  - This section states that a data usability evaluation was conducted using the six USEPA data usability (DU) criteria that are listed, yet all that was provided was the Laboratory Data Package Review (Attachment 3) and a summary paragraph on p. 6 identifying chemicals detected in blanks and noting that several matrix spike recoveries and relative percent differences were outside laboratory-specific control limits.
  - For future submittals, each of the DU criteria should be specifically addressed as follows:
    - Criterion I, Reports – list all reports from which the HHRA database was generated and note if reporting was adequate for HRA use.
    - Criterion II, Documentation – document that a specific geographic location has been identified for each sample ID listed in the database and reference a relevant figure.
    - Criterion III, Data Sources – document, with the support of the CSM that analytical methods are adequate to identify COPCs for each area and each environmental medium of interest and that broad spectrum methods were used.
    - Criterion IV, Analytical Methods and Detection Limits – confirm analytical methods and associated reporting limits as adequate for HRA.
    - Criterion V, Data Review – document that a qualified professional (e.g., risk assessor) conducted the DU evaluation and tied it to the HHRA uncertainty analysis.
    - Criterion VI, Data Quality Indicators (DQIs) – discuss the DQIs in terms of uncertainties in the identification of COPCs and EPCs, as well as the risk characterization.
  - This section notes that several matrix spike (MS) recoveries and relative percent differences (for MS duplicates [MSD]) were outside laboratory-specific control limits, but that the associated data are usable as the laboratory control samples were acceptable. The MS/MSD data are key data to support the uncertainty in soil EPCs (and associated risks). If MS recoveries are low (e.g., below the lower lab QC limit), then accuracy of

the associated EPCs must be discussed in the uncertainty analysis. If the MSD is outside of lab QC limits, then precision of the associated EPCs must be discussed in the uncertainty analysis. Laboratory control samples cannot be substituted for MS/MSD, as they are spikes of deionized water, which is not the exposure medium in the HRA.
    - Discuss in the DU evaluation the notation in Attachment 3, top of p. 4, "High frequency of "R-06": The reporting limit has been raised to account for the presence of high levels of analytes".
- Section 2.2 Chemicals of Potential Concern
    - Provide rationale for not re-evaluating metals COPCs (i.e. background analysis) using the supplemental metals sampling data.
- Section 3.0 Dose-Response Assessment
    - A list of toxicity criteria for "new" COPCs is presented in Table 3-1.
    - Replace values with the following values and update risk calculations. These values have been published for a few years.
    - Dichlorodifluoromethane: RfC = 1 E-1 mg/m3 (current RSL table, November 2011 [PPRTV])
    - 1,2-Dichloroethane: RfD: 6 E-3 mg/kg-day (current RSL table, PPRTV); RfC = 7.0 E-3 mg/m3 (current RSL table, PPRTV)
    - cis-1,2-Dichloroethylene: RfD = 2 E-3 mg/kg-day (current IRIS); RfC = 6 E-2 mg/m3 (RIVM peer-reviewed value, TERA database)
    - trans-1,2-Dichloroethylene: RfD = 2 E-2 mg/kg-day (current IRIS); RfC = 6 E-2 mg/m3 (current RSL table, PPRTV)
    - 4-Methyl-2-pentanone (MIBK): RfC = 3 mg/m3 (current IRIS)
    - Propylene: REL = 3,000 µg/m3 (3 mg/m3 [current OEHHA REL table])
    - Trichlorofluoromethane: RfC = 7 E-1 mg/m3 (current RSL table [HEAST])
    - 1,1,2-Trichlorotrifluoroethane: RfC = 3 E+1 mg/m3 (current RSL table [HEAST])
    - 1,2,3-Trichloropropane: RfD = 4 E-3 mg/kg-day (current IRIS); RfC = 3 E-4 mg/m3(current IRIS)
    - Vinyl chloride: RfC = 1 E-1 E mg/m3 (current IRIS).
    - As per Part F RAGS, the inhalation pathway should be assessed using the IUR, REL/RfC directly with the air EPCs, rather than converting units and using the dose methodology.
- Section 4.0 Conceptual Exposure Model
    - Expand this section to include a description of the "updated" receptor populations (and associated exposure pathways) for the "updated" exposure areas.
- Section 5.0 Exposure Assessment
    - Describe each exposure area in this section and identified on Figure 1-1.
- Section 5.1 Exposure Point Concentrations
    - The higher of the Student's-t UCL and the BCA Bootstrap should be selected as the EPC. Last paragraph – "The parametric Student's-t UCL was selected as the primary method of UCL estimation, based on the assumption that the means for each COPC are approximately normal even in cases when the data distributions are not normal. In cases of skewed data (standard deviation of log-transformed data exceeds 1.5) or when the frequency of detections is less than 40%, the Kaplan Meier (KM) BCa method was used to calculate the 95% UCL. When there were not enough distinct observations to calculate the KM BCa estimate, the KM (Percentile Bootstrap) was selected or the maximum detect was used as

the EPC." This rationale for the selection of UCLs is not adequate.
    - Based on a single spot check for "Sum TPH" for Area E, the maximum concentration listed in the ProUCL output (electronic page 132 of Attachment 4) did not match the maximum concentration listed in Table 2-4 and the number of samples did not match.
    - The EPC for "Sum TPH" for Area E listed in Table 5-20 did not match any of the UCLs in the ProUCL file for "Sum TPH" for Area E.
- Section 5.2 Indoor Air Vapor Exposure Point Concentrations
    - Provide the J & E model output files. The indoor air EPCs were not cross checked against the Johnson & Ettinger model output, as the latter was not provided in Attachment 5.
- Section 6.0 Risk Characterization
    - We note that soil risk calculations for chromium, vanadium, benzene, benzo(b)fluoranthene, benzo(a)pyrene, dibenz(ah)anthracene, and aromatic TPH were reproduced for Areas A, C, D, E, G, Ia, Ib, and J (all spreadsheets provided by McDaniel Lambert).
    - p. 26 – For Area N, change the range of HI to "0.004 – 0.04".
- Section 7.1 Site Characterization and Sampling Activities –It is not clear what the desired sample size is based on. Confirm methodology used and that it is based on previous calculations.
    - Only soil gas data appear to have been evaluated. Some comment should be made regarding the additional soil data.
- Figure 1-2
    - It is difficult to read some of the sample ID, for example within Area K. Also, please cross check to ensure that all soil and soil gas samples are included on the figure.
- Attachment 2, 2011 and 2012 Soil and Soil Gas Data
    - Please explain why Area M data are designated "Ma" and "Mb".

If you would like to have a discussion with me regarding this project, please contact me at 805-781-5595 to arrange a meeting.

Sincerely,

Response to Comments

Section	#	Comment	Specific Response
Revise sHHRA for the following reasons			
General Comments for revising sHHRA	1	Efficiency of review and reference. Referencing multiple sections within 2 documents to find an answer is inefficient and can lead to incorrect answers and assumptions. It is possible a reader (Agency, consultants, the public, etc.) to render an incorrect answer to a question if only one document, such as the sHHRA versus the Addendum was referenced.	Merged documents and provided Final HHRA
	2	Unclear what level of confidence new data presents without an update to Table 2-1 of the sHHRA.	Updated Table 2-1 DQA
	3	Unclear what percentage of the former data was used in the new risk calculations although it was stated in one sentence in the Addendum (page 5) that the sHHRA database was updated.	The recent sampling events were summarized in Section 1 to identify the scope of the new data incorporated. Each of the new data pacakges are summarized in Attachment 6 - there are 4 new soil data packages, and 1 new soil vapor data package. Additionally, there are 2 new ground water sampling events: 4Q12 and 2Q13. The 4Q12 data is included in Attachment 7, and the 2Q13 Padre report is still in progress. The former data accounts for the majority of the sHHRA data. In Final HHRA, there is no distinction between "old" and "new" data.
	4	Unclear as to what the new data sets within each modified EA specifically contain.	Datasets for each EA may have changed with respect to new boundaries, as well as collection of new data. The summary table in the Introduction intended to portray these changes. Attachment 6 contains the complete soil and soil gasdata set.
	5	Exposure Areas have been added or eliminated	Merged documents and provided Final HHRA
	6	Exposure Area boundaries have changed . Boundaries have expanded in some cases.	Merged documents and provided Final HHRA
	7	Risk calculations have changed for each EA.	Merged documents and provided Final HHRA
	8	Critical Sections of the sHHRA are outdated and inaccurate.	Merged documents and provided Final HHRA
	9	o Section 1.4	Updated list of site characterization studies to include latest soil, soil gas and groundwater sampling events
	10	o Section 1.6	Updated exposure area descriptions, see Table 1-2
	11	o Section 2.1	Updated data validation and usability section, six criteria were reviewed in more detail for the laboratory QC data summarized in the Data Package Reviews. Refer to Section 7 and Attachment 10 (Data Package Reviews)
	12	o Section 2.2	Updated COPC selection section, background metals evaluation discussion includes rationale for not revising the background analysis
	13	All data used to determine potential risk should be accounted for in one risk assessment.	Merged documents and provided Final HHRA
	14	7 new soil and 8 new soil gas Chemicals of Potential Concern (COPCs) were discovered.	Merged documents and provided Final HHRA
	15	Referencing parallel sections back and forth is not efficient: ie: Section 2.2 of Addendum and Section 2 of the sHHRA would need to be referenced at the same time rather than referencing one section.	Merged documents and provided Final HHRA
	16	Clear commentary needs to be added to confirm the changes in risk thresholds from the sHHRA to the Addendum. Risk thresholds for EA's D, E, Ia, Ib, J have changed .	Merged documents and provided Final HHRA, risk thresholds are consistent with Final HHRA results.
	17	Methodology represented in Table 7-1 of Addendum should be consistent with Table 2.1 of the sHHRA.	The methodology in Table 7-1 was consistent with Table 2-1, but the table was formatted differently. Provided an updated Table 2-1 with new DQA results.

Response to Comments

Section	#	Comment	Specific Response
Please provide an updated sHHRA to include			
	18	The incorporation of new data. For example Table 2.1 of sHHRA needs an update including the new data to confirm the current level of confidence the new data set provides when comparing it to "USEPA acceptable performance criteria" referenced in this table. As stated in the 3-16-12 letter "The sample density for the evaluation of soil gas does not meet an "EPA Default" which does not provide the Health Agency confidence to conclude the calculated risk is protective of public health ... " for areas A,K, N. Table 7-1 of Addendum needs to confirm if the new sample size meets "USEPA acceptable performance criteria" as stated in sHHRA Table 2.1	Table 2-1 was completely updated to reflect the new exposure areas, sample sizes, and RBCs so all of the information is in one place. Sample size calculations are based on USEPA default criteria, unless these criteria are not met, in which case the range of sample sizes is presented.
Please provide an updated sHHRA that incorporates changes within the Addendum that include the following			
Section 1, Intro.	19	Provide descriptions of the new set of exposure areas (including the Drainage Area) in Section 1.6 of the sHHRA. Provide clarity in the description of Area C that it now includes Area B (possibly Area B/C) and the revised Open Space as it now includes the former Areas F and H.	Merged documents and provided Final HHRA - this included new exposure areas in Section 1.6 of the sHHRA. Since the documents were merged, there is no need to track differences between development plans.
Section 1, Intro.	20	Add Open Space to the list of areas for which additional soil sampling was performed (Addendum p. 3, last paragraph). Also, this paragraph lists Area lb as having additional soil sampling, however data were not found for Area lb in the 2011/2012 database (Attachment 2).	Area Ib did not include not have additional soil sampling in 2012, this appears to be a typo and should have listed "Open Space" instead of "Ib". Not necessary to track changes between development plans since Final HHRA will be completely revised
Table 1.1	21	Provide text to accompany appropriate tables so that changes made in exposure area boundaries, scenarios, and datasets are clearly tracked. For some areas (e.g. , Areas Ia, lb, J where "Changes in Addendum" lists "No changes in land use") it is not clear if there were changes to boundaries or receptors.	Not necessary to track changes between development plans since Final HHRA was completely revised
Table 1.1	22	Identify in the appropriate table all of the areas for which boundaries have changed. Based on a comparison of Figure 1-3 of the sHHRA (May 2011) and Figure 1-1 of the Addendum, it appears that the following areas have had changes in boundaries: A, C, D, E, G, J, K, L, M. and N.	Not necessary to track changes between development plans since Final HHRA was completely revised
Table 1.1	23	Add "new soil data" for Area lb if additional soil sampling was conducted (as per page 3, last paragraph).	Done.
Table 1.1	24	The name of Area N should be changed to provide clarity (such as "Area N - Parking Lot") so that readers can identify the data in the database for this area (denoted as "Parking" in the database). Also, as per p. 29, 3rd paragraph, the boundaries of Area N have changed. Add that information to the table.	Clarified description of Area N in text. Not necessary to track changes between development plans since Final HHRA was completely revised.
Table 1.1	25	Drainage Area is listed as an exposure area, yet under the Land Uses column, it states this is not an exposure area. We note that Exposure Point Concentrations (EPCs) and risks are calculated for receptors in this area.	Included Drainage Area as exposure area in Final HHRA
Section 2.1 DVDU	26	This section states that a data usability evaluation was conducted using the six USEPA data usability (DU) criteria that are listed, yet all that was provided was the Laboratory Data Package Review (Attachment 3) and a summary paragraph on p. 6 identifying chemicals detected in blanks and noting that several matrix spike recoveries and relative percent differences were outside laboratory-specific control limits.	Discussed matrix spike recoveries and RPDs in more detail in Section 7, following same format as matrix spike discussion in sHHRA. Data package reviews are included as Attachment 10.
Section 2.1 DVDU	27	For future submittals, each of the DU criteria should be specifically addressed as follows: Criterion I thorugh VI	Addressed in Sections 2 and 7.

Chevron Avila Tank Farm
Response to Comments

Section	#	Comment	Specific Response
Section 2.1 DVDU	28	This section notes that several matrix spike (MS) recoveries and relative percent differences (for MS duplicates [MSD]) were outside laboratoryspecific control limits, but that the associated data are usable as the laboratory control samples were acceptable. The MS/MSD data are key data to support the uncertainty in soil EPCs (and associated risks). If MS recoveries are low (e.g., below the lower lab QC limit), then accuracy of the associated EPCs must be discussed in the uncertainty analysis. If the MSD is outside of lab QC limits, then precision of the associated EPCs must be discussed in the uncertainty analysis. Laboratory control samples cannot be substituted for MS/MSD, as they are spikes of deionized water, which is not the exposure medium in the HRA.	Matrix spikes discussed in detail in Section 7.2.3
Section 2.1 DVDU	29	Discuss in the DU evaluation the notation in Attachment 3, top of p. 4, "High frequency of "R-06": The reporting limit has been raised to account for the presence of high levels of analytes" .	Attachment 3 was updated to provide more detail. After looking into this issue further, it was noted that VOCs have a reporting limit equal to 0.5 mg/kg in two samples. Considering the small inflation on reporting limit in only two samples, this issue does not seem significant enough to discuss in the text. No changes made to Section 2 or 7.
Section 2.2 Chemicals of Potential Concern	30	Provide rationale for not re-evaluating metals COPCs (i.e. background analysis) using the supplemental metals sampling data.	Addressed in Section 2 (see footnote in Section 2.2.1, at the bottom of page 51) and Section 7.2.4 (page 149). Since the background analysis of the metals was conducted on a site-wide basis, the change in exposure area boundaries does not necessitate the need to change the background approach. The new soil data included only 5 samples analyzed for metals in 3 exposure areas: D, L and E. Presented rationale for how this small sample does not change the conclusions based on the large number of total onsite samples for metals, and examined arsenic distribution since this a metal with elevated toxicity (see Figure 7-1).
Section 3.0 Dose-Response Assessment	31	A list of toxicity criteria for "new" COPCs is presented in Table 3-1.	Merged documents and provided Final HHRA
Section 3.0 Dose-Response Assessment	32	Replace values with the following values and update risk calculations. These values have been published for a few years.	Done. Reflected in updates to toxicity criteria that have ocurred since 2007.
Section 3.0 Dose-Response Assessment	33	Dichlorodifluoromethane: RfC = 1 E-1 mg/m3 (current RSL table, November 2011 [PPRTV])	Done. Reflected in updates to toxicity criteria that have ocurred since 2007.
Section 3.0 Dose-Response Assessment	34	1 ,2-Dichloroethane: RfD: 6 E-3 mg/kg-day (current RSL table, PPRTV); RfC = 7.0 E-3 mg/m3 (current RSL table, PPRTV)	Done. Reflected in updates to toxicity criteria that have ocurred since 2007.
Section 3.0 Dose-Response Assessment	35	cis-1 ,2-Dichloroethylene: RfD = 2 E-3 mg/kg-day (current IRIS); RfC = 6 E-2 mg/m3 (RIVM peer-reviewed value, TERA database)	Updated RfD value. SLO County EHS deferred to McDaniel Lambert for RfC selection. As discussed in Section 7.3.4, an RfC was not selected for cis-1,2-dichloroethene. Both USEPA and ATSDR have determined there are insufficient inhalation studies to derive an RfC. The RIVM value suggested is based on the LOAEL from an inhalation study of limited duration for the isomer, trans-1,2-dichloroethylene. Since this is a "provisional" tolerable concentration in air (TCA), and has changed several times since the 1977 study on which it is based was published - overall low level of confidence in this value.
Section 3.0 Dose-Response Assessment	36	trans-1 ,2-Dichloroethylene: RfD = 2 E-2 mg/kg-day (current IRIS); RfC = 6 E-2 mg/m3 (current RSL table, PPRTV)	Done. Reflected in updates to toxicity criteria that have ocurred since 2007.
Section 3.0 Dose-Response Assessment	37	4-Methyl-2-pentanone (MIBK): RfC = 3 mg/m3 (current IRIS)	Done. Reflected in updates to toxicity criteria that have ocurred since 2007.

Chevron Avila Tank Farm
Response to Comments

Section	#	Comment	Specific Response
Section 3.0 Dose-Response Assessment	38	Propylene: REL = 3,000 1Jg/m3 (3 mg/m3 [current OEHHA REL table])	Done. Reflected in updates to toxicity criteria that have ocurred since 2007.
Section 3.0 Dose-Response Assessment	39	1,1 ,2-Trichlorotrifluoroethane: RfC = 3 E+1 mg/m3 (current RSL table [HEAST])	Done. Reflected in updates to toxicity criteria that have ocurred since 2007.
Section 3.0 Dose-Response Assessment	40	1 ,2,3-Trichloropropane: RfD = 4 E-3 mg/kg-day (current IRIS); RfC = 3 E-4 mg/m3(current IRIS)	Done. Reflected in updates to toxicity criteria that have ocurred since 2007.
Section 3.0 Dose-Response Assessment	41	Vinyl chloride: RfC = 1 E-1 E mg/m3 (current IRIS).	Done. Reflected in updates to toxicity criteria that have ocurred since 2007.
Section 3.0 Dose-Response Assessment	42	As per Part F RAGS, the inhalation pathway should be assessed using the IUR, REL!RfC directly with the air EPCs, rather than converting units and using the dose methodology.	RAGS F methodology was used for inhalation pathways.
Section 4.0 Conceptual Exposure Model	43	Expand this section to include a description of the "updated" receptor populations (and associated exposure pathways) for the "updated" exposure areas.	Final HHRA includes complete list of receptors and associated pathways
Section 5.0 Exposure Assessment	44	Describe each exposure area in this section and identified on Figure 1-1.	Done
Section 5.1 Exposure Point Concentrations	45	The higher of the Student's-t UCL and the BCA Bootstrap should be selected as the EPC. Last paragraph- "The parametric Student's-t UCL was selected as the primary method of UCL estimation, based on the assumption that the means for each COPC are approximately normal even in cases when the data distributions are not normal. In cases of skewed data (standard deviation of log-transformed data exceeds 1.5) or when the frequency of detections is less than 40%, the Kaplan Meier (KM) BCa method was used to calculate the 95% UCL. When there were not enough distinct observations to calculate the KM BCa estimate, the KM (Percentile Bootstrap) was selected or the maximum detect was used as the EPC." This rationale for the selection of UCLs is not adequate .	Based on discusions with SLO County EHS, we agreed to inspect UCLs that were calculated using the KM method to ensure that they are not significantly over- or underestimated. No issues were found.
Section 5.1 Exposure Point Concentrations	46	Based on a single spot check for "Sum TPH" for Area E, the maximum concentration listed in the ProUCL output (electronic page 132 of Attachment 4) did not match the maximum concentration listed in Table 2-4 and the number of samples did not match.	The maximum concentration for Sum TPH in Area E in the ProUCL output (electronic page 196 of the Attachments file) matches the maximum concentration listed in Table 2-3. The number of samples also matches. SLO County EHS verified that these numbers matched in the Addendum.
Section 5.1 Exposure Point Concentrations	47	The EPC for "Sum TPH" for Area E listed in Table 5-20 did not match any of the UCLs in the ProUCL file for "Sum TPH" for Area E.	We verified this discrepancy and fixed it in the Final HHRA. Since TPH is now evalauted as three carbon chains (TPH-g, -d, and -mo), these ProUCL outputs were re-run and included as an attachment.
Section 5.2 Indoor Air Vapor Exposure Point Concentrations	48	Provide the J & E model output files. The indoor air EPCs were not cross checked against the Johnson & Ettinger model output, as the latter was not provided in Attachment 5.	We are no longer able to provie the J&E model outputs, only the summary page. As discussed, J&E model summaries were provided for each scenario - includes soil gas concentrations, depth, attenuation factor, and resulting indoor air concentration.
Section 6.0 Risk Characterization	49	We note that soil risk calculations for chromium, vanadium, benzene, benzo(b)fluoranthene, benzo(a)pyrene, dibenz(ah)anthracene, and aromatic TPH were reproduced for Areas A, C, D, E, G, Ia, Ib, and J (all spreadsheets provided by McDaniel Lambert).	OK

Chevron Avila Tank Farm
Response to Comments

Section	#	Comment	Specific Response
Section 6.0 Risk Characterization	50	p. 26- For Area N, change the range of HI to "0.004- 0.04".	N/A. Risk results and discussion updated
Section 7.1 Site Characterization and Sampling Activities	51	It is not clear what the desired sample size is based on. Confirm methodology used and that it is based on previous calculations.	USEPA default performance criteria was used for the updated DQA. DQA methodology remained the same as previous versions, with the exception of two items previously discussed with SLO County: (1) range of acceptable sample sizes only calculated for risk drivers where default USEPA criteria are not met, and (2) 10-6 used as a threshold for any child receptor, and 10-5 used as a threshold for other commercial receptors.
Section 7.1 Site Characterization and Sampling Activities	52	Only soil gas data appear to have been evaluated. Some comment should be made regarding the additional soil data.	DQA updated to reflect data collected from 2007 to 2013. Additional soil and soil gas data for revised areas were incorporated in the new Table 2-1. Ground water pathway was not a risk driver, therefore it does not appear in Table 2-1.
Figure 1-2	53	It is difficult to read some of the sample ID, for example within Area K. Also, please cross check to ensure that all soil and soil gas samples are included on the figure.	Figure 1-2 is Figure 7-1 in the Final HHRA. Revised Figure 7-1 so sample names would not overlap.
Attachment 2, 2011 and 2012 Soil and Soil Gas Data	54	Please explain why Area M data are designated "Ma" and "Mb".	N/A. Ma and Mb are no longer exposure areas. Ma is replaced by the new Exposure Area M and Mb is replaced by Exposure Area O.

ATTACHMENT 3

Former Avila Tank Farm: PCBs at the Tank Farm
(McDaniel Lambert, Inc. 2007)

MEMORANDUM

To: Avila Tank Farm Collaborative Assessment Team

From: Chuck Lambert and Becky Countway, McDaniel Lambert, Inc.
Mike Rendina, Avocet Environmental, Inc.

Date: October 8, 2007

Re: **Former Avila Tank Farm: PCBs at the Tank Farm**

On the June 6, 2007 Avila Tank Farm Collaborative Assessment Team (ATCAT) conference call, existing site data and the area-by-area data needs for the former Avila Tank Farm (the Site) were reviewed. The team discussed various chemicals of potential concern (COPCs) and questioned the adequacy of polychlorinated biphenyl (PCB) sampling at the Site. Although PCBs have not been detected at the Site and, based on this, were not included in the 2005 Baseline Human Health Risk Assessment, the ATCAT requested a memorandum summarizing what is known about PCBs at the Site, particularly in the most industrialized areas of the former Tank Farm.

Assessment of the former Unocal Avila Tank Farm was initiated in the summer of 1997 in response to a request from the Regional Water Quality Control Board – Central Coast Region. This investigation followed a similar investigation of the Guadalupe Oil Field (GOF), where PCBs were unexpectedly encountered in diluentimpacted soil. The source of the PCB contamination at the GOF was believed to be from two sources – 1) leakage from the compressors used to lift the natural gas produced in the field, and, 2) contamination caused by the Santa Maria Refinery adding recycled oil to the diluent for use at the GOF[1] (LFR 1998; LFR 1999; McDaniel Lambert 2001).

Although the activities and processes described above for the GOF did not occur at Avila, representative shallow soil samples from areas of intensive industrial use at the Avila Tank Farm were evaluated for the presence of PCBs (Figure 1).[2]

As illustrated in Figure 1, this resulted in the collection of more than 40 PCB soil samples from around the refinery area, in the vicinity of the truck loading rack and the pump house, and along some former transmission lines and some of the above-ground storage tanks (ASTs). If there were leaking transformers or other equipment that may have contained PCBs they would most likely have been in these areas. A few PCB soil

[1] Personal communication – Dr. Robert Haddad, Chief, Assessment and Restoration Division, NOAA
[2] All analyses of PCBs at the Site have been as Aroclors.

1608 PACIFIC AVE. • STE. 201 • VENICE, CA
TEL (310) 392 6462 • FAX (310) 392 6693

samples also have been collected from open areas on the southern portion of the Site. A total of 50 soil samples (≤10 feet bgs) have been analyzed for PCBs, and included some of the most contaminated samples from the Site, such B-95 and B-122, which have some of the highest residual soil petroleum hydrocarbon concentrations detected at the Site. PCBs were not detected in any of these 50 samples (with detection limits ranging from 0.030 to 3.0 mg/kg). In addition, a number of groundwater and free petroleum samples from wells situated throughout the Site have been tested for PCBs, with none detected (i.e., <0.3 µg/l and <4.0 mg/kg, respectively). The absence of PCBs in product collected from the Avila Tank Farm is also notable, as PCBs at the Guadalupe Oil Field were detected in the free diluent.

Because the PCB evaluation at the former Avila Tank Farm focused on the areas of greatest use and impact, the coverage of samples over the 10 Evaluation Areas delineated by the ATCAT is uneven (see below). Specifically, the majority of the samples are from Evaluation Area 9, where the refinery, loading rack and pump house were located, and in the vicinity of former transmission lines and ASTs falling in Evaluation Areas 2 and 3. No PCBs samples have been collected from Evaluation Areas 1, 7 and 8, where little or no tank-farm related infrastructure was located.

No sources of PCBs have been identified at the former Avila Tank Farm. Processes that resulted in the release of PCBs at the GOF did not occur at the Avila Tank Farm. Despite the varying spatial coverage, the fact that PCB have not been detected in the most heavily industrialized areas of the Site suggests that historic activities at the Avila Tank Farm did not result in PCB contamination, and that they were appropriately excluded as COPCs in the 2005 Baseline HHRA. In addition, detection limits for samples collected from the Avila Tank Farm are adequate for risk assessment purposes. Specifically, reporting limits vary from 0.03 to 3.0 mg/kg, with the majority at 0.3 mg/kg or below (see Tables 1-7 below); the California Human Health Screening Levels for PCBs in soil are 0.089 and 0.3 mg/kg for residential and commercial use, respectively. Therefore, we believe that no additional analyses of PCBs in soil are warranted.

A summary of the PCB soil data available broken down by Evaluation Area, follows.

EVALUATION AREA 1

Evaluation Area 1 is located in the northeast corner of the site, and covers 10.29 acres. Potential sources of contamination in this area include a crude oil pipeline which traverses a portion of Area 1. Aerial deposition and surface water runoff are other potential contaminant sources. A small area of TPH-related contamination has been delineated in the vicinity of the former pipeline. Other than some company housing in the early 20th century, no other infrastructure associated with the former Avila Tank Farm was located on this portion of the property. Of the 16 soil samples collected from ≤10 feet below ground surface (bgs) in this area, none have been analyzed for PCBs from Evaluation Area 1.

EVALUATION AREA 2

Evaluation Area 2 is located in the central portion of the site, and covers 11.8 acres. Potential sources of contamination in this area include historical activities associated with the storage of petroleum in above-ground tanks. Additional infrastructure in Evaluation Area 2 included the pipelines associated with the transport and storage of petroleum products. A sizeable portion of the subsurface TPH "plume" delineated at the Site runs along the southern "boundary" of this Evaluation Area, with concentrations of TPH greater than 10,000 mg/kg. Five soil samples collected from ≤10 feet bgs have been analyzed for PCBs (Figure 1). Overall, detection limits for soils collected to date appear adequate for risk assessment purposes (PCBs – 0.030 to 3.0 mg/kg).

Table 1. Evaluation Area 2 Data Summary

Depth Range	PCBs	DLs (mg/kg)
Total ≤ 10 ft bgs	*5*	*0.03 to 3.0*
0 ≤ 2 ft bgs	0	NA
> 2 ≤ 5 ft bgs	4	0.03(1); 0.3(2); 3(1)
> 5 ≤ 10 ft bgs	1	0.03

Note: Number in parentheses indicate number of samples at that detection limit.

EVALUATION AREA 3

Evaluation Area 3 is located in the central portion of the site, and covers 15.59 acres. A sizeable portion of this evaluation area overlies the subsurface TPH plume, with concentrations over 10,000 mg/kg. Several large ASTs and their associated piping were located in this area of the Site. Eleven soil samples collected from ≤10 feet bgs have been analyzed for PCBs (Figure 1). Overall, detection limits for soils collected to date appear adequate for risk assessment purposes (PCBs – 0.030 to 3.0 mg/kg).

Table 2. Evaluation Area 3 Data Summary

Depth Range	PCBs	DLs (mg/kg)
Total ≤ 10 ft bgs	*11*	*0.03 to 3.0*
0 ≤ 2 ft bgs	0	NA
> 2 ≤ 5 ft bgs	9	0.03(4); 0.2(1); 0.3(2); 0.6(1); 3(1)
> 5 ≤ 10 ft bgs	2	0.03

EVALUATION AREA 4

Evaluation Area 4 is located in the southeast corner of the site at the base of steep slopes along the coastline, and covers 4.9 acres. No infrastructure associated with the tank farm was located in this portion of the site. Therefore, the potential sources of contamination in this area are aerial deposition and runoff. Two soil samples collected from ≤10 feet bgs have been analyzed for PCBs (Figure 1). Overall, detection limits for soils collected to date appear adequate for risk assessment purposes (PCBs – 1.1 to 1.5 mg/kg).

Table 3. Evaluation Area 4 Data Summary

Depth Range	PCBs	DLs (mg/kg)
Total ≤ 10 ft bgs	*2*	*1.1 to 1.5*
0 ≤ 2 ft bgs	2	1.1 to 1.5
> 2 ≤ 5 ft bgs	0	NA
> 5 ≤ 10 ft bgs	0	NA

EVALUATION AREA 5

Evaluation Area 5 is located in the southwest corner of the Site, and covers 3.92 acres. Two large above-ground storage tanks, and the associated piping, were located in this portion of the tank farm. The subsurface TPH "plume" delineated in the central portion of the Site extends into Evaluation Area 5. Three soil samples collected from ≤10 feet bgs have been analyzed for PCBs (Figure 1). Overall, detection limits for soils collected to date appear adequate for risk assessment purposes (PCBs – 0.030 to 0.60 mg/kg).

Table 4. Evaluation Area 5 Data Summary

Depth Range	PCBs	DLs (mg/kg)
Total ≤ 10 ft bgs	*3*	*0.03 to 0.60*
0 ≤ 2 ft bgs	0	NA
> 2 ≤ 5 ft bgs	3	0.03(2); 0.60(1)
> 5 ≤ 10 ft bgs	0	NA

EVALUATION AREA 6

Evaluation Area 6 is located on the western side of the Site, and covers 8.88 acres. Historic infrastructure in this area of the site included several ASTs and the associated piping. The eastern edge of Evaluation Area 6 overlies the subsurface TPH "plume" delineated in the central portion of the Site. One soil sample collected from ≤10 feet bgs have been analyzed for PCBs (Figure 1). Overall, detection limits for soils collected to date appear adequate for risk assessment purposes (PCBs – 0.030 mg/kg).

Table 5. Evaluation Area 6 Data Summary

Depth Range	PCBs	DLs (mg/kg)
Total ≤ 10 ft bgs	*1*	*0.03*
0 ≤ 2 ft bgs	0	NA
> 2 ≤ 5 ft bgs	1	0.03
> 5 ≤ 10 ft bgs	0	NA

EVALUATION AREA 7

Evaluation Area 7 is located on the western border of the Site, and covers 4.56 acres. Other than bordering an access road, no infrastructure was located on this portion of the Site. The pipeline to Avila Pier ran just south of this Evaluation Area. Aerial deposition

and surface water runoff are the primary potential contaminant sources. No soil samples from this area have been analyzed for PCBs.

EVALUATION AREA 8

Evaluation Area 8 is in the northwest corner of the Site and encompasses 1.8 acres. The Scout House was located in Evaluation Area 8. The primary potential sources of contamination in this area are aerial deposition and surface water runoff. No soil samples from this area have been analyzed for PCBs.

EVALUATION AREA 9

Evaluation Area 9 is in the center of the Site and covers 4.14 acres. The refinery was located in northern portion of this area, while the southern portion included the pump house and truck loading rack. This was the most heavily industrialized area of the Site. Twenty five soil samples collected from ≤10 feet bgs have been analyzed for PCBs (Figure 1). Overall, detection limits for soils collected to date appear adequate for risk assessment purposes (PCBs – 0.030 to 0.30 mg/kg).

Table 6. Evaluation Area 9 Data Summary

Depth Range	PCBs	DLs (mg/kg)
Total ≤ 10 ft bgs	*25*	*0.03 to 0.3*
0 ≤ 2 ft bgs	1	0.3
> 2 ≤ 5 ft bgs	15	0.03(12); 0.12(1); 0.3(2)
> 5 ≤ 10 ft bgs	9	0.03(6); 0.3(3)

EVALUATION AREA 10

Evaluation Area 10 includes the steep slopes bordering the northern and southern boundaries of the Site. The northern parcel covers 8.45 acres, while the southern section encompasses 20.57 acres. Other than a small AST on the southern side of Evaluation Area 10, no tank farm-related infrastructure existed in these areas of the side, although debris has been observed along the slopes below the refinery area. Other sources of contamination in Evaluation Area 10 are aerial deposition and surface water runoff. No soil samples from this the northern parcel have been analyzed for PCBs; in the southern parcel, three soil samples collected from ≤10 feet bgs have been analyzed for PCBs (Figure 1). Overall, detection limits for soils collected to date appear adequate for risk assessment purposes (PCBs – 0.030 to 1.2 mg/kg).

Table 7. Evaluation Area 10 Data Summary

Depth Range	PCBs	DLs (mg/kg)
Total ≤ 10 ft bgs	*3*	*0.03 to 1.2*
0 ≤ 2 ft bgs	1	1.2
> 2 ≤ 5 ft bgs	2	0.03(1);0.3(1)
> 5 ≤ 10 ft bgs	0	NA

July, 2001

EXECUTIVE SUMMARY

The Community Monitoring Program (CMP) was produced through a joint effort among local lead regulatory agencies, the San Luis Obispo Air Pollution Control District (APCD) and County Public Health Department (CPHD), and Unocal Corporation. The purpose of the program was to ensure that public health was protected during remediation activities. The CMP provided a framework and technical basis for monitoring activities, responded to public concerns, implemented corrective actions, and communicated results to interested parties. The CMP specified the use of state-of the-art instruments and techniques to monitor over 100 chemicals, in addition to dust and odor. Real-time measurements of eleven of these substances were used to make hour-by-hour risk management decisions to ensure that public exposure was below levels of concern.

The CMP was reviewed and augmented by several regulatory agencies, including the local lead agencies, and the San Luis Obispo Air Pollution Control District (APCD) and County Public Health Department (CPHD), in addition to statewide agencies charged with protecting public health, including the California Department of Health Services (DHS), the Office of Environmental Health Hazard Assessment (OEHHA), and the Department of Toxic Substances Control (DTSC). After input from these groups was incorporated, the final CMP was released on February 8, 1999.

The function of the Community Monitoring Team (CMT) was to execute the CMP as described above—to collect air samples throughout the town of Avila Beach during remediation activities and to evaluate the data collected vis-à-vis the health-protective standards set forth. The purpose of air sampling was to provide immediate and long-range assessments of air quality and associated potential impacts on the health of residents and visitors to Avila Beach. This program extended from October, 1998 to April, 2000, the entire time frame of the remediation process.

Chemicals of Concern and Trigger Levels

The nature of the chemicals associated with the remedial activities at Avila Beach required careful forethought in order to have reasonable assurance that potential adverse health risks associated with the remediation would not be underestimated. On the basis of two differing evaluation objectives and methods, two sets of individual chemicals were identified. One set of chemicals were identified for evaluating airborne chemical concentrations in real time on a daily basis. Another set of chemicals was evaluated for purposes of performing a human health risk assessment. Although the two lists differ, both lists represented the same suite of substances and chemicals associated with the remediation activities.

The chemicals of concern (COC) were selected based on site-specific criteria. Consideration of the source of chemicals, potential receptors, exposure pathways, and routes of exposure were important criteria used to identify the COC. The Risk Assessment Report of October 12, 2000 used the term SOPC or substances of potential concern because, strictly speaking, diesel exhaust and particulates smaller than 2.5 microns are not chemicals but a mixture of chemicals. For purposes of this report, the standard term COC will be used acknowledging the status of diesel exhaust and particulates.

Due to an inordinately large number of chemicals (exceeding a thousand) potentially present as the result of soil excavation activities, an effort was made to reduce the number of chemicals monitored and evaluated to a manageable number. The CMP identified 11 chemicals or substances for monitoring. The risk assessment was based on an evaluation of diesel exhaust, the volatile components of total petroleum hydrocarbons, hydrogen sulfide, and polynuclear aromatic hydrocarbons.

The concentrations at which the Chemicals of Concern begin to either become a trigger to increase monitoring or to affect human health were termed the trigger levels. In order to maximize the protection of public health, a series of three trigger levels were developed for each chemical with requirements for increasingly stringent engineering and project activity management controls applied at the higher concentration levels. Each level was associated with a particular course of action, such as engineering controls or the halting of operations. The three trigger level concentrations for chemicals of health concern are termed Level 1, Level 2 and Level 3:

Level 1
Concentration: 50% of agency chronic safe exposure levels (California EPA Office of Environmental Health Hazard Assessment Chronic Toxicity Reference Exposure Levels - OEHHA RELs).
Exceedance Response: Increased real-time sampling in the area of concern.

Level 2
Concentration: 75% of Agency chronic safe exposure levels (OEHHA RELs).
Exceedance Response: Implementation of engineering controls and notification of agencies.

Level 3
Concentration: 100% of agency acute safe exposure levels.
Exceedance Response: Immediate halt in excavation activities, implementation of engineering and activity management controls and notification of the agencies and the Fire Department.

Types of Monitoring Activities

Monitoring was conducted during all remediation activities and the data obtained was compared on a continual basis to the trigger levels as described above. Monitoring was carried out either by real-time or time-integrated approaches for three parameters: dust, odors and COCs. Specific monitoring activities for each parameter are indicated below:

Dust

- Visual observation
- MIE Personal Data RAM for total dust (0.5 times total dust will be assumed to be PM10[a])
- MIE Data 2000 for PM 2.5 (particulate matter of 2.5 micron aerodynamic diameter and below)
- Federal Reference Method for Time Integrated PM 10 (40 CFR 50, Appendix B),
- Airmetrics MiniVol PM10 for Time Integrated PM 10.

[a]It should be noted that since dust derived from abrasive activities associated with construction, etc., is composed of mostly larger particles, the total dust value had an assumed contribution from PM10 of 50%.

Odor

- Direct olfactory observation
- Jerome 631-X Hydrogen Sulfide sensor for the common surrogate for odor
- EPA Method TO-14, as modified for use in reduced sulfur sampling to detect reduced sulfur compounds as surrogates for malodorous compounds
- EPA Method TO-14 for a wide range of volatile organic compounds, many of which are surrogates for malodorous chemical mixtures.

Chemicals of Concern

- PhotoVac Voyager Portable GC/PID for volatile organic compounds chemicals of concern: benzene, toluene, ethyl benzene, and xylenes
- Jerome 631-X Hydrogen Sulfide sensor
- Ecochem PAS-2000 for real-time detection of total PAH compounds
- Andersen Instruments Aethalometer for particulate elemental carbon
- EPA Method TO-13 (GC/MS) for carcinogenic PAH compounds
- EPA Method TO-14 with GC/MS for toxic volatile organic compounds
- EPA Method TO-14 with GC/FID for hydrocarbon compounds
- EPA Method TO-14 with GC/FPD for reduced sulfur compounds EPA Method TO-11 for aldehydes and ketones

Meteorological Data Collection

Meteorological data were collected continuously during the project. Two locations provided localized data for use in determining appropriate air sampling locations, and in assessing the movement of air masses over the excavation pit containing potentially harmful air-borne chemicals.

Monitoring Duration, Period and Locations

Monitoring Duration: Monitoring was conducted during all major phases of the work day, which generally consisted of 7:30 AM-5:30 PM—ten hours daily, five or six days per week, depending upon remediation contractor work schedule. No sampling was conducted when the remediation work was not in progress.

Monitoring Period: Following a two week baseline period in October, 1998, initial monitoring commenced in November, 1998, extended during all periods in which work was conducted, and ceased on April 6, 2000.

Monitoring Locations: Locations for the real-time monitoring were selected on an hourly basis, depending on wind direction and work activities. These locations were noted and included in the sample data base. Sampling locations for integrated samples were selected throughout the town, and samples were collected initially in five locations. Later, after an evaluation of the data, between one and three locations were sampled.

Results

The overall result from the CMP was a successful management of the risk to the community from the remediation process. The goal of a risk factor of less than 10 in one million was achieved.

The success of the program was based on the ability of the CMP to detect rapid changes in local air quality and to provide immediate feedback to the remediation contractors so that appropriate activity management could be maintained. Since the objective of the overall Avila Beach project was the removal of the contaminated soils, the contractors focused on that activity, often diverted their attention from the impacts that their activities would have on the community. However, the implementation of the CMP resulted in a higher visibility to the monitoring activities, resulting in a priority to the community protection efforts. These efforts for minimizing the community impacts were seen in the low number of dust and odor incidents for a project this size and the few exceedances of the trigger levels.

Other than construction related disruptions (e.g., traffic, noise, etc.), the CMP monitoring detected few impacts to the community from the remediation. A general petroleum odor saturated the town for much of the project time line, but it was generally adapted to and not considered a direct health effect. A few specific odor complaints arose over the course of the project, but nothing that lasted more than a few hours at most, and all were addressed according to the CMP guidelines. Dust became an issue periodically, but with increased vigilance by the contractors, this was addressed.

The long-term impact from vehicle emissions and off-gassing of contaminants from the affected material were addressed with the real-time monitoring and integrated sampling. The results from these efforts were incorporated into the risk assessment conducted by SOMA Corporation. This risk assessment concluded that the less than lifetime reasonable maximum exposure excess

carcinogenic risk to a resident child was calculated to be nine in one million (9×10^{-6}). The average excess carcinogenic risk to a resident child was 6.4 in one million (6.4×10^{-6}). The less than lifetime reasonable maximum exposure excess carcinogenic risk to a resident adult was calculated to be 3.8 in one million (3.8×10^{-6}). The average excess carcinogenic risk to a resident adult was calculated to be 2.7 in one million (2.7×10^{-6}). These risks for cancer due to diesel exhaust and benzene do not exceed the CMP risk management goal of 10 in a million.

Other than nuisance effects such as disagreeable odors, chronic noncarcinogenic hazards were not predicted to occur. The RME chronic hazard index for the child resident was 0.63 and the average chronic hazard index for the child resident was 0.45. The acute hazard index for the child resident was 0.83. A target organ analysis was not performed to further detail noncancer effects since none of the hazard indices exceeded one.

These results showed that the CMP goal of prevention of significant impact to the health of the Avila Beach community was achieved.

1.0 INTRODUCTION

1.1 HISTORY OF THE SITE

Avila Beach has been the site of oil storage and transportation activities since the late 1800's. Underground pipelines below Front Street in the town of Avila had been in operation for about 80 years and had been used to transport gasoline, diesel and crude oil. Leaks from the pipelines occurred over the years, resulting in releases of hydrocarbon materials to subsurface soils and groundwater.

Site assessment work began in 1989, following the discovery of subsurface hydrocarbon contamination on private property undergoing construction. Work between 1989 and 1999 has included site assessments, remedial feasibility studies, interim remediation, risk assessments, air monitoring, and remediation pilot testing. Responding to the expressed concerns of the residents of the town of Avila Beach, it was decided in 1998 by Unocal, the County of San Luis Obispo, and the responsible regulatory agencies, that the best option for the community was to excavate the contaminated soil and replace it with clean soil.

The excavation and clean-up of Avila Beach was a mammoth undertaking involving the demolition of many of the structures on Front Street—the main street fronting the ocean beach—as well as the transportation and storage of large volumes of petroleum-contaminated soil. There was significant concern expressed by local agencies, including the San Luis Obispo Air Pollution Control District (SLOAPCD), County Environmental Health, and the Regional Water Quality Control Board (RWQCB), as well as local residents, about potential health impacts associated with excavation activities. Concerns focused on the potentially harmful effects of pollutants released from contaminated soil and diesel equipment used during the excavation. As a result of these concerns, provisions were included in the County excavation and air permits that required a Community Monitoring Program (CMP) to be carried out during the remediation and excavation activities. The purpose of the CMP was to insure that the residents and general public were not exposed to harmful concentrations of pollutants. The responsible party, Unocal, worked with the agencies and their consultants to put together a plan that would protect the residents of Avila Beach and provide sufficient warning should hazardous conditions be created.

Purpose and Organization of the Current Report

The purpose of this report is to describe the development, implementation and results of the CMP for the Avila Beach Remediation Project. The CMP was designed to provide assurance to the community of Avila Beach that emissions associated with the remediation process, including emissions from both the "affected" material and from heavy duty excavation equipment, would not adversely affect their health and well-being. This effort was a multi-disciplinary activity that involved participants from several local government agencies, as well as representatives from Unocal Corporation. The effort was funded by Unocal as part of their site remediation responsibilities.

This report consists of the following three major parts:

Main body of text. This part includes descriptions of the monitoring approach, the remediation activities, the data collected, significant results, and the final risk assessment. Details regarding the rationale for the monitoring approach will not be discussed as they have been documented in the Community Monitoring Plan presented in Appendix C. However, in this document, a summary of the CMP is presented. It should be noted that the term "work plan" and CMP were used interchangeably and are essentially equivalent.

Appendices. There are several appendices that contain important background information. The first two appendices, in particular, present the most important additional material regarding the execution of the CMP. Appendix C contains the CMP, which will be cited extensively as the source for descriptions of monitoring approaches, techniques, and the rationale for selecting these techniques. This document guided the performance of the monitoring activities. Appendix D contains the Human Health Risk Assessment conducted by SOMA Corporation. The Assessment presents the primary data interpretation of the monitoring data for the purpose of providing an estimate of the risk to the community associated with remediation project activities. Other appendices are included as supporting material, background descriptions, and documentary information for the data collection and remediation efforts.

Supplementary Data. The supplementary data includes all the supporting data from the program, such as hard copies of all the laboratory data, daily data collection sheets, site logs, real-time data collection logs, etc. Since this material fills three+ file cabinets, it is not all included in the report, but is cited as the source for the reduced data. These file cabinets will be stored at the San Luis County Air Pollution Control District until 2003, after which they will be sent to the Unocal Corporation corporate storage facilities.

1.2 THE COMMUNITY MONITORING PROGRAM AND TEAM

1.2.1 Summary of the Community Monitoring Program

The CMP was designed to provide the community with a rapid assessment of the potential risk to human health from remediation activities. The development and implementation of the CMP took approximately six months, and involved the following activities:

- Development of the CMP, Version 1.0, Aug. 12, 1998, which served as the basis for the Request for Proposals for the Community Monitoring Contractor.
- Selection of the Community Monitoring Contractor in October 1998, subsequently called the Community Monitoring Team (CMT).
- Development and implementation of the Baseline Sampling Plan, October 1998.
- Initial site monitoring, starting early November 1998.
- Development and implementation of the revised CMP, starting November 1998, with the final version released on February 8, 1999.
- Full implementation of the CMP during February 1999.

When implemented, the CMP undertook the following activities:

- Integrated air monitoring at fixed sites for, initially, over 100 chemicals.

- Real-time, roving monitoring for the following parameters:
  - Total suspended particulate matter (TSP)
  - Particulate matter of 10 microns or less (PM10)
  - Particulate matter of 2.5 microns or less (PM2.5)
  - Particulate elemental carbon (PEC)
  - Polycyclic aromatic hydrocarbons (PAH)
  - Hydrogen sulfide
  - Benzene, toluene, ethyl benzene, xylenes (BTEX)
  - 1,3-Butadiene
  - Dust
  - Odor
- Off-hours monitoring of excavation pit emissions for hydrocarbons and hydrogen sulfide
- Rapid posting of daily data at Community Center
- Posting of daily data on CMP web site
- Development of a comprehensive database for all laboratory and field data
- Risk assessment using the data collected from both laboratory and real-time equipment

This program was partially implemented in November 1998, gradually expanded until full implementation in February 1999, and was in full operation until December 27, 1999. Some minor changes occurred during that period regarding the numbers of secondary analytes monitored, sampling locations, and sampling frequencies, but only after adequate review by all parties and consensus that the changes would not affect the data integrity. These changes are documented in Section 4.6. After December, 1999, a minimal program was in place during the sporadic activities from January, 2000 to April, 2000.

1.2.2. Summary of Community Monitoring Plan

The CMP was the guiding document for the monitoring program. As noted above, the full document is included in Appendix C. Of particular importance is Table 1.1 which is reproduced here. This table contains the health-based or nuisance trigger concentration levels at which corrective actions were required. This table was referred to frequently as data was collected for assessment of any required action based on what was detected. The information in this table formed the heart of the program and was the center of monitoring activity.

1.2.3 The Community Monitoring Team

The CMT was established to implement and provide oversight to the CMP. Oversight and approval of the CMP were provided by Karen Brooks of the San Luis Obispo APCD and Dr. Greg Thomas of the County Public Health Department. Assistance was provided by the County Public Health Assessment Contractors, toxicologist Dr. Norman Ozaki of SOMA Corporation, and air quality scientist Dr. Gary Bertolin of SAIC. Monitoring activities and laboratory analysis were conducted initially by Environmental Analytical Services (EAS) of San Luis Obispo, a

contractor selected by Unocal in consultation with the APCD and County Environmental Health and subsequently by Air Toxics Limited of Folsom, California.

1.3 COMMUNITY MONITORING ACTIVITIES

1.3.1 Previous Monitoring Efforts

Prior to the remediation, three monitoring efforts were conducted to assess potential public health risk from possible exposure to emissions from the subsurface contamination, exclusive of remediation activities. These programs included ambient air testing in Avila Beach and other surrounding communities, soil gas testing to evaluate potential sources of contamination, and flux chamber testing to determine the nature of surface emissions from the potentially gaseous constituents.

These testing programs and the resulting health risk assessments indicated that the potential for significant risk from the existing subsurface contamination was below the threshold for action. These results were documented in the following reports:

> Mesa Associates, Ambient Air Sampling Report, U.S. EPA Method TO-14A, Prepared for Risk Science Associates, October 9, 1997.
>
> Mesa Associates, Sampling Report: Ambient Air, Soil Gas, Sampling Event: Avila Beach, CA. March 20, 1998, Prepared for Risk Science Associates, April 14, 1998.
>
> Risk Science Associates (RSA), Transmittal of Results of Reconnaissance Sampling Event #4, July 2, 1997.

Some data from these reports were used in the CMP risk assessment effort, primarily in terms of determining background levels of the chemicals of concern. The specific data sets used are cited in the risk assessment report, included in Appendix D. Further discussion of the background data is presented in Section 9.5.

1.3.2 Workday Community Monitoring

Chemical-specific trigger level concentrations were used to determine if detected concentrations of chemicals in air represented potential adverse health hazards. Concerns over potential chemical releases from open excavations during weekends and holidays lead to a distinction between “workday” and “non-workday” periods. The community workday trigger levels were set at or below safe exposure levels that have been established by regulatory agencies to protect public health. If any trigger level was exceeded, control measures, as described below, were implemented to reduce the potential for public exposure. In the event that these control measures were not successful, community notification and shelter-in-place measures were identified. The non-workday period is discussed in the next section.

In order to ensure the maximum protection of public health, the CMP trigger levels (Table 1.1) were in most cases significantly lower than regulatory safe exposure levels. The Tier 1 levels were set at 50 % of the OEHHA chronic reference exposure level or an incremental cancer risk of $10x10^{-6}$ for individual trigger compounds. If any Tier 1 level was exceeded, further monitoring was conducted, the APCD and Jacobs Engineering (Jacobs) were to be notified, and/or a risk assessment was to be performed to evaluate cumulative public exposure. A flow diagram of the noticification system is presented in Figure 1.1. The Tier 1 levels were exceeded a number of times, as will be documented in Section 7 of this report.

The Tier 2 trigger levels were set at 75% of the OEHHA chronic reference exposure level, or a total incremental cancer risk of $10x10^{-6}$ based on a health risk assessment that includes all chemicals of concern. If any Tier 2 level was exceeded, the APCD, Jacobs, and the Fire Department, were notified and engineering controls were immediately implemented to reduce ambient concentrations below the Tier 2 levels. These controls may have included water sprays, foams, tenting, wind screens, or reducing the rate of excavation, among others. The Tier 2 trigger levels were exceeded only once throughout the entire project when an exceedance for 1,3-butadiene was detected. Control measures were put into place and the problem subsided. This occurrence is discussed in Section 7 in detail.

