant has been observed within the Buyer Service Area, according to CNDDB records. No impacts to suitable habitat are anticipated.
Santa Cruz Mountains beardtongue *Penstemon rattanii* var. *kleei*	-/-/ 1B.2	Santa Clara and Santa Cruz Counties	Chaparral, lower montane coniferous forest. Sandy shale slopes, sometimes in the transition between forest and chaparral 400 - 1100m asl.	May - June	**None.** This species has been observed within the Buyer Service Area. No suitable habitat would be affected by Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Santa Cruz Mountains pussypaws *Calyptridium parryi* var. *hesseae*	-/-/ 1B.1	Monterey, Santa Clara, Santa Cruz, San Luis Obispo, and Stanislaus Counties.	Chaparral, cismontane woodland, sandy or gravelly openings 305 - 1530m asl.	May - August	**None.** CNDDB records of Santa Cruz Mountains pussypaws exist for the Buyer Service Area. Suitable habitat for this species is not expected to be affected by Transfers.
Santa Cruz tarplant, *Holocarpha macradenia*	T/E/1B.1	Alameda, Contra Costa, Monterey, Marin, Santa Cruz, and Solano Counties.	Coastal prairie, valley and foothill grassland. Light, sandy soil or sandy clay, often with non-natives 10 - 260masl.	June - October	**None.** Santa Cruz tarplant has been observed within the Buyer Service Area, according to CNDDB records. No impacts to suitable habitat are anticipated.
Scadden Flat checkerbloom *Sidalcea stipularis*	-/E/ 1B.1	Nevada County. Known from two occurrences near Grass Valley.	Marshes and swamps. Typical habitat includes montane marshes fed by springs 700 - 740m asl.	July - August	**None.** This species has been previously documented within the Seller Service Area. It is not likely to establish in rice fields due to lack of suitable habitat (i.e. montane marsh).
Sharsmith's harebell *Campanula sharsmithiae*	-/-/ 1B.2	Santa Clara and Stanislaus Counties.	Chaparral. Serpentine barrens 480 - 1820m asl.	April - June	**None.** Sharsmith's harebell has been observed within the Buyer Service Area. No impacts to suitable habitat for this species are expected.
Sharsmith's onion *Allium sharsmithiae*	-/-/ 1B.3	Alameda, Santa Clara, and Stanislaus Counties.	Cismontane woodland. Rocky, serpentine slopes 400 - 1200m asl.	March - May	**None.** CNDDB records for this species occur within the Buyer Service Area. Suitable habitat for this species should not be impacted by the proposed Transfers.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Sheldon's sedge *Carex sheldonii*	-/-/2.2	Occurs in California, Idaho, Nevada, Oregon, Utah and Washington. Within California the species occurs in Lassen, Modoc, Placer, and Plumas Counties.	Lower montane coniferous forest, marshes and swamps, riparian scrub. Mesic sites along creeks and in wet meadows 1065 - 1755m asl.	May - August	**None.** Sheldon's sedge has been observed within the Seller Service Area. Although rice fields may provide the appropriate moisture conditions, this species occurs at very high elevations and is therefore not expected to be impacted by the proposed Transfers.
shining navarretia *Navarretia nigelliformis* ssp. *radians*	-/-/1B.2	Alameda, Contra Costa, Fresno, Merced, Monterey, San Benito, San Joaquin, and San Luis Obispo Counties.	Cismontane woodland, valley and foothill grassland, and vernal pools 200 - 1000m asl. Known from grassland, and may not necessarily occur in vernal pools.	April - July	**None.** Previous CNDDB records of shining navarettia exist for the Seller Service Area. This species is unlikely to establish within rice fields due to lack of suitable habitat (i.e., vernal pools and native grassland).
Sierra blue grass *Poa sierrae*	-/-/1B.3	Butte, Madera, Nevada, Placer, Plumas, Shasta Counties.	Lower montane coniferous forest. Shady, moist, rocky slopes often in canyons 365 - 1160m asl.	April - June	**None.** This species has been documented within the Seller Service Area. This species is not likely to be impacted, given that it requires shaded rocky slope habitat not provided in rice fields.
showy golden madia *Madia radiata*	-/-/1B.1	Contra Costa, Fresno, Kings, Kern, Monterey, Santa Barbara, San Benito, Santa Clara, San Joaquin, San Luis Obispo, and Stanislaus Counties.	Valley and foothill grassland, cismontane woodland, chenopod scrub. Mostly on adobe clay in grassland or among shrubs 25 - 1125m asl.	March - May	**None.** Showy golden madia has been observed within the Buyer Service Area. No project impacts to suitable habitat for this species are anticipated.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Slender Orcutt grass *Orcuttia tenuis*	T/E/1B.1	Northern Sacramento Valley, Pit River Valley; isolated populations in Lake and Sacramento Counties.	Vernal pools.	May-October	**None.** The CNDDB contains records of slender Orcutt grass in the Seller Service Area. However, this species is not likely to occur in rice fields due to lack of suitable habitat (i.e. vernal pools).
slender-leaved pondweed *Stuckenia filiformis*	-/-/ 2.2	Occurs in California, Arizona, Nevada, Oregon, and Washington.	Marshes and swamps. Shallow, clear water of lakes and drainage channels 15 - 2310m asl.	May - July	**None.** Slender-leaved pondweed has been previously documented within the Buyer Service Area. It is not expected to occur within rice fields in the Seller Service Area given the lack of suitable natural lake and stream habitat.
slender silver moss *Anomobryum julaceum*	-/-/ 2.2	California and Oregon. Within California it occurs in Butte, Contra Costa, Humboldt, Los Angeles, Mariposa, Santa Barbara, Santa Cruz, Shasta, and Sonoma Counties.	Broadleafed upland forest, lower montane coniferous forest, north coast coniferous forest. Grows on damp rocks and soil in acidic substrates and on roadcuts 100 - 1000m asl.	--	**None.** CNDDB records of slender silver moss exist for the Buyer Service Area. Suitable habitat for this species is not expected to be affected by Transfers.
smooth lessingia *Lessingia micradenia var. glabrata*	-/-/ 1B.2	Santa Clara County.	Chaparral. Serpentine often on roadsides 120 - 485m asl.	July - November	**None.** This species has been previously documented within the Buyer Service Area. No impacts to chaparral or serpentine areas are anticipated.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Soft bird's beak *Cordylanthus mollis* ssp. *mollis*	E/R/1B.2	Located in Contra Costa, Marin, Napa, Sacramento, Solano, and Sonoma Counties.	Coastal salt marshes and swamps.	July-November	**None.** CNDDB occurrences exist for the Buyer Service Area, however this species is not likely to be affect by Transfers due to lack of suitable habitat (i.e. coastal salt marshes).
stinkbells *Fritillaria agrestis*	-/-/ 4.2	Occurs in Central and Northern California, including Alameda, Contra Costa, Fresno, Kern, Mendocino, Merced, Monterey, Mariposa, Placer, Sacramento, Santa Barbara, San Benito, Santa Clara, Santa Cruz, San Luis Obispo, San Mateo, Stanislaus, Tuolumne, Ventura, and Yuba Counties.	Cismontane woodland, chaparral, valley and foothill grassland. Sometimes on serpentine, mostly in non-native grassland or in grassy openings in clay soil 95 - 890m asl.	March - June	**None.** This species has been documented within both the Buyer and the Seller Service Areas. No impacts to suitable habitat for stinkbells are anticipated.
Succulent owl's clover *Castilleja campestris* ssp. *succulenta*	T/E/1B.2	Fresno, Madera, Merced, Mariposa, San Joaquin, and Stanislaus Counties.	Vernal pools.	April-May	**None.** Succulent owl's clover has been documented in the Seller Service Area, however this species is not likely to occur in rice fields due to lack of suitable habitat (i.e. vernal pools).

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Suisun Marsh aster *Symphyotrichum lentum*	-/-/ 1B.2	Contra Costa, Napa, Sacramento, San Joaquin, Solano, and Yolo Counties.	Saline and freshwater marshes and swamps. Most often seen along sloughs with Phragmites, Scirpus, blackberry, Typha, etc at 0-3m asl.	May - November	**None.** This species has been previously documented within both the Buyer and Seller Service Areas. This species is not expected to occur within rice fields given its sensitivity to habitat alteration and agricultural amendments. Environmental commitments would require that downstream flows are maintained, such that no impacts are anticipated in the natural habitats for the species.
talus fritillary *Fritillaria falcata*	-/-/ 1B.2	Alameda, Monterey, San Benito, Santa Clara, and Stanislaus Counties.	Chaparral, cismontane woodland, lower montane coniferous forest. On shale, granite, or serpentine talus 300 - 1525m asl.	March - May	**None.** Talus fritillary has been observed within the Buyer Service Area. Suitable habitat for this species is not expected to be affected.
Temblor buckwheat *Eriogonum temblorense*	-/-/ 1B.2	Fresno, Kern, Monterey, and San Luis Obispo Counties.	Valley and foothill grassland. Barren clay or sandstone substrates 300 - 1000m asl.	April - September	**None.** Records of temblor buckwheat exist within the Buyer Service Area. Transfers are not expected to impact any suitable habitat for this species.
Tiburon buckwheat *Eriogonum luteolum var. caninum*	-/-/ 1B.2	Alameda, Contra Costa, Marin, Sonoma Counties.	Chaparral, valley and foothill grassland, cismontane woodland, coastal prairie. Serpentine soils on sandy to gravelly sites 0 - 700m asl.	May - September	**None.** Has been observed within the Buyer Service Area. No impacts to suitable habitat for Tiburon buckwheat are expected.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
Tiburon paintbrush *Castilleja affinis* ssp. *neglecta*	E/T/ 1B.2	Marin, Napa, and Santa Clara Counties.	Valley and foothill grassland. Rocky serpentine sites 75 - 400m asl.	April - June	**None.** CNDDB records of Tiburon paintbrush exist within the Buyer Service Area. Transfers are not expected to impact suitable habitat for this species.
Tracy's eriastrum *Eriastrum tracyi*	-/R/ 1B.2	Colusa, Fresno, Glenn, Kern, Santa Clara, Shasta, Stanislaus, Tehama, Trinity, and Tulare Counties.	Chaparral, cismontane woodland. Gravelly shale or clay, often in open areas 315 - 760m asl.	June - July	**None.** Previously documented within the Buyer Service Area. No impacts to suitable habitat for this species are expected.
vernal pool smallscale *Atriplex persistens*	-/-/ 1B.2	Colusa, Glenn, Madera, Merced, Solano, Stanislaus, and Tulare Counties.	Vernal pools. Alkaline vernal pools 10 - 115m asl.	June - October	**None.** Vernal pool smallscale has been documented within the Seller Service Area. This species is not likely to establish within rice fields given the lack of vernal pool and alkaline habitat.
western leatherwood *Dirca occidentalis*	-/-/ 1B.2	Alameda, Contra Costa, Marin, Santa Clara, San Mateo, and Sonoma Counties.	Broadleafed upland forest, chaparral, closed-cone coniferous forest, cismontane woodland, north coast coniferous forest, riparian forest, riparian woodland. On mesic sites on brushy slopes 30-550m asl within mixed evergreen and foothill woodland communities.	January - April	**None.** CNDDB records of this species exist within the Buyer Service Area. Suitable habitat for western leatherwood is not expected to be affected by Transfers.
white-flowered rein orchid *Piperia candida*	-/-/ 1B.2	California, Oregon, Washington. Within California the species occurs in Del Norte, Humboldt, Mendocino, Santa Clara, Santa Cruz, Siskiyou, San Mateo, Sonoma, and Trinity Counties.	North coast coniferous forest, lower montane coniferous forest, broad leafed upland forest. Coast ranges from Santa Cruz County North on serpentine. Forest duff, mossy banks, rock outcrops and muskeg 0 - 1200m asl.	March - September	**None.** White-flowered rein orchid has been documented within the Buyer Service Area. However, no impacts to suitable habitat for this species are anticipated in the Buyer Service Area.

Common Name *Scientific name*	**Special Status* (F/S/RPR)**	**Distribution**	**Habitat Association**	**Blooming Period**	**Potential Impact**
woodland woollythreads *Monolopia gracilens*	-/-/ 1B.2	Alameda, Contra Costa, Monterey, Santa Clara, Santa Cruz, San Luis Obispo, and San Mateo Counties.	Chaparral, valley and foothill grassland (serpentine), cismontane woodland, broad leafed upland forests, north coast coniferous forest. Grassy sites in openings, sandy to rocky soils. Often seen on serpentine after burns but may have only a weak affinity to serpentine.	February - July	**None.** Has been observed within the Buyer Service Area. No impacts to suitable habitat for woodland woolly threads are anticipated.
woolly rose-mallow *Hibiscus lasiocarpos* var. *occidentalis*	-/-/ 1B.2	Butte, Contra Costa, Colusa, Glenn, Sacramento, San Joaquin, Solano, Sutter, and Yolo Counties.	Marshes and swamps (freshwater). Moist, freshwater-soaked river banks and low peat islands in sloughs. Known from the Delta watershed 0 - 150m asl.	June - September	**None.** Previously observed in the Buyer Service Area. Not likely to establish in rice fields given the lack of suitable habitat (marsh and swamp). This species is sensitive to habitat disturbance and agricultural amendments.
Wright's trichocoronis *Trichocoronis wrightii* var. *wrightii*	-/-/ 2.1	Colusa, Merced, Riverside, San Joaquin, and Sutter Counties.	Marshes and swamps, riparian forest, meadows and seeps, vernal pools. Mud flats of vernal lakes, drying river beds and alkali meadows 5 - 435m asl.	May - September	**Low.** According to the CNDDB, this species has previously been recorded in the Seller Service Area. Rice fields are not expected to support this species given the lack of suitable natural habitats.

RPR=California Rare Plant Rank
1B= Rare, threatened, or endangered in California and elsewhere
2= Plants Rare, Threatened, or Endangered in California, But More Common Elsewhere
3= Plants about which we need more information - A review list
*Status explanations:
F=Federal
E= listed as endangered under the federal Endangered Species Act
T= listed as threatened under the federal Endangered Species Act
S=State
E=Endangered
T=Threatened
R=Rare
SSC=Species of Special Concern

Appendix J
Comments and Responses

This appendix contains responses to comments received on the Draft Environmental Impact Statement/Environmental Impact Report (EIS/EIR), including all written comments received during the comment period and oral comments submitted at public meetings. The comment letters are included in Appendix O.

Table J-1 presents commenters and associated agencies or groups that submitted comments on the Draft EIS/EIR.

Table J-1. List of Commenters

Commenter	Agency/Group	Date	Comment ID
Federal Agencies			
Kathleen Martyn Goforth	United States Environmental Protection Agency	12/15/2014	FA01
State Agencies

Common Responses

Multiple comments were received on some issues. The Common Responses below provide responses to these groups of comments.

Common Response 1: CEQA Lead Agency

Commenters questioned whether San Luis & Delta-Mendota Water Authority (SLDMWA) is the appropriate California Environmental Quality Act (CEQA) lead agency, and several commenters opined the California Department of Water Resources (DWR) would be more appropriate. In Public Resources Code Section 21067, the CEQA statute defines a lead agency as "the public agency which has the principal responsibility for carrying out or approving a project which may have a significant effect upon the environment." For the range of potential transfer activities analyzed in the EIS/EIR, SLDMWA is anticipated to be negotiating transfer agreements with potential sellers on behalf of the Participating Members, and as such, would be a key party in the range of potential transfers analyzed in the EIS/EIR. Each seller would be a key party to a transfer from their agency, but they would not be involved in any other transfer. Under the current regulatory framework, no single California public agency has regulatory responsibility for reviewing and approving all Central Valley Project (CVP) water transfers. As a potential facilitator, SLDWMA is a common party and has undertaken the responsibility to evaluate a range of potential transfers under CEQA in order to provide a more comprehensive and coordinated analysis as commenters have requested in the past.

Water transfers are voluntary actions proposed by willing buyers and sellers, and are not initiated by state agencies. DWR will not be a party involved in negotiating transfers, nor will the agency be a party to any of the transfer contracts. Some commenters suggest that DWR will approve transfers, but that is not accurate. Potential sellers identified in this EIS/EIR will submit transfer information to Reclamation for review and consideration for approval under federal and state law. DWR will have a coordination role in the process because it will coordinate with Reclamation on review of potential transfer information packages (to help ensure consistency between CVP-related transfers and non-CVP-related transfers). DWR may also help facilitate transfers through State Water Project (SWP) facilities in some years. This is not a role with "principal responsibility" such that DWR should be the CEQA lead agency. More information regarding management of water transfers in California and DWR's role can be found on DWR's website: http://wwwdwr.water.ca.gov/watertransfers/.

Common Response 2: Project Opposition

Commenters expressed opposition to transfers from the Sacramento Valley. The Lead Agencies (Reclamation and SLDMWA) recognize the range of potential transfer activities that are the subject of this EIS/EIR are of interest to many people, and opinions and viewpoints about water transfers vary; many are opposed to them. Reclamation and SLDMWA will consider all public input regarding the potential transfer activities analyzed in the EIS/EIR, as well as federal and state policies and regulations concerning water transfers, when evaluating transfer proposals and deciding how to proceed.

Common Response 3: Sacramento Valley Impacts

Commenters expressed concerns that potential effects of transfers on the Sacramento Valley must be considered, including effects on groundwater resources, terrestrial resources, fisheries, and local economies. The Draft EIS/EIR includes substantial analysis on these issues:

- Groundwater resources are analyzed in detail in Section 3.3. The impact analysis finds that Alternative 2 (Full Range of Transfers) and Alternative 3 (No Cropland Modifications) could result in potentially significant impacts related to groundwater levels and subsidence. Mitigation Measure GW-1, Mitigation and Monitoring Plans, includes monitoring and mitigation to avoid significant effects.

- Fisheries resources are analyzed in detail in Section 3.7. The analysis considers flow changes from transfer operations and streamflow depletion caused by groundwater basins refilling after groundwater substitution transfers. The flow changes in streams and rivers would be insubstantial, and they would not occur at times or in locations that would have significant adverse effects on sensitive fish species.

- Terrestrial resources are analyzed in detail in Section 3.8. Cropland idling transfers have the potential to affect giant garter snakes that use rice fields and irrigation ditches as habitat, but these potential effects are avoided by the environmental commitments included in the action alternatives. Streamflow depletion from groundwater substitution transfers would have the potential to affect riparian vegetation in four creeks, but Mitigation Measure GW-1 includes monitoring and mitigation to avoid significant effects.

- Economic resources are analyzed in detail in Section 3.10. The economics analysis estimates direct, indirect, and induced economic effects of cropland idling on regional economies in participating areas. The analysis also considers increased income associated with transfer payments to sellers.

Common Response 4: Groundwater Existing Conditions

Commenters expressed concerns that the Groundwater Affected Environment section does not adequately represent the current drought conditions.

Recent groundwater levels in the Sacramento Valley

Section 3.3.1.3.2 has been revised to include additional information clarifying recent groundwater level trends within the Sacramento Valley. The following figures and discussion have been included in the Groundwater Resources section:

1. Spring 2013 to Spring 2014 change in groundwater elevation in shallow (<200 feet below ground surface [bgs]), intermediate (200-600 feet bgs), and deep (>600 feet bgs) wells.

2. Spring 2004 to Spring 2014 change in groundwater elevation in shallow (<200 feet bgs), intermediate (200-600 feet bgs), and deep (>600 feet bgs) wells.

3. Spring 2010 to Spring 2014 change in groundwater levels in wells.

4. Spring 2010 to Spring 2011 change in groundwater elevation in shallow (<200 feet bgs), intermediate (200-600 feet bgs), and deep (>600 feet bgs) wells.

5. Fall 2010 to Fall 2011 change in groundwater elevation in shallow (<200 feet bgs), intermediate (200-600 feet bgs), and deep (>600 feet bgs) wells.

6. Hydrographs for shallow and deep wells in Colusa, Corning, East Butte, West Butte, Solano, North American, South American, and Yolo subbasins.

Change in groundwater elevation figures for (a) Spring 2013 to Spring 2014, (b) Spring 2004 to Spring 2014, and (c) Spring 2010 to Spring 2014 indicate groundwater levels have decreased within the Sacramento Valley. As shown in Figure J-1 below, water year (WY) 2014 was one of the driest years on record since 1977 and it was preceded by a dry and a critical year. Spring 2014 groundwater levels have changed between +5 and -20 feet within the Sacramento Valley in comparison to Spring 2013. Comparisons of spring groundwater levels in the last decade (Spring 2004 to Spring 2014) indicate groundwater levels have declined as much as 40 feet in parts of Glenn, Colusa and Tehama County within the Sacramento Valley.

Change in groundwater elevation figures between Spring 2010 and Spring 2011 indicate an increase of up to eight feet in groundwater levels within the Sacramento Valley. This increase occurred after four consecutive years of dry weather conditions in the Sacramento Valley (two dry years, one critical dry year and one below normal year). Though the Sacramento Valley and other parts of California are currently noticing declining groundwater level trends, past groundwater trends are indicative of groundwater levels declining moderately during extended droughts and recovering to pre-drought levels after subsequent wet periods. Implementation of monitoring and mitigation measures as set forth in GW-1 would avoid potential significant adverse environmental effects. Refer to Common Response 6 for a discussion of revisions to GW-1 in response to public comments.

Figure J-1. Historical Sacramento Valley Water Year Runoff and 40-30-30 Index Year Types

Wells going dry within the Sacramento Valley

Comments were received about wells going dry in the Sacramento Valley region, particularly in Butte County. Information on this point has been added in the discussion of Groundwater Resources Affected Environment. As shown in Table J-2 below, the number of wells reported dry in Butte County is substantially higher than in other counties within the area of analysis. (The action alternatives do not include groundwater substitution transfers in Butte County.) As discussed in Section 3.3.4.1, Mitigation Measure GW-1 will monitor groundwater levels during transfers of water made available from groundwater substitution actions to avoid potentially significant effects to other legal users of water. Refer to Common Response 6 for a discussion of revisions to Mitigation Measure GW-1 in response to public comments.

