California Regional Water Quality Control Board
Central Coast Region
895 AeroVista Place, Suite 101
San Luis Obispo, California 93401

Attention: Mr. Dan Niles

Subject: Report of Findings, Supplemental Cliff Area Characterization, Former Union Oil Company of California Avila Terminal, Avila Beach, San Luis Obispo County, California

Dear Mr. Niles:

On behalf of Chevron Environmental Management Company (CEMC) Padre Associates, Inc. (Padre) has prepared this report of findings for submittal to the California Regional Water Quality Control Board, Central Coast Region (RWQCB) documenting and summarizing the results of the supplemental cliff area characterization activities completed at the subject site. CEMC proposes to meet with the RWQCB to discuss the findings of this report in relation to cliff area monitoring activities and the overall Feasibility Study process.

Padre and CEMC appreciate your continued assistance with this project. If you have any questions or comments, or require additional information, please contact Mr. Louis Cappel at (805) 786-2650, ext. 26 or lcappel@padreinc.com.

Sincerely,

PADRE ASSOCIATES, INC.

Louis J. Cappel, P.G., C.Hg.
Senior Geologist

1.0 INTRODUCTION

On behalf of Chevron Environmental Management Company (CEMC) Padre Associates, Inc. (Padre) has prepared this document for submittal to the California Regional Water Quality Control Board, Central Coast Region (RWQCB). This document presents the results of the supplemental cliff area characterization activities performed at the former Union Oil Company of California (Unocal) Avila Terminal (Project Site), Avila Beach, San Luis Obispo County, California (Plates 1 and 2).

Prior to performing the characterization activities described herein, the vast majority of characterization necessary to prepare a Feasibility Study had been completed. CEMC, along with its predecessors, has investigated surface and subsurface conditions at the Project Site in detail over the last decade. In general, historical assessment activities have provided enough information to begin considering remedial alternatives for most of the Project Site. However, groundwater monitoring data for Groundwater Monitoring Well B-223-88, and soil gas data for Probe SV-66 indicated that additional characterization was needed in a focused region along the southwestern cliff area (Plate 2). These identified data gaps prompted the supplemental cliff area characterization activities documented within this report.

As part of the supplemental cliff area characterization activities, Padre observed and documented the advancement of eight drill holes (B-224 through B-231), five of which were constructed as groundwater monitoring wells (Plate 3). Additionally, Padre performed a supplemental groundwater monitoring event of the five newly constructed groundwater monitoring wells, as well as existing Groundwater Monitoring Well B-223-88. The prime objective of the cliff area characterization activities was to gain a better understanding of the nature and distribution of petroleum hydrocarbon-related compounds in both soil/bedrock and groundwater located within approximately 600 feet of the southwest facing shore frontage (the cliff area or area of interest) of the Project Site (Plate 2). The objectives of the supplemental cliff area characterization activities have been largely satisfied. CEMC proposes to meet with the RWQCB to discuss the findings of this report in relation to cliff area monitoring activities and the overall Feasibility Study process.

1.1 OBJECTIVES

The specific objectives of the supplemental cliff area characterization activities were:

- To evaluate the source and extent of fuel-hydrocarbon-related groundwater impacts associated with Groundwater Monitoring Well B-223-88 (near Former Tank No. 55614). Groundwater Monitoring Wells B-224, B-225, and B-226 were constructed and sampled to evaluate this objective.
- To assess the extent of total petroleum hydrocarbon (TPH) and related volatile organic compounds (VOCs) in soil/bedrock encountered at the location of Drill Hole B-223 (near Former Tank No. 55614) at the depth interval of approximately 15 to 30 feet below ground surface (bgs). Drill Holes B-224 through B-228 were advanced to evaluate this specific objective.

- To assess and delineate the soil/bedrock source of elevated fuel-related VOCs in soil gas detected in Probe SV-66, as well as to determine potential groundwater impacts at this location (near Former Tank No. 201104). Groundwater Monitoring Wells B-230 and B-231 were constructed and sampled, and Drill Hole B-229 was advanced to evaluate this specific objective.
- To provide adequate information to move forward with the preparation of the Feasibility Study.

1.2 REPORT ORGANIZATION

This report is organized as follows: Section 2.0 presents background information for the Project Site, including a discussion of location, topography, geology, hydrogeology, and results of historical assessment activities; Section 3.0 presents the methodology for the cliff area characterization activities; Section 4.0 presents the results of the cliff area characterization activities; Section 5.0 provides a discussion of the nature and extent of impacted soil/bedrock and groundwater at the cliff area; and Section 6.0 provides Padre's conclusions regarding the subject assessment program.

This report includes five appendices. RWQCB correspondence is included as Appendix A. Copies of the groundwater monitoring well permits are included as Appendix B. Drill hole logs/groundwater monitoring well diagrams are included as Appendix C. Copies of groundwater monitoring field data sheets are attached as Appendix D. Appendix E is a CD-ROM containing Padre's subject report with laboratory analytical reports and chain-of-custody (COC) documentation.

2.0 BACKGROUND

Descriptions of the Project Site, the regional geology and hydrogeology, and the site-specific conditions were originally detailed in the document titled *Site Characterization, Unocal Avila Station, Avila Beach, California* (England & Associates 1998), and further expanded upon in the document titled *Final Supplemental Site Characterization, Unocal Avila Pump Station, Avila Beach, California* (England Geosystem, 2002). Provided below is a summary of those descriptions.

2.1 SITE DESCRIPTION

The Project Site consists of approximately 95 acres in San Luis Obispo County, adjacent to the community of Avila Beach, California (Plate 1). The Project Site is bordered on the north by Avila Beach Drive, on the east by an undeveloped hillside and marine terrace, on the south by the Pacific Ocean, and on the west by the community of Avila Beach (Plate 2). The area of interest is located along the southwestern cliff edge.

The original Avila Tank Farm facilities were initially constructed around 1906. At various times, the Project Site had served as an accumulation and transfer point for petroleum from oil fields in Santa Barbara County, a refinery, and a petroleum storage facility. It was slowly withdrawn from operation during the later decades of the twentieth century, and the last storage tanks were removed from operation by the late 1990s.

2.2 GEOLOGY AND HYDROGEOLOGY

2.2.1 Project Site

The Project Site is directly underlain by unconsolidated sediments and bedrock (Plate 4). Unconsolidated surficial sediments, consisting of mixtures of gravel, sand, silt, and clay, fill the north-south and east-west drainages in the central part of the Project Site, mantle the terraces bordering the cliffs on the south, and occur in the northeast corner of the Project Site where the floodplain of San Luis Obispo Creek encroaches upon the Project Site (refer to Plate 4).

Bedrock units underlie the Project Site and include (listed from youngest to oldest) the Pliocene Gragg Member of the Pismo Formation and the Miocene Obispo Formation (refer to Plate 4). Much of the central portion of the Project Site is underlain directly, or at shallow depth, by the Gragg Member. The Gragg Member consists of a basal conglomerate, which grades upward into a poorly bedded, locally diatomaceous, fine-grained silty sandstone and siltstone.

The Gragg Member unconformably overlies the Obispo Formation. The Obispo Formation consists of fine- to coarse-grained, friable to hard, rhyolitic to dacitic tuff and lapilli tuff, which outcrops primarily along the south, east, and northwest Project Site margins.

Reportedly, fracturing of the consolidated bedrock units is a function of age and hardness of the units. For instance, in the Obispo Formation, the hard silicified (brittle) units are more pervasively fractured than the friable (softer) units, and in general, the older Obispo Formation is more pervasively fractured than the softer and younger Pismo Formation.

Three hydrostratigraphic units have been identified at the Project Site, which include: 1) unconsolidated sediments (colluvium and alluvium); 2) the Gragg Member of the Pismo

Formation; and 3) the Obispo Formation. Groundwater occurs within the Pismo and Obispo Formations in both primary (intergranular) and secondary (fracture) porosity. Groundwater recharge occurs primarily in the higher elevations of the Project Site through vertical fractures in the Pismo Formation and through infiltration into the unconsolidated sediments (colluvium and alluvium) (England Geosystem, 2002).

Based on fluid level measurements recorded within the on-site groundwater monitoring wells, the groundwater flow direction at the Project Site generally follows topography and flows toward: the north to northeast for groundwater monitoring wells completed within the alluvium; southwest for groundwater monitoring wells completed within the colluvium; and north, west, and south, for groundwater monitoring wells completed within the Pismo and Obispo Formations. Groundwater flow within the Pismo and Obispo Formations occurs primarily within fractures with relatively low permeabilities and low storativities (England Geosystem, 2002).