If Tier 2 control actions were not successful and ambient concentrations exceeded Tier 3 levels (acute reference exposure levels), the APCD, Jacobs, the Public Health Assessment Contractors, and the Fire Department would have been notified and the project would have been shut down. If concentrations had exceeded the Tier 3 trigger levels for more than 4 hours and/or reached a level that was more than two times the Tier 3 levels, affected parties would have been required to Shelter-in-Place or take other actions deemed appropriate by the Incident Command Team and County Public Health Officer. A decision to move beyond Shelter-in-Place to evacuation would have been made by the Incident Command Team in consultation with the County Public Health Officer. Notification of the public would have occurred through the town public address system and/or a mobile public address system.

The CMP monitored over 100 chemicals, in addition to odors and dust. Substances were selected based on their potential for being released during remediation activities and their ability to be readily measured by the selected analytical methods. Eleven chemicals were selected as workday trigger substances that were monitored and reported continuously in real time using portable, field instruments. These eleven trigger substances were benzene, toluene, ethylbenzene, xylene, 1,3-butadiene, hydrogen sulfide, polyaromatic hydrocarbons, fine particulate matter, diesel exhaust, and odor.

1.3.3 Non-Workday and After-hours Monitoring

The non-workday and after-hours monitoring periods were defined in order to address concerns about potential emissions when normal daytime CMT staffing was not in place. Therefore, at the end of the workday, on weekends, and on holidays, the air in the currently active excavation cell was monitored using for hydrogen sulfide and total hydrocarbons using electrochemical monitors. A wireless communication system was implemented that notified CMT staff of any exceedances of the set thresholds. These thresholds were set such that measured concentrations

were compared to 50% of occupational exposure levels. If these levels were exceeded within the excavation cell, the CMT was mobilized and real-time workday community monitoring was implemented. During non-workday and after hours, all stockpiles and affected soil surfaces were covered. Therefore, the only potential project-related source of emissions during non-work hours was volatile emissions from uncovered liquid surfaces within the excavation cell. There were no actual occurrences of exceeding the non-workday and after-hours thresholds, as will be discussed in Section 7.

1.3.4 Odor and Dust Monitoring

The CMT was constantly vigilant of odors and dust in the community. Monitoring took place continually during all site activity. On-site meteorological data and real-time air sampling data were reviewed several times a day to ensure that patrol routes were focused on the areas with the highest potential for nuisance conditions. A log was kept of odor observations. Upon observation or report of odor or dust, follow-up real-time and/or time-integrated sampling was completed as soon as possible and the APCD and County Public Health Monitor were notified. Engineering controls were typically used as a first step to control odor and dust. The CMP specified that should the controls not work, activity management steps were implemented, such as reducing the size of the excavation or the number of excavators, or stopping the excavation completely. These steps were not required, as the odor and dust incidents that occurred were managed effectively with simple procedures.

1.3.5 Communications

After the data were collected, summaries of both real-time and time-integrated monitoring were provided to the lead agencies and the Public Health Assessment Contractors. A summary of this information was then posted in Avila at the Community Center and on the monitoring program web site (www.avilaCMT.org). Information about the ongoing monitoring efforts was provided at periodic community meetings. Dates of these meetings will be presented in Section 2.

The CMT and APCD staffs were available on a 24-hour basis to investigate odor or other concerns in a timely manner. During operating hours, a CMT trailer was available in Avila where monitors could be contacted directly by the community. Both during and after operating hours, the APCD, the Avila Project Hotline, and Arrie Bachrach, Jacobs Project Ombudsman, were available to serve as a channel of communication to the monitors.

TABLE 1.1. Trigger Levels

Substance (Measured As)	Units	Trigger Level	Basis[a]	Averaging Time	Number of Measure-ments[e]	Method	Required Action	Notification

Odor	complaint	NOV	Nuisance	-	Continuous	Observation		

NOTES TO TABLE 1.1:

[a] The bases are as follows: 24 CAQS = 24-hr California air quality standard; ACAQS = annual California air quality standard; 24 FAQS = 24-hr federal air quality standard; AFAQS = annual federal air quality standard; 1-hr CAQS = 1-hr California hydrogen sulfide air quality standard; AREL = acute reference exposure level; CREL = chronic reference exposure level; C = cancer.

[b] Total dust is the surrogate for PM10. The trigger level assumes 50% of total dust is PM10, based on CARB speciation profiles for road and building construction dust. A site-specific factor will be developed after remediation activities are under way and used to adjust the PM10 trigger level (Sec. 3.6.7).

[c] To be determined as the average plus two standard deviations of the 1-hr rolling mean baseline concentration or some other suitable statistical measure of variance.

[d] Other abbreviations used in this table are: PM = Particulate Matter; TBD = To Be Determined; DR = Data Ram; PDR = Personal Data Ram; PAS = Photoelectric Aerosol Sensor; APCD = Air Pollution Control District; PEC = Particulate Elemental Carbon or Soot; NOV = Notice of Violation; PHAC = Public Health Assessment Contractors; POC = Particulate Organic Carbon; Continuous = Measurements will be made essentially continuously, within the constraints of the instrumentation (Sec. 3.2).

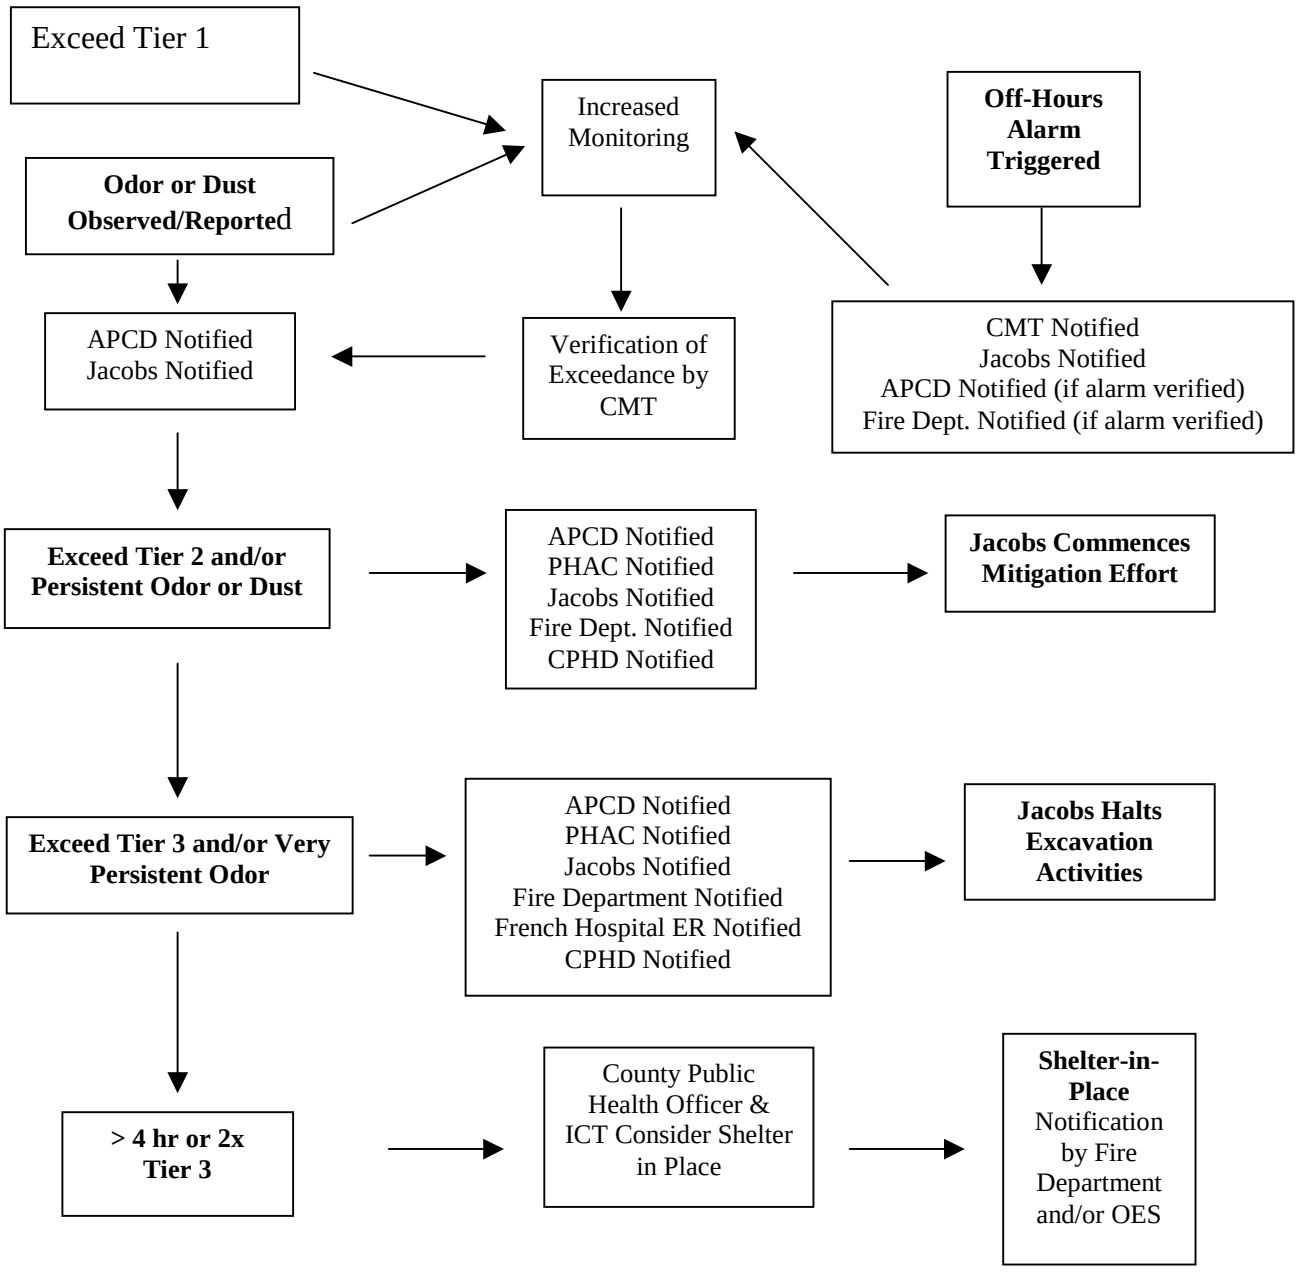
[e] The number of measurements is based solely on the limitations of the instrumentation. The Voyager can only analyze three samples per hour. Therefore, only three measurements are specified for all analytes measured by the Voyager. All other instruments are capable of nearly continuous measurements.

[f] Particulate elemental carbon (PEC) is the surrogate for diesel exhaust. The trigger level assumes that 85 wt% of diesel exhaust is PEC based on literature values. A site-specific factor will be developed after remediation activities are under way and used to adjust the diesel trigger level (Sec. 3.6.4).

[g] Separate trigger levels are reported for chronic and carcinogenic health effects for 1,3-butadiene, benzene, and diesel exhaust. When the chronic trigger level established at 50% of the chronic REL is exceeded, monitoring is increased. When the carcinogenic trigger level established at the $10x10^{-6}$ risk level is exceeded, a health risk assessment will be conducted using time-integrated data for all monitored carcinogens and noncarcinogens.

[h] Cancer-based trigger levels are to be compared to an incremental 1-hr average concentration, calculated as the difference between the upwind and downwind concentration.

Figure 1.1. Notification and Tier Process



2.0 COMMUNITY MONITORING PROGRAM DEVELOPMENT

2.1 THE CMP DEVELOPMENT PROCESS

The CMP was developed to fulfill a condition in Unocal's Permit to Operate for the Avila Beach Remediation Project, issued by the San Luis Obispo County APCD. The first formal description of the program was developed in the spring of 1998 by McDaniel-Lambert Inc., and a revised draft was submitted on August 12, 1998. The revised draft formed part of the Request for Proposals issued by Unocal in August 1998, and was the foundation for subsequent documents.

Following selection of the contract-monitoring group in September 1998, the CMP was revised in various stages. The second main version was dated October 21, 1998. A conceptual plan was developed by November 3, 1998; this was substantially revised by November 24, 1998, and was distributed to key project personnel. Following additional discussions amongst CMT members, other aspects of the program were more completely developed. These discussions resulted in the final revision, completed in late January 1999, which was released on February 9, 1999. Copies were distributed to key public agencies and outside parties, and were available for inspection by the public. The final CMP is included as Appendix C to this report. The interim versions were internal drafts that reflected input from various parties. Extensive discussions were held between Unocal representatives and consultants and between APCD and their oversight consultants during the revision period.

Changes to the CMP and how the field program was conducted after release of the February 8, 1999 version due to changes in site conditions and other circumstances were discussed with the APCD and other agencies prior to implementation. These changes, as documented in memoranda or other communications at the time they occurred, are summarized in Section 3.5.

Oversight on behalf of Unocal for the entire project was supplied by Dr. Chuck Lambert of McDaniel-Lambert, Inc., and Dr. Phyllis Fox of Environmental Management.

2.2 THE CMP TEAM

The development of the final CMP was a team effort, incorporating extensive input from many participants according their expertise. The major deliberative component of this process concerned the development of adequately health-protective trigger levels and the ability to provide real-time monitoring data to document potential exposure.

Key personnel on the CMP team included:

San Luis County Air Pollution Control District
Larry Allen
Barry Lajoie
Karen Brooks

San Luis County Public Health Department
Greg Thomas, MD
Michelle Cowan
Curt Batson

Public Health Advisory Consultant
Norm Ozaki, Ph.D., SOMA Corporation
Gary Bertolin, Ph.D., SAIC

Unocal Representative
Kevin McNichol

Unocal Consultants
Chuck Lambert, Ph.D., DABT, McDaniel-Lambert, Inc.
Phyllis Fox, Ph.D., Environmental Management

Community Monitoring Team
Steve Hoyt, Ph.D., Environmental Analytical Service
Eric Winegar, Ph.D., Applied Measurement Science

In addition to these participants, several outside parties, including staff from the Office of Environmental Health Hazard Assessment (OEHHA), and the Department of Toxic Substances Control (DTSC), reviewed and provided input to the preliminary drafts. These reviewers are listed in the acknowledgement section of the CMP Work Plan.

Key interaction between the CMP team and the CMT field crew was provided by the field crew from Jacobs Engineering, particularly John Baum, Compliance Manager; Steve Arington, Primary Excavation Foreman; and Arrie Bachrach, Jacobs Engineering Project Ombudsman. These individuals were kept apprised of all developments, particularly those that would potentially impact remediation operations.

Other county personnel involved in oversight of the excavation and in assisting APCD in their oversight of community health were Rod Farrell of Padre Associates, and MaryKate Morabito, also of Padre Associates, who at one time had worked with the CMT as part of the field crew.

2.3 COMMUNITY MONITORING TEAM

After a short time in the field, the "Community Monitoring Contractor" (the field staff) was renamed the Community Monitoring Team (CMT). This team was charged with implementing the details of the CMP Work Plan and was selected following a competitive bidding process conducted by Unocal. A key aspect of the selection process was the desire to use local resources as much as possible.

Initially, Dr. Steve Hoyt of Environmental Analytical Service, San Luis Obispo, California was the overall program manager with contractual responsibility to Unocal. He also took the lead in

developing a comprehensive database program. A number of subcontractors played major roles in providing field services.

Dr. Eric Winegar of Applied Measurement Science of Fair Oaks, California, was the project manager in charge of all field activities. Mr. Scott Santala of Mesa Associates, Nipomo, California, was the site coordinator. Mr. Julius Carstens of Oilfield Environmental and Compliance (OEC) was the field analysis manager, and worked with the assistance of Dr. Hoyt in configuring portable field instrumentation.

Staff from each of the following companies was used for various sampling and monitoring tasks:

Mesa Associates:
Eric Covington
Gretchen Scheibel
Lanaya Voelz

OEC
Leslie Nelson
Kathy Johnson
Rechai Talley
Marykate Morabito
Vicki Rocha

In April 1999, Dr. Eric Winegar became the overall program manager, replacing Steve Hoyt of EAS, and Air Toxics Limited of Folsom California became the contract laboratory. At that time, the duties of Mesa Associates were taken over by other staff as the number of sampling locations were reduced with approval of the San Luis Obispo Air Pollution Control District upon careful review of existing data. In December 1999, as activities were slowing, the staff was further cut down to Dr. Eric Winegar and Ms. Vicki Rocha, a previous employee of OEC who was then working as an independent contractor. From January 2000 to March 2000, Mr. Jesse Delacruz of Environmental Science and Engineering provided field support assistance to Dr. Winegar. Throughout these periods, Dr. Chuck Lambert and Dr. Phyllis Fox both continued in their roles as project overseers.

2.4 REGULATORY OVERSIGHT

Regulatory oversight was carried out by two main arms of local agencies. First, Padre Associates, under contract to the County Planning Department, was responsible for oversight of overall project compliance to the permit conditions. While oversight of CMP was not directly in their purview, they did report on all compliance actions, including community health issues, which were the focus of the CMP. The Padre staff also assisted in the CMP effort by providing information to the CMT about site activities and potential issues.

The San Luis Obispo County APCD was the key agency involved in developing, implementing, and providing regulatory oversight to the CMP. Several personnel from APCD were active

throughout the development process of the CMP Work Plan, which contained the trigger levels and other health-protective action levels.

In addition, APCD staff conducted regular inspections of the site, and whenever an incident occurred, staff was dispatched rapidly to investigate. Off-hours coverage was also available via scheduled duty shifts. A notable component of the APCD agency oversight was the capability for continuous coverage in the event of any incidents, including off-hours and weekends. A 24-hour number was provided to the community for reporting any incidents.

Other local agencies provided oversight for excavation activities and were only indirectly associated with the conduct of the CMP.

When incidents occurred, the procedure listed in the CMP Work Plan was followed, which included a number of notification and monitoring actions. A list of incidents and odor complaints is contained in Section 8 in conjunction with a discussion regarding field events.

Lastly, as part of the overall compliance activities, a weekly compliance meeting with Jacobs project staff, oversight contractors (Padre), and agency representatives was held to go over any issues at hand. Dr. Winegar, the CMT project manager, attended the weekly meetings and provided a summary of data collected and any incidents that had occurred.

These activities provided a high level of feedback to the responsible agencies regarding field activities and compliance with permit conditions.

2.5 CMP IMPLEMENTATION

2.5.1 Preliminary and Final Trigger Levels

Various portions of the CMP were implemented by the CMT as they were developed. In particular, preliminary and final trigger levels—the key to the process—were implemented as soon as they were developed. Preliminary trigger levels had previously been established in early versions of the CMP document. These trigger levels were used by the field crews to interpret daily field data, beginning with routine monitoring in early November 1998. In addition, preliminary data collection forms and protocols as described in early versions of the CMP were used and adhered to. It was understood that revised versions were potentially in development and would supplant these earlier versions.

2.5.2 Final Implementation

Following completion of the CMP Work Plan, the document was distributed to all relevant parties, including regulatory agencies involved in oversight of the remediation project and field personnel involved at the interface with the CMT and the public. Prior to the start of full-scale excavation, a meeting was held with all relevant project personnel (including site contractors, agency staff, CMT staff, etc., approximately 30 people) to review the communication and

notification process. Given that the implementation of the CMP was an integral part of the project, this milestone was considered critical to on-going progress.

2.5.3 Interface with Site Plans

The CMP Work Plan was intended to operate in conjunction with other plans existing for the site, including the following:

- Jacobs Engineering, Implementation Plan for Cleanup or Abatement Order 98-37 for Avila Beach Remediation Project, prepared for Unocal, June 1, 1998, and updates;

- San Luis Obispo County Office of Emergency Services, San Luis Obispo County Summary of Emergency Response Procedures for Hazardous Material Emergencies for the Avila Beach Area, March 1999; and

- Jacobs Engineering, Avila Beach Remediation Project Health and Safety Plan, Revision 01, January 1999.

The Implementation Plan, which included the requirement for air monitoring as configured in the CMP, was the guiding force in the project.

2.6 WORK PLAN IMPLEMENTATION

Due to site conditions and changing circumstances, portions of the CMP scope of work were modified as the project progressed. In order to have a complete accounting of the program, this section documents CMP changes and the rationale behind them. These changes were made and implemented with the full knowledge of the CMP team, including APCD representatives.

2.6.1 Changes in Monitoring Activities

2.6.1.1 Change in the Number of Sampling Locations

The CMP originally cited a total of five stationary sampling locations per day—four downwind and one upwind of remediation activities. The CMP also cited that after an initial period, the number of sampling locations would most likely decrease. Changes occurred on two separate occasions.

In March 1999, after several months of daily sampling at five stationary locations and after approximately three weeks of excavation proper, the need for five locations was re-assessed and the number was reduced to two. The Fire Station location was selected as the primary monitoring site, given its position adjacent to receptors (residents) and downwind of much of project operations. The second sampling location was changeable, to be selected based on the location of major project activities. The need for frequent upwind samples was also re-assessed at this time

and it was determined that the data already collected would be adequate for background concentrations determination.

In August 1999, in an effort to reduce costs, data from the two main locations collected to date—the Fire Station and Jacobs Office—were examined to determine if they were comparable, and thus if only one location could be used without sacrificing representativeness. A compilation of data was examined for the high activity period of June 24 to July 1, during which period both locations were sampled. An F-test to determine the variability between the locations was conducted along with a t-test. These tests showed that there were no statistically significant differences in the data between these two locations for the selected time period. Therefore, the Fire Station location was selected as the primary station. In addition, since site 13 (at the corner of 1st and San Francisco) was not operating, but was close to the currently operating site 17 (the Field at 1st and San Miguel), the former location was suspended.

2.6.1.2 Changes to the Selection of Sampling Locations

The Work Plan cited a procedure whereby sampling locations would be selected based on the previous day's daily meteorological conditions and by consensus within the project team. However, due to the spread of the activities across much of the town and the location of the primary sampling location mostly downwind of major activities, the daily consultation procedure was early on deemed unnecessary. A more informal and less restrictive procedure was followed for the remainder of the project.

On page 3-2, it was stated that samples would be collected at points away from the fenceline to ensure that no plumes further downwind would be missed. However, it was determined early on that the highest concentrations were found near the fenceline. Therefore, testing was concentrated at this area, with the exception of odor events or other special circumstances.

2.6.1.3 Changes to Integrated Sample Chemical Analysis

After approximately two and a half weeks of monitoring at five locations, an evaluation of the data and operations was conducted, along with an examination of the cost factors involved in analysis of the full set of integrated laboratory analysis parameters. From this evaluation, it was concluded that a number of tests could be discontinued:

- TO-14 GC/FPD sulfur analysis: a comparison of the Jerome H2S sensor with several hundred integrated laboratory analysis samples showed that the average hydrogen sulfide concentration was in the 4-5 ppbv range, while there was only one detect from the laboratory analysis. It was concluded that the integrated bag sample procedure caused a complete loss of any hydrogen sulfide or other reduced sulfur compounds present.

- TO-14 GC/FID hydrocarbon analysis: This analysis produced a large amount of information that was found to be superfluous to the assessment of human health. The hydrocarbon data would be useful for ozone formation evaluation, which was not a part of this program. In addition, there were no health effects information for the majority of

the compounds, so the data did not add any value to the community risk management function of the CMP.

- TO-13 GC/MS Full Scan: The full scan analysis was seen to produce detection limits much higher than would be needed for the risk management process. The higher sensitivity selected ion mode (SIM) analysis was continued.

2.6.1.4 Changes to Special Tests

A number of special tests that were planned and presented in the CMP Work Plan, were not implemented in the field due to a number of reasons:

- On page 3-7, it was stated that studies of PM2.5 and the PM10/PM2.5 ratio would be conducted to ensure that the real-time monitors were accurate. The only study that was conducted was a side-by-side test of the PM10 Minivol and the PDR instrument. The results of this study are shown in Section 4.3.

- Page 3-9 states that the Ecochem PAS 2000 would be calibrated specifically to the PAH compounds found in the petroleum-contaminated soils. However, it was determined that since the PAS 2000 did not supply sufficiently defined chemical data for use in risk management, this test would be unnecessary.

- An audit of the TO-14 VOC and TO-14 sulfur samplers was planned, but was never implemented. The TO-14 sulfur analysis was discontinued due to stability problems in this system. These problems are discussed in Section 6.1.8. An audit of the VOC samplers was conducted by APCD and SAIC in October 1999 and is summarized in Section 9.4.6.1.

2.6.2 Risk Assessment

In Section 2.3.3.3 of the CMP Work Plan, the risk assessment procedure was described and was intended to be conducted at various points during the remediation. However, the final "Risk Assessment for the Remediation Phase, Avila Beach, CA" was produced by SOMA Corporation in May 2000 after completion of the entire remediation. This final risk assessment differed somewhat from the assessment proposed in the CMP. The following is a list of the major differences:

1) In the CMP, it was proposed that a cancer risk assessment be carried out, "whenever Tier 1 cancer triggers are exceeded or, otherwise, at least monthly". This was not done for two reasons: (1) no Tier 1 cancer triggers were ever exceeded by the remediation activities; and (2) the large amount of effort needed to undertake the risk assessment was not deemed necessary, given the generally low concentrations of project-related chemicals found during air monitoring. In addition to these factors, efforts to assure the integrity of the project data base superceded the need for a risk assessment. Instead, a final risk assessment using all of the data gathered over the course of the project was completed.

2) In the CMP, a methodology was described for calculating the 95% UCL air concentration for various chemicals of concern. This methodology is the result of a number of meetings and discussions among the agencies, consultants, and an expert statistician (John Rice, UCB), held during late 1999 and early 2000. These procedures were made to incorporate stratified samples and the effect of differential standard deviations from background and project-related samples. These changes were necessary due to the nature of the data that was collected. The actual methodology used is described in detail in Section 2.3 and Appendix B of the final risk assessment.

3) In the CMP, the Chemicals of Concern (COCs) to be included in the risk assessment were: acetaldehyde, acrolein, benzene, 1,3-butadiene, diesel exhaust (PEC), formaldehyde, hydrogen sulfide, naphthalene, toluene, xylene, and non-diesel-exhaust PAHs. Because of a number of analytical limitations (described elsewhere in this document), as well as concerns about double counting (aldehydes are included in the diesel exhaust unit risk factor), the aldehydes (acetaldehyde, acrolein, and formaldehyde) were not included as COCs in the final document. Because of these same double counting concerns, as well as the fact that few PAHs were found in the original soil contamination, the PAHs and naphthalene were also not included as COCs in the final risk assessment. Instead, a screening evaluation for the cPAHs in soil was carried out in the final risk assessment (Section 2.1.3 "Polynuclear Aromatic Hydrocarbons"), the results of which supported the decision not to include PAHs in the final risk assessment. A complete discussion of the selection process for COCs can be found in Section 3.1 "Substances and Chemicals of Potential Concern" of the final risk assessment.

   Carcinogenic PAHs found in the original soil contamination were a concern; however, a screening evaluation of the cPAHs in soil was carried out in the final risk assessment (Section 2.1.3 "Polynuclear Aromatic Hydrocarbons"). Instead of incorporating indirect calculations that involved quantitative estimates of airborne cPAHs and the use of ratios of PEC to PM2.5, a screening evaluation assuming that all cPAHs in soil became airborne and were PM10 and smaller was performed (Section 2.1.3 of the Human Health Risk Assessment Report). The results of this evaluation supported the decision not to include the cPAHs in soil in the final risk assessment. A complete discussion of the selection process for COCs can be found in Sections 2.1 and 3.1 of the final risk assessment. SOPCs for the risk assessment were, diesel exhaust, the volatile components of total petroleum hydrocarbons, and hydrogen sulfide.

4) Protocols indicating the criteria and frequency for performing noncarcinogenic public health risk assessments are identified in the CMP. The criteria were:

   - Whenever a cancer risk assessment is triggered
   - Whenever deemed appropriate by the PHAC in consultation with the APCD
   - When concentrations deviate significantly from background
   - At least once a month

The risk assessment procedures in the CMP were written prior to the remedial activities in anticipation of the environmental data available for performing the risk assessment. Due to various project-related constraints, a final noncancer risk assessment was carried out at the conclusion of the remedial excavation project. The final "Human Health Risk Assessment for the Remediation Phase, Avila Beach, CA" was performed to address changes to the implementation of the CMP.

The decision to wait until the conclusion of the project was based on several factors. A requirement for a noncarcinogenic health risk assessment was not indicated based on the absence of a need to perform a cancer risk assessment. Because the concentration of chemicals were within the Trigger Level concentrations designated in the CMP, the APCD decided noncarcinogenic risk assessments would not be required monthly and was only necessary at the conclusion of air monitoring.

It should be noted that the final risk assessment goes into much more detail on toxicity assessment, exposure scenarios and assessment, as well as statistical and data considerations, than the CMP. For further information on the risk assessment protocol and results, please refer to the complete final risk assessment in the Appendices section of this document.

3.0 COMMUNITY OUTREACH

As the CMP was designed for the protection of community health, outreach to community stakeholders was a key component of the program. As a public agency, the APCD was the community's indirect representative in the CMP development process. However, other reporting mechanisms were put into place to provide rapid and comprehensive communication to the community regarding the results of the program.

3.1 COMMUNITY MEETINGS

Although a number of community meetings were held regarding the Avila Beach remediation process, there were three major meetings in which a key focus was the CMP. On October 21, 1998, a meeting was held at the Avila Bay Inn at which the operation of sampling equipment was demonstrated to the public and announcements regarding the on-going baseline program were made. In January 1999, other aspects of the fully developed CMP Work Plan were presented to the public, along with issues related to the risk assessment. This latter meeting was followed up by a tour of the site in February 1999, which included demonstrations of the field sampling van and integrated sampling equipment.

In addition to the community meetings, a front page article in the San Luis Obispo newspaper presented the CMP in a positive light, with favorable discussion of the program's objectives.

3.2 PAMPHLETS

Besides the publicly available CMP Work Plan, several printed communications were developed for community-wide distribution. At the January 1999 public meeting, a pamphlet was distributed that contained a short description of the CMP monitoring that had been ongoing for a couple of months. This was followed in February 1999, by a more complete description of the program, including identification of staff, definition of trigger levels, descriptions of measurement technology, and avenues for reporting problems. This pamphlet was mailed to every resident of Avila Beach.

A final pamphlet was mailed to the community in November 2000, following the completion of the final risk assessment document. This document explained the results from the CMP program and the risk assessment.

All three of these documents are contained in Appendix A.

3.3 WEB SITE AND DATA POSTINGS

Two additional avenues of community notification included the CMP web site and daily data postings at the community center.

The web site content was a replication of the CMP brochure, followed by a section with daily data postings. The goal was to post data on the www.AvilaCMT.org web site and update it periodically with daily data summaries and other critical information. The content of the web site is contained on the supplementary CDs in Appendix F. Statistics generated during the program indicated that upwards of 800 or more hits per month were generated on the site.

In addition to the web site postings, data were posted periodically at the Avila Beach Community Center. These postings contained two types of information: (1) a numerical table that contained the days' data summary compared to the trigger levels, and (2) a graphic comparison of that same information. Figures 3.1 and 3.2 contain examples of these plots. These same plots were available on the web site.

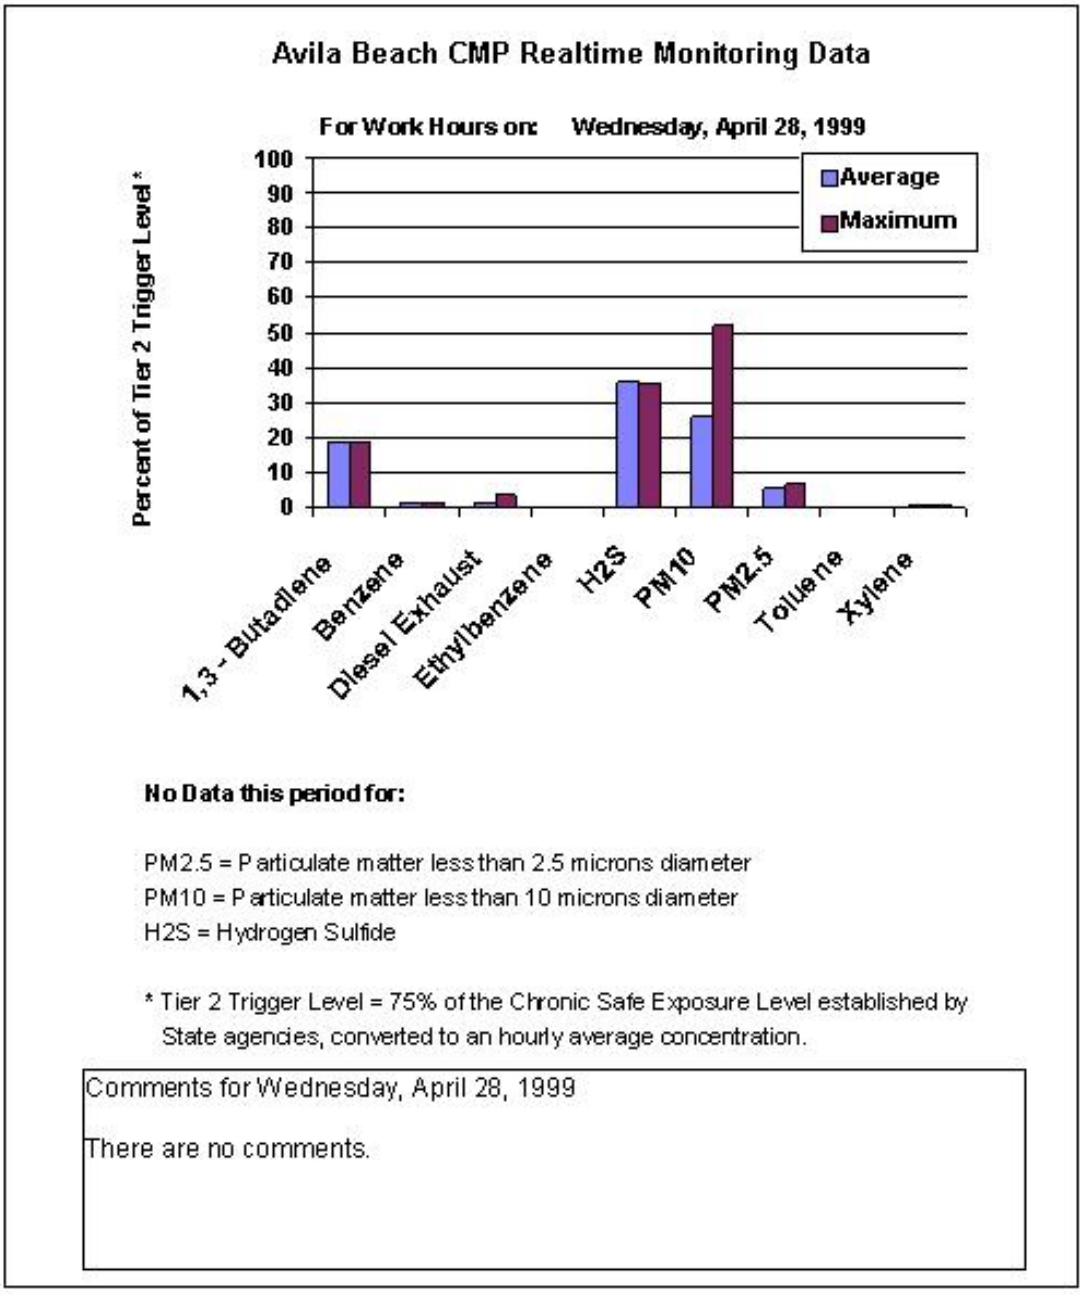


Figure 3.1. Example of daily graphic data posting for web site and Community Center

Avila Beach CMP Realtime Monitoring Data

For Work Hours on: Wednesday, April 28, 1999

Substance	Units	Daily Avg.	Max. Hour	Trigger Levels Tier1	Tier2	Tier3
Benzene	ppmv	0.002	0.002	0.100	0.140	0.240
Diesel Exhaust	ug/m3	0.239	0.797	21.000	22.000	50.000
Ethylbenzene	ppmv	0.002	0.002	1.150	1.700	2.300
H2S	ppmv	0.008	0.008	0.015	0.023	0.100
PM10	ug/m3	77.870	157.000	150.000	300.000	450.000
PM2.5	ug/m3	6.442	7.550	75.000	113.000	162.000
Toluene	ppmv	0.002	0.002	0.530	0.800	9.800
Xylene	ppmv	0.003	0.003	0.230	0.350	0.500

No Data this period for:

ppmv = parts per million byvolume

ug/m3 = micrograms per cubic meter of air

PM2.5 = Particulate matter less than 2.5 microns diameter

PM10 = Particulate matter less than 10 microns diameter

H2S = Hydrogen Sulfide

PAH = Polycyclic aromatic hydrocarbon

Trigger Levels

Tier 1 = 50% of the Chronic Safe Exposure Level established by State agencies, converted to an hourlyaverage concentration.

Tier 2 = 75% of the Chronic Safe Exposure Level established by State agencies, converted to an hourlyaverage concentration.

Tier 3 = 100% of the Acute Safe Exposure Level established by State agencies.

Figure 3.2. Example of daily numeric data posting for web site and Community Center.

3.4 FIELD CREW PUBLIC INTERACTION

The CMT field crew was the front line for inquiries related to field activities. By design, the CMT van and cart were highly visible during all project activities so that the community and local agencies could be assured that the monitoring was occurring. At the beginning of the project, there was frequent interaction of the community with the CMT staff, mainly to ask questions about what they were doing and what was being detected by the equipment. Many comments were heard that they in the community were glad that the data was being collected and that this effort was important. The community soon became familiar with the CMT and generally did not approach them unless to report a problem. As with many of the Jacobs field crew, several CMT staff became quite familiar with the community and were well-recognized. This level of recognition provided a level of trust that assisted in the CMP functions.

3.5 RESULTS OF COMMUNITY OUTREACH

The success of the community outreach program were mostly seen in the community's reliance on notification of CMT field crews or APCD of problems (odor or dust, etc.). This suggested a level of trust that had been established. The relative quiet from the community over time suggested that acceptance of the activities had been made and that no new significant concerns were being generated.

4.0 REAL-TIME CONTINUOUS MONITORING PROCEDURES

The purpose of this section is to provide a summary of the monitoring and laboratory procedures that were used in the CMP data collection effort. The CMP Work Plan (in Appendix C) provides details on most aspects of the techniques and procedures used. In addition, a general summary of CMT activities throughout the project is presented. Details relating to each portion of these time periods, including monitoring results, are presented in Section 6. Major changes to the overall plans presented in the CMP work plan were documented in Section 3.6.1.

The sampling procedures consisted of both real-time mobile and fixed integrated methods. Each of these approaches is described below. For the fixed integrated sampling methods, laboratory analysis was required, as is described below.

4.1 DATA COLLECTION PROCEDURES

4.2 REAL-TIME MONITORING APPROACH

As presented in the CMP Work Plan, the purpose of the real-time monitors was to collect data that could be used to give rapid information about potentially unsafe levels of the chemicals of concern. The reference time frame for all the measurements was 15 minutes; four of these were averaged to provide a one-hour average to compare against CMP trigger levels. The CMT field staff would communicate one-hour averages that approached the trigger levels to the appropriate CMT and project team members. If the one-hour concentrations came close to, or exceeded, the trigger level, Jacobs excavation staff would be alerted of the need to alter field activities in order to mitigate the high levels.

4.2.1 Measured Parameters

The measured parameters and the instruments used for real time monitoring are listed in Table 4.1.

Table 4.1. Summary of Real-time Monitoring Parameters and Instruments

Real-time Field Data Collection	
PEC (Diesel Exhaust)	Aethalometer AE-16
PM2.5	URG inlet, DataRam 2000
PM10 (dust)	Personal DataRAM 1000
Total PAH	PAH 2000
Hydrogen sulfide	Jerome 631-X sensor
BTEX, 1,3-butadiene	Voyager GC/PID--Instruments 204, 301, 303
Nuisance dust	Visual observations
Odors	Olfactory observations

4.2.2 Mobile Measurement Platforms

Three main methods were used to move instrumentation around the monitoring area: hand carried, modified baby carriers (two versions), and a van.

4.2.2.1 Monitoring Cart

Starting with preconstruction monitoring, real-time instruments were either hand-carried or transported in a baby carrier retrofitted with a plastic crate in which the instruments were placed. Figure 4.1 shows a CMT technician using the baby carrier. This carrier could be equipped with the Jerome H2S sensor, the Photovac, and the PDR dust sensor.

Figure 4.1. CMT Mobile Instrument Platform

The baby carrier method worked successfully until staff reductions in April 1999 required a single field technician to operate the van and the cart. The staff reduction also required additional security for the equipment, more space for other instruments and storage, and a larger platform for a car battery for overall power.

These requirements were met with the “second generation” cart, which consisted of the baby carrier modified with a large metal box, a pole for the meteorological sensors, and a larger platform underneath for battery storage. Figure 4.2 shows a photograph of this system.

Figure 4.2. CMT Instrument Cart

The box was insulated to prevent overheating of the instruments when the carrier was left unattended in the sun. Insulation was augmented by a peltier cooler to keep the temperature below critical levels for the GC and laptop computer. This system allowed the Jerome, Voyager GC, PDR and meteorological data sensors (wind speed, wind direction and temperature) to collect data automatically and to log it to the computer. The laptop computer was equipped with a multiple serial port PC card that allowed all the instruments to be directly operated via data logging software. This system had the added benefit of saving additional labor in instrument data downloading at the end of the day.

When in use, the cart was placed in an appropriate downwind position, the direction of the wind sensor was adjusted to approximately north (magnetic north), and logging was commenced. The field technician would note the grid system location and periodically make hard copy notations of measured concentrations. However, because the cart was unattended at times, redundant hard

copy recording was not continuously available. However, this redundancy turned out to be unnecessary since the data logging systems worked very well throughout the project.

4.2.2.2 Monitoring Van

A larger and more protected mobile platform was required for other instruments used in the real-time monitoring. In particular, a key piece of equipment—the aethalometer—was designed as a standard monitor requiring line power and shelter from the weather. In addition, it was seen early on in the preconstruction period that there would be a need for a mobile platform on which the field technicians would have protection from the elements while they collected data and made notes.

A converted General Motors cargo van was used as the mobile lab platform. This van was large enough to house several instruments and work space for the field technicians. The GC data required operator interaction in order to confirm the correct integration of the chromatograms, particularly in cases of possible exceedances of trigger levels. This interaction was made more effective inside the van.

Figure 4.3. Interior of Van

The van was outfitted with an extensive power supply system for use by the various instruments. Several instruments were not amenable to cart-type field operation: the aethalometer, the PAS

2000 PAH sensor, the DR2000 with cyclone inlet, and the Voyager (at least during data reduction operations).

The power supply consisted of a bank of large diesel batteries, giving a total of approximately 1000 amps of DC power at 12 volts. These batteries supplied an 1800 watt inverter that provided adequate supply for the operation of the line-power instruments for approximately 10 hours. At the end of each day, the van was parked at the CMT trailer and the batteries were re-charged overnight. Following some experimentation with various charging systems, it was found that a high-powered charger would be adequate for overnight charging. The inverter was found to be somewhat sensitive to temperature, and a fan was installed to provide cooling air. Overall, the van set up proved quite useful. The full suite of instruments could be mobilized and moved in a matter of a few minutes, and the end of the day operations of transferring data to the database were made easier by having continuous power to supply the laptop computers.

4.2.3 Inlet System

One inlet system supplied all instrumentation in the mobile monitoring van. This inlet was the University Research Glassware PM2.5 cyclone, which was operated at 10 L/min to make the correct size fractionation. The required volume was supplied by all the instrumentation in the van, including the DataRAM 2000 at 2 L/min, the aethalometer at 6 L/min, and the PAS 2000 at 2 L/min. The Voyager GC required only 120 mL/min once every 20 minutes or so, and the Jerome required only 150 mL/min for 30 seconds every minute. A secondary pump was available to make up any difference for those times that one or more of the instruments was inoperative. An on-board flow sensor was used to check the flow frequently to make sure the combined flow was 10 L/min.

The cyclone catch basin was cleaned on a daily basis, and the entire cyclone was cleaned approximately once every two months. It was found that the initial startup of the pumps in the morning stirred up residual particulate in the catch basin or other points and that the initial high values should be ignored until the readings stabilized.

4.3 REAL-TIME INSTRUMENTATION

4.3.1 Aethalometer Black Carbon Sensor

An Andersen Instruments AE-16 aethalometer was used to collect continuous data for black carbon, or particulate elemental carbon (PEC), for use as a surrogate for diesel exhaust. Figure 4.4 shows a photo of this instrument. Figure 4.5 shows the interior of the instrument, with the quartz fiber tape collection system.

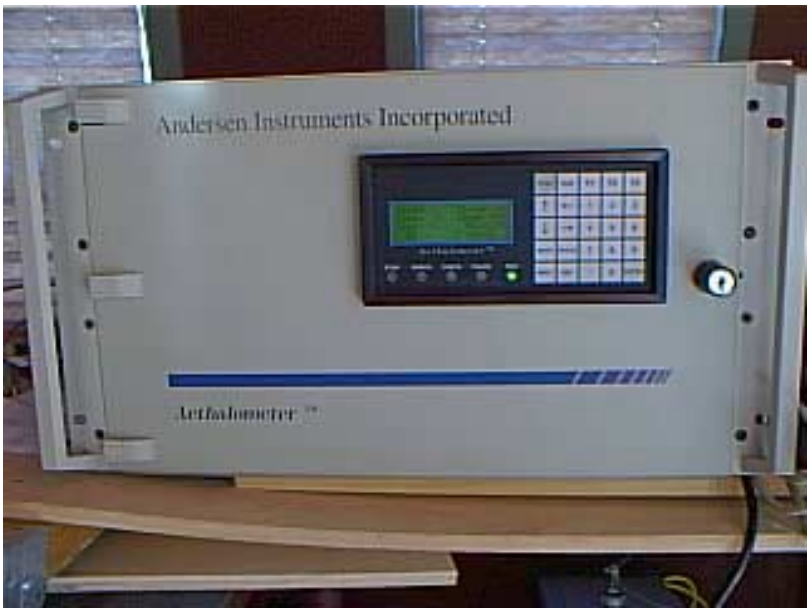

Figure 4.4. Aethalometer Black Carbon Sensor

Figure 4.5. Interior of Aethalometer

The aethalometer used an internal pump to draw approximately 6 L/min through the tape at a point below a light source and sensor. The light was an 880 nm LED. Absorption at that wavelength is solely due to PEC, excluding other colored substances. During the 15-minute time base of the measurement, the sensor collects and averages the amount of attenuation due to PEC.

At the end of the period, the data system saves the result on the on-board disk drive. Subsequent time periods are recorded throughout the day. As a backup and to track trends, the field technician noted the values frequently and manually recorded the 15-minute average displayed on the outer LCD screen.

Figure 4.6 shows an example of a 24-hour data collection test that recorded the effect of remediation activities on daily PEC values. The high early morning data peaks relative to the rest of the day demonstrate the effect of calm winds on the measured emissions due to the start-up activities of the trucks and other equipment in the morning. The start up of the cold engines is expected to produce high concentrations, and the early morning calm winds did not disperse the emissions. For much of the rest of the day, the concentrations were much lower. However, at various points throughout the day, there were sporadic high values. In the late afternoon, the concentrations increased due to both site activities and increased commuter traffic on Avila Beach Drive from Diablo Canyon workers. In the late evening and night-time hours, the background levels are low due to the low number of diesel sources in the area during that time. Thet background level of around 100 ng/m3 is consistent with a clean area relatively unimpacted by urban sources.

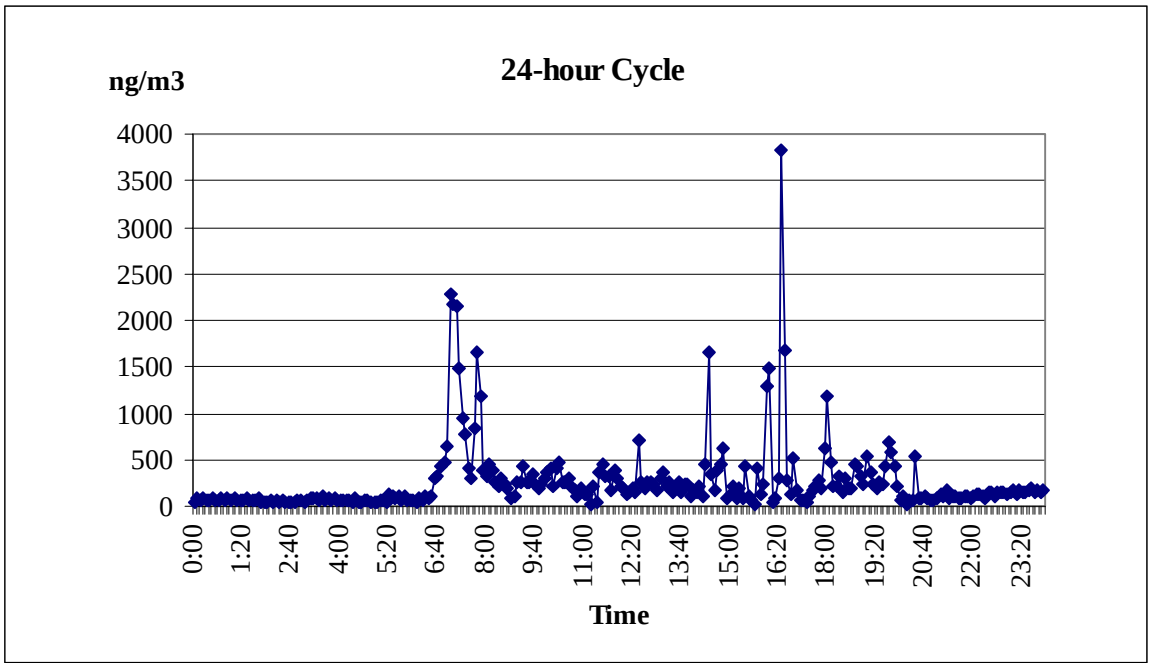

Figure 4.6. Example of 24-hour cycle of PEC values in Avila Beach

Further discussion of the aethalometer data is presented in Section 6.

4.3.2 DataRAM 2000 Particulate Monitor

Data of particulates 2.5 microns or smaller aerodynamic equivalent diameter (AED) were collected using the PM2.5 cyclone described above and the MIE DataRAM 2000. The instrument uses forward scattering of 880 nm light to detect aerosol concentration in the sampled air stream. Calibration is done with latex spheres in the factory. It has an on-board logger that averages the continuous sensor readings according to the input time base. As with the other instruments, the time base was 15 minutes. The continuous readings were displayed on the LCD readout and were checked frequently by the field technician to gauge what was being detected. Figure 4.7 shows the DataRAM 2000 light scattering photometer used in conjunction with the cyclone to monitor for PM2.5.

Figure 4.7. DataRAM 2000 Sensor used for PM2.5 Monitoring

Directly above the instrument inlet, the sample conditioner/heater was used to dry out high humidity air that causes the growth of the hydrophilic portions of aerosols and the agglomeration of smaller particles.

The calibration of the DR2000 was made at the factory, but was checked periodically by the on-board calibration disk that is placed in the beam path. The calibration remained satisfactory throughout the project.

While the instrument failed a number of times due to power supply or pump problems, the internal optical detection system appeared to have operated satisfactorily throughout the project.

4.3.3 Voyager Portable Gas Chromatograph

The Photovac Voyager portable gas chromatograph was used for quantitative detection of volatile chemicals of concern, including benzene, toluene, ethyl benzene, m and p-xylene, o-xylene, and 1,3-butadiene. These compounds are very volatile and would be expected components of diesel exhaust, but also originate from contaminated soil. 1,3-Butadiene would be expected only as an exhaust by-product.

The Voyager is a field-portable instrument designed specifically for use in remediation or similar types of real-time, on-site analysis of toxic chemical species. Figure 4.8 shows a photograph of the unit.

Figure 4.8. Photovac Voyager Portable GC

Figure 4.9. Voyager GC Inside the Van

Figure 4.9 shows the typical placement of the instrument inside the van. The common sampling line for the PAS 2000, the aethalometer, the DR 2000 and the Voyager, came down through the roof of the van and sampling points for each instrument were teed or appropriately configured. The on-board pump of the Voyager sampled at 120 mL a minute for 30 seconds to purge the line from the GC to the larger continuously purged inlet line.

The sample that was drawn into the instrument passed through a 1 mL loop. From this loop, variable amounts of gas could be injected under instrument control, depending upon the desired level of sensitivity. For this program, maximum sensitivity was always sought, so the maximum sampling volume was always selected.

The Voyager GC consists of four columns: three analytical columns with typical chromatographic stationary phases and one deactivated silica transfer line. A special column switching apparatus configured with valves to direct flow through the various columns provides the necessary combination of phases to accomplish the desired separation. The Voyagers used in the CMP were configured with Assay #1, which consisted of a 4 meter, 0.53 mm diameter with 2 um thickness SPB-35 (phenyl-methyl) phase (Column A), a 20 meter, 0.32 mm diameter with 1 um thickness WAX phase (Column B), and a 15 meter, 0.32 mm diameter with 12 um thickness methyl silicone phase (Column C). Column A was used for BTEX and Column C was used for 1,3-butadiene.

The Voyager was configured with both photoionization (PID) (at an energy of 10.6 eV) and electron capture detectors (ECD). The ECD was not used in these analyses.

The run time for the BTEX compounds was approximately 20 minutes and for 1,3-butadiene, approximately 3 minutes. The analysis sequence was set to run automatically with one analysis

following the other by a brief delay. Data were collected and saved automatically with compound identification and quantification performed automatically according to the calibration parameters input previously.