Table J-2. Summary of Dry Wells Reported in 2014

Counties	Number of wells reported dry in 2014	Information received as of
Shasta	3	9/16/2014
Tehama	34	10/2/2014
Glenn	26	10/23/2014
Butte	60	12/4/2014
Colusa	8	7/7/2014
Sutter	Data not available	Data not available
Yuba	Data not available	Data not available
Solano	1	11/12/2014
Yolo	2*	10/21/2014
Sacramento	1	10/16/2014

*Number of dry wells reported includes data only for October; data for prior months not reported

Concerns regarding pumping in the Tuscan Formation

Commenters expressed concerns that transfer-related pumping would be concentrated in the Tuscan Formation. As shown in Figure J-2, groundwater substitution pumping associated with the range of potential activities analyzed under the Proposed Action would occur primarily outside the Tuscan formation, either from the Tehama Formation or other formations not identified in Figure J-2. Some of the groundwater substitution pumping wells for Glenn-Colusa Irrigation District, Reclamation District 1004, and Butte Water District lie within (or near) the potentially disputed Tuscan and Tehama subsurface formations. Pumping from these wells will be closely monitored through the implementation of Mitigation Measure GW-1 to avoid potentially adverse effects. Refer to Common Response 6 for a discussion of revisions to Mitigation Measure GW-1 in response to public comments.

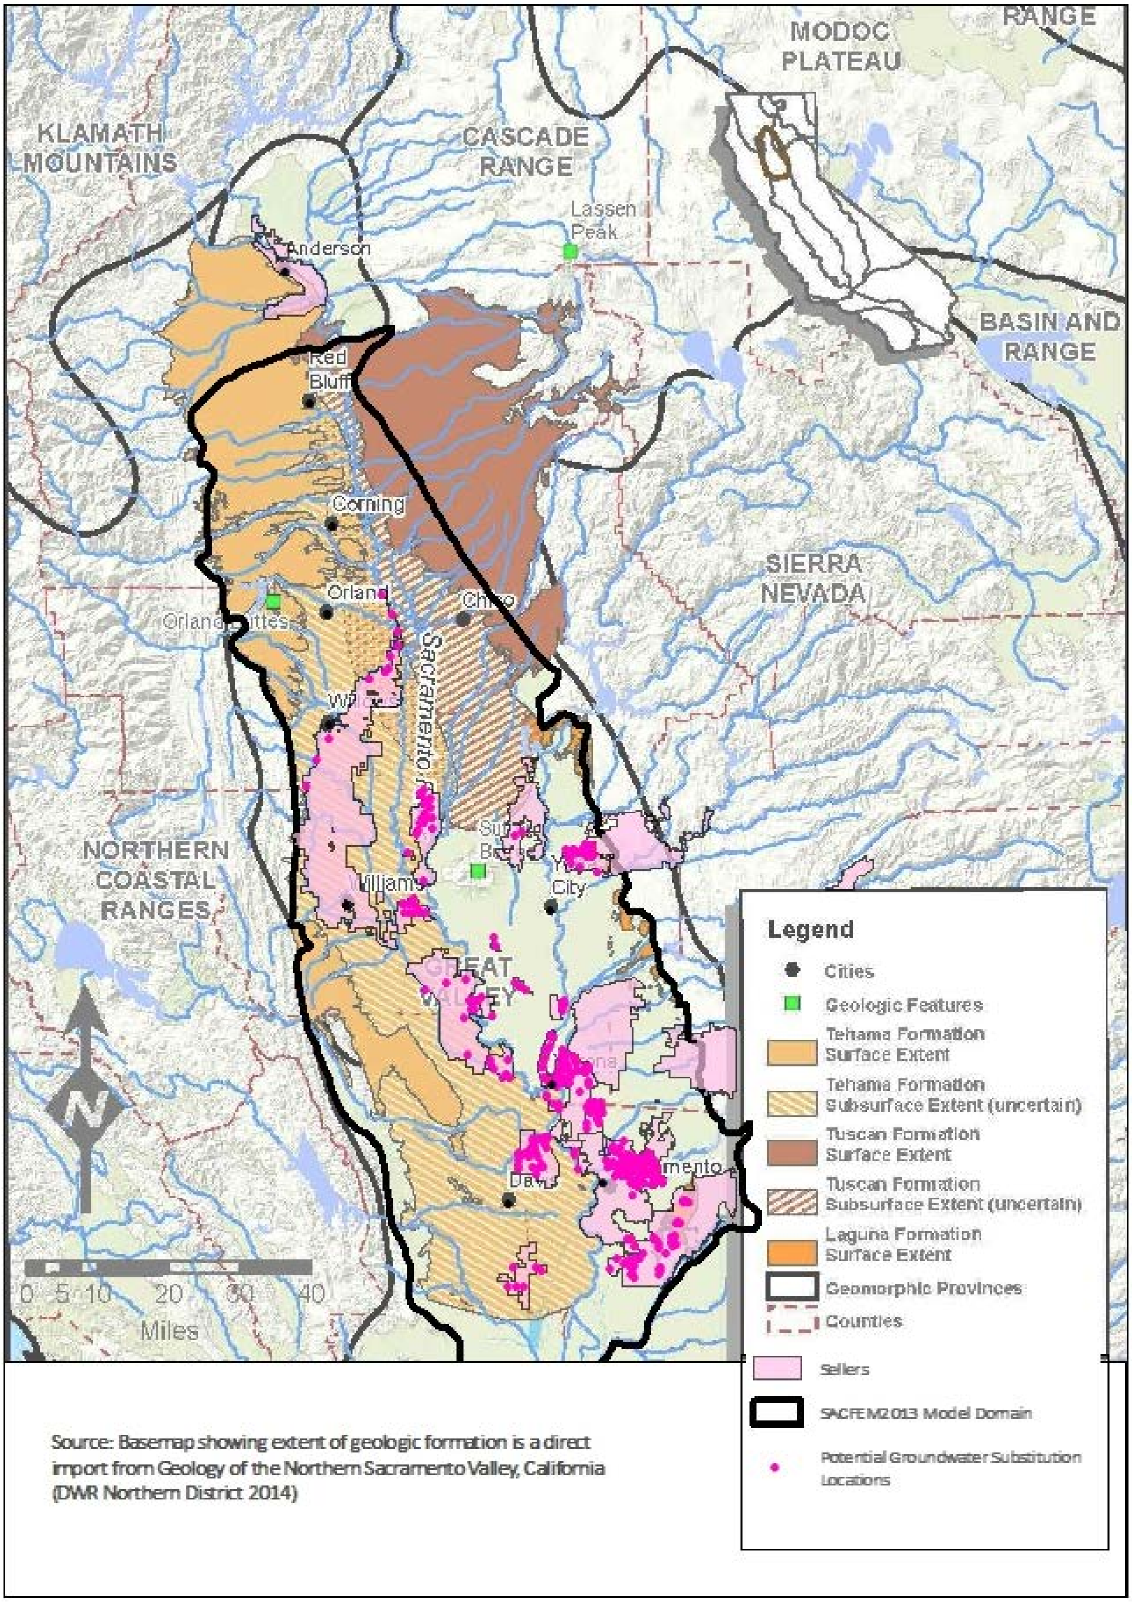

Figure J-2. Extent of Tuscan and Tehama Formations with respect to groundwater substitution pumping under Proposed Action

Common Response 5: Model Timeframe

Comments were received on the period of analysis for the various models used to analyze the environmental effects of transfers. The period of analysis for the Sacramento Valley Finite Element Groundwater Model (SACFEM2013), CalSim II, and the Transfer Operations Model (TOM) was water years (WY) 1970 through 2003. This period was used because it is common to both SACFEM2013 and CalSim II. The full simulation period for SACFEM2013 is WY 1970 through 2010 while the full simulation period for CalSim II is WY 1922 through 2003. TOM was developed, and the analysis conducted, for the common 34-year period of WY 1970 through 2003.

Several commenters asserted that the period was inadequate because it ended in 2003 and did not include the most recent 11 years when (1) the hydrology in the Sacramento Valley was drier than average, (2) hydrological factors were potentially affected by climate change, and (3) there were frequent transfers. Other comments focused on the changes that have occurred in population, water demand, regulations, and CVP and SWP operations since 2003. Each of these concerns is addressed in the following paragraphs.

Recent hydrology was drier than average

Sacramento Valley hydrology has been drier than average since 2003. Figure J-1 shows the observed Sacramento Valley river runoff in millions of acre-feet (MAF) for the complete available record, as calculated by DWR. Runoff illustrated in this figure is the sum of the Sacramento River at Bend Bridge, the Feather River inflow to Lake Oroville, the Yuba River at Smartville, and the American River inflow to Folsom Lake. Runoff is used to calculate the Sacramento Valley Water Year Type Index (40-30-30 Index) to define the year type as either wet, above normal, below normal, dry, or critical. The water year runoff of these four rivers provides a good indicator of the range and variability of the hydrology of the Sacramento Valley.

Additional information illustrated in Figure J-1 includes years in the historical record that were classified as “Shasta Critical” per the definition contained in Sacramento River Settlement Contracts. These years are identified in the figure because in such years the availability of surface water for many areas in the Sacramento Valley is further limited, beyond that in other critical years. The period of analysis used to support the EIS/EIR is shaded.

The long-term average annual runoff from these four rivers is approximately 17.8 MAF. The average annual runoff for the period 2004 through 2014 is 15.7 MAF, while the average annual runoff for the period of analysis is 18.6 MAF. While it is true that the period from 2004 through 2014 has been drier than both the long-term average and the average for the period of analysis, this does not invalidate the analysis supporting the discussions in the environmental document. Hydrology in the period of analysis adequately represents the historical range and the variability that has occurred in the Sacramento Valley, and includes two multi-year droughts: 1976-77 and 1987-92. The drought of

1976-77 was more severe than any single year or 2-year period from 2004 through 2014, and the 1987-92 drought was more prolonged than any recent 6-year period.

Additionally, the EIS/EIR is intended to assess environmental conditions resulting from implementation of the range of potential transfer activities under the Proposed Action for a 10-year period. A key consideration, therefore, is whether there exists within the period of analysis any 10-year period that is representative of a reasonable worst-case condition for Sacramento Valley hydrology. Within the period of analysis, there are several 10-year periods that are considerably drier than the 2004 through 2014 period. For example, the average annual runoff for the 10-year period 1985 through 1994 is 12.7 MAF. This is comparable to the minimum average annual runoff, 12.3 MAF in 1928 through 1937, for any 10-year period in the available record. The analysis includes a period similar to the driest 10 years on record, and drier than the period from 2004 through 2014.

Climate change

Some commenters suggested that not including the most recent 11-year period ignored the effects of climate change that have occurred since 2003, and will occur over the life of the project. Based on a review of the historical hydrology for the Sacramento Valley, any climate change effects that may have occurred since 2003 are difficult to discern within the historical variability. The most recent 11-year period is not outside the range of the historical record or the period analyzed in the EIS/EIR. While it is possible that the next 10 years may become the driest on record, potentially influenced to some unknown extent by climate change, it would be speculative to develop hydrology for the 2015 through 2024 period as a series of 10 consecutive critical years based on potential climate change or as a worst-case condition. Additionally, the mitigation measure to protect groundwater resources (Mitigation Measure GW-1) was developed to avoid or reduce impacts based on actual conditions at the time of transfer rather than predicted conditions from the modeling effort. If climate change does result in different conditions in the next ten years, Mitigation Measure GW-1 would continue to protect the resource (but may require reduced pumping or other actions to reduce effects more often).

Transfer frequency

Comments were received asserting the Lead Agencies did not analyze transfers occurring at the same frequency as they occurred in recent years. These comments compared the average frequency of transfers throughout the entire simulation period to shorter periods in the recent past. Commenters suggested that the frequency of transfers analyzed was approximately 36 percent of all years, or 12 out of 33 years analyzed. This frequency was compared to transfers in more recent years. However, because the EIS/EIR is intended to assess environmental conditions resulting from implementation of the range of potential transfer activities under the Proposed Action for a 10-year period, a more appropriate comparison is to look at the frequency of transfers analyzed over specific 10-year periods. For example, analysis for the period 1987 through 1994 included transfers in seven out of eight years, including transfers in six consecutive years, which is similar to what has occurred in recent years. The frequency and volume of transfers were determined based on assumptions for three primary factors that limit transfers: demand for transfer water, supply of transfer water, and capacity to convey transfer water from seller to buyer.

Changes in demands, regulations, and operations since 2003

Commenters also suggested that the period of analysis was inadequate because it does not represent existing demands, regulations, and CVP/SWP operations. On this issue there were differences in the understanding of model inputs and assumptions across the range of commenters. Some commenters suggested the models (SACFEM2013 and CalSim II) operated under "historical" assumptions rather than reflecting current conditions (e.g., the demands, regulations, and operations of the model in a particular year of simulation reflect what historically occurred). These included comments that modeling ignored the effects of biological opinions issued in 2008 and 2009 on the operation of the CVP/SWP. Other commenters suggested that the level of demand assumed in CalSim II and SACFEM2013 was not appropriate because demands have changed since model demands were developed.

Both CalSim II and SACFEM2013 simulate demands that are developed to approximate a fixed level of development. CalSim II demands approximate a 2005 level of development while demands in SACFEM2013 approximate a 2010 level of development. This means that population, land use, and agricultural demands used in the models are representative of demands that existed in those years. These demands are then used with historical hydrology inputs, primarily precipitation, reservoir inflows, and unregulated flows, in model simulations. Therefore, demands simulated for WY 1970 in the models are representative of approximately 2005 and 2010 levels of development, not 1970.

Actual demand for water within the Sacramento Valley changes every year based on numerous factors. Since 2005, demand on water supplies, and particularly demands on groundwater, have likely increased. The most significant demand changes in the Sacramento Valley since 2005 include development of additional irrigated lands, particularly in permanent crops, and increases in population. Both of these changes primarily affect groundwater resources as new irrigated lands and many municipalities meet their demands using groundwater. Therefore, it is more important that these changes be considered in SACFEM2013 than in CalSim II. Demands in SACFEM2013 are based on land use data and surveys taken as recently as 2010 (see Appendix M for more information). These land use surveys show an increase in permanent crops and a slight increase in the total irrigated acreage. Additionally, recently developed agricultural lands are in areas outside of existing water districts and away from surface water sources where groundwater is the only source of water. This information is incorporated in SACFEM2013 by combining recent land use surveys with the historical precipitation record to develop demands that vary in each year of the simulation, with higher demands for groundwater in drier years. While there have been changes in demand since 2010, the range of demands simulated in SACFEM2013 is representative of existing conditions in the Sacramento Valley.

Sacramento Valley agricultural demands in CalSim II approximate a 2005 level of development and vary in each year of the simulation. The focus of CalSim II is simulation of the surface water system and operations of the CVP and SWP. Demands for surface water within the Sacramento Valley have been relatively stable since 2005. This can be seen through review of Reclamation delivery data to Sacramento River Settlement Contractors, other water service contractors, and diversion data from other river systems. The majority of surface water demands and the associated water rights and contracts were developed many decades ago and have been stable over the most recent decade.

The regulatory constraints on CVP and SWP operations have changed significantly since 2005 and CalSim II modeling used in preparation of the EIS/EIR was modified to reflect these changes. The most notable change since 2005 was the incorporation of the reasonable and prudent alternatives contained in the U.S. Fish and Wildlife Service's 2008 biological opinion on Delta smelt and the National Marine Fisheries Service's 2009 biological opinion on Chinook salmon and other species. The regulatory constraints described in these biological opinions are included in the CalSim II simulation of existing CVP and SWP operations. CalSim II simulates the current regulatory conditions and a fixed level of development demand as the existing condition, and uses the historical hydrology for the period 1922 through 2003 to help understand CVP/SWP operations under a range of hydrologic conditions.

Common Response 6: Groundwater Mitigation

Commenters indicated they would like more specificity in the required groundwater monitoring and mitigation in Mitigation Measure GW-1. In particular, they wanted to understand the monitoring triggers that would cause mitigation actions in the Mitigation Plans to go into effect.

The primary triggers used to establish impacts to groundwater levels are the Basin Management Objectives (BMOs) set by Groundwater Management Plans (GMPs). In the Sacramento Valley, several counties have established GMPs to provide guidance in managing the resource. While the GMPs aid in establishing best practices, not all of the GMPs set quantitative groundwater elevation triggers for their BMOs. Table J-3 lists the counties in the Sacramento Valley with existing GMPs. The table also provides a description of the BMOs as described in each GMP. This list is provided for the entire Sacramento Valley; however, in addition to listing counties that contain potential groundwater substitution pumping sellers, the list also contains counties that do not (e.g., Butte).

Table J-3. Groundwater Management Plans and BMOs in the Sacramento Valley

County	Basin Management Plan	Groundwater Basin Management Objective
Shasta (Anderson Cottonwood Irrigation District Groundwater Management Plan)	http://www.andersoncottonwoodirrigationdistrict.org/uploads/2/7/2/8/2728665/acid_gwmp.pdf	Pg. 3-2: No set elevation thresholds.
Shasta County (Shasta County Water Agency)	http://www.co.shasta.ca.us/index/pw_index/engineering/water_agency.aspx	No elevation thresholds.
Tehama County (Tehama County Flood Control and Water Conservation District)	http://www.tehamacountypublicworks.ca.gov/Flood/ Groundwater trigger levels for each sub-basin located here: http://www.tehamacountypublicworks.ca.gov/Flood/groundwater.htm	Trigger levels vary based on groundwater measurements in each monitoring well. Trigger levels generally follow a pattern of: • Historical low of spring measurements plus 20% of the range of spring measurements: notify and inform public. • Second consecutive year of groundwater levels at or below spring trigger level 1: monitor and investigate cause. • Historical low of spring measurements: consider management options. • Historical low of late groundwater measurements: notify public and begin investigations.
Glenn County	http://www.glenncountywater.org/documents/GlennCoBMOdocument_000.pdf	There are 17 basin management sub-areas in the basin. BMOs for groundwater levels are established separately for each sub-area. No clear BMOs have yet been established. Objectives for the sub-areas are qualitative and relate to maintaining groundwater surface elevations at a level that will assure an adequate and affordable irrigation water supply; sustainable agricultural water supply; and adequate groundwater supply for all domestic users. Additionally, some BMOs state that the objective is to develop an understanding of groundwater levels in the sub-area. Elevation thresholds vary depending on the sub-area and monitoring well within each sub-area.
Butte County	http://www.buttecounty.net/Portals/26/GWMP/Section_3__1-7-05_2.pdf	Pg. 3-4: Groundwater level declines in many areas of the county have been observed. These range from 0.8 to 2.0 feet per year. Declining groundwater levels are used as a trigger for close observation of groundwater level trends.
Colusa County	http://colusagroundwater.ucdavis.edu/Technical%20Materials%20for%20Posting/ColusaCo_GMP_Volume-1_9-10-08.pdf	Pg. 34: From a review of the groundwater level hydrographs on Figure II.5, it can be seen that the extent to which the groundwater basin is utilized throughout the County varies significantly. Accordingly, the assessment of changes in groundwater levels in the respective areas must be performed with full consideration of the historic levels. It is premature to attempt to set groundwater level targets or thresholds in Colusa County. It is, however, very important to evaluate the groundwater level data in relation to historic data and report the results of that evaluation together with an assessment of overall hydrologic conditions, known changes in land use, etc.

County	Basin Management Plan	Groundwater Basin Management Objective
Sutter County	http://www.co.sutter.ca.us/pdf/pw/wr/gmp/Sutter_County_Final_GMP_20120319.pdf	There are three BMOs for groundwater levels. One is related to low groundwater levels: • Avoid ongoing declines in groundwater levels during water year types identified by DWR to be "above normal" or "wet" for the Sacramento Valley. The BMO also states "groundwater levels are to be managed to ensure adequate water supplies while avoiding adverse impacts and mitigating them if and when they do occur. Adverse impacts related to groundwater levels can occur from excessively high or low groundwater levels. What constitutes an excessively high or low groundwater level may change over time, and will also vary by land use and hydrologic and climatic conditions.
Yuba County Water Agency	http://www.ycwa.com/documents/943	Pg. 3-12: No specific threshold. Qualitative objectives: • Avoid potential unreasonable impacts that may occur from changes in groundwater surface elevations because of external transfers. • Monitor any lowering of groundwater surface elevations that may occur as a result of groundwater extraction to meet local demands in drier years.
Nevada County (Martis Valley Groundwater Management Plan)	http://www.pcwa.net/files/docs/enviro/MartisValleyGMPFinal07.22.2013.pdf	Very general BMO about protecting groundwater quantity. Plan includes details on the establishment of a groundwater elevation monitoring program.
Placer County Water Agency (Western Placer County Groundwater Management Plan)	http://www.pcwa.net/general-information/environmental-and-planning-documents.html and http://www.pcwa.net/files/docs/enviro/WPCGMP_Groundwater_Management_Plan_07.pdf	Pg. 3-8: discusses the need to create a uniform groundwater elevation monitoring program. No thresholds are set because, historically, data have not been collected consistently.
El Dorado County	No plan available.	
Sacramento Groundwater Authority	http://www.sgah2o.org/sga/files/2008-SGA-GMP-FINAL-20090206-print_ready.pdf	Pg. 29: "SGA members intend that overall groundwater elevations in the basin be improved over time, and that the groundwater basin be managed such that the impacts during drier years will be minimized when surface water supplies are curtailed and are replaced by increased groundwater supplies. This is accomplished, similar to what is done in the Central Sacramento Basin, by measuring groundwater levels in more than 30 wells throughout the SGA. A similar 5 square mile grid pattern is used to monitor groundwater levels over time throughout the basin. SGA monitors groundwater elevations twice a year.