2.2.2 Cliff Area

Generally, the cliff area is directly underlain by colluvium and terrace deposits (Plate 4). Colluvium overlies the terrace deposits in the cliff area. The colluvium and terrace deposits vary in thickness from between approximately 10 to 30 feet and are underlain by the consolidated Obispo Formation. The groundwater potentiometric surface maps illustrate that the general groundwater flow beneath this area is to the south to southwest, away from the topographically high recharge areas. As previously mentioned, groundwater flow within the consolidated formations occurs primarily within fractures with relatively low permeabilities and low storativities.

Cliff springs have been identified at eight locations at the cliff area, which are designated in sequence from northwest to southeast as locations H, G, E, A, B, C, F, and D (England Geosystem, 2001a). Cliff spring monitoring locations in the area of interest are presented on Plate 3. Cliff springs appear to be in hydraulic communication with the groundwater identified at the cliff area based on groundwater elevations documented within cliff area groundwater monitoring wells and the elevations of cliff spring monitoring locations.

2.3 PREVIOUS INVESTIGATIONS AND DATA GAPS WITHIN THE CLIFF AREA

The vast majority of characterization needed to prepare a Feasibility Study has been completed. CEMC, along with its predecessors, has investigated surface and subsurface conditions at the Project Site in detail over the last decade (England & Associates, 1998, 2000; England Geosystem, 2001a, b, 2002, 2003; Avocet, 2005, 2008; Padre, 2011). The investigations have included soil/bedrock sampling, groundwater monitoring, and soil gas sampling throughout the Project Site (Plate 3). In general, those investigations have adequately characterized most of the Project Site. However, soil/bedrock and groundwater analytical results from Groundwater Monitoring Well B-223-88 and soil gas results from Probe SV-66 in the vicinity of Former Tank No. 201104 (Avocet, 2008), combined with the proximity of these impacts to the cliff face, indicated a need for further characterization in this area. Therefore, a scope of work to address these data needs was developed and presented in Avocet's *Work Plan* and *Work Plan Addendum* dated July 24, 2009 and October 5, 2009, respectively. The following data gaps were identified in these subject documents.

2.3.1 Vicinity of Groundwater Monitoring Well B-223

Provided below are the identified data gaps in the area of Groundwater Monitoring Well B-223.

1. Most TPH detected in soil/bedrock samples at the cliff area occurs at a relatively shallow depth (10 feet or less) and consists largely of high molecular weight hydrocarbons with low to non-detectable concentrations of VOCs (Plates 5 through 8). The TPH detected in soil/bedrock samples collected from Drill Hole B-223, however, was detected principally at depths greater than 10 feet (i.e., 15 to 25 feet) and was comprised largely of low molecular weight TPH containing moderate concentrations of fuel-related VOCs. This discovery was unexpected at the time as TPH with similar chemical characteristics had not previously been identified in the area and no known local source of low molecular weight TPH had been identified.
2. It is not uncommon for low to moderate concentrations of TPH to be detected in groundwater samples from cliff area groundwater monitoring wells (Padre, 2011). This TPH is usually comprised of high molecular weight hydrocarbons (>C10 carbon range) and the samples rarely contain elevated concentrations of VOCs. However, Groundwater Monitoring Well B-223 is unique among the cliff area groundwater monitoring wells in that the TPH detected in groundwater samples consists primarily of low molecular weight hydrocarbons (<C10) and contains elevated concentrations of benzene, toluene, ethyl benzene, and total xylenes (BTEX) and other fuel-related VOCs, as well as fuel oxygenate tertiary butyl alcohol (TBA) relative to other nearby groundwater monitoring wells. Neither the source nor the extent of this fuel-related impact had been determined.

2.3.2 Vicinity of Probe SV-66

Provided below is the identified data gap in the area of Former Tank No. 201104.

1. The elevated soil gas VOC and methane concentrations indicated in Probe SV-66 suggest that fuel-related petroleum hydrocarbons are present in soil/bedrock at this location (Avocet, 2008). Soil samples were not collected during construction of Probe SV-66, and the only other drill hole met refusal at approximately 5 feet when the original concrete slab was encountered that was associated with Former Tank No. 201104.

3.0 METHODS OF ASSESSMENT

The cliff area characterization activities were completed in accordance with Avocet's Work Plan and Work Plan Addendum dated July 24, 2009 and October 5, 2009, respectively. The RWQCB conditionally approved the proposed cliff area assessment activities in a letter dated October 21, 2009 (Appendix A). Provided below is a summary of the methods of assessment implemented during the course of the supplemental cliff area characterization activities.

3.1 PROJECT PLANNING

3.1.1 Site Health and Safety Plan

Padre revised and updated the existing site-specific health and safety plan (HASP) for the Project Site. The HASP included procedures, equipment, and materials utilized to protect worker and community health and safety during the course of the subject assessment activities. The HASP also included provisions for daily tailgate safety meetings, safe work permit (SWP) procedures, job safety analysis (JSA), behavior-based safety (BBS) observations, and journey management plans (JMP).

3.1.2 Permitting

To facilitate the cliff area characterization activities, Padre obtained a Coastal Zone Minor Use Permit from the County of San Luis Obispo Planning and Building Department (SLOPBD) to construct a temporary access road and up to five groundwater monitoring wells. Padre also obtained groundwater monitoring well permits required for the five drill holes constructed as groundwater monitoring wells from the County of San Luis Obispo Public Health Department (SLOPHD). Copies of the permits are included as Appendix B – Permits.

3.1.3 Notification

Padre notified the RWQCB several weeks prior to initiating field work at the Project Site.

3.1.4 Underground Service Alert and Private Utility Locator

Each drill hole location was marked with white paint or construction lath painted white, and Underground Service Alert was contacted at least 48 hours prior to the commencement of field activities. Additionally, Padre contracted the private utility-locating contractor Pacific Coast Locators of La Crescenta, California to evaluate the areas of the proposed assessment for subsurface obstructions.

3.2 DRILL HOLE ADVANCEMENT, SOIL SAMPLE COLLECTION, GROUNDWATER MONITORING WELL CONSTRUCTION, DEVELOPMENT, AND SURVEY

Between June 20, 2011 and August 4, 2011 Padre observed and documented the advancement of eight drill holes, five of which were constructed as 2-inch diameter PVC groundwater monitoring wells (B-224, B-225, B-226, B-230, and B-231) at the Project Site (refer to Plate 3). Drill holes were manually cleared to approximate depths of 5 feet utilizing a hand auger. All drill holes were initially advanced and completed using a hollow-stem auger drilling rig operated by S/G Drilling Company of Lompoc, California (C-57 License No. 611394). However, the hollow-stem auger drilling rig met practical mechanical refusal at the locations of

Drill Holes B-230 and B-231 at approximate depths of 52 feet and 46 feet, respectively, due to hard bedrock conditions. Drill Holes B-230 and B-231 were then abandoned in-place by backfilling each hole with cement slurry from the total drilling depth to the ground surface. To attain the desired drilling depths for groundwater monitoring well construction, the locations of abandoned Drill Holes B-230 and B-231 were subsequently over-drilled and completed as groundwater monitoring wells using an air-rotary casing hammer (ARCH) drilling rig operated by Cascade Drilling, L.P., of La Habra, California (C-57 License No. 938110).

Drill holes not completed as groundwater monitoring wells (B-227, B-228, and B-229) were advanced to approximate total depths of 60 feet. Drill holes completed as monitoring wells (B-224, B-225, B-226, B-230, and B-231) were all advanced to approximate total depths of 95 feet with the exception of B-231, which was advanced to a depth of approximately 100 feet. Soil/bedrock samples were collected from each drill hole location at approximately 5-foot intervals from a depth of approximately 5 feet to the total depth of each drill hole with the hollow-stem auger drilling rig, and at 10-foot intervals using the ARCH drilling rig. For drill holes completed using hollow-stem auger drilling methods, discrete-depth soil samples were collected utilizing a split spoon sampler driven into the formation at the desired depth by a 140 pound auto-trip hammer. For drill holes completed using ARCH drilling technology, the soil cuttings were transported by air pressure up the drill hole casing into a cyclone at the ground surface, where soil samples from the desired depths were collected, and containerized in stainless steel soil sampling sleeves. It was not feasible to collect discrete depth samples using the ARCH drilling rig due to the hard bedrock conditions.

Soil/bedrock samples were lithologically logged by Padre using the Unified Soil Classification System (USCS) and bedrock classification terminology, and were screened for the presence of VOCs using a photoionization detector (PID). Selected soil/bedrock samples were submitted for chemical analyses. Soil/bedrock samples that were retained for chemical analyses were sealed, labeled, and preserved on ice in the field. COC forms were used to document sample management procedures.