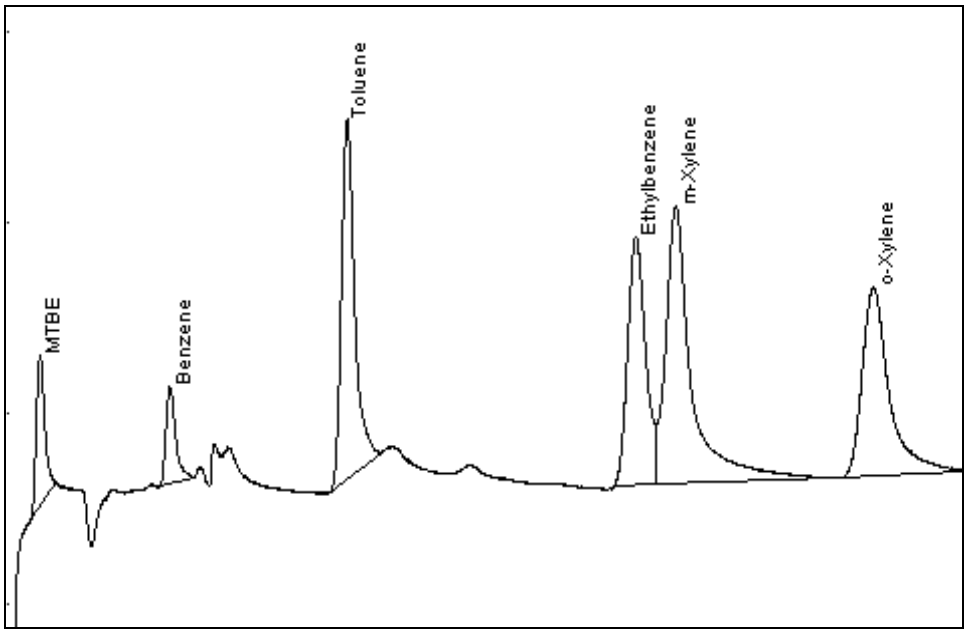

Figure 4.10. Example Calibration Check Chromatogram

Table 4.2. Example Quantitation Results

PEAK REPORT:

# Name	Conc (PPM)	Area (mVS)	Height (mV)	R.T. (S)	Status
1 MTBE	0.050	44.0	4.563	117.7	Cal
2 Benzene	0.050	32.7	2.729	259.5	Cal
3 Toluene	0.209	166	10.3	452.0	Cal
4 Ethylbenzene	0.201	156	6.981	766.0	Cal
5 m-Xylene	0.201	252	7.798	809.7	Cal
6 o-Xylene	0.199	181	5.267	1024.7	Cal

Three Voyager GCs were used during the project, two as part of the original design and a third loaner unit as a replacement during times when instruments were being repaired or were inoperative. Problems with the instruments occurred throughout the project, though for the most part adequate data was collected for at least one of the instruments continuously. Internal quality control assessment of the data provided by the Voyager will be presented in Section 8.4.

4.3.4 Jerome Hydrogen Sulfide Sensor

Hydrogen sulfide was detected with the Jerome 631-X gold film sensor. This sensor consists of a film of gold across which the sampled air is passed. The hydrogen sulfide molecules are adsorbed on the surface of the gold film and cause a change in the film's sensitivity that is proportional to the number of molecules on the surface. This change is translated into a concentration on the display. Figure 4.11 shows the unit and Figure 4.12 shows the plumbing diagram of the unit.

Figure 4.11. Jerome Sensor

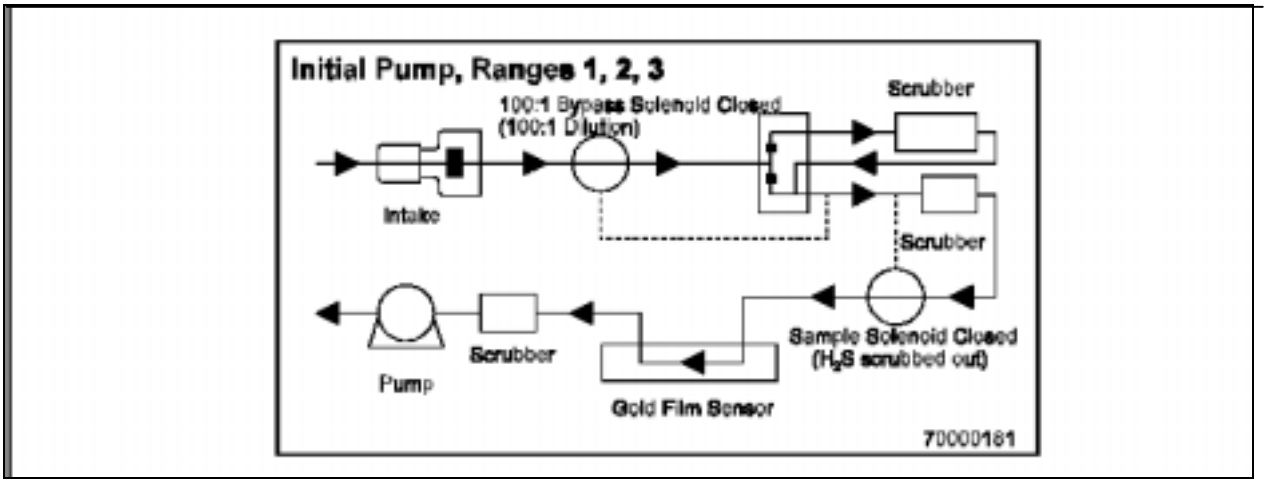

Figure 4.12. Schematic of Jerome Sensor

The Jerome was sensitive down to 1 ppbv of hydrogen sulfide. Data were initially collected on a 15 minute basis but were subsequently collected on a 1-minute basis for correlation with meteorological and odor data. Two Jerome sensors were used, and when one or the other was returned to the factory for recalibration or repair, which happened several times, a loaner was made available for use.

4.3.5 Personal DataRAM Particulate Monitor

The MIE Personal DataRAM (PDR) was used to measure total suspended particulate as a surrogate for PM10. Figure 4.13 shows a photo of the instrument. Figure 4.2 shows how it was deployed on the met sensor mast of the cart (at the top of the photo).

Figure 4.13. MIE Personal DataRAM

Several aspects of this instrument proved to be problematic for this use. First, since the instrument is a passive dust monitor that relies on openings at the sides, there is a directional bias to aerosol sampling. Second, the inlets are not designed for aerodynamically correct sampling of multiple particle sizes—there is a built in bias for larger particles above 10 microns. Third, the optical sensing methodology is effectively limited to smaller particles due to the inherent constraints of Mie scattering. Lastly, since the passive inlets do not allow for heating and drying of the samples, in high humidity atmospheres there is a possibility of agglomeration of smaller particles into larger sizes due to absorption of water vapor.

The limitations described above were evident on several occasions. The dependence on relative humidity became evident on the first full day of excavation, March 1, 1999. On the morning of March 1, the readings for the PDR rose to over 800 ug/m3 immediately and decreased over the course of the day, as shown in Figure 4.14. However, it was clear that these high readings were not due to excavation activities. First, major activities did not start until after noontime as noted by the field crew. This fact is confirmed by the aethalometer data, as shown in Figure 4.15. The

PEC data shows low levels during the morning, followed by higher spikes in the afternoon, corresponding to truck activity.

Second, it was clear that atmospheric conditions were unusual—there was a moderate haze emanating from the beach area, the surf was unusually heavy, and the wind was calm, with approximately 70% of the winds less than 3 mph. . Figure 4.16 indicates that the wind was coming from the ocean for the majority of the day, suggesting an effect from the surf.

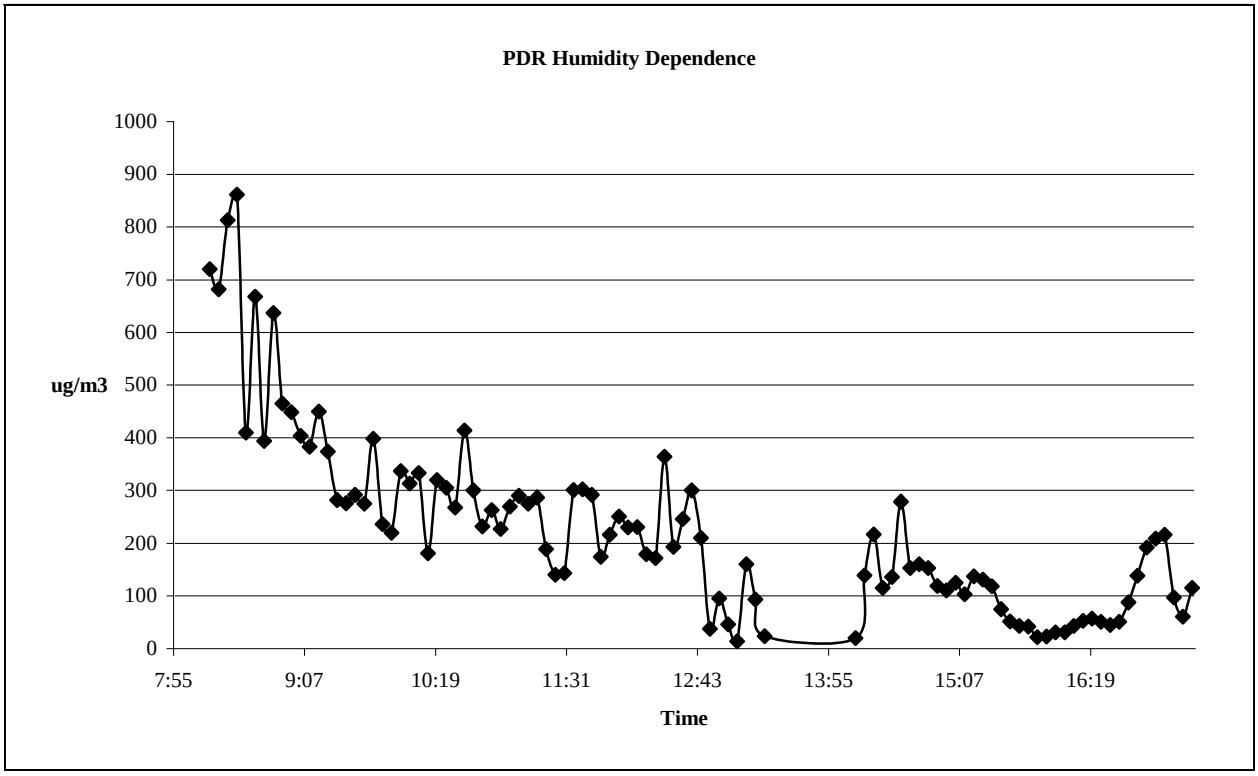

Figure 4.14. PDR Data for March 1, 1999

In addition to the decrease over time of total particulate that corresponds to increased turbulence with the daytime warming trend and dissipation of the night time calm, the aethalometer data for diesel exhaust showed low levels in the morning followed by higher levels in the afternoon after the haul trucks commenced their runs. Therefore, on the basis of all this information, it was concluded that the PDR sensor was responding to increased water vapor in the air and possibly other surf-derived sulfate aerosols.

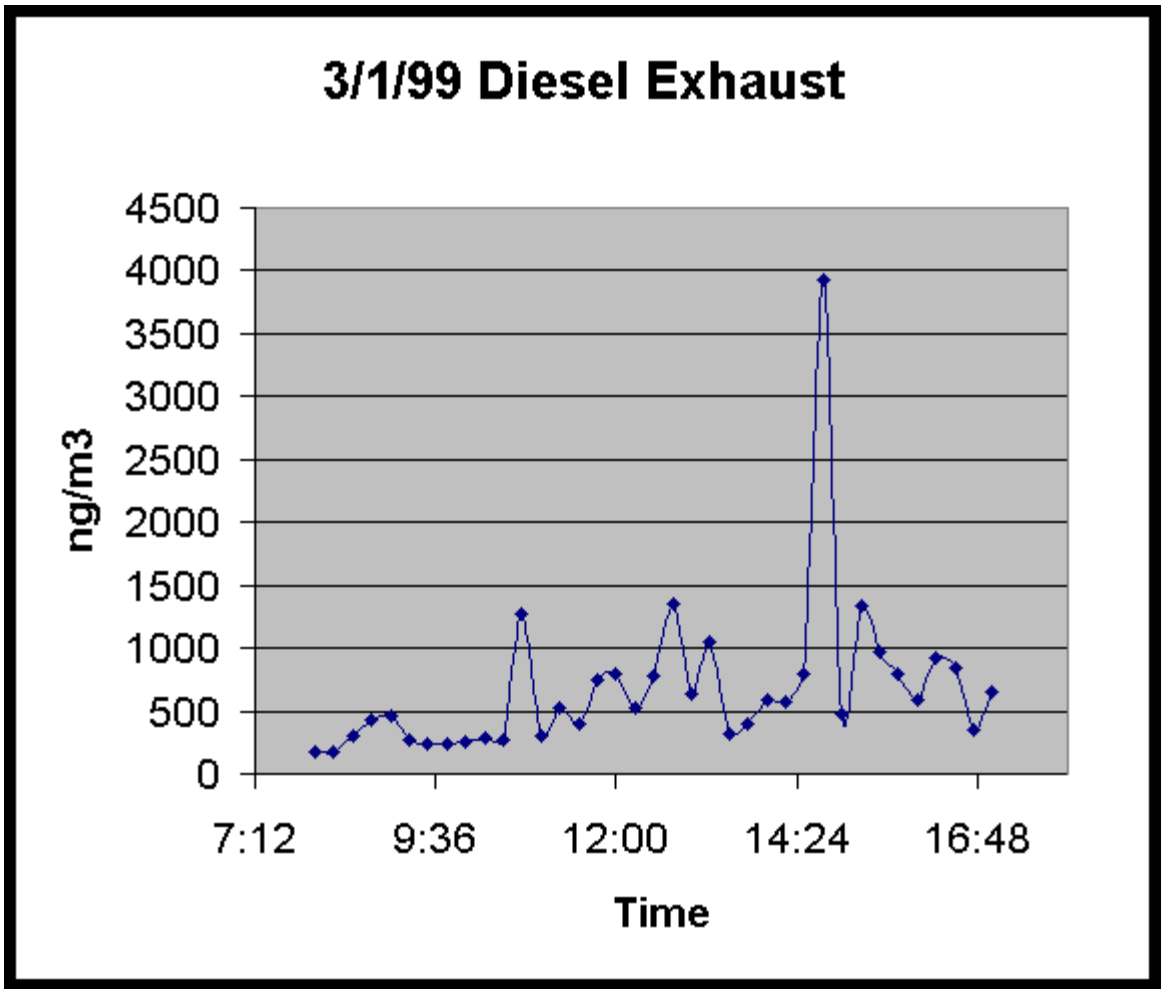

Figure 4.15. Aethalometer Data for March 1, 1999

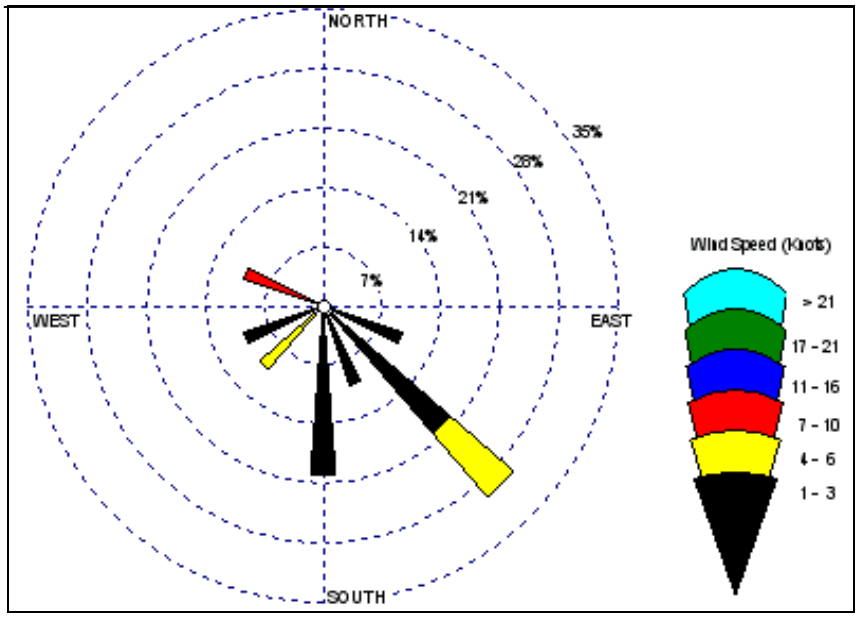

Figure 4.16. Wind Rose for March 1, 1999

Due to this finding and further investigation into the operational limitations of the PDR, the device was not used when the humidity exceeded 70% RH. This occurred only infrequently as the average relative humidity was in the 50-60% range, notwithstanding the proximity to the ocean.

The sampling efficiency of the PDR was tested on several occasions in order to calibrate its response to aerosol levels at the Avila Beach location during excavation. This was done by sampling with the PDR alongside an Airmetrics Minivol sampler with a PM10 impactor for size segregation. Sampling was conducted for the same time period by both devices. Figure 4.17 and Table 4.3 show the results of the comparison between the two methods.

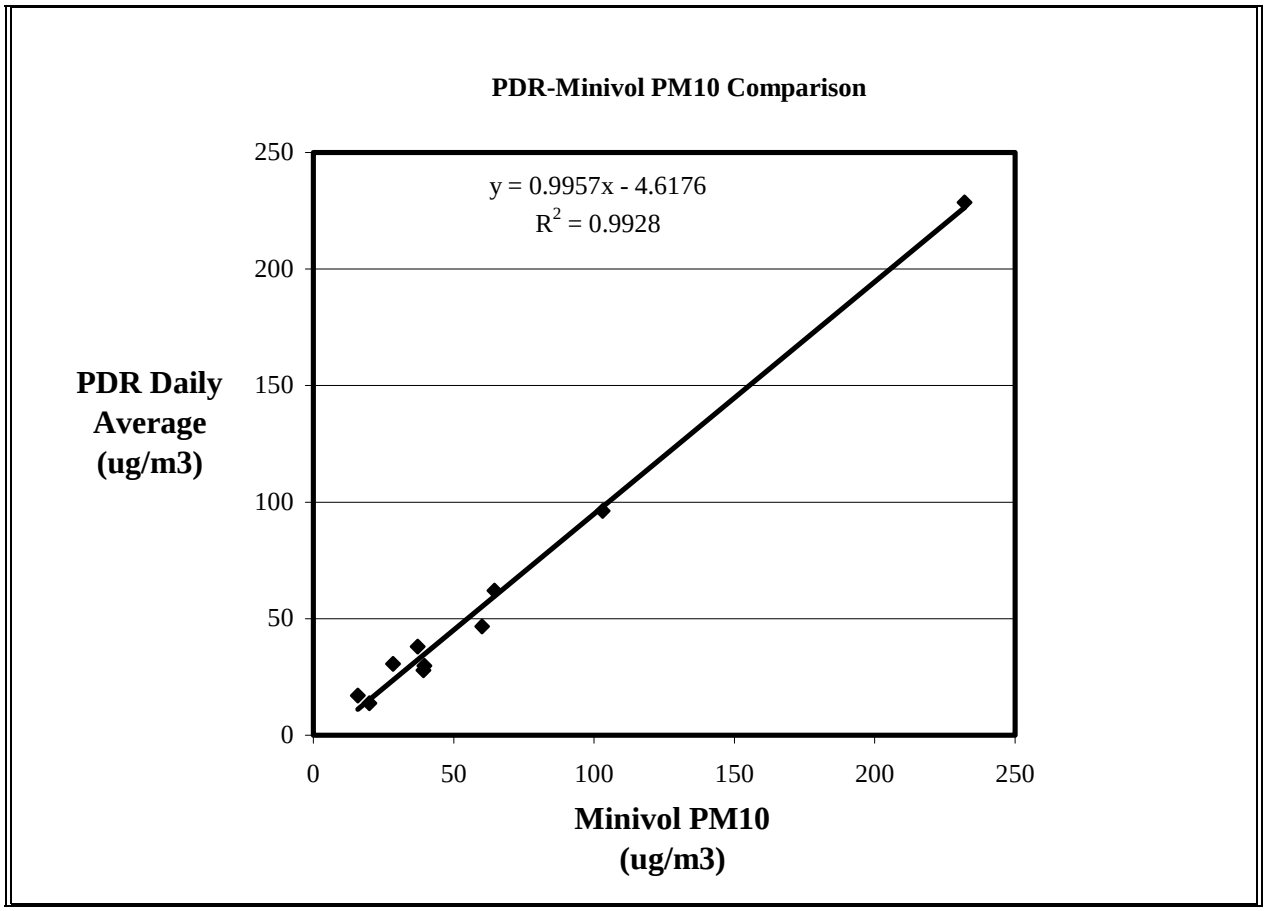

Figure 4.17. PDR vs. Minivol Comparison

Table 4.3. PDR vs. Minivol Comparison

MiniVol PM10 Summary		
DATE	**Minivol (ug/m3)**	**PDR (ug/m3)**
2/24/99	28.3	30.6
2/26/99	20.0	13.8
3/1/99	232.0	228.6
3/2/99	103.0	96.2
3/4/99	15.9	17.0
3/17/99	64.6	62.0
3/18/99	60.1	46.7
3/22/99	37.1	38.0
3/23/99	39.5	29.8
3/24/99	39.2	27.9

These data suggest that the combination of the sensor characteristics, the instrument inlet, the average wind velocity and the construction and combustion derived aerosols results in an effective sampling size selection of approximately 10 um AED for the PDR, the same as for the Minivol impactor.

This finding was useful as it suggested that, instead of a surrogate for PM10 from total dust, the PDR provided data that were comparable to a specific PM10 monitor.

4.3.6 PAS 2000 Total PAH Sensor

Particulate-bound PAH was monitored using the Ecochem PAS 2000 instrument. This instrument uses low-energy UV light to photoionize the bound PAH molecules on the surface of particles. The low-energy selectively ionizes only PAH molecules, ignoring other aromatic target species.

The instrument provides a continuous read-out of PAH concentration. The read-out was averaged over the usual 15-minute time base as with the other instruments. Due to its rapid response, short-term peaks of less than 5 seconds in response to passing vehicles were often seen.

Due to uncertainty in how the data would be used for risk management, the PAS2000 data were used only in a qualitative sense. The only instance in which the PAH data suggested a potential problem was when the instrument was located directly across from the Maxigrinder, a large debris grinding machine that was handling material from Cell 3 demolition. However, this was a short-term event and the other instruments did not show values of concern.

Figure 4.18. PAS 2000 Particulate-bound PAH Sensor

4.3.7 Snapshot Portable Gas Chromatograph

The PhotoVac Snapshot Portable GC was evaluated for use in augmenting the Voyagers for rapid detection of BTEX in the field. It was used on a preliminary basis at the beginning of the Baseline and Preconstruction monitoring periods, but was soon rejected due to its operational difficulty and its relatively high detection limit of 100-200 ppbv for BTEX, which was an appreciable fraction of the trigger levels. Its use was abandoned in favor of the Voyager portable GC.

4.3.8 Instrument Quality Assurance

In order to assure high quality data, a program of daily checks was used to assess the operation of the field instruments.

4.3.8.1 Daily checks

- PDR Particulate Sensor. Before the PDR was used each day, it was zeroed using zero air flowing through a special reclosable plastic bag. After approximately 2 minutes, the sensor indicates if the calibration is still good. If the calibration was not good, the test was repeated. Additional failures meant a factory calibration check was in order.

Although a factory calibration check was never needed, the calibration was checked in the course of other servicing at the factory and never needed adjustment.

- DR2000 Particulate Sensor. The DR was factory calibrated. Two user checks for quality assurance are possible—the periodic auto-zero and the periodic internal calibration check. The instrument was always operated (checked??)on an auto-zero basis for auto-zero once every 2 hours. The periodic internal check was performed manually and was done about once every two weeks. Internal checks always showed an acceptable continuing calibration value of ±5%.

- Voyager Portable GCs. The Voyager GCs were checked first thing every morning on a daily basis using two mixes of the target compounds. A 50 ppbv BTEX standard prepared from a stock 5 ppmv standard was used to check calibration for BTEX and a 100 ppbv standard of 1,3-butadiene was used to check for its continuing calibration. An acceptance criterion of ±30% was used. If this value was exceeded, the test was repeated. If additional failures occurred, the instrument was removed from service until a satisfactory response was obtained. Further details on Voyager data assessment are provided in Section 8.

- Aethalometer. The aethalometer calibration depended on the internal value of sigma, a constant empirically derived from cross-calibration studies with integrated sampling methods and laboratory analysis. Once set, this value does not change. The only other check required is the flow sensor, which was checked approximately once every 3 months and always showed satisfactory operation.

- Jerome H2S Sensor. The Jerome is factory calibrated and cannot be changed by the user. However, checks of its operation are possible against a prepared standard. Periodic checks of the sensor against a 5 ppmv hydrogen sulfide standard always showed adequate agreement. Cases of poor operation were immediately identified by unusual daily readings when checked against the other instrument or the standard. If this occurred, the instrument was returned to the factory for re-calibration. Due to the heavy use of the instrument, this occurred several times and several new sensors were installed in the course of repair.

- PAS 2000 Sensor. The PAS was factory calibrated and due to its use as a qualitative sensor only, the calibration was not checked during the project.

4.3.8.2 Standards Preparation and Certification

The BTEX and 1,3-butadiene standards used for daily continuing calibration checks were prepared from a commercial stock 5 ppmv standard by static dilution into a Tedlar bag. Over the course of the program, these standards were checked by a number of means. First, various prepared standards were checked against other previously prepared standards to compare response. The responses were also compared to what would be expected from the dilution of the 5 ppmv standard.

A number of standards were submitted to the laboratory for analysis by TO-14. In all cases, the results showed adequate comparability with laboratory-prepared standards, showing that the field crew's preparation technique was sound.

4.3.8.3 Instrumental Problems

Due to continuous use of the field instruments, a number of problems occurred. As much as possible, factory replacement units or rentals were used to ensure that continuous coverage would be maintained.

- Voyager GCs. The Voyager GCs were problematic from the beginning. A number of quality problems with the instruments were evident immediately, including a short in the case that prevented continuous operation and software glitches that caused problematic data interpretation. The largest problem was caused by an internal contamination of some part in the instrument that could not be flushed out and that did not respond to cleaning efforts. Several factory servicing failed to remedy the problem. While it did not prevent continuing use of the instrument, it did cause additional labor to be expended in more tedious data manipulation and interpretation.

- Aethalometer. The aethalometer failed on two occasions for the same reason—pump failure. In the first case, the pump failed due to quality problems with the pump itself and until a replacement could be obtained, an external pump was used. The second case of failure was due to an overheating pump caused by misplacement of the ventilation slots on the top of the instrument. In both cases, minimal data were lost due to servicing.

- DR2000. The DR2000 failed on one occasion early in the program due to internal pump failure. A second failure occurred when the power supply failed. In both these cases, minimal data collection time was lost.

- PDR. The PDR experienced a number of problems, several of which required factory servicing. In order to limit the need for continual battery replacement, an external battery pack was used. However, the cable connection for the power supply was sensitive to misalignment, which happened frequently. This was never fully repaired satisfactorily, but field fixes were made to ensure continuing operation. Other problems included failures of the internal logger and front switches. These malfunctions were repaired quickly in most cases and only once was a replacement unit needed.

- Jerome. The Jerome H2S gold foil sensor has only a limited lifetime, and due to the program requirement of continual one-minute values, it frequently became dysfunctional. While waiting for replacements, a loaner instrument was used.

4.4 OFF-HOURS SENSOR

4.4.1 Monitoring Strategy

The off-hours sensor system was designed to collect continuous data from a point over the excavation pit and to notify CMT staff in the event of an exceedance of trigger thresholds. The trigger threshold was 5 ppmv for hydrogen sulfide, which is 50% of the TLV level, and 25 ppmv for total hydrocarbons, which is 50% of the TLV for hexane, which was a surrogate for total hydrocarbons.

Two sensors were installed: CEA, Inc. electrochemical sensors for total hydrocarbons and for hydrogen sulfide. The detection limit was cited to be nominally 1 ppmv for these two chemicals.

These two sensors were connected to a data logger that continuously collected data. In the event of an exceedance, the logger sent a pre-programmed alphanumeric page notification via cellular phone. The notification contained the message that an exceedance had occurred and what the concentration was. The system also transmitted various system fault messages such as power outages, and times it was actuated or deactuated.

The sensors were placed in a weather-proof box with the data logger, cell phone and a 12 VDC battery. A small pump pulled sample from a probe through a manifold that exposed the sensor to the flow. The response time was in the order of 3 minutes.

The probe consisted of a 100 foot teflon tube inside of a larger silicone protective tube. At the end, an inlet funnel with a filter was attached. The end of the probe was extended over the active area of the pit at the end of each day and retrieved at the beginning of the following day. Since it was battery powered and cell-phone connected, there was no need for direct connection to any utility supply. The battery was swapped with a fresh one by CMT technicians once every two days.

Figure 4.19 shows a photo of the sensor system. Figure 4.20 shows a photo of the sensor extended over the pit area. Another larger extender allowed the probe to be placed further outward from the sheet pile wall.

Figure 4.19. Sensor Cart.

Figure 4.20. Sensor Probe over Pit Water

4.4.2 Operation

The sensors were calibrated by flowing a standard of hexane for the hydrocarbon sensor or hydrogen sulfide for the hydrogen sulfide sensor through the sampling manifold and noting the response. The response factor was entered into the data logger so that continuous quantification was possible.

The response was found to be nonlinear for hexane, contrary to the manufacturers claims, but was linear for hydrogen sulfide. Table 4.4 shows the response obtained on June 17, 1999 from various concentrations of hydrogen sulfide to the Jerome sensor for confirmation and the H2S sensor. Figure 4.21 shows the calibration curve obtained.

Table 4.4. Example Calibration of H2S Sensor

Jerome (ppmv)	Sensor (ppmv)
3.0	0.0
4.0	0.7
5.0	1.3
7.1	4.5
18.0	10.6

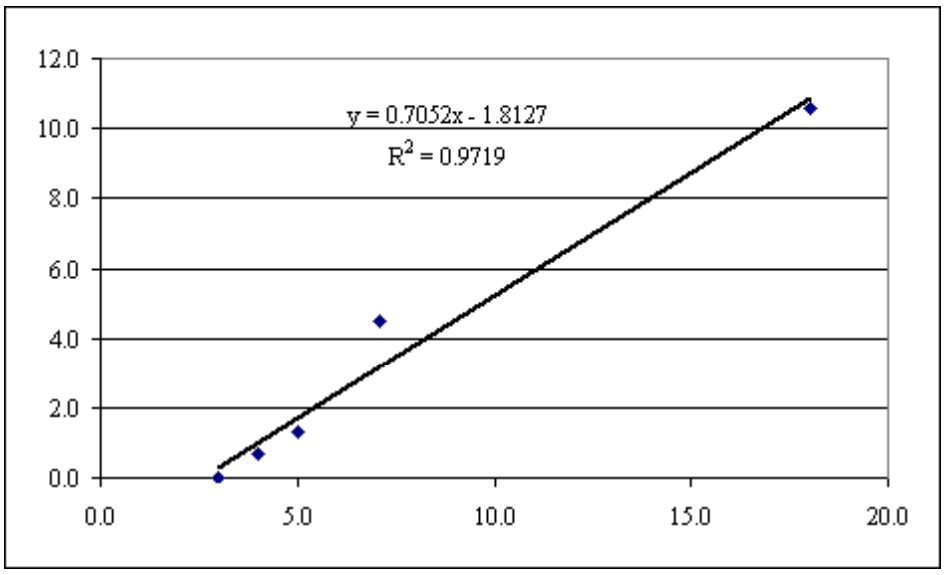

Figure 4.21. Calibration Curve for H2S Sensor

The operation of the sensor was troublesome for a number of reasons. Although the calibration shown in Figure 4.21 is approximately linear, in many cases it was nonlinear and unstable, and

could not be coaxed to be otherwise, contrary to specifications. In addition, as the data shows, the absolute sensor calibration as provided was significantly off from the external calibration as provided by the Jerome.

However, the most significant problem was the temperature dependence of the sensor, which again was contrary to the expressed specifications of the manufacturer. After a number of false alarms, it was determined that the sensor began to register detections as the temperature rose, which was verified by a plot of the temperature vs. response over time. A replacement sensor was obtained, which ameliorated the problem to a small degree, but did not remove it.

The temperature problem was mitigated somewhat by insulating the sensor box, placing a reflective cover over the box, and opening the lid to allow more air circulation. The operation of the off-hours sensor system was much more time intensive than expected due to these problems.

Other problems occurred as a result of telecommunications issues. In mid-June, a continuing communication problem began that could not be solved by either CMT or the logger manufacturer. Finally, in July, the sensor was sent back to the factory. The investigation took three weeks with the factory finally not being able to solve the problem. A replacement cell phone was obtained and with some other adjustments, communication was restored.

For the remainder of the project, the system required a lot of attention but operated satisfactorily.

4.4.3 Exceedances

Other than false alarms, there were no exceedances of the target concentrations levels from emissions from the active pit areas.

4.5 FIELD CREW OBSERVATIONS

One of the responsibilities of each CMT field technician was to observe potential dust and odor problems. This was done as a routine part of their roaming function, both to collect instrumental data and to monitor the events in the pit. Dust and odor exceedances will be discussed in Section 8.

4.6 FIELD MONITORING

Field monitoring was conducted every day of the excavation period during which significant activities were conducted. Close communications with the site foremen were maintained throughout the project, with daily updates on status and forecasts for upcoming activities. For the preconstruction period, few activities were conducted on Saturdays, but after the start of the active excavation, a Monday-Saturday schedule was followed by the remediation crew, and the CMT adhered to this schedule. On some Saturdays, activities were minimal; however monitoring continued throughout.

The daily monitoring schedule typically started at approximately 7:30 AM and ended about 5 PM, following the shut-down of major site activities. While site crew were present at 7 AM, no real activities commenced until approximately 7:30 AM following the daily safety meeting and planning activities. Cessation of activities at the end of the day was the cue for the CMT staff to begin the daily downloading of data and posting of data to the database, etc. These activities frequently lasted into the late evening. The objective was to keep up with this task so that a timely reporting of trends could be made to the project team and to the community.

5.0 INTEGRATED SAMPLING AND ANALYSIS PROCEDURES

The collection of integrated samples satisfied two data needs in the CMP. First, a larger number of target compounds could be collected with standard integrated methods, compared to just a few with the real-time instruments. The total number of compounds analyzed during the first part of the program was over 100. Second, the laboratory analysis afforded a much higher sensitivity for the monitored compounds compared with field analysis (at least a factor of ten higher). Third, several species could simply not be monitored using a real-time field instrument due to inherent limitations in the technology. Therefore, integrated sampling provided a valuable second dimension in the community risk management by giving a broad and deep confirmation of the effects on the community from the remediation activities.

Table 5.1 contains a list of the integrated sampling approach along with the laboratory that conducted the analysis for each set of methods.

Table 5.1. Integrated Sampling Methods and Laboratories

Integrated Sampling	
Integrated Data-Environmental Analytical Service	
BTEX, butadiene	Summa canister, TO-14
Hydrocarbons	Summa canister, TO-14
PAH-full scan	HiVol PUF/XAD. GC/MS Full Scan
PAH-SIM	HiVol PUF/XAD. GC/MS--SIM
Aldehydes/Ketones	DNPH Cart, HPLC
Sulfur species	Tedlar Bag, GC/FPD
Integrated Data-Air Toxics Limited	
BTEX, butadiene	Summa canister, TO-14/15
PAH-SIM	HiVol PUF/XAD. GC/MS--SIM
Aldehydes/Ketones	DNPH Cart, HPLC
Integrated Data-Chester LabNet	
PM10	HiVol/Gravimetric
Cascade Impactor	HiVol Impactor/Gravimetric
MiniVol PM10	Low volume Impactor/Gravimetric

Two laboratories provided the analysis service: Environmental Analytical Service, and Air Toxics Limited. More details about the laboratory analysis procedures are presented in Section 5.2.

The integrated sampling program consisted of a large set of toxic volatile and semi-volatile organic compounds that are commonly associated with vehicle exhaust and emissions from

remediation activities. The rationale for choosing this list is contained in the CMP Work Plan in Appendix C The list of chemical parameters sampled changed over the course of the program as changes were made in laboratory analysis and after examination of initial data.

All standard integrated CMP samples were collected using the combined VOC/Carbonyl/Sulfur sampler with the High Volume PUF sampler. Both samplers were placed on 4 x 4 ft. pads, as shown in Figure 5.1. The samplers were attached to the pads and could be moved with relative ease. Further details relating to these samplers are presented below.

Figure 5.1. VOC and PUF Samplers

5.1 VOLATILE ORGANIC COMPOUNDS

5.1.1 Sampling Method

A custom sampler was constructed to collect VOC and carbonyl samples. Figure 5.2 shows the system. Figure 5.3 shows a schematic of the system. The enclosure provided protection from weather and outside intrusions.

Figure 5.2. VOC-Carbonyl Sampler

The system consisted of a manifold flow system that produced a negative pressure flow for the inlet line and the carbonyl sampler and a positive pressure for the canister sampler.

The main pump used produced a flow of approximately 4 L/min that purged the inlet line and provided a pressurized flow to the canister. A second pump produced the lower flow for the carbonyl sampler. This flow was directed from the main inlet through the carbonyl sampler system that was controlled by a rotameter with an integrated needle valve. The other main flow was directed towards the flow controller for the Summa canister. Canister flow was set for 20 mL/min; for a 10 hour sampling day, this would provide a positive pressure of 10-15 psig. This positive pressure would allow the bypassing of the pressurization step in the laboratory and provide the lowest possible detection limits.

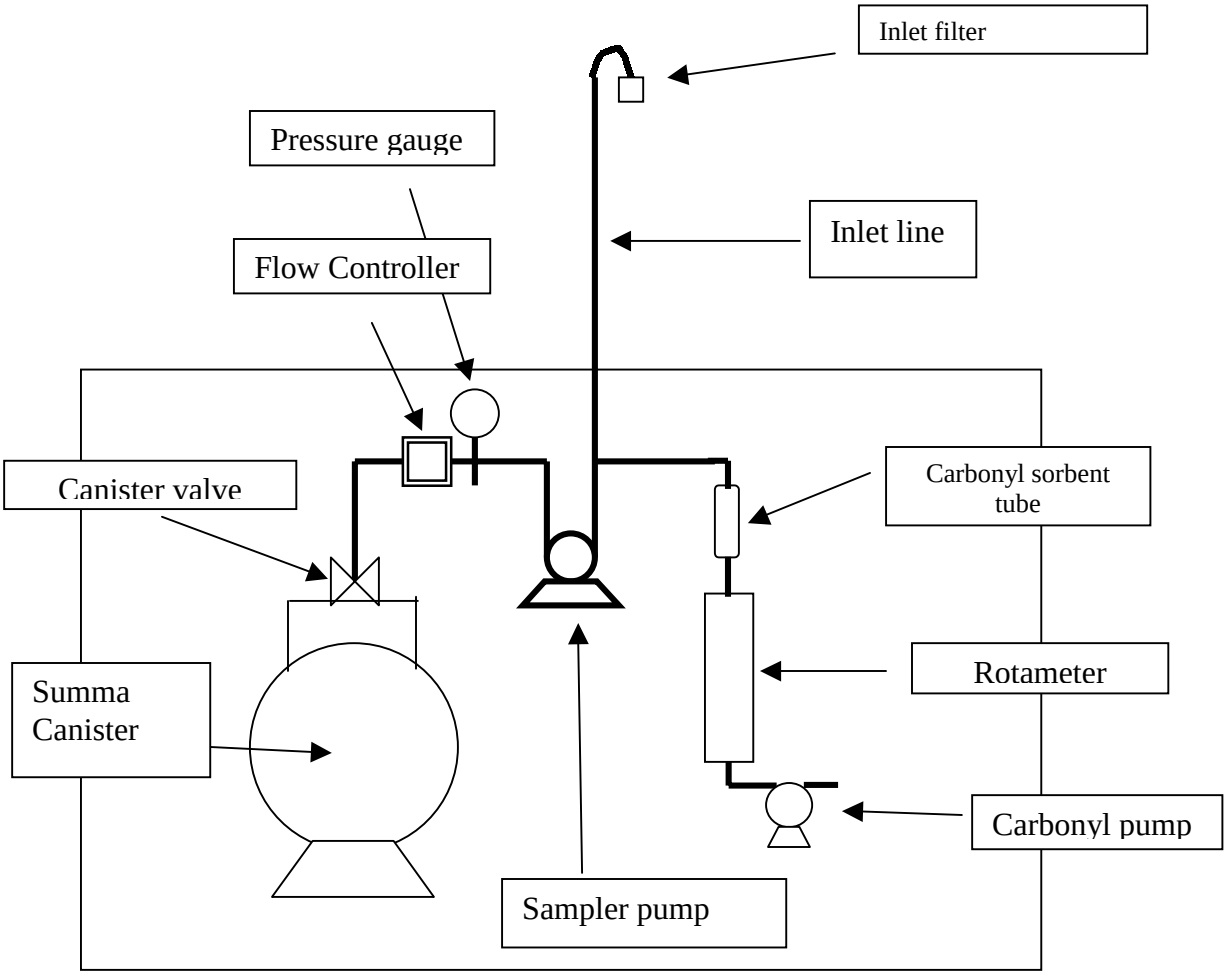

Figure 5.3. Sampler Schematic.

The on and off times were collected by two timers, one that actuated the main pump approximately two minutes prior opening the solenoid valve on the canister and the second one controlling the power for the carbonyl sampler. These samplers were serviced once per day: when the samples from the current day were removed and sample media for the next day loaded. The flow was checked periodically throughout the day. Although the flow controllers were designed to operate at a set flow rate, they frequently required adjustments due to temperature effects, clogging or other problems.

5.1.1.1 Sampler Certification

The samplers were certified by collecting ultra high purity (UHP) air from a tedlar bag through the sampler inlet into the sample canister over a short period of time (~30 minutes) and analyzing the results in a normal fashion. The initial certification showed that some residual contamination was present, however, after some flushing with clean air, the levels decreased to concentrations less than the detection limit of the analysis.

5.1.2 Analysis Method

All samples were analyzed using EPA Method TO-14 GC/MS full scan. This method used a cryotrapping system with a high resolution capillary column to analyze for volatile organic compounds using full scan GC/MS. The cryotrapping system could measure compounds down to 0.1 ppbV. Since there were two laboratories supplying the analysis, some details in the analysis differed.

At EAS, samples were analyzed on an HP 5890 Series II gas chromatograph and HP 5971 MSD quadrupole mass spectrometer detector. A 100 to 1000 mL gas sample was loaded from the air sampling canister or bag through a Nafion dryer onto the freezeout loop. The ATL system used an HP 5973 MSD system with a proprietary sample drier.

A gas phase internal standard mixture was injected with each sample prior to sample loading. The freezeout loop was constructed of 1/8" x 8” nickel tubing packed with glass beads and was immersed in liquid argon or oxygen while the sample was drawn through the loop using a vacuum pump connected to a mass flow controller adjusted to a flow of 50 ml/min.

After the sample was trapped, it was thermally desorbed at 150° C using an electric heater and was cryofocussed onto the beginning of a 0.32 mm ID deactivated fused silica capillary column. The cryofocussed loop was then warmed and the compounds were injected onto a 60 meter, DB-5, 0.25 mm ID fused silica capillary column in the GC. The GC was temperature programmed from -10° C to 220° C at a ramp rate of 13° C/min. As the column was heated, the compounds elute off the column and enter the mass spectrometer.

The MS was scanned from 45 to 300 AMU with a scan rate of 1 to 2 seconds for the Full Scan. The GC/MS was tuned and operated according to the specifications outlined in the EPA draft SOW for VOC compounds in ambient air, and EPA Method 8260 in the SW 846 Test Methods. Compounds were calibrated by the external standard procedure using NIST traceable air standards as described below. The relative percent difference (RPD) of a duplicate pair was less then 30% at 10 ppbV and the average MDL was approximately 0.1 ppbV for most compounds at a 500 ml load volume.

The standards used for the routine analytical tests were commercial NBS/NIST traceable gas standards normally ordered at a concentration of 2 to 10 ppmV. Commercial standards were available for the TO-14 GC/MS target list. Special in-house standards were prepared for special projects where commercial standards were not available or when commercial standards need to be diluted.

The GC/MS compounds were calibrated by using a dilution of the NBS/NIST traceable standard. The initial calibration curve consists of three to five calibration points. The continuing calibration consists of one point for the GC/MS Full Scan. The response factors for the initial calibration curve were to be within 30% RSD. If the response factor for the daily standard was more than 30% RPD from the average response factor of the initial calibration a new calibration curve was prepared.

Standards were prepared by using a gas dilution system on the gas chromatograph or by making static dilutions to atmospheric levels. The gas dilution system was constructed from an eight-port gas sampling valve with various size sample loops. The loops were filled with the standard and flushed with "zero air". The gas dilution system was used for the daily instrument calibration.

5.1.2.1 QC Criteria

Table 5.2. shows the quality control criteria used for laboratory analysis. Both EAS and ATL followed the same general QC criteria.

Table 5.2. QC Criteria

Parameter:	**Criteria:**	**Corrective Action:**
Blank	< 0.20 ppbv	Clean Instrument, Analyze another blank
Continuing Calibration	±30 % Initial Calibration	Re-Run Initial Calibration
Duplicate or MSD	< 30 %	Reanalyze duplicate or matrix spike.
Matrix Spike	70% to 130%	Reanalyze Matrix Spike.

Table 5.3 contains the target analyte list. After Air Toxics began analysis, acrolein was added to the VOC analysis list due to the instability of the hydrazone derivative on the acidic DNPH sample media used in Method TO-11. Air Toxics had expanded the TO-14 method sufficiently to provide for detection of low levels of acrolein using Summa canisters, so it was added to that list.

Table 5.3. EAS VOC Target List

Compound	MDL (ppbv)
Benzene	0.1
Toluene	0.1
Ethylbenzene	0.1
Xylenes	0.1
1,3-Butadiene	0.1
Methyl-tert-butyl ether	0.1-2.0
Ethylene dibromide	0.1-2.0
Ethylene dichloride	0.1-2.0

5.2 SEMI VOLATILE ORGANIC COMPOUNDS

5.2.1 Sampling Method

The semi-volatile organic compounds were collected using a standard TO-13 sampling apparatus. Figure 5.4 shows the high volume PUF sampler obtained from Andersen Instruments and Figure 5.5 shows the sampler head. This sampler produces flows at approximately 180 L/min. Calibration was performed using the valve restrictor and magnahelic pressure gauge, and flow was monitored using the Dickson circular paper gauge recorder.

Figure 5.4. High Volume PUF Sampler

Figure 5.5. PUF/XAD Sampler Head

The sample media were processed daily by removing that day's sample at the end of the day and placing the next day media into the sampler head. Extra sample heads allowed a simple switching of the heads and prevented the need to change media in the field and to potentially expose the media to contamination.

5.2.2 Initial Calibration and On-going Checks

Initial calibration was performed using the variable restrictor valve and a magnahelic gauge. On-going calibration checks were performed by checking the flow rate at the beginning and end of each work day. The values were recorded and the agreement to specifications was calculated. Assessment of these values is presented in Section 9.

5.2.3 Analysis Method

Samples collected from the TO-13 sampler were analyzed using the TO-13 analysis method. Samples for semi volatile organic compounds were collected on a combined PUF/XAD resin cartridge with a 102 mm quartz fiber pre filter. The sampler was the high volume type sampler described above. The PUF plug, XAD resin, and filter were combined and extracted in a soxhlet extractor using 400 ml of a 10:1 mixture of hexane/ethyl ether spiked with a surrogate standard mix. The extract was concentrated to 1.0 ml using a KD concentrator. After concentration internal standard was added to the mix.

The extracts were analyzed for target compounds by injecting a 1 to 2 ul sample in a split/splitless injector on an HP 5890 GC and HP 5970 MSD mass spectrometer in the full scan mode. The compounds were separated on a 30 meter, DB-5 column designed for the analysis of semi volatile organic compounds by EPA Method 8270. The column was temperature programmed from 35 C to 275 C at 10 C per minute. The signal was processed and integrated using the HP Chemstation and HP Enviroquant software. The mass spectrometer was calibrated using commercially available standards for the target semi-volatile organic compounds. The detection limit for the method was about 0.5 ug/sample.

Two types of semi-volatile analyses were performed—full scan GC/MS and SIM (selected ion monitoring) GC/MS. The SIM mode was used for a subset of the full scan list in order to obtain lower detection limits. Initially, the higher concentrations of naphthalene prevented a single SIM analysis run due to instrumental limitations.

After the laboratory change, Air Toxics was able to do a single SIM GC/MS analysis for the subset list. Table 5.5 shows the analyte list for the full-scan EAS analyses.

Table 5.5. Analyte List for the EAS SIM Analyses

Target Compound	MW (g/mol)

5.3 CARBONYL ANALYSES

5.3.1 Sampling Method

The carbonyl sampling method, based on EPA Compendium Method TO-11, was integrated with the VOC sampler, as described above, and shown in Figures 5.2 and 5.3. The flow of the sampler was set with the rotameter valve to 1.5 L/min. This rotameter was cross-checked against a primary reference laminar flow element during the external audit, and more frequently with the Minibuck bubble meter. With this nominal flow, the total volume collected over the 10 hour sampling period was 900 L. The sampling system worked with a moderate degree of stability, with adjustments made occasionally.

5.3.2 Analysis Method

Formaldehyde and carbonyl samples were collected onto DNPH (2,4-dinitrophenyl-hydrazine) cartridges purchased from Supelco or Waters. Some early batches of custom made DNPH cartridges from a regional laboratory were impeding flow due to too-tightly packed sorbent. A different vendor was chosed subsequently to supply the media.

The samples were collected at a target flow rate of 1.5 L/min. A formaldehyde blank was run on each batch of cartridges to characterize the background formaldehyde (carbonyls) on the cartridges. Formaldehyde is an effective indicator for contamination of the sample media.

The carbonyl-DNPH derivatives were eluted with 2 mL of carbonyl-free methanol. The derivatives were analyzed by HPLC with UV detection at 360 nm. The mobile phase was distilled water/acetonitrile: 40/60 v/v at 1.5 mL/min. A 100 ul sample of the methanol extract was injected onto two 25 cm Restek Pinnacle TO-11 columns that were connected in series. A Shimadzu Model LC-6A Pump and SPD-6AV UV detector were used for analysis. The output of the detector was integrated by computer on the HP Chemstation Software. The standards used were commercially available carbonyl-DNPH derivatives of the target compound list of 17 carbonyls shown in Table 5.8.

Table 5.8. EAS Carbonyl Analysis list

Target Compound	MW g/mol
Formaldehyde	30.0
Acetaldehyde	44.0
2-Propanone	58.1
Propanal	58.1
2-Butanone	72
Butryaldehyde	72
Benzaldehyde	106.1
Cyclohexanone	98.0
Pentanal	74.14
Hexanal	86.14
Heptanal	100.17
Octanal	112.17
Nonanal	124.17
Decanal	136.17
Undecanal	148.17
Dodecanal	160.17
Acrolein	56.06

The acrolein analysis proved to be problematic due to losses in the sorbent collection cartridge. As a result, all acrolein data provided by EAS were suspect, and after further examination were discarded. Further details on this issue are presented in Section 9, Data Assessment.

Benzaldehyde	106.11
Isopentanal	86.14
Pentanal	86.14
o-Tolualdehyde	120.15
m,p-Tolualdehyde	120.15

5.4 TOTAL REDUCED SULFUR

5.4.1 Sampling Method

The total reduced sulfur method was based on a modification of EPA Compendium Method To-14 and standard industry practice for sample collection using Tedlar bags. The sampling method for reduced sulfur species was a custom sampler consisting of a Pelican air-tight case that contained a 10 liter Tedlar bag. This case was in the bottom section of the metal sampler housing shown in Figure 5.2. Two types of filling techniques were used—the evacuated "lung" chamber approach, and the direct approach through a pump with elastomeric wetted surfaces to avoid losses from contact on metal. Flows were approximately 20 mL/minute. Both approaches proved equally difficult to operate consistently well. The pump frequently changed flow rates or stopped, probably due to the low flow rate, which is difficult to control in a simple system. Flows were checked once every two hours with an Alltech mass flow sensor.

In addition to sampling difficulties, it appeared over time that the stability of the sulfur compounds was being compromised due to heat in the sampler container. This was deduced by comparing the detected concentrations from the laboratory analysis with the Jerome analysis conducted on-site. The average Jerome result was approximately 4 ppbv, while the average laboratory result was non-detect at a detection limit of 1 ppbv. Due to this finding, routine sulfur sampling and analysis was ceased in March, 1999.

5.4.2 Analysis Method

EPA TO-14 GC/FPD is a GC method using a flame photometric detector. The method uses a cryotrapping/cryofocussing system with a high resolution capillary column to analyze for reduced sulfur compounds. The method can measure TRS compounds down to 1 ppbv.

Samples were analyzed on an HP 5890 Series II gas chromatograph with an HP flame photometric detector. A 100-200 ml gas sample was loaded from the air sampling canister or bag and then injected onto the freezoutloop/cryotrap. The concentrator was constructed of Teflon tubing, which is inert to the reactive sulfur compounds. The freeze out loop was constructed of 1/8" x 8" Teflon tubing packed with deactivated glass beads. The loop was immersed in liquid oxygen while the sample was drawn into it using a vacuum pump connected to a mass flow controller adjusted to a flow of 50 ml/min.

After the sample was trapped, it was thermally desorbed at 100° C and was cryofocussed onto the beginning of a 0.32 mm ID deactivated fused silica capillary column. The cryofocussed loop was then warmed and the compounds were injected onto a 30 meter, SBP-1, 4.0 micron fused silica capillary column in the GC. The GC was temperature programmed from 30° C to 250° C at a ramp rate of 10° C/min. As the column is heated, the compounds elute off the column and enter the detector. The detector converts all TRS compounds to an excited S2 that is measured by a photomultiplier tube resulting in a response that was logarithmic.