County	Basin Management Plan	Groundwater Basin Management Objective
Central Sacramento County	http://www.amwater.com/files/CSCGMP_final.pdf	Pg. 3-3: An operating range for groundwater elevations in the basin defines the upper and lower groundwater elevation thresholds. Upper and lower elevation limits are defined for 5 square mile polygons throughout the basin. Each polygon represents its own management unit with lower and upper elevation attributes. Groundwater elevation contour maps are found on pages 3-4 and 3-5 of the plan. Lower groundwater thresholds range from -90 feet msl in the southwestern part of the basin to 150 feet msl in the northeastern part of the basin. Upper groundwater thresholds range from -70 feet msl in the southwestern part of the basin to 200 feet msl in the northeastern part of the basin.
South Area Water Council	http://www.water.ca.gov/groundwater/docs/GWMP/SJ-20_SouthBasin_GWMP_2011.pdf	Similar to the Sacramento Groundwater Authority and Central Sacramento County, the South Area Water Council's groundwater management plan uses several wells throughout the basin to gather groundwater elevation data and high/low thresholds would be based on individual wells. The BMO, on p. 2-2, states generally: Maintain or enhance groundwater elevations to meet the long-term needs of groundwater users within the Groundwater Management Area.
Yolo County	http://www.water.ca.gov/groundwater/docs/GWMP/SR-35_YoloCountyFCWCD_GWMP_2006.pdf	p. 12: "when ¾ of monitoring wells reach within 25% of the lowest water level recorded for that well. Spring and fall measurements will be analyzed separately."

In areas where quantitative BMOs do not exist, Reclamation, SLDMWA, and the potential seller(s) will coordinate closely with potentially affected third parties to collect and monitor groundwater data. If warranted, additional groundwater level monitoring to address concerns from third parties will be incorporated in the monitoring and mitigation plans required by Mitigation Measure GW-1. The monitoring plan, which must be reviewed and approved by Reclamation, includes the seller's plan to monitor groundwater levels to avoid any potentially significant impacts that may result from the proposed transfer. If a third party has a concern that warrants the inclusion of additional monitoring, Reclamation and the seller will adjust the plan to address the concern.

Common Response 7: Subsidence

Commenters expressed concern that utilizing groundwater in lieu of the surface water made available for transfer from groundwater substitution actions could cause subsidence, and the mitigation measures should be clarified to be certain they would reduce or avoid this subsidence. While Section 3.3 of the EIS/EIR addresses the potential for subsidence to the degree reasonable and appropriate based on available data, the lead agencies recognize that in many areas of the Sacramento Valley the potential for subsidence remains unclear. While monitoring efforts may not have detected historic subsidence, the potential exists for future subsidence. This uncertainty has caused the lead agencies to develop a process to help clarify how mitigation to avoid significant subsidence impacts would be implemented. This process requires monitoring for subsidence and identifies a multi-stage process to help address the uncertainty in the potential effects.

Stage 1: Groundwater Levels

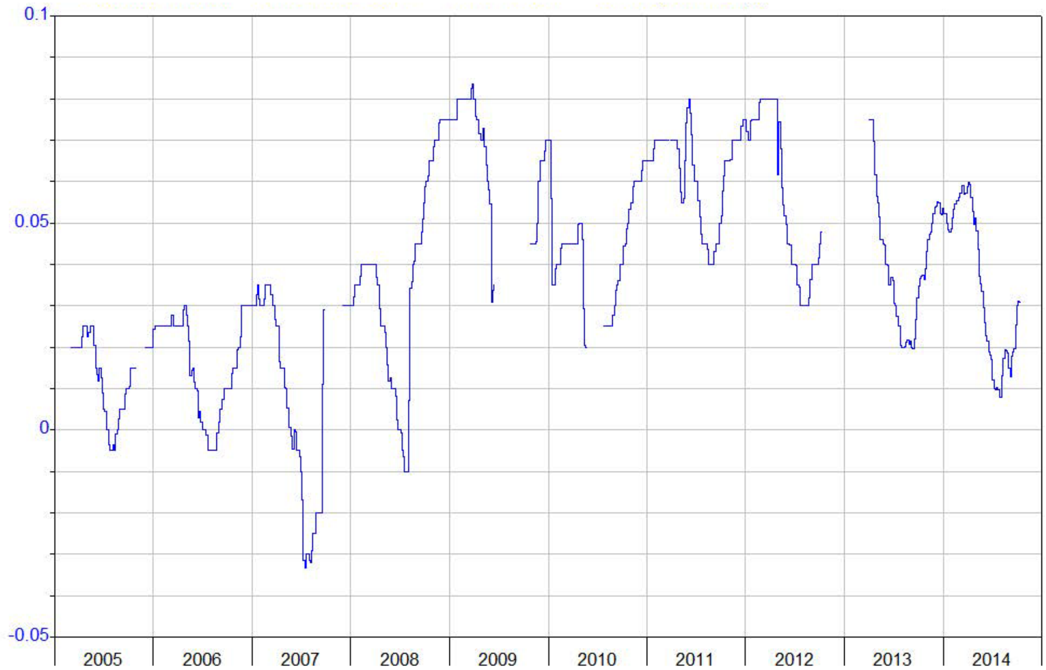
Irreversible subsidence would not occur if groundwater levels stay above historic low levels for the entire transfer period. As groundwater is pumped from an aquifer, the pore water pressure in the aquifer is reduced. This reduction in pore water pressure increases the effective stress on the structure of the aquifer itself. This increase in effective stress can cause the aquifer structure to deform, or compress, resulting in the subsidence of the ground surface elevation. Subsidence can be irreversible if the reduced effective stress is lower than the historically low effective stress. Typically this would be the result of groundwater levels reaching levels lower than the historical low level.

Before a transfer, each seller will examine local groundwater conditions and groundwater level changes based on past pumping events or groundwater substitution transfers. This existing information will be the basis to estimate if groundwater levels are likely to decline below historic low levels as a result of the proposed transfer. If the pre-transfer assessment indicates that groundwater levels will stay above historic low levels, and this finding is confirmed by monitoring during the transfer-related pumping period, then no additional actions for subsidence monitoring or mitigation are necessary. Sellers would need to proceed to stage 2 for land surface elevation monitoring if the pre-transfer estimates indicate that groundwater levels are anticipated to decline below historic low levels. If monitoring during the transfer-related pumping period (confirmed by two measurements within seven days) indicates that groundwater levels have fallen below historic low levels, sellers must immediately stop pumping from transfer wells in the area that is affected or proceed to stage 2.

Stage 2: Ground Surface Elevations

Stage 2 includes monthly ground surface monitoring during transfer-related pumping if pumping could cause groundwater levels to fall below historic low levels, as described in Stage 1. If ground surface elevations decrease between 0.1 and 0.2 foot, the seller will evaluate the accuracy of the information based on the current limitations of technology, professional engineering/surveying judgment, and any other data available in or near the transferring area. If the elevations decline more than 0.2 foot, this change could indicate inelastic subsidence, which would trigger a shift to Stage 3.

The threshold of 0.1 foot was chosen as this value is typical of the elastic (i.e., recoverable) portion of subsidence; the threshold of 0.2 foot was selected considering limitations of current land survey technology. This threshold is supported by a review of data from extensometers within the Sacramento Valley. Figure J-3 shows the subsidence data from extensometer 22N02W15C002M, in Glenn County. This extensometer has not been identified as having long-term declining trends, but exhibits a small amount of movement (up to about 0.1 foot).



Source: DWR Water Data Library 2014

Figure J-3. Measured Ground Surface Displacement at Extensometer 22N02W15C002M in Glenn County

Stage 3: Local Investigation

If the threshold of 0.2 foot of ground surface elevation change is exceeded, the seller shall cease groundwater substitution pumping for the transfer until one of the following occurs: (1) groundwater levels recover above historic low groundwater levels; (2) seller completes a more detailed local investigation identifying hydrogeologic conditions that could potentially allow continued transfer-related pumping from a subset of wells (if the seller can provide evidence that this pumping is not expected to cause additional subsidence); or (3) seller completes an investigation of local infrastructure that could be affected by subsidence (such as water delivery infrastructure, water supply facilities, flood protection facilities, highways, etc.) indicating the local threshold of subsidence that could be experienced before these facilities would be adversely affected. Any option should also consider the effect of non-transfer pumping that may be causing subsidence.

Stage 4: Mitigation

If subsidence effects to local infrastructure occur despite monitoring efforts, then the sellers must work with the lead agencies to determine whether the measured subsidence may be caused by transfer-related pumping. Any significant adverse subsidence effects caused by transfer pumping activities must be addressed. A contingency plan must be developed in the event that a need for further corrective action is necessary. This contingency plan must be approved by Reclamation before transfer-related pumping could continue after Stage 3.

Stage 5: Continued Monitoring

The sellers will continue to monitor for subsidence while groundwater levels remain below historic low levels. If the seller has ceased transfer-related pumping but groundwater levels remain below historic lows, subsidence monitoring will need to continue until the spring following the transfer. The results of subsidence monitoring will be factored into monitoring and mitigation plans for future transfers.

Common Response 8: Streamflow Depletion Factor

Commenters had questions about the streamflow depletion factor described in Mitigation Measure WS-1. Some of the comments reflected confusion about the purpose of this mitigation measure. These commenters indicated that Mitigation Measure WS-1 should help with potential streamflow depletion impacts to small streams and their biological resources. This mitigation measure, however, is specific to CVP and SWP water supplies. Section 3.1, Water Supply, assessed the potential impacts from streamflow depletion to surface water supplies. The assessment found that Reclamation and DWR would take actions to continue to meet water quality and flow standards during and after water transfers, and these actions would result in decreased water supply deliveries to CVP and SWP contractors that receive Delta exports. Supply impacts to other users in the Sacramento Valley were not identified. Mitigation Measure WS-1 is focused on avoiding the supply effects to CVP and SWP contractors that receive Delta exports. Section 3.7 analyzed streamflow depletion impacts to fisheries, and determined that the changes in flows on small creeks and streams would be small and would not be at times or locations that would have significant effects on sensitive fish species. Section 3.8 assessed streamflow depletion impacts on riparian vegetation, and found the potential for significant impacts. These potential impacts would be reduced through the groundwater monitoring and mitigation requirements in Mitigation Measure GW-1.

Specific questions and comments are discussed below in more detail.

Process to develop the streamflow depletion factor

Several commenters wanted to better understand the process to develop and enforce the streamflow depletion factor. Reclamation and DWR will develop the streamflow depletion factor in cooperation with buyers and sellers, based on the best available technical information. The process will be generally similar to the process used in past years to develop the Draft Technical Information for Preparing Water Transfer Proposals (also known as the Water Transfer White Paper). As part of this process, Reclamation and DWR identify new information, consider monitoring information from past transfers, and edit the Water Transfer White Paper.

Reclamation and DWR have established regular meetings throughout the year to review transfer proposals and assess how ongoing transfers are working. Any changes or updates to streamflow depletion factors for future water transfers would work within this existing interagency structure. This group receives monitoring data from transfers and feedback from the CVP and SWP operators throughout the year, and can identify when new information is available and when updates to the streamflow depletion factor would be appropriate. They would raise this issue to management levels at both organizations.

At this point, Reclamation and DWR would work with the buyers and sellers to review the most recent monitoring or modeling information to identify potential refinements to the streamflow depletion factor. The resulting refinements would be published in an update to the technical information papers on DWR's water transfer website.

Monitoring and modeling

Commenters asked what type of monitoring and modeling would be used to update the streamflow depletion factor. Mitigation Measure GW-1 requires extensive groundwater monitoring for groundwater substitution transfers under the action alternatives. In addition to this transfer-specific monitoring, Reclamation, DWR, and other state and federal agencies monitor streamflows throughout the Sacramento Valley.

During development of this EIS/EIR, the lead agencies updated the SACFEM2013 groundwater model and applied this model to assess the action alternatives. This model could be used in the future to investigate whether monitoring information is consistent with the projected changes to the groundwater aquifer, or whether the modeling parameters should be modified based on monitoring. Additionally, the SACFEM2013 model includes some uncertainties about hydraulic properties that could be clarified through monitoring efforts. The lead agencies are planning to work with the sellers to solicit grant funds to obtain additional information about key hydraulic factors related to groundwater/surface water interaction. If this monitoring information becomes available, it would be used to update the groundwater model and may lead to modifications to the streamflow depletion factor.

Timing

The EIS/EIR explained in multiple places that groundwater utilized in lieu of the surface water made available from groundwater substitution actions could affect groundwater levels and recharge for multiple years after a transfer. Commenters wanted to understand how the streamflow depletion factor could mitigate for transfer-related streamflow effects in years following transfers. Additionally, commenters mentioned that if water is "backed up" into storage before it can be moved through the Delta, the groundwater pumped in lieu of diverting the surface water could cause streamflow effects before the transfer occurs, which should also be addressed through the streamflow depletion factor.

As discussed at the beginning of this common response, the streamflow depletion factor is focused on mitigating impacts to CVP and SWP water users. The impacts disclosed in Section 3.1 consider the impacts to supplies from when pumping begins until the groundwater aquifer recovers. The streamflow depletion factor equates to a percentage of the total groundwater substitution transfer that will not be available for transfer to the transferee, and is intended to offset the streamflow effects of the added groundwater pumping due to transfer. This percentage would account for supply impacts in transfer years and years following transfers. The CVP and SWP would be responsible for using this retained water to account for current and future supply impacts.

Size of the streamflow depletion factor

Several commenters wanted to know more about the specific percentage for the streamflow depletion factor. Specifically, several commenters asked if the percentage would stay the same, and what a minimum percentage would be. The streamflow depletion percentage could vary based on monitoring and modeling data.

The analysis for Mitigation Measure WS-1, to address potential streamflow depletion effects on CVP and SWP water supplies, identified several issues relevant to development of a streamflow depletion factor. Analysis indicates that the effect of groundwater substitution transfers on CVP/SWP water supplies varies depending on hydrology and system conditions after the transfer. For example, when the post-transfer hydrology is dry the effect on CVP/SWP water supply can be greater than when the post-transfer hydrology is wet. This difference in the effect can generally be explained by the fact that during drier conditions the Delta is more likely to be in balance; therefore, streamflow depletions are more likely to affect CVP/SWP water supplies. Additionally, sensitivity analyses were conducted to better understand how uncertainty in key model inputs, those inputs that are likely to have the largest effect on streamflow depletion, may affect the streamflow depletion factor. Results of these analyses indicate that the minimum streamflow depletion factor for the purpose of Mitigation Measure WS-1 is approximately 13 percent of the volume pumped as a groundwater substitution transfer. This minimum streamflow depletion percentage has been added to the text of Mitigation Measure WS-1 to help clarify the measure.

Public Involvement

Commenters asked if the public would have a chance to comment if the streamflow depletion factor changes in the future. Reclamation and DWR would consider public feedback when identifying if refinements to the streamflow depletion factor are necessary, including any potential third party concerns. The Water Transfer White Paper is reviewed annually and updated as needed; new versions are published in draft form on DWR's water transfer website.

Common Response 9: Refuge Water Supplies

Some commenters questioned Reclamation's ability to meet requirements to provide Level 4 (Level 2 [L2] and Incremental Level 4 [IL4]) water supplies as stipulated under the Central Valley Project Improvement Act (CVPIA) and were concerned about possible adverse effects on refuge habitat if Reclamation were unable to comply. Reclamation is committed to meeting their requirements to work with U.S. Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife (CDFW), and the Grassland Water District/Grassland Resource Conservation District to attempt to provide Level 4 water when possible.

Inclusion of refuge transfers in action alternatives

Several commenters suggested that the action alternatives should include transfers to refuges. Reclamation, however, views refuge-related water purchases and transfers as a separate federal action having independent utility from all other potential voluntary water transfers. For such refuge water transfers, Reclamation (as a "willing buyer"), in cooperation with willing sellers, negotiates and develops agreements to purchase water for transfer to CVPIA refuges and prepares the associated National Environmental Policy Act/Endangered Species Act (NEPA/ESA) environmental compliance documents, as applicable.

For the range of potential water transfers evaluated under the Long-Term Water Transfers EIS/EIR, Reclamation's federal action would be to approve and facilitate transfers initiated by non-governmental buyers and sellers. This difference is not a sign of a difference in priority, but rather a difference in the type of federal action taken by Reclamation.

Pumping priority through the Delta

Commenters expressed concern that refuge north-to-south water transfers may have a lower priority for conveyance through the Delta than water transfers under the action alternatives, which could decrease the amount of water received. Before Reclamation can facilitate water transfers, it must first provide CVP water to meet all regulatory requirements mandated by the State Water Resources Control Board (Delta flow and water quality standards), CVPIA (specifically the "(b)(2) water" and refuge L2 water), and the Reasonable and Prudent Alternative actions listed in the USFWS's (2008) and National Oceanic and Atmospheric Administration (NOAA) Fisheries' (2009) respective Biological Opinions on the Coordinated Operations of the CVP and SWP. Reclamation must then meet its contractual obligations to CVP agricultural and municipal and industrial (M&I) water service contractors. If all these requirements are satisfied and excess pumping capacity is available, only then will Reclamation facilitate potential north-to-south water transfers. Water transfers under this EIS/EIR cannot affect Reclamation's ability to deliver allocated CVP L2 water to refuges.

Table J-4 shows Reclamation's refuge related water transfers ("re-allocation" regarding L2 supplies) from 2009 through 2013. Most of these transfers do not need to be moved through the Delta. Merced Irrigation District (ID) is one exception, but Merced ID has multiple means of delivering transferred water and it does not need to be conveyed through the Delta (see Section 2.3.2.3 of the EIS/EIR for more information). Additionally, Reclamation has permanently purchased water from Corning, Thames, and Proberta Water Districts (WDs) that is moved through the Delta in some years; however, this water is more frequently used for refuges in the Sacramento Valley and is not conveyed through the Delta. Because the Level 4 refuge transfers typically do not rely on through-Delta conveyance, the action alternatives are not expected to affect the potential for refuges to receive these supplies.

Table J-4. Refuge Transferred Water Supplies, 2009-2013

Seller	Water Transferred (AF)[1]	Notes
WY 2013		
Corning, Thames, and Proberta WDs	3,308	Permanently purchased NOD IL4 water transferred to the Kern NWR SOD
SJRECWA	19,500	Purchased IL4
Merced ID	7,256	Purchased for the East Bear Creek Unit of the San Luis NWR Complex as L2, then exchanged to meet SOD IL4 demands
WY 2012		
SJRECWA	25,000	Purchased IL4
Santa Clara Valley WD	10,000	Purchased IL4
Merced ID	3,480	Purchased for the East Bear Creek Unit of the San Luis NWR Complex as L2, then exchanged to meet SOD IL4 demands
WY 2011		
SJRECWA	50,333	Purchased IL4
Panoche WD	4,250	Purchased IL4
San Luis WD	5,000	Purchased IL4
Santa Clara Valley WD	10,000	Purchased IL4
Merced ID	1,627	Purchased for the East Bear Creek Unit of the San Luis NWR Complex as L2, then exchanged to meet SOD IL4 demands
East Side Canal and Irrigation Company	3,291	Purchased as L2, then exchanged to meet IL4 demands
WY 2010		
Corning, Thames, and Proberta WDs and Sacramento Valley NWR Complex	4,506	Permanently purchased NOD IL4 water and reallocated NOD conserved L2 water delivered to Kern NWR and GRCD

Seller	Water Transferred (AF)[1]	Notes
SJRECWA	35,714	Purchased IL4
Kern-Tulare WD	7,000	Purchased IL4
Panoche WD	10,000	Purchased IL4
Merced ID	500	Purchased for the East Bear Creek Unit of the San Luis NWR Complex as L2, then exchanged to meet SOD IL4 demands
Stevinson WD	4,080	Purchased for the East Bear Creek Unit of the San Luis NWR Complex as L2, then exchanged to meet SOD IL4 demands
WY 2009		
Sacramento Valley NWR Complex	5,342	NOD Conserved L2 water delivered to Kern NWR and the GCRD
SJRECWA	18,687	Purchased IL4
Stevinson WD	4,280	Purchased as L2, then exchanged to meet IL4 demands

Key:
AF – Acre-feet, GRCD – Grasslands Resource Conservation District, ID – Irrigation District, IL4 – Incremental Level 4, L2 – Level 2, NOD – North of Delta, NWR – National Wildlife Refuge, SJRECWA – San Joaquin River Exchange Contractors Water Authority, SOD – South of Delta, WD – Water District, WY – Water Year
Note 1: Gross amount of transferred water (IL4) and re-allocated L2. Conveyance losses from source to destination were incurred and are not represented here; therefore, the amount total does not reflect the amount delivered to the refuges.

Ongoing shortages in Incremental Level 4 water supplies

Commenters expressed concern that IL4 water supplies have not been met in recent years. Reclamation is committed to providing refuge water supplies, and is working to meet that objective through efforts independent of the water transfer activities evaluated in this EIS/EIR. As discussed above, Reclamation purchases for refuge water supplies are wholly separate actions implemented by Reclamation and are not part of the purpose and need/project objectives for the range of potential water transfer activities evaluated in this EIS/EIR.

Potential to affect northern California refuges

Commenters mentioned the potential for water transfers to affect northern California refuges, either through decreased groundwater levels or by affecting forage areas for wildlife that lives in the refuge. These potential effects are analyzed in Section 3.8. The analysis finds that groundwater substitution transfers would not likely have significant effects on refuge areas, but Mitigation Measure GW-1 has been clarified (see Common Responses 6, 7, and 10) to further ensure that such potential effects are avoided.

Increased transfer costs

Several commenters discussed the action alternatives to cause increased demand for transfers, which could increase the price of transfers for the refuges. As shown in Table J-4, the sellers for Refuge IL4 supplies differ from those under the action alternatives. The exception is Merced ID, which is required to deliver water (L2 and IL4) to the Merced National Wildlife Refuge as a condition under its Federal Energy Regulatory Commission (FERC) permit.

Merced ID must fulfill this FERC provision before it could sell water to other buyers.

The range of potential transfers evaluated in this EIS/EIR would not affect the prices for the main source of water for refuge transfers. The single main seller of water supplies for refuge transfers is the San Joaquin River Exchange Contractors Water Authority (SJRECWA). The SJRECWA and Reclamation have negotiated a five-year contract for refuge water supplies, which is expected to be fully executed in Spring 2015, which includes quantities and prices. These quantities and prices have been negotiated, and the prices are independent of the potential future transfers evaluated in this document. In the past, five-year contracts have been extended for additional years, so the contract terms (including price) may stay in effect for longer than five years.

