

Total Maximum Daily Load Progress Report		Laguna de Santa Rosa Nutrient TMDL
Regional Water Board	North Coast, Region 1	<b>STATUS</b> <input type="checkbox"/> Conditions Improving <input type="checkbox"/> Data Inconclusive <input checked="" type="checkbox"/> <b>Improvement Needed</b> <input type="checkbox"/> TMDL Achieved/Waterbody Delisted
Beneficial uses affected	COLD, WARM, and others	
Pollutants addressed:	Ammonia & Total Nitrogen	
Implemented through:	NPDES Permits and Grants	
Approval date:	May 1995	

**TMDL summary:** The Laguna de Santa Rosa watershed encompasses a 254 mi<sup>2</sup> basin that drains to the Russian River. The mainstem Laguna is one of the largest freshwater wetland systems in California, is eutrophic in the summer, and is impaired by nitrogen, phosphorus, and low dissolved oxygen levels. TMDLs for nitrogen and ammonia were established in 1995 in the [Waste Reduction Strategy](#) in order to reduce ammonia toxicity to aquatic life and raise levels of dissolved oxygen. Ammonia and nitrogen were identified as coming from the Laguna Wastewater Treatment Plant, runoff from dairies, urban runoff, non-irrigated agriculture, septic systems, and open space stormwater runoff. The Strategy established seasonal goals for total nitrogen and total ammonia at four locations, expressed as total loads and as concentrations. The goals were to be attained primarily by implementing 319 Grants for dairy infrastructure improvements, revisions to NPDES wastewater permits and treatment plant upgrades, implementing the NPDES stormwater program, and working with a task force to encourage voluntary improvements.

### TMDL Loading Goal Attainment

### Water Quality Outcomes

- Nitrogen sources to the Laguna were reduced as a result of operational improvements at the City of Santa Rosa's Laguna Wastewater Treatment Plant and improvements in waste storage and disposal activities at dairies.
- TMDL goals for Ammonia and Total Nitrogen concentrations have been generally met.
- TMDL goals for total loads have not been met and currently exceed goals.
- Measured loads from 1995 to 2000 were relatively higher due to higher stream flows.
- Reductions of phosphorus are needed to control eutrophication.
- High sediment oxygen demand in the substrate of the Laguna continues to cause low dissolved oxygen levels.
- In 2002, phosphorus and nitrogen were added as impairments in the Laguna due to continued water quality problems from eutrophication. A new TMDL is currently under development.

### Laguna de Santa Rosa Water Quality