The log of the concentration and the log of the area counts were plotted to give a slope of about 0.5 for all sulfur species. Concentrations of individual compounds were calibrated by the

external standard procedure using NIST traceable gas standards as described below. The precision as measured by the relative percent difference (RPD) of a duplicate pair was less then 30% at 10 ppbV. The MDL of the method was 1.0 ppbV for all of the reduced sulfur compounds.

Table 5.10. Reduced Sulfur Compound List (TO14 GC/FPD)

Hydrogen Sulfide	34.08	1
Carbonyl Sulfide	60.07	1

2,5-Dimethylthiophene	112.19	1
Diethyl Disulfide	122.25	1

5.5 HYDROCARBON SPECIATION

5.5.1 Sampling Method

Hydrocarbons were sampled using the same sampler used for the VOC samples. The hydrocarbon speciation analysis was a separate analysis from the same canister sample.

5.5.2 Analysis Method

Hydrocarbon speciation was performed using the single column approach in which the C_2 to C_{11} hydrocarbons and stable oxygenates were analyzed using a single fused silica capillary column on an HP 5890 GC with dual FID detectors. Both detectors were used with two identical capillary columns to give two channels for the analysis of samples. A 100 to 200ml sample was loaded onto a 1/8" by 8" glass bead freeze out loop immersed in liquid oxygen. The components were desorbed onto a capillary cryofocussing loop with 90 C hot water. They were then desorbed from the cryofocus loop, and separated using a 100-meter, 0.25-micron fused silica PetroCol capillary column with a 0.5-micron phase coating. The column was programmed from -20 C to 225 C at 4 C/min. Total analysis time was about 65 minutes.

The compounds were detected on a FID set to operate at high sensitivity. The detector temperature was 275 C. The chromatographs were integrated using the HP Chemstation computer data station and stored on a hard disk drive for reintegration or further examination if required at a later date. Data from the integrator were entered into an Excel spreadsheet to generate the final report.

Hydrocarbon compounds were quantitatively calibrated using a NIST traceable propane/hexane/standard that may contain other hydrocarbons. On the FID, hydrocarbons have a uniform response based on the number of carbon atoms so the individual compounds are calibrated against the propane and hexane peak. The other hydrocarbons were used as a QC check to make sure the detector response was uniform. The C2 to C4 hydrocarbons were calibrated using propane and the C5 to C12 hydrocarbons were calibrated using hexane. The calibrated response was checked by quantitatively analyzing the 57 component EPA PAMS sample and other reference samples provided by agencies or other participant labs.

Qualitative calibration of the hydrocarbon retention times was done using pure materials for about 82 target hydrocarbons and spiking them into a 35 liter SUMMA canister that was pressurized to 120 psig. The retention times of individual hydrocarbons in this mix were calibrated against commercial gas standard blends for the light hydrocarbons and 6 liter SUMMA canisters spiked with 10 to 15 target compounds for the heavier hydrocarbons. The retention times were verified using a Kovats retention time index available for the PetroCol 100 m capillary column. The retention times were qualitatively checked against the 57 component EPA PAMS sample.

The hydrocarbon sampling was maintained during the preconstruction period and the initial stages start of the Cell 1 period, but was discontinued due to the changes discussed elsewhere in this report.

5.6 PM10

Federal Reference Method for Time Integrated PM 10 (40 CFR 50, Appendix B) was used for collection of PM10. Figure 5.6 shows a photograph of the sampler. Two PM10 samplers were maintained for the preconstruction period, after which only one was maintained at the Post Office location.

Figure 5.6. PM10 Sampler

5.7 SIZE-FRACTIONATED PARTICULATE MATTER

A number of samples were collected using an Anderson Model 2000 cascade impactor . The flow was calibrated using the valve restrictor and magnahelic pressure gauge and was monitored using a Dickson paper circular gauge recorder. The flow was set to approximately 40 CFM in order to collect an adequate amount of material on the filter during the 10 hour daytime test period. Technical contacts at Andersen led us to believe that the cut point curves were available for a 40 CFM flow rate. Unfortunately, it was later learned that this was not the case and that only a 20 CFM size cut curve for the cascade impactor was available. As a result, these data could not be adequately interpreted.

5.8 SAMPLING LOCATIONS

Sampling locations varied during the different phases of the project in accordance with on-going evaluations of meteorological conditions, operations, and the potential for community exposure. The original plan was to sample at five stationary locations, which was done during the preconstruction period and for a few weeks after the beginning of the excavation period itself.

At that point in time, a re-evaluation was made and changes to the data collection scheme were made, including the number of sampling points and the parameters to be analyzed. Detailed discussions of the changes to the program were made in Section 2.6, and specific summaries of the sampling locations will be presented in Section 8.

6.0 METEOROLOGICAL DATA COLLECTION

Meteorological data collection was critical for understanding the origin and dispersion of the measured parameters. Multiple sites were used to collect data since micrometeorological effects were considered to be a potential issue. More critical than this, was the need for immediate access to wind data along with the COC data collected. The data collected with these systems are discussed in conjunction with the other field data in Section 8.

The following Table 6.1 shows a summary of the various meteorological data collection instruments.

Table 6.1. Meteorological Data Collection

Meteorological Data	
WS, WD, Temp--Contractor Lot	Tracer Research System
WS, WD, Temp--Tank Farm	RM Young
WS, WD--Community Center	Xontech System
WS, WD, Temp, BP, RH--Van	Davis Instruments Weather Wizard III
WS, WD, Temp—Cart	Davis Instruments Weather Monitor II

6.1 FIXED METEOROLOGICAL MONITORS

6.1.1 Contractors Lot

The main site was a 10 meter tower installed in the contractors lot by Tracer Research Corp under contract to Jacobs Engineering. This tower was designed under the PSD guidelines, with instruments to record wind direction, wind speed, temperature at two heights, dew point, rain, and light intensity. Data were logged on an hourly basis, with hard copy strip chart backup and were downloaded via modem. The data logging equipment was maintained in the CMT trailer, with CMT staff changing paper periodically. Tracer staff also visited periodically to maintain the instruments and to do calibration checks. The data from these efforts were compiled by Tracer and sent directly to Jacobs Engineering.

A parallel ESC 3300 data logger was set up for CMP use. This logger was wired directly into the same collection points as the Tracer system.

6.1.2 Tank Farm

A limited monitoring station was set up at the water tower at the Unocal Tank Farm. This station collected data for wind speed, wind direction, and temperature on an hourly basis. These data were maintained for possible use and were not consulted nor compiled regularly. They were only

available as raw downloaded data logger text files. The wind speed and wind direction sensors were a RM Young Model 5103 combination sensor, with a Model 107 temperature sensor inside a passively aspirated shield.

Figure 6.1. Meteorological Sensor set at Tank Farm

6.1.3 Community Center

During the Baseline study and until the Tracer met tower could be installed, a portable meteorological station was set up at the Community Center. This system was set up and maintained by Xontech Environmental. This system collected only wind speed and direction. These data were used to compile the meteorological data from October, 1998 to April, 1999, presented below in conjunction with other field data for that time period.

6.2 MOBILE METEOROLOGICAL MONITORS

6.2.1 Monitoring Van

The monitoring van was equipped with portable meteorological sensors that could be adjusted easily for the various configurations the van was parked in. Equipment consisted of a Davis Instruments Weather Wizard III with three cup wind speed anemometer, a single van direction

sensor, and a combination temperature and relative humidity sensor. Inside temperature and barometric pressure were collected in the console that also held the data logging module. Each time the van was parked, the reference direction of the direction sensor was adjusted by twisting the stand on which it was attached. This was done using a compass and did not account for magnetic declination. The mast the sensors was mounted on was approximately 10 feet off the ground and 4 feet above the top of the van, as is shown in Figure 6.2.

Figure 6.2. Monitoring Van Meteorological Sensors

Data were averaged on a minute by minute basis and were downloaded daily into the database. This data set served as the time basis for the other data since it was collected the most frequently.

These data are not to be considered rigorous for several reasons. The sensors were only of a semi-professional quality and were not intended for strict scientific use. In addition, the siting process was approximate, as the direction was not corrected to true north. Finally, the height above the van was not sufficient to meet standard siting criteria. As was intended, these data were used to gain a general indication of the micrometeorological conditions that might affect dispersion of the detected chemicals of concern.

6.2.2 Cart

The mobile cart also carried meteorological sensors for wind speed, wind direction, and temperature. The temperature data were considered to be biased due to the sensor's location in the console, which was often closed inside the metal instrument case. The sensor mast was approximately 7 feet above the ground, as is shown in Figure 6.3. As with the van sensors, these data were used for general wind indications and were not considered to be rigorous

Figure 6.3. The Mobile Meteorological Cart

7.0 RESULTS AND DISCUSSION OF MONITORING DATA

This section contains the results based on monitoring data collected during all phases of the project, including the Baseline Study. The Background Data will be discussed in Section 8, Data Management. The time period for the project is broken down into four major phases for ease of reporting:

- Baseline Study
- Preconstruction
- Excavation
- Outlying Properties

As the main excavation period extended over several months, discussion of the excavation phase will be broken down into monthly summaries. The other phases will be treated as single time periods.

7.1 SUMMARY OF REMEDIATION PROJECT ACTIVITIES

The purpose of this section is to provide a description of the excavation activities that were monitored by the CMP. This description is based primarily on observations made by CMT staff during daily monitoring of the excavation. Two types of emissions were expected: vehicular exhaust from haul trucks, excavators, and other earth-moving equipment, and emissions from the petroleum-contaminated soil and oil-contaminated groundwater in excavation cells. The CMP was designed to collect data for both of these potential sources.

Descriptions of the site activities will be presented in a narrative, followed by a table that notes key event dates and descriptions. Table 7.1 contains a summary of major project phases.

Table 7.1. Summary of Major Phases of the Project

Dates	Excavation Activity	CMT Activity	Purpose	Comments
Oct. 21-Oct. 31, 1998	Site Prep--utility relocation, Tank Farm Preparation	Baseline Study	Determine pre-excavation baseline pollutant levels	Results included in background data set for use in risk assessment.
Nov. 1 to Nov. 14, 1998	Site Prep--utility relocation, Tank Farm Preparation	Preparation/Mobilization/ Staff Training	Prepare for main excavation work with installation of equipment at main sampling sites. Also, to prepare real-time measurement systems for implementation.	No data collection until November 11.
Nov. 11 , 1998 to Mar. 1999	Site Prep--Sheet pile installation, site prep.	Preconstruction Monitoring	Provide initial data for public protection during startup activities.	Major re-working of CMP Work Plan conducted during this time period. Development of data base.
Mar. 1, 1999 to Dec. 11, 1999	Excavation in cells.	Monitoring during excavation activities.	Routine CMP monitoring	Various special tests also conducted in this time period.
Dec. 11, 1999 to Dec. 27, 1999	Pit closed, backfill and sheet pile removal.	Limited monitoring--sheet pile removal only.	Sheetpile removal and backfill were only activities--no open pit remained.	
Jan. 2 to April 6, 2000	Outlying Properties excavation	Limited monitoring during outlying plume excavation.	Continue monitoring during limited excavations.	Limited informal monitoring included only PEC, dust, H2S, PAH. No VOCs. Data not included in data base.

Presentation of the major site activities will be made, followed by a more detailed accounting of results from sample collection, both real-time and integrated, on a month by month basis during the main excavation period.

7.1.1 General Site Preparation

General site preparation began in October 1998, and consisted mainly of utility changes, such as the re-routing or closing of utility services in areas that would be disrupted. During this phase, truck traffic was only slightly different from a non-construction time period. Only two or three

extra construction-oriented trucks were in use, in addition to one back hoe that was used sporadically for short periods to open up areas for trench work.

Site preparation activities were deemed to not contribute substantially to normal emissions in town or to compromise baseline monitoring. The baseline monitoring program was conducted from October 21, 1998 to October 30, 1998. Beginning in early November, preconstruction monitoring commenced so that any changes to ambient air quality from the increasingly scaled up activities could be monitored.

Initial site demolition commenced on December 2, 1998 at the west end of town. This activity was heavily monitored both visually and with instrumentation. The data did not record substantial impacts to the atmosphere from dust-producing activities. Following this initial demolition, smaller demolitions occurred at various times, as needed. The Cell 3 demolition, for example, did not occur until much later.

Figures 7.1 and 7.2 show photographs of representative activities associated with the preconstruction phase. Other than some backhoe work, major equipment use was minimal.

Figure 7.1. Pipeline Cutting

Figure 7.2. Utility Relocation

7.1.2 Main Excavation

The excavation was organized into cells according to the location and type of contamination to be removed. Figure 7.3 shows a map of the town and the cell organization.

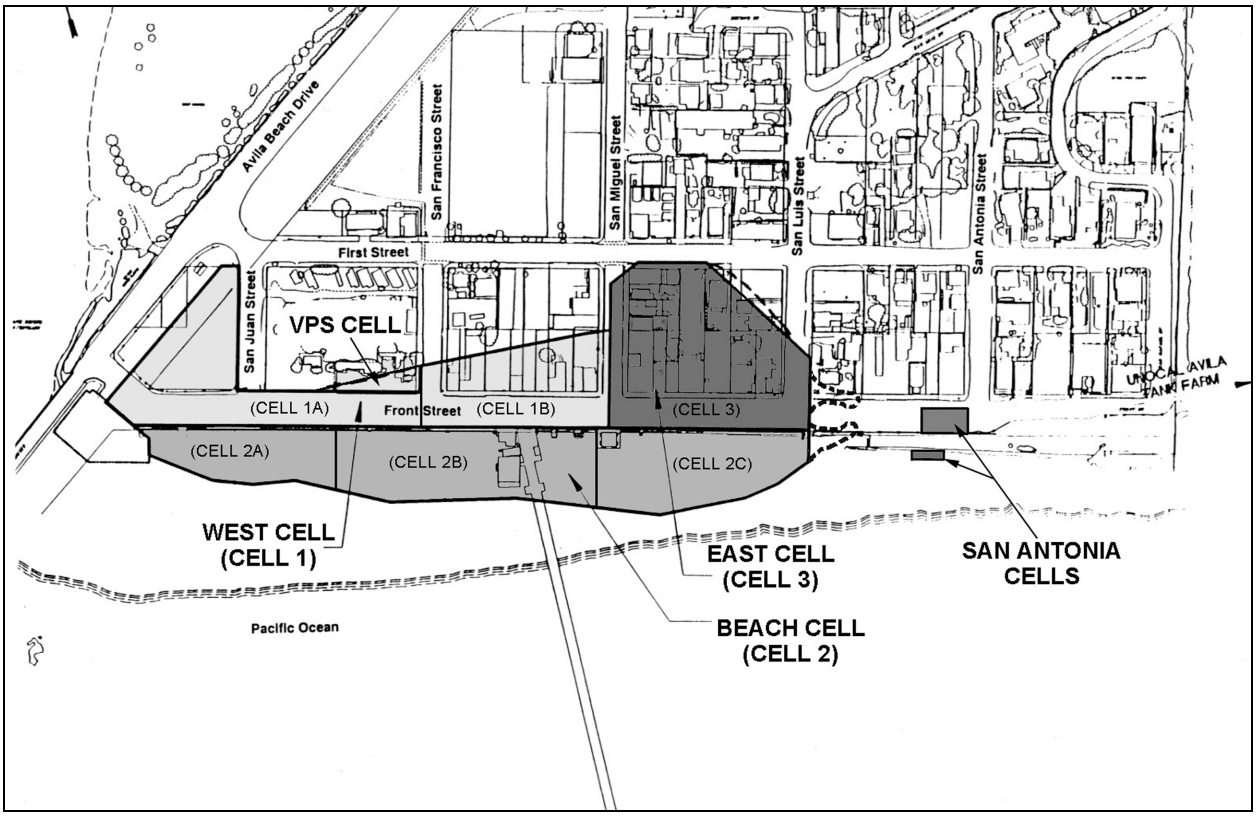

Figure 7.3. Map of Cell Organization of Excavation.

The above map does not include the Lyons-Togazzini property along Avila Beach Drive, between 1st St. and San Miguel Street, or the small Bachino property on Avila Beach Drive near the end of Laurel Street. These cells were small and did not require sheet piling. Figure 7.29 shows a more detailed map of the town, including sampling sites and the outlying properties.

7.1.3 Types of Emission Producing Activities

There were a number of emission-producing activities in which the equipment, the duration, or the location, made the activity noteworthy. The sections below present photographs of various sources of emissions that were included in as monitoring targets during the project.

7.1.3.1 Sheet-pile Driving

Sheet piling installation operations used a large crane with an external power-assist unit to drive the sheet pile into the ground. A standard pile driver was used on a short-term basis to install the pier piles. All of these pieces of equipment produced periodic spurts of uncontrolled diesel exhaust, while the pile driver produced a continuous stream of emissions. Figures 7.4 and 7.5

show examples of these puffs of exhaust fumes. While the time resolution of the aethalometer was not sufficient to capture individual pieces of equipment, the overall impact from these operations were captured in the 15 minute averages. The crane in Figure 7.6 shows a large plume, attributable to the continuous nature of the pile installation compared to the sheet pile.

Figure 7.4 Puff of Diesel Exhaust

Figure 7.5. Sheet Pile Crane in Operation

Figure 7.6. Pile Crane in Operation

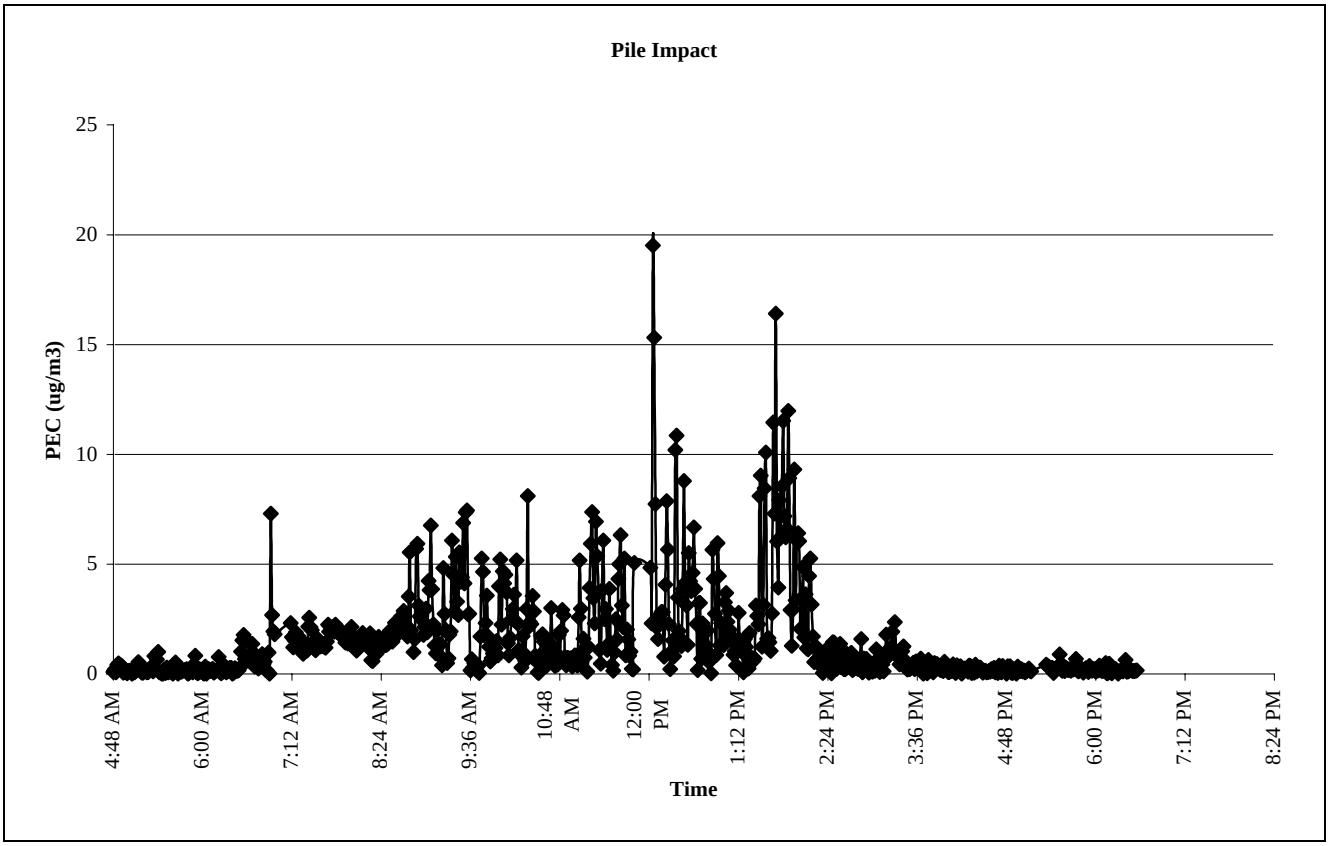

Figure 7.7. Pile Crane Emissions

The pile crane data show the meteorological dependence of the emissions and the short-term duration of the plumes. This set of data was collected on a 1-minute basis in order to detect shorter-term phenomena. As can be seen in Figure 7.7, above, there were several high data points; however, these episodes lasted for only one or two minutes. Sustained high concentrations of this magnitude during normal operations did not occur. When the time dependence of the wind direction shift from southerly to northerly was examined, it is evident that shifts in wind direction corresponds well with sudden decreases in emission concentrations. The wind began to shift at around 2 PM and completed a 180 degree shift by 3 PM. This shift was away from populated areas. The detected concentrations reflect this change, decreasing from average 15 minute values in the 5-10 ug/m3 range to less than 1 ug/m3.

Figure 7.8 shows a wind rose for the same day. The wind rose indicates that the monitoring van, located downwind (north of the crane), would have directly captured the emissions from the crane. In addition to the pile crane, a sheet pile crane was also in operation at the time. Therefore, the measured values reflect the combined effects of two cranes.

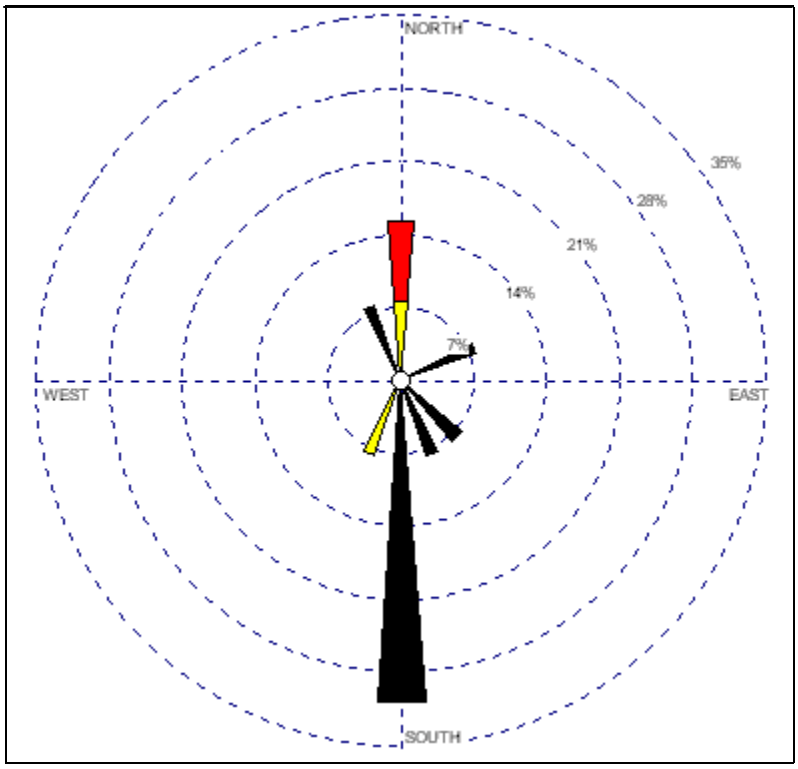

Figure 7.8. Wind Directions for Dec. 17, 1999

Figure 7.9 shows the potential for dust generation from the sheet piling operation.

Figure 7.9. Dust and Odor from Sheet Pile Installation

7.1.3.2 Excavation and Pit Equipment

A major source of emissions was the equipment used in the excavation pit. This equipment included excavators, backhoes, front loaders, haul trucks, plus miscellaneous other equipment such as cranes and sheet pile drivers, etc. The pit equipment worked consistently throughout the project, serving as the primary means to move the soil up and out of the pit area. Haul trucks were another consistent presence. Figures 7.10 and 7.11 show examples of pit equipment in use.

Figure 7.10. Photograph of Excavators in Action.

Figure 7.11. Pit Equipment in Use

A major emitter that was used for only a few days was the Maxigrinder, a unit used to grind large amounts of demolition debris. Figure 7.12 shows a photo of the Maxigrinder in use. Figure 7.13 shows the PAH emissions that were detected directly downwind of the unit, which were significantly higher than any other piece of equipment. It should be noted that these data are not representative of common exposure scenarios since the inlet of the monitoring van was directly downwind of the exhaust plume. Since there were no specific trigger levels associated with particulate-bound PAH, these data were used only as indicators of potential trigger level exceedances. In this case, the data were monitored closely. The standard trigger levels were not exceeded due to the short-term duration of the peaks.

Figure 7.12. Maxigrinder used in grinding construction debris

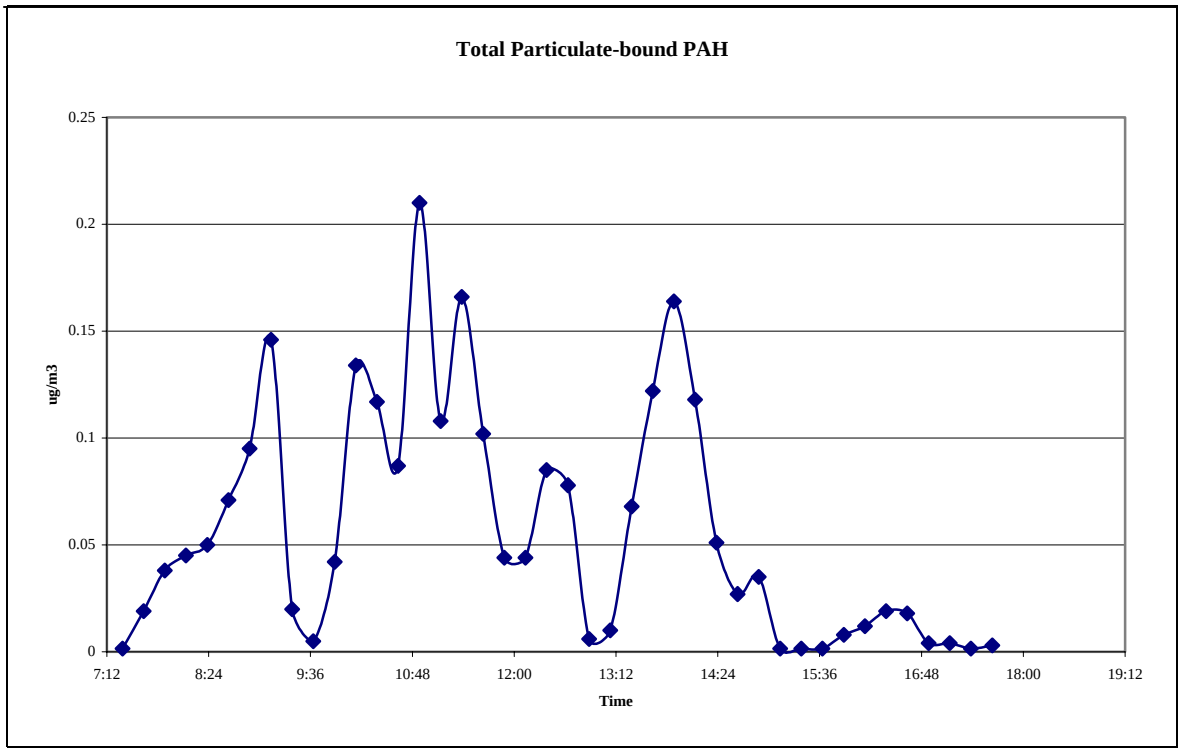

Figure 7.13. Downwind Impact of Maxigrinder

7.1.3.3 Trucks

A large number of trucks were used for various activities. There were three main categories of trucks: (1) short-haul trucks used to haul the affected soil from the pit to the stockpile area; (2) clean fill trucks used to bring clean sand in for backfilling completed excavation areas; and (3) long-haul disposal trucks used to haul the affected soil to the soil disposal site. The short haul trucks were the primary source of emissions in the town area, followed by the backfill trucks. The long-haul trucks operated from the stockpile area at the Tank Farm and out Cave Landing Road, bypassing the town. Figure 7.14 shows a photo of typical types of haul trucks. The haul trucks are behind the water truck in the foreground.

Figure 7.14. Haul and Watering Trucks

Figure 7.15 contains a summary of truck loads on a daily basis. The number of truck loads does not correspond directly with fuel usage. Peak fuel usage corresponds with pit equipment in use in September when both Cell 2 and Cell 3 were in operation.

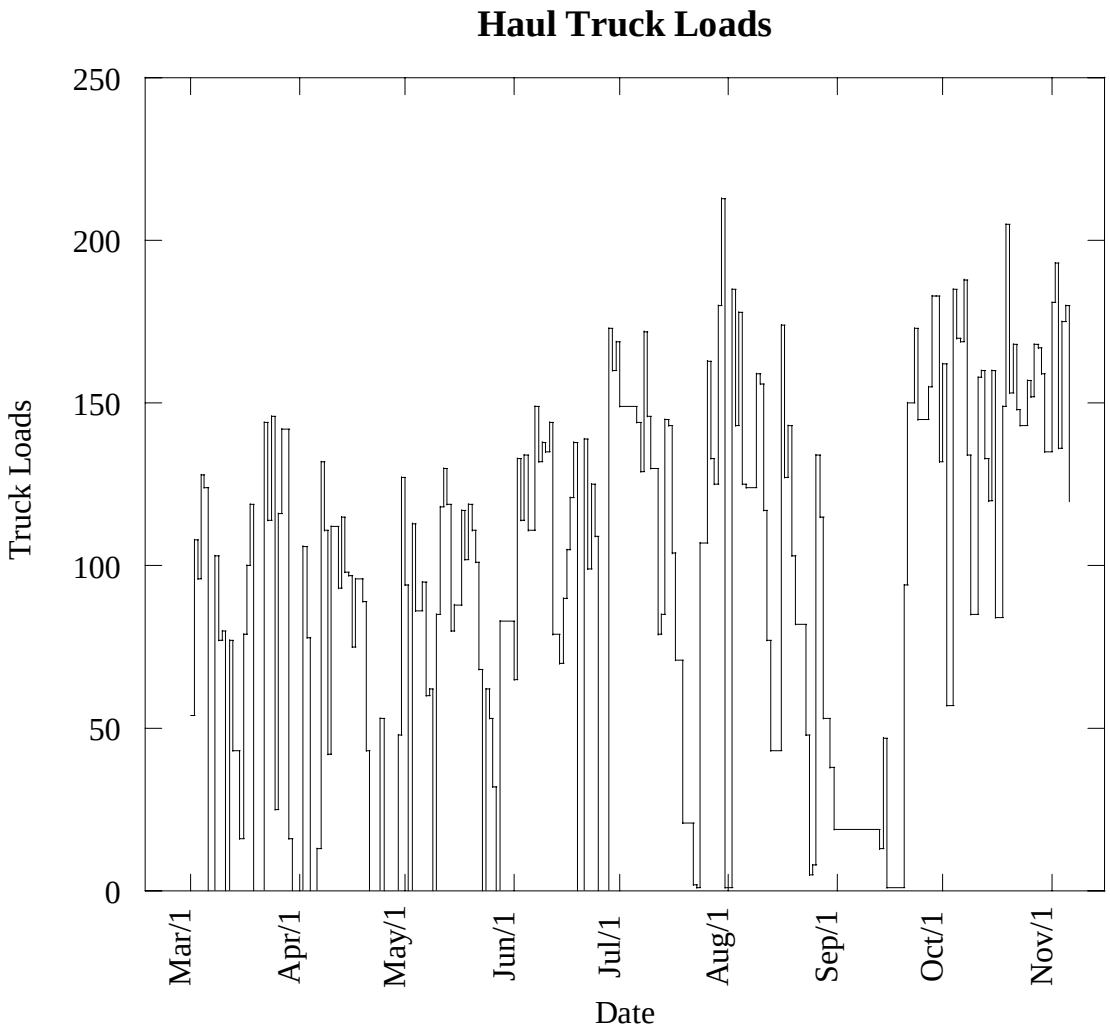

Figure 7.15. Haul Truck Loads

7.1.3.4 Dust and Odor Emissions

Dust and odor emissions were a concern throughout the duration of the project. One of the key functions of the CMT was to monitor both parameters. Key incidents for both these parameters are discussed below in relation to each month's data summary.

Dust was generated by a number of activities. For instance, when the wet soil on truck tires was tracked onto roads and subsequently dried, substantial dust accumulated. The dried mud appeared to be more of a problem than wind-blown dust from the ground, since the action of the vehicles on the road caused a grinding motion, making the particles more fine and susceptible to

entrainment in winds. The problem was dealt with by frequent waterings by a water truck and by using street cleaners to sweep up the excess dried soil. Figure 7.16 shows a street cleaner in action. The amount of dirt on the ground is evident from the tire tracks.

Dust was also periodically generated by demolition and soil moving activity. Figure 7.17 shows dust being generated by demolition activities. While these activities produced high levels of dust in the immediate area, the dust settled quickly. Typical average 15 minute values were less than the trigger level.

Figure 7.16. Street Cleaner in Operation.

Figure 7.17. Dust Generation from Demolition

Consistent efforts were made in the pit excavation area to keep dust to a minimum. However, due to the number of vehicles and activities, this was a difficult task. Figure 7.18 shows, as an example, the breadth of simultaneous activities in Cell 3, many of which had the potential to produce dust.

Figure 7.18. Multiple Cell Activities

Odors were another continuous problem. Specific odor complaints are addressed below in relation to each month's data. In general, odor complaints were related to a number of specific activities. First, at times when wind speeds were low or wind direction was out of the southwest, there was a higher incidence of diesel-fume complaints. Second, a specific odor problem was associated with sheet piling operations in one particular area along Front and San Luis Street. Data collected during the investigation of this latter problem are presented in Section 9.

The main type of odor was of petroleum, associated with exposed affected material. While not particularly intense, this general odor was noticeable when coming into town after being away for some time. Figure 7.19 shows a photograph of a particularly odorous pile of affected material, with intense odors probably due to the influence of marine organisms and the degradation of material into odorous organic compounds. Data on the composition of the headspace vapors are presented in Section 9.

Figure 7.19. Odorous Material in Cell 2C

Figure 7.20 shows a photograph of petroleum material that is oozing out from exposed affected soil. This type of petroleum exposure contributed to the constant ambient petroleum odor.

Figure 7.20. Oil Residue from Soil

7.1.3.4.1 Meteorological dependence

Emissions from on-site equipment were subject to the general meteorological conditions of the site. The wind-roses for each time period, presented below, show how the site activities could impact downwind receptors. As an example of the specific micro-meteorological dependence, Figure 7.21 shows the wind rose for June 22, 1999, the only day for which there was an exceedance of a volatile organic chemical of concern—1,3-butadiene.

On this day, the monitoring van was parked near the corner of San Francisco and 1st Streets, near to where clean fill trucks were converting their trailers from a two-segment haul configuration to a one-trailer configuration. Concentrations of 1,3-butadiene exceeded the Tier 2 trigger level, necessitating changes in site operations. Figure 7.22 shows the time-resolved data from that period. Apparently, plumes from the truck traffic impacted the monitoring inlet directly, causing the high concentrations.

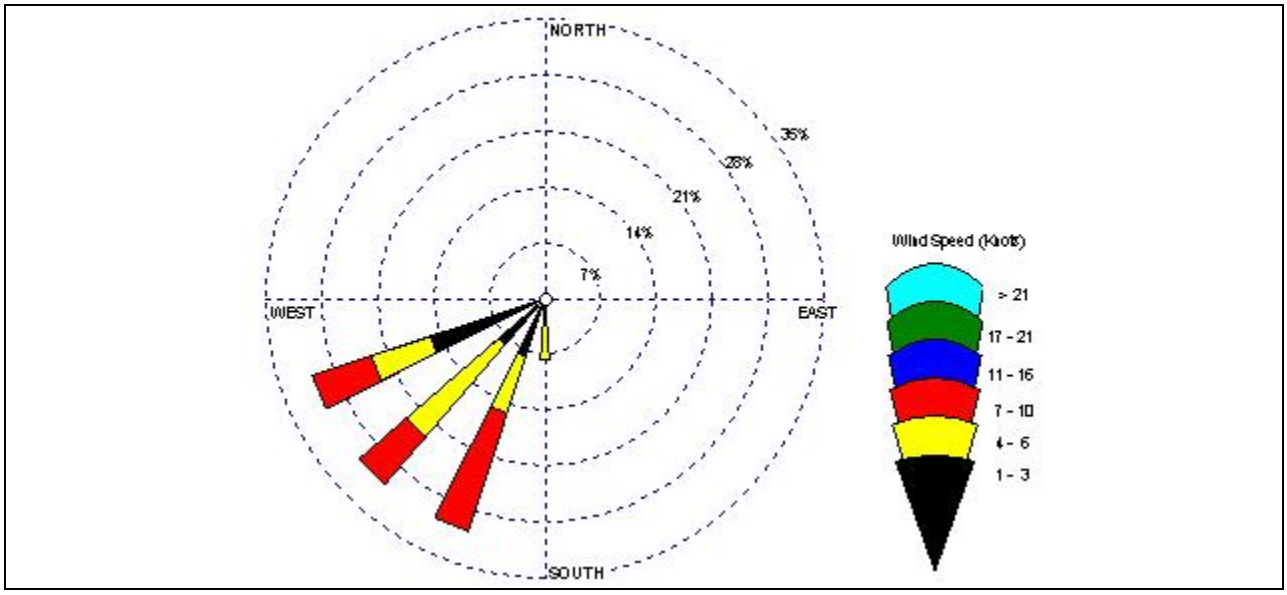

Figure 7.21. Wind Rose for June 22, 1999 Showing Directional Dependence of Emissions

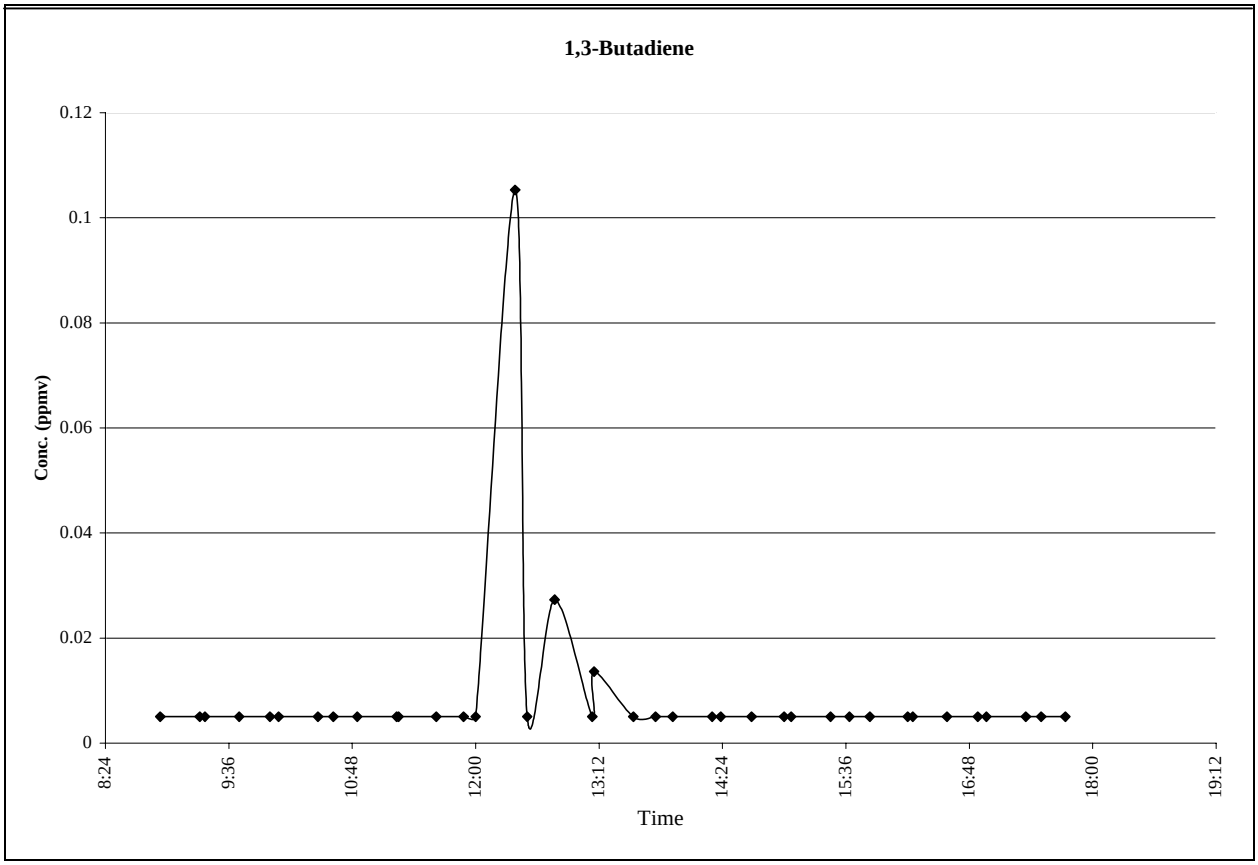

Figure 7.22. 1,3-Butadiene Data for June 22, 1999 Exceedance

7.1.3.4.2 Control measures

Various control measures were used throughout the project to reduce the impact of emissions from project activities. These measures had been planned previously and were part of the operating permit for the project.

As mentioned above, dust was a major problem due to dried soil on the streets. Besides a street cleaner, washing of the street was performed periodically, as shown in Figure 7.23. In add ition, truck tires were brushed off prior to leaving the active area. While these efforts made a substantial impact on the amount of dust generated, there were still a few instances of exceedances. Some of these instances were due to circumstances beyond reasonable control.

Figure 7.23. Street Washing to Control Dust

Another measure to control odor or chemical emissions from the affected soil, included the covering of stockpiled material. While most of the affected soil was immediately hauled to the Tank Farm stockpile, any remaining material in the pit was either covered with clean fill or or a tarp. Figure 7.24 shows a small in-pit stockpile covered with a tarp.

Figure 7.24. Tarp Covering In-pit Stockpile

The Tank Farm stockpile area was designed to store affected soil before it was transported to the final storage area. Figure 7.25 shows a typical pile under the canopy prior to being loaded onto long-haul trucks.

Figure 7.25. Tank Farm Stockpile Area

The Tank Farm piles were covered with tarps or foam on a daily basis. Figure 7.26 shows the application of odor suppression foam to the pile.

Figure 7.26. Application of Odor Suppression Foam to Stockpile

Data on the effectiveness of the suppressant material are presented in Section 9.

Several pieces of pit equipment had soot and chemical traps installed that substantially reduced emissions. Figure 7.27 shows an emission stack with an oxidation catalyst installed.

Figure 7.27. Close up of control equipment on emission stack

The following filters were installed on various pieces of equipment:

- Four (4) DPX catalyzed soot filters (Engelhard): >90% PM reduction, >70% hydrocarbon reduction, >70% CO reduction;
- Fourteen (14) DVC oxidation catalysts (Engelhard): 20% PM reduction (soluble organic fraction only), >70% hydrocarbon reduction, >70% CO reduction.

The reductions are approximate, with actual performance depending on engine type, duty cycle, fuel and lubrication characteristics, etc. These specifications are based on the manufacturers' product information. No independent verification of these specifications were made.

7.1.3.5 Emissions Factor Calculations

Table 7.2 contains the results of using standard emission factors based on fuel usage to predict emission amounts for various constituents. These data were obtained from the Jacobs Engineering report presented to APCD on a monthly basis. This report was based on AP-42 emission factors and fuel usage as monitored by equipment operators. Figure 7.28 shows a plot of the fuel usage over the main project time line, with peak usage occurring in September 1999, when Cells 2 and 3 were both active.

7.2 SAMPLING AND MONITORING LOCATIONS

Sampling was conducted with integrated sample collection equipment, while monitoring was conducted with continuous or semicontinuous monitoring or analysis equipment. The sampling locations were fixed, while the monitoring locations varied according to current activities.

Sampling locations for integrated laboratory analysis samples for the CMP are indicated in Figure 7.29. The integrated sampling locations are identified by name and number. Only the sampling locations used are noted; a larger number was initially designated but some were never implemented due to various circumstances. Table 7.3 contains a list of all the integrated sampling locations used. Mobile monitoring locations were noted in a grid system and integrated with each set of data, as noted below.

The primary fixed sampling point was the rooftop of the Fire Station, location 5. This location was key to assessing the exposure of the main town population as it was located in the main residential area. In addition, it was downwind for much of the excavation period and was far back enough from specific activities to capture a range of potential emissions from the various sources on site.

Other locations were closer to the main project activities, such as Jacobs Office (location 1) and the corner of 1st and San Francisco (location 13). These locations were immediately impacted by site activities, particularly location 13, which captured direct emissions from truck traffic coming

in and out of the entrance to Cell 2 and from the old trailer park area where clean fill trucks passed through and adjusted their rigs.

Location 17 was added to the list and was a good sampling point due to its location downwind and its proximity to traffic along 1st and San Miguel Streets, which became heavier as cell 3 progressed.

The background location was used only sporadically at the beginning of the program until it was determined that an adequate number of background samples had been collected.

For mobile monitoring, the town was divided into grids approximately 100 feet square, following the same grid that Jacobs set forth for the excavation pit sampling. A numbering system for the field data allowed the field technicians to record the location of data collection and any notable observational comments, in addition to a hard copy of the output from the instruments. The grid points were associated with each point of data collected. These data were recorded manually along with the downloaded data files from the instruments and were input into the database. As a result, a fully searchable index of locations was available if necessary.

Due to somewhat predictable wind conditions and site activities, some locations were more commonly chosen for monitoring. A location along 1st near San Francisco was useful for the Cell 1 and Cell 2A and 2B work, particularly since it was along the main road used by the fill trucks. A location directly on San Francisco Street was also useful for the same reason, but was better for activities closer to the center of town.

Another frequent monitoring point was along 1st Street between San Miguel and San Juan. This location was favored due to its proximity to receptors along 1st Street and the potential coverage for a wide range of activities in Cells 2C and 3. Other frequent locations were on San Miguel near 1st Street, close to the Fire Station, and along San Miguel close to Front Street prior to its closing. Monitoring locations were typically moved once per day.

All samples, both real-time and integrated, were collected during daytime hours since the purpose of the program was to assess the impact of daytime site activities.

Table 7.3. Integrated Field Sampling Locations

Integrated Sampling Locations			
Site ID	**Designation**	**Description**	**Comments**
1	Jacob's Office	Adjacent to 479 First St.	Standard station

7.3 SITE METEOROLOGY

The general meteorology was typical of a seaside area—onshore flow during the day with offshore flow at night, and transitions between the two at various hours of the morning or evening. Daytime meteorology was only of particular interest as it interacted directly with project activities.

As discussed previously, wind speed and direction data were collected by several systems during different phase of the project. A detailed listing of the meteorology will not be presented here. The wind data for the Baseline and preconstruction period were not amenable to the database wind rose calculation, so histogram charts were used to represent the data trends. Figure 7.30 contains composite histogram plots of monthly wind speed and wind direction for the Baseline and preconstruction periods.

These data show that the dominant wind direction was out of the southern sectors, as is seen in the classic wind rose representations. As far as can be determined from long-term workers in the area, a review of informal hand notation data from the Tank Farm, and APCD observations, the wind data collected in 1998-2000 was representative of typical long-term conditions, although there is no other source of data available for comparison.

All wind speed is expressed in miles per hour, and direction is degree, and all direction data shows the direction the wind is coming from. Figure 7.30 shows frequency plots for wind speed and wind direction for the Preconstruction period. Data for this period was collected at the Tank Farm. Figure 7.31 contains wind roses for the main excavation and outlying property phases, from March, 1999 to April, 2000. These data were collected from the 10 meter tower in the contractors parking lot. These data show the typical trends as discussed above. Note that the scales for all these wind roses are identical. Figure 7.32 shows a summary project wind rose superimposed on a map of Avila Beach. The Figure indicates the tendency for emissions to disperse towards the town. This general pattern can be visualized for the various phases and activities, such as truck traffic up Front St.

Daily meteorological data are available from the project database, including micrometeorological data on a minute by minute basis at various monitoring sites. These data were used for the real-time examination of detected target parameters and to interpret downwind impacts. No long-term trends were expected from this set of data; however, the parking lot tower data with its more rigorous collection methods were intended for interpreting long-term trends, as discussed here.

7.4 BASELINE TEST PERIOD RESULTS

The Baseline Study was designed to collect data on Chemicals of Concern concentrations over a period during which little to no remediation activity was occurring. The Baseline Study was conducted from October 20 through October 30, 1998. The work plan for this program is included in Appendix B. The data collected in this effort were used in conjunction with previous data sets to provide a picture of the pre-excavation levels of the COCs, and were used along with other background information as input into risk assessment background determination. These data were not used for calculation of community exposure from the remediation, but for a determination of background in the town prior to major project activities.

7.5 TYPES OF EMISSION PRODUCING ACTIVITIES

Over the Baseline Study time period there was some sporadic site activity, mainly related to utility relocation, as discussed previously. These activities were sporadic at most and did not consistently produce emissions. It was concluded that this time period was representative of non-project background conditions.

Only daytime, time integrated samples were collected during this time period in order to capture the normal daytime emission profile. Only sporadic real-time data were collected but they were not tabulated nor put into the database. Table 7.4 shows the locations where samples were collected, as shown on the map in Figure 7.29.

Since the sampling was not designed to be continuous, collection was sporadic and the data are best interpreted as averages. Table 7.5 shows the average of the baseline data for VOCs, including both carbonyl compounds and conventional volatile species. These data are reported

in ppbv, following convention for volatile species. This table includes the data for acrolein by Method TO-11, which was seen to be incorrect and which was replaced by Method TO-14 after April, 1999. Therefore, the data in this table for acrolein should be viewed with caution.

Table 7.6 shows the average for the PAH species, which include both the GC/MS full scan and SIM analyses. These data are reported in ug/m3, following convention for semivolatile compounds. Where SIM data are missing, the full scan are used. Otherwise, the SIM data are reported due to the lower detectability and the probability of a real detection due to the short sampling time.

Both the VOC and PAH data are plotted in Figures 7.35 and 7.36 on arbitrary concentration scales. Note that the full scale does not include the highest data point so that the lower levels could be more easily seen. These highest points were most likely due to contamination or a one-time anomaly, so putting in the full scale value would mis-represent the true magnitude of the concentrations detected.