Cumulative impacts

Commenters suggested that refuge transfers should be included as a cumulative project. Most of the transfers under this EIS/EIR are from sellers concentrated in the Sacramento Valley, while most refuge transfers would be from sellers in the San Joaquin Valley. Therefore, most of the refuge transfers would not produce cumulative impacts in conjunction with the range of potential transfer activities associated with the action alternatives. Refuge transfers have been added as a cumulative project in Chapter 4.

Mitigation measures needed to protect refuges

Commenters suggested that mitigation measures are necessary to reduce perceived impacts to refuges, and these measures should include a portion of the transfer supply being delivered to refuges. The EIS/EIR analyzed potential impacts but did not identify significant impacts to refuges or the species that depend on them; therefore, mitigation was not necessary.

Common Response 10: Environmental Commitments/Mitigation Measures

The following revisions to certain environmental commitments and mitigation measures have been proposed in response to comments.

GW-1 (revised)

In section 3.3.4.1.2 Monitoring Program, the following text changes are proposed: (New text is shown as underlined; deleted text is shown as ~~strikethrough~~.)

Vegetation Effects

Sellers will monitor groundwater depth data to verify that significant adverse effects to deep-rooted vegetation are avoided or allow sellers to modify actions before significant effects occur. If monitoring data indicate that water levels have dropped below root zones (i.e., more than 10 feet where groundwater was 10 to 25 feet below ground surface prior to starting the transfer of surface water made available from groundwater substitution actions), the seller must implement actions set forth in the mitigation plan. If historic data show that groundwater elevations in the area of transfer have typically varied by more than this amount annually during the proposed transfer period, then the transfer may be allowed to proceed. If there is no deep-rooted vegetation (i.e., oak trees and riparian trees that would have tap roots greater than 10 feet deep) within one-half mile of the transfer wells or the vegetation is located along waterways that will continue to have water during the transfer, the transfer may be allowed to proceed. If no existing monitoring points exist in the shallow aquifer, monitoring would be based on visual observations of the health of these areas of deep-rooted vegetation. If significant adverse impacts to deep-rooted vegetation (that is, loss of a substantial percentage of the deep-rooted vegetation as determined by Reclamation based on site-specific circumstances in consultation with a qualified biologist) occur as a result of the transfer despite the monitoring efforts and implementation of the mitigation plan, the seller will prepare a report documenting the result of the restoration activity to plant, maintain, and monitor restoration of vegetation for 5 years to replace the losses.

GGS Measures (revised)

- As part of the approval process for long-term water transfers, Reclamation will have access to the land to verify how the water transfer is being made available and to verify that actions to protect the giant garter snake are being implemented. At the end of each water transfer year, Reclamation will prepare a monitoring report that contains the following:

  - Maps of all cropland idling actions that occurred within the range of potential transfer activities analyzed in this EIS/EIR,
  - Results of any newly available scientific research and monitoring results pertinent to water transfer actions, and
  - A discussion of conservation measure effectiveness.

  The report will be submitted to USFWS and shared with California Department of Fish and Wildlife (CDFW) in February, prior to the next year of potential transfers. Reclamation will coordinate with USFWS and CDFW on the contents and findings of the annual report prior to additional transfers.

- Reclamation will establish annual meetings with the Service to discuss the contents and findings of the annual report. These meetings will be scheduled following the distribution of the monitoring report and prior to the next transfer season.

- Reclamation will establish annual meetings with the Service to discuss the contents and findings of the annual report. These meetings will be scheduled following the distribution of the monitoring report and prior to the next transfer season.

- Reclamation will provide a map(s) to the USFWS in June of each year showing the parcels of riceland that are ~~idled~~ proposed for the purpose of transferring water for that year. These maps will be prepared to comport with Reclamation's geographic information system (GIS) standards.

- Movement corridors for aquatic species (including pond turtle and giant garter snake) include major irrigation and drainage canals. The water seller will keep adequate water in major irrigation and drainage canals. Canal water depths should be similar to years when transfers do not occur or, where information on existing water depths is limited, at least two feet of water will be considered sufficient.

- Districts proposing water transfers made available from idled rice fields will ensure that adequate water is available for giant garter snake priority habitat with a high likelihood of giant garter snake occurrence. The determination of priority habitat will be made through coordination with giant garter snake experts, GIS analysis of proximity to historic tule marsh, and GIS analysis of suitable habitat. The priority habitat areas are indicated on the priority habitat maps for participating water agencies and will be maintained by Reclamation. As new information becomes available, these maps will be updated in coordination with USFWS and CDFW. In addition to mapped priority habitat, fields abutting or immediately adjacent to federal wildlife refuges will be considered priority habitat.

- Maintaining water in smaller drains and conveyance infrastructure supports key habitat attributes such as emergent vegetation used by giant garter snakes for escape cover and foraging habitat. If crop idling/shifting occurs in priority habitat areas, Reclamation will work with contractors to document that adequate water remains in drains and canals in those priority areas. Documentation may include flow records, photo documentation, or other means of documentation agreed to by Reclamation and USFWS.

- ~~Areas with known priority giant garter snake populations~~ Mapped priority habitat known to be occupied by giant garter snake and priority habitats with a high likelihood for giant garter snake occurrence (60 percent or greater probability) will not be permitted to participate in cropland idling/shifting transfers. Water sellers can request a case-by-case evaluation of whether a specific field would be precluded from participating in long-term water transfers. These areas include lands adjacent to naturalized lands and refuges and corridors between these areas, including:

  - Fields abutting or immediately adjacent to Little Butte Creek between Llano Seco and Upper Butte Basin Wildlife Area, Butte

Creek between Upper Butte Basin and Gray Lodge Wildlife areas, Colusa Basin drainage canal between Delevan and Colusa National Wildlife Refuges, Gilsizer Slough, Colusa Drainage Canal, the land side of the Toe Drain along the Sutter Bypass, Willow Slough and Willow Slough Bypass in Yolo County, Hunters and Logan Creeks between Sacramento and Delevan National Wildlife Refuges, and

– Lands in the Natomas Basin.

- Sellers will ~~continue to voluntarily~~ perform giant garter snake best management practices, including educating maintenance personnel to recognize and avoid contact with giant garter snake, ~~cleaning~~ <u>dredging</u> only one side of a conveyance channel per year, and implementing other measures to enhance habitat for giant garter snake. <u>Implementation of best management practices will be documented by the sellers and verified by Reclamation and</u> ~~information on the effectiveness of these measures, along with recommendations for additional measures~~ will be <u>included in the annual monitoring report.</u>

Birds (revised)

- In order to limit reduction in the amount of over-winter forage for migratory birds, including greater sandhill crane, cropland idling transfers will be minimized near known wintering areas <u>that support high concentrations of waterfowl and shorebirds, such as wildlife refuges and established wildlife areas</u>. ~~in the Butte Sink.~~

Common Response 11: Surface Water/Groundwater Interactions and Vegetation/Wildlife

Several commenters questioned the basis for the 1 cubic feet per second (cfs) and 10 percent thresholds used in this portion of the analysis, others questioned the validity of the analysis regarding surface water-groundwater interactions to support local vegetation communities, and some questioned the overall appropriateness of the modeled data. The following response includes information regarding these factors. Additional information can also be found in Section 3.3 Groundwater Resources.

Thresholds

The 10 percent screening threshold for instream flow in rivers and creeks is one of multiple criteria used to determine whether there could be potentially significant impacts on aquatic and terrestrial resources. Use of the 10 percent threshold is described in Section 3.7.2.1.3 of the EIS/EIR. As stated in the text, the use of the 10 percent value is to distinguish between effects that are a result of "model noise" and actual impacts of an alternative. Experts in the field often use this criterion to evaluate potential impacts to Central Valley fisheries.

The effects analysis in this EIS/EIR also evaluates whether an alternative changes instream flows more than 1 cfs. This threshold was more biological in nature and was applied to every month of modeling. If a change of greater than 1 cfs occurred in any single month during the entire modeled period (1976-2003), the waterway was examined further for potential biological effects. The combination of the1 cfs and 10 percent threshold criteria provides an extremely conservative screening process through which each river or stream was analyzed. If either criterion was not met for a river or stream, a further analysis was conducted to evaluate the biological significance of the flow change, such as those conducted for the Bear River, Cache Creek, Stony Creek, Coon Creek, and Little Chico Creek.

Flows in smaller waterways with less than 1 cfs are expected to be within the normal range of annual fluctuation; some of these waterways are ephemeral and are subject to a wide range of flow conditions dependent on annual hydrology. Other smaller waterways are part of a managed system (i.e., canals) that also results in variation in flows. These small waterways were not analyzed further as groundwater substitution impacts on surface waterways are expected to be within this annual variation.

Groundwater table effects on vegetation

The analysis acknowledges that there are groundwater and surface water interactions, and focuses the analysis primarily on surface water where terrestrial ecosystems are most likely to be affected. The flow regime (i.e., ephemeral, seasonal, perennial) within rivers and creeks would remain unchanged and groundwater replenishment would occur naturally; therefore, riparian vegetation would continue to have access to water and is not expected to be substantially affected by groundwater transfers. Farther from creeks and rivers, the groundwater levels are substantially below the surface in many areas (i.e., typically between 30-70 feet in depth, as discussed in Appendix E), as described in Section 3.8.2.1 Assessment/Evaluations Methods of the EIS/EIR. Therefore, groundwater table effects were considered and were not expected to result in substantial impacts on vegetation because groundwater depths are greater than the rooting depth of typical vegetation associated with upland communities, which is expected to be substantially less than 15 feet.

Changes in surface water flows

Creeks and rivers where modeling predicted more than a 10 percent reduction and more than a 1 cfs reduction in streamflows were analyzed in more detail to determine potential effects on vegetation and wildlife. Section 3.8.2.4 of the EIS/EIR acknowledges that there are potentially significant impacts to natural communities and wildlife associated with periodic reductions in creek flows of more than 10 percent. These impacts would be mitigated to a less-than-significant level through implementation of Mitigation Measure GW-1.

Vegetation effects in the North Delta area

Several commenters refer to text in Section 3.8.2.1.1 that analyzes the potential for shallow groundwater changes to affect vegetation. In this area of the North Delta, groundwater levels are high. The groundwater model estimated a maximum modeled reduction of 0.3 to 0.8 feet over the growing season, and plants are expected to adjust to this small reduction. It is true that plants may not be able to respond quickly to sudden large changes in depth to groundwater; however, large changes are only expected to occur in areas where the groundwater table is already too deep for tree roots. The modeling covered a wide range of groundwater levels, including relatively low levels associated with the 1976-77 drought. Although areas in the North Delta could experience maximum modeled reductions of groundwater levels between 0.3 to 0.8 feet, these reductions are expected to occur slowly and would not substantially alter the suitability of shallowly-flooded habitat for wildlife. Further, the modeled change showed that these areas recovered from year to year and, therefore, were not expected to be substantially changed. Sacramento Valley wetlands are generally supplied by surface water (e.g., rice fields, agricultural ditches, and duck clubs), and not by groundwater. Therefore, vegetation and wildlife that occur in these wetlands would not be affected by changes in groundwater levels. Mitigation Measure GW-1 has been reworded to better explain how potentially significant vegetation effects would be avoided. See Common Responses 6, 7, 8, and 10 for additional information.

Appropriateness of modeled data

The CalSim II simulation was based on historic hydrology for 1970 through 2003; additional information on the appropriateness of the modeled data is described in Common Response 5.

Common Response 12: Wildlife - Giant Garter Snake

Several commenters noted that environmental commitments contained in the Draft EIS/EIR are not identical to information in past Biological Opinions issued by USFWS for water transfer projects or in the *2013 Draft Technical Information for Preparing Water Transfer Proposals.* The commenters further question why the Draft EIS/EIR does not include previously approved commitments to ensure protection of giant garter snake (i.e., limiting parcel size for idling and prohibiting the same field from being idled more than two consecutive seasons). The commenters are correct that environmental commitments in the Draft EIS/EIR are modified from past water transfer documents, including the 2013 Draft Technical Information. However, commitments in the EIS/EIR are consistent with the recent 2014 Water Transfer Biological Opinion. Guidance for preparation of water transfer proposals will be revised annually (as necessary) to reflect how transfers would be implemented, and includes the prescribed measures in project-specific CEQA/NEPA and Section 7 documents that cover the area where transfers are proposed. Refinement of prior year's environmental commitments was based on best available scientific data that provides better information on where giant garter snake populations are likely to be found. Commitments that broadly restrict idling across the service area were refined to focus on cropland idling restrictions in areas where giant garter snake have a high likelihood of occurrence.

Giant garter snake priority habitat areas have been identified by Reclamation and maps have been developed (Halstead 2014) for each water district using the best available scientific information on habitat use, known populations, and historic tule marsh zones. The purpose of these maps is to identify areas with the highest probability of giant garter snake occurrence so that water transfer actions can be avoided within these areas. The range of transfer activities in the action alternatives could result in up to 10.5 percent of rice field idling throughout the sellers' service area; however, idling would be focused in areas where giant garter snake occurrence probability is low. These habitat restrictions, along with retaining water within conveyance structures that provide habitat movement corridor, avoid potentially significant impacts from cropland idling.

Commenters also expressed concern over the ability to enforce the environmental commitments, lack agency oversight, and opportunities for adaptive management of habitat over the 10-year term of analysis. The environmental commitments have been clarified and refined to address these concerns, including requirement of an annual monitoring report to the USFWS and CDFW that includes maps of idled fields in the previous year, results of current giant garter snake surveys, new scientific research, and recommendations for future protection measures. The monitoring report will be followed by coordination efforts between Reclamation and the wildlife agencies.

Common Response 13: Migratory Birds

Several commenters asserted that the Draft EIS/EIR lacks adequate discussion of cropland idling effects on migratory bird populations, particularly waterfowl.

Sections 3.8.2.1.2 and 3.8.2.4.3 of the Draft EIS/EIR identify and evaluate potential impacts of cropland idling/shifting on terrestrial wildlife species that use seasonally flooded agriculture for some portion of their lifecycle, including wintering waterfowl and shorebirds. To address commenters' concerns regarding impacts specific to migratory birds, additional information was added to the section to further describe these potential impacts.

The Draft EIS/EIR acknowledges the importance of agricultural lands within the project area for migratory birds, particularly those traveling on the Pacific Flyway. Section 3.8.2.4.1 (including Tables 3.8-8 and 3.8-9) describes and quantifies the maximum potential loss of residual feed for migratory birds, which in all cases was insubstantial and would amount to a maximum two percent reduction of upland cropland in Glenn, Colusa, and Yolo Counties and a maximum nine percent reduction of upland cropland in Sutter and Solano Counties. This section also identifies the maximum reductions in rice acreage, which again would be insubstantial in all cases and could amount to up to 10.5 percent across the sellers' service area. Although the project may reduce the availability of cropland, it would not affect post–harvest practices (i.e., flooding, burning, disking, or rolling). Specifically, the project would not include transfers of rice decomposition water and so would not reduce the availability of water for post-harvest flooding. The majority of forage available to migratory birds in the project area is in the form of decomposing waste grains during post-harvest flooding. Farmers in the Sacramento Valley only flood-up a fraction of the cropland planted; typically around 60 percent in normal water years (Miller et al 2010, Central Valley Joint Venture 2006) and as little as 15 percent in critically dry years (Buttner 2014). The decision on whether to flood is not based on what was produced for the year but instead is determined by the availability of fall and winter water. Therefore, the project would not result in a reduction of winter forage for migrating birds, specifically waterfowl and shorebirds, because it would not affect the availability of water for post-harvest flooding.

Several commenters alleged that the environmental commitment for migratory birds, including Sandhill Crane, is specific to the Butte Sink and neglects other important habitat outside the Butte Sink. To further ensure there are no significant adverse impacts on migratory birds, including greater sandhill crane, the environmental commitment pertaining to the Butte Sink has been refined to limit water transfer activities near all wildlife refuges and established wildlife areas within the seller's service area that support high concentrations of waterfowl and shorebirds.

Several commenters recommended using TRUEMET bioenergetics modeling to determine the impacts of the project on wintering waterfowl (i.e., reduction in carry capacity) based on changes in the availability of winter forage. However, this modeling approach is not applicable to the range of transfer actions in the alternatives because fallowing is expected to be within the annual variation experienced for forage and because water transfers are not expected to reduce the availability of forage for wintering waterfowl. Therefore, TRUMET bioenergetics modeling will not be used.

Common Response 14: Water Transfers Approval Process

As described in Chapters 1 and 2 of the Draft EIS/EIR, Reclamation and SLDMWA are preparing an EIS/EIR for a range of potential water transfer activities in an effort to streamline and facilitate the process for reviewing and approving yearly temporary transfers, and to accommodate transfers that may extend over multiple years. Water transfers are one of the critical elements integrated into the California Water Action Plan for dealing with or managing critically dry periods. Appropriate water transfers are promoted under federal and state water policies as an effective incentive for improved water management, as well as a way to promote water conservation, particularly in drought years, as long as transfers are consistent with state and federal law. The Governor's emergency drought proclamations and executive orders have recognized the importance of water transfers for effective water management by including provisions to streamline and expedite transfers.

The purpose of this EIS/EIR is to provide a streamlining tool by providing a comprehensive, long-range, project-level view of the potential environment impacts associated with a range of potential transfer activities over a ten-year period, to both expedite approval of water transfers and to reduce participant uncertainty. The Lead Agencies recognize, throughout the EIS/EIR, that each transfer is unique and must be considered on its individual factual merits, using all the information that is available at the time of transfer approval and execution of the conveyance or letter of agreement with the respective project agency in accordance with the applicable legal requirements. Annual approval of transfers is required by Reclamation, irrespective of the EIS/EIR term or the duration of a water transfer contract.

The Lead Agencies are not managing a bank or program. The participating potential willing buyers and sellers will continue to negotiate and propose individual water transfers, including the transfer quantity, method, and use. Individual transfers would be voluntary, independent transactions between willing buyers and sellers subject to review and approval by Reclamation, the selling entity, and the buying entity (or SLDMWA on the buyer's behalf). Each transfer has independent utility and is not dependent on, nor does it dictate the nature and scope of, the potential for long-term transfers that are analyzed in the EIS/EIR. Implementation of the range of potential water transfers analyzed in this EIS/EIR (annual and multiyear, if any) would be subject to Reclamation's annual review and approval.

Reclamation's Potential Action is to review and approve potential transfer activities, if appropriate, based on detailed review of the specific proposed transfer. Reclamation is not soliciting potential buyers or sellers for transfers. The potential buyers and sellers listed in this document could seek to transfer up to the maximum quantities analyzed in this EIS/EIR using this document for NEPA and CEQA compliance, or could propose other transfers outside of this range subject to appropriate environmental review and compliance with any other applicable requirements. Buyers and sellers must implement measures incorporated into the Proposed Action to avoid or reduce potential environmental impacts to obtain Reclamation approval of the transfer. Reclamation technical experts review all proposed transfers prior to approval of the transfer to ensure that impacts of the proposed transfer are within the scope of analysis in this EIS/EIR (or require the preparation of further environmental documentation in the event that new or substantially more severe adverse impacts are presented by the proposed transfer). Reclamation ensures that the identified mitigation measures are implemented through review of monthly reports, field visits, and necessary coordination with transfer participants. Reclamation and SLDMWA have developed a Mitigation, Monitoring, and Reporting Plan, which is included in Appendix K of the Final EIS/EIR. The requirements of monitoring and mitigation as they apply to each individual transfer will be included in the transfer approval.

Reclamation will review each water transfer proposal with a view to the proposal's adequacy in addressing the technical information needed. To fully consider the proposal, site specific conditions may require additional information and considerations beyond that described in current guidance (such as including the Technical Information Document for Preparing Water Transfer Proposals, which is jointly prepared by DWR and Reclamation). This EIS/EIR does not predetermine those needs or those facts and does not foreclose the requirement and consideration of additional information (or further environmental review if necessary based on the potential for new or more severe environmental effects). The final quantity of water, if any, to be transferred is dependent on numerous factors, including future changes in hydrologic conditions, export capacity available for transfer water, negotiations between buyers and sellers, and Reclamation approval. Additional information regarding the process by which individual transfer proposals would be presented, evaluated, and potentially approved, can be found on Reclamation's website at http://www.usbr.gov/mp/watertransfer/ and DWR's website at http://www.water.ca.gov/watertransfers/proposals.cfm.

Detailed Comments and Responses

Individual responses to comments are presented in the following section.

Comment Letter FA01, Kathleen Martyn Goforth, United States Environmental Protection Agency

Comment FA01-1

Comment
The Environmental Protection Agency has reviewed the Draft Environmental Impact Statement (DEIS) for the above referenced document. Our review is pursuant to the National Environmental Policy Act, Council on Environmental Quality regulations (40 CFR Parts 1500-1508), and our NEPA review authority under Section 309 of the Clean Air Act.

The Long Term Water Transfer Project would implement a 10-year water transfer program to move water from willing sellers upstream of the Sacramento/San Joaquin Delta to willing buyers south of the Delta. Long-term water transfers have the potential to provide improved flexibility in the allocation, management, and use of water resources. When implemented in conjunction with a water management system that include efficiency improvement, conservation, and environmental protection, they can be an important tool for ensuring that California's scarce water supplies are put to their highest priority use.

While EPA supports the goal of improving water management flexibility, we also recognize that the Delta faces interrelated problems of inadequate water supplies, instream flow deficits, water quality impairments, and degraded aquatic habitats. Many of the groundwater aquifers that previously supported ecosystem processes across the estuary and provided water consumers with a hedge against drought have been overdrawn and depleted to historic levels. The extreme drought of the past 3 years has produced precipitous declines in groundwater elevations statewide, including level decreases of more than 10 feet for some monitored wells in the project area. Land subsidence associated with groundwater overdraft not only impacts infrastructure, water quality, and ecosystems, but also permanently reduces the State's capacity to store water underground. Water transfers would affect each of these conditions; therefore, they must be carefully designed and implemented, based upon the best available data, to ensure that adverse impacts are minimized and the interest of all affected parties and the environment are appropriately considered.