Each drill hole completed as a groundwater monitoring well was constructed with 2-inch diameter, Schedule 40 PVC casing. Refer to Table 1 for a summary of groundwater monitoring well construction details. The well casings for Groundwater Monitoring Wells B-224, B-225, B-226, and B-230 consist of approximately 30 feet of 0.020-inch slot screen casing, and 65 feet of blank casing. The well casing for B-231 consists of approximately 30 feet of 0.020-inch slot screen casing, and 70 feet of blank casing. Each drill hole annulus was backfilled with No. 3 Monterey Sand from the bottom of the drill hole to approximately 2 to 3 feet above the screened portion. A 4-foot to 5-foot thick layer of bentonite pellets was placed on top of the upper filter pack and hydrated in-place. The remaining annular space to approximately six inches below grade was backfilled with cement slurry. The groundwater monitoring wells were completed at the ground surface with a watertight, above-ground well monument set in concrete. Following the construction of each groundwater monitoring well, the newly constructed groundwater monitoring wells were developed by a combination of surging and bailing. Copies of the drill hole logs/groundwater monitoring well construction diagrams are presented in Appendix C.

A California-licensed land surveyor provided by Rick Engineering of San Luis Obispo, California surveyed the locations and top of casing elevations of the newly constructed

groundwater monitoring wells to a local benchmark. The location and elevation of each well top of casing was surveyed to the nearest 0.01 foot by the licensed surveyor.

3.3 GROUNDWATER MONITORING ACTIVITIES

3.3.1 Fluid Level Measurement

On August 10, 2011 a total of 31 fluid level measurements were recorded from the existing groundwater monitoring well network in the cliff area at the Project Site (including newly constructed Groundwater Monitoring Wells B-224, B-225, B-226, B-230, and B-231) as part of the supplemental groundwater monitoring event. Fluid level measurements were recorded to the nearest 0.01 foot, from the top of the casing at each groundwater monitoring well. Groundwater monitoring field data sheets are included as Appendix D.

3.3.2 Groundwater Purging and Sampling

On August 11 and 12, 2011 groundwater samples were collected from newly constructed Groundwater Monitoring Wells B-224, B-225, B-226, B-230, and B-231, as well as from existing Groundwater Monitoring Well B-223-88. Groundwater monitoring field data sheets are included as Appendix D. Groundwater monitoring well B-231 was purged and sampled using hand bailing methods due to the small volume of groundwater present within the well casing. All of the remaining five groundwater monitoring wells (B-223-88, B-224, B-225, B-226, and B-230) were purged and sampled utilizing low-flow techniques.

Low-Flow Purging and Sampling. Low-flow refers to the groundwater velocity that is imparted during pumping to the formation pore water adjacent to the well screen. Practically speaking, a pump is placed at a discrete-depth within the well and is operated at a rate to minimize drawdown, and to isolate groundwater from the formation adjacent to the well screen. Groundwater quality parameters are continuously monitored to verify that formation-quality groundwater is being obtained.

The equipment required to utilize low-flow purging and sampling techniques included a portable bladder pump, pump controller, a compressed air supply (compressed gas cylinder), and a flow cell with water quality instruments that measured temperature, electrical conductivity (EC), pH, dissolved oxygen (DO), and oxidation-reduction potential (ORP). The compressed air attached to the pump controller via an air hose; polyethylene tubing connects the controller to the pump air inlet. Groundwater was discharged from the pump through polyethylene tubing into the flow cell where purged groundwater parameters were measured and recorded on field forms. An electronic water level indicator was utilized to measure depth to water or drawdown, which provided data regarding the appropriate pumping rate.

The optimum flow rate was established as soon as possible, using groundwater level measurements for confirmation. Groundwater levels were monitored periodically during the course of the purging activities in an attempt to maintain less than approximately 4-inches of drawdown. Purging continued until water quality parameters stabilized, which is defined by three consecutive measurements taken 3 to 5 minutes apart meeting the criteria below.

Parameter	Stability Criteria - Low Flow Purge
temperature	+/-1 ºC
pH	+/-0.1
conductivity	+/-3%
DO	+/-10% or 0.30 mg/L if <1 mg/L
ORP	+/-10 millivolts

Subsequent to when the purged groundwater parameters stabilized, the flow cell was disconnected and the appropriate groundwater sample containers were filled. Groundwater samples were sealed, labeled, and preserved on ice in the field. COC forms were used to document water sample management procedures.

Disposable Bailer Purging and Sampling. Groundwater Monitoring Well B-231 was purged and sampled utilizing disposable bailers as opposed to low-flow techniques due to the limited water column in the casing. Padre used depth to water and total depth measurements collected from the groundwater monitoring well to calculate the well casing volume and required purge volume. A minimum of three well casing volumes of groundwater were purged, while recording physical water quality parameters including pH, temperature, and specific conductance. Upon removal of the three well casing volumes and the general stabilization of water quality parameters, purging was considered to be complete.

Upon recovery of the groundwater level to a minimum of 80 percent of the initial static water level, the purged groundwater monitoring well was sampled using a new disposable bailer which was lowered into the water column for sample retrieval. The groundwater sample within the bailer was then decanted into labeled laboratory-provided containers appropriate for the required chemical analyses. Following the water sample preparation, the water sample was transferred and stored in an on-site cooler packed with ice. Concurrent with the water sample preservation activities, strict COC procedures were implemented.

3.4 LABORATORY ANALYTICAL PROGRAM

All soil/bedrock and groundwater samples were chemically analyzed by Oilfield Environmental and Compliance, Inc. (OEC) located in Santa Maria, California. OEC is certified by the State of California Public Health Department to complete the required analyses, where applicable.

3.4.1 Soil/Bedrock Samples

All soil/bedrock samples submitted for chemical analyses were analyzed for the presence of the following constituents:

- TPH C4-C10, and full list VOCs including fuel oxygenates by U.S. EPA Method 8260B; and
- TPH C10-C25 and C25-C40 using gas chromatography/mass spectrometry (GC/MS) by U.S. EPA Method 8270.

Selected soil/bedrock samples were additionally chemically analyzed for the presence of total lead by U.S. EPA Method 6010B.

3.4.2 Groundwater Samples

All groundwater samples collected from newly constructed groundwater monitoring wells were chemically analyzed for the following constituents:

- TPH C4-C10, and full list VOCs including fuel oxygenates by U.S. EPA Method 8260B;
- TPH C10-C25 and C25-C40 using GC/MS by U.S. EPA Method 8270;
- Polycyclic aromatic hydrocarbons (PAHs) by U.S. EPA Method 8270C-SIM; and
- Dissolved metals by U.S. EPA 6000/7000 series methods.

3.5 QUALITY ASSURANCE/QUALITY CONTROL

Quality assurance / quality control (QA / QC) procedures were utilized in soil/bedrock and groundwater sample collection, and chemical analyses. The purpose of the QA / QC procedures was to ensure the reliability and compatibility of all data generated during the subject assessment program. Additionally, quality control water samples were collected during the field activities, including a groundwater field duplicate, equipment and trip blank water samples.

3.5.1 Field QA / QC Procedures

Field QA / QC procedures were performed at the Project Site, and consisted of the following measures:

- COC forms were used for sample submittal to the laboratory.
- Daily information regarding sample collection was recorded on field data sheets and/or in the field logbooks. Sample types, descriptions, sample identification numbers, and sample times were collected and recorded on field data sheets and/or in the field logbooks.

COC records were utilized to document sample collection and were submitted to the laboratory performing the chemical analyses. A COC record accompanied all samples submitted for chemical analyses.

Field QA / QC samples were collected and submitted for chemical analysis along with the groundwater samples using the following sampling frequency:

- **Trip Blanks.** Trip blank water samples were placed in coolers with aqueous samples to be chemically analyzed for VOCs.
- **Field Duplicates.** Duplicate groundwater samples were collected at a frequency of approximately 10% of the field samples collected during the groundwater monitoring event, and were chemically analyzed for the constituents of its duplicate.
- **Equipment Blanks.** An equipment blank water sample was collected at the end of the groundwater monitoring activities and was chemically analyzed for the same analyses as required for the groundwater samples collected at the Project Site.

Trip Blank Samples. Trip blank water samples consist of a sample of the deionized water provided by the laboratory and stored with the unique samples collected during each day

of field activities. The purpose of the trip blank sample was to evaluate the potential for cross-contamination of aqueous samples during handling. The trip blank samples were handled in the same manner as all other samples and submitted for VOCs analyses.

Field Duplicate Samples. The duplicate groundwater sample was chemically analyzed in order to evaluate the analytical procedures and methods employed by the laboratory. The duplicate groundwater samples were collected concurrently to the corresponding monitoring well sample, and were chemically analyzed for the identical constituents of its duplicate.

Equipment Blanks. The equipment blank was used to determine the efficacy of decontamination procedures for sampling equipment, and was collected when non-dedicated sampling equipment was used. The equipment blank sample consisted of deionized water poured over or pumped through the decontaminated sampling equipment, and the collection of rinsate into the sample containers. The rinsate was then submitted for chemical analyses for the same constituents required for the groundwater samples collected at the Project Site.

3.5.2 Laboratory QA / QC Procedures

Laboratory QA / QC procedures include the following:

- Chemical analyses were performed within the required holding time for all samples;
- A state-certified hazardous waste testing laboratory conducted the required analyses;
- The laboratory provided the following information for each sample:
  - Method blank data;
  - Surrogate recovery, instrument tuning, and calibration data; and
  - Signed laboratory reports including the sample designation, date of sample collection, date of sample analysis, laboratory analytical method employed, sample volume, and the minimum reporting limit (RL).

3.6 DECONTAMINATION PROCEDURES

Field equipment was cleaned before use, between drill hole/groundwater monitoring well locations, and after completion of field work. Cleaning procedures for sampling equipment consisted of a non-phosphate detergent wash, two rinses with tap water, and a final de-ionized water rinse. The auger flights were pressure-washed prior to coming to the Project Site and after the completion of each drill hole.

3.7 ASSESSMENT DERIVED WASTES

Purged groundwater and wash water were appropriately stored in an on-site poly tank. Soil cuttings were appropriately containerized in lined, 20 cubic yard roll-off bins equipped with lids. These assessment derived wastes were subsequently transported for off-site disposal at an appropriate CEMC-approved disposal facility.

4.0 RESULTS AND DISCUSSION

4.1 FIELD OBSERVATIONS

Padre visually observed the soil/bedrock samples collected and soil/bedrock cuttings generated during the course of the subject assessment activities. The maximum depth of assessment at the Project Site by Padre was to approximately 100 feet. Drill hole logs are included in Appendix C. Geologic cross-sections are presented as Plates 6, 7, and 8.

Geologic formations encountered during the course of the supplemental soil/bedrock and groundwater assessment activities consisted of unconsolidated colluvium, marine terrace deposits, and consolidated bedrock of the Obispo Formation. In the area of the subject assessment activities, colluvium and terrace deposits comprise the native surficial soil layers directly overlying bedrock of the Obispo Formation. The colluvium and terrace deposits encountered range in thickness from approximately 2 feet to 30 feet. Colluvial soils including silty sand, clayey sand, silt, and clay, were encountered in seven of the eight drill holes advanced at the Project Site (B-224, B-225, B-226, B-227, B-228, B230, and B-231). Marine terrace deposits underlying the colluvial deposits were encountered in three drill holes advanced at the Project Site (B-225, B-226, and B-231) and consisted of poorly graded sand, and silty sand.

With the exception of Drill Hole B-229, bedrock members of the Obispo Formation were encountered in all drill holes from beneath the unconsolidated sediments to the total depth of each drill hole. Tuff and tuffaceous sandstone to siltstone that is relatively weathered, friable, and massive to moderately fractured was observed in six drill holes (B-224, B-225, B-226, B-227, B-228, and B-229). Siliceous tuff that is hard, slightly weathered, and massive to pervasively fractured was observed in the two drill holes advanced farthest to the southeast (B-230 and B-231) beneath Former Tank No. 201104. In Drill Hole B-229, dark brown claystone was encountered from depths of approximately 23 feet to 47 feet. This claystone deposit underlies tuffaceous sandstone and overlies siliceous tuff of the Obispo Formation along unconformities. Episodic deposition of the volcanic sediments of the Obispo Formation in a marine environment along with other marine sediments, and / or the subsequent extensive folding and faulting of the unit may account for the occurrence of the claystone at this location.

Suspected petroleum hydrocarbon-containing soil/bedrock was observed at the locations of Drill Holes B-224, B-226, B-229, B230, and B-231. Suspected hydrocarbon impacts to soil were most prevalent beneath Former Tank No. 201104, where elevated PID readings and gasoline-like odors from soil cuttings were documented from depths of just below the former tank pad (approximately 3 feet bgs) to approximate maximum depths of 100 feet (B-231).

Groundwater was encountered in Drill Holes B-224 and B-225 at approximate depths of 75 and 90 feet, respectively. However, groundwater was not initially encountered on the date of drilling within any of the drill holes advanced at the Project Site. Groundwater monitoring wells were constructed based on historical groundwater level data and an understanding of the hydrogeological conditions at the cliff area. Within approximately 24-hours of the construction of each groundwater monitoring well, groundwater entered the wells from the formation and gradually elevated, becoming static within approximately 48-hours. However, the groundwater

elevation at Groundwater Monitoring Well B-231 was likely not static approximately one week after groundwater monitoring well construction activities based on a comparison with nearby Groundwater Monitoring Well B-230.

4.2 GROUNDWATER POTENTIOMETRIC SURFACE

As part of the supplemental groundwater sampling event, on August 10, 2011 Padre gauged all of the groundwater monitoring wells completed within the Obispo Formation in the area of interest (Table 5 and Appendix D). Plate 9 depicts the groundwater potentiometric surface of the cliff area for groundwater monitoring wells completed within the Obispo Formation. It should be noted that this plate is simplified as if the area of interest was underlain by unconsolidated sediments (i.e. alluvium) and not by a structurally diverse fractured bedrock unit. Therefore, it should be considered an accurate portrayal of the groundwater potentiometric surface on a macroscopic scale. The groundwater flow direction was calculated to flow toward the south to southwest under an approximate hydraulic gradient of 0.3 feet/foot (Plate 9). Calculated groundwater elevations ranged from -9.91 feet (B-231) to 117.19 feet (B-78) above mean sea level (MSL). The depth to static groundwater levels below the top of well casings ranged from 1.10 feet (B-57-20) to 101.03 feet (B-231).

Although all the groundwater monitoring wells in the cliff area are constructed within the Obispo Formation, there appears to be a significant variability in groundwater elevations. Groundwater Monitoring Wells B-230 and B-231 (completed in siliceous tuff) exhibited a much lower groundwater elevation (approximately 20 feet) in comparison with nearby (250 feet northwest) Groundwater Monitoring Wells B-224, B-225, and B-226 (completed in tuffaceous sandstone) that are constructed at a similar ground surface elevation and with similar groundwater monitoring well construction details. This occurrence is consistent with the fact that the Obispo Formation is a lithologically diverse and structurally complex hydrostratigraphic unit as previously documented at the Project Site. It should be noted the groundwater elevation at Groundwater Monitoring Well B-231 was likely not static at the time of gauging.

4.3 LABORATORY ANALYTICAL RESULTS

Provided below is a summary of analytical laboratory results for soil/bedrock and groundwater samples chemically analyzed as part of the supplemental cliff area characterization activities. The analytical laboratory reports and COC documentation are provided on the CD in Appendix E of this report.

4.3.1 Soil/Bedrock

The soil/bedrock sample laboratory analytical results collected during this assessment are summarized in Tables 2, 3, and 4. The estimated lateral distribution of TPH in soil/bedrock is presented as Plate 5, and geologic-cross sections with the estimated extent of TPH in soil/bedrock are illustrated on Plates 6, 7, and 8. The laboratory analytical results for soil/bedrock were compared to established Commercial U.S. EPA Region IX Regional Screening Levels for Chemical Contaminants at Superfund Sites (Commercial RSL) (U.S. EPA, 2011). It should be noted that soil/bedrock samples collected from the ARCH drilling rig cyclone were disturbed, and therefore may not be representative of subsurface conditions. However, it likely provides an indication if petroleum hydrocarbon contamination is present (refer to notes in

Tables 2 and 3). A discussion of the results for soil/bedrock samples for the various categories of compounds is presented below.

TPH. Concentrations of the sum of total TPH C4-C40 greater than or equal to 100 milligrams per kilogram (mg/kg) were indicated in nine of the ninety-nine (9%) soil samples chemically analyzed, with concentrations ranging from 126 mg/kg (B-229-10') to 6,650 mg/kg (B-230-15') (refer to Table 2). Of these nine soil samples that exceeded 100 mg/kg TPH C4-C40, three soil samples (B-230-5', B-230-10', and B-230-15') indicated concentrations of greater than 1,000 mg/kg TPH C4-C40. Approximately 75% of the reported TPH concentrations consist of TPH in the C4-C10 carbon range (C4-C10), which indicates the majority of TPH is non-asphaltic. TPH in the C10-C25 carbon range (C10-C25) and TPH in the C25-C40 carbon range (C25-C40) account for approximately 12% and 13% of the reported TPH concentrations, respectively.

Quantifiable concentrations (excluding J flag results) of TPH C4-C10 were indicated in 16 of the 99 soil samples chemically analyzed, ranging from 0.53 mg/kg (B-230-70') to 5,800 mg/kg (B-230-15'), with five soil samples indicated at concentrations greater than or equal to 100 mg/kg TPH C4-C10. Quantifiable concentrations of TPH C10-C25 were indicated in 12 of the 99 soil samples chemically analyzed, ranging from 12 mg/kg (B-230-45') to 850 mg/kg (B-230-15'), with five soil samples indicated at concentrations greater than or equal to 100 mg/kg TPH C10-C25. Quantifiable concentrations of TPH C25-C40 were indicated in 16 of the 99 soil samples chemically analyzed, ranging from 53 mg/kg (B-230-55') to 550 mg/kg (B-229-40'), with three soil samples indicated at concentrations greater than or equal to 100 mg/kg TPH C25-C40.

BTEX. Detectable concentrations of BTEX constituents were indicated in 43 of 99 (43%) soil samples chemically analyzed, generally at trace concentrations. BTEX constituents were indicated at maximum concentrations in soil sample B-230-10' at concentrations of 11 mg/kg, 62 mg/kg, 15 mg/kg, and 150 mg/kg, respectively. Indicated concentrations of benzene in Soil Samples B-230-10' (11 mg/kg) and B-230-15' (6.2 mg/kg) exceeded the established Commercial RSL for benzene of 5.4 mg/kg.

Other VOCs and Fuel Oxygenates. For the purpose of this section, the term “other VOCs” refers to VOCs other than BTEX compounds (Table 3). Concentrations of lead scavenger compounds 1,2-dibromoethane (EDB) and 1,2-dichloroethane (EDC) were indicated in one and seventeen of the ninety-nine soil samples chemically analyzed, respectively. EDB was indicated at an estimated concentration of 0.0040J mg/kg in Soil Sample B-229-60'. Quantifiable concentrations of EDC ranged from 0.0050 mg/kg (B-230-75' and B-230-85') to 0.74 mg/kg (B-230-15'). None of the indicated EDB and EDC concentrations exceeded established Commercial RSLs. Fuel component compounds (i.e., n-propylbenzene, isopropylbenzene, and 1,2,4-trimethylbenzene) were indicated at trace concentrations in several soil samples, all of which were below established Commercial RSLs.

Fuel oxygenate MTBE was indicated at quantifiable concentrations of 0.0058 mg/kg (B-225-30’) and 0.0077 mg/kg (B-224-60’), which are below the established Commercial RSL of 220 mg/kg. Quantifiable concentrations of fuel oxygenate TBA ranged from 0.053 mg/kg (B-229-30') to 2.1 mg/kg (B-230-20'). TBA does not have an established Commercial RSL.

Total Lead. Total lead was chemically analyzed in soil samples collected from drill hole locations B-229, B-230, and B-231 because of the occurrence of lead scavengers EDB and EDC in this area (Former Tank No. 201104). Total lead concentrations in soil ranged from 0.058 mg/kg (B-229-40') to 18 mg/kg (B-231-30') (Table 4). Total lead concentrations reported for soil samples chemically analyzed were compared to their respective Total Threshold Limit Concentration (TTLC) values and Soluble Threshold Limit Concentration (STLC) values for toxic hazardous waste, as listed in Title 22 of the California Code of Regulations, Section 66261.24(a)(2)(A) (Title 22, CCR). Total lead concentrations did not exceed their respective TTLC value for any of the soil samples chemically analyzed. Total lead concentrations did not exceed their respective STLC value by more than 10 times or their respective Toxicity Characteristic Leaching Procedure (TCLP) value by more than 20 times. Additionally, indicated total lead concentrations did not exceed the established Commercial RSL.

4.3.2 Groundwater

The groundwater sample laboratory analytical results collected during the course of the subject assessment event (B-223-88, B-224, B-225, B-226, B-230, and B-231) are summarized in Tables 5 through 8. The groundwater sample analytical results are illustrated on Plates 10 through 14, along with results from the second quarter 2011 (2Q11) groundwater monitoring event to allow for a better evaluation of the distribution of dissolved-phase compounds at the cliff area. The laboratory analytical results for groundwater samples were compared to established State of California Primary Maximum Contaminant Levels (MCLs) (California Code of Regulations, Title 22). A discussion of the results for groundwater samples collected as part of the supplemental groundwater monitoring event is presented below.

TPH. TPH C4-C10 was indicated in five of the six groundwater samples chemically analyzed at concentrations ranging from 110 micrograms per liter (µg/L) (B-224) to 14,000 µg/L (B-230), with four (B-223-88, B-226, B-230, and B-231) of the six groundwater samples exceeding 1,000 µg/L (Table 5 and Plate 10). TPH C10-C40 (sum of TPH C10-C25 and TPH C25-C40) were indicated in all six groundwater samples chemically analyzed at concentrations ranging from 100 µg/L (B-226) to 3,750 µg/L (B-230), with four (B-223-88, B-224, B-230, and B-231) of the six groundwater samples exceeding 1,000 µg/L (Plate 11).

BTEX. BTEX constituents were indicated in all of the groundwater samples chemically analyzed, with the exception to the groundwater sample collected from Groundwater Monitoring Well B-224 (Table 5). Maximum BTEX concentrations were indicated in the groundwater sample collected from Groundwater Monitoring Well B-230, at concentrations of 1,800 µg/L, 3,100 µg/L, 330 µg/L, and 2,000 µg/L, respectively. Benzene was indicated in five of the six groundwater samples at concentrations ranging from 0.13 J µg/L (B-225) to 1,800 µg/L (B-230), with four (B-223-88, B-226, B-230, and B-231) of the six groundwater samples exceeding the established MCL for benzene of 1 µg/L (Plate 12). TEX constituents exceeded established MCLs in the groundwater sample collected from Groundwater Monitoring Well B-230.

Other VOCs and Fuel Oxygenates. For the purpose of this section, the term “other VOCs” refers to VOCs other than BTEX compounds (Table 5 and Table 6). Collectively, lead scavenger compounds EDB and EDC were indicated in two of the six groundwater samples collected (Groundwater Monitoring Wells B-230 and B-231) (Plate 14). EDB was indicated at a

concentration of 270 µg/L in the groundwater sample collected from Groundwater Monitoring Well B-230, which exceeds the MCL of 0.05 µg/L. EDC was indicated at concentrations of 60 µg/L (B-231) and 450 µg/L (B-230), which exceed the MCL of 0.5 µg/L. Collectively, fuel component compounds (i.e., n-propylbenzene, isopropylbenzene, and 1,2,4-trimethylbenzene) were indicated in all six of the groundwater samples chemically analyzed. These subject compounds do not have established MCLs.

Collectively, fuel oxygenates MTBE and TBA were indicated in three (B-224, B-230, and B-231) of the six groundwater samples chemically analyzed (Plate 13). MTBE was indicated at a concentration of 53 µg/L in the groundwater sample collected from Groundwater Monitoring Well B-224, which exceeds the MCL of 13 µg/L. TBA was indicated at concentrations of 3,800 µg/L (B-230) and 4,600 µg/L (B-231); TBA does not have an established MCL.

Polycyclic Aromatic Hydrocarbons (PAHs). Three PAH constituents were indicated at relatively low concentrations in the groundwater samples chemically analyzed, which included acenaphthene, fluorene, and naphthalene (Table 7). Acenaphthene was indicated at a concentration of 0.060 J µg/L in the groundwater sample collected from Groundwater Monitoring Well B-231. Fluorene was indicated at a concentration of 0.040 J µg/L in the groundwater sample collected from Groundwater Monitoring Well B-224. Naphthalene was indicated in all the samples chemically analyzed, with a maximum concentration of 48 µg/L in the groundwater sample collected from Groundwater Monitoring Well B-230. None of the subject PAH compounds have established MCLs.

Dissolved Metals. Collectively, dissolved metals antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, molybdenum, nickel, selenium, and zinc were indicated at detectable concentrations in the groundwater samples chemically analyzed. Three of the indicated metals exceeded established MCLs including arsenic (B-224 at 0.19 milligrams per liter [mg/L]), cadmium (B-230 at 0.0066 mg/L), and lead (B-230 at 0.049 mg/L). These metals concentrations are generally consistent with historical groundwater analytical results for other groundwater monitoring wells constructed at the Project Site, with the exception to dissolved lead.

4.4 QUALITY ASSURANCE / QUALITY CONTROL

4.4.1 Field QA / QC

Field QA / QC samples were collected and submitted for chemical analysis along with the groundwater samples. These QA / QC samples included trip blanks, equipment blanks and field duplicate samples.

Trip blanks were prepared and chemically analyzed for VOC constituents. Detectable concentrations of VOC constituents were not indicated in the trip blank samples, which indicate that cross-contamination did not occur during shipping of the groundwater samples.

Dedicated sampling equipment was not used at Groundwater Monitoring Well B-230 (portable bladder pump was used) due to the limited amount of groundwater in the well casing, so an equipment blank (EB) was collected and chemically analyzed for TPH, VOCs, fuel oxygenates, PAHs, and dissolved metals. TPH, VOCs, fuel oxygenates, and PAHs were not indicated at quantifiable concentrations in the equipment blank sample. Dissolved metals

barium, chromium, and selenium were indicated at trace concentrations in equipment blank sample EB. It can be concluded that the constituents indicated in the equipment blank samples do not significantly affect the data quality and indicates field equipment was properly decontaminated.

A field duplicate (DUP) was collected and chemically analyzed for the constituents of its field groundwater sample (B-226). The field duplicate sample had similar results as its field groundwater samples, and therefore confirms the reliability of the analytical process.

4.4.2 Laboratory QA / QC Results

Standard QA / QC field procedures and laboratory procedures were developed and implemented as part of the monitoring activities completed at the Project Site. The primary quality control feature utilized was data validation. The data from each of the chemical analyses were evaluated in the following areas:

- Data completeness;
- Holding times;
- System monitoring compounds (surrogates);
- Laboratory control standards;
- Matrix spike/matrix spike duplicates (MS/MSD); and
- Compound identification and quantification.

Overall, the data quality was acceptable, and the collected data support the project data quality objectives.

5.0 NATURE AND EXTENT OF IMPACTED SOIL/BEDROCK AND GROUNDWATER AT THE CLIFF AREA

Provided below is a discussion of the nature and extent of impacted soil/bedrock and groundwater at the cliff area of the Project Site.

5.1 SOIL/BEDROCK

This supplemental characterization program and previous investigation activities completed by others allow for the delineation of the extent of petroleum hydrocarbons in soil/bedrock at the cliff area of the Project Site. This interpretation is based primarily upon available soil/bedrock analytical data, and the location and geometry of former potential contaminant sources (tanks, pipelines, etc.). The lateral extent of TPH in soil/bedrock at concentrations greater than 100 mg/kg, 1,000 mg/kg, and 10,000 mg/kg is presented on Plate 5. This plate illustrates two primary discrete areas of TPH in soil/bedrock in the area of interest, which is described below.

5.1.1 Former Tank No. 55614

Although the lateral distribution is depicted as a single, continuous area of TPH-impacted soil measuring approximately 360 feet in length by 60 feet in width, geologic cross-sections graphically presented as Plates 6 and 7, as well as differences in TPH chemistry, show that the plume is comprised of a number of smaller, discrete, overlapping plumes and is likely the result of a number of smaller releases. Most TPH detected in this area occurs at a relatively shallow depth (10 feet or less), and consists largely of high molecular weight hydrocarbons with low to non-detectable concentrations of VOCs. The TPH detected in Drill Hole B-223, however, is detected principally at depths greater than 10 feet (i.e., 15 to 30 feet), and is comprised largely of low molecular weight petroleum hydrocarbons containing moderate concentrations of fuel-related VOCs. The petroleum hydrocarbon source in the area of Drill Hole B-223 appears to be localized and associated with the southwest area of Former Tank No. 55614. The extent of petroleum hydrocarbon-impacted soil/bedrock at this location has been sufficiently defined. The impacted material is primarily located within unconsolidated sediments and not bedrock.

5.1.2 Former Tank No. 201104

A localized, roughly circular area of fuel-related petroleum hydrocarbons approximately 90 feet in diameter is delineated beneath Former Tank No. 201104. The petroleum hydrocarbons encountered in soil/bedrock in this area contain elevated concentrations of TPH C4-C10, BTEX, fuel oxygenate TBA, and lead scavengers EDB and EDC. The impacts to soil/bedrock in this area starts at shallow depths of approximately 5 feet and extends to a maximum depth of approximately 45 feet (Plates 6, 7, and 8). The highest concentrations of petroleum hydrocarbons in soil/bedrock at this location are indicated in Drill Hole B-230 between approximate depths of 5 feet to 15 feet. Former Tank No. 201104 is the likely source of impacted soil/bedrock at this location. The extent of petroleum hydrocarbon-impacted soil/bedrock at this location has been sufficiently defined to the extent feasible. The impacted material is primarily located within unconsolidated sediments and not bedrock.

5.2 GROUNDWATER

Groundwater impacts in the cliff area are concentrated in two locations associated with the likely release points, Former Tank Nos. 55614 and 201104. Unlike most of the affected groundwater at the Project Site, fuel-related compounds are found at elevated concentrations at these locations. Provided below is a discussion of the occurrence of fuel-related impacted groundwater in the area of interest.

5.2.1 Former Tank No. 55614

The likely source of the fuel-related impacted groundwater in this area is localized and adjacent to the southwest area of Former Tank No. 55614. Fuel-related compounds indicated in this area include TPH C4-C10, BTEX, fuel oxygenates MTBE and TBA, and other fuel-related VOC compounds (i.e., n-propylbenzene, isopropylbenzene, and 1,2,4-trimethylbenzene). The center of mass associated with the fuel-related impacts in groundwater is located at Groundwater Monitoring Well B-223-88. Groundwater Monitoring Wells B-224, B-225, and B-226 delineate the lighter-end impacts to groundwater at this location toward the northwest, north and east, respectively. Cliff Spring Monitoring Locations D and F are located toward the west and southwest, respectively, have not historically indicated elevated concentrations of fuel-related compounds (VOCs and TPH C4-C10 not detected; TPH C10-C40 maximum concentrations of 1,690 µg/L at Monitoring Location D and 1,790 µg/L at Monitoring Location F). This data provides an indication that there is not a significant lateral migration of dissolved-phase petroleum hydrocarbons off-site toward the south-southwest of the cliff area.

5.2.2 Former Tank No. 201104

The source of the fuel-related impacted groundwater in this area appears to be localized and associated with Former Tank No. 201104. Fuel-related compounds indicated in groundwater in this area include TPH C4-C10, BTEX, fuel oxygenate TBA, lead scavengers EDB and EDC, other fuel-related VOC compounds (i.e., n-propylbenzene, isopropylbenzene, and 1,2,4-trimethylbenzene), and potentially dissolved lead. Collectively, Groundwater Monitoring Wells B-230 and B-231 contain elevated concentrations of these constituents. Groundwater monitoring wells B-226, B-201, and B-215 delineate the lighter-end impacts to groundwater at this location toward the northwest, north, and northeast, respectively. Since cliff springs have not been identified south-southwest of this area, this location lacks a sentinel monitoring point in this direction. However, the lack of prominent fractures in the cliff face and cliff springs, and slow groundwater recharge characteristics of groundwater monitoring wells B-230 and B-231 argue against any significant lateral migration of dissolved-phase petroleum hydrocarbons in this area, but the lack of quantitative data create sufficient uncertainty to warrant further consideration.

6.0 SUMMARY AND CONCLUSIONS

At the request of CEMC, Padre conducted supplemental cliff area characterization activities at the Project Site. Based on our historical research, observations during the course of field assessment activities, and laboratory analytical results of the supplemental assessment activities, Padre provides the following summary, and makes the conclusions presented below.

Prior to performing the characterization activities described herein, the vast majority of characterization necessary to prepare a Feasibility Study had been completed. CEMC, along with its predecessors, had investigated surface and subsurface conditions at the Project Site in detail over the last decade. In general, historical assessment activities have provided enough information to begin considering remedial alternatives for most of the Project Site. However, groundwater monitoring data for Groundwater Monitoring Well B-223-88, and soil gas data for Probe SV-66 indicated that additional characterization was needed in a focused region along the southwestern cliff area (Plate 2). These identified data gaps prompted the supplemental cliff area characterization activities documented within this report.

As part of the supplemental cliff area characterization activities, Padre observed and documented the advancement of eight drill holes (B-224 through B-231), five of which were constructed as groundwater monitoring wells (Plate 3). Additionally, Padre performed a supplemental groundwater monitoring event of the five newly constructed groundwater monitoring wells, as well as existing Groundwater Monitoring Well B-223-88. The objective of the cliff area characterization activities was to gain a better understanding of the nature and distribution of petroleum hydrocarbon-related compounds in both soil/bedrock and groundwater located within approximately 600 feet of the southwest facing shore frontage (the cliff area or area of interest) of the Project Site (Plate 2). The objectives of the supplemental cliff area characterization activities have been largely satisfied.

The supplemental cliff area characterization activities defined two localized areas of lighter-end petroleum hydrocarbon-impacted soil/bedrock (primarily within soil or unconsolidated sediments) and groundwater (within bedrock fractures) at the cliff area of the Project Site. These areas include the: (1) southwest area adjacent to Former Tank No. 55614 (vicinity of Groundwater Monitoring Well B-223-88); and (2) area of Former Tank No. 201104 (Drill Hole B-229, and Groundwater Monitoring Wells B-230 and B-231) (Plates 5 through 13).

Fuel-related impacted soil/bedrock at Former Tank No. 55614 (vicinity of Groundwater Monitoring Well B-223-88) has been sufficiently defined, and occurs at approximate depths between 15 feet to 30 feet. Fuel-related impacted soil/bedrock at Former Tank No. 201104 (Drill Hole B-229, and Groundwater Monitoring Wells B-230 and B-231) has been sufficiently defined to the extent feasible, and occurs at approximate depths between 5 feet to 45 feet.

Fuel-related impacts to groundwater have been also identified in the cliff area at likely release points, Former Tank Nos. 55614 (Groundwater Monitoring Well B-223-88) and 201104 (Groundwater Monitoring Wells B-230 and B-231). Groundwater monitoring well data indicates that fuel-related impacts are sufficiently defined at these locations to the extent feasible toward the west, north, and east. However, these locations are too near the cliff face to construct additional groundwater monitoring wells toward the south-southwest. In the case of Tank No.

55614 (monitored by Groundwater Monitoring Well B-223-88) Cliff Spring Monitoring Locations D and F historically acted as sentinel monitoring points, and have never detected significant concentrations of dissolved-phase petroleum hydrocarbons associated with historical site operations.

Since cliff springs have not been identified south-southwest of Former Tank No. 201104 (Groundwater Monitoring Wells B-230 and B-231), this location lacks a similar sentinel monitoring point. The lack of prominent fractures in the cliff face, no presence of cliff springs, slow groundwater recharge characteristics and groundwater elevations below MSL at Groundwater Monitoring Wells B-230 and B-231 suggest insignificant lateral migration of dissolved-phase petroleum hydrocarbons in this area.

7.0 LIMITATIONS

This document has been prepared for the sole benefit of Chevron Environmental Management Company. No other persons may rely on the findings of this document without the expressed written consent of the client and Padre Associates, Inc.

In performing our professional services, Padre has attempted to apply present engineering and scientific judgment and use a level of effort consistent with the standard of practice measured on the date of work and in locale of the Project Site for similar type studies. Padre Associates, Inc. makes no warranty, express or implied.

The analyses and interpretations presented in this document have been developed based on the results from the review of existing information pertaining to the site, soil/bedrock and groundwater sampling at discrete locations at the Project Site, and the result from the laboratory analyses of the soil/bedrock and groundwater samples. It should be recognized that contamination can vary between sampling locations and between areas.

Commercial RSL:		--	--	--	--	5.4	45,000	27	2,700	220	--	0.17	2.2

Notes:
All results in milligrams per kilogram (mg/kg)
<10 = not indicated at or above the method reporting limit
TPH = total petroleum hydrocarbons
BTEX = benzene, toluene, ethylbenzene, and total xylenes
MTBE = methyl tertiary butl ether
TBA = tertiary butyl ether
EDB = 1,2-Dibromoethane
EDC = 1,2-Dichloroethane
* = Column calculated as the sum of the indicated concentrations for TPH in three carbon ranges (C4-C10, C10-C25, and C25-C40).
Sum of TPH does not include J flag or estimated results.
Commercial RSL = Environmental Protection Agency (EPA) Regional Screening Levels for Chemical Contaminants at Superfund Sites.
1.5 = Result ≥ Commercial RSL.
-- = not established
J = Estimated value; results are less than the method reporting limit and above the method detection limit.
Soil samples collected in August 2011 were disturbed because they were collected from an air-rotary drilling rig cyclone.

B-231-30'	6/27/2011	**18**

Commercial RSL	800
TTLC	1,000
TCLP	5
STLC	5

Notes:

All results in milligrams per kilogram (mg/kg), except STLC and TCLP results in milligrams per liter (mg/L)

<15 = not indicated at or above the method reporting limit

Commercial RSL = Environmental Protection Agency (EPA) Regional Screening Levels for Chemical Contaminants at Superfund Sites.

50 = Result that exceeds referenced regulatory criteria

STLC = Soluble Threshold Limit Concentration

TTLC = Total Threshold Limit Concentration

TCLP = Toxicity Characteristic Leaching Procedure

J = Estimated value; results are less than the method reporting limit and above the method detection limit.

MCL:							--	--	--	--	1	150	300	1750	13	--	0.05	0.5

Notes:
TOC = top of casing elevation
AMSL = above mean sea level
(ft.) = feet
DTW = depth to water
GWE = groundwater elevation
All results in micrograms per liter (ug/L)
TPH = total petroleum hydrocarbons
BTEX = benzene, toluene, ethylbenzene, and total xylenes
MTBE = methyl tertiary butl ether
TBA = tertiary butyl ether
EDB = 1,2-Dibromoethane
EDC = 1,2-Dichloroethane
J-flag = estimated result that is above the method detection limit, but below the method reporting limit
<50 = not indicated at or above the method reporting limit
LNAPL = light non-aqueous phase liquid
* = Column calculated as the sum of the indicated concentrations for TPH in C10-C25 and C25-C40, which does not include J-flag results
MCL = Maximum Contaminant Level (State of California)
50 = Result that exceeds MCL
-- = not established

	MCL:	0.006	0.05	1	0.004	0.005	0.05	--	--	0.015	0.002	--	0.1	0.05	--	0.002	--	--

Notes:
All results in milligrams per liter (mg/L)
<0.1 = not indicated at or above the method reporting limit
50 = Result that exceeds MCL
MCL = Maximum Contaminant Level (State of California)
-- = not established
J = Estimated value; results are less than the method reporting limit and above the method detection limit.

October 21, 2009

Mr. Kyle Rutherford
kyru@chevron.com
Project Manger
Chevron Environmental Management Company
4051 Broad Street, Suite 230
San Luis Obispo, CA 93401

Dear Mr. Rutherford:

SITE CLEANUP PROGRAM: AVILA TANK FARM — CONCURRENCE WITH PROPOSED SCOPE OF WORK FOR CLIFF AREA CHARACTERIZATION WORKPLAN AND WORKPLAN ADDENDUM

Central Coast Regional Water Quality Control Board (Water Board) staff reviewed the July 24, 2009 "Work Plan for Cliff Area Characterization, Former Avila Tank Farm," and the October 5, 2009 "Cliff Area Characterization Work Plan Addendum, Former Avila Tank Farm." Chevron provided the addendum in response to Water Board staff's comments to the workplan provided in an email dated September 25, 2009. Water Board staff concurs with the scope of work for the proposed investigation detailed in the workplan and addendum, and looks forward to field mobilization.

Staff understands that Chevron needs clearance from the Coastal Commission for creating an access road to reach the easternmost investigation points. Thus, a schedule for commencing field work will be developed based on the Coastal Commission's determination. As such, please provide an investigation report within **90 days** of completing field work, while keeping Water Board staff apprised of your schedule for mobilization and completion of the investigation.

If you have questions please contact **Dan Niles at (805) 549-3355**, or his supervisor Thea Tryon at (805) 542-4776.

Sincerely,

Roger W. Briggs
Executive Officer

MONITORING WELL PERMIT APPLICATION

Name of Well Owner Chevron EMC Phone No. (805) 546-6920
Name of Property Owner Same as Above Phone No. ( )
Mailing Address of Property Owner P.O. Box 1332, San Luis Obispo, CA 93406
Name of Drilling Contractor Randy Glaze C-57 License No. 611394
Drilling Company Name S/G Drilling
Business Address 308 N. First St., Lompoc, CA Phone No. (805) 735-3454

Proposed Well Site Address 10 San Rafel St. City or Area of County Avila Beach
Assessor's Parcel No. 076-181-047, -058, -059 Township 32 S Range 12 E Section NA
Parcel Size (acres) 72 In Coastal Zone? Yes GPS Coordinates 35° 10' 39.38" N 120° 43' 37.68" W
Is the parcel served water by a public water agency? Yes ☐ No ☑ Is the proposed well located within city limits? Yes ☐ No ☑

Well Type	Purpose of Well		Drilling Method	
☑ Construction	☑ Monitoring	☐ Soil Testing	☑ Rotary	☐ Cable Tool
☐ Repair/Modify	☐ Test well	☐ Cathodic Protection	☐ Reverse Rotary	☐ Other
	☐ Vapor Extraction	☐ Sparging	☐ Air Rotary	

Proposed Depth 95' and 105' Casing Diameter 2" Annular Seal Depth 0-63' (95-foot well)
Number of Wells 5 0-53' (105-foot well)
Agency requiring monitoring well implementation, and/or reason for monitoring well- Regional Water Quality Control Board - Central Coast Region. For further characterization of TPH-containing soil & groundwater at the subject site.

I hereby agree to comply with all applicable laws and regulations of the County of San Luis Obispo and the State of California pertaining to well construction, destruction, repair or modification. Within sixty days after completion of the well, I will furnish Environmental Health Services with a completed well log. This application becomes a valid permit following sign off by Environmental Health Services.
Only the above named C-57 licensed driller may sign this permit application.

Signed _____ Date 2/21/11
Drilling Contractor
Print Drilling Contractor Name _____

Note: The "Well Permit Plot Plan" shall be attached to this application and indicate within a two hundred foot radius around the proposed well the following items: A) Property lines, B) Sewage disposal and/or sewer lines, C) Animal enclosures and/or any other concentrated sources of pollution, D) All intermittent or perennial, natural or artificial water bodies or water courses, E) Surface water drainage pattern of the site, F) Existing wells, G) Access roads. The proposed site shall be designated with a flagged surveyor's stake labeled "Well Site." (See second page) **Drilling shall not commence until this application is approved.**

LOG OF DRILL HOLE B-226

Former Unocal Avila Terminal
10 San Rafael Street
Avila Beach, CA

Chevron EMC

Project Number	: 0801-0896	Boring Total Depth	: 95 feet
Project Name	: Cliff Area Characterization	Drilling Date	: 6/22/11
Logged By	: Paul G. Lavelle	Completed With	: 2-inch Monitoring Well
Checked By	: Louis J. Cappel	Initial Water Depth	: Dry
Driller/Method	: S/G Drilling / HSA	Static Water Depth	: 77.15 feet (6/23/11)

Depth in Feet	Water Level	USCS	GRAPHIC	Samples Collected	PID (ppmv)	Blow Count	DESCRIPTION
50		Tmo					TUFFACEOUS SANDSTONE; pale yellow (5Y 7/4); some coarse sand to fine gravel sized volcanic glass fragments; damp.
55		Tmo			0.4	37-50/5"	TUFFACEOUS SILTSTONE; gray to white (5Y 5/1 - 5Y 8/1); very fine grained; few fine fractures lined with dark gray clayey ash layers; crushes to soft powder; weathered; dry.
60					0.3	50/6"	Same as above, with abundant sub-vertical fractures and volcanic glass fragments; becomes slightly harder.
65					0.2	50/4"	TUFFACEOUS SANDSTONE; gray (5Y 6/1); fine to medium grained; some medium grained subangular volcanic glass fragments; moderately indurated; massive; friable.
70		Tmo			0.0	50/4"	Becomes fine to coarse grained; damp; slight hydrocarbon odor.
75					0.0	50/5"

0		SM					Colluvium (Qcol): Silty SAND (SM); dark yellowish brown (10YR 4/4); fine grained sand with silt; few fine roots and subangular to subrounded gravel including fragments of weathered sandstone (Pismo Formation); trace medium sand and clay; loose; dry.
5		SM		■	0.0	1-3-4	Becomes very dark brown (10 YR 2/2); organic odor; few fine roots; loose; wet.
10		SM		■	18.1	2-3-4	Becomes olive (2.5Y 4/3); little clay; some subrounded weathered fine grained sandstone-siltstone gravel of Pismo Formation.
15		SC		■	466.1	6-5-5	Clayey SAND (SC); dark greenish gray (Gley 3/10Y); very fine sand with clay; little silt; loose; moist; hydrocarbon staining and odor.
20		SP		■	>999	12-20-11	Terrace Deposits: Poorly-graded SAND (SP); fine to medium grained; some subrounded quartz grains; little silt; medium dense; moist; strong hydrocarbon staining and odor.
25		Tmo		■	407.0	50/1"	Obispo Formation (Tmo): TUFF; white (5Y 8/1); siliceous; very fine grained; slightly mottled with iron oxide staining in fractures; brittle; hard; crushes to very fine powder; hard drilling.

LOG OF DRILL HOLE B-231

Former Unocal Avila Terminal
10 San Rafael Street
Avila Beach, CA

Chevron EMC

Project Number	: 0801-0896	Boring Total Depth	: 100 feet
Project Name	: Cliff Area Characterization	Drilling Date	: 6/27/11, 8/4/2011
Logged By	: Paul G. Lavelle/Louis J. Cappel	Completed With	: 2-inch Monitoring Well
Checked By	: Louis J. Cappel	Initial Water Depth	: Dry
Driller-Method	: S/G-HSA / Cascade-Air Rotary	Static Water Depth	: 98.03 feet

Depth in Feet	Water Level	USCS	GRAPHIC	Samples Collected	PID (ppmv)	Blow Count	DESCRIPTION
25							TUFF; white (5Y 8/1); siliceous; fractured; brittle; hard; dry.
30				■	13.2	50/1"	Same as above, with hydrocarbon odor; poor recovery.
35		Tmo		■	73.6	50/2"	Same as above, with few dark green streaks on rock fragments; very hard and brittle; hydrocarbon odor; poor recovery.
40				■	18.7	50/1"	Becomes light gray (5Y 7/1); massive; hard; damp; poor recovery.
45				□	--	50/1"	<No recovery> Cuttings same as above; farctures into 1/4 to 1/2-inch angular fragments. <Refusal with HSA 6/27/11. Backfilled with cement slurry.> <Overdrilled with air rotary rig on 8/4/2011.>
50				■	21.3	NA	Strong petroleum hydrocarbon odor.

RE: Former Unocal Avila Terminal

Work Order: 1102999

Dear Client:

Enclosed is an analytical report for the above referenced project. The samples included in this report were received on 22-Jun-11 10:15 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Assurance Manual, applicable standard operating procedures, and other related documentation. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Lisa Race

Laboratory Manager

Notes and Definitions

QM-12	The spike level was outside acceptance limits. The batch was accepted based on acceptable recovery of the remaining spikes.
J	Detected but below the RL/PQL; therefore, result is an estimated concentration .
B-06	The method blank contains analyte at a concentration above the RL/PQL.
DET	Analyte DETECTED
ND	Analyte NOT DETECTED at or above the Method Limit (MDL)
NR	Not Reported
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference

RE: Former Unocal Avila Terminal

Work Order: 1103073

Dear Client:

Enclosed is an analytical report for the above referenced project. The samples included in this report were received on 24-Jun-11 16:31 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Assurance Manual, applicable standard operating procedures, and other related documentation. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Lisa Race

Laboratory Manager

Notes and Definitions

S-GC	Surrogate recovery outside of control limits. The data was accepted based on valid recovery of the remaining surrogates.
QR-04	The RPD exceeded the QC control limits.
QM-12	The spike level was outside acceptance limits. The batch was accepted based on acceptable recovery of the remaining spikes.
QM-08	The spike recovery was outside acceptance limits for the MS and/or MSD. The QC Batch was accepted based on LCS/LCSD percent recoveries and RPD values.
J	Detected but below the RL/PQL; therefore, result is an estimated concentration .
DET	Analyte DETECTED
ND	Analyte NOT DETECTED at or above the Method Limit (MDL)
NR	Not Reported
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference

RE: Former Unocal Avila Terminal

Work Order: 1103124

Dear Client:

Enclosed is an analytical report for the above referenced project. The samples included in this report were received on 29-Jun-11 12:30 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Assurance Manual, applicable standard operating procedures, and other related documentation. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Lisa Race

Laboratory Manager