Table 7.5. Baseline Study Average Data for Detected Volatile Organic Compounds

Compound	Ave. (ppbv)	Max (ppbv)

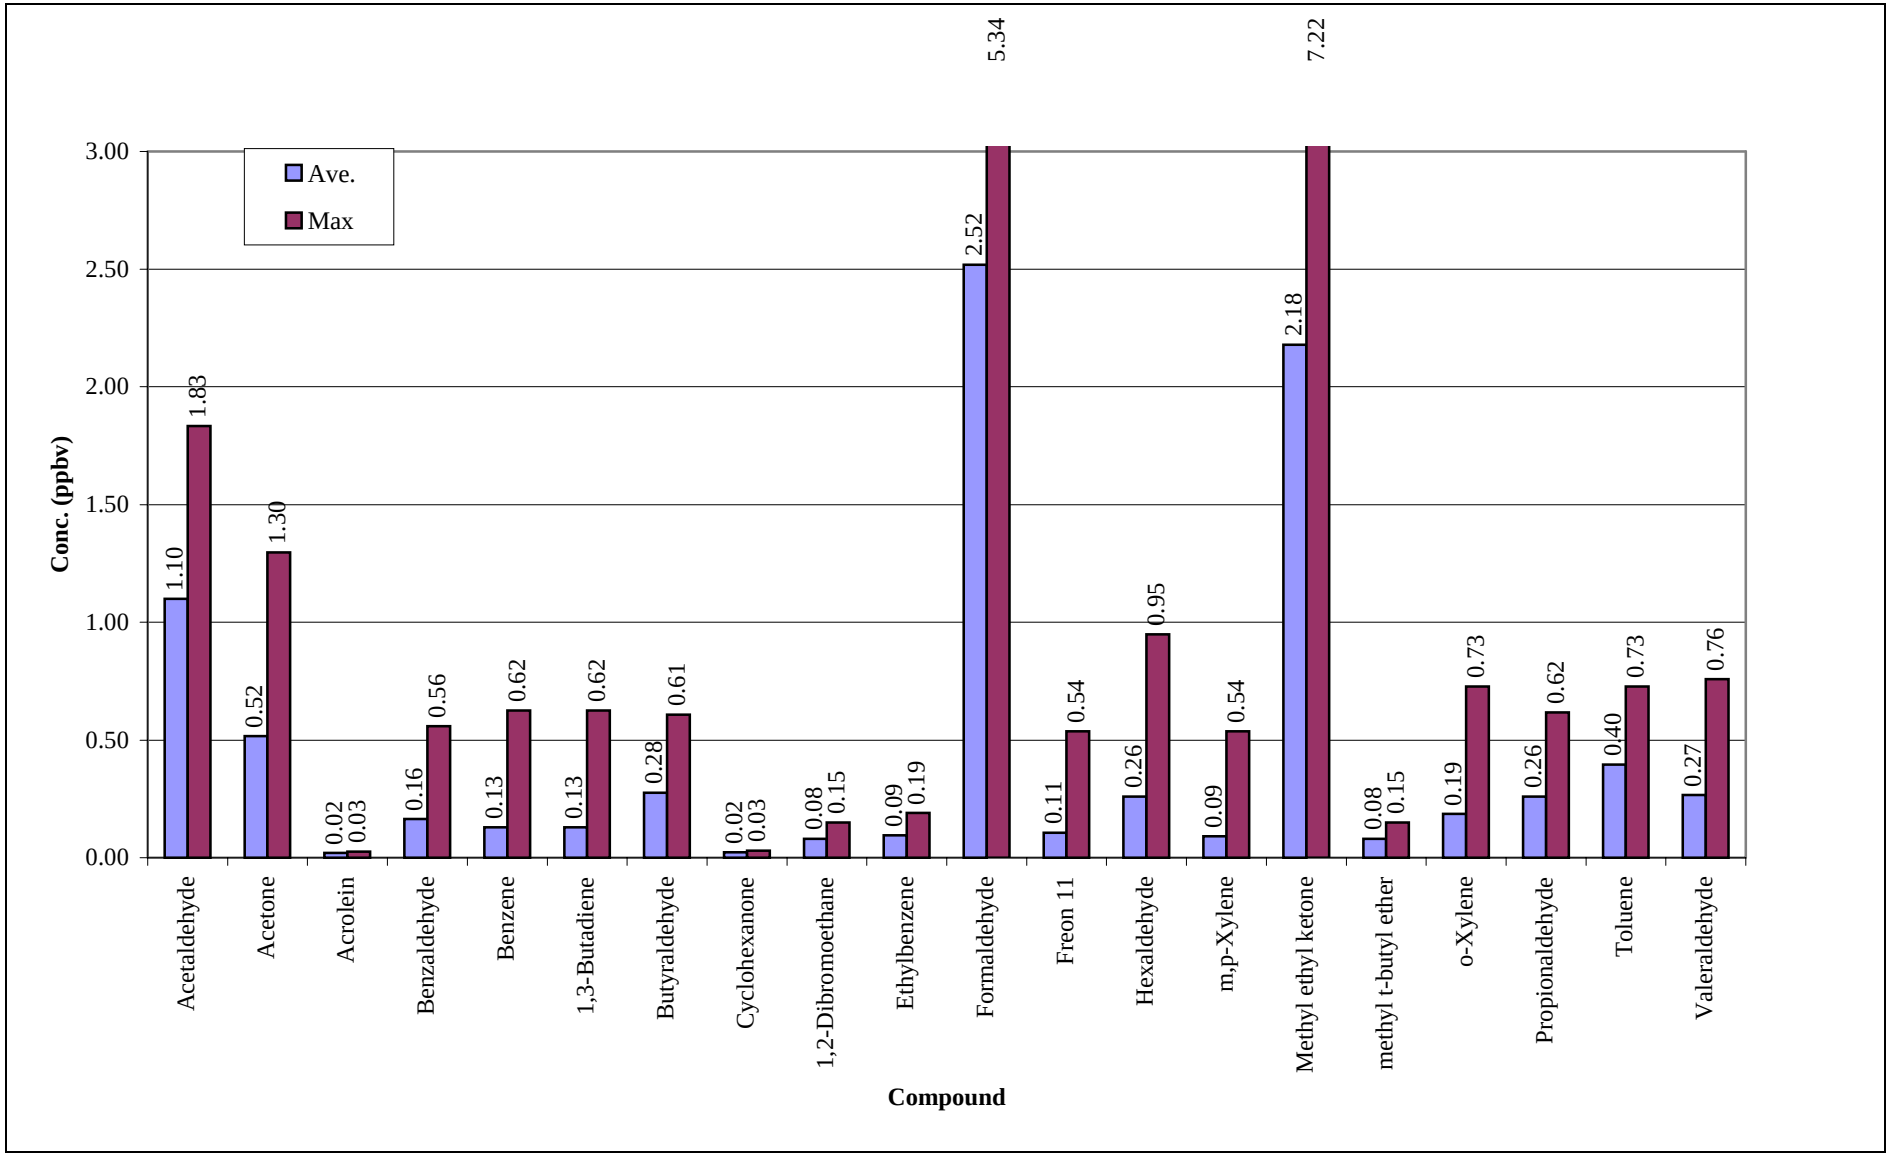

Figure 7.33. Baseline Study volatile organic compounds average concentrations

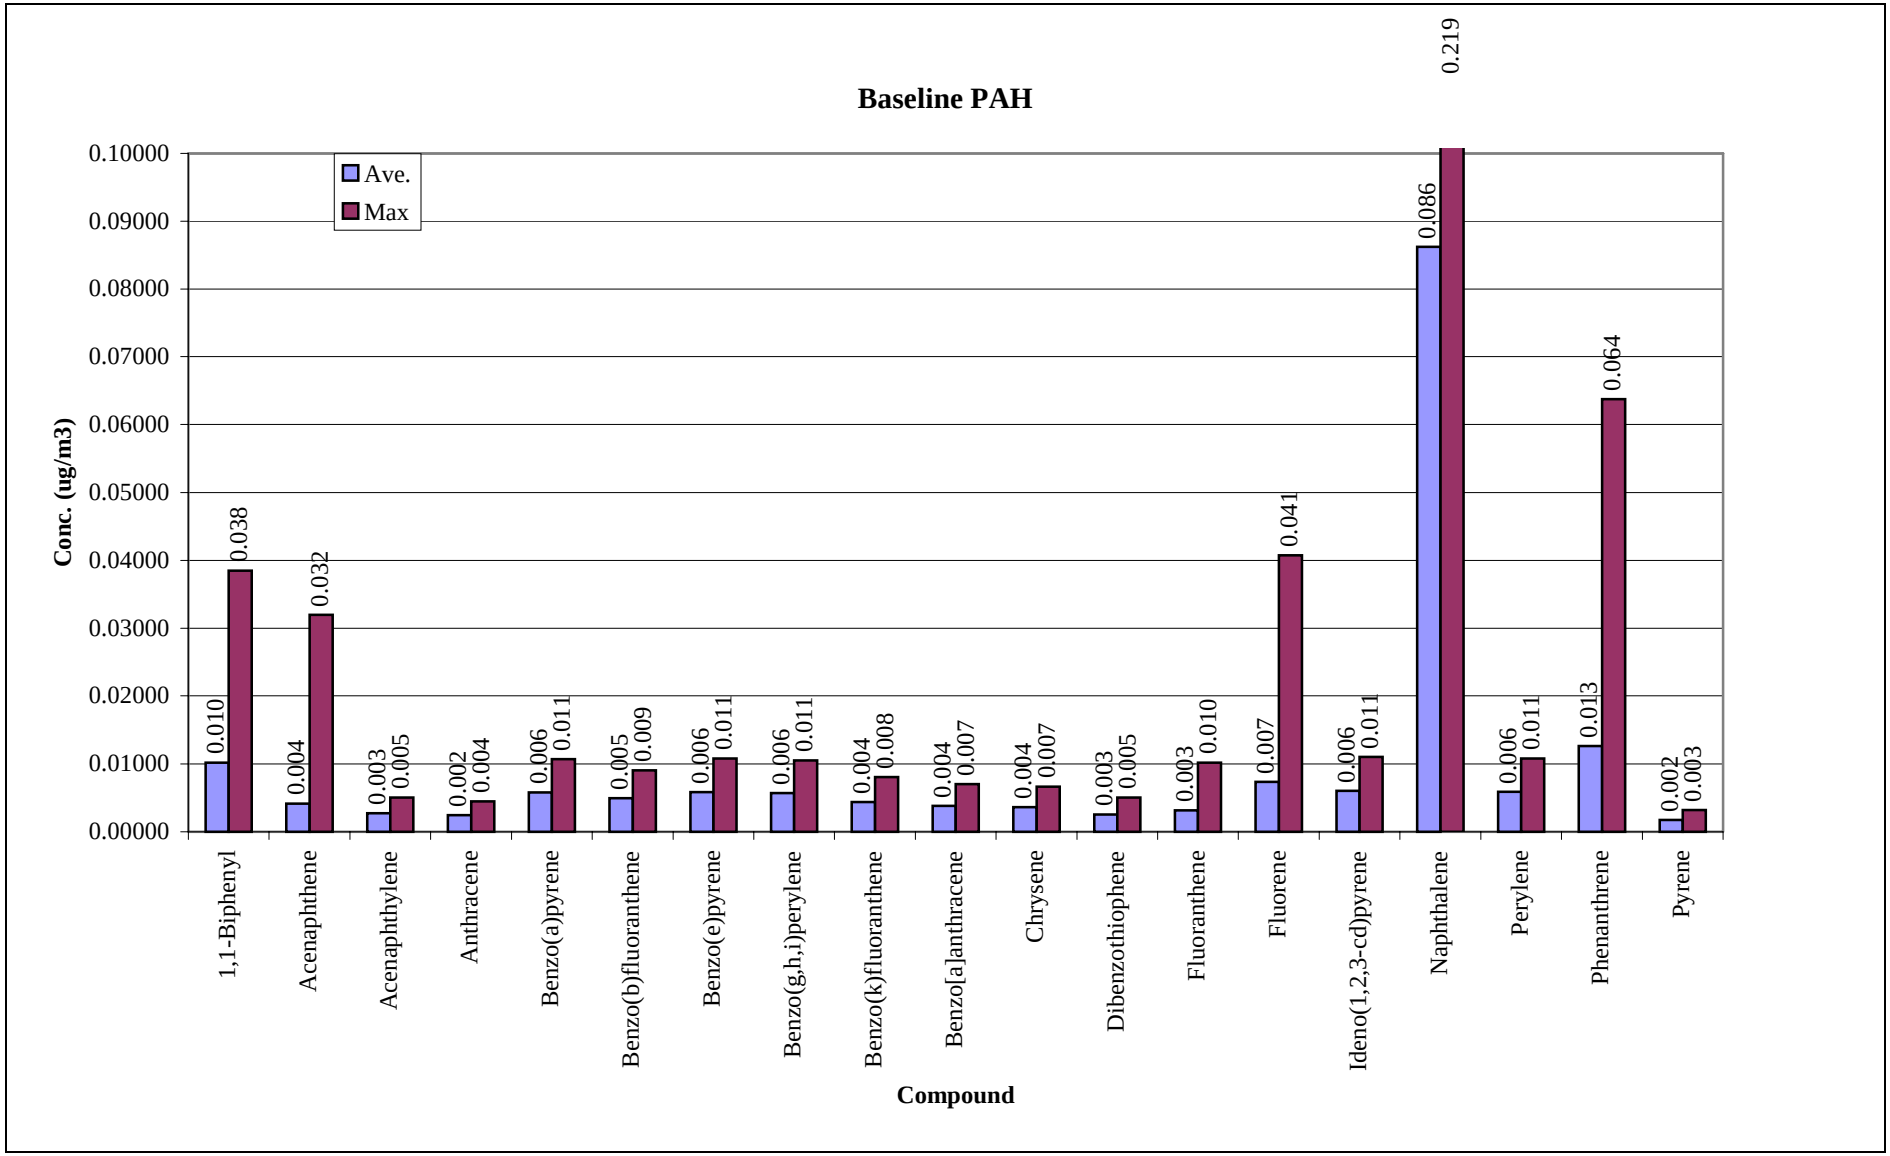

Figure 7.34. Baseline Study average PAH concentrations

In order to establish the background levels for the Chemicals of Concern for use in the the risk assessment, the Baseline Study data were used along with the background data obtained in previous studies or in Avila Beach background locations. The procedures used in this determination are presented in the risk assessment document, included as Appendix D.

7.6 PRECONSTRUCTION PERIOD

The Preconstruction period covered the interval from November 11, 1998 to February 27, 1999. Monitoring during this period commenced earlier than expected due to an incident in the community in which a residence experienced offgassing from the sewer system due to utility work nearby. The potential for concern over this incident prompted the start of continuous monitoring and sampling for both real-time and integrated methods. This effort rapidly expanded and continued throughout the 3+ months of site preparation before actual excavation began.

7.6.1 Site Activities

During the Preconstruction period, site preparation activities began in earnest. Major activities included project site preparation, preparation and demolition of buildings along Front Street, commencement of installation of sheet pile, etc. Table 7.7 contains a list of major activities. Table 7.8 contains a list of the major incidents responded to by the CMT.

Table 7.7. Major Phase Activities

DATE	KEY EVENT
11/15/1998	Beach soil augmentation commenced
12/2/1998	Demolition of Front St. buildings commenced
12/15/98	Other demolition conducted.
1/5/1999	Sheet pile installation begun
1/18/1999	Tank farm canopy installation begun.

Table 7.8. Major Incidents Responded to by CMT

DATE	INCIDENT
11/10/1998	Odor complaint due to gas emitted from backed up sewer system. Utility work was being conducted nearby. CMT responded within 4 minutes of the call from APCD.
11/25/1998	Dust complaint from resident stating that her house was being inundated with project dust. APCD contacted and blinds and other materials removed by APCD for further testing.
1/7/1999	Notification that the fire department has received at least three complaints from neighbors regarding the noise from the monitoring equipment on their roof. Chief Gorman was advised that CMT would place a sound barrier around the base of the sampler stand to muffle as much noise as possible without affecting the sampler.
1/11/1999	At about 13:25 the CMT observed a dust "plume" coming form the community center parking lot as a result of a strong wind gust. A water trunk was deployed to suppress the dust. The APCD was notified at about 14:50 that visible dust had been observed but that an exceedance had not occurred.
1/16/1999	Possible exceedance (of preliminary PAH triggers) of total PAH on two occasions: a 5 minute exceedance at 8:35 and a 10 minute exceedance at 14:10. Due to nearby trucks
1/28/1999	Re-entrained road dust was observed at the corner of First St. and San Miguel St. by the CMT. The APCD was notified at 15:00. Mitigation measures to control the dust included re-routing the dump trucks going to the tank farm to the Cave Landing Rd. route, and the use of water on San Francisco St. and First St.
1/29/1999	An odor was detected in the localized work area. No odors were detected past Front St. or in the community. No target substances were exceeded.
2/5/1999	A complaint was received at 15:45 from the Jacobs Ombudsman regarding the noise of the Hi-Vol PUF on the Fire Station roof. CMT confirmed that the sampler was operating correctly and assured the source of the complaint that steps had been taken to reduce the noise. Further steps were investigated.
2/11/1999	A second complaint from the same source as above was received at 16:30 regarding the noise from the PUF sampler on the Fire Station roof. The CMT repositioned the sampler and the exhaust hose to reduce noise in his direction. A significant reduction in noise was achieved.

7.6.2 Monitoring Locations

Table 7.9 contains a comprehensive list of the integrated sampling conducted during the Preconstruction phase. For the majority of this time period, two locations were sampled—the Fire Station and the Community Center parking lot. Various other locations were sampled for special purposes, such as the Unocal pier for background determination, and Front Street locations to capture emissions from test truck runs.

Table 7.10 contains a list of the real-time monitoring locations. The real-time monitoring started on a sporadic basis in November as time was needed to mobilize, configure and train the field technician crew. In addition, the data collection procedures were still being worked out and the database was not in operation. Hard copy data were recorded during this time period but were

not input into the database. Data collection for input into the database began on December 15., 1999. By that time, many of the technical issues with the instruments had been resolved and routine monitoring was in progress.

7.6.3 Data Presentation

Table 7.11 contains the average VOC concentrations detected over the preconstruction period and Figure 7.35 contains a plot of these data. The maximum value corresponds to a single sample and does not reflect the overall status of the measured air. The plot contains some high, outlier values for benzene and toluene, all of which contribute to higher overall averages. As no concentrations as high as these were recorded throughout the remainder of the project, these values were likely anomalies and did not represent actual conditions. These values occurred in the same short period in early February along with high values of hydrocarbons. The GC/MS data did not record as high values for that time period but are still higher than average. Regardless, as there was no specific reason to reject these data, they are included in the data reporting.

Table 7.11. Preconstruction Period Average Concentrations of Volatile Organic Compounds

Compound	Ave (ppbv)	Max (ppbv)
Acetaldehyde	0.65	1.56
Acetone	0.64	1.73
Benzaldehyde	0.10	0.32
Benzene	1.52	11.03
Butadiene,1,3-	0.08	0.11
Butyraldehyde	0.07	0.24
Cyclohexanone	0.03	0.04
Dibromoethane,1,2-	0.08	0.11
Dichloroethane,1,2-	0.08	0.11
Ethylbenzene	0.08	0.17
Formaldehyde	1.32	3.97
Freon 11	0.12	0.23
Hexaldehyde	0.05	0.16
Methyl ethyl ketone	1.23	2.75
Methyl t-butyl ether	0.08	0.26
Propionaldehyde	0.11	0.39
Toluene	0.84	6.43
Valeraldehyde	0.10	0.38
Xylene,m,p-	0.17	0.69
Xylene,o-	0.09	0.19

The average of the integrated PAH analyses are contained in Table 7.12 and Figure 7.36. These data show low levels of most compounds, although a high level of naphthalene. High levels of naphthalene are not unusual and are generally attributed to higher ambient levels in the atmosphere and frequent contamination in the laboratory analysis or sample media. A discussion of the naphthalene laboratory issue is contained in Section 9. Note that in Table 7.12 the lower case compound names are indicative of the higher sensitivity SIM analysis.

Table 7.12. Preconstruction Period Average PAH Concentrations

Compound	Ave. (ug/m3)	Max (ug/m3)

(Lower case compound names indicate SIM analysis)

Data for the Preconstruction period are contained in Tables 7.13 to 7.16. Tables 7.13 and 7.14 contain daily and overall averages of the real-time data for volatiles and Tables 7.15 and 7.16 contain daily and overall averages of the real-time data for particulates. Figures 7.35 and 7.36 contain plots of the data. It should be noted that the concentration scale is arbitrary on these plots in order to show the lower concentration detections. The highest concentrations were significantly higher and do not represent typical concentrations detected.

Blank entries in these table represent periods in which either the instrument had not yet been placed in service or were out of service on that particular day.

As is evident from the concentrations recorded, volatile constituents were not frequently detectable—the majority were non-detect. The average noted is highly influenced by a large number of non-detects, with half the detection limit being used in the calculation of the average in the place of a detection value.

The particulate data appear representative of general low-level impacts to the atmosphere during the preconstruction period. The aethalometer data collection commenced on February 22, later on in the Preconstruction period, and the data set does not include impacts from the sheet pile operations that were seen later to have a higher impact on downwind particulate concentrations.

7.7 EXCAVATION PHASE

The excavation phase began with the removal of overburden in Cell 1A, beginning March 1, 1999, and continued through December 27, 1999 when the last sheet pile was removed from Cell 3. The excavation process consisted of first removing the clean overburden to a storage site, either at the Tank Farm or adjacent to the excavation areas, and then removing the affected material. Soil testing was conducted regularly to determine the contamination level throughout both the vertical and horizontal extent of the pit area. Following certification that the cleanup levels were reached, clean backfill was put into place, compacted, and graded. During this last process, sheet pile may have been removed, depending on the need for it in the other cells. The cell was complete when the last sheet pile was removed, which may have been months after the start and some time after the placement of the last clean fill.

The progress of the excavation from cell to cell was uneven, with much overlap of activities between cells. There was no definite start and stop of activities at each, with preparation work commencing in future cells while some cells were under active excavation. As a result, a breakdown of time periods associated with a single cell was impossible. In this report, the time line of the excavation is represented by monthly increments.

Air monitoring began shortly after the commencement of excavation activities since the effects from first exposure of the affected material to the atmosphere were unknown. There was some anticipation that high levels of hydrocarbons and hydrogen sulfide would be released due to the quantity and concentration of the subsurface contamination. Therefore, the CMT was ready to provide data during this initial phase, as well as continued integrated sampling.

The data collected did not show a substantial impact to the atmosphere from exposure of the contaminated soil. While there were some instances of high petroleum odor in periods of calm, the downwind concentrations were much lower than the trigger levels as set by the CMP Work Plan. In addition, some monitoring conducted close to the pit area where odors were strongest, showed relatively low levels of BTEX target compounds (See Section 10.3.2.1).

Data from the remainder of the excavation period are presented below. Table 7.17 contains a list of the integrated sampling locations where data were collected, from March 1, 1999 to November 22, 1999, when the last open pit in Cell 3 was closed. The real-time monitoring was conducted from March 1, 1999 to December 27, 1999 when the last sheet pile was removed. Table 7.18 contains a list of the days of real-time monitoring over this time period. Table 7.19 contains a list of significant activities for the time period; Table 7.20 contains a list of associated incidents.

Since trends are more easily seen in a group of data and particular data points are more easily interpreted in context, the data set for the entire excavation phase will be presented as monthly averages. This is justified as specific daily circumstances are not as important when determining overall health effects as are long-term trends. Tables7.21-24 present real-time and integrated data for the monthly periods during the Excavation period. The high points in these table correspond quite well with the periods of highest activities—September to October, 1999 when three cells were in progress simultaneously.

Abbreviations
AETH: aethalometer—diesel exhaust;
PAS: PAS2000—particulate bound PAH;
DR: DataRAM 2000—PM2.5;
PDR: personal DataRAM 1000—PM10
J1: Jerome—Hydrogen sulfide
J2: Jerome—Hydrogen sulfide
J8: Jerome—Hydrogen sulfide
V204: Voyager GC/PID—BTEX, 1,3-butadiene
V301: Voyager GC/PID—BTEX, 1,3-butadiene
V303: Voyager GC/PID—BTEX, 1,3-butadiene

Table 7.19. Summary of Key Events during Excavation

Date	Key Event
3/1/1999	Overburden removal in Cell 1A begun.
3/2/1999	First full day of excavation in Cell 1A; approximately 100 trucks employed.
3/8/1999	Groundwater reached in Cell 1A; excavation of affected soil begun.
3/28/1999	Main part of major plume for Cell 1A reached.
4/23/1999	Backfilling and sand augmentation of Cell 1A begun.
4/26/1999	Overburden excavation in Cell 1B commences.
4/30/1999	Cell 1B activities increasing; groundwater reached.
4/30/1999	Sheet pile removal from parts of Cell 1A beginning. More than one half of backfill completed.
5/3/1999	In Cell 1B, groundwater and affected soil reached.
5/10/1999	Yacht Club moved away from site without mishap. Activity in Cell 2A begins with sheet pile installation.
5/13/1999	Preparation work for Cell 2B begins with pier dismantling.
5/17/1999	Cell 1A is completely backfilled. Activity completed.
5/19/1999	Laying down of sheet pile for Cell 2B installation begun.
5/23/1999	Backfilling in Cell 1B begins. Excavation nears completion.
5/24/1999	Cell 2A piling and overburden moving into Cell 1A.
5/27/1999	Excavation in Cell 1B complete. Cell 2A sheet piling complete. Pier dismantling begun.
5/31/1999	Cell 2A excavation begun, with affected soils being reached.
6/10/1999	Excavation of a hot spot in corner of Cell 1B begun. This is completed within 24 hrs.
6/17/1999	Cell 2B sheet pile completed. Overburden removal begun.
6/21/1999	Affected soil and groundwater reached in Cell 2B.
6/22/1999	Backfill of west end of Cell 2A begun with sand and gravel. Cell 1B backfill in the polishing stages.
6/26/1999	Cell 1B serving as a stockpile for Cell 2B overburden material. Cell 2C sheet piling and overburden removal begun.
6/28/1999	Sheet piling removal commenced in Cell 2A.
7/13/1999	Installation of new seawall in Cell 2A begun with the unloading of pre-cast sections.
7/15/1999	Cell 2C activity ramps up, with sheet pile installation and removal of overburden.
7/16/1999	Cell 2A backfill completed except for high quality sand to be imported when seawall installed.
7/17/1999	Cell 2B excavation complete.
7/24/1999	Connection between Cell 2A and 2B removed completely.
7/26/1999	Backfilling begun in Cell 2B. In Cell 2A seawall construction begun.
7/27/1999	Demolition begun in Cell 3 with media in full force.
7/28/1999	Demolition of 50 San Miguel and the Jetty complete. Excavation of Cell 2C ramping up.
7/30/1999	Demolition of Ferini Building in Cell 3.
8/2/1999	Demolition of tenplex in Cell 3.
8/2/1999	Demolition of Old Custom House in Cell 3.
8/9/1999	Demolition of Martin House in Cell 3. Sheet pile driving begun in Cell 2E.

Date	Key Event
8/13/1999	Demolition of the Sea Barn in Cell 3.
8/19/1999	Overburden removal in Cell 2E. Excavation of Cell 2E moving forward rapidly.
8/24/1999	Backfilling commenced in Cell 2C.
8/26/1999	Avila Grocery move begun in Cell 3.
9/10/1999	Preparatory work taking place in Cell 2D.
9/14/1999	Excavation begun in Cell 2D.
9/15/1999	Sheet pile installation begun in Cell 3. Excavation completed in Cell 2D.
9/16/1999	Backfill commenced in Cell 2E. Stockpile is gone in Cell 1A and plastic liner removed.
9/20/1999	Commencement of excavation in southwest corner of Cell 3.
10/7/1999	Last section put in place on the east end of the sea wall in Cell 2C.
10/8/1999	Cell 1A almost returned to pre-excavation contours – looking like Triangle Park again.
10/14/1999	Backfill complete in Cell 2E. Sand compacted in Cell 1A; final grade complete.
10/19/1999	All sheet pile removed from Cell 2C; backfilling and grading throughout the cell. Waves can be heard in town again.
10/20/1999	Backfilling commenced in southwest corner of Cell 3.
10/21/1999	Re-excavation for placement of gravel in Cell 2D begun.
10/22/1999	Grading of Cell 2A to 2C completed.
10/27/1999	An exploratory pit uncovered a small plume of contamination along Avila Beach Dr. The pit was backfilled by mid-afternoon.
10/28/1999	Deadline for finishing work on the beach (October 31) is met.
11/22/1999	Excavation of Cell 3 completed. Backfill continuing.
11/30/1999	Ribbon cutting held to celebrate the opening of the west end of the beach.
12/2/1999	Small dig behind the Avila Pizza Pantry commenced. Data distribution suggested a plume extending away from the main area thought to be contaminated. More soil testing was undertaken.
12/3/1999	VPS Cell excavation completed. Sea wall cap construction begun.
12/27/1999	End of sheet pile removal, real-time monitoring ends.

Table 7.20. Summary of Incidents during Excavation

DATE	INCIDENT
3/1/1999	Some dust was observed in Cells 1A and 1B. Water trucks were employed. The APCD was on site and advised additional watering for dust control.
3/2/1999	Total dust (PDR) exceedance in AM; steadily decreasing concentrations in the PM. APCD was notified at 13:40. The dust was likely not related to construction activities as wind was coming from the south and weather conditions were unusual.
3/23/1999	Odors were detected in the Cell 1A area and in the community near San Francisco St. and First St. The APCD was notified at 15:05.
3/25/1999	Transient to mild petroleum odors were evident most of the day in the areas of First St. to San Francisco St. and the community center parking lot.
3/29/1999	Two complaints received regarding: (1) Diesel exhaust from the start up and idling of project trucks in the AM. Monitoring equipment was placed in the area of the complaint to monitor PEC, PAHs and PM2.5 dust. (2) Dust in the area of First and San Miguel Streets. The APCD was notified of both complaints.
3/31/1999	The CMT received an anonymous odor complaint. Moderate petroleum odors were confirmed.
4/28/1999	Odor detected at 9:30. Source was a manhole on Avila Beach Dr. and was not related to the project.
5/19/1999	High wind causing dust plumes from Cell 2A area.
5/23/1999	Generalized petroleum odor evident throughout the town due to excavation in Cell 1B in highly contaminated southeast corner.
5/24/1999	One odor and noise complaint was received by the APCD at 15:30. No unusual conditions were recorded.
6/14/1999	PM10 exceedance between 13:30 and 14:30 due to significant trunk activity. APCD was notified.
6/23/1999	Two exceedances of target substances recorded: 1,3 Butadiene and PM10 on the corner of San Francisco and First Streets. The APCD was notified in both cases and truck traffic was stopped and manual watering of beach properties was undertaken.
7/15/1999	A Tier 1 odor exceedance was registered, resulting from 3 odor complaints made in the mid-late afternoon. CMT responded to an APCD call within 3 minutes with field instrumentation. Odor was described as sulfur-like. Source may have been the pile of creosote pier pilings stored in Cell 2C.
7/16/1999	Odor complaint received at 10:30 through APCD and the Fire Department. CMT responded with instruments and increased monitoring. Two types of odors were noted: (1) a heavy, sour odor; (2) a light odor similar to odorized gas.
7/17/1999	Odor complaint received at 11:00 from a resident northeast of the fire station. Intermittent odors were detected at this location throughout the day and were attributed to sheet piling operations in Cell 2C.
7/27/1999	Meeting held in Avilia to discuss odor complaints. Most of the evidence pointed to a past leaking gas line that posed no safety issue. The petroleum odor is expected from the affected material. It was decided to further investigate the source of the odors, including the geologic features that may contribute odor.
7/29/1999	APCD was informed of high odor in Cell 2C area, although there were no exceedances of target substances.

DATE	INCIDENT
8/5/1999	Two odor complaints were received. The first was for sulfurous odors, likely originating from the tank farm stockpile area. The second was for petroleum odors in the Fire Station/San Luis/First St. area, directly downwind of the grinder and excavation activities. APCD was informed but no exceedances of target substances were recorded.
8/13/1999	Short-term high values of diesel exhaust and PAH attributed to the Maxigrinder.
9/2/1999	Tier 1 dust exceedance at 16-17:00 due to truck loading activities. Watering was increased and activity stopped early.
9/9/1999	Tier 1 dust exceedance in the late afternoon. APCD notified and area watered.
9/30/1999	Tier 1 dust exceedance caused by the fine soils and activities in Cell 3. High readings commenced at 14:15. Watering was commenced and the APCD was notified. High diesel and PAH values were also recorded but did not exceed acceptable levels.
10/6/1999	Tier 1 dust exceedance around 14-15:00, mainly due to high gusts of wind. Watering was commenced and the APCD was notified.
11/5/1999	A PM2.5 exceedance occurred 12:30-15:00. This level was not attributable to project activities, but to natural haze.
11/30/1999	APCD received an odor complaint but odor was not associated with project activities.

7.8 OUTLYING PROPERTIES

The outlying properties consisted of a small area in front of the Inn at Avila Beach, a larger property along Avila Beach Drive between San Miguel and the entrance to 1st St., and a lot along Avila Beach Drive near the foot of Laurel Street. These properties were contaminated with only minor levels of material and did not warrant the full scale excavation nor monitoring programs.

These properties were excavated between January 4, 2000 and April 6, 2000, with many long periods of inactivity between these dates due to normal project delays and the passage of major storm systems. A much reduced level of monitoring was conducted during this time, in terms of both sampling scope and intensity. Only the instrumentation capable of unattended continuous monitoring were used. The data collected were checked periodically to assess any trends. No data from this period were entered into the database since the collection frequency was sparse and the database had been tailored for a particular sampling period for use in the risk assessment. In addition, the data base for the risk assessment had been fixed as the period ending December 27, 1999, the end of Cell 3 activities.

In general, the data collected over this time period show very low concentrations of pollutants. This is because activities were of low intensity and utilized only a few pieces of equipment. In addition, the pace of activity and the removal rate were slower. Weather problems slowed the removal rate, but also contributed to much lower dust levels than would be expected from soil removal. The number of diesel vehicles used was also low, which kept levels of diesel exhaust to a minimum. Comparison of the data collected with the standard CMP trigger levels, indicated that in no instance were trigger levels reached. Indeed, for most of the time, the values were consistent with background levels.

Table 7.26 shows the data collected over time periods that correspond with the excavation of outlying properties activities. No incidents were recorded during this time period.

Table 7.26. Summary of Outlying Property Activities

1/5/2000	Eastern edge of San Antonia plume reached and backfill begun Dec. 6.
3/14/2000	No excavation this week due to heavy rain.
3/29/2000	Resumption of work after 15 days of non-operation due to rain.
2/7/2000	Lyons-Togazzini property work started. Small potentially affected soil areas removed.
3/9/2000	Excavation of Lyons-Togazzini completed.
3/13/2000	Bachino Property excavation begun.
3/14/2000	Backfill of Lyons-Togazzini completed.
4/6/2000	Backfill of Bachino completed. Monitoring ceased.

7.9 ANCILLARY DATA—HYDROCARBON AND SULFUR COMPOUNDS

While two sets of ancillary data were collected as part of the original monitoring plan, both were decreased in scope and eventually dropped. The hydrocarbon data were expected to be useful for assessing potential emissions of a wide range of unusual hydrocarbon species that could be emitted from the surfaces of the petroleum excavations or from vehicle exhaust. Measurement of reduced sulfur species was intended to augment the Jerome hydrogen sulfide sensor data and to provide integrated data on the presence of a wide range of odorous reduced sulfur species.

Sampling and analytical problems led to the rejection or qualification of the ancillary data. A first review of the hydrocarbon data suggested that it was too complex to be easily assigned to specific sources. In addition, the species of potential public health interest were covered by other analyses and were therefore redundant. As a result, analysis of hydrocarbon data was ceased in early April, 1999.

A later analysis of the data set indicated another problem that was not evident previously. As discussed in Section 10.4.4.3, comparison of the GC/FID with the GC/MS data showed a clear overall high bias in the GC/FID data. Since the FID is a non-specific detector, it was presumed that high background levels were causing this bias across the board. Therefore, these data were considered unusable for a quantitative evaluation of emissions from the site.

The hydrogen sulfide data were affected by sample instability, as discussed in Section 10.4.4.2, and were deemed unusable. For this reasons, these data are not presented in this report. However, the entire set of ancillary data is contained in the database.

8.0 DATA MANAGEMENT

8.1 DATA MANAGEMENT SYSTEM

The purpose of the database management system was two-fold. First, the system needed to provide cognizant users with a complete dataset from which to analyze and interpret data. Second, and key to the rapid response function of the CMP, the system needed to allow for rapid access to data from remote locations. In addition to the local project staff and nearby parties in San Luis Obispo, the project team consisted of individuals located in the San Francisco Bay Area and in Southern California. The database management system was designed to provide this group with accessibility, ease of use, completeness, and rapid response, so that decisions could be made rapidly and with a consensus among the project team.

8.1.1 Description

The database system consisted of a custom-developed relational database written in Microsoft Access. The system had several modules, including:

- Data Capture
  - Real-time instrument data
  - Laboratory data
  - Van and cart meteorological data
  - Tower meteorological data
  - Site logs

- Data validation

- Data posting

- Reporting
  - Daily comparison to trigger levels, both graphic and table
  - Period comparison to trigger levels, both graphic and table
  - Summary table—real time or lab data
  - Graph of time series data—real time or lab data
  - Daily field data graph
  - Field data by location
  - Meteorological data—summary and wind rose
  - Data inventory—real time and laboratory
  - Laboratory hold time report

- Maintenance
  - Change passwords
  - Calculate rolling averages
  - Options for ND calculation

8.1.2 Development

A preliminary system was initiated by an initial contractor. However, this effort was terminated in favor of an alternate approach proposed by another group. Following the cessation of the first efforts, two contractors were used to provide assistance in preparing the database system. Mr. Brock Taylor of Pacific Computing, and Dr. Barry Floyd of Cal Poly San Luis Obispo carried out the coding tasks under the direction of the field project manager, Dr. Eric Winegar.

8.1.3 Operation

The goal in developing the database was to provide external users with the capability to dial into the project trailer via the NT server and to connect to the database using their personal profile. The CMT trailer was outfitted with five telephone lines so that multiple users could access the project database simultaneously. A central NT server with a multiple line router was used to maintain security for each of the users, while continuing to allow on-site users access to the network.

Outside users were able to dial in, access data remotely, and have the data copied to an Excel spreadsheet format for further personal exploration. Local printing was performed by configuring a remote printer connection.

Overall, the external users found that the system served their needs. The speed of the system was limited by the 56K modem speed available in Avila and at each user's location. In addition, as the database became larger, the processing time, in addition to the transmit time, increased. As miscellaneous user connection issues became more frequent, the database was subsequently distributed in CD format, which each user could access at will. This system proved successful.

8.1.4 Daily Data Review

The daily data review process consisted of the following steps:

- Site coordinator checked on field technicians throughout the day for consistency, accuracy and completeness.
- During the importation process, errors in the data logged in the instrument were noted and corrected or deleted. These data were reconciled with the field data sheets maintained by the field technician.
- The importation process included several data validation steps that allowed mistakes to be caught before entry into the system. Wrong dates, missed data points, data values out of range were all automatically reviewed before allowing the process to continue.
- Finally, before posting into the main database, the final data were reviewed by the project manager for accuracy and consistency. The most frequent errors were outliers due to instrumental problems.

8.2 DATA BASE AUDIT

In order to provide assurance that the database yielded accurate results to users, three checks of the system were performed:

- Verification of calculation algorithms
- Verification of report table contents
- Audit of input data files

8.2.1 Algorithm Accuracy

During the development process, key parts of the program that were being coded and readied to deploy were tested for output accuracy. This was done by calculating the output value both manually and via the database using the same dataset. If any discrepancy was found, the data were remedied. The special stratified standard deviation function, which was added to the system, was checked by two separate individuals to confirm that the complicated calculation was implemented correctly.

8.2.2 Audit Results

The database was audited by verifying the values in the system with the actual laboratory reports. This was performed on a limited basis by Mr. Barry Lajoie of APCD and by CMT staff.

Mr. Lajoie compared a set of approximately thirty work orders from Air Toxics Limited to data that had been imported into the database. There were only three small deviations between the two sets of data. Another more extensive audit was performed by CMT staff, in which 39% of the work orders for both Air Toxics Limited and EAS were compared to the values in the database. Less than ten errors were noted, and were primarily associated with missing data. From these two efforts, it was concluded that the database management system was accurately storing and reproducing the data from the laboratory and field instruments.

9.0 DATA QUALITY ASSESSMENT

9.1 DATA INVENTORY

The overall data capture rate was determined to be greater than 95%, as determined from the intended sample collection scheme.

9.1.1. Field

Table 9.1 contains a complete data inventory of the field data, and Table 9.2 contains a summary of these data. The values are the number of data points collected on each day. Gaps are due to instrumental or other problems that prevented the deployment of monitoring equipment for that day. The gray periods are weekends, holidays, or other time periods in which no site activities occurred and no monitoring was needed.

The data inventory shows a high level of coverage for the excavation period. As such, the complete data set was deemed useful for use in the execution of the health risk assessment, as described in Appendix D.

As shown in Table 9.2, the total number of data points was over 180,000. This extensive coverage provided the community with a high degree of confidence that no extraneous activities were missed.

Table 9.1. Inventory of Real-time Field Data.

Table 9.2. Summary of Field Analysis Data—Number of Samples

Data Points	AETH	PAS	DR	PDR	J1	J2	J8	V204	V301	V303
Total	15,783	11,212	16,935	18,334	31,131	69,303	14,743	2,260	4,839	93
Grand Total	184,633									

9.1.2. Laboratory

Table 9.3 contains the laboratory data inventory. As with the field data, the coverage for the project period was reviewed closely and deemed complete. The complete data set contains an extraordinary sample density for a small area. This density, along with the quality of the data, allowed the data to be used for a rigorous risk assessment procedure, as shown in Appendix D.

9.2. SPECIAL DATA COLLECTION

9.2.1. Soil Odor Test

In late July 1999, during the installation of sheet pile in Cell 3 along the south side of Front St., a number of odor complaints were registered. The odor was described as "natural-gas like," and "mercaptan-like." A number of measures were taken to assess this odor, including the collection of additional grab samples downwind of the cell, additional monitoring by CMT technicians, and a soil odor test. The soil odor test was developed in response to concerns about additional odor releases during the next phase of sheet pile installation along San Luis Street.

It was surmised that the odor was emitted as a result of high-energy sheet pile pushing, which caused the release of either adsorbed mercaptans from a previously known natural gas leak, or the formation of odorous sulfur compounds from the friction of sheet pile on various types of sulfur-containing subsurface rocks. The natural gas leak scenario was raised based on recollections of an old sealed off natural gas pipeline in the area along Front Street. Figure 9.1 shows a photograph of steam rising from the sheet pile as it is being pushed into the ground around the time that the odors were released.

The soil odor test necessitated the collection of a number of soil samples at points near to the suspected points of emission, and near to the position of the next phase of sheet pile installation. The soil samples were collected into small glass bottles, which were shipped to the laboratory for analysis. The analysis consisted of heating the vials to 100°C and extracting an aliquot for injection into the gas chromatograph for reduced sulfur analysis.

Figure 9.2 shows a map of the soil sampling locations. Table 9.5 shows the listing of the sampling points, and Table 9.6 contains the results of the soil headspace analysis. The sample points were located in an area that was being excavated for installation of a drainage system, so subsurface soil was exposed and could be sampled. It was assumed that the soil in this area was similar to the area nearby (within 15 feet) that had produced the noxious odors during sheet pile installation.

Figure 9.1. Steam from Sheet Pile Installation

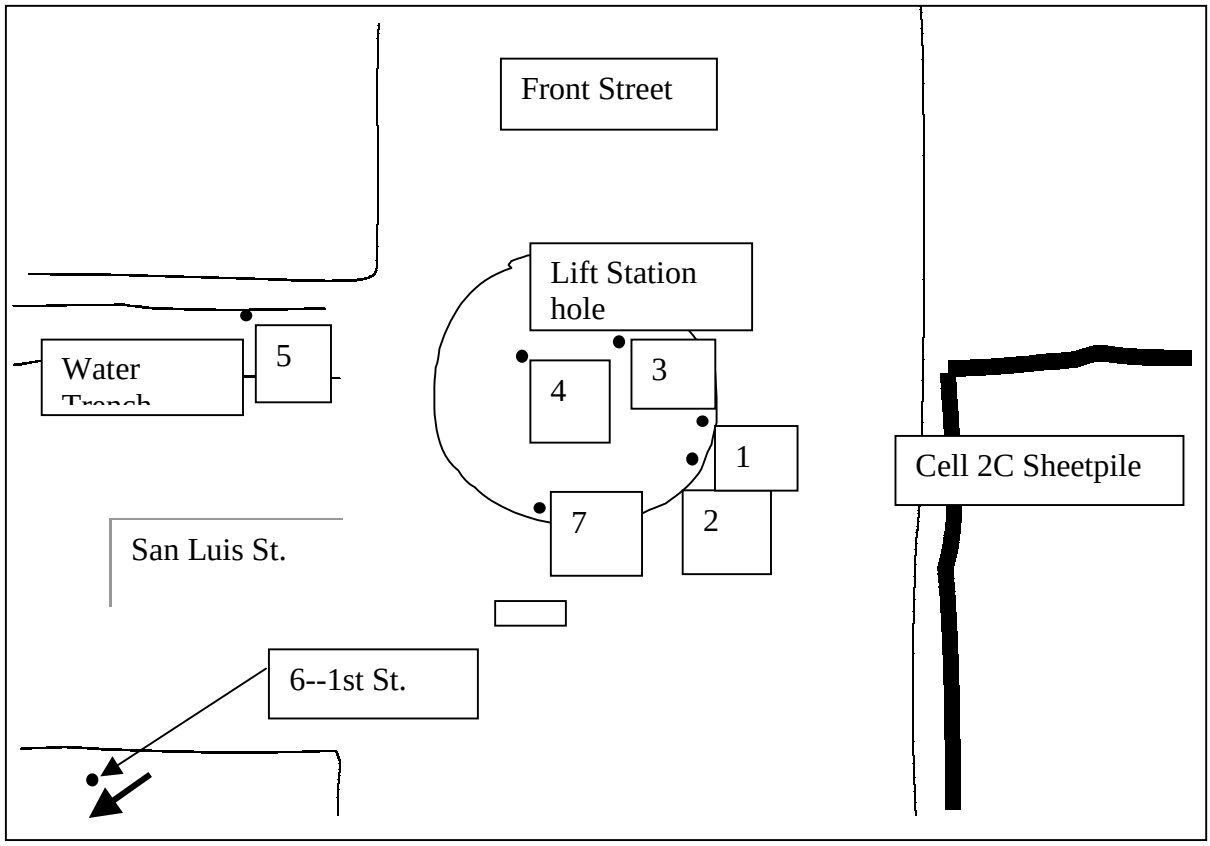

Figure 9.2. Map of Soil Sampling Locations

Table 9.5. List of Soil Sampling Locations

Number	Description
1	1 foot below Asphalt
2	1 foot below Asphalt, two feet laterally from #1
3	6 feet below Asphalt, next to water drain pipe
4	2 feet below Asphalt, adjacent to pipeline
5	6 inches below Asphalt, in water pipeline trench
7	1 foot below Asphalt
6	6 inches below sidewalk, 1st St. middle of San Luis/San Miguel block.

2-Ethylthiophene			1.8			9.4	10.2
2,5-Dimethylthiophene			6.5		4.2	2.8	21.6
Diethyl Disulfide	5.1	1.1	1.7	4.5	2.6	10.4	13.5

The results show a high variability in the odor species concentration. While there is some indication of a difference for carbonyl sulfide at different locations, none of the concentrations were above the reported odor threshold of 100 ppbv. Several other species, however, such as methyl mercaptan, dimethyl disulfide, the various thiophenes, and diethyl disulfide, all have relatively low odor thresholds, suggesting that the soil did indeed contain the potential for noxious odors. However, the spatial aspect of the data suggested little difference between soil samples in the different locations, leading to the conclusion that soil odor tests were unlikely to predict the potential for odorous emissions during sheet pile installation.

The result of this test was the conclusion that no prediction could be made for future odor emissions and that in order to handle the potential for problems, an increased odor patrol would be initiated to patrol the area during subsequent sheet pile installation.

The last portion of sheet pile installation proceeded without any odor emissions, suggesting that the source of the odor was localized, possibly from remnants of leaking natural gas odorants.

9.2.2. Inside of Cell Tests

9.2.2.1.Voyager Tests

During the height of Cell 1A excavation, air samples were collected and analysed at the area with calmest daytime air and most contaminated material in the cell, the southwest corner. The purpose of this was to determine the response for the off-hours sensor. The information was also useful for determining the potential for emissions to off-site receptors.

The samples showed moderate levels of BTEX, with a maximum of 100 ppbv of toluene. Other compounds were detected at lower levels, with many peaks corresponding to unidentified compounds. While interesting from a general perspective, these data were not of particular value to the CMP.

Jacobs Engineering safety staff regularly collected data inside the pit using handheld PID and hydrogen sulfide sensors. While the data from these efforts are not available, the data never surpassed the limit for worker health and safety, both for hydrocarbons (50 ppmv) and hydrogen sulfide (10 ppmv). However, these limits could potentially not be exceeded while still having some impact to odors or ambient air trigger levels.

9.2.2.2.Soil Headspace VOC Speciation

Four sets of speciation data were collected in order to assess the nature of emissions directly from the affected material.

The first two sets of speciation data consisted of a headspace sample, though not rigorously sealed against ambient air intrusions, collected using Summa canisters from a batch of freshly excavated affected soil in Cell 2C, an area that had been associated with localized odors. Tables 9.7 and 9.8 show the results of the sampling and laboratory speciation. In both cases, the standard analytes were provided, along with the top ten tentatively identified compounds (TICs).

Table 9.7. Soil Emissions Speciation—Cell 2C, August 4, 1999

8/4/99	ppbv

Bicyclo[2.2.1]heptane, 2-(2-propenyl)-	200
1H-Inden-1-one, octahydro-7a-methyl-, ci	140
Cyclopropane, 1-hexyl-2-propyl-, cis-	170
Cyclohexene, 3-methyl-6-(1-methylethyl)-	140
Tricyclo[3.3.1.13,7]decane	180
Tricyclo[4.3.1.13,8]undecane, 3-chloro-	130
2H-Inden-2-one, 1,4,5,6,7,7a-hexahydro-7	130
5-Undecene, 5-methyl-, (Z)-	190
Tricyclo[3.3.1.13,7]decane, 1,3-dimethyl	160
7-Heptadecyne, 1-chloro-	150

Both of the samples show detects of acrolein, suggesting that ambient air from the pit area that was impacted by diesel exhaust infiltrated the headspace container. The presence of these high levels of acrolein supports the downwind detection of this compound in regular CMP sampling locations.

The TICs show a number of unusual compounds that are high in cyclic species. This was unexpected since the hydrocarbons in the affected soil were typically straight chain alkane type species. However, it is possible that these species were caused by microbial degradation of the petroleum products, since the area the soil was drawn from near the beach where marine life was present. Because of the unusual mix of compounds present, these data were not useful for understanding the odor phenomenon associated with the affected soil in that area.

Other headspace samples were collected from the San Antonia plume and the Lyons-Togazzini property. Table 9.9 shows a full hydrocarbon speciation analysis performed on these headspace samples. These data show a wide range of hydrocarbons present, dominated by higher carbon number species. This is not unexpected since the products had been present for many years, allowing the more volatile species to escape.

9.2.2.3.H2S/Odor

Several tests were made inside the excavation pits using the Jerome H2S sensor. In these cases, ambient air samples from approximate breathing zone were collected, or the Jerome probe was placed very close to the soil or hydrocarbon contaminated standing water. In the majority of the cases, no hydrogen sulfide was detected, suggesting that the amounts detected downwind during the CMP monitoring were primarily due to emissions from diesel equipment.

This assertion was confirmed in one test in which a Jerome was placed approximately 3 feet downwind of an idling truck exhaust pipe. The data showed 20 ppmv of H2S in one sample, and 5 ppmv in another sample. While this test is not definitive, it supports the contention that the exhaust was causing the hydrogen sulfide emissions, not the petroleum product contaminated soil.

One pit did display specific H2S odors that were confirmed by the Jerome H2S sensor. The VPS pit, which was a small area remaining in Cell 1 where the VPS recovery equipment was located, was noticed to produce a slight hydrogen sulfide odor. When the perimeter of the pit was tested with the Jerome, several high readings were detected, ranging from background levels of 3-5 ppbv to 20 ppbv. These values were supportive of an olfactory detection. Samples collected over the active pit area showed low levels of H2S. Downwind samples showed general background levels, suggesting that, even with detectable levels at the pit area, the downwind sampling locations near the fence line were sufficiently distant to allow a high level of dilution to the odor plume.

9.2.3. Foam Efficacy Test

In early August 1999, questions arose concerning the effectiveness of the foaming process for controlling emissions of VOCs and odor from the stockpile at the Tank Farm. To assay foam efficacy, a test was performed on unfoamed vs. foamed soil.

The testing process involved placing an inverted plastic garbage can on the soil surface. After equilibrating for 5 minutes, a grab Summa canister sample was collected of the gas inside the container. The sample was then analyzed for total non-methane hydrocarbons using US EPA Compendium Method TO-12 (preconcentrated direct flame ionization detection). Three surfaces were tested: uncontrolled bare soil surface, controlled surface (covered with foam approximately one to two inches thick that had been applied 15 minutes earlier), and controlled surface (foam covering) after approximately 12 hours following application.

The results of these tests were as follows (all results are ppmv of non-methane carbon):

- Uncontrolled: 19.0 ppmv (3.2 ppmv as hexane)

- Controlled—15 minutes post-application: 3.7 ppmv (0.62 ppmv as hexane)
- Controlled—12 hours post-application: 2.4 ppmv (0.40 ppmv as hexane)

Using the equation: efficiency = (uncontrolled-controlled)/controlled, the suppression efficiency was calculated as 84.0%. It should be noted that this was a minimum control for two reasons: (1) the 12 hour post-application data point was used, which is approximately 40% lower than the immediate post-application, and (2) the foam itself has a hydrocarbon emission that contributes to the totals. The proportion of the total that the foam contributes to would raise the efficiency if subtracted from each measurement. The amount of emission from the foam itself is unknown. Figure 9.3 shows a photograph of the foaming process during this test.

Figure 9.3. Stockpile Foaming for Odor Suppression

9.3. BACKGROUND DATA COLLECTION

The purpose of background data collection was to obtain information on Chemical of Concern levels in Avila Beach prior to remediation activities. This information allows for a more balanced assessment of the impact of the remediation activities.

In early October 1999, a project team meeting was held to select the data sets to be used for defining background conditions. There were a number of data sets examined; each was evaluated for its representativeness of Avila Beach.

The background data sets chosen included the following:

- Previous Avila Data from 1998 and 1999;
- Unocal Pier samples collected during construction activities;
- Data sets from Avila Beach during non-construction time periods, including the Baseline Sampling period;
- Data from surrounding areas, such as Pismo Beach and San Luis Obispo; and
- Other general background data useful for general applications, but not for calculations.

A detailed listing of the background data is included in the Risk Assessment report included in Appendix D.

Dr. John Rice, Chairman of the Statistics Department at UC Berkeley, was retained to assist the team in understanding the appropriate treatment of concentration data. Based on discussions at the meeting, two procedures were developed: one that provided for the calculation of statistics for a stratified sample design that was in use, and the other that utilized the background data from other locations to be used in correcting for background concentrations. Dr. Rice produced two memoranda that discussed the methodology for correct statistical calculations. These two memoranda are reproduced in the Risk Assessment document, Appendix D.

9.4. DATA QUALITY REVIEW

Implementation of mobile field analysis followed the protocols set forth in the CMP Work Plan. The purpose of this section is to review data quality and to assess the overall uncertainty associated with the data.

9.4.1. Voyager Quality Assurance Data

The daily use of the Voyager GCs was the most important effort in terms of daily quality control checks. As cited in Section 5, the other field instruments were calibrated at the factory and did not require daily checks; any issues with calibration and performance of these instruments were cited in Section 5. In this discussion, quality control of the Voyager is presented.

Quality assurance procedures implemented for the field GCs included:

- Method detection limit study
- Initial multi-point calibration
- Daily QC checks
- Audit samples

9.4.1.1.Method Detection Limit Study

The method detection limit study was conducted at the beginning of the program. The study followed the standard protocol of running a minimum of seven replicate analyses of a low-level standard, and calculating the MDL by multipying the standard deviation of those values by 3.14. Tables 9.10 and 9.11 show the results of these studies. The values obtained were used throughout the program.