Response
The Lead Agencies agree that adverse impacts from groundwater subsidence must be minimized. For that reason, Section 3.2 includes an analysis of

potential impacts to groundwater levels and subsidence. It also includes Mitigation Measure GW-1 to avoid potential effects to groundwater resources.

Comment FA01-2

Comment
In the DEIS, BOR concludes that, after mitigation, the proposed project would result in less than significant or beneficial environmental impacts for all resources. Based on our review, EPA finds that the DEIS does not contain sufficient information to support this conclusion for many resource areas, particularly groundwater, air quality, fisheries, and wildlife.

Response
The EPA's subsequent comments focus on lack of clarity for the mitigation measures in these resources. Based on comments from the EPA and other reviewers, the Lead Agencies have clarified and strengthened Mitigation Measures WS-1, GW-1, AQ-1, and AQ-2. These mitigation measures support the Lead Agencies' conclusions regarding the impacts.

Comment FA01-3

Comment
The DEIS identifies potentially significant impacts to groundwater levels and land subsidence associated with groundwater substitution water transfers. It states that proposed mitigation would reduce these impacts to less than significant for all groundwater basins in the seller's service area. However, the proposed mitigation is vague and defers the responsibility for developing detailed mitigation plans to the water transfer applicants. This precludes meaningful evaluation of the viability and effectiveness of BOR's proposed approach to mitigation.

Response
Refer to Common Responses 6 and 7.

Comment FA01-4

Comment
Furthermore, the modeling performed to assess groundwater-related impacts depends upon a data set spanning 1970 to 2003. The use of this truncated data set means that recent trends and current existing conditions are not appropriately taken into account in the impact analysis. Absent sufficient information regarding both mitigation and existing conditions, the DEIS does not demonstrate that the proposed project would not adversely affect groundwater levels.

Response
See Common Response 5.

Comment FA01-5

Comment
Similarly, while the DEIS concludes that mitigation measures would render potential impacts to air quality to less than significant levels, the two mitigation measures proposed for air impacts essentially amount to a guarantee from BOR that emissions will not be allowed to exceed applicable thresholds. Without information on how these measures would be implemented and enforced on a transfer by transfer basis, it is not clear that the mitigation would successfully prevent exceedance of de minimis value under EPA's General Conformity rule or local air quality thresholds.

Response
The mitigation measures in the EIS/EIR have been modified to clarify enforcement provisions that will ensure implementation of the action alternatives would not result in significant adverse impacts to air quality.

Comment FA01-6

Comment
Finally, the DEIS analysis with regard to fisheries and terrestrial wildlife understates a number of potentially significant adverse impacts upon these resources, thereby rendering unsupportable the conclusion that these impacts will be less than significant. For both fisheries and wildlife impacts, significance thresholds identified in the DEIS are focused around special status species, with insufficient regard for other native communities. It is not clear why the DEIS concludes that most potential impacts to non-special-status species are inherently less than significant.

Response
The DEIS does not conclude or assume that most potential impacts to non-special-status species are inherently less than significant. Sections 3.7.2.1.5 and 3.8.2.1.7 of the Draft EIS/EIR describe assessment methods for fish and terrestrial wildlife, respectively. Impacts on terrestrial wildlife were assessed based on how the range of potential transfer activities evaluated in this document may affect natural communities and aquatic habitats that are used by wildlife during all or part of their lifecycle. Where impacts to natural communities were determined to be less than significant, impacts to terrestrial species were also determined to be less than significant. The impacts analysis for fish looked at the full range of potential effects to all target species in all waterways that could potentially be affected by each alternative using the best available science and analytical tools possible. The approach is described in Sections 3.7.2.1 and 3.8.2.1, significance thresholds are listed in Sections 3.7.2.2 and 3.8.2.2, and the results for each alternative are provided in Sections 3.7.2.3 through 3.7.2.6 and 3.8.2.3 through 3.8.2.6. The methodology and supporting information behind the findings of less than significant for biological impacts are summarized in these sections.

Comment FA01-7

Comment

Even where special status species are concerned, the impact analysis frequently depends upon conjecture, without sufficient justification or citation for significance thresholds established and impact assessments made. For example, potential impacts to migratory bird species receive only a summary consideration. Wintering waterfowl in the Sacramento Valley gather as much as 50 percent of their nourishment from rice farms, yet the DEIS concludes that the 16% reduction in flooded rice field in some regions along the Sacramento River (11% when averaged across the entire sellers' service area) would be a less than significant project effect. The DEIS states that migrating species will simply choose appropriate habitat upon arrival. Neither this assumption, nor the conclusion that follows from it are well founded.

Response

The EIS/EIR analysis of biological resources covers a very large study area and incorporates data from a variety of sources. Conclusions regarding impacts were made by highly-qualified experts based on review and analyses of those data, taking into consideration the stated thresholds of significance. Notwithstanding, Section 3.8.2.4.3 for special-status bird impacts has been expanded to include all migratory bird use of flooded agricultural lands. To further ensure that any potentially substantial impacts on migratory birds are avoided, environmental commitments have been refined to minimize crop idling in known wintering areas that support high concentrations of waterfowl and shorebirds, such as refuges and established wildlife areas. The EIS/EIR acknowledges the importance of rice fields for wintering waterfowl; however, the project does not include transfers of rice decomposition water. Water transfers would not reduce the availability of water for post-harvest flooding; while different fields may be flooded, water transfers would not substantial reduce forage for wintering waterfowl. See Common Response 10 (Environmental Commitments/Mitigation Measures) and Common Response 13 (Migratory Birds) for additional discussion of migratory birds.

Comment FA01-8

Comment

Similar data gaps and unsupported conclusions are common throughout the DEIS and warrant substantial revision prior to the publication of the Final EIS. The level of detail missing from the DEIS, particularly with regard to the specific provisions of likely transfer actions and the expected requirements of future mitigation, results in an EIS document more appropriate to a programmatic analysis. Without further details regarding these aspects of the proposed project, EPA believes that the FEIS will not be sufficient to support project-level decision-making.

Response
The Lead Agencies have addressed EPA's requests as described in the comment responses to allow project-level decision-making. See Common Response 14.

Comment FA01-9

Comment
Based on EPA's review of the Draft EIS, we have rated the Proposed Action as Environmental Concerns - Insufficient Information (EC-2). This rating reflects the potentially significant adverse environmental impacts that the project, as proposed, may have upon the terrestrial and aquatic environments of the Delta and Sacramento Valley, the lack of consideration of appropriate mitigation for some project impacts, and the need for improved disclosure related to air quality, water quality, groundwater, fisheries, vegetation/wildlife, economics, project alternatives, and mitigation. Please see the enclosed Summary of EPA Rating Definitions for a description of the rating system. Further discussion of our concerns is provided in the enclosed Detailed Comments.

EPA appreciates the opportunity to provide comments for this project. When the Final EIS is released for public review, please send one hard copy and one CD to the address above (Mail Code: ENF 4-2). If you have any questions, please contact me at (415) 972-3873 or contact Carter Jessop, the lead reviewer for this project. Carter can be reached at (415) 972-3815 or jessop.carter@epa.gov.

Response
The Final EIS/EIR includes responses to the EPA's comments, and edits to the EIS/EIR where appropriate to address concerns. See Common Response 14.

Comment FA01-10

Comment
The proposed project spans five air basins, including numerous attainment, nonattainment, and maintenance areas for a number of National Ambient Air Quality criteria pollutants. Groundwater substitution water transfers would necessitate the use of diesel, natural gas, or electrically powered pumps. According to the DEIS (p. 3.5-38), and as referenced in Appendix F (page F-1), the emissions from these pumps, in particular those powered by diesel fuel, have the potential to exceed the applicable de minimis value for nitrogen oxide (NOx) established under EPA's General Conformity Rule for the Sacramento Metro non-attainment area. Table F-1 indicates that unmitigated emissions would exceed the de minimis threshold nearly fourfold. In addition, groundwater substitution pumping has the potential to emit criteria pollutants at levels that exceed local air district significance thresholds for volatile organic compounds (VOCs) and NOx in the Feather River Air Quality Management District and for NOx for the Sacramento Metropolitan AQMD.

In order to address these potential impacts, the DEIS includes mitigation measure AQ-1: "Reduce pumping at diesel or natural gas wells to reduce pumping below significance levels." (p. 3.5-43) It indicates that, following application of this measure, all project emissions are modeled to fall below applicable thresholds. EPA is concerned that measure AQ-1 is very vague. The single paragraph description provided is insufficient to determine whether this measure is capable of achieving the described emission reductions. It is unclear how BOR would limit diesel or natural gas well pumping and manage individual transfer permit to ensure cumulative compliance. The mechanisms for both emissions accounting and enforcement are similarly unclear.

Response
The mitigation measures in the EIS/EIR have been modified to clarify recordkeeping requirements that will ensure implementation of the action alternatives would not result in significant or adverse impacts to air quality.

Comment FA01-11

Comment
Measure AQ-1 also stipulates that "if an agency is transferring water through cropland idling and groundwater substitution, the reduction in vehicle emissions can partially offset groundwater substitution pumping at a rate of 4.25 acre-feet for water produced by idling to one acre-foot of groundwater pumped." The DEIS provides no citation or explanation for how the 4.25 AF/1 AF ratio was determined. Given the range of potential emissions rates associated with pumps of various ages/tiers and fuel types, plus the differing water needs of various crops, it is unclear how a single ratio of groundwater pumping to cropland idling was derived and deemed universally applicable.

Response
The ratio of 4.25 acre-feet of water produced by idling to one acre-foot of groundwater pumped is not reflective of emissions from the groundwater pumps, but rather of emissions that would occur from farm equipment operating on the field. The reference for Byron Buck & Associates 2009 (as cited in Section 3.5, Air Quality) provides detailed information on how the ratio was calculated. The ratio represents the best available information to estimate emission reductions from cropland idling.

Comment FA01-12

Comment
EPA's guidance on the General Conformity applicability analysis states, "the Federal agency can take measures to reduce its emissions from the proposed action to in fact below de minimis levels and, thus, the rule would not apply. The change must be State or Federally enforceable to guarantee that emissions would be below de minimis in the future." While California Environmental Quality Act mitigation measures may be enforceable under state law, the vague

language of AQ-1 falls short of guaranteeing the de minimis thresholds will not be exceeded. Without additional information regarding the mechanism and enforcement for mitigation measure AQ-1, the DEIS does not demonstrate that emissions of NOx in the Sacramento Metro non-attainment area would be limited to below the de minimus threshold.

Response
The mitigation measures in the EIS/EIR have been modified to clarify enforcement provisions that will ensure implementation of the action alternatives would not result in significant adverse impacts to air quality.

Comment FA01-13

Comment
Recommendation: Include in the FEIS a detailed description of the processes by which BOR would approve, disapprove or approve with conditions those transfer applications within the Sacramento Metro AQMD such that emissions are maintained below the applicable de minimis and local significance thresholds; similarly for the Feather River AQMD. In order to demonstrate compliance with the General Conformity Rule, the FEIS should clearly show how the proposed mitigation measure would be implemented and enforced. Describe the mechanism for compliance assurance and enforcement, and clearly demonstrate the calculation leading to the 4.25 AF of water produced by idling to one AF of groundwater pumped ratio. Explain why this value is appropriate for all pumping/idling scenarios.

Response
The mitigation measures in the EIS/EIR have been modified to clarify enforcement provisions that will ensure implementation of the action alternatives would not result in significant adverse impacts to air quality. Additionally, the discussion on the 4.25 AF of water produced by idling to one AF of groundwater pumped ratio was expanded.

Comment FA01-14

Comment
The Department of Agriculture's Natural Resource Conservation Service has a program to promote agricultural production and environmental quality as compatible goals, optimize environmental benefits and help farmers and ranchers meet Federal, State, Tribal, and local environmental regulations. Through the Environmental Quality Improvement Program (EQIP), NRCS provide incentive funding to agricultural producers specifically to reduce NOx, VOCs, PM10 and PM2.5. Currently, incentive funds are available throughout California. The funded conservation practices include the replacement of internal combustion engines in irrigation pumps. For more information, go to http://www.nrcs.usda.gov/wps/portal/nrc/detail/ca/programs/financial/eqip/?cid=stelprdb1247003. As the DEIS notes, a California Air Resources Board

airborne toxic control measure contain a schedule for the replacement of older and dirtier diesel agricultural engines.

Recommendation: Work with irrigation districts to ensure that individual growers participating in the project are aware of NRCS incentive funding to reduce project related air quality impacts. The FEIS should describe this program and the benefits it might offer for reducing potentially significant air quality impacts with regard to General Conformity.

Response
The individual growers are operating in compliance with ATCM, including any necessary retrofitting and repowering to meet the emission reduction requirements. The EIS/EIR has been clarified to include a discussion of the incentive program described in this comment. The mitigation measures have been modified to include a requirement to notify individual growers about the incentive program.

Comment FA01-15

Comment
The proposed project has the potential to cause or exacerbate overdraft of groundwater in the sellers' service area if groundwater substitution transfers are not carefully managed, and if mitigation is not aggressively enforced. One of the primary mechanisms whereby water transfers would be made possible under the proposed action is by groundwater substitution. A seller would pump groundwater in lieu of drawing that same volume of surface water from canal or stream flow. That surface water allocation (less carriage water) would then be sold downstream to a willing buyer in the buyer service area. California's limited regulation of groundwater resources has allowed overdraft of groundwater in part of the State. When groundwater elevations fall below historic lows, aquifer of certain geologies are subject to collapse, resulting in land subsidence. Areas subject to land subsidence have experienced particularly severe financial and ecological repercussion from groundwater overdraft. These impacts stretch far beyond the individuals pumping the groundwater, impacting entire communities and ecosystems. Furthermore, in dry and critical years, a lack of available water lead a greater proportion of water users to pump groundwater to supplement diminished surface water supplies. These circumstances are likely to co-occur with periods of the greatest number of groundwater substitution transfers.

Response
The monitoring and mitigation plans that are required by Mitigation Measure GW-1 include aspects related to water levels and subsidence. Groundwater levels are required to be monitored before, during, and after a groundwater substitution pumping transfer. The location and type of testing will be dependent on the area of the potential transfer. In areas that may be prone to subsidence because groundwater levels could fall below historic low levels,

additional monitoring to ensure compliance with performance criteria will be required (see Common Response 7 for additional information). The plans will also include mitigation for issues related to substantial declines in groundwater levels and for significant subsidence impacts related to the projects in this EIS/EIR. The plans include mitigation measures such as reducing transfer pumping if warranted based on monitoring data. Reclamation will review the available data prior to approving the monitoring and mitigation plans. These plans are required prior to initiating a groundwater substitution transfer.

Comment FA01-16

Comment

The analysis of groundwater impacts assumes that transfers would occur at a rate of 12 out of 33 years, or 36% of the time (p. 2-13), based upon the period of record from 1970 to 2003. This data set is truncated to this period due to the limitation of the CalSim II model used, not because this period was deemed to be the most appropriate to represent future conditions. In fact, according to the DEIS (p. 1-17), north-of-delta to south-of-delta water transfers have taken place in 9 of the past 15 water years -- a rate of 60%. This is nearly double the transfer frequency assumed by the modeling performed.

The proposed project would likely ease and expedite the water transfer process during its 10-year term by removing the need for independent environmental review for transfer approval. The available data suggest that drought frequency will increase and water supply reliability decrease in coming decades as the effects of global climate change take hold of the State (p. 3.6-12). For this reason, it seems reasonable to assume that the frequency of water transfers during the 10-year project term would be at least equivalent to the past 15 years, if not more frequent. This discrepancy could potentially have very substantial influence on the predicted environmental impact of the project. The conclusion reached in the DEIS regarding impact upon groundwater elevations, land subsidence, streamflow, water quality, fisheries, wildlife, and economics are predicated on the assumption that natural recharge in non-transfer years will replenish groundwater aquifers. If the modeling performed were based upon the past 15 years of record, the environmental outcomes predicted for each of these resource areas would likely differ from those described in the DEIS.

Response

See Common Response 5.

Comment FA01-17

Comment

Recommendations: Complete additional modeling that is more representative of current and future reasonably foreseeable conditions with regard to transfer frequency. These results should be incorporated into each major resource area so potential adverse effects can be properly characterized. If the framework of

CalSim II does not accommodate such modeling, we recommend that BOR perform a sensitivity analysis to determine the effect of this discrepancy upon overall conclusions regarding project impacts. In addition, BOR should consider what additional tools might be available for more accurately predicting likely project impacts in the event that transfer frequency occurs closer to the rate observed in the past 15 years.

Response
See Common Response 5.

Comment FA01-18

Comment
The DEIS is internally inconsistent in defining and treating baseline/existing groundwater elevations. The characterization of existing groundwater conditions uses data sets that conclude at dates ranging from 1995 to 2013, and none include data from the 2013-2014 critical drought year. Where older, outdated data are used, it is possible that recent trends in groundwater elevation or land subsidence are not represented in the analysis. The current drought is perhaps the most severe the state has ever experienced and would be the relevant baseline for additional impact from the proposed action, slated to commence in 2015. According to the California Department of Water Resources' November 2014 Drought Update, over 50 percent of monitored wells in the Central and Sacramento Valleys have experienced groundwater level decreases of 2.5 feet or more from spring of 2013 to spring of 2014, with over 20% experiencing decreases of more than 10 feet. For the period from spring 2010 to spring 2014, nearly 30% of monitored wells have experienced declines in excess of 10 feet. While the most severe declines occur in the San Joaquin basin, precipitous declines are none-the-less prevalent across a majority of the sellers' service area. Due to these recent declines, some of the monitored wells in the sellers' service area may have reached historic low levels. Consequently, we are concerned that the extent of, or potential for, land subsidence may be greater than is reflected in the DEIS.

Response
See Common Response 4, Common Response 6, and Common Response 7.

Comment FA01-19

Comment
According to the DEIS, five of eleven extensometers placed in the Sacramento Valley Groundwater Basin to monitor land subsidence are showing some amount of subsidence on an annual basis. This suggests that groundwater elevations are likely falling below historic lows in some portions of the Sacramento Basin. Analysis of data from the National Aeronautics and Space Administration (NASA) Gravity Recovery and Climate Experiment (GRACE) satellite mission suggests that, in the Central Valley, including the Sacramento

basin, substantial loss of groundwater storage has occurred across the period of 2003 to 2010.

Response
Section 3.3.1.3.2 has been revised to include monthly groundwater storage estimates for Sacramento and San Joaquin Valley from the NASA effort (Famiglietti et al. 2011).

Comment FA01-20

Comment
Recommendation: Ensure that the most current groundwater elevation and land subsidence data available are used in the characterization of existing conditions and the determination of likely project effects in the FEIS. The FEIS should examine all available data source regarding groundwater elevations in the seller's service area and include a more thorough consideration of alternate data sources, given data limitation at some monitoring points. We recommend that the FEIS include specific requirements that prohibit the pumping of groundwater below historic lows where the risk of subsidence is present.

Response
See Common Response 4 and Common Response 7.

Comment FA01-21

Comment
The DEIS outlines a monitoring and mitigation measure for ensuring that potentially significant impacts to groundwater are offset; however, this measure (GW-1, p. 3.3-88) largely defers the specific to a required monitoring and mitigation plan to be developed by the water seller for approval by DWR and BOR in an independent post-NEPA permitting process. While a general framework is offered in the DEIS for how mitigation would be constructed, greater detail is needed to sufficiently demonstrate that environmental harm would be offset. The DEIS states that measure GW-1 will mitigate all impacts from groundwater pumping, placing responsibility for mitigating any "significant adverse impacts" of groundwater pumping on the water seller. Beyond the statement that mitigation "could include… curtailment of pumping until water levels raise above historic lows if non-reversible subsidence is detected," no more specific mitigation threshold or trigger are provided. Inelastic subsidence is a permanent impact. Implementation of mitigation after it has been monitored to occur mean that an irreversible and irretrievable commitment of resources will have occurred. The measure also does not include monitoring or mitigation specifically related to minimizing harm to the aquatic environment. It is not clear what action could or would be taken if groundwater substitution pumping were found to be dewatering a stream or water body (see comment on stream flow and fisheries impacts).

Response
Groundwater Mitigation Measure GW-1 requires the development of an approved monitoring and mitigation plan to identify and deal with potential impacts from groundwater substitution pumping. In counties where BMOs currently exist, the BMOs will be used as monitoring criteria. In counties where BMOs do not exist, critical changes to groundwater levels will be established through coordination with and feedback from third parties. Potential groundwater substitution sellers are required to develop monitoring and mitigation plans as part of Mitigation Measure GW-1. These plans are subject to review and approval prior to commencing a transfer. The seller will be required to successfully implement GW-1 in order to transfer water. Common Responses 6 and 7 include additional information.

Comment FA01-22

Comment
Measure GW-1 includes language placing financial responsibility on the transferring party for any repercussions of their pumping on others, including the cost to neighbors if the neighbors' pumping expenses increase, and the costs of infrastructure repair or improvements that may be required due to lower groundwater elevations or non-reversible land subsidence. However, as presented in the DEIS, these provisions are unlikely to be enforceable. The DEIS does not include metrics by which claims would be judged and processed, and responsibility apportioned, nor timeframes in which decisions would be made. Also, the DEIS does not define how "assurances that adequate financial resources are available to cover reasonably anticipated mitigation needs" would be made. Where offsetting a neighbor's pumping expenses or replacing public infrastructure is concerned, the expense to the transferring party could easily exceed the financial benefit of the water transfer by many times over.

Response
Common Responses 6 and 7 discuss groundwater mitigation and subsidence, respectively. Sellers must indicate that they understand the financial commitments associated with potential mitigation and they can meet those commitments.