Table 9.10. Voyager 301 MDL Study Results

Voyager MDL Study					
Inst: 301					
Run	benzene	toluene	ethylbenzene	m-xylene	o-xylene
1	10	40	40	41	47

s	0.533	0.76	1.04	1.501	1.25
$\bar{x}$	11	41	41.8	43.6	48.9
	99.5% C.I.= $\bar{x}$ + 3.355s				
99.5% C.I.	12.79	43.54	45.22	48.68	53.06
MDL	9.2	38.5	38.3	38.6	44.7

Table 9.11. Voyager 303 MDL Study Results

Inst: 303	benzene	toluene	ethylbenzene	m-xylene	o-xylene
1	10	44	39	26	39
2	10	43	42	32	38
3	10	43	35	23	41
4	10	43	37	23	38
5	10	43	39	36	41
6	10	43	39	37	42
S	0	0.4	2.3	6.3	1.7
x	10	43.16667	38.5	29.5	39.8
	99.5% C.I.= x + 3.499s				
99.5% C.I.	10	44.6	46.7	51.7	45.9
MDL	10	41.7	30.3	7.3	33.8

A similar study was conducted for 1,3-butadiene. However, its values suggested a much lower MDL, which appeared unrealistic. Therefore, an arbitrary 10 ppbv detection limit was chosed based on a level that could be easily seen.

9.4.1.2.Initial Calibration Curve

A five-point calibration curve was used to establish the calibration function for the data system. An initial calibration was performed and if changes in the system necessitated it, a recalibration was performed. Recalibration was necessary only a few times. Table 9.12 shows an example of an initial calibration data set. The range of calibration was from 10 ppbv to 200 ppbv for benzene, and from approximately 50 to 250 ppbv for the other analytes. The acceptance criterion for linearity was a correlation coefficient of $r^2 > 0.995$. This was accomplished without many difficulties.

9.4.1.3.Daily QC Checks

Daily calibration checks for all analytes were performed before the instruments were used in the field. The acceptance criterion was ±30%. Table 9.13 shows the results of a subset of the daily QC check data, showing that this criterion was met at a high frequency. No instrument was used unless this criterion was met. In some cases, several runs were needed, frequently because of problems with the standards and not the instrument. The standards were used over a period of several days, and if poor recovery was noted, a new standard was prepared and re-analyzed. After several instances of poor recovery, the analyst was able to judge whether the problem was associated with the instrument or the standard.

Figure 9.4 shows a control chart with the average of daily QC checks. It is evident that the average daily recovery was well within the required specifications.

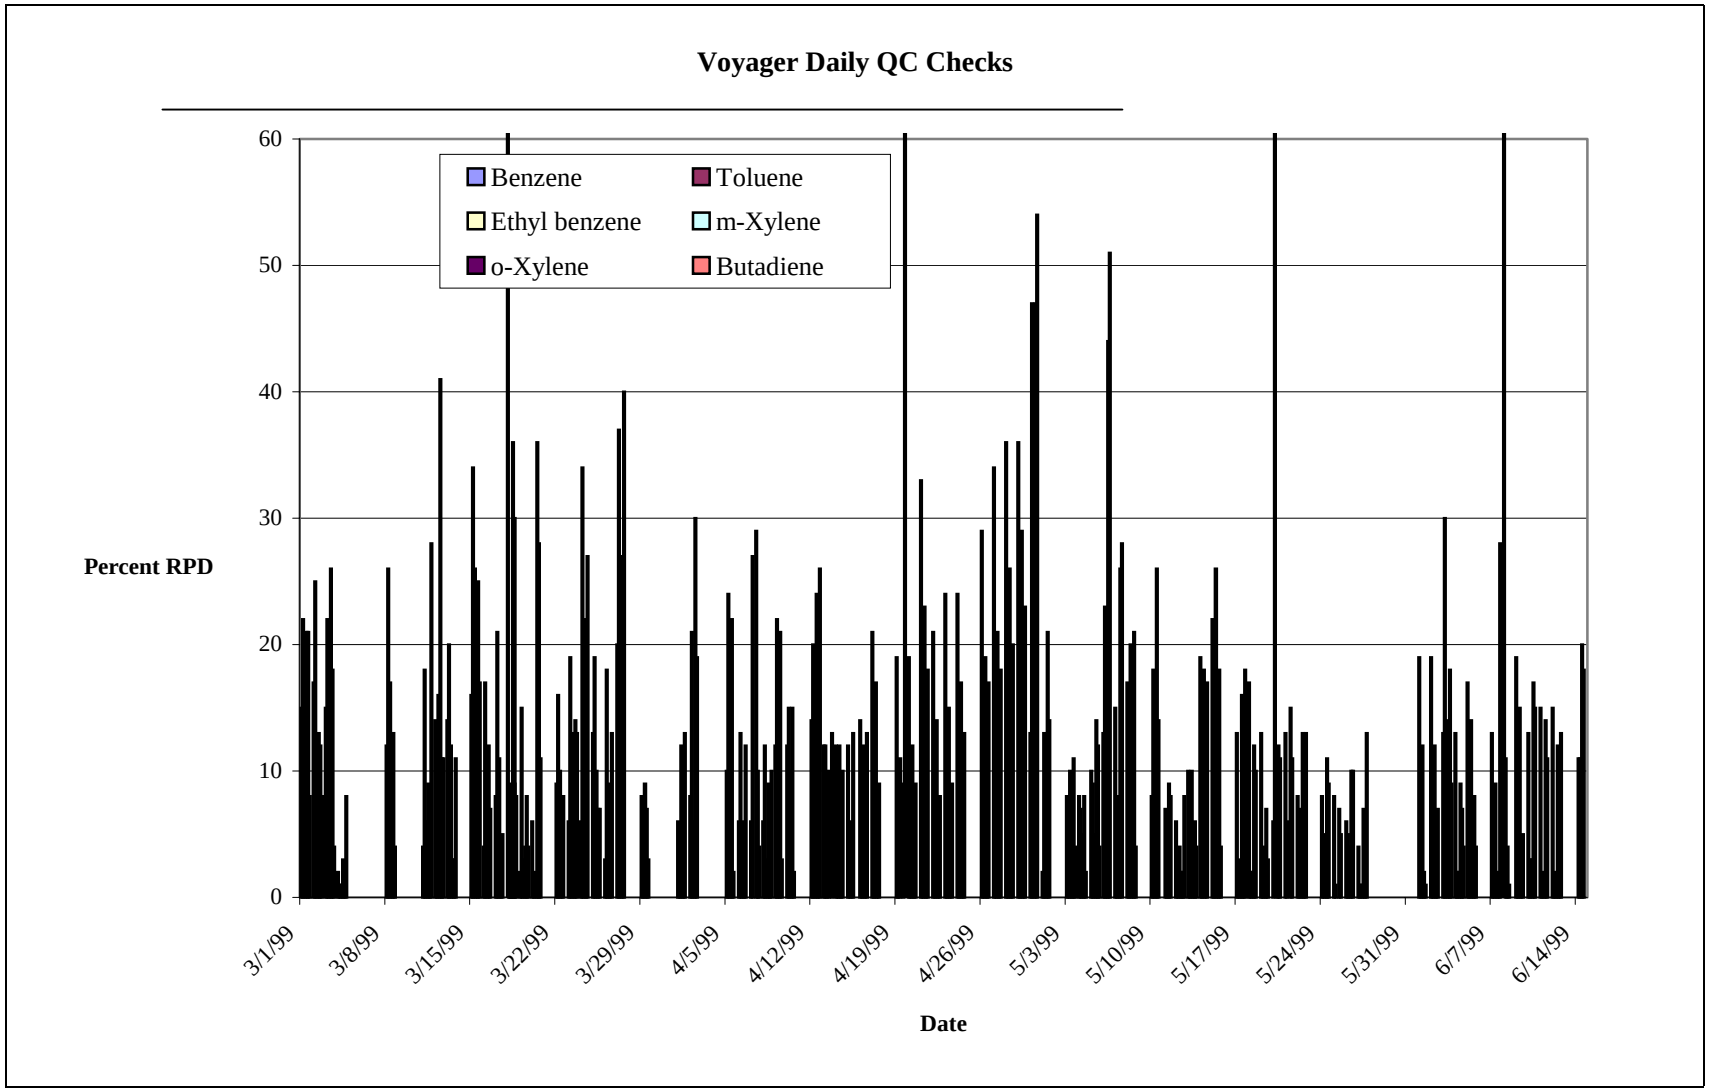

Figure 9.4. Subset of Daily QC Check Data

Relative Percent Difference (%)	Benzene	Toluene	Ethyl benzene	m-Xylene	o-Xylene	1,3-Butadiene
n=264	15.8	13.4	12.1	12.7	14.1	10.1

9.4.2. Field Instrument Calibration

Except for the Voyager GC, the real-time field instruments were all factory calibrated. However, some minimal checking could be conducted to provide the assurance that the unit was still operating within standard guidelines.

For the the DR2000, calibration was checked periodically using the on-board optical calibration disk. This procedure consisted of inserting the disk and commencing the internal routine that compared the current response to the pre-set calibration response. The agreement was shown as a percentage. If the agreement was greater than 10 percent, the unit should be returned to the factory for recalibration. The results of this test consistently showed that the calibration was within acceptable limits.

The PDR1000 calibration was checked daily during the zeroing process with the zero air bag. In this procedure, clean air is used to provide a zero background level in which the internal optics can be checked. This test immediately indicated that the calibration was within acceptable limits. This test always produced a positive indication that calibration was still within acceptable limits.

The aethalometer calibration function was governed by the internal sigma value, which is proportional to the absorption coefficient of black carbon. This value was supposed to be fixed at the factory prior to shipping and would not therefore require adjustment. However, it was determined after the field program was completed that the sigma value had been set incorrectly from the beginning. The sigma value in place during the field program was 21, while the correct value should have been a value 16, or a factor of 1.31 too high. The result of this incorrect value was to produce a consistent low bias in the data. However, compared to other uncertainties surrounding the diesel emission estimate, this uncertainty is not significantly different from the error bounds of the other measurements, which were generally between ± 30 to 50 percent.

Among the uncertainties associated with diesel emission estimates are the lack of agreement on the actual definition of diesel exhaust, and the correct way to measure it. There is no one method for completely measuring diesel exhaust, but rather a number of ways to measure the carbon associated with it. The definitions of these carbon fractions are all operational and depend solely on how the analysis is conducted. The main analysis that is conducted is thermal optical reflectance (TOR). The various fractions of carbon that are analyzed in this method are carbonate

carbon, volatile carbon, organic carbon, several fractions of elemental carbon, and pyrolyzed carbon.

The PEC analysis provided by the aethalometer produces a value for black carbon that is not included in this set of carbon fractions. Since most definitions of diesel exhaust are based on the TOR method, various cross-calibrations have been performed that provide for a comparison function that goes into the sigma value in the aethalometer so that the data are comparable to the other sets of measurements.

However, the TOR method is fraught with uncertainties since the definintion of the various carbon fractions are operational, each laboratory that produces data can produce a different set of carbon fractions. The net result is a wide uncertainty in not only the identification of the fractions but the quantitation of those fractions. Since these major uncertainties in the carbon fractions is incorporated into the value of sigma, this leads to a large uncertainty in the diesel exhaust value.

An additional source of uncertainty associated with the diesel value lies the determination of the percentage of diesel exhaust that is elemental carbon. The value that was used for the risk assessment was a conservative 64%, which was obtained from CARB and the South Coast AQMD. Other literature values range form 17% to 90%. Most calculations are based on a large mix of primarily on-road diesel vehicles. However, it has been shown that each type of carbon aerosol effectively has its own mix and that a site-specific sigma value should be developed for use with the aethalometer. Without an in-depth study of the absorption characteristics of the carbon fraction and a comparison with the usual operational definitions of the carbon fractions, the value of sigma has a high level of uncertainty associated with it.

Other uncertain factors relating to diesel exhaust are the possible presence of different carcinogenic PAH compounds. While these compounds were measured directly in this program, the connection between those species and risk from diesel has not be made. This lack of connection provides for another layer of uncertainty around the aethalometer results.

The conclusion is that, given the conflicting approaches for quantifying diesel exhaust, the aethalometer data incorporate a high degree of uncertainty and should be viewed carefully.

9.4.3. Field Sampler Quality Assurance

9.4.3.1. Sampler Flow

The manual and automated integrated samplers were checked on a regular basis to determine the consistency of flow rates. Due to the problems of temperature dependence of the flow rates for the VOC samplers, these units were checked several times a day and adjustments made as necessary. In most cases, the flow either changed very little or changed dramatically, indicating a larger problem than temperature dependence. These changes were noted in the daily field sheets. Each set of data was evaluated prior to being sent out for analysis, following receipt of the data analysis, and prior to being incorporated into the database. Therefore, any problems in the data collection were weeded out.

Figure 9.5 shows a subset of the flow precision data collected from one sampler over a brief period of use. The data show that the agreement between the beginning and end of the day is within the nominal specification of ±10% with initial calibration value.

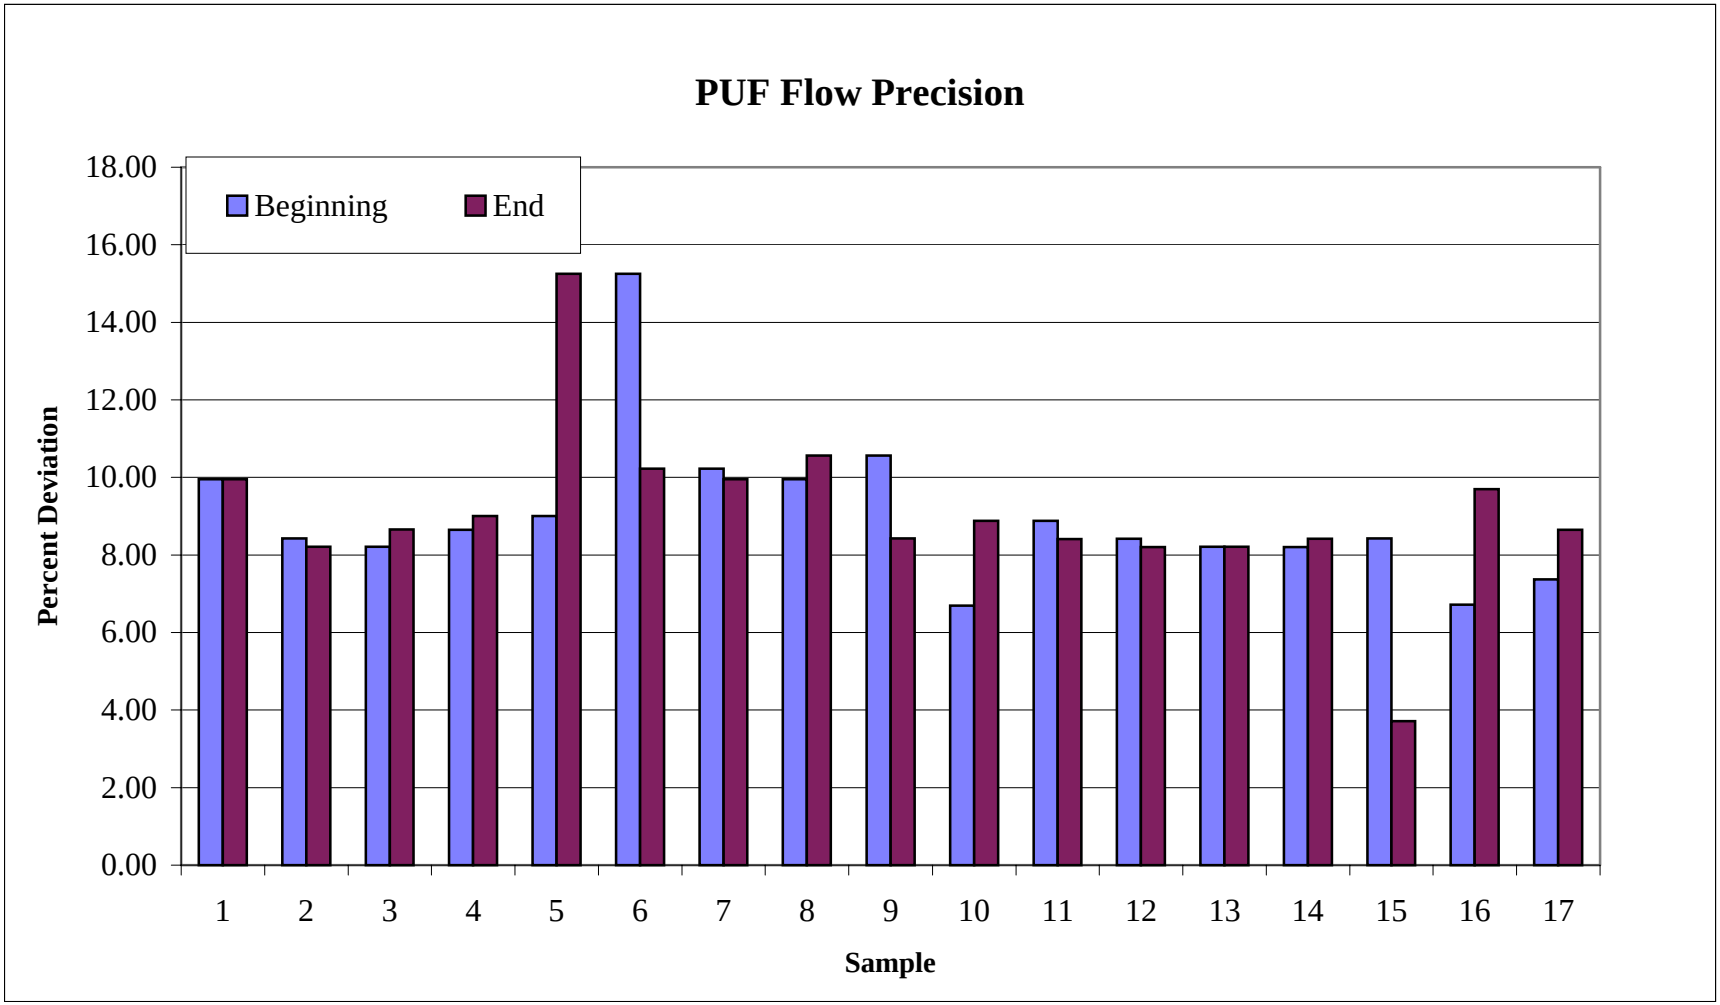

Figure 9.5. Example Flow Precision for PUF Sampler

9.4.3.2. Field Blanks

Field blanks were collected periodically to assess the potential for contamination of the samplers. Table 9.14 shows the average of detection of these field blanks. These values are close to the detection limits for each of the compounds and are on average much lower than the average of the field results. The small number of these detections in the overall number of blanks suggests a minimal impact from any contamination. Therefore, there is no substantial impact to the data quality from these low-level contaminations.

For TO-13 field blanks, there were no detections of target species other than naphthalene, which is a common contaminant in this type of sample media. The net effect of this contamination was an effective detection limit a factor of 5 higher than would have been the case in the absence of this contamination.

Table 9.14. Detected Results from Field Blank Analyses

Compound	Conc. (ppbv)	Count
Acetaldehyde	0.06	6
Acetone	0.14	2
Acrolein	0.37	6
Benzaldehyde	0.02	4
Benzene	0.13	1
Carbonyl Sulfide	2.27	4
Formaldehyde	0.42	7
Freon 11	0.16	2
Hydrogen Sulfide	4.17	2
i-Butane	0.22	2
i-Pentane	0.29	2
IsoButene	0.32	3
m,p-Xylene	0.15	5
n-Butane	0.60	3
n-Heptane	0.23	2
n-Hexane	0.31	3
n-Octane	0.22	1
n-Pentane	0.44	2
o-Xylene	0.17	1
Propane	1.30	3
Tetrahydrothiophene	2.11	3
TNMHC	34.88	3
Toluene	0.23	8

9.4.3.3. Field Duplicates

Field duplicates were performed on a periodic basis to assess the precision of the sampling process. Table 9.15 contains the results of these tests, from a compilation of analyte by analyte comparisons. The data show that 77% of the detected compounds were within the general ±50%

criterion for field duplicate samples. These data show that the sampling precision is adequate for the data's intended use.

Table 9.15. Field Duplicate Summary

RPD Range	Percent
-200%	1.9
-175%	2.8
-150%	2.6
-125%	2.0
-100%	1.9
-75%	4.9

100%	1.8
125%	1.1
150%	1.1
175%	1.1
200%	0.0

9.4.4. Laboratory and Analytical Data Issues

9.4.4.1. Sample Hold Time

Sample hold time became a critical issue due to a large number of exceedances that were not reported promptly and that potentially compromised a large portion of data. The situation arose at EAS was that due to laboratory overload, many sets of data were not reported in a timely fashion, thereby allowing a number of other quality issues to occur without detection. The major problem that arose was the exceedance of sample hold time as specified in the CMP Work Plan. Since the turnaround time agreed to initially was not met, a review of the data could not conducted in a timely fashion. The net effect was that although substantial support exists in the literature for a longer hold time for various samples, the exceedances of the agreed upon hold time specified in the CMP was grounds for qualification of the data.

Table 9.16 shows an analysis of hold times as reported by EAS for the period of October 1998 to March 1999. The table shows the number of days that the samples exceeded the contract hold times. For all methods, a large number of missed hold times were reported. While some of the hold times as specified in the CMP Work Plan may have been conservative; however, since the criteria were clearly specified, these data were outside of bounds. In particular, the BTEX data from TO-14 and the TO-14 FID could support a 30 day hold time as suggested in the outside

literature, but other methods such as TO-11 are less forgiving. Regardless of these factors, the net effect was that these data were considered to be of a lower quality due to the missed hold times, and were all flagged in the data base system. These data were excluded from the data set used in the risk assessment calculations. This lapse caused a considerable impact to the quantity and quality of the data set available for use in the program for evaluation of impacts to the community. The net result of this problem was the removal of EAS as the contract laboratory and the substitution of Air Toxics in its place. A high degree of scrutiny was made on the subsequent data so that this lapse would not occur again.

Table 9.16. Missed Hold Times

Method	Ave Days	Count	Max Days
TO11	6	61	47
TO13 FS	6	13	10
TO13 SIM	16	62	22
TO14 FID	11	96	27
TO14 GCMS	16	94	41
TO14 TRS	1	2	1

9.4.4.2. Sulfur compounds-stability

Hydrogen sulfide is known to be unstable in Tedlar bags over an extended period of time, ranging from 4 hours to 48 hours, depending on the matrix. For ambient air, the commonly accepted value is 48 hours from sample collection to analysis. For this reason, the hold time specified was 48 hours after receipt. However, over time it was found that the use of Tedlar bags for the integrated sampling was unsatisfactory as seen from the large discrepancy in the field analysis results as generated by the Jerome hydrogen sulfide sensor compared to the results obtained from the laboratory analysis.

Figure 9.6 shows a plot of laboratory and field analysis data over the project time frame. Over the period from October 1998 to April 1999 in which samples were collected in Tedlar bags, the laboratory data are mostly non-detect (the 0.5 ppbv value shown is the result of the database substitution of one-half the detection limit for non-detects).

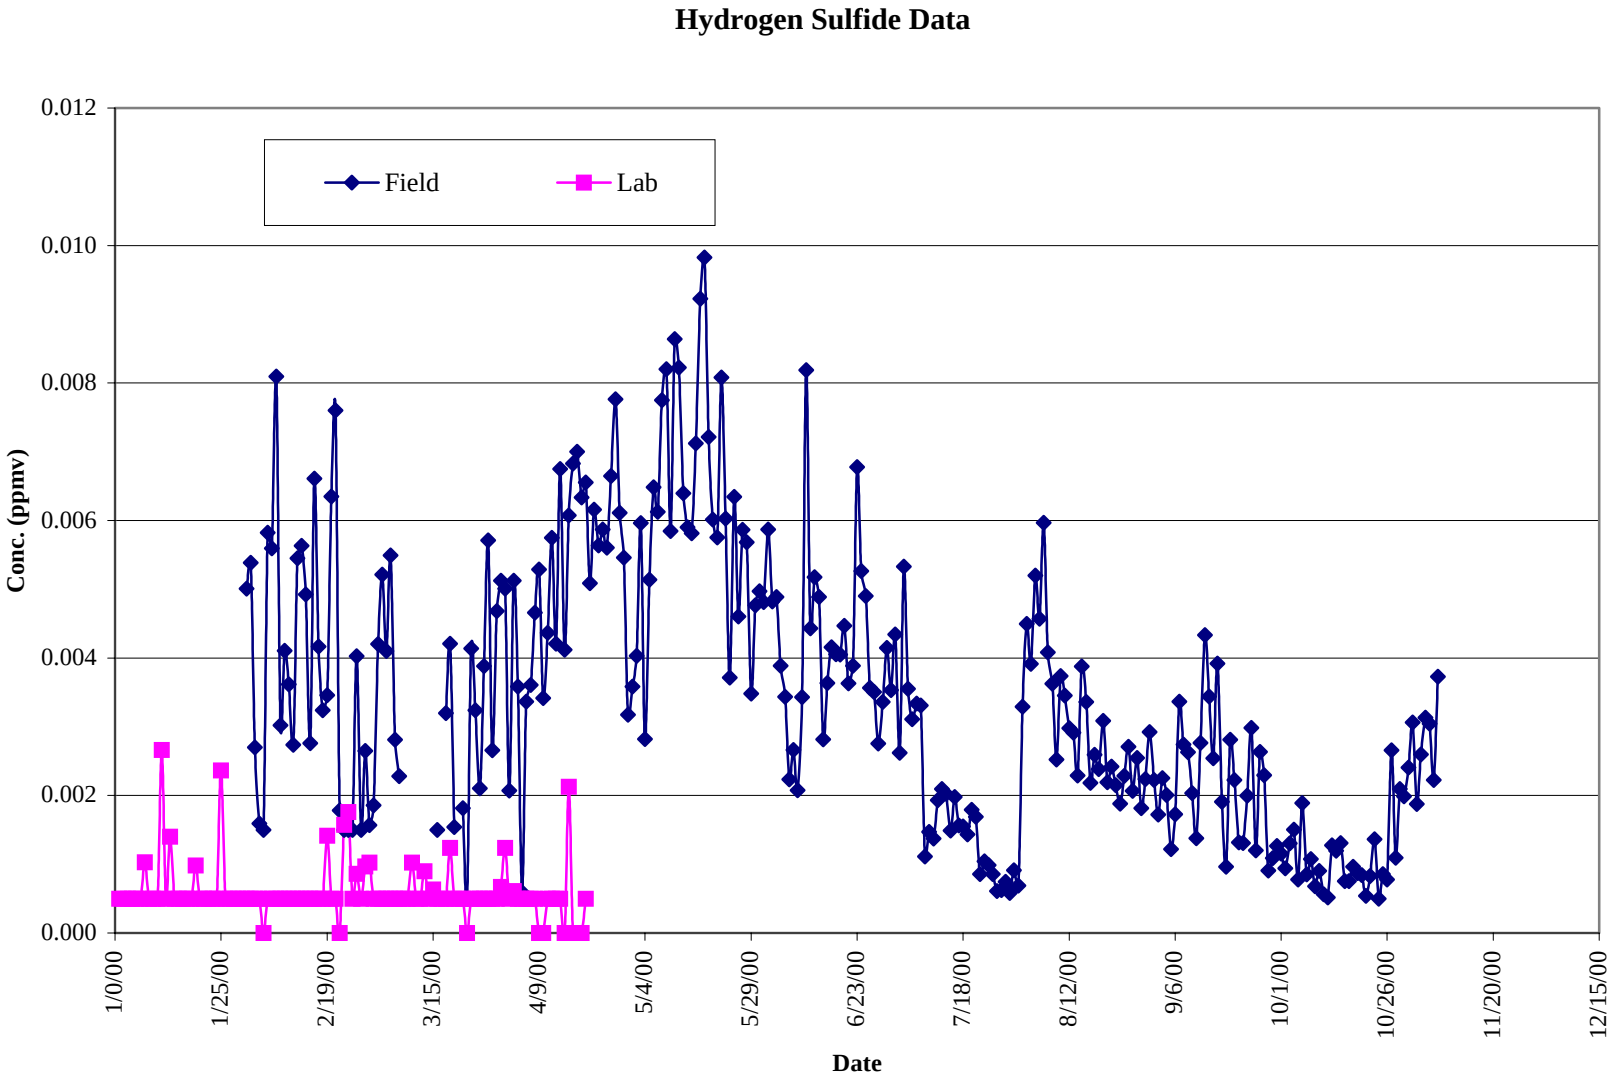

Figure 9.6. Comparison of Field to Laboratory Data for Hydrogen Sulfide

However, for this sample period, the disparity is seen in the average value from field analysis of 3.9 ppbv analysis compared to the laboratory analysis value of 0.6 ppbv.

The suspected reason for this disparity was the use of Tedlar bags in the sampler boxes. The sampler boxers were often out in the sun, resulting in heating of the bags and sample degradation. Although no specific testing was conducted to further explore this issue, sulfur sampling was discontinued after April 2, 1999. As a result of this finding, the laboratory-derived hydrogen sulfide data collected over the first part of the project was not used. The field-analysis data was deemed correct and was used for various purposes throughout the program. Part of the confidence in these data lies in the frequent factory recalibration conducted on the two Jerome instruments.

9.4.4.3. GC/FID vs. GC/MS

During the preconstruction and early excavation phases of the project, GC/FID analyses were conducted for hydrocarbon detection, along with GC/MS analysis for Chemical of Concern analysis. While the two analyses should show a good agreement, a close examination of the two sets of data for common analytes shows a bias towards high values in the GC/FID data.

Table 9.17 shows the BTEX averages and average differences of 48 pairs of results at a single location (Fire Station) for the period from November 13, 1998 to March 13, 1999.

Table 9.17. Comparison GC/FID to GC/MS

	Benzene	Toluene	Ethyl benzene	m,p-Xylene	o-Xylene
FID (ppbv)	1.59	2.37	1.30	1.67	1.01
MS (ppbv)	0.93	1.23	0.08	0.21	0.10
RPD (%)	80%	65%	138%	128%	117%

These data show that across the board, the GC/FID data overestimated the BTEX concentrations, as represented in the high relative percent difference between the two numbers. In comparing these two data sets, generally, the GC/MS analysis is considered more accurate than the GC/FID analysis because of the higher resolving power of its MS detection, and because the GC/FID data can suffer from unknown interferences. Therefore, the GC/MS data is considered of greater value and was used exclusive of the GC/FID data for the risk assessment determination.

9.4.4.4. Acrolein

A key componet for the noncancer effects from diesel exhaust was identified as acrolein. Therefore, this compound was of particular interest. The method used for sample collection for acrolein was thought to be adequate based on EPA methodology. However, a data assessment following the initial period of excavation suggested that the acrolein data were likely incorrect, probably due to losses in the sampling media. In addition, in January 1999, a new version of

EPA Compendium Method TO-11, which was called TO-11A, was put forth, and in it the statement was made that acrolein can not be adequately sampled using the DNPH coated silica gel tubes that was in current use. The finding was that due to the acidic matrix of the DNPH, the derivative that is formed decomposes and cannot be accurately quantified, leading to a low bias in the result. This problem had previously been seen in stack testing, but had not been fully explored for ambient air. It was decided that an alternate way to sample for acrolein needed to be found. The effect of this discovery was that the data collected from October, 1998 to April, 1999 were incorrect and could not be used.

An alternative method developed by Air Toxics Limited was implemented based on their initial laboratory method development. However, following several weeks of sampling, initial data review of data from Air Toxics showed some very high levels of acrolein compared not only to previous data, but to other literature data from around California. These outside data suggested typical ambient levels should be much lower than what was being seen in the Avila Beach samples. While these outside data were likely also flawed due to their reliance on the DNPD method, the actual concentrations detected were of concern.

For comparison between the old and new method, Figure 9.7 presents all the acrolein data, demonstrating the difference in the two methods.

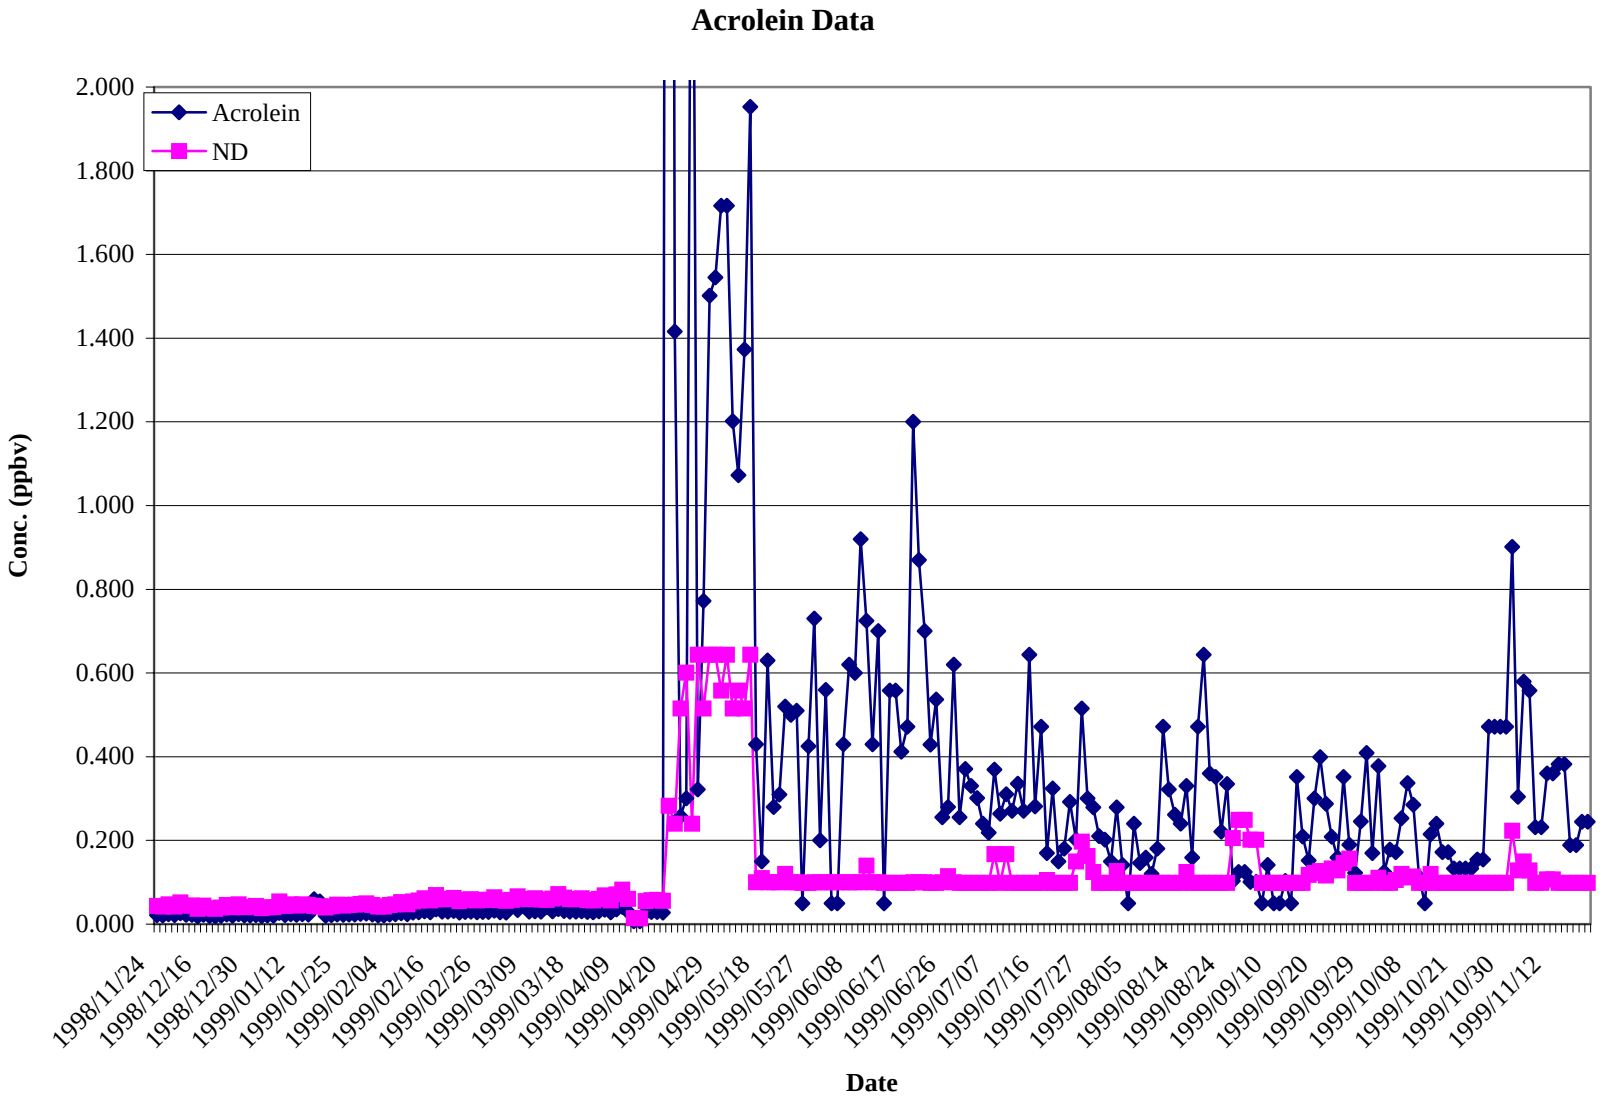

Figure 9.7. All Acrolein Data

In order to collect usable data, various tests were conducted in order to assure a correct evaluation of acrolein. Air Toxics Limited, the contract laboratory that replaced EAS and began operations in mid-April, had previously investigated the acrolein degradation problem and recommended the use of the Summa canister for the sampling. Their work indicated that detection limits down to 0.1 ppbv could be achieved.

Three types of tests were conducted: laboratory test, hold time tests, and sampler tests.

- Laboratory tests

  The first set of tests was conducted to evaluate the possible losses from the normal sorbent sampling using TO-11A. In this test, a set of DNPH sorbent tubes were spiked with a standard and analyzed periodically over 72 hours. The data are shown in Table 9.18 and Figure 9.8. These data clearly demonstrate the rapid degradation of acrolein in the TO-11A sorbent method.

Table 9.18. Acrolein Stability Data

Time (hr)	Mass	% Loss
0	35	-
1	24	32.1%
2	20	43.4%
4	20	43.4%
7.5	20	43.4%
16	19	46.2%
24	18	49.1%
48	14	60.4%
72	13	63.2%
Triplicate Samples Average		

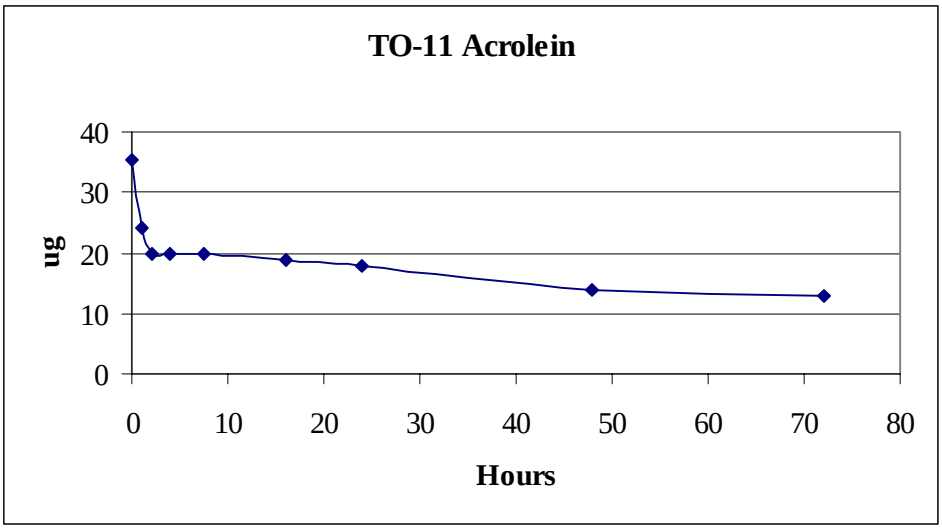

Figure 9.8. Plot of Stability Data

- Hold Time Study

  Since it was clear that the sorbent was not appropriate, tests were conducted to evaluate acrolein stability in Summa canisters. To do this, three canisters were spiked with 5 ppbv acrolein and repeatedly analyzed over 18 days. Figure 9.9 shows the results on the basis of area counts. This data set shows adequate stability for the standard 14 day hold time for canister samples. The solid symbol in the plot shows the analysis data point, and the error bars indicate the estimated uncertainty in each value based on a 10 % variability. The data points all show a consistent value within that acceptable error bounds, suggesting good stability in the canister.

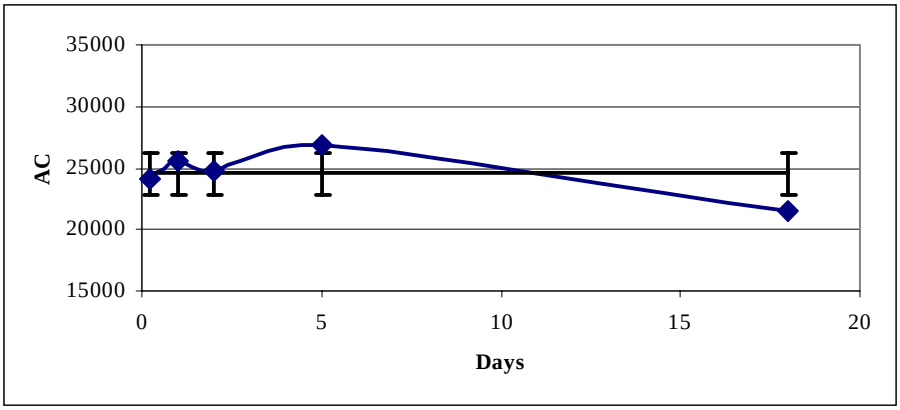

Figure 9.9. Hold Time Study Data

- Sampler Tests

  In these tests, the field samplers, or various components of the sampler, were sampled with clean air following normal sample collection. The data in Table 9.19 show the carry over from the field samples on a consistent basis.

Table 9.19. Results of Sampler Tests

15-Jul	ppbv
System 17	0.24
8-Aug	
System 5	0.13
System 17	0.16
Air	ND
Flow cont.-UN01	0.24
11-Sep	
Pump-17	0.27
Pump-5	0.33
Filter	0.27
Flow cont.-DR01	0.69
Ave.	0.29

These data show that the clean air which had flowed through the sampler previously used to sample ambient air had detectable levels of acrolein. The 0.29 ppbv represents the average carryover value from the sampler. The overall acrolein field sample average was 0.45 ppbv, and with a carryover value of 0.29, it is shown that acrolein is quite "sticky." Daily values from samplers with exposed flow controllers (that is, used previously) are therefore suspect and warrant a qualification of the complete acrolein data set to that point.

Following these tests, it was found that the flow controllers required a daily cleaning. After this action, concentrations appeared to stabilize suggesting a possibly useful method. However, since the time and resources were not available for a complete study of the problems, it was determined that these data should not be utilized for risk determination. The net result of these tests was an understanding of the problematic nature of acrolein sampling and analysis, and a clear conclusion that the data were of insufficient quality to use in the risk assessment program.

9.4.5. Spikes and Internal Laboratory QC

9.4.5.1. Blanks

Standard laboratory protocol for both EAS and Air Toxics was to analyze system blanks on a daily basis prior to analysis. If any result was greater than the detection limits, the system was

adjusted and re-run until clean. For the VOC analyses, this procedure was not difficult in that there was no sample media to deal with. However, for the TO-13 SVOC and TO-11 carbonyl analyses, both of which utilize sorbents, there was greater potential for laboratory contamination to affect the final data. The laboratory data all showed acceptable blanks for TO-14 for BTEX and sulfur species. Tables 9.20 and 9.21 show the results of blanks for TO-11 and TO-13. These levels are not significant and were found only on a limited number of sample media. Therefore, they did not affect the data quality.

Table 9.20. TO-11 Laboratory Blank Data

Compound	ug/sample
Formaldehyde	0.17
Acetaldehyde	0.12
Benzaldehyde	0.40
Benzaldehyde	0.11
Hexaldehyde	0.22

Blanks	ug/sample
Naphthalene	2.8
Acenaphthene	0.52
Pyrene	3.0
1,1'-Biphenyl	0.57
Chrysene	0.30

9.4.5.2. Internal QC

Standard EAS practice for internal quality control was to perform spike analysis and to duplicate spike analysis on a sample batch basis. The duplicate spike analysis was in lieu of duplicate samples for precision determination.

Tables 9.22 to 9.25 show the results of 30 sample batches, all showing acceptable spike recovery and duplicate spike analysis precision.

Table 9.22. EAS Internal QC for TO-14

Percent	Benzene	Toluene	Ethyl benzene	m-Xylene	o-Xylene
Spike Recovery (%)	96.60	102.1	96.4	90.3	90.1
Duplicate Analysis (%RPD)	5.60	4.2	5.7	7.0	8.3

Table 9.23. EAS Internal QC for TO-11

	Formaldehyde	Acetaldehyde	Acrolein	Acetone	Propionaldehyde
Spike Recovery (%)	92.6	90.8	90.3	94.8	89.4
Duplicate Analysis (%RPD)	4.5	4.8	7.1	3.6	5.1
	Butyaldehyde	Methyl ethyl ketone	Benzaldehyde	Valeraldehyde/ Cyclohexanone	Hexaldehyde
Spike Recovery (%)	94.2	89.9	93.3	86.1	94.4
Duplicate Analysis (%RPD)	3.4	5.3	3.8	4.9	7.4

Table 9.24. Internal QC for TO-13

	Acenapthene	Pyrene
Recovery (%)	55.2	48.8

Table 9.25. EAS Internal QC for Sulfur Analysis

	Spike	
Percent	H2S	DMS
Spike Recovery	112.03	104.85
Duplicate Analysis (RPD)	8.41	8.52

9.4.5.3. Laboratory Duplicates

For Air Toxics, the measure of analysis precision was performed using duplicate analyses of field samples. Table 9.26 shows the results of these analyses. The standard criterion for this analysis was an RPD of ±30%. The data show that 88% of the duplicate analyses had an RPD of less than 25%, indicating adequate laboratory precision.

Table 9.26. Duplicate Analysis Data

RPD Range	Percent
-200%	0.0
-175%	0.0
-150%	3.4
-125%	0.1
-100%	0.0
-75%	0.6
-50%	2.2
-25%	11.8
0%	74.7
25%	1.2
50%	3.9
75%	0.0
100%	0.1
125%	1.6
150%	0.0
175%	0.1

9.4.5.4. Surrogates

Method surrogate data were not recorded for input into the database, but were reviewed as part of the data package for each submission. If any internal surrogate was out of specifications, this would have been noted in the laboratory narrative. There were less than five instances of this occurring, due to both the simple ambient air matrix and the quality of the laboratory analyses. As a result, no qualification of the data was necessary due to surrogate exceedances.

9.4.6. Results of Laboratory Quality Assurance

An overall review of laboratory quality assurance shows that the internal quality assurance for both EAS and Air Toxics was acceptable. Therefore, the data provided to the CMP were of sufficient quality for a valid risk assessment.

9.4.6.1. Audit Results

An audit of field sample systems was conducted on November 12 and 13, 1999 of both the integrated and real-time data collection efforts. Audit findings included the following:

- Field GC accuracy is adequate, although not what was expected given the system performance and QA program associated with it;
- Field precision is adequate, as noted from the comparisons between the field audit samples and the regular samples;

- Laboratory accuracy is adequate based on blind audit samples presented to the laboratory prepared by a third party.

9.5. SUMMARY OF DATA ASSESSMENT

Any field data set will have error associated with it, and this program was no exception. The above discussion presented the various quality assurance indicators that provide a measure of the usefulness of the data for the intended use. The quality assurance data needs to be judged in relation to the initial quality objectives for both measurement tools and final data quality.

There are five factors commonly considered in the assessment of overall data quality:

- *Precision*. The precision of the data set was measured using the combination of duplicate samples and duplicate analyses. The field duplicate samples provided an average RPD of less than the target of 50%.
- *Accuracy*. Accuracy is represented by a statement of how close the measured values were to the "actual" value. This was determined by laboratory spikes and field spikes. The laboratory spikes all showed an agreement within the specified ±25% true value. The audit data also support this agreement level.
- *Representativeness* is a function of the type of sample collected and where it was collected. Considering the large number of samples collected and the high level of coverage throughout the town, the representiveness for this program was very good.
- *Completeness* is measure of how many data points were collected versus the number intended to be collected. For this program, the completeness factor was above 90%.
- *Comparability* relates to the ability of the data sets to be compared to other standard programs. The use of standard EPA methods and accepted testing methods provided a high degree of comparability.

The combination of these factors led to the conclusion that the data set was of an acceptable quality for its intended use in a risk assessment.

10.0 CONCLUSIONS

The CMP consisted of two major phases: real-time continuous management of risk through the use of mobile monitoring instruments, and the assessment of chronic risk from both integrated sampling and real-time data. The risk assessment was conducted by SOMA Corporation using the data acquired through CMP sampling and monitoring.

This section provides a three items:

1) A summary of the overall dataset, including grand averages over the entire project period;

2) A précis of the the results of the risk assessment, and;

3) Conclusions regarding the success of the CMP.

10.1 SUMMARY OF DATA SET

In Section 7, the project time period was split into the Baseline, Preconstruction, Excavation, and Outlying Properties, and the data presented as averages for those periods. For the entire project time period, the grand averages are presented in Tables 10.1 to 10.4. Figures 10.1 to 10.4 show bar charts of these same sets of data for comparison. As with previous plots, note that the concentration scale is arbitrary in most cases.These averages were obtained from the database program and represent the entire project period.

Figure 10.5 shows a map of Avila Beach with a wind rose for the entire program superimposed over it, showing the dominant wind directions and speeds for the period that these averages cover.

Figure 10.6 shows a plot of key representative indicators for odor, dust and diesel exhaust, the parameters that were of greatest concern to the health and welfare of Avila Beach residents.

10.2 RISK ASSESSMENT SUMMARY

The full risk assessment document is included in Appendix D. In it, the conclusion is documented that the additional risk to the community was within the limits targeted by the CMP. The following text was extracted from the conclusion of the risk assessment document included in Appendix D and is reproduced here for convenience:

"The HHRA was performed to evaluate the actual and potential risks to human health from excavation activities performed by Unocal at Avila Beach…..Diesel exhaust and petroleum hydrocarbons were evaluated as the substance and chemicals of potential concern. Quantitative estimates of carcinogenic risks and noncarcinogenic adverse health effects were evaluated within the context of potential residential exposures. Risks to both children and adults were analyzed. The primary exposure pathway and route of exposure centered on airborne pathways and inhalation exposures. This emphasis was due to the physical and chemical characteristics of the substances and chemicals of concern. All significant exposure pathways involved emission and migration into air. Air was the environmental medium through which the chemical mixtures and other chemicals of potential concern were dispersed.

The less than lifetime reasonable maximum exposure excess carcinogenic risk to a resident child was calculated to be nine in one million (9×10^{-6})…. The average excess carcinogenic risk to a resident child was 6.4 in one million (6.4×10^{-6})…. The less than lifetime reasonable maximum exposure excess carcinogenic risk to a resident adult was calculated to be 3.8 in one million (3.8×10^{-6})…. The average excess carcinogenic risk to a resident adult was calculated to be 2.7 in one million (2.7×10^{-6})…. These risks for cancer due to diesel exhaust and benzene do not exceed the CMP risk management goal of 10 in a million….

Other than nuisance effects such as disagreeable odors, chronic noncarcinogenic hazards are not predicted to occur. The RME chronic hazard index for the child resident is 0.63… and the average chronic hazard index for the child resident is 0.45…. The acute hazard index for the child resident is 0.83…. A target organ analysis was not performed to further detail noncancer effects since none of the hazard indices exceeded one.

These quantitative estimates of carcinogenic risk and noncarcinogenic hazards are consistent with the stated objectives of the Community Monitoring Plan for the protection of public health. The estimates demonstrate the effectiveness of the monitoring program and controls for limiting dispersion of airborne chemicals associated with the remediation activities.

Uncertainty associated with the risk characterization results was qualitatively evaluated… and integrated to qualitatively evaluate the overall uncertainty. The overall uncertainty is moderate to high with a bias toward overestimation of risks."

10.3 EVALUATION OF THE COMMUNITY MONITORING PROGRAM

An evaluation of the Community Monitoring Program starts with a restatement of the the purpose and objectives of the program, which come from the introduction to Community Monitoring Program document. In this concluding portion of this report, each of these statements will be evaluated in terms of what this report has presented.

Purpose of the CMP

The ultimate goal of the CMP was to protect public health during remediation activities. Given the broad nature of this purpose, it can be evaluated best after examining the success of reaching the objectives of the program. This question will be revisited after examining these objectives.

Objectives of the CMP

The four objectives of the CMP were to

- Provide a framework and technical basis to monitor
- Respond to public concerns
- Implement corrective actions
- Communicate the resulting data to interested parties

Each of these objectives will be examined in turn.

Objective 1. Provide a framework and technical basis for monitoring

This objective was met successfully through the implementation of a knowledgeable staff and state of the art equipment. The staff that directed the CMP were top technical personnel and well-known in the field. The technicians were able individuals experienced in technical work and quickly learned the details of operating the various pieces of equipment. Although some problems were experienced in the laboratory front, successful efforts were made to compensate for these problems by bringing on another well-respected air laboratory.

The equipment was considered technologically advanced and current. A balance was sought between advanced capability and operational efficiency, though sometimes the maintenance overhead required for the sensitive equipment limited their flexibility. The implementation of a mobile monitoring platform was unique for this combination of equipment, which garnered attention from several outside groups.

Overall, the equipment selected and used met the objectives of providing real-time, sensitive detection of the key chemical parameters of interest.

Objective 2. Respond to public concerns.

This objective was met through several means. Several public meetings were held in which the approach to monitoring and information sharing was dessiminated. Several key personnel in the CMP project team were public agency staff whose explicit responsibility was the protection of

public health. Weekly meetings with local agencies were held to review any concerns or problems. Issues were dealt with quickly as they arose.

As noted previously, the CMP was reviewed by several state and local agencies prior to finalizing it. When completed, the CMP document was made available to any outside party.

Two phamplets were prepared and distributed to every resident in Avila Beach. These phamplets contained names and contact information so that any person could contact the appropriate person to express their concerns.

The CMT technicians were constantly available for responding to public concerns, and they were instructed to communicate these concerns to CMP management and APCD.

These efforts show the responsiveness to public concerns on both a larger public basis and on individual bases. The success of this objective was seen in the decrease in public comment and concern over the passage of the project.

Objective 3. Implement corrective actions.

This objective was met through the trigger level process and the lines of notification, as described in Section 1. Several corrective actions were implemented on the basis of exceedances of trigger levels. While only a few Notice of Violations were issued, there were other circumstances in which the enforcement authority of APCD was visible.

Objective 4. Communicate the resultant data to interested parties.

The results from the CMT data collection were communicated in several ways. First, data was posted on the Community Center bulletin board or window. Second, the CMT web site provided a description of the program and posted daily data on a regular basis. Third, any outside request was responded to and data provided upon request. Finally, the reports and documents produced in support of this program were made available to the public at APCD and the County Health Department.

After the final risk assessment, a phamplet with the results was published and distributed to every household in Avila Beach.

These efforts demonstrate a successful meeting of this objective.

Realization of the Purpose of the Community Monitoring Program

That the CMP was successful in meeting its purpose of protecting the public health during remediation was borne out by the results of the human health risk assessment. As presented in Section 10.2, the goal of an overall risk of less than 10 in one million was met. Other goals for manageing risk levels for various other populations in the town were also met, as stated above.

Through meeting the specific CMP objectives and with the results of the risk assessment, it can be concluded that the Community Monitoring Program was successful and that public health was protected throughout the remediation project.

RISK ASSESSMENT
AVILA BEACH PROJECT SITE

1.0 INTRODUCTION

Union Oil of California (Unocal) began mobilization for a large-scale remediation project in the Community of Avila Beach during the fall of 1998. The object was the excavation of petroleum-affected soil along the beachfront and property immediately adjacent to it on the south side of town. The project was anticipated to take one year. Excavation activities were initiated in March of 1999 and concluded in April of 2000. Due to the large amount of chemically affected soil to be excavated and the logistics of excavation, the San Luis Obispo County Air Pollution Control District and the San Luis Obispo County Health Department, the two local agencies charged with regulatory oversight, required extensive air quality monitoring in order to monitor and prevent potential adverse public health effects to the Community of Avila Beach. The monitoring program was formally presented and described in the Community Monitoring Program (CMP), published February 8, 1999 (SLOAPCD-SLOPHD, 1999). A Final Report containing the CMP with revisions will be released later this year.

The CMP requires the evaluation of potential health risks associated with Unocal's remediation efforts based on actual ambient air monitoring data. In compliance with the CMP, SOMA Corporation (SOMA) has prepared this risk assessment for the San Luis Obispo Air Pollution Control District and the San Luis Obispo County Health Department.

The key assumptions and methods used in the development of Human Health Risk Assessments (HHRA) are presented in the first section of this report. This risk assessment is a site-specific evaluation that incorporates all of the project activities and modifications that have been made to the monitoring program. Revisions have been

made to the monitoring program since the initial publication of the CMP. Those revisions reflect the changing nature of the project as it has progressed since the beginning of 1999. Thus, some aspects of this risk assessment differ from the February 8, 1999 version of the CMP, but are consistent with the CMP as it was revised and implemented during the course of the project.

The assumptions and methods described for conducting the HHRA are health conservative and are designed to yield overestimates of human exposure and risk. This approach is consistent with the requirements of public health agencies to ensure that potential health risks are not underestimated. The quantification of risk presented in this report is summarized for each scenario as both the average estimate of exposure and risk and the reasonable maximum estimate (REM) of exposure and risk.

The conceptual model presented in Figure 1A and Figure 1B, Conceptual Site Model Site Remediation Activities, summarizes potential exposure pathways associated with Unocal's remediation efforts at Avila Beach. The major pathways of concern are those related to the potential inhalation exposure to diesel exhaust and volatile organic compounds (VOCs). Diesel exhaust and the VOCs associated with petroleum hydrocarbons in soil are the primary sources of potential chemical exposures from the project. A possible secondary exposure pathway may occur if polynuclear aromatic hydrocarbons (PAHs) in excavated soil become absorbed to dust particles that may become airborne. A more detailed discussion of PAH-affected dust is presented in Section 2.1.3.

2.0 HUMAN HEALTH RISK ASSESSMENT: APPROACH

The HHRA presented here is an evaluation of potential residential inhalation exposures resulting from the excavation and transport of chemically affected soils at the project site. The guidance discussed in the Community Monitoring Plan (SLOAPCD-SLOPHD, 1999), including subsequent revisions and modifications, form the framework within which the HHRA was performed. The health risk calculations were performed consistent with the guidance described in the 1993 California Air Pollution Control Officers Association (CAPCOA) Air Toxics "Hot Spots" Program Revised 1992 Risk Assessment

Guidelines, and with guidance from the Office of Environmental Health Hazard Assessment (OEHHA) of the California Environmental Protection Agency (Cal EPA).

Both average and upper-bound cancer risks were estimated. Average risks were calculated by estimating exposure point concentrations based on the arithmetic mean of the data collected since the mobilization of heavy equipment on November 15, 1998. Upper-bound risks were calculated by estimating the reasonable maximum exposure (RME) point concentrations using the lower of the 95 percent upper confidence limit (UCL) concentration or the highest measured daily concentration of each chemical of concern over the same period of record. The reasonable maximum estimate is based on data that represents the 95 percent upper confidence limit (UCL) on the arithmetic mean. The 95 percent UCL is defined as, "…a value that, when calculated repeatedly for randomly drawn subsets of site data, equals or exceeds the true mean 95 percent of the time."(US EPA 1992) The calculation of the reasonable maximum exposure, as used in this report, contains many worst-case assumptions that contribute to an overall conservativeness. The underlying assumption to this approach is that if worst-case conditions do not indicate significant potential risks, potential risks under "reasonable maximum" conditions would also not exceed established levels of significance. If the quantitative estimates of exposure and risks exceed the established criteria using these conservative assumptions and methods, then more detailed site-specific information and procedures would be used to perform a more refined risk assessment.

2.1 Substances (and Chemicals) of Potential Concern

For the evaluation of potential inhalation exposures at the Avila Beach Site, the substances of potential concern (SOPC) are diesel exhaust and the volatile components of total petroleum hydrocarbon (TPH). The equipment used to excavate and transport soils (excavators, trucks, tractors, etc.) is a source of diesel exhaust. The TPH-affected excavated soils and, to a lesser degree, diesel exhaust, are sources of the volatile components of TPH and other volatile organic compounds (VOCs). Hydrogen sulfide is also included as a chemical of potential concern. The sources of hydrogen sulfide are diesel exhaust, soil, and groundwater.

2.1.1 Diesel Exhaust

Diesel exhaust is a complex mixture of over a thousand chemical compounds in gaseous, vapor, and fine particulate states. The chemical components exhibit carcinogenic and other toxicological characteristics. The particulate fraction of diesel exhaust consists of carbon soot or particulate elemental carbon (PEC) (80 to 90 percent organic and inorganic carbon), an SO_4 fraction, metals, and other aerosols; the soot is predominantly PEC particles smaller than 2.5 microns in diameter ($PM_{2.5}$). The percent carbon soot varies with the type of diesel engine, type of diesel fuel, and other operating conditions. Based on a review of the literature for the type of equipment used by Unocal, a 64 percent carbon soot fraction was found to be appropriate for characterizing diesel exhaust (South Coast AQMD 1999, STAPPA/ALAPCO 2000). Because of the complex composition of diesel exhaust, PEC data converted to a diesel PM_{10} equivalence was used as a surrogate for diesel exhaust concentrations in air. PEC has been measured continuously using an aethalometer since February 1999. The data obtained from the aethalometer was divided by 0.64 in order to convert the PEC concentration to a concentration that represents total diesel particulates.

The air samples collected with the Andersen Instruments Model AE16 aethalometer were collected through a sampling port fitted with a selective particle size restricter that limited the particle size in the air samples to 2.5 microns and smaller. Diesel exhaust is made of approximately 94 percent particulates 2.5 microns and smaller (ARB 1998). Since 98 percent of the particles emitted from diesel engines are 10 microns and smaller in diameter, the aethalometer data is corrected using a factor of 98/94 to represent the PM_{10} fraction of diesel exhaust.

The use of PM_{10} as a surrogate for whole diesel exhaust is a practice established by the Air Resources Board (ARB), under a recommendation made by OEHHA (ARB, 1998). Because the toxicity values used in the cancer risk evaluations and the evaluations of risk of adverse, non-cancer health effects were derived from whole diesel exhaust exposure studies, an evaluation of the individual components of diesel exhaust was not conducted.

2.1.2 Total Petroleum Hydrocarbons

Benzene, toluene, ethylbenzene, and xylenes are used as surrogates for the toxic components of TPH-affected soils. Because measurements of these SOPCs include indistinguishable contributions from both diesel exhaust and volatiles from TPH-affected soils, the exposures associated with TPH from soil may be overestimated.

2.1.3 Polynuclear Aromatic Hydrocarbons

Low concentrations of PAHs have been found in soil. Table 1, PAH Summary Statistics, presents PAH soil data collected at Avila Beach (Table 2-2, Avila Beach PAH Summary Statistics, SLOAPCD-SLOPHD, 1999) prior to remediation. TPH-affected soil was generally found at or below the water table and was wet and oily. This condition significantly reduced the potential for fugitive dust. Additionally, decontamination procedures were also followed before vehicles carrying soil were permitted to leave the excavation area. Overburden removal generated dust; however, this dust is not TPH-affected. Because it is unlikely that dust generated by truck traffic contains significant PAH concentrations, it is unlikely that inhalation risks associated with fugitive dust are significant. Thus, a quantitative estimate of risk was not performed; however, in order to confirm these facts a worst-case quantitative screen was performed.

The quantitative screen of PAHs was based on the assumption that the maximum detected concentrations of the individual carcinogenic PAHs presented in Table 1, PAH Summary Statistics, were representative of the soil that was assumed to be the source of fugitive dust. The maximum carcinogenic PAH concentrations in Table 1 were summed after correcting for the toxicity equivalence to benzo(a)pyrene. Table 2, Benzo(a)pyrene-Equivalent Concentrations and Slope Factors of Carcinogenic PAHs, presents the results of the quantitative transformations. These worst-case soil concentrations were used to estimate potential PAH concentrations in fugitive dust. It was assumed for purposes of this evaluation that the particle size of this PAH-affected soil is 10 microns in diameter or less and the 24-hour average airborne particulate concentration reaches the State PM_{10} 24-hour standard of 50 ug/m^3. Based on these assumptions, it was calculated that a B(a)P equivalent concentration of 1.85×10^{-5} ug/m^3 and a dibenzo(a,h)anthracene concentration

of 4 x 10^{-6} ug/m^3 would be observed in ambient air.** A risk estimate of 3.0 x 10^{-10} (i.e., a risk of three in ten billion) was calculated for potential risks to a child associated with fugitive dust based on the maximum concentrations of the carcinogenic PAHs in Table 1. This estimate of risk is insignificant, and supports the decision to preclude a detailed quantitative risk assessment of inhalation-related risks due to potential PAH concentrations in fugitive dust.

2.1.4 Hydrogen Sulfide

Hydrogen sulfide (H_2S) is also evaluated quantitatively as a chemical of potential concern. Concentrations of hydrogen sulfide have been detected periodically during the course of excavation activities. The origin of this gas monitored at the site is diesel exhaust and the natural decomposition of organic materials in soil and groundwater. The component of measured hydrogen sulfide concentrations in air from diesel exhaust is incorporated in the method used to quantitatively evaluate the noncarcinogenic adverse health effects of diesel exhaust. This approach incorporates hydrogen sulfide as a chemical component of the over one thousand chemical compounds in diesel exhaust and can not differentiate the quantitative contribution of hydrogen sulfide to potential adverse health effects. Hydrogen sulfide was monitored independently because of its toxicity characteristics and because it has a secondary source in the soil and groundwater

The independent quantification of potential adverse health effects of hydrogen sulfide that will be performed in this HHRA can result in a duplication of the quantification of potential risks. There is uncertainty in performing an independent quantification of potential noncarcinogenic adverse health effects from hydrogen sulfide that will result in an overestimate of risk. A large part of the uncertainly arises if the sampling location of the measured hydrogen sulfide concentration is not taken into consideration when

---

** These concentrations were calculated according to the following sample calculation:

$$Air\ Concentration = \left(\frac{0.37 mg}{10^9 ug}\right)\left(50 ug/m^3\right) = 1.85x10^{-8} mg/m^3 = 1.85x10^{-5} ug/m^3$$

interpreting monitored concentration results. For example, if hydrogen sulfide is measured in the excavation pit, close to newly excavated material, the source is more likely to be from soil and groundwater rather than diesel exhaust, and the potential for residential exposures is not significant due to the containment in the pit and air dilution over the distance to the residential receptors. This factor is discussed in the Uncertainty Section.

2.2 Project-Related Data

Five types of environmental monitoring data were collected at Avila Beach: 1) workday real-time data, 2) non-workday real-time data, 3) time-integrated data, 4) meteorological data, and 5) nuisance observation data. The data used for quantifying risk was based primarily on time-integrated data. Time-integrated data resulted from samples that were collected over an eight- to ten-hour period and submitted to an off-site certified laboratory for chemical analysis. The only field data used for evaluating risk was collected with the Andersen Instruments Model AE16 aethalometer and the Jerome Model 631X. The aethalometer field instrument was used to measure ambient concentrations of particulate elemental carbon associated with diesel exhaust. The Jerome was used to monitor airborne hydrogen sulfide concentrations. The chemical data for the project was entered into an Access database. Table 3, Statistical Summary Data, presents statistical summary data for the substances and chemicals of potential concern that were evaluated in the risk assessment. The data represents a period of approximately 13 months from November 15, 1998 through December 27, 1999.

Hydrogen sulfide gas was monitored continuously using a Jerome Model 631X field instrument. This instrument uses a gold film sensor to detect hydrogen sulfide from 0.001 to 50 parts per million (ppm). This approach permitted continuous monitoring of potential hydrogen sulfide concentrations in air in order to prevent exceedence of trigger levels. In addition, hydrogen sulfide was evaluated independently for potential noncarcinogenic adverse health risks. It was also included in the noncarcinogenic evaluation of diesel exhaust.

During the course of the remediation activities, some of the sampling and analysis methods initially described in the CMP to collect and analyze environmental samples were revised. Table 4, Summary of Data Sources, presents information about the methods used to collect and analyze the environmental samples that formed the basis of the data used in the risk assessment.

Although the plan for monitoring potential chemical releases during the remediation project required the collection of environmental samples on a daily basis, only data that met the project data quality objectives presented in the CMP were used in the risk calculations. To address missing data points and identify upper-bound estimates of the exposure point concentrations, the background-corrected 95 percent upper confidence limit (UCL) concentrations of the arithmetic mean are calculated from the available data for each chemical. Detailed information regarding the data collected and sample validation procedures will be discussed in the Final CMP report.

The existence of multiple sampling locations on any given day has resulted in a database that reflects a stratified sample design. Because of this, the calculation of the 95 percent UCL required the incorporation of statistical techniques that considered the effect of the stratification on the standard deviation. In addition, background concentrations of chemicals of concern were subtracted from the monitored chemical concentrations in an effort to identify chemical concentrations that are specifically associated with Unocal's remediation activities. The methods used to account for background and calculate the 95 percent UCL are discussed in the following section.

2.3 Background-Corrections to the Site Data

To account for background concentrations originating from normal public traffic patterns and other, non-excavation related sources; the project-related chemical concentrations are corrected for background contributions (Rice, 1999). This is accomplished by subtracting the mean background concentration from mean project-related concentration, then calculating the 95 percent UCL concentration.

2.3.1 Background Data

Background data was collected for the substances and chemicals of potential concern due to the presence of non-project-related sources. The use of private automobiles and trucks, natural phenomena such as wave action, fog, and wind, as well as the use of fireplaces and barbecues contribute to a background concentration of chemicals and substances that are similar to those associated with Unocal's remediation activities. The background data collected for Avila Beach are presented in Appendix A, Background Data for the Substances and Chemicals of Potential Concern. A more detailed description of background monitoring activities and the resulting data are presented in the Final Avila Beach Community Monitoring Program Report. In addition, a brief description of the local and regional factors affecting air quality in the Avila Beach vicinity is provided to aid the reader's understanding of what constitutes the "background."

Small coastal communities in San Luis Obispo County such as Avila Beach enjoy good air quality due to the relative absence of nearby industrial sources and the presence of prevailing ocean breezes. These conditions provide good dispersion and dilution of polluted air. Local pre-existing sources of target pollutants within the Avila Beach area include, but are not limited to: exhaust from automobile traffic within town and along Avila Beach Drive, evaporative emissions from parked automobiles, diesel and gasoline powered marine vessels, stationary diesel engines (pumps, generator sets etc.), restaurants, outdoor barbecues, residential fireplaces, and possibly the subsurface hydrocarbon contamination targeted by the clean-up efforts. Various stationary, area, and mobile sources within the County, and transport from sources located outside of the county, may influence background concentrations on a more regional level.

Background BTEX and PAH concentrations were measured prior to the initiation of clean-up activities between October 20 and November 13, 1998 using EPA methods TO-14 and TO-13 respectively. All BTEX and PAH background samples were collected over a 10-hour workday during the mobilization period from approximately 7:00 AM to

5:00pm. In all, thirty-eight 10-hour integrated BTEX samples and thirty-two 10-hour integrated PAH samples were collected over 10 and 11 days respectively.

The decision to use and deploy the aethalometer to monitor diesel exhaust soot levels was not made until after the initiation of over-burden removal activities during the mobilization period. For this reason, pre-project background diesel soot data does not exist in the project database. Therefore, background diesel soot levels were monitored during the excavation phase of the project on several Sundays and over the Labor Day weekend of 1999 when no project activities occurred. It is important to note that though chemically affected soils and groundwater were exposed to ambient air after excavation activities were initiated, these sources of VOCs and semi-VOCs are not sources of black carbon (diesel exhaust soot). Thus, background measurements of carbon black background concentrations measured by the aethalometer were unaffected by open excavation pits.

Hydrogen sulfide exposure point concentrations used in this risk assessment have been corrected for background concentrations. Background hydrogen sulfide data was collected over 7 days in November 1998 and February 1999 and is presented in Appendix A. Hydrogen sulfide background data were collected prior to the initiation of excavation activities. Open excavation pits represent a source of hydrogen sulfide. TPH-affected soils and ground water are potential sources (if not the dominant source) of hydrogen sulfide. Even during periods of no project activity such as weekends and holidays, open excavation pits represent potential sources of hydrogen sulfide. The exposure point concentrations employed in this risk assessment have been corrected for background.

2.3.2 Background Correction Method

The 95 percent UCL concentration is based on the difference between the project-related and background concentrations and includes consideration of the standard deviation of the difference. Copies of John Rice's evaluation of the required statistical procedures are presented in Appendix B. These relationships are given by the following formulas:

$$D = \bar{x} - \bar{y}$$ Equation 1

Where:

D = Difference of the mean of the project-related concentration, $\bar{x}$, and the mean of the background concentration, $\bar{y}$

$$S_D = \sqrt{\frac{S_x^{\,2}}{n_x} + \frac{S_y^{\,2}}{n_y}} = \sqrt{S_{\bar{x}}^2 + S_{\bar{y}}^2}$$ Equation 2

Where:

S_D = Standard error of D

S_x = Standard deviation of project-related data

S_y = Standard deviation of background data

n_x = Number of project-related data points

n_y = Number of background data points

$S_{\bar{x}}$ = Standard error of the mean of the project-related data

$S_{\bar{y}}$ = Standard error of the mean of the background data

The calculation of the 95 percent UCL is given by the formula:

$$95\%\ Upper\ Confidence\ Limit = D + Z_{1-\alpha} S_D$$ Equation 3

Where:

$Z_{(1-\alpha)}$ = 1.65 (rounded from 1.645), where α is equal to 0.05 (Gilbert 1987)

The 95 percent UCL from Equation 3 for each of the chemicals or SOPCs will be used as the exposure point concentrations for the exposure estimates and risk calculations.

2.4 Exposure Assessment and Exposure Parameter Variables

Table 5, Parameters for Estimating Exposure, presents the exposure parameters for the calculation of a lifetime average daily dose for the evaluation of excess cancer risks. A residential exposure scenario is assumed for the HHRA. Variations from U.S. EPA, DTSC, and CAPCOA default residential exposure parameters are discussed below. The evaluation of adverse non-cancer health effects is performed by comparing exposure point concentrations to both the chronic and acute reference exposure levels (RELs). This approach is consistent with CAPCOA guidelines (CAPCOA 1993). Additional details regarding adverse non-cancer health effects are presented in Section 2.6.

A 15-month exposure duration was evaluated for the estimates of excess cancer risks. This period represents the actual period of excavation, as well as the mobilization and demobilization activities from November 15, 1998 through April 2000. This site-specific exposure duration differs from the typical residential exposure duration of 30 years or a lifetime exposure duration of 70 years. The potential exposure duration at the Site was limited to the actual duration of the remediation schedule since it was assumed that it was the remediation activities that carried with it the potential for chemical exposures. All other potential exposure parameters are consistent with a residential risk assessment. Cancer risks are averaged over a 70-year lifetime. The exposure frequency for residents is assumed to be 313 days per year based on a conservative assumption that excavation activities were performed up to six days per week. This estimate of exposure frequency was calculated by subtracting 52 Sundays (the number of Sundays in 1999) from 365 days. Because of the short exposure duration, exposure estimates for a child and an adult were developed separately.

2.5 Estimates of Excess Cancer Risk

Cancer slope factors, derived from unit risk values published by the OEHHA, were used to estimate risk. The use of cancer slope factors permitted the risk assessment of children and adults independently. Table 6, Carcinogenic Toxicity Criteria, lists the cancer slope factors and unit risk values for substances of potential concern. Cancer risk was estimated for two receptor types, a child and an adult. For modeling purposes, a child is

considered a person 6 years of age or under; an adult is over 6 years. Table 7, Residential Carcinogenic Risks and Noncarcinogenic Hazard Indices: 95 Percent Upper Confidence Level Source Term – Inhalation, and Table 8, Residential Carcinogenic Risks and Noncarcinogenic Hazard Indices: Arithmetic Mean Source Term – Inhalation, present the calculation spreadsheet used to calculate the RME and average excess carcinogenic risks, respectively. The RME associated risks for the child and adult and the average excess carcinogenic risks for the child and adult did not exceed the project-related significance level of 10 in one million (10×10^{-6}) identified in the CMP (SLOAPCD-SLOPHD, 1999).

Health risks from exposures to diesel exhaust are difficult to precisely quantify using a chemical-specific approach because diesel exhaust is a complex mixture of gases, vapors, and fine particles comprising numerous compounds, most of which cannot be readily measured in the environment. The contribution of each of these components to the carcinogenic activity of diesel exhaust is not known. OEHHA has developed toxicity data for whole diesel exhaust using particulate matter as a surrogate, obviating the need to do a chemical-by-chemical risk analysis. This approach differs from the chemical-specific evaluation described in the February 1998 CMP. SOMA has calculated estimates of potential risks due to diesel exhaust based on toxicity data identified by OEHHA. Potential risks of cancer due to petroleum hydrocarbon chemical compounds are calculated based on benzene as a surrogate.

2.6 Estimates of Risk of Adverse Non-Cancer Health Effects

Hazards from both acute and chronic non-cancer adverse health effects were evaluated in the HHRA. For the evaluation of acute exposures, the maximum 10-hour time-weighted average concentration for benzene, toluene, ethylbenzene, and xylenes, were converted to equivalent one-hour data by dividing the time-weighted average concentration by a time-scaling factor of 0.7 for a ten-hour averaging time period (U.S. EPA, 1995). In the case of diesel exhaust and hydrogen sulfide, the maximum rolling 1-hour average concentration was queried from essentially continuous short-term measurements in the database. The maximum equivalent one-hour concentration was divided by the chemical-

specific acute REL (Table 9, Non-Carcinogenic Toxicity Criteria for Substances of Potential Concern) to calculate a chemical-specific RME and average acute Hazard Quotient (HQ) (Tables 7 and 8 respectively). The chemical-specific acute HQs were summed to yield a total acute Hazard Index (HI). The total acute HI was calculated to be 0.83, which is below the level at which a target-organ analysis is required. Thus, no target-organ analysis was performed.

In the evaluation of chronic exposures, annual average 10-hour time-integrated concentrations for benzene, toluene, ethylbenzene, and xylenes (see Sections 2.2 and 2.3 for details on exposure point concentrations) were used. For hydrogen sulfide and diesel exhaust, the statistical summaries of all valid data over the period of interest were used. The estimate of the annual average chemical-specific concentration (Equation 3) was divided by the chronic RELs (Table 9, Non-carcinogenic Toxicity Criteria) to calculate a chemical-specific chronic HQ. The chemical-specific chronic HQs were then summed to yield a total chronic HI of 0.45. If the total chronic HI exceeds a value of one, a more detailed target-organ analysis would be conducted. Since an exceedence was not encountered, a target organ analysis was not undertaken.

3.0 UNCERTAINTY ANALYSIS

The methods and procedures used in the HHRA result in conditional estimates of risk that incorporate numerous assumptions concerning chemical toxicity and human exposure. This situation has resulted in uncertainties that are inherent in the estimates of potential cancer risk and noncancer health hazard presented in the HHRA. The use of site-specific data reduces the uncertainty in some parameters but unavoidably leaves others.

The U.S. EPA and Cal EPA use conservativeness to purposely overestimate risk in order to address uncertainty in the quantification of exposure and toxicity data and to avoid underestimates of risk. One of the principal criticisms of the risk assessment process has been the compounding of conservative assumptions that are contained in the various methods, procedures, and toxicity criteria that biases the assessment to a yet higher level of conservativism. The relative magnitude of the uncertainties and biases must be

considered in interpreting the results of this HHRA. This section presents a discussion of the uncertainty and bias in the HHRA.

3.1 Substances (and Chemicals) of Potential Concern

An important source of uncertainty lies in the selection of the substances and chemicals of potential concern. The California Air Resources Board (ARB) has only recently classified diesel exhaust as a toxic air contaminant. As previously described, diesel exhaust was selected as a substance of potential concern because of the large number of diesel-fueled heavy equipment used in the remediation of Avila Beach. Diesel exhaust is an extremely complex mixture of over a thousand individual chemical compounds in gaseous, vapor, and fine particulate states. Particulate elemental carbon has been identified by ARB as an appropriate surrogate for diesel exhaust measurements. Particulate elemental carbon concentrations in ambient air were measured directly with an Andersen Instruments Model AE16 aethalometer field instrument.

The conversion of particulate elemental carbon to an equivalent concentration of diesel exhaust involves the use of an estimate of percent elemental carbon in diesel exhaust. On the surface, this value would appear to be a relatively easy value to identify. Unfortunately, the percent particulate elemental carbon or PEC is a value that is contingent on many different variables related to the generation of diesel exhaust. Factors such as the type of engine, type of diesel fuel used, type of lubricating oil, engine wear, load, operating speed, and engine emission controls affect the percent elemental carbon released. Due to the importance of the estimate of percent elemental carbon to the calculation of risk, the estimate of risk is subject to uncertainty from the variability of this parameter. A value of 64 percent was used in this analysis (South Coast AQMD 1999, STAPPA/ALAPCO 2000).

Benzene, toluene, ethylbenzene, and xylene (BTEX) were selected as surrogate chemicals of potential concern for the numerous petroleum hydrocarbons associated with the various fuel products that have leaked from Unocal's pipeline that connected the tank farm to the terminals at the end of the Unocal pier. The BTEX group of chemicals has

traditionally been used as surrogates for petroleum hydrocarbons. The use of these chemicals may over- or underestimates the risks associated with petroleum hydrocarbons.

Hydrogen sulfide was separately selected as a chemical of potential concern even though it is a component of diesel exhaust. This resulted in an overestimate of the contribution of hydrogen sulfide to potential noncarcinogenic hazards due to the inability to differentiate the fraction of hydrogen sulfide in diesel exhaust from the fraction of hydrogen sulfide emitted by organic decomposition in soil and groundwater. Since the fraction of hydrogen sulfide from diesel exhaust was included in the noncarcinogenic evaluation of diesel exhaust as a complex mixture, the independent evaluation of hydrogen sulfide concentrations based on Jerome data overlapped and duplicated the quantification of hydrogen sulfide from diesel exhaust.

3.2 Exposure Assessment

Receptors and exposure scenarios were identified based on the most sensitive observed receptors and land use. To the extent that actual land use and activity patterns do not conform to those evaluated, uncertainties are introduced.

3.2.1 Selection of Exposure Pathways

The potential exposure pathways quantified in this HHRA were identified on the basis of the conceptual model and contaminant fate and transport considerations. To the extent that these factors may not accurately predict the migration of chemicals at Avila Beach, uncertainty is introduced into the exposure assessment.

3.2.2 Exposure Point Concentrations

The HHRA is based on available data from the analysis of time-integrated samples collected from locations identified in the CMP. With the exception of the Andersen Instruments Model AE16 aethalometer data (surrogate for diesel exhaust) and the hydrogen sulfide (H_2S) data collected with the Jerome Model 631X, real-time monitoring data was not used to quantify risk in the HHRA. This decision was made to avoid the mathematical bias introduced by high reporting limits inherent in most field instruments

used for real-time monitoring. The reporting limit for the aethalometer for a 15-minute sample collected at 6 L/minute is 11 ng/m^3, a value sufficiently low for purposes of risk assessment. Similarly, the reporting limit for the Jerome 631X is 1 ppb (part per billion) for a 15-second sample.

A reasonably large data set representing approximately a year of data formed the basis for the calculation of the exposure point concentrations (EPC). The estimation of the EPC is affected by the sampling strategy, accuracy of sampled concentrations in representing potential exposures in the residential community, the treatment of nondetectable concentrations and high detection limits, background concentrations of diesel exhaust and BTEX from traffic not related to the remediation activities, and the location of the samplers. In the case of diesel exhaust, the identification of percent particulate elemental carbon affects the estimation of the EPC of diesel exhaust.

An obvious difficulty in evaluating chemical data for identifying appropriate EPCs is the identification of source-specific chemical concentrations. This shortcoming can result in potentially biased EPCs that will overestimate risk. For example, benzene is found in diesel exhaust, incomplete combustion of gasoline, and potentially from TPH-affected soil and groundwater. The chemical-specific concentration of benzene in air is quantified at Avila Beach by sample collection using summa canisters and chemical analysis by Method TO-14. The source of measured benzene by TO-14 is extremely important in the identification of an appropriate EPC. If the benzene originates exclusively from diesel exhaust, then the measured concentration from TO-14 should be ignored since benzene in diesel exhaust is quantified using particulate elemental carbon aethalometer data as a surrogate. In actuality, the detected benzene may originate from any single or combination of sources at Avila Beach. Acknowledging the inability to differentiate chemical-specific sources, it is assumed that all BTEX chemicals detected by TO-14 originate independently from diesel exhaust. This assumption is very conservative because it results in overestimates of risk from these chemicals to the extent that they are found in diesel exhaust.

The sample collection strategy was intended to obtain data at a location approximating the nearest residential location. In practice the sampling location of the aethalometer and the use of the Jerome instrument were used to collect data that represented maximum potential worst-case exposure concentrations. The aethalometer was installed in a mobile van and the van was generally sited downwind, immediately adjacent to the excavation activity. At these monitoring locations, the diesel exhaust sample concentrations would be close to maximum to estimate potential exposures and would likely overestimate exposures to community residents who live further downwind. The overall effect of distance from the excavation activities to the point of potential exposures within the residential community is a lowering of exposure point concentrations and resulting risks. Although still in draft status with a cautionary statement not to cite or quote, the publication entitled, Proposed Risk Management Guidance for the Permitting of New Stationary Diesel- Fueled Engines from the California Air Resources Board (ARB) documents the effect of distance on estimates of risk. In general, the highest estimates of risk occur within the first 330 feet from the source and falls off drastically (ARB 2000). The effect of distance was not taken into account in calculating risk and resulted in an overestimate of risk.

The percent elemental carbon fraction of diesel exhaust is an important parameter for the calculation of airborne diesel exhaust concentrations. The Andersen Instruments Model AE16 aethalometer was used to measure concentrations of particulate elemental carbon in ambient air at Avila Beach during the remediation activities. This measured concentration was corrected to calculate an equivalent concentration of the total particulate fraction of diesel exhaust. The calculation required a representative estimate of the percent elemental carbon fraction in diesel exhaust. Because of the numerous variables that affect the measured percent elemental carbon fraction in diesel exhaust, variability in the estimate is a given. The percent elemental carbon varies with the type of diesel engine, type of diesel fuel, and other operating conditions. A percent elemental carbon fraction of 64 percent was found to be appropriate for characterizing diesel exhaust at Avila Beach based on a review of the literature for the type of equipment used by Unocal (South Coast AQMD 1999, STAPPA/ALAPCO 2000). To the extent that a variety of diesel-powered equipment was used at Avila Beach, the use of a value of 64

percent for the percent elemental carbon may over- or underestimate equipment-specific diesel exhaust concentrations.

The Jerome Model 631X was used to monitor hydrogen sulfide on a daily basis. Ambient air in the immediate area of the excavation and directly inside the excavation pit was monitored for hydrogen sulfide. Hydrogen sulfide monitoring was undertaken to prevent acute exposures at the time of monitoring. When monitored concentrations that could lead to acute exposures were observed, engineering controls were instituted to control and lower hydrogen sulfide concentrations. The observed concentrations for hydrogen sulfide overestimate exposure and risk to the residential community. The use of maximum observed concentrations at the excavation pit for evaluating potential acute exposures to hydrogen sulfide overestimate acute hazards in this risk assessment.

3.2.3 Exposure Parameters

The exposure parameters used to estimate chemical intake are a mixture of standard upper-bound default estimates and site-specific parameters. In reality, there may be considerable variation in the activity patterns and physiological response of individuals. It is possible that the exposure parameters used in this evaluation do not represent actual exposure conditions. For example, it was assumed that excavation activities were carried out 6 days per week. In reality, 5-day workweeks were the norm, although 6-day workweeks were in evidence. Another example is the assumption that the exposure duration was 15 months. This exposure period represents the actual project duration from November 1998 through April 2000. The importance of representativeness draws attention to the incongruence of the actual time period between November 15, 1998 and April 2000, a time period of 17 months. In reality, the highest period of diesel exhaust emissions occurred during the heaviest period of actual excavation from March 1999 to December 1999, a period of 10 months. An exposure duration of 15 months considered the following conditions:

- Approximately 4 months of mobilization, from November 15, 1998 through the end of February 1999, that included activities such as equipment preparation, removal of street and sidewalk pavement, demolition of

buildings, underground and above ground utility removal, sheet pile driving, overburden excavation and removal, historical and archeological surveys, canopy installation

- 10 months of heavy excavation
- Inclement weather conditions
- Work delays due to agency reviews and permit approvals

Although the Unocal soil remediation project in Avila Beach lasted approximately 17 months, approximately 2 months were taken up by work delays from inclement weather, agency review and permit approvals and other conditions that resulted in work stoppage. An exposure duration of 15 months may slightly over- or underestimate the actual period of potential exposures due to remediation-related activities.

The collection of time-integrated data terminated on December 27, 1999 when the beachfront areas of Avila Beach were cleaned up. After December, field instruments were used to monitor air quality during field activities from January 2000 to April 2000. The rationale for the decision to change the monitoring procedures was the existence of approximately 10 months of monitoring data that provided a predictive ability for tracking air quality to avoid exceedence of trigger levels. The rationale also considered the fact that the remaining excavations scheduled for the year 2000 were all small and contained areas. These excavations were known as: 1) San Antonia, 2) Lyons-Toggazzini property, and 3) Ferris-Bachino property plumes. The outcome of this series of decisions was to use air quality data representative of the worst-case beachfront excavation areas for calculating risk during the 4-month period from January to April 2000. This approach resulted in an overestimate of risk.

The use of a less than lifetime exposure duration of 15 months also raises questions about the nature of the dose-rate relationship. In general, the use of cancer slope factors in the calculation of risk implies a lifetime exposure duration of 70 years. The calculation of carcinogenic risk for a less than lifetime exposure duration of 15 months assumes a linear relationship between risk and dose. This may not be the case particularly in the case of

children where growth and normal development occur at rapid rates. The effect of dose on childhood risks may not be linear; however, our present knowledge about the effect of dose over time does not permit us to address the concern by revising the risk algorithms currently recommended by regulatory agencies. The calculation of risk for a 70-year exposure duration would not provide a meaningful estimate of risk at Avila Beach. The method used in the Avila Beach risk assessment is consistent with US EPA and DTSC guidelines.

3.3 Toxicity Assessment

The primary uncertainties associated with the toxicity assessment are related to derivation of toxicity criteria for the substances and chemicals of potential concern. Toxicity criteria developed by Cal EPA were used to estimate potential cancer and noncancer health effects from exposure to the substances and chemicals of potential concern at the site. These values are generally derived from animal studies by applying conservative (health-protective) assumptions and are intended to protect the most sensitive potentially exposed individuals. In the case of benzene and diesel exhaust, data from human epidemiological studies were used by Cal EPA to calculate the cancer slope factors.

In the evaluation of potential noncancer chronic adverse health effects, SOMA used Reference Exposure Levels (RELs) developed by Cal EPA. RELs are concentrations or doses at or below which adverse health effects are not likely to occur in the general population from a lifetime of exposure to hazardous airborne substances. The basis for the RELs is the most sensitive relevant adverse health effect reported in the medical and toxicological literature. RELs are designed to protect the most sensitive individuals in the population by the inclusion of margins of safety (Cal EPA 1999). A key assumption to the use of RELs is that a population threshold exists below which adverse health effects will not occur in a population. The REL is an estimate of that threshold. The REL for both chronic and acute adverse health effects were used in this evaluation. The heterogeneity of a general population is a source of uncertainty.

The derivation of the cancer slope factors (CSFs) used to estimate carcinogenic risk for benzene and diesel exhaust was based on human epidemiological data. The use of human

epidemiological data decreases the amount of uncertainty in the derivation of the toxicity criteria in contrast to criteria that are typically based on animal studies. For example, it eliminates the uncertainty associated with the necessity of performing interspecies and low dose extrapolations

The CSFs are considered to be plausible upper bounds of risk at a 95 percent confidence level. Thus, there is a high probability that the true risks do not exceed these levels and are much lower than the estimated values. The U.S. EPA Carcinogenic Assessment Group states that the use of upper-bound risk estimates is appropriate for estimating the upper bounds of cancer risk, but that the lower limit of risk may be as low as zero (U.S. EPA 1989)

3.4 Risk Characterization

The methods and procedures used in the characterization of risk are consistent with CAPCOA, Cal EPA and U.S. EPA guidelines. In the case of carcinogenic risks, it was assumed that risks across various carcinogens and types of cancers were additive. This assumption results in an uncertainty in the risk assessment that may over- or underestimate risk. Synergistic and antagonistic phenomena are not fully understood for the substances and chemicals of potential concern. In the case of diesel exhaust, this issue is addressed by the use of CSF and noncancer toxicity criteria that incorporate whole diesel exhaust. By using whole diesel exhaust in the exposure experiments to derive a CSF and noncancer toxicity criteria, the interactive effects of the mixture of chemicals that constitute diesel exhaust are taken into account. Considering the large number of chemicals detected in diesel exhaust, the availability of toxicity data on whole exhaust offers an enormous advantage over the method of performing chemical-specific risk assessments. In summing the carcinogenic risks for diesel exhaust with benzene from other sources, there is uncertainty in the interactive effects of the chemical constituents of diesel exhaust and the other chemicals of TPH.

Finally, the risk assessment process brings together the various methods and procedures that have inherent uncertainties, so the results of the risk characterization step represent a compilation and compounding of all uncertainties linked to the process. The

conservativeness incorporated into the risk assessment methods and procedures are likely to result in estimates of risk that are higher than risks that may actually or potentially occur. The overestimate may be as high as one to two orders of magnitude.

4.0 SUMMARY AND CONCLUSIONS

This HHRA was performed to evaluate the actual and potential risks to human health from excavation activities performed by Unocal at Avila Beach. This section summarizes the results of the HHRA.

Diesel exhaust and petroleum hydrocarbons were evaluated as the substance and chemicals of potential concern. Quantitative estimates of carcinogenic risks and noncarcinogenic adverse health effects were evaluated within the context of potential residential exposures. Risks to both children and adults were analyzed. As indicated in the Conceptual Site Model, the primary exposure pathway and route of exposure centered on airborne pathways and inhalation exposures. This emphasis was due to the physical and chemical characteristics of the substances and chemicals of concern. All significant exposure pathways involved emission and migration into air. Air was the environmental medium through which the chemical mixtures and other chemicals of potential concern were dispersed.

The less than lifetime reasonable maximum exposure excess carcinogenic risk to a resident child was calculated to be nine in one million (9×10^{-6}) (Table 7). The average excess carcinogenic risk to a resident child was 6.4 in one million (6.4×10^{-6}) (Table 8). The less than lifetime reasonable maximum exposure excess carcinogenic risk to a resident adult was calculated to be 3.8 in one million (3.8×10^{-6}) (Table 7). The average excess carcinogenic risk to a resident adult was calculated to be 2.7 in one million (2.7×10^{-6}) (Table 8). These risks for cancer due to diesel exhaust and benzene do not exceed the CMP risk management goal of 10 in a million. The calculated RME and average estimates of excess carcinogenic risks are summarized in Table 10, Summary Residential Carcinogenic Risks and Noncarcinogenic Hazard Indices: 95 Percent Upper Confidence Limit Source Term - Inhalation and Table 11, Summary Residential Carcinogenic Risks

and Noncarcinogenic Hazard Indices: Arithmetic Mean Source Term - Inhalation respectively.

Other than nuisance effects such as disagreeable odors, chronic noncarcinogenic hazards are not predicted to occur. The RME chronic hazard index for the child resident is 0.63 (Table 7) and the average chronic hazard index for the child resident is 0.45 (Table 8). The acute hazard index for the child resident is 0.83. Noncarcinogenic RME and average hazards are summarized in Tables 10 and 11 respectively. A target organ analysis was not performed to further detail noncancer effects since none of the hazard indices exceeded one.

These quantitative estimates of carcinogenic risk and noncarcinogenic hazards are consistent with the stated objectives of the Community Monitoring Plan for the protection of public health. The estimates demonstrate the effectiveness of the monitoring program and controls for limiting dispersion of airborne chemicals associated with the remediation activities.

Uncertainty associated with the risk characterization results was qualitatively evaluated, as presented in Section 3.0, and integrated to qualitatively evaluate the overall uncertainty. The overall uncertainty is moderate to high with a bias toward overestimation of risks.

Notes:
Diesel's average air concentration (corrected for background) includes the 1.04 factor for the PM2.5 fraction to a PM10 equivalent concentration.
The maximum 10-hour average for benzene, toluene, ethylbenzene and xylene is divided by 0.7 to convert to a one-hour average maximum.

Table 9. Non-Carcinogenic Toxicity Criteria for Substances of Potential Concern

Chemical	Chronic REL (ug/m^3)	Chronic REL Source	Acute REL (ug/m^3)	Acute REL Source
Benzene	71	CAPCOA, 1993	1300	OEHHA, 1999
Diesel exhaust	5	U.S. EPA, 1999 a	50	Chronic REL x 10
Ethylbenzene	1000	U.S. EPA, 1999 b	--	--
Hydrogen Sulfide	9	OEHHA, 2000	42	OEHHA, 1999
Toluene	200	CAPCOA, 1993	37000	OEHHA, 1999
Xylenes	300	CAPCOA, 1993	22000	OEHHA, 1999

Notes:
REL - Reference Exposure Level
-- Not applicable
m^3 - cubic meter
ug - microgram

APPENDIX B

Statistical Guidance – John Rice

Correcting Upper Confidence Limits for Background

John Rice

October 2, 1999

We can view this as a standard two-sample problem (see section 11.2 of the reference below). The model is that we have n observations, $X_1, \ldots, X_n$, a sample from a population which has a mean μ_X and a sample of m observations, $Y_1, \ldots, Y_m$ from a population which has mean μ_Y. The samples have means $\bar{X}$ and $\bar{Y}$ which are estimates of μ_X and μ_Y and standard deviations S_X and S_Y. The difference $\mu_X - \mu_Y$ is estimated by $D = \bar{X} - \bar{Y}$ and we wish to quantify the uncertainty in this estimate by using an upper confidence limit. Translating into the situation of interest: the Y_i represent background observations and the X_i represent project observations.

The uncertainty in $\bar{X}$ is quantified by it's standard error, $S_{\bar{X}} = S_X/\sqrt{n}$. Similarly, the standard error of $\bar{Y}$ is $S_{\bar{Y}} = S_Y/\sqrt{m}$. The standard error of the difference is

$$\begin{aligned} S_D &= \sqrt{S_{\bar{X}}^2 + S_{\bar{Y}}^2} \\ &= \sqrt{\frac{S_X^2}{n} + \frac{S_Y^2}{m}} \end{aligned}$$

The estimated difference, D, is a linear function of all the observations, and if the number of elements in the combination is large, as it is in the case at hand, the distribution of D is nearly Gaussian, by the central limit theorem. This enables us to use the Gaussian distribution to set an upper confidence limit of the form $D + z(\alpha)S_D$, where $z(\alpha)$ is that point of the standard normal distribution which has probability α to its right. For example, for a 95% confidence interval $z(\alpha) = 1.65$.

This estimate of the background correction and the construction of an upper confidence limit does not rely on an assumption that the populations are normally distributed, as evidenced by normal shaped histograms of the observations. It relies on the central limit theorem, which says that the probability distribution of a linear combination of random variables is approximately normal. In the example at hand, the number of elements in the linear combination is in the hundreds, which should be large enough for the normal approximation to be quite good. The only exception would likely be if there were a small number of observations which were orders of magnitude larger than the others, so that excluding them would change the mean dramatically.

It does not appear to me to be necessary or reasonable to use the lognormal distribution in this situation. In a situation involving a single sample an upper confidence limit for a single mean can be derived under the assumption that the data are log normally distributed. In our situation, we are talking about two samples and similar results do not exist, to my knowledge. Even if they did, their validity would depend crucially on the assumption that the populations were log normal.

Note on Weighting Multiple Daily Samples

John Rice

October 23, 1999

Phyllis: I'm writing about how to account for the fact that on many days there were multiple samples on the Avilla project, while there was at least one sample on almost every day. This is a little more complicated than I thought initially. We have to decide not only how to weight the samples of each day, but how to go about estimating the variance of the resulting weighted average. The point of view I am going to take is that the exposure time during the life of the project is divided into daily strata and that within each stratum (day), locations are sampled. We wish to estimate average daily exposure, that average being over days and locations. I am going to use a model for stratified random sampling that says that within each stratum, locations are randomly sampled. See my book for details on stratified random sampling. In fact I imagine that the locations were not actually chosen randomly, but assume the variability was as if they were. If this is a serious limitation on what I am going to propose, we will have to get into exactly what the locations were on each day, what the set of possible locations was, etc. That will probably take a lot more time, and may well not be worth it.

Some notation:

- Let there be D days in all
- Let there be n_d samples on day d. Let N denote the total number of samples.
- Let X_{id} be the value of the i-th sample on day d.
- Let $\bar{X}_d$ be the average of the samples on day d.

The stratified estimate of average daily exposure is

$$\bar{X}_{ST} = \frac{1}{D} \sum_{d=1}^{D} \bar{X}_d \; . \tag{1}$$

That is, you just average within each day and then average the results.

Now we have to be careful about how to estimate the standard error of $\bar{X}_{ST}$. I will assume that the variability between possible locations within each day is the same from day to day. Let

$$\hat{\sigma}^2 = \frac{1}{N - D} \sum_{d=1}^{D} \sum_{i=1}^{n_d} (X_{id} - \bar{X}_d)^2 \; . \tag{2}$$

Note that those days for which $n_d = 1$ contribute nothing at all to this estimate. We are basically estimating the variability between locations within days, and there is no such information on those days. We can now estimate the variance of $\bar{X}_{ST}$ by

$$\widehat{\mathrm{Var}}(\bar{X}_{ST}) = \frac{\hat{\sigma}^2}{D^2} \sum_{d=1}^{D} \frac{1}{n_d} \tag{3}$$

The estimated standard error of $\bar{X}_{ST}$ is the square root of this quantity. It is then used in constructing confidence intervals, etc. Stratified sampling is typically more accurate than simple random sampling and this standard error will be smaller than what would be computed from the variance of the $\bar{X}_d$.

ATTACHMENT 5

Final Screening Human Health Risk Assessment for the Cliff Springs at the Former Avila Tank Farm
(McDaniel Lambert, Inc. 2007)

MEMORANDUM

To: Avila Tank Farm Collaborative Assessment Team

From: Charles E. Lambert, Ph.D., DABT
Rebecca E. Countway, M.S.

Date: November 20, 2007

Re: FINAL Screening Human Health Risk Assessment for the Cliff Springs at the Former Avila Tank Farm

Introduction

This memorandum describes the results of a screening Human Health Risk Assessment (sHHRA) evaluating possible impacts to human health from potentially petroleum impacted water seeping from the cliff springs at the former Avila Tank Farm (the Site). This assessment addresses a data gap previously identified by the California Central Coast Regional Water Quality Control Board (RWQCB) and discussed again during the June 6, 2007 Avila Tank Farm Collaborative Assessment Team (ATCAT) conference call, when existing site data and the area-by-area data needs for the former Avila Tank Farm (the Site) were reviewed. This particular recreational receptor was not evaluated in the 2005 Baseline Human Health Risk Assessment for the former Avila Tank Farm. During the call the ATCAT discussed the safety of beach users recreating at the bottom of the cliff springs, and potential contact with the spring water. This memorandum addresses this concern and finds that there are no significant risks to beach users who would have unrealistically high contact with seeps over a nine year period.

Background

The cliff springs are ephemeral, year-round, and emergent features that are present in years with average or above average rainfall (RWQCB Staff). These springs have highly variable seasonal flow volumes, however, when there is flow the volumes are so low as to make sample collection difficult (Mike Rendina, Avocet – personal communication). The water does not pool at the base of the cliffs, but rather is rapidly absorbed by the sand. The cliff springs can produce significant algal growth (see pictures below).

Chemicals of Potential Concern

Chemicals of potential concern (COPCs) for water from the cliff springs were selected based on all available sampling data for these ephemeral features. The data were provided by Avocet Environmental, Inc. in a database received via email on July 8, 2007. The database includes information on 67 cliff springs samples (including 3 duplicates) collected from February 1998 through May 2007. Table 1 presents a summary of the frequency and range of detections for all chemicals analyzed. Water collected from the cliff springs has been analyzed for total petroleum hydrocarbons (TPH), volatile organic compounds (VOCs), and polycyclic aromatic hydrocarbons (PAHs).

Views of cliff spring/seeps from a distance

Up close view of cliff springs/seeps including algal growth and lack of pooling

Data used in this screening evaluation was not subjected to a formal data usability analysis. However, laboratory data reports were reviewed and summarized for 3 of the key data usability criteria (USEPA 1992):

1. Analytical Methods and Detection Limits: Documents that the appropriate analytical methods are able to identify COPCs and that detection limits that meet risk assessment requirements.
2. Data Review: An examination of laboratory and method performance for the samples and analytes.
3. Data Quality Indicators: Data quality indicators provide quantitative measures of the completeness, comparability, representativeness, precision, and accuracy of the environmental analytical data. These indicators are assessed through the review of sampling and analytical data and accompanying documentation.

The laboratory data report summaries are included as Attachment 1, and the laboratory data reports are included as Attachment 2. Review of the complete laboratory data reports and associated electronic database found that overall, the data adequately meet the required criteria, with the following key exceptions:

1. Data Quality Indicators:
   - The only data quality indicators included in the Zymax Envirotechnology laboratory reports are surrogate recoveries. Despite the absence of other laboratory quality

control data, the results reported by Zymax Envirotechnology were included in this risk evaluation.

- Surrogate recoveries for PAHs reported by Zymax Envirotechnology for samples 38669-01 and 38669-03 were below 50% and therefore the results may be underestimated; however, the results were reported as nondetects, and included in this assessment.
- Benz(a)anthracene (BaA) was identified as detected in BC Laboratories samples 0604210-01 and -02; however, BaA was detected above the practical quantitation limit (PQL) in the method blank at the same levels as reported for the samples. Therefore, these two results were considered as non-detect (at the practical quantitation limit of 0.10 ug/L) in this screening assessment.
- Gasoline range hydrocarbons detected in Test America sample NPK3519-01 identified as "possible carryover" from previous samples, which was unrelated to the cliff springs seeps. Despite the uncertainty associated with this result, it was included in this conservative screening assessment. This result is not associated with the maximum TPH value evaluated in the risk assessment (1.7 mg/L detected in June 2006).
- No extractable TPH data (C10-C25 and C25-C40) are available for Test America samples associated with batches NPK3519 and NQA2829; the only extractable TPH analyses were for extract that had been subjected to silica gel cleanup. The impact of this "missing" data on the health risk evaluation likely is minimal, as Test America commonly reported similar TPH results for silica gel and non-silica gel extracts, and the silica gel results associated with these samples are below the maximum TPH value used in the health evaluation.
- Phenanthrene was identified as detected in Test America sample NQE3244-02; however, phenanthrene was detected above the method reporting limit (MRL) in the method blank at a level higher than reported for the aforementioned sample. Therefore, this result was considered as non-detect (at the method reporting limit of 0.0939 ug/L) in this screening assessment..

2. Chain of custody forms were not found for several of the BC Laboratories reports (batch numbers 0603215, 0604210, 0605312, and 0606525). However, the remainder of these data packages were complete, therefore all associated results were included in this screening risk evaluation.

3. With respect to analytes included in EPA 8260 and 8270 SIM analyses, some discrepancies were observed between the electronic database and the hardcopy laboratory reports. For example, methylnapthalenes were included in the Test America analyses of PAHs (8270 SIM), but were not recorded in the electronic database. The COPC summary included as Table 1 is consistent with information included in the laboratory reports.