Comment FA01-23

Comment
Recommendation: Provide greater detail about monitoring and mitigation measure GW-1 in the FEIS. The FEIS should include clearly defined mitigation triggers for the foreseeable range of potential environmental impacts associated with groundwater substitution transfers, including potential impacts to groundwater elevations, land subsidence, streamflow, fisheries, vegetation, and wildlife. We recommend that Measure GW-1 be revised to improve its enforceability, including providing metrics by which claims would be judged and responsibility would be apportioned, and timeframes in which decisions and

distribution of reimbursement would be made. The FEIS should also define what constitutes "adequate financial resources to cover reasonably anticipated mitigation needs" and how their availability would be ensured.

Response
Groundwater Mitigation Measure GW-1 requires the development of an approved monitoring and mitigation plan to identify and deal with potential impacts from groundwater substitution pumping. Common Response 6 provides additional information. In counties where BMOs currently exist, the BMOs will be used as monitoring criteria. In counties where BMOs do not exist, critical changes to groundwater levels will be established through coordination with and feedback from third parties. Potential groundwater substitution sellers are required to develop monitoring and mitigation plans as part of Mitigation Measure GW-1. These plans are subject to review and approval prior to commencing a transfer. The seller will be required to successfully implement GW-1 in order to transfer water. Common Response 7 also includes additional information related to subsidence monitoring and mitigation.

Comment FA01-24

Comment
Page 3.7-26 of the DEIS states that stream flow reductions as the result of groundwater declines would have a less than significant impact upon fisheries and riparian resources because they "would be observed at monitoring wells in the region and adverse effects on riparian vegetation would be mitigated by implementation of Mitigation Measure GW-1." The principle mitigation for this impact is the curtailment of pumping until natural recharge corrects the environmental impact. The DEIS overestimates the effectiveness of this measure in avoiding harm to fisheries and riparian resources. Following the curtailment of pumping, a lag time would exist between when the effects of groundwater on streamflows are detected and when the curtailment of pumping would result in the augmentation of stream flows. This lag time could be months to years depending on specific ground and surface water conditions. During this lag time, significant adverse impacts to fisheries could occur.

Response
All references to mitigation measures in Section 3.7, Fisheries, have been removed. Mitigation measures are unnecessary because the effects of the range of potential activities analyzed under the action alternatives would be less than significant without them.

Comment FA01-25

Comment
Recommendation: Define, in the FEIS, triggers that would be used to make the decision to continue pumping or to cease pumping. For example, define at what

depth below historic lows groundwater pumping would be curtailed, and at what point land subsidence measures are considered to be too great to be elastic and pumping would cease. The FEIS should more accurately characterize the potential for harm to fisheries resources during the lag time between impact observation and mitigation benefit.

Response
See Common Responses 6 and 7. Section 3.7 determines there are no significant effects to fisheries.

Comment FA01-26

Comment
In September of this year, Governor Jerry Brown signed a suite of three bills -- AB 1739, SB 1168, and SB 1319 -- collectively called the Sustainable Groundwater Management Act, with the intended goal of moving toward the sustainable management of unadjudicated groundwater basins throughout the state. This legislation will be enacted across the term of the Long Term Water Transfers project and has the potential to affect the proposed project.

Recommendation: Discuss the Sustainable Groundwater Management Act in the FEIS. The stipulations of this legislation should be identified in the "Regulatory Framework" portion of section 3.3. The FEIS should also discuss the potential effects of this legislation on the actions proposed for this project.

Response
Section 3.3.1.2 has been revised to include summaries of the sustainable groundwater management acts (AB 1739, SB 1168, and SB 1319).

Comment FA01-27

Comment
Streamflow Impacts and Water Quality. The proposed project would affect the quantity and timing of streamflow throughout the sellers' service area and downstream into the Sacramento/San Joaquin Delta. In an aquatic ecosystem that has already been severely degraded by reduced instream flows related to freshwater diversion and groundwater overdraft, any action with the potential to further reduce flows has the potential to significantly impair water quality. The DEIS states that, due to the timing and magnitude of potential impacts to streamflow, the project will not cause violation of any Delta water quality standards (p. 3.2-40).

Response
Changes in the flow resulting from transfer alternatives were modeled to assist in the evaluation of potential impacts due to changes in flow in the seller's and buyer's service areas. Appendix C presents a DSM2 modeling analysis of Delta conditions for the alternatives. The modeling addresses regulated parameters to

determine the magnitude of changes to these parameters that could occur if the system operations defined by any of the alternatives were implemented instead of base operations. The flow analysis included changes in south Delta stage heights. Based on water quality standards and objectives, it was determined that any changes in operations resulting from the action alternatives would not significantly affect the quantity and timing of streamflow such that water quality would be impacted.

Comment FA01-28

Comment

The release of transfer carriage water, defined as the "portion of the transfer that is not diverted in the Delta and becomes Delta outflow" (p. 2-29), has the potential to increase outflows by an average of 1.8% (p. 3.2-47) between October and June. The DEIS states that streamflow losses associated with reservoir refilling, groundwater recharge, and loss of irrigation return water are modeled to reduce Delta outflows by up to 0.3 percent during the spring and winter months (3.2-47). However, as discussed in our comments on groundwater resources, the DEIS analysis assumes that water transfers will take place in approximately 35% of water years, while in the past 15 years, transfers have occurred at almost double this frequency. In the event that transfers occur as often as, or perhaps more often than, observed in recent history, groundwater aquifers may not fully recharge between transfers, resulting in greater impacts to streamflow. Furthermore, it is unclear how the increase in Delta outflow was calculated given that the percent of a given water transfer that will be required for carriage is variable – assumed for some transfers to be as much as 20% (Sacramento River) and for others to not apply at all (EBMUD diversions) (p. B-18). If the data presented in the DEIS are average values, it is necessary to understand the maximum possible streamflow loses in order to determine the range of possible project impacts.

Response

See Common Response 5 for a discussion of transfer frequency.

Comment FA01-29

Comment

Recommendations: Describe in the FEIS how an increase in transfer frequency might affect expected streamflow and water quality impacts. Clarify how the proportion of a transfer deemed "carriage water" is determined and how these values were used to calculate expected change in streamflow resulting from project actions.

Response

See Common Response 5 for a discussion of transfer frequency.

Comment FA01-30

Comment

The California State Water Resources Control Board (State Board) has proposed flow criteria for the lower San Joaquin River Basin [Footnote: State Water Resources Control Board, December 2012, Public Draft Substitute Environmental Document in Support of Potential Changes to the Water Quality Control Plan for the San Francisco Bay/ Sacramento-San Joaquin Delta Estuary: San Joaquin River Flows and Southern Delta Water Quality. http://www.waterboards.ca.gov/waterrights/water_isues/programs/bay_delta/bay_delta_plan/water_quality_control_planning/2012_sed/] and is in the process of preparing a comprehensive update of the Bay Delta Water Quality Control Plan (Bay Delta WQCP) that will include flow criteria for the Delta as a whole. [Footnote: http://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/bay_delta_plan/water_quality_control_planning/] The State Board's 2010 Flows Report [Footnote: http://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/deltaflow/docs/final_rpt080310.pdf] underscores the need to increase flows to and through the estuary to support ecosystem processes, safeguard aquatic life, and protect imperiled species. It is not clear whether or how the proposed project would comply with these new requirement at all times.

Response

The exact content of future flow and water quality requirements in the Delta is not known at this time. Requirements for increased flow and improved water quality could require Reclamation, DWR, and other water rights holders to make changes in operations and diversions to meet standards. Reclamation would need to consider these requirements and determine how best to meet them, but the requirements would not be met through independent water transfers (as described in this EIS/EIR). The purpose and need/project objectives for this effort addresses the need for water supplies during years with shortages under current conditions. The water transfers described in this EIS/EIR would not contribute to meeting any new flow standards, but they would be operated so that they did not reduce the ability of Reclamation, DWR, and other water rights holders to meet the standards.

Comment FA01-31

Comment

Any water transfer program will have to be designed for operational flexibility so it can comply with existing water quality standards (such as the X2 salinity standard within D-1641 [Footnote: http://www.waterboards.ca.gov/waterrights/water_isues/programs/bay_delta/decision_1641/index.shtml. X2 refers to the distance from the Golden Gate up the axis of the estuary to the point where daily average salinity is 2 parts per thousand at 1 meter off the bottom. X2 provides a surrogate measure for the low salinity zone favored by an assemblage of native fish where abundance and survival is statistically greater than in other parts of the estuary. http://online.sfsu.edu/modelds/Files/References/JassbyEtAl1995EcoApps.pdf]), and potentially more stringent standards once the comprehensive Bay Delta WQCP is completed. On the whole, these new requirements are anticipated to necessitate that less water be diverted for human consumption and more be left in the river for aquatic life. While Appendix B provides detailed analysis of the project's potential effects on the X2 salinity standard, the current text of the DEIS constitutes an insufficient summary of these data (p. 3.2-40). In addition, the modeling performed for assessing impacts to the position of X2 relies upon monthly averages of that position. Monthly averages are not the appropriate “time step” as they can mask violations and standards. Impacts to the position of X2 must be analyzed and evaluated in the units in which the standard is written in order to demonstrate compliance.

Response
Additional information regarding a summary of Delta conditions resulting from the transfer alternatives has been added to Section 3.2. Water transfers are a flexible tool (as required by the purpose and need and project objectives). Appendix C includes additional information on Delta conditions, including water quality.

Comment FA01-32

Comment
Recommendations: Recent proposals by the State Board to include specific flow requirements in future Water Quality Control Plans for the Sacramento/San Joaquin River Delta should be discussed in the FEIS. Explain how the proposed project would be designed and operated with the flexibility needed to achieve compliance with current water quality standards and future standards that might be significantly more stringent.

Response
See Response to Comment FA01-30.

Comment FA01-33

Comment
Streamflow modeling data should be analyzed to determine any change in the position of X2 on a daily basis through time in order to demonstrate that water transfers would not cause the X2 standard to be violated. Include in the FEIS a fuller summary of the data contained in Appendix B to properly support the assertion that the proposed project would not violate the existing X2 standard. If any violations of the X2 standard are found in the modeling to occur on a daily basis, the FEIS should identify this significant impact, indicate the frequency of modeled exceedance, and discuss mitigation that would prevent this impact.

Response
Additional information regarding a summary of Delta conditions resulting from the transfer alternatives has been added to Section 3.2. Appendix C includes more detail.

Comment FA01-34

Comment
The DEIS states that changes in streamflow of less than ten cubic feet per second (cfs) are assumed to have no impact upon water quality (p. 3.2-27). This assumption is not supported with appropriate citation or data. The explanation that changes of less than 10 cfs are outside the accuracy of the model employed is insufficient to demonstrate that this threshold is physically or chemically appropriate. Depending on water levels and flow conditions, a loss of 10 cfs could degrade water quality.

Response
This standard has been removed from the Assessment Methods section. The impact analysis previously presented changes in flows that were below this threshold.

Comment FA01-35

Comment
Recommendation: Explain, in the FEIS, the basis for the assumption that streamflow changes of less than 10 cfs would not affect water quality. If data supporting such an assumption are not available, we recommend that BOR reconsider its use of this assumption for its analysis. If a lower threshold for significance is deemed appropriate, but the available modeling tools lack the resolution to predict all impacts at this threshold, we recommend that the remaining uncertainty be clearly identified in the FEIS and a precautionary approach be taken with regard to permitting water transfer related actions.

Response
This standard has been removed from the Assessment Methods section. The impact analysis previously presented changes in flows that were below this threshold.

Comment FA01-36

Comment
The DEIS consider potential streamflow impacts to smaller tributaries in Section 3.7. It states that, for rivers and their major tributaries, groundwater and streamflow modeling was compared against historical flow data to assess impacts to surface water flows. For smaller streams and water bodies, where insufficient data were available to allow this approach, the analysis assumed that streamflow response was similar to that of larger adjacent modeled

waterways. This approach is significantly flawed. Model resolution is not the appropriate basis for excluding smaller waterways from a more detailed examination. Smaller water bodies will respond differently to changes in groundwater contributions than will larger water bodies and are potentially much more sensitive to small changes in f1ow magnitude and frequency. Where a loss or reduction in groundwater contributions to a section of a large water way may result in a small reduction in flow, but no loss of ecological function, the same reduction in groundwater contributions to a smaller tributary stream could result in near or complete dewatering and a significant degradation of ecological function.

Response
The analysis uses the best available modeling and analysis tools. No such tools were available for these smaller streams, therefore a more quantitative analysis could not be conducted for them. A qualitative assessment based on best professional judgment, inferences predicated on facts, and the reasonable assumption that changes in flow in smaller streams were similar to those of adjacent larger streams were used to analyze these smaller streams. Overall, the analysis is very conservative. The assertion by the commenter that smaller water bodies respond differently from larger water bodies may be true under some site-specific circumstances, but the opposite may also be true under other site-specific circumstances. Due to the uncertainty of potential responses and based on available data, Reclamation and SLDMWA assume, for the purposes of this EIS/EIR, that the smaller streams respond similarly to larger streams. As specific transfers are proposed, and if warranted under site-specific conditions, additional quantitative analysis of smaller streams may be appropriate. See responses to Comments FA01-37 and NG10-28 for additional discussion of site-specific streamflow data. See Common Response 14 for additional discussion regarding consideration of specific transfer proposals.

Comment FA01-37

Comment
Recommendations: Additional site specific information, including streamflow data and the likely proportion of flow contributed by groundwater, is needed in order to determine the likely effect of groundwater substitution transfers on smaller streams and waterbodies in the seller's service area. The FEIS should explicitly identify where uncertainty exists due to model limitations, and describe the range of potential impacts contained within that uncertainty. In the absence of the necessary site specific data for a more comprehensive analysis, we recommend that BOR consider taking a precautious approach to minimize potential ecological risk.

Response
Site specific information was gathered for each stream. When limited or no information was available, the analysis considered the size of the stream, whether it was ephemeral, and the effects of groundwater substitution pumping

on other neighboring waterways. Overall, the analysis is very conservative. See response to Comment NG10-28 for more information.

Comment FA01-38

Comment

The DEIS states that changes in stream flows on the San Joaquin River and in the Sacramento/San Joaquin Delta will be less than significant because total reductions in flow will be only a fraction of a percent. A two percent reduction in flow is identified as the threshold for significance for this impact. A more refined analysis of impacts to species would have to be conducted to determine whether this significance threshold is biologically appropriate. According to the State Board, [Footnote: State Water Resources Control Board, 3 Aug. 2010, Development of Flow Criteria for the Sacramento-San Joaquin Delta Ecosystem Prepared Pursuant to the Sacramento-San Joaquin Delta Reform Act of 2009, (2010 Flows Report), available at http://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/deltaflow/docs/final_rpt080310.pdf] U.S. Fish and Wildlife Service, [Footnote: "Interior remains concerned that the San Joaquin Basin salmonid populations continue to decline and believes that flow increases are needed to improve salmonid survival and habitat." USFWS May 23, 2011 Phase I Scoping Comments: http://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/bay_delta_plan/water_quality_control_planning/cmmnts052311/amy_aufdemberge.pdf] NMFS, [Footnote: "Inadequate flow to support fish and their habitats is directly and indirectly linked to many stressors in the San Joaquin river basin and is a primary threat to steelhead and salmon." NMFS Feb. 4, 2011 Phase I Scoping Comments: https://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/bay_delta_plan/water_quality_control _planning/cmmnts020811/010411dpowell.pdf] and the California Department of Fish and Wildlife, [Footnote: "…current Delta water flows for environmental resources are not adequate to maintain, recover, or restore the functions and processes that support native Delta fish." Executive Summary of California Department of Fish and Game, November 23, 2010, Quantifiable Biological Objectives and Flow Criteria for Aquatic and Terrestrial Species of Concern Dependent on the Delta.] existing conditions in the San Joaquin River basin are not adequate to protect aquatic life. All three fisheries agencies identified salmon and steelhead populations as declining under current flow conditions. The DEIS does not provide sufficient support for the conclusion that this further reduction in flow would not adversely affect these species or other native aquatic species.

Response

The analysis compares conditions under each action alternative to existing conditions to determine the potential for significant adverse effects. The analysis found that the incremental effect of the range of potential transfer activities analyzed under the action alternatives would be less than significant.

See Section 3.7.2.4 of the EIS/EIR for a detailed explanation of the bases of this conclusion.

The commenter would like the thresholds of significance under CEQA to be zero such that any change, no matter how small, would be significant. The preparers of the EIS/EIR who model hydrology have indicated the changes to the environment are barely perceptible. As such, they are within the range of normal operations of existing facilities and are less than significant under CEQA.

Comment FA01-39

Comment
The DEIS indicates that, under the proposed project, the many waterways in the project area are likely to experience higher flows during some portions of the year but lower flows during wetter periods. There are many benefits to maintaining flood flows in rivers in wet years as they inundate floodplains and initiate ecosystem processes that support aquatic life. Juvenile salmon will rear on seasonally inundated floodplains when available. This has been found to increase growth and survival in the Central Valley, specifically in the Yolo Bypass and the Cosumnes River floodplain. [Footnote: T.R. Sommer, M.L Nobriga, W.C. Harrell, W. Batham, and W.J. Kimmerer, 2001. Floodplain rearing of juvenile Chinook salmon: evidence of enhanced growth and survival. Can. J. Fish. Aquat. Sci. 58: 325-333.] [Footnote: C.A. Jeffres, J.J. Opperman, and P. Moyle. 2008. Ephemeral floodplain habitats provide best growth conditions for juvenile Chinook salmon in California river. Environmental Biology of Fishes, Published online June 6, 2008: www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/deltaflow/docs/exhibits/usdoi/spprt_docs/doi_jeffres_2008.pdf] These benefits to the ecosystem would be lost if peak flows and flood pulses are suppressed, and contribute increased stress on fish populations that are already adversely affected by flow diversions (e .g., loss of spawning gravels, reduced foraging habitat, loss of cold water).

Response
Reclamation and SLDMWA do not disagree with this statement and do not see any conflict between the analysis and this statement. The ten percent screening threshold for instream flow in rivers and creeks is one of multiple criteria used to determine whether there were significant impacts on aquatic and terrestrial resources. Use of the ten percent threshold is described in Section 3.7.2.1.3. See response to Comment NG10-28 for additional information.

The analysis used two screening criteria to determine whether there were substantial flow reductions in waterways: a greater than 1 cfs reduction criterion and a greater that 10 percent reduction criterion. Flow reductions in the majority of waterways did not meet either of these criteria (see Table 3.7-3). Because there is high environmental heterogeneity in these Central Valley streams, a change of 1 cfs, either higher or lower, is not uncommon. This is why the 1 cfs criterion, in combination with the 10 percent criterion, were used and were considered highly conservative for detecting substantial flow changes. For those waterways with changes greater than the criteria, Section 3.7.2 includes a further biological analysis that considers the types of biological benefits discussed in the comment. Flow changes during wet periods represent a very small percent of flow during these periods (a barely perceptible change), and would not alter floodplain inundation. See response to Comment NG10-28 for additional information.

Comment FA01-40

Comment
Recommendation: More thoroughly analyze the project's potential impacts on native ecosystems, including sensitive and endangered species, from changes in streamflow. Clearly define, in the FEIS, the criteria used for defining harm to species. Where significant impacts are found to occur, the FEIS should discuss potential mitigation measures.

Response
See response to Comment FA01-39. Because streamflow changes associated with the range of potential transfer activities analyzed under the action alternatives are insubstantial, no significant impacts on native ecosystems from changes in streamflow are anticipated.

Comment FA01-41

Comment
The idling of cropland has the potential to result in increased sediment runoff to local waterbodies. The document contends that this impact is expected to be less than significant due to the crust-like surface formed on rice fields after they are drained and the assumption that farmers idling upland crops will employ soil retention measures (p. 3.2-29). The DEIS does not discuss the possible benefits of planting cover crops toward preventing sediment runoff, especially where landowners choose not to employ other erosion control techniques.

Response
The commenter is correct that runoff from idling of cropland was not found to have a significant impact on water quality. As a result, mitigation measures such as cover crops were not evaluated as part of this study. However, additional information was added to Section 2.3.2.1 to describe how non-irrigated vegetation left on idled fields may improve the existing condition and habitat value of these fields.

Comment FA01-42

Comment
Recommendations: Discuss, in the FEIS, the feasibility and benefit of planting or encouraging the growth of cover vegetation for reducing soil erosion and sediment runoff into waterways.

Response
The analysis of runoff from idled fields found this type of action was not necessary to reduce soil erosion, but it could improve existing conditions and habitat value. Text has been added in Section 2.3.2.1 to describe how non-irrigated vegetation left on idled fields may improve the habitat value of these fields.

Comment FA01-43

Comment
Fisheries. Chapter 3.7 of the DEIS assesses the project's potential impacts upon fisheries. EPA finds that the analysis performed lacks the resolution necessary to identify the full range of potentially significant adverse impacts the project may have upon fisheries, including potential impacts on special status species. The modeling performed for this analysis relied upon the flawed assumptions that a transfer action would have no adverse impact upon fisheries if modeled flow reduction were of less than one cubic foot per second (cfs) or less than a ten percent change in mean flow by water year type (p. 3.7-20). These assumptions inappropriately limit the scope of the impact analysis and undermine the accuracy of the conclusions reached.

Response
The EIS/EIR employs the best available tools. When tools were not available, the analysis required assumptions, inference, and best professional judgment. There were several steps to the analysis, including the screening analysis of 1 cfs and 10 percent, followed by a biological analysis. The 10 percent assumption used was based on previous legally certified documents (as discussed in Section 3.7.2.1.3) and is, therefore, appropriate for use. The 1 cfs assumption was an additional criterion needed for larger streams. Ultimately, the range of potential activities under the Proposed Action, throughout the many analyses conducted, was found to be less than significant in all waterways for fisheries resources.