Total petroleum hydrocarbons in cliff springs water have been analyzed in discrete carbon ranges (C4-C10, C10-C25, and C25-C40) via the gas chromatography/mass spectrometry (GC/MS) combination method, EPA Method 8015B (gas chromatography/flame ionization detector, GC/FID), and EPA Method 8015C, also GC/FID. In addition, the nature of the high molecular weight TPH fractions has been investigated by treating select duplicate water samples with silica gel to remove the polar fraction prior to analysis, or by filtering the samples to remove organic debris (i.e., algae) prior to analysis. The summary data included in Table 1 are for only the standard TPH analytical results for the carbon ranges C4-C10, C10-C25, and C25-C40 (no silica gel cleanup or filtering). Table 1 also includes data for "Sum TPH", which was created by

summing the discrete carbon range results for each sample. Some of the samples did not include data for all three carbon ranges, so the Sum TPH was comprised of only the available carbon ranges. When a carbon range was not detected, the range was included in the Sum TPH calculation using ½ of the reporting limit (RL). No aromatic or aliphatic TPH data are available for water samples from the cliff springs. They also have not been analyzed for inorganic compounds, or for semi-volatile compounds (SVOCs) other than PAHs, as hydrocarbons comprised of 20 or more carbon atoms (C20+) have a negligible (<<0.1 mg/L) solubility in water (TPHCWG 1997, Yaws and Yang 1990).

Table 1 includes the rationale for whether or not a chemical was carried forward as a COPC. Any chemical that has been detected in water samples collected from the cliff springs was included in the assessment as a COPC. Although only one PAH was detected in the cliff springs samples, all 18 PAHs were included as COPCs. The following chemicals were identified as COPCs and carried forward in the sHHRA: TPH, acenaphthene, acenaphthylene, anthracene, benz(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(g,h,i)perylene, benzo(a)pyrene, chrysene, dibenz(a,h)anthracene, fluoranthene, fluorene, indeno(1,2,3-c,d)pyrene, naphthalene, 1- and 2-methylnaphthalene, phenanthrene, and pyrene.

Dose-Response Assessment

The toxicity values used in the sHHRA are summarized in Table 2. In accordance with Cal/EPA's suggested hierarchy of sources to identify dose-response values (Cal/EPA 1992), relevant carcinogenic and noncarcinogenic dose-response values were obtained from the following sources (in descending order of preference):

- OEHHA Toxicity Criteria Database (Cal/EPA 2007)
- Integrated Risk Information System (IRIS) database (USEPA 2007)
- Total Petroleum Hydrocarbon Criteria Working Group Series: Volumes 4 and 5 (TPHCWG 1997 and 1999)

Toxicity information for TPH is available for two components of TPH: the aliphatic and aromatic fractions. Although TPH also includes NSO/asphaltenes, however, the literature is inadequate to assess the toxicity of these components to humans.[1] Most of the available mammalian toxicity data for TPH fractions, as well as individual compounds within those fractions, are for the aliphatic and aromatic fractions. The TPHCWG has derived reference doses for various carbon ranges within the aliphatic and aromatic fractions, shown in Table 3 below.

For this screening risk assessment, the most conservative reference doses for the entire aliphatic range (C5-C35, 1.0 mg/m^3) and the entire aromatic range (C5-C35, 0.2 mg/m^3) were considered as toxicity values for TPH. However, as described above, the only petroleum hydrocarbon data for the cliff springs samples are for the entire C4-C10, C10-C25 and C25-C40 carbon ranges; no aliphatic and aromatic fraction data are available. In the absence of fraction data, and in order to be health protective, TPH was evaluated assuming that it was composed entirely of the more toxic aromatic fraction. This approach also likely compensates for any additional toxicity that may be due to the NSO/asphaltene components (TPHCWG 1997).

[1] NSO refers to the fraction of oil with nitrogen, sulfur, and oxygen-containing compounds. This fraction is also referred to as the NSO/resin or the polar fraction.

Table 3. TPH Fraction Reference Doses

*Equivalent Carbon Number**	*Oral RfD (mg/kg-day)*	*Inhalation RfC (mg/m^3)*	*Critical Health Effect*
Aliphatic Fractions			
>5-6 and >6-8	*5.0*	*18.4*	*Nephrotoxicity & hepatotoxicity*
>8-10, >10-12, and >12-16	*0.1*	*1.0*	*Hepatic & hematological changes*
>16-35	*2.0*	*Not Available*	*Hepatic granuloma*
Selected Value	*0.1*	*1.0*	
Aromatic Fractions

>16-21 and >21-35	*0.03*	*Not Available*	*Nephrotoxicity*
Selected Value	*0.03*	*0.2*	

(TPHCWG 1997)

*Carbon number correlated with the retention time of constituents in a boiling point gas chromatography column normalized to the n-alkanes.

Another health protective aspect of this approach is that the toxicity of individual compounds (e.g., noncancer hazard for PAHs) was used to help derive the reference dose for a particular TPH fraction (in this case the aromatic C20-C40 fraction). In many cliff springs samples, both PAHs and TPH were analyzed, and the discrete risk from these individual compounds and as well as the TPH are included in the total determination of risk. In this way, the TPH assessment methodology results in a "double counting" of the toxicity for petroleum compounds that are evaluated individually, but also occur within a particular TPH fraction.

Conceptual Exposure Model

The USEPA (1989) defines an exposure pathway as "the course a chemical or pollutant takes from the source to the organism exposed." A complete exposure pathway requires four key elements: chemical sources; migration routes (i.e., environmental transport); potentially exposed human receptors; and routes of exposure to impacted media (e.g., inhalation of chemicals in air). All four factors are required for a complete exposure pathway; if any one factor is missing, the pathway is considered incomplete. Because an incomplete pathway does not pose a potential health hazard, incomplete exposure pathways were not included in this health evaluation.

This screening risk assessment focuses specifically on potential exposure to water seeping from the cliff springs along Avila Beach adjacent to the former Avila Tank Farm. These features are ephemeral, and do not result in actual pools of water at the base of the cliffs (Mike Rendina, Avocet - personal communication). To be exposed to this water, a person would have to have contact with the water as it flows down the surface of the cliff face. However, in order to be health protective, this evaluation considers that the springs result in hypothetical wadeable pools of water, with potential ingestion of seep-related water via collection into hands or a container. Given the unattractive nature of the mechanism for exposure to the cliff springs, the sHHRA assumes that only older children and adolescents could be exposed (aged 7 through 16). Adult supervision would prevent exposure of younger children, and adults simply would not be attracted to these features.

The resulting exposure scenario evaluated in this screening risk assessment is a ***hypothetical*** *cliff spring recreational user* who is exposed to cliff springs water via ingestion and dermal contact.

Exposure Assessment

Exposure point concentrations were based on maximum cliff springs seep water concentrations for samples collected from February 1998 through May 2007. For COPCs that were not detected, one-half the minimum detection limit was used as the EPC. The resulting representative concentrations for COPCs in water are presented in Table 4.

The exposure intake factors are derived from the equations shown below. Intake factors are used to determine the amount of COPC that each receptor is potentially exposed to via each exposure route. The intake factors (the amount of environmental medium someone is exposed to) were used to evaluate both cancer risk and noncancer hazard.

Cliff Spring Water Exposure - Incidental Ingestion

The following equation was used to quantify intake from the ingestion pathway:

$$I_w = (C_w)(IngR)(EF)(ED) / (BW)(AT)$$

where

I_w	=	intake from incidental ingestion of water for a COPC (mg/kg-d)
C_w	=	maximum concentration of COPC in water (mg/L)
IngR	=	ingestion rate (L/day)
EF	=	exposure frequency (d/y)
ED	=	exposure duration (y)
BW	=	body weight (kg)
AT	=	averaging time (d) - ED x 365d/y (noncarcinogens), 70y x 365d/y (carcinogens)

Cliff Spring Water Exposure - Dermal Contact

The following equation was used to quantify intake from the dermal contact pathway:

$$I_w = (C_w)(SA)(PC)(CF)(ET)(EF)(ED) / (BW)(AT)$$

where

I_w	=	intake from dermal contact with water for a COPC (mg/kg-d)
C_w	=	maximum concentration of a COPC in water (mg/L)
SA	=	skin surface area in contact with surface water (cm^2/d)
CF	=	conversion factor 10^{-3} (L/cm^3)
PC	=	dermal permeability constant (cm/hr) (Table 5)
EF	=	exposure frequency (d/y)
ED	=	exposure duration (y)
ET	=	exposure time (h/d)
BW	=	body weight (kg)
AT	=	averaging time (d), ED x 365d/y (noncarcinogens), 70y x 365d/y (carcinogens)

The exposure factors and associated assumptions for the exposure of hypothetical waders to the cliff springs are described below, and the resulting intake factors presented in Tables 6 and 7.

- *Ingestion Rate:* Given the actual lack of pooling water, hypothetical waders are unlikely to actually ingest water from the cliff springs. In order to be health protective, the ingestion rate for swimming, 0.05 L/day, was applied (EPA 1989).
- *Exposure Frequency:* The cliff springs are ephemeral features, emergent following rainy periods. Although Southern California's rainy season is generally considered to extend from November through March or April, the flow from the cliff springs has been observed at times throughout the year. During the recent extraordinarily wet rainy season of 2004-2005, water samples were collected from the cliff springs from mid-November

2004 through early-June 2005, or over a total of 29 weeks. Although flow from the cliff springs varies greatly from year-to-year, in order to be health protective hypothetical waders were assumed to be exposed to water from the cliff springs on two days per week for 29 weeks. This results in an exposure frequency of 58 days per year.

- *Exposure Duration:* Hypothetical waders are assumed to be local residents, aged 7 to 16, for a maximum exposure duration of 9 years.
- *Body Weight:* The mean 50th percentile body weight of boys and girls aged 7 to16 is 43 kg (EPA 1997).
- *Averaging Time:* The life expectancy of 70 years (25,550 days) was used as the averaging time for exposure to carcinogenic contaminants (EPA 2002). The averaging time for non-carcinogenic effects is equal to the exposure duration of 9 years (3,285 days).
- *Skin Surface Area Available for Contact:* Hypothetical waders were assumed to wear a short-sleeved shirt and shorts (no shoes), resulting in exposure of hands, forearms, lower legs, and feet. The resulting skin surface area available for contact is 4,093 cm^2, the average of the 50th percentile total skin surface area for males and females aged 7 through 16 years (EPA 2004).
- *Permeability Constant:* Chemical-specific, see Table 8.
- *Exposure Time*: The exposure time for hypothetical waders was assumed to be one hour per event. This is EPA's recommended swimming duration of 60 minutes per event, based on the 50th percentile value (EPA 1997).

Risk Characterization

In human health risk assessments, two different values are calculated to evaluate potential health impacts: the incremental lifetime cancer risk (ILCR) and the Hazard Index (HI). The ILCR is compared to a range of acceptable probabilities to determine whether the potential risk poses an unacceptable health threat. The USEPA currently uses an ILCR of 10^{-4} to 10^{-7} as the range of acceptable risk (USEPA 1990, 1991). The risk that is acceptable is very much dependent on site-specific characteristics that include: the number of people potentially exposed, the likelihood of exposure, the chemicals driving the risk, the future use(s) of the site, and the decisions of local risk managers including the RWQCB. A risk level of $1x10^{-5}$ is used as a point of departure for risk management decisions under Cal/EPA Proposition 65 and has been used in the County of San Luis Obispo (McDaniel Lambert 2003).

The potential for health effects resulting from exposure to a noncarcinogenic COPC is evaluated by comparing a receptor's exposure or intake level to the reference dose (RfD) of that COPC (USEPA 1989), a ratio that is termed the Hazard Quotient (HQ). If the HQ is greater than 1.0, there may be concern for potential noncarcinogenic health effects. The level of concern increases as the HQ increases above unity, although the two are not linearly related (USEPA 1989). When receptors are exposed to more than one COPC through multiple pathways, it is useful to develop a total Hazard Index, the sum of HQs across COPCs and pathways (USEPA 1986). The HI is also compared to a threshold level of 1.0.

The table below presents the ICLR and HI results for each receptor. Because the reasonable maximum exposure (RME) approach was used to quantify potential health risks, if the RME values are below acceptable limits, then all other, lesser exposures related to the Site are below these limits (USEPA 1989).

Table 8. Summary of Cliff Springs Health Risks

Receptor	Total Cancer Risk (ILCR)*	Risk Contribution	Total Noncancer Hazard (HI)	Risk Contribution
Maximum EPCs				
Hypothetical Recreational Cliff Spring User	1.7E-06	BaP ND** (45%)	0.22	Aromatic TPH (99.99%)

*1.7E-06 = 0.0000017 = 1.7 excess cancers per million people exposed.
**ND = Benzo(a)pyrene, not detected.

As shown in Table 8, the estimated cancer risk to hypothetical waders is within the 10^{-4} (1 in 10,000) to 10^{-7} (1 in 10,000,000) risk management range stipulated by the USEPA (1990), and is below the Cal/EPA Proposition 65 point of departure (10 in 1,000,000). Cancer risk at the Site is driven largely by dermal contact with nondetect concentrations of benzo(a)pyrene in cliff springs water (Table 9). Only one PAH was detected (naphthalene), therefore BaP was included in the assessment and evaluated at half the minimum report limit. Although naphthalene has been identified as a carcinogen via the inhalation pathway, it is not considered carcinogenic via the oral pathway. Given that no carcinogenic PAHs (via the oral pathway) were detected, the actual cancer risk likely is less than $1x10^{-6}$. The estimated noncancer hazards are below the level of concern of 1.0 (Table 8). Dermal contact with total petroleum hydrocarbons, as the aromatic fraction, in water is responsible for nearly the total noncancer hazard (Table 10).

Conclusions

This screening risk assessment demonstrates the cliff springs do not pose a significant risk to a hypothetical cliff spring recreational user. This recreational user was assumed to come into contact with the springs for one hour per day, 58 days per year, for nine years (ages 7 through 16). They were assumed to not only expose much of their body to the seep runoff, but also to drink the same amount a person would if they were swimming each of those 58 days per year in a pool filled with seep water. Because the cliff springs are ephemeral features that do not result in pools of water, it is very unlikely that beach goers could actually be exposed to the levels of chemicals evaluated in this screening assessment, therefore actual risks from the cliff springs are likely much lower.

Note:
LogKp = -2.80 + 0.66 logKow - 0.0056*MW (USEPA 2004, Equation 3.8)
kp = permeability constant in centimeters per hour
Carbon Group Information regarding Kow from TPHCWG, vol 3, p 33 - 38
PAH Information regarding Kow from ATSDR

Table 6
Intake Factors for Exposure Via Ingestion of Seep Water

Oral Seep Water Intake Factor (IForal):

$$IF_{oral} = \frac{IngR \times EF \times ED}{BW \times AT}$$

IF_{oral} = Oral Intake Factor, L water/kg body weight-day
IR = Ingestion Rate, L/day
EF = Exposure Frequency, days/year
ED = Exposure Duration, years
BW = Body Weight, kg
AT = Averaging Time, days

Exposure Variable	Hypothetical Cliff Spring Recreational User
IngR	0.05
EF	58
ED	9
BW	43
$AT_{carcinogens}$	25550
$AT_{nonarcinogens}$	3285

PATHWAY-SPECIFIC INTAKE FACTORS:

Chemical-Specific Intake Factors via Water Ingestion (IF_{oral}), L water/kg body weight-day

Carcinogens x BF	2.38E-05
Noncarcinogens x BF	1.85E-04

Table 7
Intake Factors for Dermal Exposure to Seep Water

Dermal Water Intake Factor (IFdermal):

$$IF_{dermal} = \frac{SA \times PC \times CF \times ET \times EF \times ED}{BW \times AT}$$

IF_{dermal} = Dermal Intake Factor, L water/kg body weight-day
SA = Surface Area, cm^2
PC = Dermal Permeability Constant, cm/hour
CF = Volumetric Conversion Factor, 1 Liter/1000 cm^3
ET = Exposure Time, hours/day
EF = Exposure Frequency, days/year
ED = Exposure Duration, years
BW = Body Weight, kg
AT = Averaging Time, days

Exposure Variable	Hypothetical Cliff Spring Recreational User
SA	4093
CF	0.001
ET	1
EF	58
ED	9
BW	43
$AT_{carcinogens}$	25550
$AT_{nonarcinogens}$	3285

PATHWAY-SPECIFIC INTAKE FACTORS:
Chemical-Specific Intake Factors via Dermal Water Contact (IF_{dermal}),L water/kg body weight-day

Carcinogens x PC	1.94E-03
Noncarcinogens x PC	1.51E-02

Attachment 1: Laboratory Data Package Reviews – Cliff Springs Seep Samples

Samples collected on February 17, 1998 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 13331-##	
	Samples: CS-1 to -4
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260) PAHs (EPA 3510 and 8270)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL); PAHs 2.0 ug/L (PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on March 22, 1998 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 14176-##	
	Samples: CS-1, -4, -5, -6
	Analyses: Filtered TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on August 19, 1998 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 14863-##	
	Samples: CS-5
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on March 7, 2001 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 23117-##	
	Samples: CS-1 to -5; OSS-1 to -4
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Filtered TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Silica Gel TPH C10-25, C25-40 (EPA 3510, EPA 3630 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on April 26, 2001 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 23656-##	
	Samples: CS-1 to -5 (entered in electronic database as CS-B, and CS-E to -H; Field Blank (not included in electronic database; ND)
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Filtered TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) - not entered in electronic database
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on February 22, 2002 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 26705-##	
	Samples: CS-2
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Filtered TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Silica Gel TPH C10-25, C25-40 (EPA 3510, EPA 3630 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL); VOCs 0.5 to 1.0 ug/L(PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on April 1, 2003 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 31230-##	
	Samples: CS-2
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Silica Gel TPH C10-25, C25-40 (EPA 3510, EPA 3630 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260) PAHs (EPA 3510 and 8270 SIM)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL); PAHs 0.1 ug/L (PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on May 6, 2003 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 31230-##	
	Samples: CS-E, CS-G
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Silica Gel TPH C10-25, C25-40 (EPA 3510, EPA 3630 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260) PAHs (EPA 3510 and 8270 SIM)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL); PAHs 0.1 ug/L (PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on January 14, 2004 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 34427-##	
	Samples: CS-A
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Silica Gel TPH C10-25, C25-40 (EPA 3510, EPA 3630 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds

Samples collected on January 12, 2005 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 38669-##	
	Samples: CS-A, CS-C, CS-G
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Silica Gel TPH C10-25, C25-40 (EPA 3510, EPA 3630 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260) PAHs (EPA 3510 and 8270 SIM)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL); PAHs 0.1 ug/L (PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds
Yes	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses; surrogate recoveries for CS-A and CS-C for Silica Gel TPH C10-25, C25-40 and PAHs below QC limit of 50% therefore results may be underestimated
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on February 9, 2005 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 38953-##	
	Samples: CS-A
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Silica Gel TPH C10-25, C25-40 (EPA 3510, EPA 3630 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260) PAHs (EPA 3510 and 8270 SIM)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL); PAHs 0.1 ug/L (PQL)
Yes No	Results given on a per sample basis Qualified Data

No	Tentatively identified compounds
Yes	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on March 31, 2005 Analyzed by *Zymax Envirotechnology* Laboratory Batch Numbers 38953-##	
	Samples: CS-A, CS-G, CS-I
	Analyses: TPH C10-25, C25-40 (EPA 3510 and GC/MS Combination) Silica Gel TPH C10-25, C25-40 (EPA 3510, EPA 3630 and GC/MS Combination) TPH C4-C10 (EPA 5030 and GC/MS Combination) VOCs (EPA 5030 and EPA 8260) PAHs (EPA 3510 and 8270 SIM)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 100 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL); PAHs 0.1 ug/L (PQL)
Yes No No	Results given on a per sample basis Qualified Data Tentatively identified compounds
Yes	Narrative explanation of qualified data/No qualified data
No	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Lab sheets include only surrogate recoveries for TPH analyses
NA	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on April 26, 2005 Analyzed by *BC Laboratories* Laboratory Batch Numbers 0504271-##	
	Samples: CS-A, CS-E, CS-G
	Analyses: TPH C10-25, C25-40 (EPA 8015C - GC/FID) TPH C4-C10 (EPA 8260 - GC/FID) VOCs (EPA 8260)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 10 to 50 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL)
Yes Yes No	Results given on a per sample basis Qualified Data: Continuing Calibration Verification (CCV) for 1,2,3-Trichlorobenzene not within limits Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note:
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on June 9, 2005 Analyzed by *BC Laboratories* Laboratory Batch Numbers 0505785-##	
	Samples: CS-A, CS-E
	Analyses: TPH C10-25, C25-40 (EPA 8015C - GC/FID) TPH C4-C10 (EPA 8260 - GC/FID) VOCs (EPA 8260)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 10 to 50 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL)
Yes Yes No	Results given on a per sample basis Qualified Data: Continuing Calibration Verification (CCV) for bromochloromethane, dichlorodifluoromethane, and 1,1,2-trichlorotrifluoroethane not within limits Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note:
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on March 31, 2006 Analyzed by *BC Laboratories* Laboratory Batch Numbers 0603215-##	
	Samples: AT-A, AT-E, AT-G and duplicates
	Analyses: TPH C10-25, C25-40 (GC/MS) TPH C4-C10 (EPA 8260) VOCs (EPA 8260)
No	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 50 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL)
Yes Yes No	Results given on a per sample basis Qualified Data: Continuing Calibration Verification (CCV) for dichlorodifluoromethane, and n-propylbenzene not within limits Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note:
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on April 27, 2006 Analyzed by *BC Laboratories* Laboratory Batch Numbers 0604210-##	
	Samples: AT-B, AT-D
	Analyses: TPH C10-25, C25-40 (GC/MS) TPH C4-C10 (EPA 8260) VOCs (EPA 8260) PAHs (EPA 8270 SIM)
No	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 50 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL); PAHs 0.1 ug/L (PQL)
Yes Yes No	Results given on a per sample basis Qualified Data: Continuing Calibration Verification (CCV) for t-Butyl alcohol not within limits Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: surrogate recovery for 1,2-dichloroethane-d4 outside limits; benz(a)anthracene detected in method blank above PQL (benzo(g,h,i)perylene and dibenz(a,h)anthracene also detected in method blank)
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)

No	Raw laboratory data

Samples collected on May 25, 2006 Analyzed by *BC Laboratories* Laboratory Batch Numbers 0605312-##	
	Samples: AT-A, AT-F
	Analyses: TPH C10-25, C25-40 (GC/MS) Silica Gel TPH C10-25, C25-40 (GC/MS) TPH C4-C10 (EPA 8260) VOCs (EPA 8260)
No	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 50 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL)
Yes Yes No	Results given on a per sample basis Qualified Data: Continuing Calibration Verification (CCV) for Naphthalene (8260) not within limits Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data
Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: surrogate recovery for 1,2-dichloroethane-d4 outside control limits/matrix interferences verified; TPH detected in method blank for Silica Gel cleaned extracts above PQL; methylene chloride detected in continuing calibration blank >0.5 PQL but < PQL
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on June 30, 2006 Analyzed by *BC Laboratories* Laboratory Batch Numbers 0606525-##	
	Samples: CS-E
	Analyses: TPH C10-25, C25-40 (GC/MS) Silica Gel TPH C10-25, C25-40 (GC/MS) TPH C4-C10 (EPA 8260) VOCs (EPA 8260)
No	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH 50 ug/L (PQL); VOCs 0.5 to 1.0 ug/L (PQL)
Yes Yes No	Results given on a per sample basis Qualified Data: Continuing Calibration Verification (CCV) for bromomethane and 2,2-dichloropropane not within limits Tentatively identified compounds
No	Narrative explanation of qualified data/No qualified data

Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: surrogate recoveries for 1,2-dichloroethane-d4 and p-terphenyl-d14 (TPH and silica gel TPH, including MS/MSD, LCS and method blanks) outside limits; diesel TPH detected in method blank for Silica Gel cleaned extracts above PQL; diesel TPH detected in method blank for TPH >0.5 PQL but < PQL
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Discrepancies between hardcopy laboratory reports and electronic database:

- VOCs not included in BC Laboratories reports with 8260 analyses but recorded in electronic database include 2-chloroethylvinyl ether and dichlorotrifluoroethane
- VOCs included in all 6 BC Laboratories reports with 8260 analyses but not included in electronic database – 1,1,2-trichloro-1,2,2-trifluoroethane (Freon 113)
- VOCs included in 4 of 6 BC Laboratories reports (batch numbers 0504271, 0505785, 0605312, and 0606525) with 8260 analyses but not included in electronic database – methyl-tert-butyl ether
- VOCs included in 2 of 6 BC Laboratories reports with 8260 analyses but not included in electronic database (batch numbers 0603215 and 0604210) – t-amyl methyl ether, t-butyl alcohol, diispropyl ether, and ethyl t-butyl ether

Samples collected on November 22, 2006 Analyzed by *Test America* Laboratory Batch Numbers NPK3519-##	
	Samples: AT-CS-A, AT-CS-B, trip blank
	Analyses: Silica Gel TPH C10-25, C25-40 (EPA 3510 and 8015B) TPH C4-C10 (EPA 8015B) VOCs (EPA 8260) PAHs (EPA 3510 and EPA 8270 SIM)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH C4-C10 50 ug/L (MRL); TPH C10-C40 94.3 ug/L (MRL); VOCs 0.5 to 50.0 ug/L (PQL) ; PAHs 0.0943 to 0.0971 ug/L (MRL)
Yes No No	Results given on a per sample basis Qualified Data: AT-CS-A detect C4-C10 TPH "result may be elevated due to carryover from previously analyzed sample"; Extractable hydrocarbons only analyzed following treatment with silica gel Tentatively identified compounds
Yes	Narrative explanation of qualified data/No qualified data
Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Laboratory control sample (LCS) 1,2,3-trichloropropane recovery outside acceptable limits; No matrix spike/matrix spike duplicates (MS/MSD) for PAH analyses due to insufficient sample volume
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on January 25, 2007 Analyzed by *Test America* Laboratory Batch Numbers NQA2829-##

Yes Yes No	Results given on a per sample basis Qualified Data: Laboratory control sample (LCS) naphthalene recovery above acceptable limits but "analyte not detected, data not impacted" Tentatively identified compounds
Yes	Narrative explanation of qualified data/No qualified data
Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: No matrix spike/matrix spike duplicates (MS/MSD) for PAH analyses due to insufficient sample volume; 1,2,4- and 1,2,3-trichlorobenzene and hexachlorobutadiene detected in laboratory blanks between MDL and MRL (J values)
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on March 23, 2007 Analyzed by *Test America* Laboratory Batch Numbers NQC3393-##	
	Samples: AT-CS-B, trip blank
	Analyses: TPH C10-25, C25-40 (EPA 3510 and 8015B) Silica Gel TPH C10-25, C25-40 (EPA 3510 and 8015B) TPH C4-C10 (EPA 8015B) VOCs (EPA 8260) PAHs (EPA 3510 and EPA 8270 SIM)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH C4-C10 50 ug/L (MRL); TPH C10-C40 94.8 ug/L (MRL); PAHs 0.0948 ug/L (MRL)
Yes	Results given on a per sample basis

Yes No	Qualified Data: Acetone detected in trip blank between MDL and MRL (J value) Tentatively identified compounds
Yes	Narrative explanation of qualified data/No qualified data
Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Laboratory control sample (LCS) nitrobenzene-d5 surrogate recovery above acceptable limit; No matrix spike/matrix spike duplicates (MS/MSD) for PAH analyses due to insufficient sample volume; methylene chloride detected in laboratory blank between MDL and MRL (J value)
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on April 25, 2007 Analyzed by *Test America* Laboratory Batch Numbers NQD3265-##	
	Samples: AT-CS-B, trip blank
	Analyses: TPH C10-25, C25-40 (EPA 3510 and 8015B) Silica Gel TPH C10-25, C25-40 (EPA 3510 and 8015B) TPH C4-C10 (EPA 8015B) VOCs (EPA 8260) PAHs (EPA 3510 and EPA 8270 SIM)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH C4-C10 50 ug/L (MRL); TPH C10-C40 95.2 ug/L (MRL); PAHs 0.0952 ug/L (MRL)
Yes No No	Results given on a per sample basis Qualified Data: Tentatively identified compounds
Yes	Narrative explanation of qualified data/No qualified data
Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Matrix spike duplicate (MSD) fluoranthene recovery above acceptable limit; 1,2,3-trichlorobenzene detected in laboratory blank above MRL
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Samples collected on May 23, 2007 Analyzed by *Test America* Laboratory Batch Numbers NQE3244-##	
	Samples: AT-CS-B, trip blank
	Analyses: TPH C10-25, C25-40 (EPA 3510 and 8015B) Silica Gel TPH C10-25, C25-40 (EPA 3510 and 8015B)

	TPH C4-C10 (EPA 8015B) VOCs (EPA 8260) PAHs (EPA 3510 and EPA 8270 SIM)
Yes	Includes all chain of custody forms
Yes	Identification of analytical methods and detection limits Detection Limits Notes: TPH C4-C10 50 ug/L (MRL); TPH C10-C40 95.2 ug/L (MRL); PAHs 0.0952 ug/L (MRL)
Yes Yes No	Results given on a per sample basis Qualified Data: Phenanthrene detected at level between MDL and MRL (J value); phenanthrene detected in laboratory blank at level greater than MRL Tentatively identified compounds
Yes	Narrative explanation of qualified data/No qualified data
Yes	Includes project quality control data (blanks, LCS/LCSD, MS/MSD) QC Note: Matrix spike duplicate (MSD) fluoranthene recovery above acceptable limit; 1,2,3-trichlorobenzene detected in laboratory blank above MRL
Yes	Definitions and descriptions of flagged data (J values)
Yes	Hardcopy of laboratory electronic files (see Attachment 2)
No	Raw laboratory data

Discrepancies between hardcopy laboratory reports and electronic database:

- VOCs included in all 5 Test America reports with 8260 analyses (laboratory batches NPK3519, NQB2770, NQC3393, NQD3265 and NQE3244), but not included in electronic database – probably because not previously included in 8260 analyses by previous laboratory: acetone, 2-butanone, carbon disulfide, 2-haxanone, diisopropyl ether, and 4-methyl-2-pentanone.
    - Acetone only analyted ever detected, at an estimated value of 4.07 ug/L (MRL = 50 ug/L) in a trip blank (NQC3393-01)
- VOCs included in only 2 (NPK3519 and NQD3265) of 5 Test America reports with 8260 analyses, but not included in electronic database – probably because not previously included in 8260 analyses by previous laboratory: tert-amyl methyl ether, ethyl tert-butyl ether, and tertiary butyl alcohol.
- VOCs included in all 5 Test America reports with 8260 analyses but not included in electronic database even though recorded for earlier laboratories – dibromochloromethane (b/c named chlorodibromoethane), 1,2-dibromoethane, and methyl-tert-butyl ether
- VOCs not included in all 5 Test America reports with 8260 analyses but recorded for earlier laboratories – dichlortrifluoromethane
- PAHs included in all 6 Test America reports (all had 8270 SIM analyses) but not included in electronic database – probably because not previously included in 8270 analyses by previous laboratory: 1-methylnaphthalene, 2-methylnaphthalene
- Test America had the following results identified as estimated values, but they are not J-qualified in the electronic database:
    - NQC3393-02 (AT-CS-B) Oil Range TPH 53.6 ug/L (MRL 94.8 ug/L)

- NQC3393-02 (AT-CS-B) C25-C40 TPH following silica gel 43.8 ug/L (MRL 95.2 ug/L)
- NQD3265-02 (AT-CS-B) Oil Range TPH 75.7 ug/L (MRL 95.2 ug/L)
- NQD3265-02 (AT-CS-B) C25-C40 TPH following silica gel 44.8 ug/L (MRL 94.8 ug/L)
- NQE3244-02 (AT-CS-B) Phenanthrene 0.0845 ug/L (MRL 0.0939 ug/L)

14176-3	CS-5 (Filtered) A	100.	180.	ND	87
14176-4	CS-6 (Filtered) E	100.	ND	ND	96

ZymaX envirotechnology, inc. is certified by CA Department of Health Services: Laboratory #1717
*PQL - Practical Quantitation Limit
**Results listed as ND would have been reported if present at or above the listed PQL.

Note: Samples were filtered prior to analysis.

Note: Analyzed by GC/MS Combination.
Note: Extracted by EPA 3510 on 05/27/98.
Note: TPH (C10-C25) quantitated against diesel fuel.
Note: TPH (C25-C40) quantitated against crude oil.

Mike Rendina
Avocet Environmental, Inc.
16 Technology, Ste. 154
Irvine, CA 92618

Subject: Unocal Avila Tank Farm, ZymaX Lab ID 38669

Dear Mr. Rendina:

For samples ID CS-A and CS-C, ZymaX Lab ID 38669-1 and 38669-3 respectively, the surrogate recoveries for the PNA-SIM and silica gel treated TPH-diesel/crude oil were below the QC limit of 50%. The low surrogate recoveries were due to emulsion problem encountered during sample extraction. The samples were re-analyzed and the re-analysis results yielded similarly low surrogate recoveries. It should be noted that the low surrogate recoveries suggest that the reported PNA-SIM and TPH-diesel/crude oil results might be correspondingly underestimated.

If you have any questions, feel free to call me at (805) 544-4696.

Sincerely,
ZymaX envirotechnology, inc.

Michael Ng
Acting Lab Director

Notes and Definitions

V11	The Continuing Calibration Verification (CCV) recovery is not within established control limits.
S09	The surrogate recovery on the sample for this compound was not within the control limits.
M01	Analyte detected in the Method Blank at or above the PQL.
J	Estimated value
ND	Analyte NOT DETECTED at or above the reporting limit
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Notes and Definitions

V11	The Continuing Calibration Verification (CCV) recovery is not within established control limits.
S09	The surrogate recovery on the sample for this compound was not within the control limits.
M01	Analyte detected in the Method Blank at or above the PQL.
J	Estimated value
B02	Analyte detected in the Continuing Calibration Blank (CCB) at a level between the PQL and 1/2 the PQL.
A19	Surrogate is high due to matrix interference. Interferences verified through second extraction/analysis.
ND	Analyte NOT DETECTED at or above the reporting limit
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference

Date of Report: 07/17/2006

Crude Oil - C25 - C40	BPG0701	BPG0701-BLK1	109.05	ug/L	50	24	M01
p-Terphenyl-d14 (Surrogate)	BPG0701	BPG0701-BLK1	43.6	%	62 - 122 (LCL - UCL)		S09

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Notes and Definitions

V11	The Continuing Calibration Verification (CCV) recovery is not within established control limits.
S09	The surrogate recovery on the sample for this compound was not within the control limits.
M02	Analyte detected in the Method Blank at a level between the PQL and 1/2 the PQL.
M01	Analyte detected in the Method Blank at or above the PQL.
ND	Analyte NOT DETECTED at or above the reporting limit
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Additional Laboratory Comments:
Revised Report 01/16/07

TPH-GRO result for NPK3519-01 is probable carryover from sample analyzed immediately prior to this sample.
See attached chromatograms.

Revised Report 01/02/2007

Added Oil Range C25-C40.
California Certification Number: 01168CA

The Chain(s) of Custody, 5 pages, are included and are an integral part of this report.

These results relate only to the items tested. This report shall not be reproduced except in full and with permission of the laboratory.

Estimated uncertainity is available upon request.

This report has been electronically signed.

DATA QUALIFIERS AND DEFINITIONS

A-01	Evaluated for C25-C40.
CF7	Result may be elevated due to carry over from previously analyzed sample.
J	Analyte detected at a level less than the Reporting Limit (RL) and greater than or equal to the Method Detection Limit (MDL). Concentrations within this range are estimated.
L1	Laboratory Control Sample and/or Laboratory Control Sample Duplicate recovery was above acceptance limits.
MNR1	There was no MS/MSD analyzed with this batch due to insufficient sample volume. See Blank Spike.
QSG	Silica Gel clean-up performed on extracts.

COOLER RECEIPT FORM **BC#** NPK3519

Cooler Received/Opened On 11/28/06 7:45

1. Indicate the Airbill Tracking Number (last 4 digits for Fedex only) and Name of Courier below: 5394

(Fed-Ex) UPS Velocity DHL Route Off-street Misc.

2. Temperature of representative sample or temperature blank when opened: 0.6 **Degrees Celsius**
(indicate IR Gun ID#)

NA A00466 A00750 A01124 100190 101282 (90942856)

3. Were custody seals on outside of cooler?..... (YES)....NO....NA

a. If yes, how many and where: 1 Front

4. Were the seals intact, signed, and dated correctly?..... (YES)....NO...NA

5. Were custody papers inside cooler?..... (YES)....NO...NA

I certify that I opened the cooler and answered questions 1-5 (intial)..... JR

6. Were custody seals on containers: YES (NO) and Intact YES NO (NA)

were these signed, and dated correctly?..... (YES)...NO...NA

7. What kind of packing material used? (Bubblewrap) Peanuts Vermiculite Foam Insert

(Plastic bag) Paper Other_____ None

8. Cooling process: (Ice) Ice-pack Ice (direct contact) Dry ice Other None

9. Did all containers arrive in good condition (unbroken)?..... (YES)...NO...NA

10. Were all container labels complete (#, date, signed, pres., etc)?..... (YES)...NO...NA

11. Did all container labels and tags agree with custody papers?..... (YES)...NO...NA

12. a. Were VOA vials received?..... (YES)...NO...NA

b. Was there any observable head space present in any VOA vial?..... YES...(NO)...NA

I certify that I unloaded the cooler and answered questions 6-12 (intial)..... KG

13. a. On preserved bottles did the pH test strips suggest that preservation reached the correct pH level? (YES)...NO...NA

b. Did the bottle labels indicate that the correct preservatives were used..... (YES)...NO...NA

If preservation in-house was needed, record standard ID of preservative used here_____

14. Was residual chlorine present?..... YES...NO...(NA)

I certify that I checked for chlorine and pH as per SOP and answered questions 13-14 (intial)..... KG

15. Were custody papers properly filled out (ink, signed, etc)?..... (YES)...NO...NA

16. Did you sign the custody papers in the appropriate place?..... (YES)...NO...NA

17. Were correct containers used for the analysis requested?..... (YES)...NO...NA

18. Was sufficient amount of sample sent in each container?..... (YES)...NO...NA

I certify that I entered this project into LIMS and answered questions 15-18 (intial)..... KG

I certify that I attached a label with the unique LIMS number to each container (intial)..... KG

19. Were there Non-Conformance issues at login YES (NO) Was a PIPE generated YES (NO) #_____

DATA QUALIFIERS AND DEFINITIONS

A-01	DRO evaluated from C10 to C25.
A-01a	GRO evaluated from C4-C10.
A-01b	ORO evaluated from C25 to C40.
MNR1	There was no MS/MSD analyzed with this batch due to insufficient sample volume. See Blank Spike.
QSG	Silica Gel clean-up performed on extracts.

COOLER RECEIPT FORM

BC#

Cooler Received/Opened On: January 26, 2007@ 800

1. Indicate the Airbill Tracking Number (last 4 digits for Fedex only) and Name of Courier below: 7006

Fed-Ex

2. Temperature of representative sample or temperature blank when opened: 0.9 Degrees Celsius
(indicate IR Gun ID#)

92171982

3. Were custody seals on outside of cooler?..... YES...NO...NA

a. If yes, how many and where:_____

4. Were the seals intact, signed, and dated correctly?..... YES....NO...NA

5. Were custody papers inside cooler?..... YES...NO...NA

I certify that I opened the cooler and answered questions 1-5 (intial)..... _____

6. Were custody seals on containers: YES NO and Intact YES NO NA

were these signed, and dated correctly?..... YES...NO...NA

7. What kind of packing material used? Bubblewrap Peanuts Vermiculite Foam Insert

Plastic bag Paper Other_____ None

8. Cooling process: Ice Ice-pack Ice (direct contact) Dry ice Other None

9. Did all containers arrive in good condition (unbroken)?..... YES...NO...NA

10. Were all container labels complete (#, date, signed, pres., etc)?..... YES...NO...NA

11. Did all container labels and tags agree with custody papers?..... YES...NO...NA

12. a. Were VOA vials received?..... YES...NO...NA

b. Was there any observable head space present in any VOA vial?..... YES...NO...NA

I certify that I unloaded the cooler and answered questions 6-12 (intial)..... WS

13. a. On preserved bottles did the pH test strips suggest that preservation reached the correct pH level? YES...NO...NA

b. Did the bottle labels indicate that the correct preservatives were used..... YES...NO...NA

If preservation in-house was needed, record standard ID of preservative used here_____

14. Was residual chlorine present?..... YES...NO...NA

I certify that I checked for chlorine and pH as per SOP and answered questions 13-14 (intial)..... WS

15. Were custody papers properly filled out (ink, signed, etc)?..... YES...NO...NA

16. Did you sign the custody papers in the appropriate place?..... YES...NO...NA

17. Were correct containers used for the analysis requested?..... YES...NO...NA

18. Was sufficient amount of sample sent in each container?..... YES...NO...NA

I certify that I entered this project into LIMS and answered questions 15-18 (intial)..... WS

I certify that I attached a label with the unique LIMS number to each container (intial)..... WS

19. Were there Non-Conformance issues at login YES NO Was a PIPE generated YES NO #_____

BIS = Broken in shipment

If you have received this material in error, please notify us immediately at 615-726-0177.

California Certification Number: 01168CA

The Chain(s) of Custody, 2 pages, are included and are an integral part of this report.

These results relate only to the items tested. This report shall not be reproduced except in full and with permission of the laboratory.

Estimated uncertainity is available upon request.

This report has been electronically signed.

DATA QUALIFIERS AND DEFINITIONS

A-01	Data reported is for range C10 - C25
A-01a	Data Reported is for range C25 to C40
J	Analyte detected at a level less than the Reporting Limit (RL) and greater than or equal to the Method Detection Limit (MDL). Concentrations within this range are estimated.
L	Laboratory Control Sample and/or Laboratory Control Sample Duplicate recovery was above the acceptance limits. Analyte not detected, data not impacted.
MNR1	There was no MS/MSD analyzed with this batch due to insufficient sample volume. See Blank Spike.
QSG	Silica Gel clean-up performed on extracts.

Nashville Division
COOLER RECEIPT FORM BC#

Cooler Received/Opened On 2/24/07 @ 7:50

1. Indicate the Airbill Tracking Number (last 4 digits for Fedex only) and Name of Courier below: 2720

Fed-Ex UPS Velocity DHL Route Off-street Misc.

2. Temperature of representative sample or temperature blank when opened: 2.3 **Degrees Celsius**
(indicate IR Gun ID#)

NA A00466 A00750 A01124 100190 101282 10594 90942856

3. Were custody seals on outside of cooler?..... YES...NO....NA

a. If yes, how many and where:_____

4. Were the seals intact, signed, and dated correctly?..... YES....NO...NA

5. Were custody papers inside cooler?..... YES...NO...NA

I certify that I opened the cooler and answered questions 1-5 (intial)..... JR

6. Were custody seals on containers: YES NO and Intact YES NO NA

were these signed, and dated correctly?..... YES...NO...NA

7. What kind of packing material used? Bubblewrap Peanuts Vermiculite Foam Insert Plastic bag Paper Other_____ None

8. Cooling process: Ice Ice-pack Ice (direct contact) Dry ice Other None

9. Did all containers arrive in good condition (unbroken)?..... YES...NO...NA

10. Were all container labels complete (#, date, signed, pres., etc)?..... YES...NO...NA

11. Did all container labels and tags agree with custody papers?..... YES...NO...NA

12. a. Were VOA vials received?..... YES...NO...NA

b. Was there any observable head space present in any VOA vial?..... YES...NO...NA

I certify that I unloaded the cooler and answered questions 6-12 (intial)..... JR

13. a. On preserved bottles did the pH test strips suggest that preservation reached the correct pH level? YES...NO...NA

b. Did the bottle labels indicate that the correct preservatives were used..... YES...NO...NA

If preservation in-house was needed, record standard ID of preservative used here_____

14. Was residual chlorine present?..... YES...NO...NA

I certify that I checked for chlorine and pH as per SOP and answered questions 13-14 (intial)..... WS

15. Were custody papers properly filled out (ink, signed, etc)?..... YES...NO...NA

16. Did you sign the custody papers in the appropriate place?..... YES...NO...NA

17. Were correct containers used for the analysis requested?..... YES...NO...NA

18. Was sufficient amount of sample sent in each container?..... YES...NO...NA

I certify that I entered this project into LIMS and answered questions 15-18 (intial)..... WS

I certify that I attached a label with the unique LIMS number to each container (intial)..... WS

19. Were there Non-Conformance issues at login YES NO Was a PIPE generated YES NO #_____

BIS = Broken in shipment

DATA QUALIFIERS AND DEFINITIONS

A-01	C10-C25
A-01a	C25-C40
J	Analyte detected at a level less than the Reporting Limit (RL) and greater than or equal to the Method Detection Limit (MDL). Concentrations within this range are estimated.
MNR1	There was no MS/MSD analyzed with this batch due to insufficient sample volume. See Blank Spike.
QSG	Silica Gel clean-up performed on extracts.
Z1	Surrogate recovery was above acceptance limits.
ND	Not detected at the reporting limit (or method detection limit if shown)

Nashville Division
COOLER RECEIPT FORM BC#

Cooler Received/Opened On: 3/24/2007 @ 8:00

Indicate the Airbill Tracking Number (last 4 digits for Fedex only) and Name of Courier below: 6750

Fed-Ex

2. Temperature of representative sample or temperature blank when opened: 1.8 **Degrees Celsius**
(indicate IR Gun ID#)

92171982

3. Were custody seals on outside of cooler?..... YES...(NO)...NA

a. If yes, how many and where:_____

4. Were the seals intact, signed, and dated correctly?..... YES....NO...(NA)

5. Were custody papers inside cooler?..... YES...NO...NA

I certify that I opened the cooler and answered questions 1-5 (intial)..... _____

6. Were custody seals on containers: YES (NO) and Intact YES NO (NA)

were these signed, and dated correctly?..... YES...NO...(NA)

7. What kind of packing material used? Bubblewrap Peanuts Vermiculite Foam Insert

Plastic bag Paper Other_____ None

8. Cooling process: Ice Ice-pack Ice (direct contact) Dry ice Other None

9. Did all containers arrive in good condition (unbroken)?..... YES...NO...NA

10. Were all container labels complete (#, date, signed, pres., etc)?..... YES...NO...NA

11. Did all container labels and tags agree with custody papers?..... YES...NO...NA

12. a. Were VOA vials received?..... YES...NO...NA

b. Was there any observable head space present in any VOA vial?..... YES...NO...NA

I certify that I unloaded the cooler and answered questions 6-12 (intial)..... JR

13. a. On preserved bottles did the pH test strips suggest that preservation reached the correct pH level? YES...NO...NA

b. Did the bottle labels indicate that the correct preservatives were used..... YES...NO...NA

If preservation in-house was needed, record standard ID of preservative used here_____

14. Was residual chlorine present?..... YES...NO...NA

I certify that I checked for chlorine and pH as per SOP and answered questions 13-14 (intial)..... JR

15. Were custody papers properly filled out (ink, signed, etc)?..... YES....NO...NA

16. Did you sign the custody papers in the appropriate place?..... YES....NO...NA

17. Were correct containers used for the analysis requested?..... YES...NO...NA

18. Was sufficient amount of sample sent in each container?..... YES...NO...NA

I certify that I entered this project into LIMS and answered questions 15-18 (intial)..... JR

I certify that I attached a label with the unique LIMS number to each container (intial)..... JR

19. Were there Non-Conformance issues at login YES (NO) Was a PIPE generated YES NO #_____

TB

BIS = Broken in shipment

DATA QUALIFIERS AND DEFINITIONS

A-01	C10-C25
A-01a	C25-C40
B	Analyte was detected in the associated Method Blank.
J	Analyte detected at a level less than the Reporting Limit (RL) and greater than or equal to the Method Detection Limit (MDL). Concentrations within this range are estimated.
M7	The MS and/or MSD were above the acceptance limits. See Blank Spike (LCS).
QSG	Silica Gel clean-up performed on extracts.
ND	Not detected at the reporting limit (or method detection limit if shown)

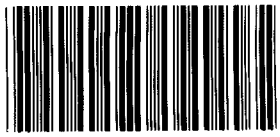
COOLER RECEIPT FORM



NQD3265

Cooler Received/Opened On 04/26/2007 @ 0750

1. Tracking # 6509 (last 4 digits, FedEx)

Courier: Fed-Ex IR Gun ID Raynger ST

2. Temperature of rep. sample or temp blank when opened: 0.9 *Degrees Celsius*

3. If Item #2 temperature is 0°C or less, was the representative sample or temp blank frozen? YES NO...(NA)

4. Were custody seals on outside of cooler? YES...(NO)...NA

If yes, how many and where: N/A

5. Were the seals intact, signed, and dated correctly? YES...NO...(NA)

6. Were custody papers inside cooler? (YES)...NO...NA

I certify that I opened the cooler and answered questions 1-6 (intial) MJ

7. Were custody seals on containers: YES (NO) and Intact YES...NO...(NA)

Were these signed and dated correctly? YES...NO...(NA)

8. Packing mat'l used? (Bubblewrap) Plastic bag Peanuts Vermiculite Foam Insert Paper Other None

9. Cooling process: (Ice) Ice-pack Ice (direct contact) Dry ice Other None

10. Did all containers arrive in good condition (unbroken)? (YES)...NO...NA

11. Were all container labels complete (#, date, signed, pres., etc)? (YES)...NO...NA

12. Did all container labels and tags agree with custody papers? (YES)...NO...NA

13a. Were VOA vials received? (YES)...NO...NA

b. Was there any observable headspace present in any VOA vial? YES...(NO)...NA

14. Was there a Trip Blank in this cooler? (YES)...NO...NA If multiple coolers, sequence #_____

I certify that I unloaded the cooler and answered questions 7-14 (intial) MJ

15a. On pres'd bottles, did pH test strips suggest preservation reached the correct pH level? YES...NO...(NA)

b. Did the bottle labels indicate that the correct preservatives were used (YES)...NO...NA

If preservation in-house was needed, record standard ID of preservative used here_____

16. Was residual chlorine present? YES...(NO)...NA

I certify that I checked for chlorine and pH as per SOP and answered questions 15-16 (intial) MJ

17. Were custody papers properly filled out (ink, signed, etc)? (YES)...NO...NA

18. Did you sign the custody papers in the appropriate place? (YES)...NO...NA

19. Were correct containers used for the analysis requested? (YES)...NO...NA

20. Was sufficient amount of sample sent in each container? (YES)...NO...NA

I certify that I entered this project into LIMS and answered questions 17-20 (intial) MJ

I certify that I attached a label with the unique LIMS number to each container (intial) MJ

21. Were there Non-Conformance issues at login? YES...(NO) Was a PIPE generated? YES...NO...#_____

DATA QUALIFIERS AND DEFINITIONS

A-01	C10 - C25
A-01a	C25 - C40
B	Analyte was detected in the associated Method Blank.
J	Analyte detected at a level less than the Reporting Limit (RL) and greater than or equal to the Method Detection Limit (MDL). Concentrations within this range are estimated.
MNR1	There was no MS/MSD analyzed with this batch due to insufficient sample volume. See Blank Spike.
QSG	Silica Gel clean-up performed on extracts.
ND	Not detected at the reporting limit (or method detection limit if shown)

METHOD MODIFICATION NOTES

Nashville, TN

COOLER RECEIPT FORM

NQE3244

Cooler Received/Opened On 05/2407 @ 08:00

1. Tracking # 2742 (last 4 digits, FedEx)

Courier: _____FED-EX IR Gun ID_A01124

2. Temperature of rep. sample or temp blank when opened: 0.2 Degrees Celsius

3. If Item #2 temperature is 0°C or less, was the representative sample or temp blank frozen? YES NO NA

4. Were custody seals on outside of cooler? YES NO NA

If yes, how many and where: _____

5. Were the seals intact, signed, and dated correctly? YES NO NA

6. Were custody papers inside cooler? YES NO NA

I certify that I opened the cooler and answered questions 1-6 (intial) _____

7. Were custody seals on containers: YES NO and Intact YES NO NA

Were these signed and dated correctly? YES NO NA

8. Packing mat'l used? Bubblewrap Plastic bag Peanuts Vermiculite Foam Insert Paper Other None

9. Cooling process: Ice Ice-pack Ice (direct contact) Dry ice Other None

10. Did all containers arrive in good condition (unbroken)? YES NO NA

11. Were all container labels complete (#, date, signed, pres., etc)? YES NO NA

12. Did all container labels and tags agree with custody papers? YES NO NA

13a. Were VOA vials received? YES NO NA

b. Was there any observable headspace present in any VOA vial? YES NO NA

14. Was there a Trip Blank in this cooler? YES NO NA If multiple coolers, sequence # NA

I certify that I unloaded the cooler and answered questions 7-14 (intial) _____

15a. On pres'd bottles, did pH test strips suggest preservation reached the correct pH level? YES NO NA

b. Did the bottle labels indicate that the correct preservatives were used YES NO NA

If preservation in-house was needed, record standard ID of preservative used here _____

16. Was residual chlorine present? YES NO NA ws 5/24/07

I certify that I checked for chlorine and pH as per SOP and answered questions 15-16 (intial) ws

17. Were custody papers properly filled out (ink, signed, etc)? YES NO NA

18. Did you sign the custody papers in the appropriate place? YES NO NA

19. Were correct containers used for the analysis requested? YES NO NA

20. Was sufficient amount of sample sent in each container? YES NO NA

I certify that I entered this project into LIMS and answered questions 17-20 (intial) ws

I certify that I attached a label with the unique LIMS number to each container (intial) ws

21. Were there Non-Conformance issues at login? YES NO Was a PIPE generated? YES NO #_____

ws 5/24/07 ws 5/24/07

CUC was free of different particulate

BIS = Broken in shipment