Comment FA01-44

Comment
The DEIS contends that any change in flow of less than ten percent falls within the "noise of model outputs and beyond the ability to measure actual changes" (pg. 3.7-20). It is not logical nor acceptable for purposes of this analysis to conclude that biological impacts are limited to the range of flow changes

capable of being represented by the model employed. Research has examined the effects of implementing freshwater flow prescriptions for rivers and estuaries that mimic the pattern of the natural hydrographs in order to protect aquatic species with life histories adapted to such flow patterns. [Footnote: “Major researchers involved in developing ecologically protective flow prescriptions concur that mimicking the unimpaired hydrographic conditions of a river is essential to protecting populations of native aquatic species and promoting natural ecological functions”. (Sparks 1995; Walker et al. 1995; Richter et al. 1996: Poff et al. 1997: Tharme and King 1998: Bunn and Arthington 2002: Richter et al. 2003; Tharme 2003: Poff et al. 2006; Poff et al. 2007: Brown and Bauer 2009). SED. Appendix C. p. 116] For example, work performed by Richter, et. al. [Footnote: Richter, B.D., Davis, M., Apse, C., and Konrad, C. P. 2011. A presumptive standard for environmental flow protection. River Research and Applications. DOI: 10.1002/rra.1511. http://eflownet.org/downloads/documents/Richter&al2011.pdf] on riverine systems in Florida, Michigan, Maine, and the European Union found that the maximum cumulative depletion of flows allowable to ensure adequate protection of aquatic species ranged from 6- 20% year-round or in low-flow months and 20-35% in higher flow months. These scientists recommended the equivalent of no less than 90% of natural flow to achieve a high-level of ecological protection, and no less than 80% of natural flow to achieve a moderate level of ecological protection. Central Valley watersheds experience a much higher proportion of flow alteration than these scenarios. For example, during a median year in the San Joaquin River system, only 31% of the natural flow is allowed to remain in the river channel. [Footnote: EPA Comments on the Bay Delta Water Quality Control Plan, Phase I SED. March 28, 2013. Available at: http://www.epa.gov/sites/production/files/documents/sfdelta-epa-comments-swrcb-wqcp-phase1-sed3-28-2013.pdf] In a system that is so severely impacted with regard to streamflow, additional reductions in flow of less than ten percent have the potential to cause significant adverse impacts.

Response

The ten percent screening threshold for instream flow in rivers and creeks is one of multiple criteria used to determine whether there were significant impacts on aquatic and terrestrial resources. Use of the ten percent threshold is described in Section 3.7.2.1.3. See response to Comment NG10-28 for additional information. While the hydrologic models used for the analysis are considered to be the best available, they are not perfect and a certain amount of “noise” is associated with them. It is not reasonable or appropriate to consider any model as having perfect predictive power.

Comment FA01-45

Comment

Similarly, because streams and stream flows vary greatly at the reach scale due to environmental heterogeneity, changes of less than 1 cfs can have significant adverse effects on fishes and amphibians, depending on the specific reach affected and the conditions in that reach at the time of impact. Fishes, especially special status species, rely on high quality reaches as refugia for population persistence. Any degradation of reach quality has the potential to affect population vitality.

Response
Reclamation and SLDMWA agree that there is high environmental heterogeneity in these Central Valley streams. As a result, a change in 1 cfs, either higher or lower, is not uncommon. This is why the 1 cfs criterion, in combination with the 10 percent criterion, were used and were considered highly conservative for detecting substantial flow changes. See responses to Comments FA01-39 and NG10-28 for additional information. The commenter would like the thresholds of significance under CEQA to be zero such that any change, no matter how small, would be significant. The preparers of the EIS/EIR have indicated the changes to the environment are barely perceptible. As such, they are within the range of normal operations of existing facilities and are less than significant under CEQA.

Comment FA01-46

Comment
According to the DEIS, the Central Valley Project Improvement Act of 1992 requires that a transfer "will not adversely affect water supplies for fish and wildlife purposes" (p. 1-11). Based upon the information provided in the DEIS, it is not clear that this provision would be met if the "Full Range of Transfer Measures" project alternative (the preferred alternative) is implemented as currently described.

Response
See response to Comment NG10-36.

Comment FA01-47

Comment
Recommendations: Perform additional modeling and analysis to more accurately assess potential impacts of the project upon fisheries. We recommend discarding the flawed assumptions that underpin the analysis performed for the DEIS. The FEIS should disclose when model resolution is too coarse to capture flow changes with the potential to adversely impact fisheries, and identify measures that would avoid or mitigate adverse impacts to fisheries and the aquatic environment in connection with actions authorized by the proposed project. Explain how and when the need for implementation of such measures would be determined.

Response
The EIS/EIR contains a complete analysis of fisheries resources impacts. See response to Comment NG10-36 for a more detailed description of the analysis.

Comment FA01-48

Comment

The bulk of the analysis presented in section 3.7 of the DEIS focuses primarily upon the proposed project's potential impacts upon a short list of “species of management concern”. It is unclear why the numerous other native fishes potentially affected by the proposed project are not more thoroughly examined. For example, page 3.7-9 provides a list of waterways that do not contain special-status fish species, followed by the statement, “as a result, no further biological analysis was conducted in these waterways". It is not clear why the DEIS concludes that potential impact to non-special-status species are inherently less than significant. Numerous native species may inhabit these waterways and may be exposed to adverse conditions as a consequence of this project. Furthermore, the DEIS does not demonstrate that potential impact to fish assemblages or communities were considered, only impacts upon individual species. While protection of individual special status species is important, the project's potential impacts upon fisheries at the ecosystem scale may be equally significant and worthy of consideration.

Response

A discussion of effects to native species and conclusion of no impacts have been added to the section.

Comment FA01-49

Comment

Recommendations: Discuss, in the FEIS, the proposed project's potential impact upon all native species, rather than focusing solely upon “species of management concern”; this should include analysis of potential impacts upon waterways previously eliminated from analysis for fisheries impacts. We recommend that the FEIS analyze potential impacts to multi-species communities, rather than focus solely on single-species impacts.

Response

A discussion of effects to native species and conclusion of no impacts have been added to the section.

Comment FA01-50

Comment

The DEIS explains that native fishes assemblages in the deep-bodied fishes zone have been replaced largely by non-native assemblages, citing "Moyle (2002)" (page 3.7-6). While this is generally true for the San Joaquin River, it is not an accurate characterization for the Sacramento River system. Many more recent studies of fishes in the Sacramento River system have been produced since 2002 that more accurately characterize the current condition of fisheries in that system.

Response
Reclamation contacted EPA and requested they provide the references offered in this comment. EPA suggested that Reclamation contact one or more of the four fisheries biologists whose names and employers were provided by EPA in their response. All four individuals were contacted and Reclamation received responses from Peter Moyle, Michael Marchetti, and Larry Brown with the information needed to address this comment. The text has been updated based on their responses.

Comment FA01-51

Comment
Recommendations: A review of available scientific literature related to the fish assemblages of the Sacramento River should be conducted and the most current reliable data should be employed for defining existing conditions and determining potential project impacts. Based on this review, clarify the potential for the proposed project to adversely affect native fish assemblages in the deep-bodied fishes zone. EPA would be willing to assist BOR in acquiring the relevant literature, if needed.

Response
See response to Comment FA01-50.

Comment FA01-52

Comment
The DEIS understates potentially significant impacts to anadromous fish species by focusing on peak habitation times and locations, without regard for the potentially substantial number of individuals who may occur in waterways outside of peak times. For instance, water transfers, which would occur from July through September, would coincide with the spawning period of winter-run Chinook salmon. The DEIS states that "spawning occurs upstream of the areas potentially affected by the transfers. Due in part to elevated water temperatures in these downstream areas during this period, emigration would be complete before water transfers commence in July." (pg. 3.7-12) While most winter-run emigration is completed between Sept-June, not all emigration is complete by the end of June, and this is important for such a diminished species because every individual counts. Depending on the water year and river conditions, some fish continue to emigrate beyond June. Therefore, the conclusion that no potential effect to winter-run Chinook salmon emigration would occur is not supported. Similarly, the DEIS indicates that impacts to spring-run Chinook salmon would be less than significant because "the bulk of upstream migration (March-September, peaking May-June) and emigration (November-June) would be complete before water transfers commence in July" (pg. 3.7-13 to 14).

Response
The section referred to by the commenter is an initial discussion of potential effects. Later in the document (Section 3.7.2.4 for the Proposed Action), there is a full analysis of potential impacts to flows in the Sacramento River for all months and water year types, including those that were suggested by the commenter. The analysis concludes that impacts would be less than significant because there are no substantial changes in flows in waterways that winter- and spring-run Chinook salmon inhabit except Little Chico Creek, which is discussed separately.

Comment FA01-53

Comment
While most migration may occur outside the proposed transfer period, the DEIS does not discuss in sufficient detail the potential adverse effects of the proposed project upon those migrating or emigrating fish that would be present in waterways affected by transfer actions. Furthermore, the DEIS contends that, while summer rearing of Central Valley steelhead would overlap with water transfers in the Seller Service Area, "the majority of rearing ... would occur in the cooler sections of rivers and creeks above the influence for the water transfers." (page 3.7-15). This statement requires a citation if it is to serve as the basis for concluding that potential adverse effects on Central Valley steelhead summer rearing is unlikely to occur. Again, while most of the rearing may occur outside the area to be adversely affected by water transfers, the DEIS suggests that this is not the case for all rearing, and this potential adverse effect is not quantified or analyzed in sufficient detail.

Response
The text has been changed and reference provided, although it is not the basis for conclusions drawn later. The lack of changes in flows in the rivers is the basis for these conclusions.

Comment FA01-54

Comment
Recommendation: The FEIS should accurately characterize the potential impact upon winter-run Chinook salmon and Central Valley steelhead. Where adverse impacts are likely to occur, potential mitigation measures should be proposed and analyzed.

Response
See response to Comment NG10-36 for a more detailed description of the analysis. No mitigation was necessary because the analysis shows no significant impacts are anticipated.

Comment FA01-55

Comment
The discussion of potential impacts to steelhead and hardhead understates potential impacts and ignores the potential consequence for these populations where consecutive dry or critically-dry water years occur. The DEIS states that, although juvenile steelhead and hardhead could be present in some rivers affected by reduction in flows, those reductions occur "only one month and one water year type in one month," and therefore this impact is not expected to have a substantial effect on these species (page 3.7-28), but the potential adverse effects on these species during this one month period are not clearly characterized. If mortality is possible due to adverse stream conditions, then the brief duration of this impact does not necessary ensure minimal harm. Furthermore, if a dry or critically-dry year follows one of the same, the adverse effects during this one month period could be compounded.

Response
The text has been clarified to address this comment. Reclamation and SLDMWA have provided further biological information to support the conclusion that there would be less than significant impacts to fisheries resources in Stony Creek.

Comment FA01-56

Comment
Recommendations: Clearly explain the criteria used to conclude that these potential effects on steelhead and hardhead would be less than significant. The cumulative effect analysis should encompass consecutive dry and critically-dry years.

Response
As described in Section 3.7.2.4, a reduction of 10.0 percent in one water year type and one month is infrequent and, therefore, not considered a "substantial" effect to the habitat of target species, which is the significance criterion used in the EIS/EIR.

Comment FA01-57

Comment
Migratory Birds. With the large-scale conversion of Central Valley riparian forests and wetlands to agriculture and suburban development, birds and other wildlife have become increasingly dependent on agricultural lands for food and cover. Ricelands serve as essential breeding and wintering habitat for nearly 187 species of birds, 27 species of mammals, and 15 species of reptiles (of which 30 are considered special-status species) [Footnote: "Wildlife Known to Use California Ricelands," 2011. Prepared for California Rice Commission http://calrice.org/pdf /wildlife/Species-Report.pdf]. The DEIS focuses almost

exclusively on the proposed project's potential adverse effects upon special status species while potentially significant adverse effects upon migratory birds are either discounted or ignored altogether. Ricelands provide a high-value food source from the 75,000 tons of grain estimated to remain on the ground each year due to harvesting inefficiencies. As a result, wintering waterfowl are estimated to gather more than 50% of their nourishment from ricelands.

Response
See response to Comment FA01-7.

Comment FA01-58

Comment
The DEIS contends that a reduction in acres of flooded agricultural fields in the Delta resulting from the idling of cropland and the shifting of crops would not affect species migrating to the project area during spring because these species would simply select suitable habitat upon arrival (Section 3.8.2.4.1). But the proposed project could remove up to 51,473 acres (p. 3.8-64) of valuable farmed wetlands from the landscape and the DEIS' apparent conclusion that migratory bird population can quickly adapt to a radically altered mosaic of fallowed fields and farmed wetlands seems flawed and not supported by scientific documentation. Furthermore, the DEIS appears to incorrectly assume that all other factors will be held equal while cropland idling and water transfers take place. This is not the case. The critically-dry water years in which the maximum amount of water transfers are likely to take place are also the years when Delta farmers are most likely to fallow their lands, either voluntarily or due to water shortage, and these outcomes could greatly compound the adverse effects of the proposed project. For instance, the California Rice Commission reports that while farmers flood between 150,000 and 350,000 acres of ricelands annually in the Southern Sacramento Valley and Delta, farmers planted ~20% fewer acres during 2014 and may flood as little as 50,000 acres of ricelands in the 2014-2015 season due to the ongoing drought and water shortages. [Footnote: "Wintering Waterfowl Habitat Concerns Looms Large," California Rice Commission, September 16 2014, http://calrice.org/blog/?id=1410890340&author=California+Rice+Commission]

Response
See response to Comment FA01-7.

Comment FA01-59

Comment
Recommendations: The FEIS should thoroughly characterize the potential reduction in resting and forage habitat for migratory bird species resulting from cropland idling and crop shifting. The FEIS should consider these potential impacts in the context of current trends regarding habitat availability and anticipated future conditions resulting from climate change and changes in

farming practices. The FEIS should discuss means for ensuring that sufficient wetted habitat (natural wetland or flooded field) is available for migrating bird species.

Response

Habitat variability due to changes in farming practices is common within the potential transfer areas and is reasonably certain to continue into the future. The range of potential transfer activities analyzed in this EIS/EIR will not significantly affect the degree of change within this highly variable landscape. Effects from climate change, although reasonably certain to occur, are not expected to result in substantial changes to existing habitat conditions during the 10-year term of analysis.

Comment FA01-60

Comment

Riparian Communities. The project has the potential to have significant adverse effects on riparian systems, but the DEIS discounts these potential effects, in part because "changes in stream flow attributable to the Proposed Action would fall within historical ranges" (page 3.8-52). It should be recognized, however, that water management practices administered by federal and State agencies and local irrigation districts have already caused great stress on riparian systems and their associated fish and wildlife species. Recent consumptive patterns involving surface water diversions and groundwater pumping have, in effect, simulated, for fish and wildlife, severe and prolonged drought conditions whether or not drought conditions are actually present. The shift in hydrological conditions has caused a shift in species composition as native fishes have been overwhelmed and replaced by introduced and invasive aquatic species. Additional stress on these aquatic ecosystems could reinforce these adverse effects and potentially cause permanent, unmitigable impacts. The DEIS identified impacts to Cache, Stony, Coon, and Little Chico creeks that would be significant, with Little Chico Creek going to zero flow under some project scenarios. By their nature, no-flow conditions can lead to long-term and irreplaceable losses of ecosystem function.

Response

See Common Response 11. As described and analyzed in Section 3.8 of the EIS/EIR, the range of potential transfer activities analyzed in this EIS/EIR would not result in significant losses in ecosystem functions.

Comment FA01-61

Comment

Recommendation: Revise the EIS to more accurately characterize potential impacts to riparian communities. Identify robust mitigation measures that would ensure that the proposed project would not diminish instream flows in waterbodies affected by the proposed project.

Response
See Common Response 10 and Common Response 11 related to effects to vegetation communities.

Comment FA01-62

Comment
The DEIS identifies GW-1 as a mitigation measure for off-setting the potential adverse effects on stream flows from groundwater substitution, but the proposed measure may not provide full compensation for the potential significant adverse effects on riparian systems. Based on the information provided in the DEIS, it appears that the proposed project does not contain provisions for preventing the complete dewatering of smaller streams near groundwater pumping zones. As mitigation measure GW-1 is designed to be reactionary, dewatered stream conditions might persist for extended periods before natural recharge to aquifers could restore base flows. This could result in serious indirect costs, such as the loss of mature riparian vegetation essential to the structure and function of riparian systems. Even if measures are taken to restore the riparian forests, the genetic losses could be permanent and full restoration may not be possible.

Response
The monitoring requirements of Mitigation Measure GW-1 have been clarified. See Common Response 10 for additional information.

Comment FA01-63

Comment
Recommendations: Revise measure GW-1 to address potentially irreversible adverse effects to riparian systems and related habitats from the implementation of the proposed project. Include, in the proposed monitoring plan, monitoring of any small tributary streams near the point of groundwater extraction. We recommend that specific mitigation triggers be established identifying the percent reduction in flow outside the natural range that would require a cessation of pumping.

Response
See response to Comment FA01-62.

Comment FA01-64

Comment
Range of Alternatives. In the development of project alternatives, BOR employed a screening criterion that all alternatives must be immediate, flexible, and provide new water to the buyers' service area. The requirement that all project alternatives provide water was used to screen out potential project components involving the conservation or transfer of water within the seller service area (Table 2-1). It is unclear why this screening criterion was deemed

necessary and how it relates to the project "need" of immediately implementable and flexible water supplies to alleviate shortages (p. 1-2). The restriction imposed that the alternatives need to “provide water” screens out all alternatives that would promote reducing demand in the buyer area and having water rights holders operate within the limit of their existing legal water rights. Some of the alternatives screened out by this criterion might be found to be environmentally and economically preferable. For example, retirement of drainage impaired areas that leach selenium into the San Joaquin River has been documented to have environmental and economic benefits in a National Economic Development Analysis conducted as part of the San Luis Drainage Feature Re-evaluation FEIS. [Footnote: San Luis Drainage Feature Re-evaluation Final EIS (2007) available at: http://www.usbr.gov/mp/nepa/nepa_projdetails.cfm?Project_ID=61] It is unclear why within basin transfers in the buyers service area, considered in conjunction with demand reducing measures, such as conservation and land fallowing, would not meet the underlying project need to supply water to meet shortages.

Response
The Lead Agencies established the purpose and need and project objectives to best describe their underlying reasons for considering an action. The objective to "develop supplemental water supply for member agencies during times of CVP shortages to meet existing demands" reflects the water shortages felt by transfer recipients and their desire to receive additional water during these shortages.

Reclamation, as an agency, has multiple planning efforts ongoing to satisfy their directives. The San Luis Drainage Feature Re-Evaluation reflects different objectives, and is being carried forward as a different project to achieve those objectives. See responses to Comments NG03-125 and NG03-141 for additional information.

Comment FA01-65

Comment
It is also unclear why groundwater storage ("Build new facilities to recharge and extract groundwater for use in buyer service area") in the buyers service area was deemed as not providing new water supply. If aquifers are recharged in wet years, then that water is pumped and used in dry years, it seems this alternative would offer "new supply" in circumstances similar to those when pumping of groundwater from the seller's service area would enable groundwater substitution transfers.

Response
The detailed reasons for screening out the Groundwater Storage Alternative are explained in Appendix A, Section 4.1.13. Groundwater storage could provide water during dry or critical years, but that supply depends on having an

available source of water to recharge. Agencies in the buyer service area face water shortages in most years and would not have additional water available for recharge. Without an adequate source of recharge water, this measure would not provide sufficient water to reduce CVP shortages.

Comment FA01-66

Comment
Recommendation: Explain how the screening criteria were developed and why the requirement that a project component provide new water was deemed appropriate and necessary. A number of the measures eliminated from further consideration in Table 2-1 warrant further consideration and discussion. The FEIS should explain why measures to limit demand and enable within basin exchange of water in the buyer service area, considered in conjunction with one another, would not meet the screening criteria identified.

Response
Appendix A includes additional detail on how the screening criteria were developed and why measures were eliminated from further consideration.

Comment Letter SA01, Helen Birss, California Department of Fish and Wildlife

Comment SA01-1

Comment
The California Department of Fish and Wildlife (CDFW) has reviewed the Bureau of Reclamation and San Luis & Delta-Mendota Water Authority (SLDMWA) Draft Environmental Impact Statement/Environmental Impact Report (EIS/EIR) for the Long-Term Water Transfers Project (Project). Thank you for providing CDFW the opportunity to address its area of statutory responsibility in the EIS/EIR (Cal. Code Regs., tit. 14, §§15086 & 15088).

The goal of the Project is to reduce Central Valley Project (CVP) supply shortages caused by dry hydrologic years by transferring water from entities upstream from the Sacramento-San Joaquin Delta to SLDWMA Participating Members and other CVP water contractors south of the Delta. Water would be made available for transfer through groundwater substitution, cropland idling, crop shifting, reservoir release, and conservation. The EIS/EIR evaluates potential impacts of water transfers over a 10-year period, 2015 through 2024.

CEQA Role: CDFW is a Trustee Agency as defined in the Guidelines for the Implementation of the California Environmental Quality Act (Cal. Code Regs., tit. 14, § 15000 et seq.; hereafter CEQA Guidelines) with responsibility for commenting on projects that could affect fish and wildlife resources (CEQA Guidelines, § 15386). CDFW has jurisdiction over the conservation, protection, and management of fish, wildlife, native plants, and the habitat necessary for biologically sustainable populations of those species (i.e., biological resources).

As a Trustee Agency, CDFW is responsible for providing, as available, biological expertise to review and comment upon environmental documents and impacts arising from project activities, as those terms are used under CEQA (Fish & G. Code, § 1802). CDFW anticipates that it may use the final EIS/EIR and act as a Responsible Agency as part of possible future consideration and issuance of discretionary approvals, described below.

Discretionary Approvals: State Threatened, Endangered, and Candidate Species: CDFW has discretionary authority over activities that could result in the "take" of any species listed as candidate, threatened, or endangered pursuant to the California Endangered Species Act (CESA; Fish & G. Code, § 2050 et seq.). DFW considers most adverse impacts on CESA listed species, for the purposes of CEQA, to be significant without mitigation. Take of any CESA-listed species is prohibited except as authorized by state law (Fish & G. Code, §§ 2080 & 2085). Consequently, if Project activities result in take of CESA-listed species, CDFW recommends that the Project proponent seek appropriate authorization prior to Project implementation. This may include an incidental take permit (ITP) or a consistency determination in certain circumstances (Fish & G. Code, §§ 2080.1 & 2081 subd. (b)).

Rivers, Lakes, and Streams: An entity may not: substantially divert or obstruct the natural flow of; substantially change or use any material from the bed, channel, or bank of; or dispose of any debris, waste, or other material into, any river, stream, or lake unless certain conditions are met. For such activities, the entity must provide written notification to CDFW. Based on the written notification and site specific conditions, CDFW will determine if the activity may substantially adversely affect an existing fish or wildlife resource and issue a Lake or Streambed Alteration (LSA) Agreement to the entity that includes reasonable measures necessary to protect the resource (Fish & G. Code, § 1600 et seq.).

Note that CDFW must comply with CEQA prior to issuance of an ITP or LSA Agreement for a project. As such, CDFW may consider the Lead Agency's CEQA documentation for the project. To minimize additional requirements by CDFW and/or under CEQA, the final EIR should fully disclose potential Project impacts on CESA-listed species and any river, lake, or stream, and provide adequate avoidance, minimization, mitigation, monitoring and reporting measures for issuance of an ITP or LSA agreement.

Response

The action alternatives do not include actions that would trigger the need for a Lake or Streambed Alteration Agreement with CDFW. The EIS/EIR addresses potential effects to both federal- and state-listed species in Sections 3.7, Fisheries and 3.8, Vegetation and Wildlife.

Comment SA01-2

Comment
Section ES.2.2, Page ES-6, Table ES-2:

The EIS/EIR states that Merced Irrigation District (ID) is a Potential Seller of 30,000 acft of water. However, Merced ID is seeking a new license from the Federal Energy Regulatory Commission (FERC) for continued operation of the Merced River Hydroelectric Project, and in July 2014, CDFW submitted to FERC recommended mitigation measures for the new license, including significant changes to in stream flow releases and reservoir operations. In September 2014, Merced ID responded to CDFW's recommendations in a document filed with FERC as part of the FERC Project No. 2179 administrative record titled, "Merced ID's Reply to Comments, Recommendations, Preliminary Terms and Conditions, and Preliminary Fishway Prescriptions." On pages 106-107 of this document, Merced ID predicted that compliance with CDFW flow recommendations "increases the average annual water supply shortage by more than 100,000 ac-ft and creates shortages in most year types. [CDFW's] recommendation reduces average annual carryover capacity storage by ... 73,000 ac-ft compared to the Merced ID's Proposed Project." Analogous recommendations by the U.S. Fish and Wildlife Service (USFWS) and other agencies to modify flow releases and reservoir operations received similar responses from Merced ID, all indicating significant water supply shortages and reduced carryover volumes if the recommended mitigation measures were implemented. There appears to be a substantive disconnect between these kinds of water supply evaluations in the FERC administrative record and the Project EIS/EIR which lists Merced ID as a willing seller of up to 30,000 ac-ft annually.

CDFW recommends that the EIS/EIR scope reference the ongoing FERC relicensing and incorporate the water supply and carryover volume analyses submitted by Merced ID to FERC. A Draft Environmental Impact Statement prepared by FERC for Merced ID's Hydroelectric Project is estimated to be issued in March 2015 and finalized in August 2015.

Response
Merced ID's FERC relicensing process is ongoing, and the license terms are not yet finalized. The FERC license requirements will have to be met before water could be transferred under the action alternatives. See Common Response 14.

Comment SA01-3

Comment
Section ES.3.2, Page ES-9, Table ES-3:

This section states, "[i]n the No Action/No Project Alternative the Buyer Service Area would experience shortages and could increase groundwater pumping, idle cropland, or retire land to address those shortages." However, this may not be an accurate description of this alternative because the Buyer Service Area currently utilizes short-term transfers to address their water needs. Further, due to existing transfers, the Central Valley Project Improvement Act Refuge Water Supply Program, which maintains and improves wetland habitat areas, is currently experiencing water transfer capacity issues concerning its already limited water supply, even without implementation of the Project. For example, this year at the Volta Wildlife Area, the last known population of giant garter snake (Thamnophis giga, GGS) in the western San Joaquin Valley was threatened with incidental take pursuant to CESA due to surface water supply limitations and likely operational constraints of conveyance systems needed to provide water needed for habitat. Cumulative impacts from short-term transfers and long term transfers proposed by the Project may have a significant impact on fish and wildlife that utilize refuges by resulting in a substantial adverse impact on sensitive species or interfering substantially with the movement of native migratory species.

CDFW recommends that that EIS/EIR describe the relationship between the existing short-term water transfers and long term transfers proposed by the Project, including an analysis of cumulative impacts from these activities, and any potentially significant impacts on fish and wildlife resources. Mitigation should be proposed if warranted.

Response
This EIS/EIR analyzes a range of potential transfer activities that may be proposed during the period 2015-2024. The transfers could be either short-term (single year) or long-term, as discussed in Section 2.3.2.7. The No Action/No Project Alternative assumes that theses short-term and long-term transfers would not move forward, which would mean that buyers included in this EIS/EIR would not purchase transfers that would need to be conveyed through the Delta.

Additional information about refuge-related issues is included in Common Response 9.

Comment SA01-4

Comment
Section 2.3.2.4, Page 2-30:

This section references, but does not clearly define, "protected aquatic habitats." Project activities could result in substantial adverse impacts on aquatic habitats that are not clearly designated as "protected aquatic habitats."

CDFW recommends that the EIS/EIR expand the definition of "protected aquatic habitats" to include public lands under conservation easement, State wildlife areas and ecological reserves, federal refuges, and private managed wetlands because management efforts to protect GGS occur on these lands.

Also identify how and to whom the seller will demonstrate that any impacts to special-status species have been addressed, including through coordination with CDFW and USFWS.

Response
Protected aquatic habitats include those lands with aquatic habitat and natural resource protections such as those identified by the commenter. See Common Response 14 for water transfer process.

Comment SA01-5

Comment
Section 2.3.2.4, Page 2-30:

This section states that the determination of Priority GGS habitat will be made through coordination with GGS experts, Geographic Information System (GIS) analysis of habitat proximity to historic tule (*Schoenoplectus sp*.) marsh, and GIS analysis of suitable habitat. However, this may not be sufficient to ensure appropriate identification of GGS habitat or areas that should be "prioritized" for species conservation. This could result in a substantial adverse impact on the species should appropriate habitat be overlooked.

CDFW recommends that the EIS/EIR state that consultation with CDFW and USFWS is required to ensure appropriate identification of GGS habitat and to evaluate which fields to fallow, through review of the CDFW's California Natural Diversity Database (CNDDB), review of rice fields which will be in production, and fallowing away from canals in a patchwork fashion to maximize habitat connectivity.

Response
Existing priority habitat areas have been identified based on the best available information on habitat use, known populations, and historic marsh habitat. Reclamation has prepared a Biological Assessment for the USFWS on the program. The water agencies requesting transfers will need to consult with CDFW if there is the potential to take listed species as a result of their transfers. See Common Response 14 for water transfer process.

Comment SA01-6

Comment
Section 2.4, Page 2-41, Table 2.9:

This table states that use of transfer water in the Buyer Service Area may result in increased irrigation on drainage impaired lands in the Buyer Service Area which could affect water quality, but that this impact is less than significant. However, significant environmental damage to fish and wildlife resources has occurred in the past from discharge of drainage from impaired lands. Many federal, state, and private managed wetland areas in the Central Valley are located at the lower end of watershed drainage areas and receive irrigation return flows as part of their water supply.

CDFW recommends the EIS/EIR analyze potentially significant impacts from increased irrigation on drainage impaired lands on Central Valley managed wetland public trust fish and wildlife resources.

Response
Table 2-9 a summary of potential impacts, but Section 3.2 of the EIS/EIR includes a more detailed analysis of the potential effects of irrigation return flows on water quality. Though there is the potential for transfer water in the buyer service area to result in increased irrigation runoff in the buyer service area, the effects to water quality were determined to be less than significant. Effects on wildlife are therefore anticipated to be less than significant. While there are and have been contaminant issues in some portions of the buyer service area (e.g., selenium contamination), the action alternatives are not expected to exacerbate these existing conditions.

Comment SA01-7

Comment
Table 2.9 of this section states that cropland idling/shifting could alter the amount of suitable habitat for natural communities and special-status wildlife species associated with seasonally flooded agriculture and associated irrigation waterways. This impact is identified as less than significant. However, cropland idling/shifting could have a significant impact on habitat availability for shorebirds, resident and migratory waterfowl, and special-status species in the Central Valley, especially if shifting reduces the amount of seasonally flooded post-harvest rice and corn. Seasonal flooding of postharvest rice and corn provides a substantial percentage of habitat and food supplies for migratory waterfowl. The 2006 Central Valley Joint Venture Implementation Plan estimates that 170,000 acres of post-harvest rice is needed for wintering waterfowl and wintering shorebirds in order to meet bird conservation goals.

CDFW recommends that the EIS/EIR address potentially significant impacts of cropland/idling shifting on fish and wildlife resources. Impacts could be mitigated if buyers of transfer water created equivalent habitat or habitat values to those that would be lost.

Response
Cropland idling would not affect fish. Section 3.8.2.4.3 of the Draft EIS/EIR evaluates potential impacts of cropland idling/shifting on terrestrial wildlife species, including migratory birds. As stated in Section 2.7.2.4.1, cropland idling is not likely to affect fisheries resources because this action would not substantially affect flows within natural waterways. Mitigation is not proposed to compensate for the temporary loss of terrestrial wildlife habitat because the Draft EIS/EIR concludes that impacts to wildlife are less than significant. The

commenter is concerned with the reduction of post-harvest forage for migratory waterfowl. The project does not include transfers of rice decomposition water and would not reduce the availability of water for post-harvest flooding. See response to Comment FA01-7 and Common Response 13 (Migratory Birds) for additional discussion of migratory bird impacts.

Comment SA01-8

Comment
Section 3.1.2.1, Page 3.1-14:

SACFEM2013 was used to model streamflow depletion from groundwater substitutions. Outputs from this model were used in a post-processing tool to simulate transfers and delta exports in order to analyze potential impacts to surface water supplies. However, it is unclear why monitoring data collected from 2007-2010 transfers were not used to support the models.

CDFW recommends that the EIS/EIR explain what type of data (i.e., surface flow depletions from groundwater substitution pumping) were collected by the Sellers from all years that transfers took place, and specifically from the recent four consecutive years of transfers (2007 -2010). The document should discuss why these data were not used in the analysis of impacts to streamflow from groundwater substitution pumping.

Response
See Common Response 5.

Comment SA01-9

Comment
Section 3.3.4.1, Page 3.3-88 to 3.3-91:

Groundwater substitution transfers can create time delays between additional groundwater pumping and potential impacts on stream systems. These delays may have significant impacts on timing and availability of surface flow to resident and anadromous fish species, special status species, and other fish and wildlife resources. The Department of Water Resources has been studying stream flow depletions as they relate to Sacramento Valley groundwater substitution transfers for several years.

CDFW recommends that the EIS/EIR include the results of the Department of Water Resources studies and analyze potential impacts on fish and wildlife resources resulting from time delays.

Response
The regional groundwater model used, SACFEM2013, incorporates the latest information about how groundwater pumping can alter the timing and amount of stream flows (see Section 3.1.2.1 and Appendix D for more information on

SACFEM). The effects of any changes to the timing and amount of stream flow on resident and anadromous fish were then analyzed in Section 3.7.2.4. Reclamation has coordinated with DWR throughout the process of developing the EIS/EIR, including model development.

Comment SA01-10

Comment
Section 3.7.1.3.2, Page 3.7-9:

This section lists the names of five creeks where no sampling information is available to indicate the presence of special-status fish species. Presence was assumed and further biological analyses were conducted in these waterways. However, this section inconsistently lists four of the five same creeks (along with 15 others) and states that a review of field sampling data and reports indicates that there is no evidence of the presence of special-status fish species in these waterways and, as a result, no further biological analysis was conducted.

CDFW recommends that the EIS/EIR clarify whether these five creeks may support special-status fish species.

Response
This section has been corrected. Biological analyses were conducted on the five creeks for which it was assumed special status species were present.

Comment SA01-11

Comment
Section 3.8, Page 3.8-20, Table 3.8-1:

The EIS/EIR includes western pond turtle (Actinemys marmorata, WPT) as a "listed" species. However, WPT is a Species of Special Concern (SSC), and is not CESA-listed or listed under the federal Endangered Species Act. Pacific pond turtle is used throughout the EIS/EIR in reference to WPT.

CDFW recommends that WPT be described as an SSC and moved to the following rows that describe SSC in Table 3.8-1. The species should be consistently referred to as "western pond turtle (WPT)" throughout the EIS/EIR.

Response
In the Draft EIS/EIR, the western pond turtle was inadvertently included under listed wildlife species and was also identified as a species of special concern, when in fact it is only the latter. The pond turtles' common name has changed many times and will be retained as pacific pond turtle. The document refers to the common name as pacific pond turtle and this will be reflected in Table 3.8-1 as only a species of special concern.

Comment SA01-12

Comment
Section 1.3.2.4, Page 1-14:

This section addresses impacts on fish and wildlife resources, and states that Water Code sections 1725 and 1736 require the State Water Resources Control Board to make a finding that proposed transfers would not result in unreasonable impacts on fish and wildlife or other instream beneficial uses prior to approving a change in post-1914 water rights.

CDFW recommends adding the following information is to Section 1.3.2.4 for regulatory consistency and clarity: California Code of Regulations Title 23 section 794 requires the petitioner to 1) provide information identifying any effects of the proposed changes on fish, wildlife, and other instream beneficial uses, and 2) request consultation with CDFW and the Regional Water Quality Control Board regarding potential effects of the proposed changes on water quality, fish, wildlife and other in stream beneficial uses. The petition for change will not be accepted by the State Water Resources Control Board unless it contains the required information and consultation request. Early communication with CDFW would streamline the consultation process through "up front" coordination regarding assessment of the potential impact to fish and wildlife resources. The State Water Resources Control Board will use this information in making their finding that proposed transfers do not result in unreasonable impacts on fish and wildlife or other instream beneficial uses.

Response
This text has been added.

Comment SA01-13

Comment
Section 2.3.2.1, Page 2-10:

CDFW recommends that the EIS/EIR clarify if water transferred via forbearance agreements were analyzed as part of the Project. If not, impacts from potential increases in groundwater pumping by seller agencies forbearing CVP water should be analyzed as a reasonably foreseeable future action/probable future project in the cumulative impacts analysis of each section.

Response
As described in Section 2.3.2.1, the transfers analyzed in the EIS/EIR could involve forbearance agreements of base supply or transfer agreements for CVP project water. Both transfer mechanisms would involve the same methods to make water available and move it; therefore, the environmental effects would not vary with the contract vehicle selected.

Comment SA01-14

Comment
Section 2.3.2.4, Page 2-29 to 2-30:

It is common for CDFW to review proposed water transfer CEQA documents, typically Negative Declarations, which do not address Environmental Commitments. Data may not be available to support the transfer request relative to potential impacts to fish and wildlife.

CDFW recommends that all proposed water transfers address Environmental Commitments and potential impacts on fish and wildlife. Include analysis of any previous transfers, monitoring, and mitigation efforts, and identification of how much water was actually transferred in previous years. Annual review of mapped acreage, diverted acre feet of water and monitoring and reporting results would provide a basis to develop baseline information on potential impacts of future proposed transfers.

This section states that Bureau of Reclamation would provide maps to USFWS in June of each year showing the parcels of riceland that are idled for the purpose of transferring water for that year.

CDFW recommends that the EIS/EIR state that these maps would also be provided to CDFW and the GGS interagency management team in order to provide coordination for conservation and management of Central Valley GGS populations.

Response
See Common Response 14 for water transfer process. All transfers that could occur under this environmental document would need to incorporate the environmental commitments as part of the way water transfers are identified and operated. Reclamation will share the maps with riceland idling with the CDFW and the giant garter snake (GGS) interagency management team.

Comment SA01-15

Comment
Section 3.7.1.3.3, Page 3.7-15:

Summer rearing of Central Valley steelhead would overlap with water transfers occurring in the Seller Service Area (July-September), both in the Sacramento and San Joaquin River and their tributaries. Thus, water transfers have the potential to impact steelhead. The majority of rearing, however, would occur in the cooler sections of rivers and creeks above the influence for the transfers. Earlier in the Draft EIS/EIR, it is stated that water made available from groundwater substitution transfers may start as early as April (Page 2-10).

CDFW recommends that the EIS/EIR clarify when groundwater substitution transfers could begin and, if necessary, analyze impacts on Central Valley steel head that may be impacted by groundwater transfers occurring in April, May and June.

Response
This section has been corrected to include the April-September period.

Comment SA01-16

Comment
Section 3.7.2.1.3, Page 3.7-20:

For smaller tributaries, the impact analysis compared modeled groundwater depletion flow rates to available data on mean flow rates for the historical period of record and identified changes to these monthly average flow rates that would result from water transfer actions. Significant impacts on fisheries resources due to stream flow depletions are more likely to occur during low-flow periods of any given month.

CDFW recommends that the EIS/EIR analyze the impacts from groundwater pumping on the low-flow period of each month, rather than the average stream flow for the entire month, in order to determine the significance of impacts on fisheries resources and special-status fish species during this sensitive period.

Response
While Reclamation and SLDMWA recognize the importance of low flow periods, limitations to the model's precision preclude such types of analysis. Mean monthly flows provide a reasonable and appropriate basis to characterize impacts for disclosure and decision-making purposes.

Comment SA01-17

Comment
This section states that development of the impact analysis involved literature review, review of known occurrences of special-status species based on the CNDDB, USFWS regional species lists, information from National Oceanic and Atmospheric Association fisheries website, and results of hydrologic modeling.

CDFW recommends that the EIS/EIR also include a discussion of how monitoring plans and monitoring data from previous years were used to show that transfers did not adversely affect fisheries resources.

Response
The analysis did use past monitoring data and a description was added to Section 3.7.2.1

Comment SA01-18

Comment
This section states that historical stream flow information for small streams were gathered where available and used as the measure of baseline flow. For locations for which historical flow data were limited or unavailable, a qualitative discussion of potential impacts is included for these locations.

CDFW recommends that the EIS/EIR include a table or an appendix to show which streams used available historic flow data, what this data included, and which streams lacked historic data and were subject to a qualitative analysis. This information will guide where additional stream flow efforts are needed relative to fisheries resource needs.

Response
This information has been added to Table 3.7-3 for streams for which it was used. For all other small streams, the use of historical data was not necessary.

Comment SA01-19

Comment
Section 3.7.2.4.1, Page 3.7-26 – 3.7-27:

Eastside/Cross Canal and Salt Creek have the potential for impacts on special-status fish species due to flow reductions, although no data were available to determine the proportional reduction in base flows (i.e., if a greater than 10 percent reduction would occur). This section states that these waterways are 1) "generally" not immediately adjacent to groundwater substitution transfers; 2) other "nearby" small waterways are not experiencing flow decreases that are causing significant impacts to aquatic resources; and 3) flow reductions would be observed at monitoring wells in the region and any adverse effects would be mitigated by implementation of Mitigation Measure GW-1. The mitigation plan would include curtailment of the pumping until natural recharge corrects the environmental impact. Therefore, the impacts on fisheries resources would be less than significant. However, it is unclear what the trigger for pumping curtailment would be and how cessation of pumping to allow natural recharge to "correct the environmental impact" mitigates this impact to a less than significant level if the impact has already occurred.

CDFW recommends that the EIS/EIR define "generally not immediately adjacent," explain how the determination was made that other "nearby" small waterways are not experiencing flow decreases that are impacting aquatic resources, and how these surrogate waterways relate to the potentially impacted streams. Additionally, the EIS/EIR should identify 1) how the placement and use of monitoring wells would be able to observe instream flow reductions, 2) how the trigger for curtailment of pumping that causes an adverse impact was derived, and 3) if the time from observation of streamflow reductions that result in adverse impacts to the cessation of groundwater pumping would be responsive enough to mitigate for impacts (Barlow and Leake 2012). This recommendation also applies to Section 3.7.6.1.1, which analyzes the cumulative impacts on fisheries resources and special-status fish species in Cache Creek, Stony Creek, Coon Creek, Little Chico Creek, Bear River, Eastside/Cross Canal and Salt Creek and Section 3.8.2.4.1, which analyzes the effects of substantially reduced stream flows as a result of groundwater substitution pumping on the riparian natural communities in Cache and Stony Creeks.

Response
No effects on fisheries were found and mitigation measures are unnecessary. All references to environmental commitments were removed from the fisheries section (Section 3.7) to avoid confusion, except in Section 3.7.4 which indicates that environmental commitments are unnecessary. Additional vegetation monitoring requirements have been added to GW-1 (see Common Response 10).

Comment SA01-20

Comment
This section lists 21 waterways where the Project would have a less than significant impact on fisheries resources and special-status fish species. The basis for this determination is that modeled flow changes would be small and no substantial effect on water quality would result from implementing the Proposed Action.

CDFW recommends that "water quality" in the previous sentence be replaced with "fisheries resources" and tables similar to Tables 3.8-5 and 3.8-7, which show the average monthly flow by water year type in Cache Creek and Stony Creek, respectively, under the No Action/No Project alternative (using historical data) and the Project (using the groundwater model's prediction of reduced flows from the Proposed Action), be included for all streams that have the potential to be impacted by the Proposed Action. As stated above, CDFW recommends that the analysis of potential impacts from groundwater pumping use data from the low-flow period of each month, rather than the average stream flow for the entire month, to determine the significance of impacts to fisheries resources and special-status fish species during this sensitive period.

Response
This text was changed as requested.

Regarding an examination of intra-monthly modeling outputs: While the lead agencies recognize the importance of low flow periods, limitations to the model's precision preclude such types of analysis. Mean monthly flows provide a reasonable and appropriate basis to characterize impacts for disclosure and decision-making purposes.

Comment SA01-21

Comment
Section 3.7.2.4.1, Pages 3.7-28 to 3.7-29:
