Wind Speed: Calm	Wind Direction: Calm		Air Temperature: 88.9°F	
Beach Conditions:	BEACH AREA SCOURED: (Yes) / No		TIDE POOLS PRESENT: (Yes) / No	
Location: IZ-1, IZ-2, IZ-3 beach scour and some beach deposits, more scour visible than 10/15/12				
Notes:				
Surf Conditions:	CALM	(MODERATE)	ROUGH/STORMY	
Notes:				
Presence of General Public:	0	1	2	(3+)
Notes:				
Hydrocarbon Odor:	NONE	(INTERMITTENT)	PERSISTENT	
Location: Intermittent odor at IZ-3 (no odor at IZ-2, IZ-1)				
FID Reading: 0.0 ppm				
Notes:				
Tide Pool/Ocean Water Appearance:	(CLEAR)	TURBID		
Hydrocarbon Sheen:	(YES)	NO	COLOR:	
Area of Sheen (ft^2): ≈ 0.25 ft^2 in ≈ 1.0 ft^2 tide pool area				
Location: IZ-3 (no sheen observed at IZ-2 or IZ-1) sheen observed at				
Notes: different tide pool location than 10/15/12, no sheen observed at previous location (10/15/12)				
NOTIFICATIONS				
Notification to Padre PM (date, time, type): 10/16/12, 1740, phone call				
Notification to Chevron (date, time, type): 10/16/12, 1740, Chevron PM present at site				
Notification to Agencies (date, time, type):				
Notes:				
NOTES: CDFG representative Melissa Boggs and Chevron PM Rik Williams present. CDFG collected sheen samples; given limited area of sheen/tidepool area & minimal amount of water left to collect aqueous samples. Collected aqueous sample full bottle set from tidepool immediately adjacent to tidepool with visible sheen.

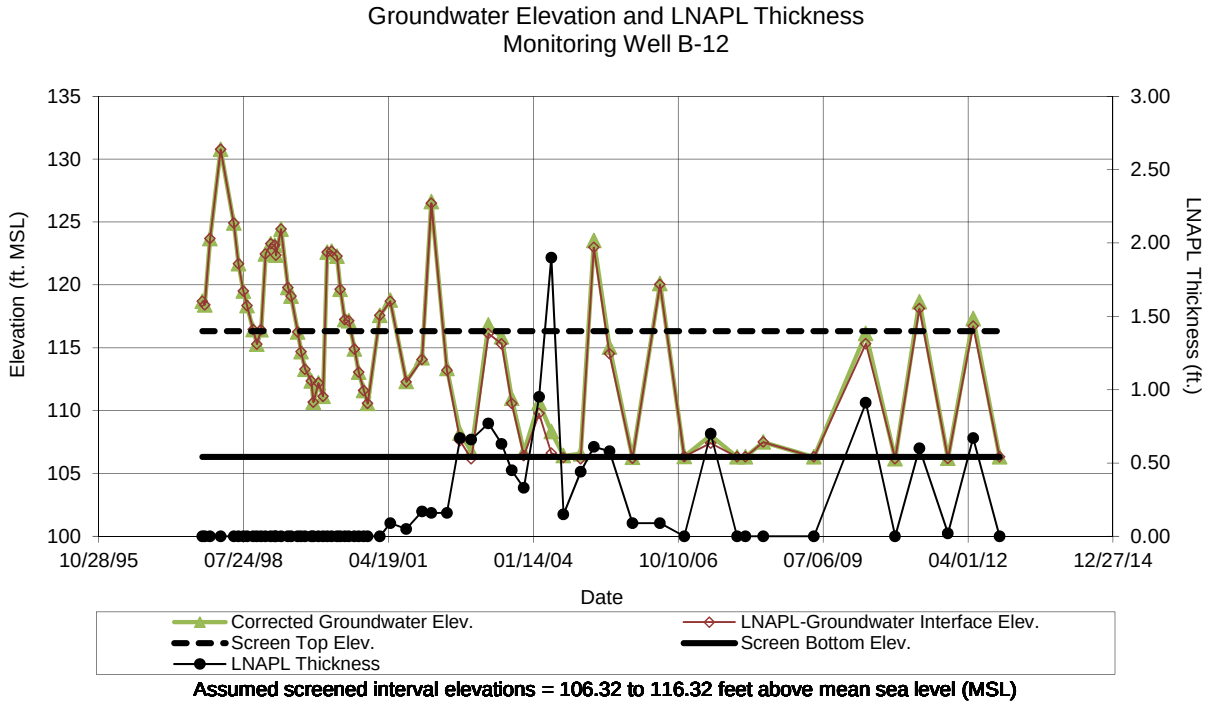
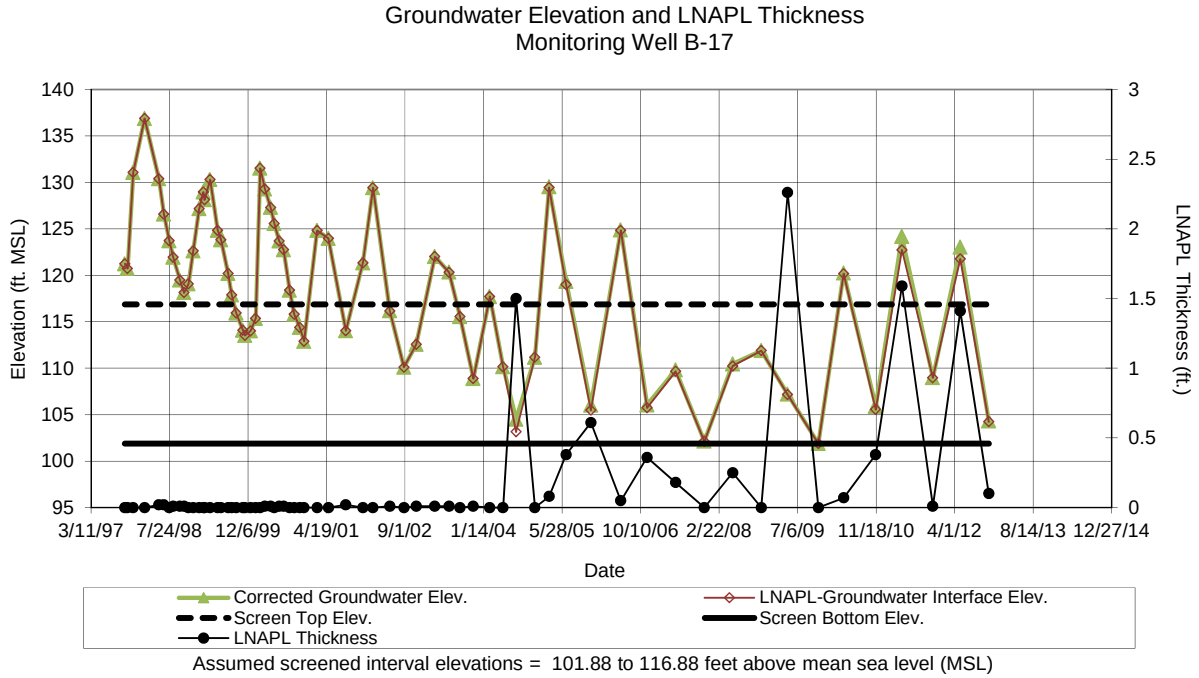
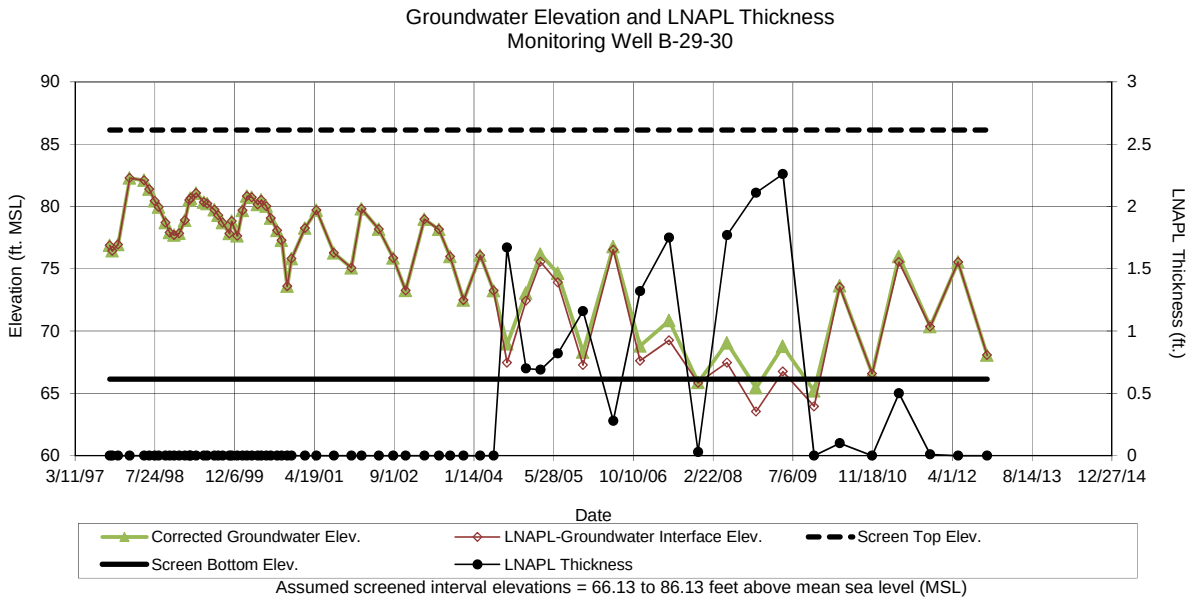
APPENDIX F
GROUNDWATER MONITORING WELL HYDROGRAPHS FOR SELECTED WELLS WITH MEASUREABLE LNAPL



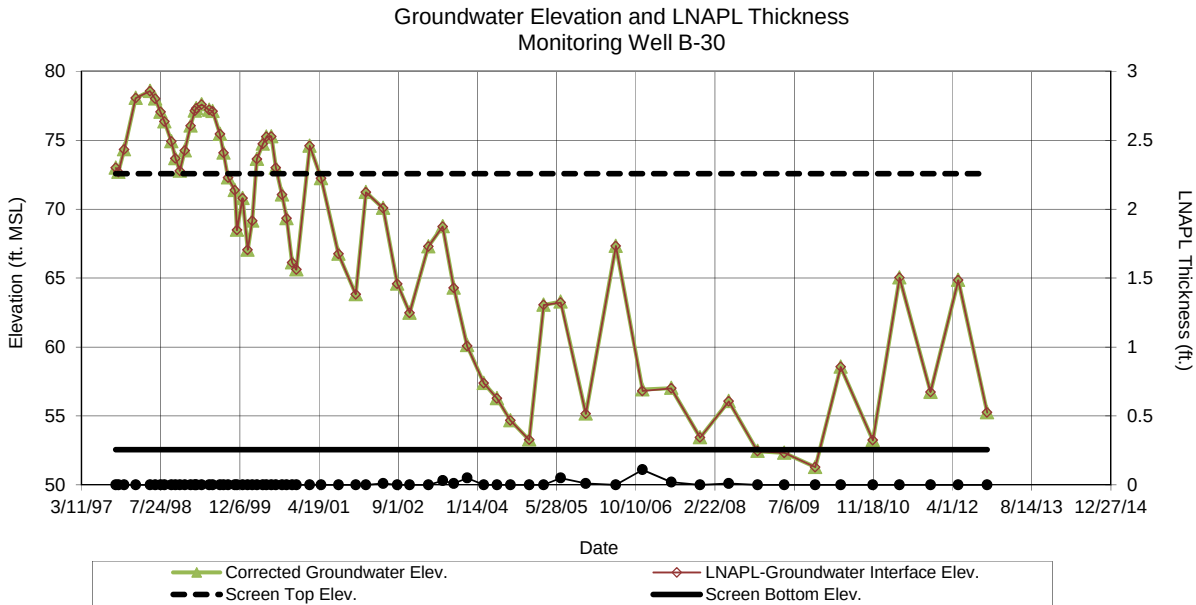
Assumed screened interval elevations = 106.32 to 116.32 feet above mean sea level (MSL)



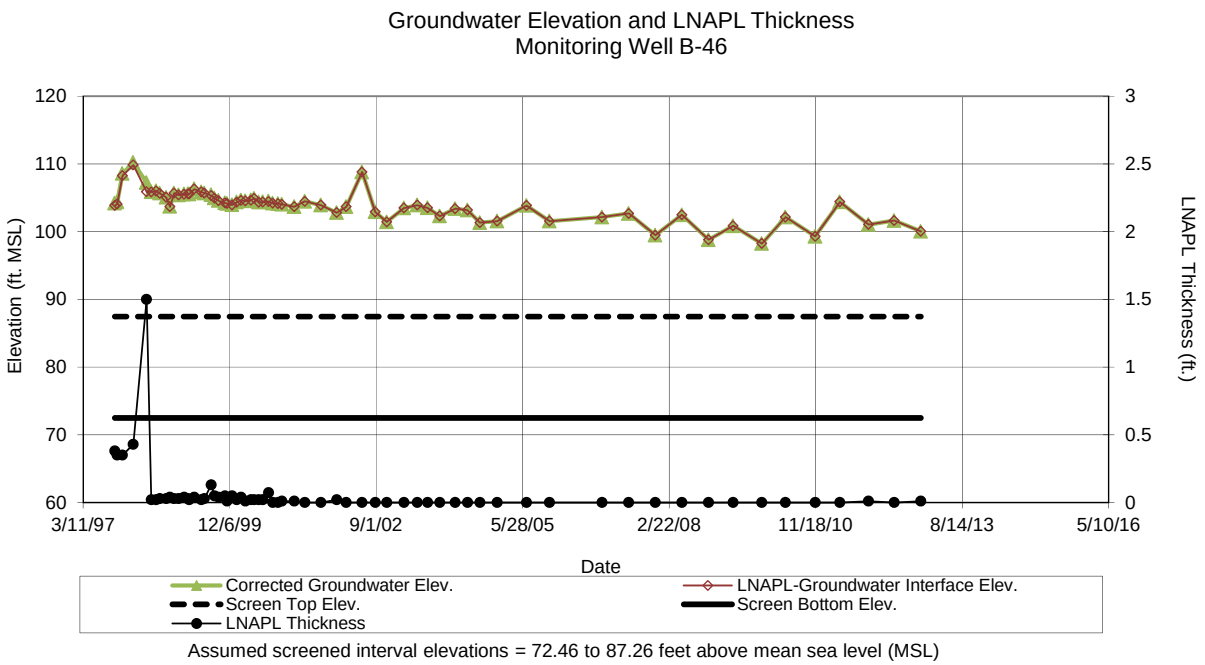
Assumed screened interval elevations = 101.88 to 116.88 feet above mean sea level (MSL)



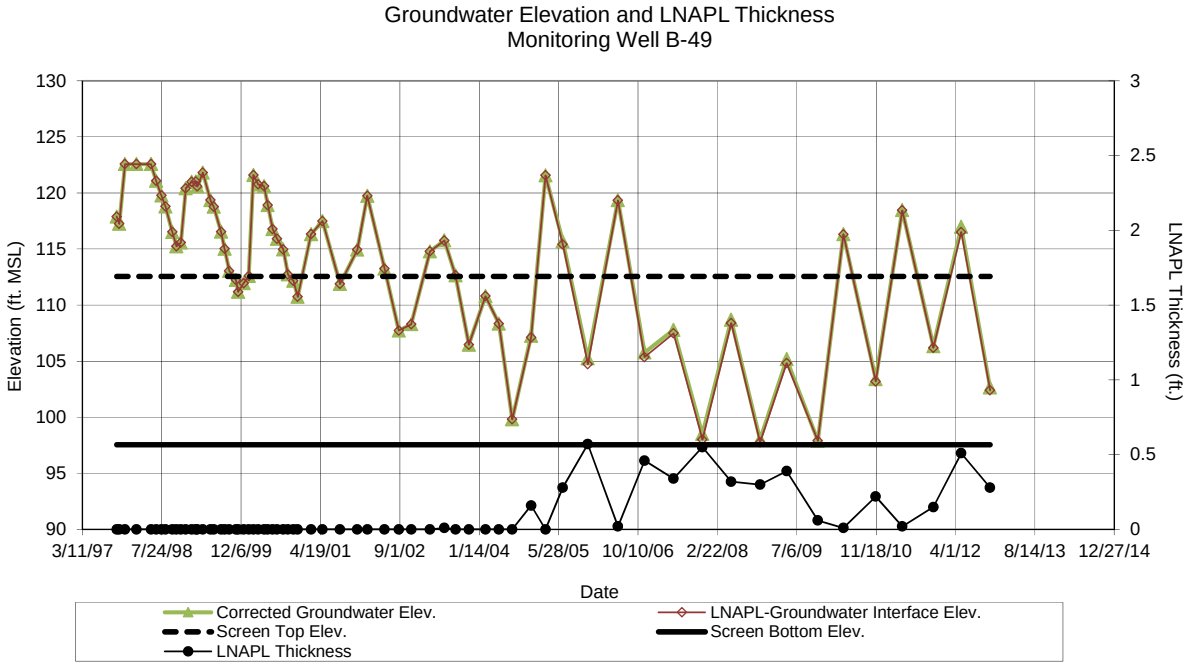
Assumed screened interval elevations = 66.13 to 86.13 feet above mean sea level (MSL)



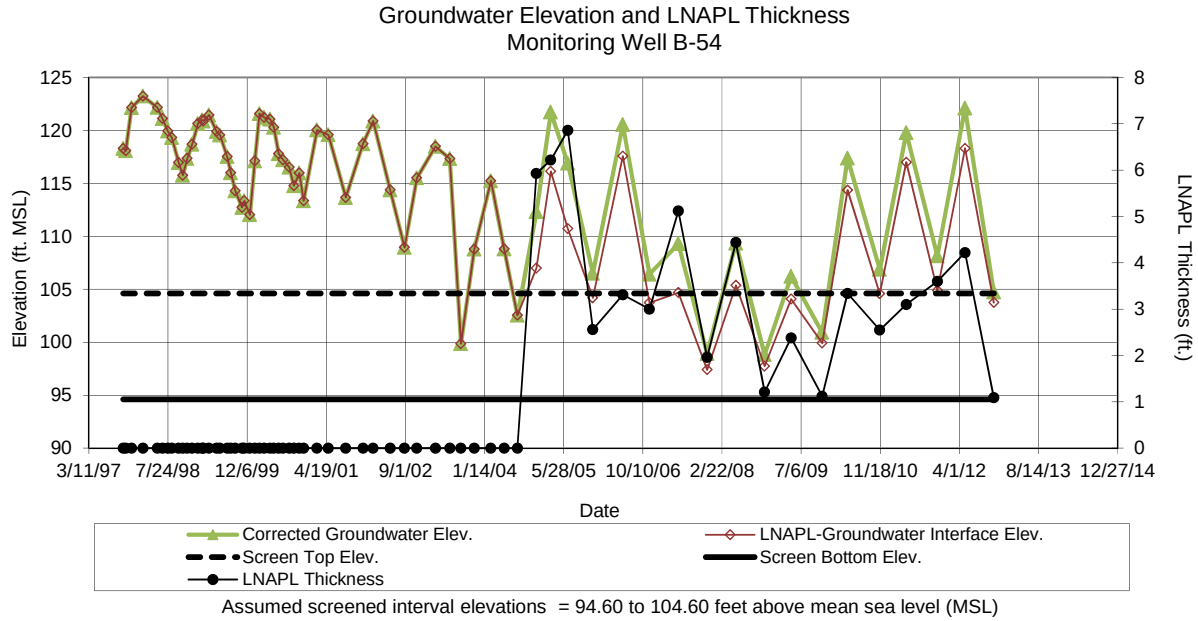
Assumed screened interval elevations = 52.57 to 72.57 feet above mean sea level (MSL)



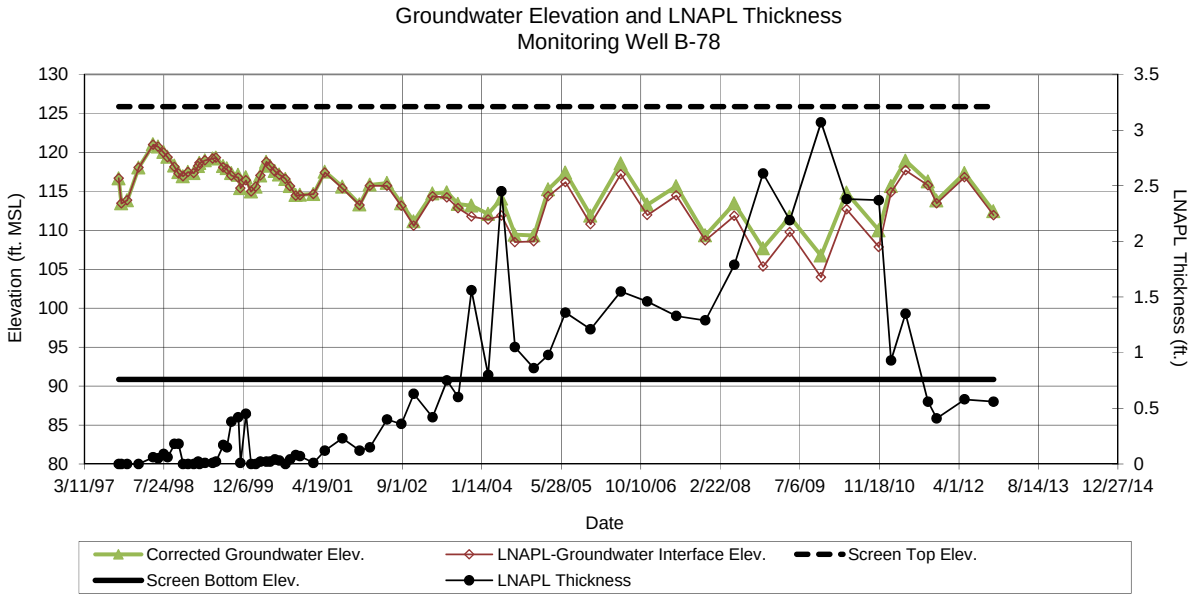
Assumed screened interval elevations = 72.46 to 87.26 feet above mean sea level (MSL)



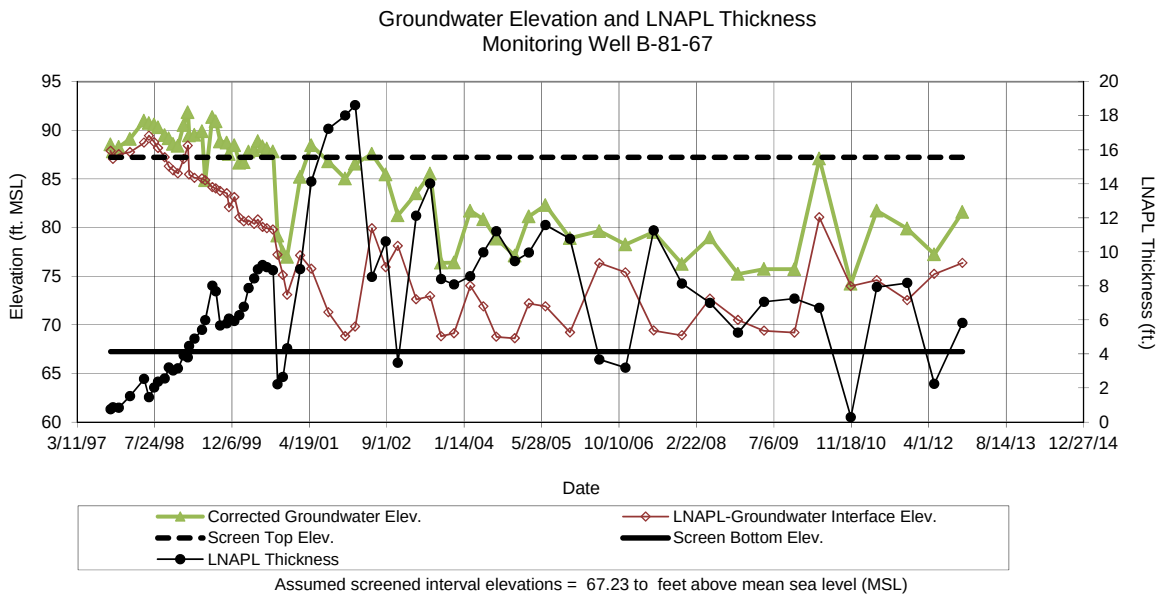
Assumed screened interval elevations = 97.55 to 112.55 feet above mean sea level (MSL)



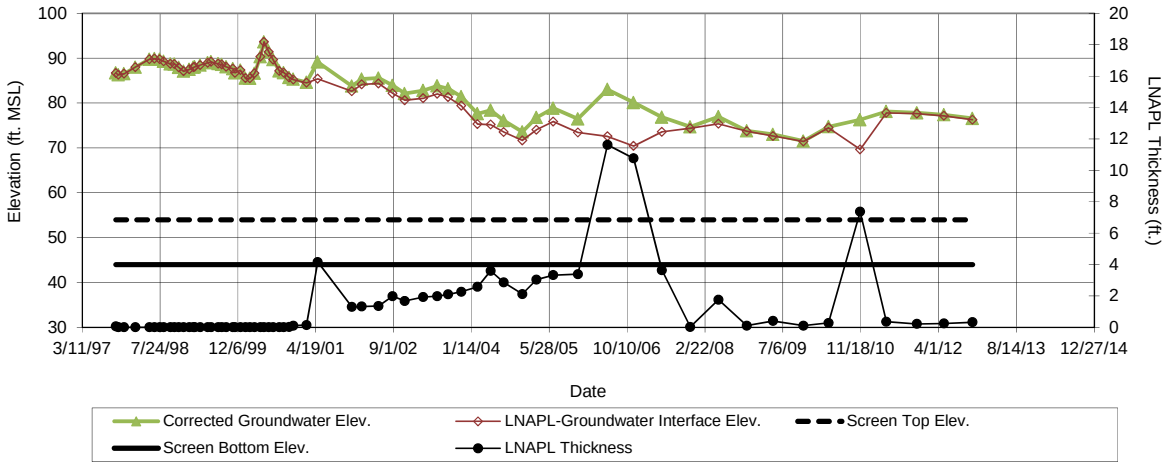
Assumed screened interval elevations = 94.60 to 104.60 feet above mean sea level (MSL)



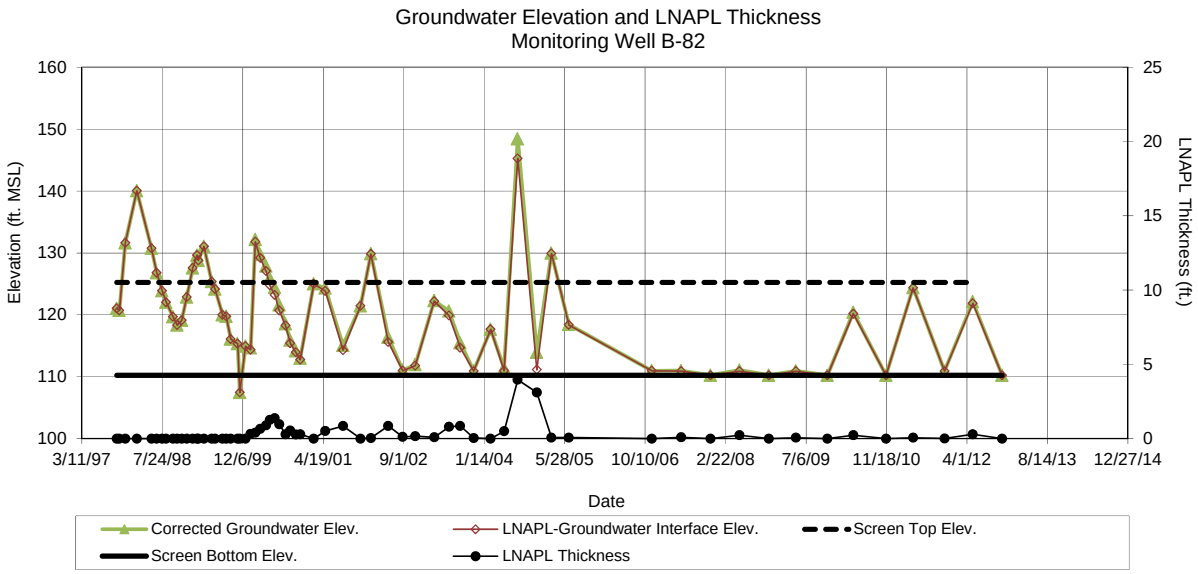
Assumed screened interval elevations = 90.88 to 125.88 feet above mean sea level (MSL)



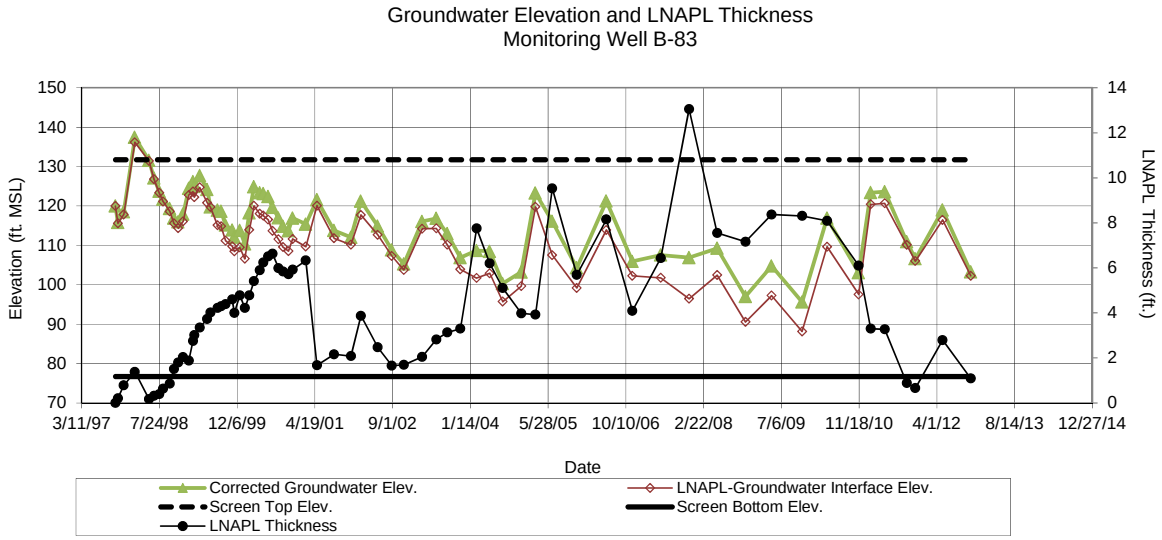
Assumed screened interval elevations = 67.23 to feet above mean sea level (MSL)



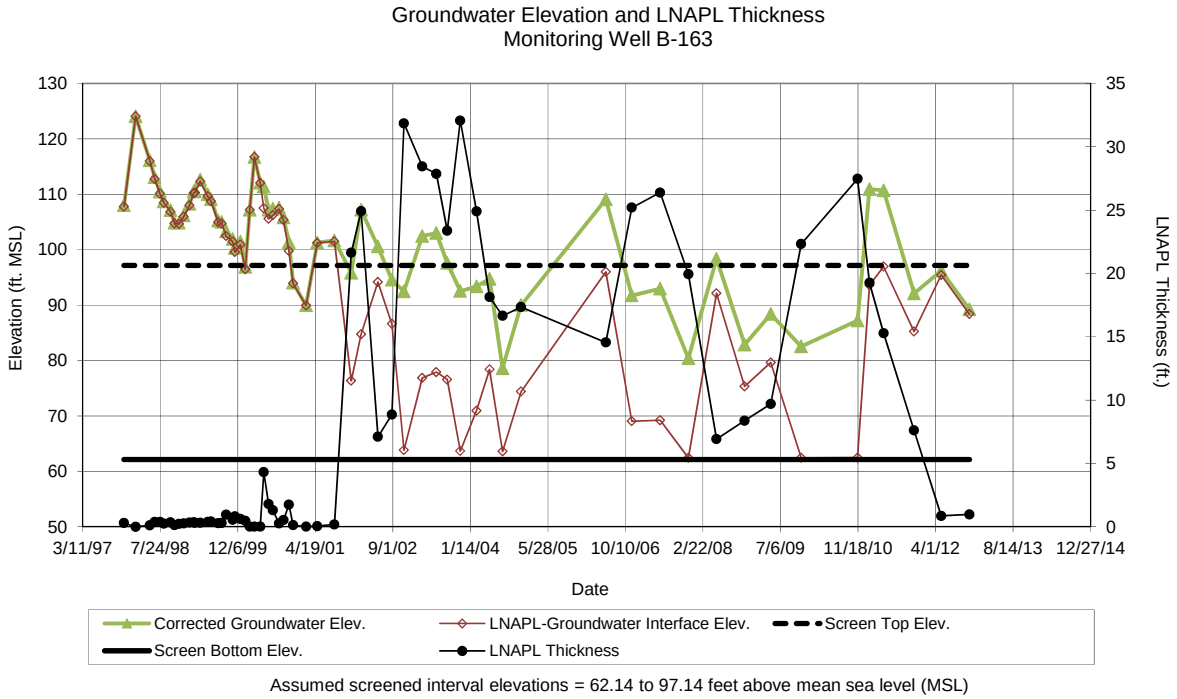
Assumed screened interval elevations = 43.96 to 53.96 feet above mean sea level (MSL)



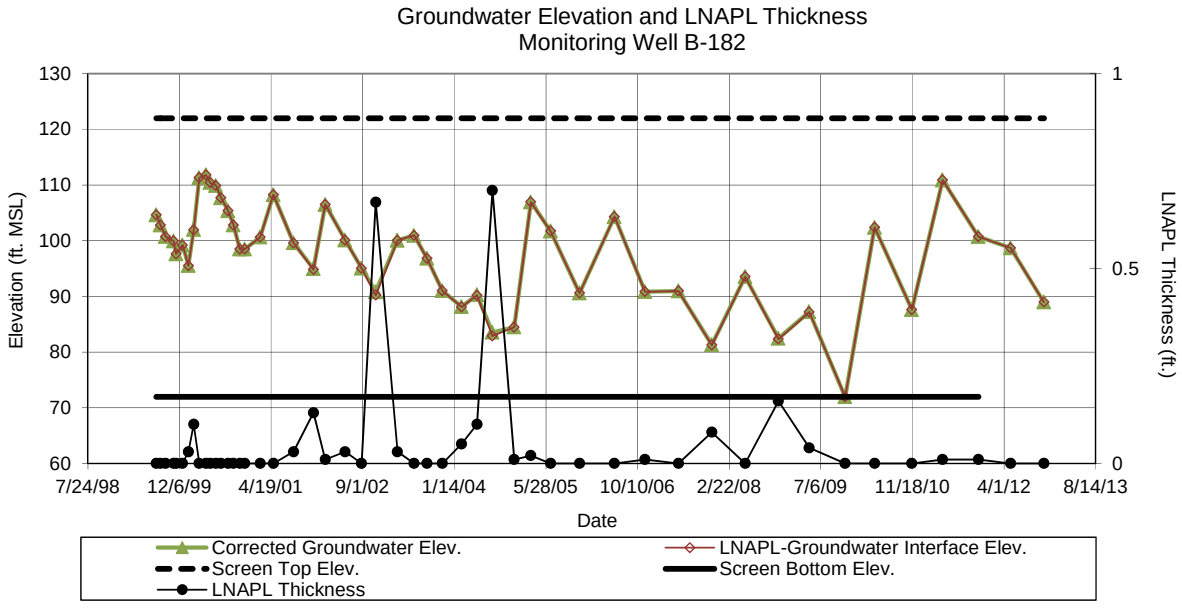
Assumed screened interval elevations = 110.24 to 125.24 feet above mean sea level (MSL)



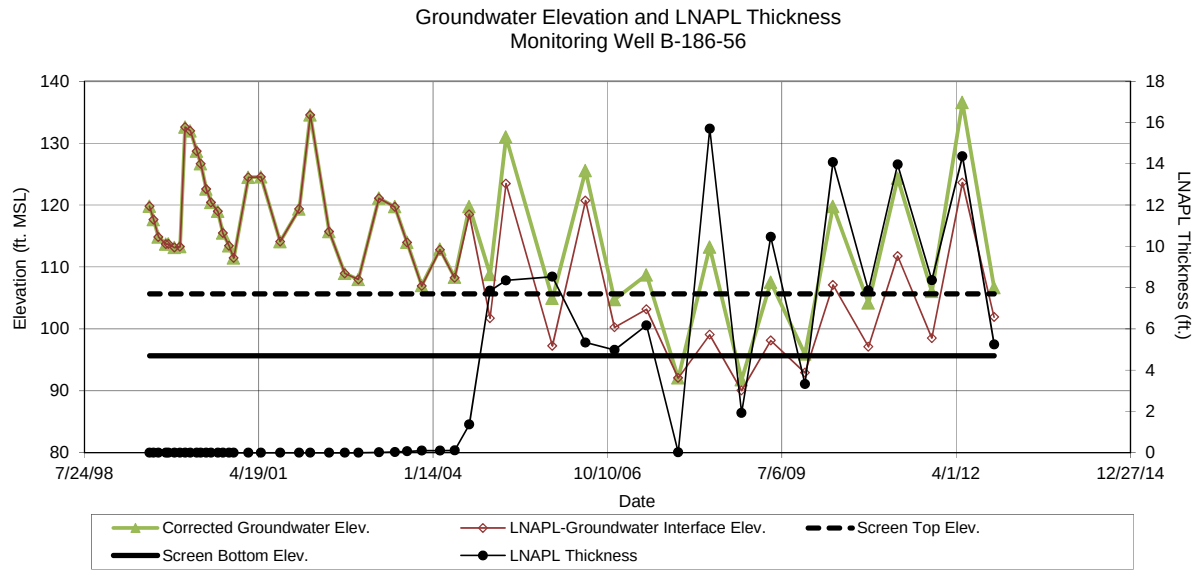
Assumed screened interval elevations = 76.70 to 131.70 feet above mean sea level (MSL)



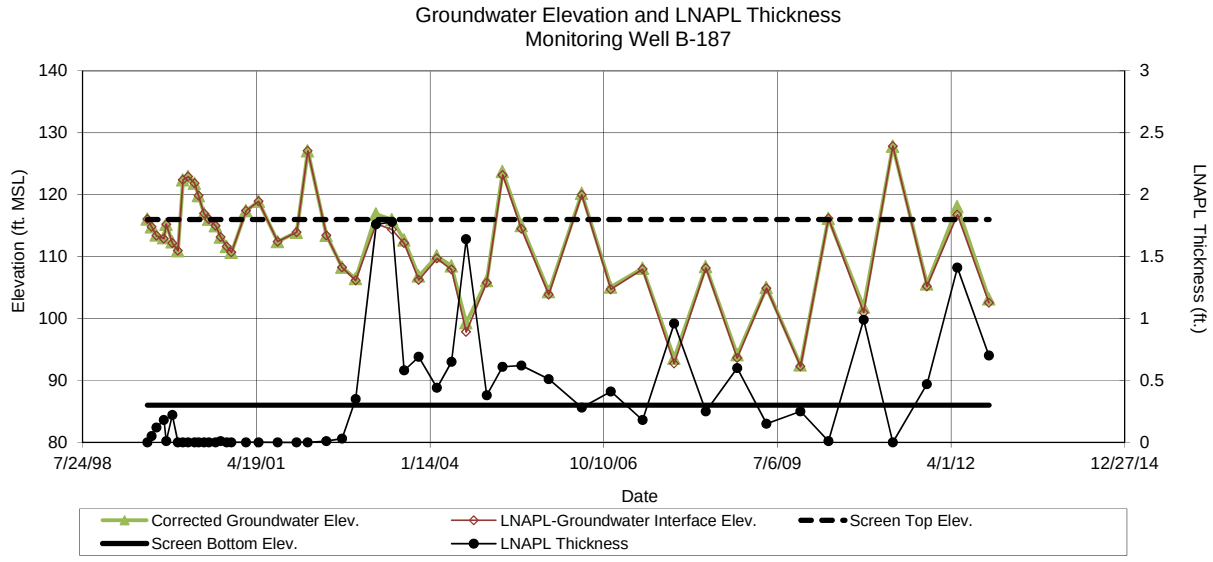
Assumed screened interval elevations = 62.14 to 97.14 feet above mean sea level (MSL)



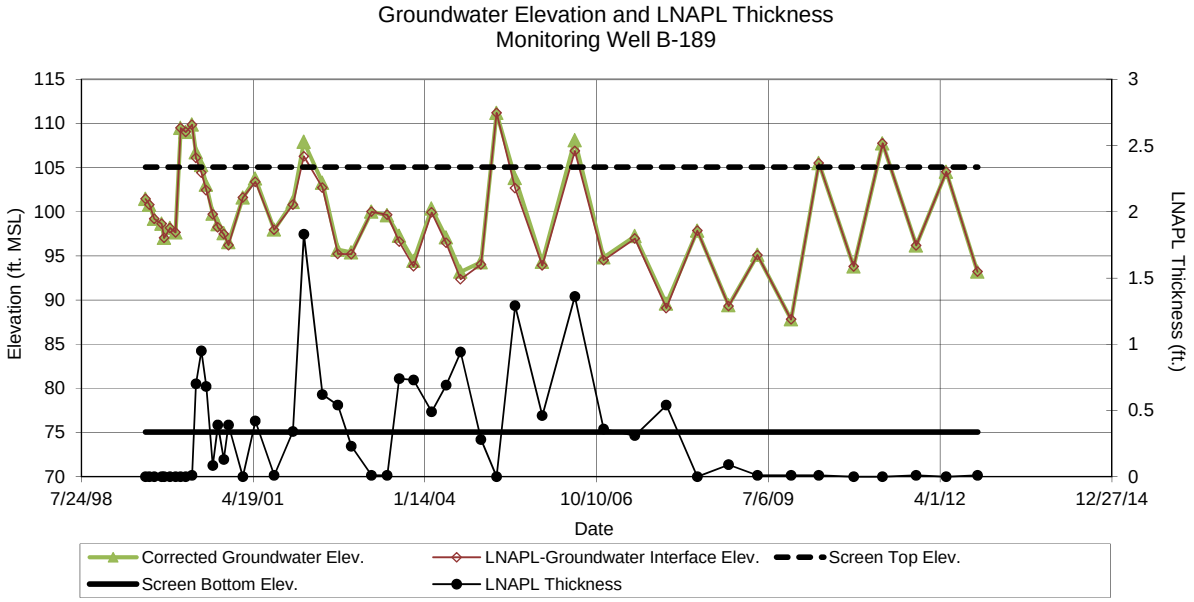
Assumed screened interval elevations = 71.94 to 121.94 feet above mean sea level



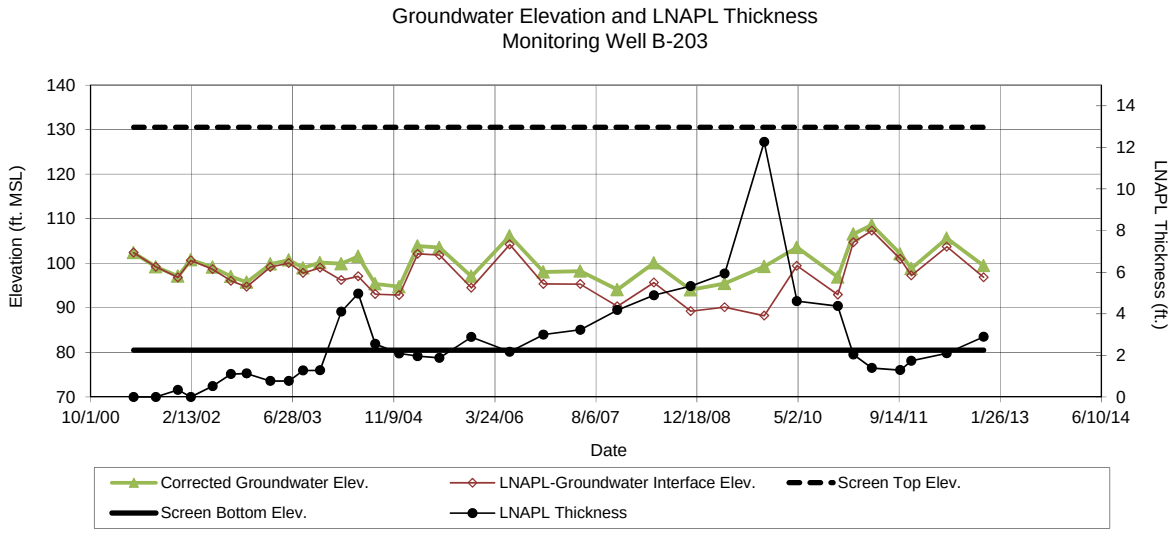
Assumed screened interval elevations = 95.67 to 105.67 feet above mean sea level (MSL)



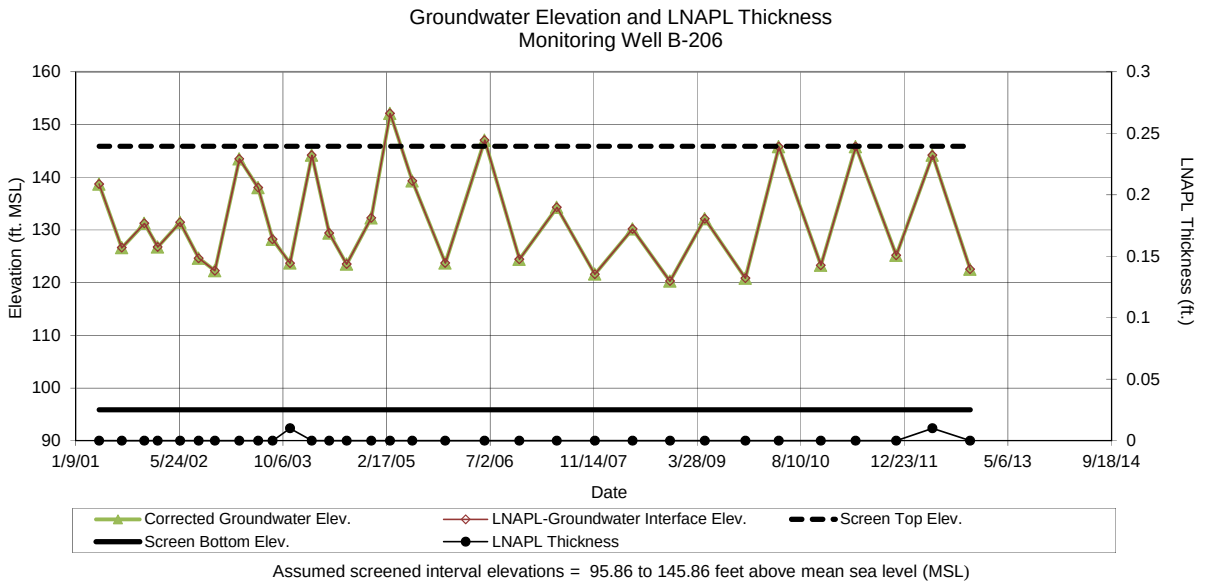
Assumed screened interval elevations = 86.00 to 116.00 feet above mean sea level (MSL)



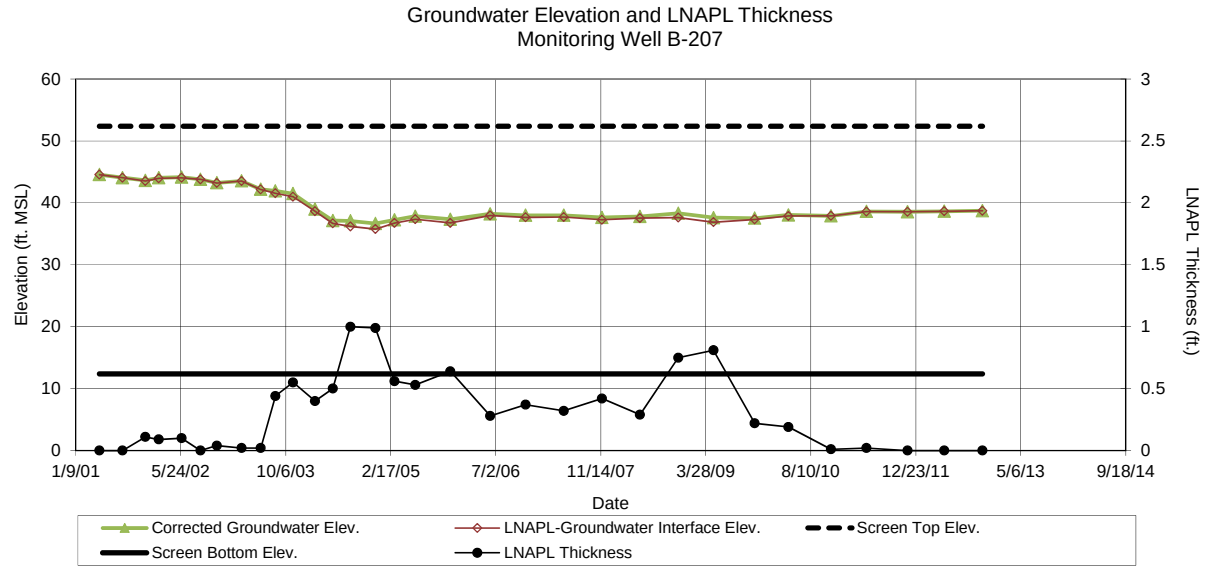
Assumed screened interval elevations = 75.06 to 105.06 feet above mean sea level (MSL)



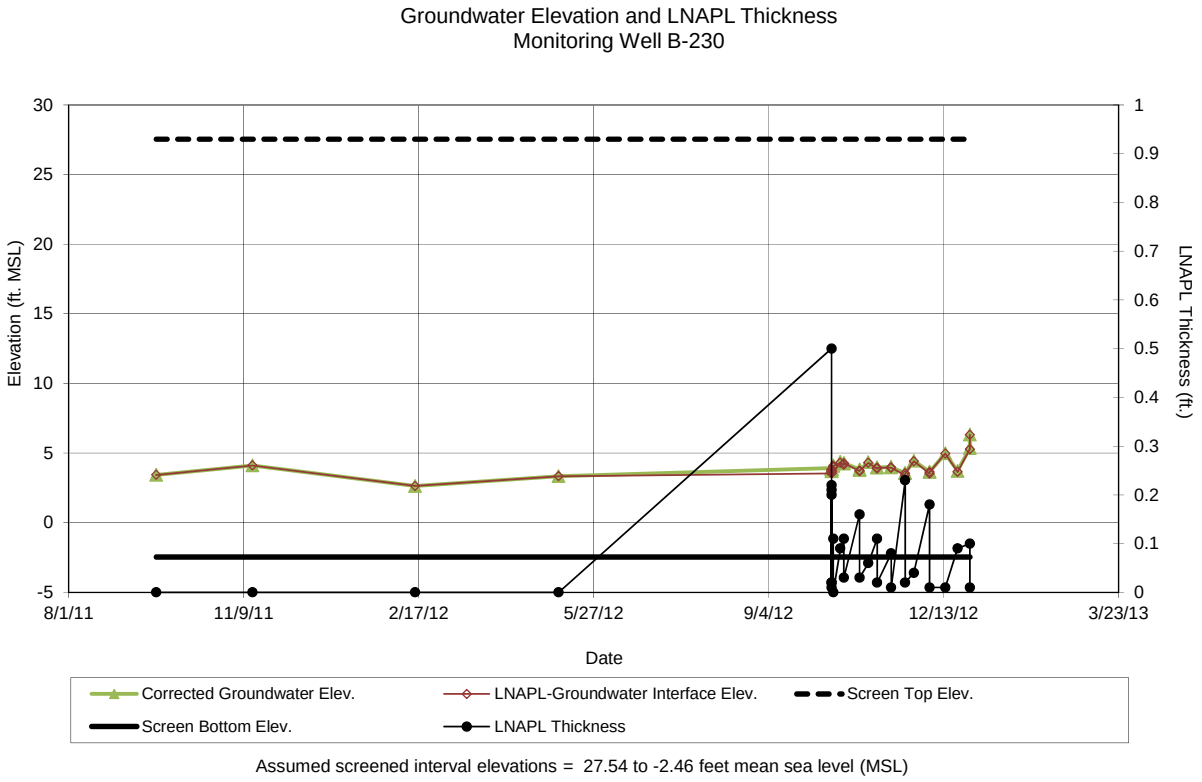
Assumed screened interval elevations = 80.52 to 130.52 feet above mean sea level (MSL)



Assumed screened interval elevations = 95.86 to 145.86 feet above mean sea level (MSL)



Assumed screened interval elevations = 12.38 to 52.38 feet above mean sea level (MSL)



Assumed screened interval elevations = 27.54 to -2.46 feet mean sea level (MSL)

Notes:
All results in milligrams per kilogram (mg/kg)
<10 = not indicated at or above the method reporting limit
TPH = total petroleum hydrocarbons
(1) = TPH sum does not include J flag results
J = Estimated value; results are less than the reporting limit and above the detection limit.

RE: Former Unocal Avila Terminal

Work Order: 1105253

Dear Client:

Enclosed is an analytical report for the above referenced project. The samples included in this report were received on 02-Nov-11 16:22 and analyzed in accordance with the attached chain-of-custody.

Unless otherwise noted, all analytical testing was accomplished in accordance with the guidelines established in our Quality Assurance Manual, applicable standard operating procedures, and other related documentation. The results in this analytical report are limited to the samples tested and any reproduction thereof must be made in its entirety.

If you have any questions regarding this report, please do not hesitate to contact the undersigned.

Sincerely,

Lisa Race

Laboratory Manager

Padre Associates, Inc. - SLO	Project: Former Unocal Avila Terminal	
369 Pacific Street	Project Number: 0801-0896 Land Farming Bench-Scale Test	**Reported:**
San Luis Obispo CA, 93401	Project Manager: Louis Cappel	16-Nov-11 17:10

Notes and Definitions

S-GC	Surrogate recovery outside of control limits. The data was accepted based on valid recovery of the remaining surrogates.
S-04	The surrogate recovery for this sample is outside of established control limits due to a sample matrix effect.
R-05	The sample was diluted due to the presence of high levels of non-target analytes resulting in elevated reporting limits.
R-01	The Reporting Limit has been raised to account for matrix interference.
QR-04	The RPD exceeded the QC control limits.
QR-03	The RPD value for the sample duplicate or MS/MSD was outside of QC acceptance limits due to matrix interference. QC batch accepted based on LCS and/or LCSD recovery and/or RPD values.
QR-02	The RPD result exceeded the QC control limits; however, both percent recoveries were acceptable. Sample results for the QC batch were accepted based on percent recoveries and completeness of QC data.
QM-09	The spike recovery was outside acceptance limits for the LCSD. The batch was accepted based on acceptable LCS recovery.
QM-07	The spike recovery was outside acceptance limits for the MS and/or MSD. The batch was accepted based on acceptable LCS recovery.
J	Detected but below the RL/PQL; therefore, result is an estimated concentration .
HT-pH	Water pH should be analyzed within 15 minutes of sampling. Soil pH should be analyzed as soon as possible.
C-05	To reduce matrix interference, the sample extract has undergone GPC clean-up, method 3640, which is specific to contamination from high molecular weight material.
C-03	To reduce matrix interference, the sample extract has undergone silica-gel clean-up, method 3630, which is specific to polar compound contamination.
C-01	To reduce matrix interference, the sample extract has undergone sulfuric acid clean-up, method 3665, which is specific to hydrocarbon contamination.
>212	>212
DET	Analyte DETECTED
ND	Analyte NOT DETECTED at or above the Method Limit (MDL)
NR	Not Reported
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference

Hazardous Material Bioassay Screen
Polisini and Miller. CA Fish & Game Lab. 1988

Project: Former Onocal Avila 0801-0896

Sample #	Sample description	Date / Time	Analysis	Method	Result	Units	Completed
-1	**OEC# 1105253-30**	11/1/11 1119	Haz. Mat Bioassay (Screen)	Polisini & Miller	**PASS**	Pass/Fail	**11/23/11**
	T2C-4'						
-2	**OEC#1105253-36**	11/1/11 1153	Haz. Mat Bioassay (Screen)	Polisini & Miller	**PASS**	Pass/Fail	**11/23/11**
	T2C-6'						
-3	**OEC# 1105253-40**	11/2/11 0955	Haz. Mat Bioassay (Screen)	Polisini & Miller	**PASS**	Pass/Fail	**11/23/11**
	T3A-2'						
-4	**OEC# 1105253-53**	11/2/11 1125	Haz. Mat Bioassay (Screen)	Polisini & Miller	**PASS**	Pass/Fail	**11/23/11**
	T3B-6'						

The Hazardous Waste Bioassay Screen (Static/Acute) is conducted under the guidelines of Polisini & Miller, 1988. The tests are conducted under the conditions listed below unless noted (*****) and accompanied with written explanation.

Sample Extraction: Mechanical Shaker/ ASTM II Water
Control Water Source: Reverse Osmosis with 5% Tap
Control Water Hardness: 40-48 mg/L CaCO3

Feeding: None
Temperature Range: 18 - 22°C
Photoperiod: 16hr. Light/ 8hr. Dark

Test Chamber Volume: 10L
Number of Replicates: 2
Fish per Chamber: 10.
Tanks aerated: None
Aeration Rate: (Maintain DO > 4ppm.)

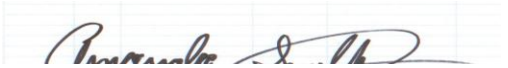
Test Endpoints: Survival at 96 hours
Test Organism: *Pimephales promelas*

Source: Thomas Fish Company
Fish Batch Number: 102

Ave. Length (mm) 34. min 32. max 35.
Ave. Wt. (g) 0.44 min 0.28 max 0.53

Results Explained:
State of CA limit for Non-Haz. Designation > 500. mg/L
Pass: LC50 > 750 mg/l (<40% dead in 750 mg/l conc)
Fail>40% dead in 750mg/l (definitive test recommended)

Start Bioassay: 11/19/2011
Report Completion Date: 11/23/2011
Data Review:



Fail LC50< 400mg/l (>60% dead in 400 mg/l conc.)

Venice, California 90291

Data Usability Evaluation
Human Health Risk Assessment Database
Unocal Avila Tank Farm
Avila Beach, California

Dear Dr. Lambert:

The purpose of this document is to evaluate the usability of the Unocal Avila Beach Tank Farm historical environmental analytical data (data) for use in the human health risk assessment. This data has been collected over the past 7 years by one primary investigator (England & Associates, Inc., who after October 2000 conducted business as England Geosystem, Inc.) and two secondary investigators (Fluor Daniel GTI, Inc. and Avocet Environmental, Inc.). With few exceptions, the environmental samples were tested by a single analytical laboratory, ZymaX envirotechnology, inc. The United States Environmental Protection Agency (USEPA), in their document entitled *Guidance for Data Usability in Risk Assessment (Part A)*, lists six criteria for evaluating the usability of environmental analytical data (data) collected for baseline human health risk assessment (USEPA, April 1992). These include:

Criterion I - Reports: In this case, the assessment and characterization reports containing the historical or legacy environmental analytical data. The data should be reported in a format that provides adequate data and data documentation.

Criterion II - Documentation: Data collection and analysis procedures must be accurately documented to substantiate the analysis of the sample, conclusions derived from the data, and the reliability of the analytical data.

Criterion III - Data Sources: For historical analytical data to be useful in quantitative risk assessment, sampling design, sampling and analytical techniques, and detection limits must be well documented.

Criterion IV - Analytical Methods and Detection Limits: Appropriate analytical methods are able to identify chemicals of potential concern (COPCs) and have detection limits that meet risk assessment requirements.

Criterion V - Data Review: An examination of laboratory and method performance for the samples and analytes.

Criterion VI - Data Quality Indicators: Data quality indicators provide quantitative measures of the completeness, comparability, representativeness, precision, and accuracy of the environmental analytical data. These indicators are evaluated through the review of sampling and analytical data and accompanying documentation.

The following sections will review the soil, soil gas and ground water environmental analytical data intended for use in the human health risk assessment in light of these six criteria.

CRITERION I – REPORTS

Over forty reports were used to assemble the soil, soil gas and ground water environmental analytical database intended for use in the human health risk assessment. Following is a review of each report or group of reports in terms of the presence or absence of certain types of documentation suggested by the USEPA (1992). The review will be conducted in the form of a Report Content Checklist. The items in the checklist are abbreviated descriptions derived from Exhibit 19. Data and Documentation Needed for Risk Assessment as reproduced below:

Data and Documentation
• Site description with a detailed map indicating site location, showing the site relative to surrounding structures, terrain features, population or receptors, indicating air and water flow, and describing the operative industrial processes, if appropriate.
• Site map with sample locations (including soil depths) identified.
• Description of the sampling design and procedures including rationale.
• Description of analytical method used and detection limits including SQLs and detection limits for non-detect data.
• Results given on a per-sample basis, qualified for analytical limitations and error, and accompanied by SQLs. Estimated quantities of compounds/tentatively identified compounds.
• Field conditions and physical parameter data as appropriate for the media involved in the exposure assessment.
• Narrative explanation of qualified data on an analyte and sample basis, indicating direction of bias.
• QC data results for audits, blanks, replicates and spikes from the field and laboratory.
• Definitions and descriptions of flagged data.
• Hardcopy or diskette results (from the analytical laboratory).
• Raw data (instrument output, chromatograms, spectra).

In the Report Content Checklists, the word "Yes" to the left of the documentation item indicates that the report(s) contain the recommended information and the word "No" indicates that the suggested documentation is not contained within the report(s). In general, the reports include very good documentation of the: 1) site location and surrounding features, 2) sampling design rationale and procedures, 3) analytical methods and detection limits, 4) analytical results on a

per-sample basis, and 5) descriptions of the field conditions and physical parameters (e.g., soil texture, porosity, moisture content, etc.). The reports include good documentation of field and laboratory quality control (QC) data results and laboratory raw data – particularly GC/MS total ion current traces (TICs) for samples containing hydrocarbons; and relatively poor documentation of qualified data and tentatively identified compounds.

CRITERION II – DOCUMENTATION

The objective of the documentation review is to ensure that each analytical result can be traced to a sample location and that the procedure(s) used to collect the environmental samples were appropriate. The three acceptable types of documentation used to trace samples and analytical methods are chain-of-custody forms, standard operating procedures (SOPs), and field and analytical records. All of the reports contain very good maps depicting the geographic location of sample collection. Almost all of the sample locations were surveyed by a licensed land surveyor to permit accurate location of the sample collection point on a map. All the reports contained descriptions of sample collection procedures which were judged to be in general compliance with standard operating procedures common to the environmental engineering industry. All of the samples were appropriately labeled and handled in accordance with standard chain-of-custody protocols and copies of the chains-of-custody are included in the laboratory reports. All of the reports contain field records describing the time of sample collection, the nature and appearance of the sample, and documentation of field measurements (pH, temperature, etc.), where appropriate.

CRITERION III – DATA SOURCES

The objective of the data source review is to ensure that the analytical techniques used for the investigation are appropriate to identify COPCs for each exposure area and environmental medium of interest. The Avila facility served as a petroleum storage and distribution facility for more than 80 years. Therefore, most of the samples collected at the site were analyzed for the presence of petroleum (total petroleum hydrocarbons, TPH) and petroleum-related compounds including volatile aromatic hydrocarbons (benzene, toluene, ethyl benzene, and total xylenes, collectively referred to as BTEX), volatile organic compounds (VOCs) and polycyclic (or

polynuclear) aromatic hydrocarbons (PAHs). Samples were also analyzed for various non-petroleum compounds such as metals, polychlorinated biphenyls (PCBs), herbicides, and pesticides. All of these tests were performed using USEPA, State of California, or other approved methods. A panel of three university professors with expertise in site characterization and remediation who were commissioned by the Regional Water Quality Control Board and Unocal to review the Avila Tank Farm site characterization documents concluded that *"This level of chemical identification is considered to be appropriate for this type of site and no recommendations regarding additional constituents are warranted at this time"*.

Since characterization of the site began in late 1997, essentially all of the samples collected at the site have been tested by ZymaX envirotechnology, a California Department of Health Services certified environmental testing laboratory located in San Luis Obispo, California. All of the samples tested by ZymaX were tested using the same USEPA, State of California, or other approved methods and, therefore, the data are considered comparable.

CRITERION IV – ANALYTICAL METHODS AND DETECTION LIMITS

For a chemical result to be usable for assessing risk, the analytical method must appropriately identify the chemical form or species, and the sample detection limit must be at or below a concentration that is associated with risk benchmark levels. The Unocal Avila Tank Farm environmental monitoring dataset contains almost 100,000 records. All of these samples were tested by California Department of Health Services-certified environmental testing laboratories using USEPA, State of California, or other (ASTM, LUFT, etc.) approved analytical methods. The analytical methods utilized by the laboratories are considered appropriate to identify the COPCs at the site. In general, the detection limits associated with these analytical methods were significantly below risk benchmarks (e.g., USEPA Region IX Preliminary Remediation Goals [PRGs]).

CRITERION V – DATA REVIEW

For the most part, analytical data collected during site characterization of the Unocal Avila Tank Farm have received a minimum level of review. In general, reviews were performed and documented to demonstrate that all analyses were performed in accordance with USEPA, State of California, or other (ASTM, LUFT, etc.) approved analytical methods. The data were also reviewed for data completeness to ensure that all of the samples delivered to the laboratory and scheduled for testing were analyzed and reported and that the samples were tested within the appropriate holding times. Less frequently were field (duplicates, trip blanks) and/or laboratory (instrument calibration, surrogate recovery, etc.) quality control procedures reviewed to comment on the quality of the analytical data. The ground water monitoring program routinely uses field duplicates and trip blanks to assess the accuracy and representativeness of the data. The most commonly performed laboratory quality control review was an inspection of surrogate standard recoveries (method accuracy) to ensure that the recoveries were within the acceptable range.

CRITERION VI – DATA QUALITY INDICATORS

The data quality indicators (DQI) provide quantitative measures of the achievement of quality objectives. The five DQIs include: 1) completeness – a measure of the amount of usable data resulting from a data collection activity; 2) comparability – the confidence with which data are considered to be equivalent – only comparable data sets can be combined; 3) representativeness – the extent to which data define the true risk to human health and the environment; 4) precision – a quantitative measure of variability; and 5) accuracy – a measure of the closeness of a reported concentrations to the true value.

Several phases of site characterization extending over a period of seven years have resulted in the collection and testing of thousands of soil, soil gas and ground water samples for a variety of petroleum and petroleum-related compounds. This number of samples is considered adequate to provide a database of sufficient size and completeness for risk assessment purposes. Essentially all of the samples collected at the Avila Tank Farm were tested by ZymaX envirotechnology. All of these samples were collected using comparable and standard field procedures, handled in accordance with standard chain-of-custody protocols, and tested by the same analytical laboratory using the same USEPA, State of California, or other approved analytical methods. Therefore, the data comprising the database are considered reasonably comparable for use in risk assessment.

One objective of the site characterizations has been to investigate "areas of concern" based on historical land-use patterns for "constituents of potential concern". These investigations started off using broad spectrum tests (VOCs, sVOCs, metals, PCBs, etc.) to evaluate the potential for a wide range of potential contaminants. Once areas of contamination were identified, these areas were further studied to characterize the nature and extent of the contaminant. Hundreds of borings have been drilled and thousands of samples have been collected and tested for petroleum and petroleum-related compounds. The density of borings covering the site and the number of samples tested suggest that the database is reasonably representative of the range of COPC concentrations present at the site for use in risk assessment. A review of the reports indicates that holding times, extraction procedures, and the results of field quality control samples (equipment and trip blanks) are within acceptable limits and support the representativeness of the analytical data.

Precision is determined by evaluating: (1) the sampling variability; and (2) the measurement error. Assessment of measurement error is accomplished using the results of field duplicate samples, which are commonly used for liquid samples, but rarely used for solid samples. More than 90 field (ground water) duplicates (field quality control samples) have been collected at the Avila Tank Farm to assess data precision. These samples were generally tested for TPH in three carbon ranges (C_4-C_{10}, C_{10}-C_{25}, and C_{25}-C_{40}) and BTEX. Commonly, the relative percent difference (RPD) for duplicate samples (the absolute difference between two duplicate measurements divided by the mean, and multiplied by 100), is calculated to rapidly assess the precision of a set of measurements. Precision is deemed acceptable when the obtained precision result is less than or equal to (≤) 30 percent. Of the 93 duplicate ground water samples evaluated, representing over 500 individual measurements (e.g., 93 samples tested for TPH and

BTEX), only five measurements have exceeded an RPD of 30 percent. Therefore, the overall precision of the analytical data is deemed acceptable.

Accuracy is a measure of overestimation or underestimation of reported concentrations and is evaluated from the results of spiked samples. To acquire and maintain DHS-certification, the laboratories routinely perform a number of internal quality checks to ensure the accuracy of the analytical process. These internal checks include: matrix spikes – adding some or all of the analytes of interest to a sample, sample extract, or a blank and measuring the percent recovery (%R); duplicate analysis – the analysis of duplicate samples to measure precision; method blanks – a sample free of contaminants to assess the integrity of the analytical system; and surrogate standards – samples are spiked with compounds closely related to the analytes of interest (surrogates) before sample preparation and surrogate recoveries are documented. If any of these internal checks do not meet quality control standards (i.e., %R within acceptable ranges and/or contaminant free blanks) designed to ensure analytical precision and accuracy, corrective action must be taken and the samples reanalyzed. Essentially all of the samples comprising the risk assessment dataset were analyzed by ZymaX envirotechnology. All of these samples were subjected to the above-described internal checks, but in general only the results of the percent surrogate recovery are included on the laboratory reports. A review of a representative sampling of these reports indicates that the surrogate recoveries are within acceptable ranges for the various analytical methods (e.g., 40-120% for EPA 8270 SIM). Although we are unable to quantitate accuracy using the information provided on the laboratory reports, the data is available and may be requested from ZymaX. Based on the known analytical laboratory internal checks it is our opinion that the laboratory performance is sufficiently accurate to allow the data to be used in human health risk assessment.

Avocet Environmental, Inc. sincerely appreciates the opportunity to be of service. If you have any questions, please do not hesitate to call (949) 296-0977.

Executive Summary

The purpose of this document is to evaluate the usability of the Unocal Avila Beach Tank Farm 2007 environmental analytical data, the 2005 trench samples analytical data, and the 2005 wetland samples analytical data (data) for use in the human health risk assessment. This has been done by performing data validation and data usability on the data following EPA guidance.

The data validation evaluation summarizes the quality assurance evaluation of the data according to precision, accuracy, representativeness, completeness, and comparability (PARCC) relative to the National Functional Guidelines, providing an assessment of the data and identifying potential sources of error, uncertainty, and bias that may affect the overall usability. The laboratory reports were evaluated based on the following documents: *Contract Laboratory Program National Functional Guidelines for Organic Data Review*, October 1999, *Contract Laboratory Program National Functional Guidelines for Inorganic Data Review*, October 2004. Professional judgment was used in some cases to qualify the results. Attachments A through C show the results of the data validation evaluation for the 2007 Soil and Air data, the 2005 Trench data, and the 2005 Wetlands data.

The data usability evaluation was performed using the criteria provided by USEPA in the *Guidance for Data Usability in Risk Assessment* (Part A), Final (USEPA, 1992a). The 6 criteria are labeled: Reports; Documentation; Data Sources; Analytical Methods and Detection Limits; Data Review; and, Data Quality Indicators, and are described in detail in Attachment D. Spatial representativeness of the data is explicitly addressed in Attachment E, in the context of coverage of the source terms, and adequacy of the data to support risk assessment.

There is some overlap between data validation and data usability. The overlap mostly concerns the role of the PARCC parameters evaluation, which occurs in both evaluations. However, the data validation is aimed summarizing according to quality assurance metrics. Qualifiers are added to data as a consequence of any inconsistencies with the functional guidelines. Data usability also involves evaluation of the data with respect to the PARCC parameters, but the goal is to evaluate data for a specific use or purpose. This evaluation does not address the adequacy of the data to support a decision, but does address the usability of the data for the given purpose, which in this case is a human health risk assessment. That is: Can the data be used in a risk assessment? Note that data adequacy is a statistical issue for which guidance is provided in EPA's Data Quality Assessment (DQA) document (EPA G-9, 2006). DQA is associated more directly with and Data Quality Objectives that were established for the site risk assessment, although DQA can be used to evaluate retrospective DQOs. Data adequacy or data quality assessment is ultimately performed through sample size calculations.

The data usability performed for these data reached into some data adequacy areas, but only on a qualitative way. That is, evaluations were performed of the spatial representativeness or adequacy of the data to characterize each source term on the site,

and to support risk assessment in each evaluation area that has been defined. Evaluation areas A through M have been defined (see Attachment D). The intended land use for evaluation areas A through L is commercial, for evaluation are is residential, which has an associated parking area, and recreational use is assumed for land that winds between evaluation areas A through M.

This document is organized by Attachments that are stand-alone documents for the data validation and data usability that have been performed. Data validation for the different data sets are presented in Attachments A through C, followed by the data usability evaluation in Attachment D, and spatial representativeness in Attachment E. Highlights of the most significant findings in the Avila data validation and data usability that were conducted include (note that each item is described in more detail in the Attachments):

- Comparability of the various data sets is an issue. The results were not consistently reported in wet weight or dry weight. In some cases, how the results were reported was not specifically noted in the laboratory documentation. Assumptions were made based on the available information to complete the data validation and data usability evaluations.
- Data packages from 2005 sampling were not complete enough to do a full review of all QC data to provide a complete discussion of data usability. For example, the Sediment results only include QC data for surrogates, no other positive and negative control (blanks, spikes, replicates) were included; for the Trench data, in many cases the continuing calibration verification recovery was not within limits, but the magnitude and direction of the recovery was not specified to fully determine the effect. All Sediment results are considered usable only for screening information.
- Most of the reporting limit issues were related to high dilution factors during the sample analysis. Thus, in general sensitivity was acceptable for risk assessment.
- There were results associated with only one sample that were not considered usable. Volatile fuel hydrocarbons in sample SV-51-01 had severely low recoveries for the associated matrix spike and MSD, so these data should not be used for this human health risk assessment.
- Several air samples were received with significant vacuum remaining in the canister which resulted in elevated reporting limits.
- The data in the south-east corner were analyzed at a different laboratory, and the concentrations are greater than elsewhere in general, despite a lack of apparent source term.
- The source terms appear to be adequately characterized, however, it is not clear that there is enough data in each evaluation area to support evaluation area specific human health risk assessments. There might be sufficient justification to combine and/or redraw areas to bring more data into play. For example, there are as many samples outside the evaluation areas as there are inside them. So, in effect, there are more samples than needed for the risk assessment for the "in between" recreational scenario, but not enough samples for risk assessment in some evaluation areas. This latter statement is of most concern for the only residential area (evaluation area M), which has very few samples in general, and

very few surface soil samples in particular. The few data points do not seem sufficient for risk assessment. Note that DQOs have not been presented, in which case DQA cannot be performed easily to determine adequacy of the data to support risk assessment. That is, sample size calculations cannot be performed to determine adequacy of the data unless (retrospective) DQOs are established. The data usability evaluation performed has qualitatively considered spatial representation of the data to support risk assessment. If a quantitative analysis were to be performed, more samples might be indicated for some evaluation areas.

List of Acronyms and Abbreviations

LCS/LCSD	Laboratory Control Sample / Laboratory Control Sample Duplicate
MS/MSD	Matrix Spike / Matrix Spike Duplicate
mg/L	Milligrams per Liter
ND	Not Detected
NFG	National Functional Guidelines
PARCC	Precision, Accuracy, Representativeness, Comparability, Completeness
QA/QC	Quality Assurance / Quality Control
RL	Reporting Limit
RPD	Relative Percent Difference
SDG	Sample Delivery Group
SVOC	Semivolatile Organic Compound
µg/L	Micrograms per Liter
USEPA	United States Environmental Protection Agency
VOC	Volatile Organic Compound
%D	Percent Difference
%R	Percent Recovery
%RSD	Percent Relative Standard Deviation

1. INTRODUCTION

This Data Validation Report has been prepared by Neptune and Company, Inc. to assess the validity of laboratory analytical data associated with work at the Avila Tank Farm Property in Avila Beach, California. For this data validation laboratory reports were provided from TestAmerica, Irvine, California. The TestAmerica laboratory reports were provided as Adobe Acrobat files, with file names IQG1327_REVISION, IQG1351_REVISION, and IQG1730_REVISION. These laboratory reports contained the results for samples analyzed for Elements/Metals, Volatile Fuel Hydrocarbons, Hydrocarbon Distribution, Volatile Organics with Oxygenates, and Semi-Volatile Organic Compounds (PAHs). Laboratory reports, as Adobe Acrobat files, were also received that included analyses conducted by Air Toxics Ltd, Folsom, California for Modified TO-15 and Modified ASTM Method D-1946.

Analysis	Number of Samples*	Matrix
Air Toxics, Modified TO-15	231	Air
Methane and fixed gases, Modified ASTM Method D-1946	100	Air
Elements/Metals, Method 6010B	89	Soil
Arsenic, Method 6020	89	Soil
Mercury, Method 7471A	89	Soil
Volatile Fuel Hydrocarbons, Methods 5030/8015M	85	Soil
Hydrocarbon Distribution, Method CADHS/8015Mod	89	Soil
Volatile Organics with Oxygenates, Method 8260B	92	Soil
Semi-Volatile Organic Hydrocarbons (PAHs), Method 8270C, Single Ion Monitoring	89	Soil

* Sample count does not include QC samples such as Laboratory Blanks, LCS, CCV, or similar.

The laboratory reports included summary results for both the samples and quality control samples analyzed with the sample batches. This summary information included analyte results, surrogate recovery data (where applicable), Continuing Calibration Verification (CCV) and LCS/LCSD and MS/MSD results (where applicable). No internal standard information (other than qualifiers added by the laboratory), raw data (e.g. chromatograms) ICP Interference Check Sample, ICP Serial Dilution initial or continuing calibration was provided unless noted below. All data appear to be censored at the reporting limit, with no data reported below

this value. The reporting limit was not defined in the laboratory reports. It is assumed the RL is greater than the method detection limit.

The laboratory reports were evaluated based on the following documents: *Contract Laboratory Program National Functional Guidelines for Organic Data Review*, October 1999, *Contract Laboratory Program National Functional Guidelines for Inorganic Data Review*, October 2004. Professional judgment was used in some cases to qualify the results.

This report summarizes the quality assurance evaluation of the data according to precision, accuracy, representativeness, completeness, and comparability (PARCC) relative to the National Functional Guidelines. This report provides an assessment of the data and identifies potential sources of error, uncertainty, and bias that may affect the overall usability.

Qualifiers	
J-	Estimated: The associated numerical value is an estimated quantity with a potentially negative bias. The analyte was detected but the reported value may not be accurate or precise. The "J-" qualification indicates the data fell outside the QC limits, but the exceedance was not sufficient to cause rejection of the data.
J+	Estimated: The associated numerical value is an estimated quantity with a potentially positive bias. The analyte was detected but the reported value may not be accurate or precise. The "J+" qualification indicates the data fell outside the QC limits, but the exceedance was not sufficient to cause rejection of the data.
J	Estimated: The associated numerical value is an estimated quantity. It is not possible to assess the direction of the potential bias. The analyte was detected but the reported value may not be accurate or precise. The "J" qualification indicates the data fell outside the QC limits, but the exceedance was not sufficient to cause rejection of the data.
R	Rejected: The datum is unusable (the compound or analyte may or may not be present). Use of the "R" qualifier indicates a significant variance from functional guideline acceptance criteria.
UJ	Estimated/Nondetected: Analyses were performed for the compound or analyte, but it was not detected. This qualification is used to flag possible false negative results in the case where low bias in the analytical system is indicated by low calibration response, surrogate, or other spike recovery.
E	The analyte exceeded the calibration range of the instrument. There is greater uncertainty associated with the reported value.

PARCC Criteria

Precision is a measure of the agreement or reproducibility of analytical results under a given
set of conditions. It is a quantity that cannot be measured directly but is calculated from percent recovery data. Precision is expressed as the relative percent difference (RPD):

$$RPD = \text{Absolute Value of } (D1-D2)/\{1/2(D1+D2)\} \times 100$$

Where D1 and D2 are the reported concentrations for sample and duplicate analyses.

An RPD outside the numerical QC limit in either MS/MSD samples or LCS/LCSD indicates imprecision but does not imply accuracy or allow for directional qualification (e.g. J+ or J-). For this data set, duplicate results were only reviewed for replicate LCS and MS data. No replicate native sample results were evaluated.

Accuracy is a measure of the agreement of an experimental determination and the true value of the parameter being measured. It is used to identify bias in a given measurement system Recoveries outside acceptable QC limits may be caused by factors such as instrumentation, analyst error, or matrix interference. Accuracy is assessed through the analysis of spiked matrix samples and laboratory control samples containing analytes of interest and surrogate compounds. Surrogate spikes were added to every environmental sample, blank, LCS, MS/MSD, and standard, for the organic analyses. The soil samples analyzed in this report also included LCS and MS results. Accuracy of inorganic analyses is determined using the percent recoveries of MS and LCS analyses.

Percent recovery (%R) is calculated using the following equation:

$$\%R = (A-B)/C \times 100$$

where:
A = measured concentration in the spiked sample
B = measured concentration of the spike compound in the unspiked sample
C = concentration of the spike

Spike recoveries outside the acceptable QC accuracy limits provide an indication of bias, where the reported data may overestimate or underestimate the actual concentration of compounds detected. This directional bias information can be used to provide J- or J+ qualification, when no other qualifiers complicate the datum.

Representativeness is a qualitative parameter that expresses the degree to which the sample data are characteristic of a population. It is evaluated herein by reviewing the QC results of blanks, samples and holding times. Positive detects

of compounds in the blank samples identify compounds that may have been introduced into the samples during sample collection, transport, preparation, or analysis. The QA/QC blanks collected and analyzed are method blanks, trip blanks, and field blanks.

Contamination found in both the environmental sample and a laboratory blank sample are usually assumed to be laboratory artifact if the concentration in the environmental sample is less than 10 times the blank value for common laboratory contaminants or 5 times the blank value for other laboratory contaminants.

Holding times are evaluated to assure that the sample integrity is intact for accurate sample preparation and analysis. Holding times will be specific for each method and matrix analyzed. Holding time exceedances can cause loss of sample constituents due to biodegradation, precipitation, volatization, and chemical degradation. In accordance with EPA guidance (USEPA 1999 and 2004), sample results for analyses that were performed after the method holding time but less than two times the method holding time were qualified as estimated (J- or UJ) and sample results for analyses that were performed after two times the method holding time were qualified as rejected (R).

Comparability is a qualitative expression of the confidence with which one data set may be compared to another. In the data validation context it provides an assessment of the equivalence of the analytical results to data obtained from other analyses. Comparability is also dependent upon other PARCC criteria, because only when precision, accuracy, and representativeness are known can data sets be compared with confidence.

Completeness is defined as the percentage of acceptable sample results compared to the total number of sample results. Completeness equals the total number of sample results for each fraction minus the total number of rejected sample results divided by the total number of sample results multiplied by 100. Percent completeness is calculated using the following equation:

$$\%C = (T - R)/T \times 100$$

where:
%C = percent completeness
T = total number of sample results
R = total number of rejected sample results

Basis for qualifying data**:**

Surrogates: A directional qualifier (e.g. +/-) was not used for surrogate. The sample was J qualified if the recovery exceeded limits (above or below) and

sample had detected analytes. If the sample was ND for all analytes, and the recovery exceeded the upper limit, the sample was qualified with a U. If the sample was ND for all analytes, and the recovery was below the lower limit, the sample was qualified with a UJ. Qualifiers were not applied to individual sets of analytes since the raw data was not available to verify which surrogates were associated with which analytes.

CCV: CCV samples were qualified with a J- / J+ for all detected analytes in which the recovery was below/above the QC limit. These qualifiers apply to all samples within the associated batch. Samples were qualified with a UJ if the analytes were ND and the recovery was below limit. Samples that were ND, and the recovery exceeded the QC limit were not qualified.

LCS: LCS samples were qualified with a J- / J+ for all detected analytes in which the recovery was below/above the QC limit. These qualifiers apply to all samples within the associated batch. Samples were qualified with a UJ if the analytes were ND and the recovery was below limit. Samples that were ND, and the recovery exceeded the QC limit were not qualified.

MS/MSD: LCS samples were qualified with a J- / J+ for all detected analytes in which the recovery was below/above the QC limit. These qualifiers only apply to the samples that were spiked. Samples were qualified with a UJ if the analytes were ND and the recovery was below limit. Samples that were ND, and the recovery exceeded the QC limit were not qualified.

Blanks: Samples were only qualified based upon blank information if the analyte was detected in a sample and its concentration was equal or less than 5X the value in the associated blank.

The following sections present a review of QC data for each analytical method.

2. EPA Method TO-15 Modified – Determination of VOCs in Air

A total of 231 samples air samples that were analyzed using EPA Method TO-15 were validated. None of the sample results were rejected based on holding time or other quality assurance/control issues. The TO-15 samples did not include matrix spikes. A number of samples were received with significant vacuum remaining in the canister. The residual canister vacuum resulted in elevated reporting limits. All samples were analyzed within the required holding time of 30 days from date of collection.

2.1. Quality Control Results

2.1.1. Surrogates

Surrogates were reviewed for each sample. All surrogates were within the QC limits with the following exceptions in the table below.

Lab Sample ID	Client Sample ID	Compound	Recovery (limits)	Qualifier
0711373B-14A	SV-39-15	1,2-Dichloroethane-d4	167% (70-130%)	J
0711373B-16A	SV-61A-15	1,2-Dichloroethane-d4	142% (70-130%)	J
0711413C-14A	SV-35-15	1,2-Dichloroethane-d4	188% (70-130%)	J
0711413C-34A	SV-27-05	1,2-Dichloroethane-d4	140% (70-130%)	J
0707341BR1-31A	SV-36-05	1,2-Dichloroethane-d4	136% (70-130%)	J
0707341BR1-33A	SV-66-05	1,2-Dichloroethane-d4	140% (70-130%)	J
0707341BR1-35A	SV-35-05	1,2-Dichloroethane-d4	170% (70-130%)	J
0707341BR1-38A	SV-38-15	1,2-Dichloroethane-d4	155% (70-130%)	J
0707341CR1-40A	SV-01-15	1,2-Dichloroethane-d4	133% (70-130%)	J
0707373BR1-21A	SV-58-15	1,2-Dichloroethane-d4	155% (70-130%)	J
0707373BR1-23A	SV-43-14	1,2-Dichloroethane-d4	228% (70-130%)	J
0707373BR1-24A	SV-60-05	1,2-Dichloroethane-d4	143% (70-130%)	J
0707373C-47A	SV-15-15	1,2-Dichloroethane-d4	161% (70-130%)	J
0707390A-04A	SV-39-06	1,2-Dichloroethane-d4	147% (70-130%)	J
0707390A-15A	SV-16-15	1,2-Dichloroethane-d4	239% (70-130%)	J
0707390A-18A	SV-62-15	1,2-Dichloroethane-d4	131% (70-130%)	J
0707390B-32A	SV-58A-15	1,2-Dichloroethane-d4	154% (70-130%)	J

2.1.2. Continuing Calibration Samples (CCV)

Continuing Calibration Verification (CCV) samples were reviewed for each sample batch. All analytes were within the QC limits with the following exceptions. The samples associated with those CCVs that did not meet the QC criteria are provided below.

Lab Sample ID	Client Sample ID	Compound	Recovery (limits)	Qualifier
0707341A-22B	CCV	Dichlorodifluoromethane (Freon 12)	69% (70-130%)	J-, all associated samples
0707341BR1-40A	CCV	Naphthalene	68% (70-130%)	J-, all associated samples
0707341BR1-40A	CCV	2,2,4-Trimethylpentane	67% (70-130%)	J-, all associated samples
0707341BR1-40B	CCV	Naphthalene	68% (70-130%)	J-, all associated samples
0707341BR1-40C	CCV	Dichlorodifluoromethane (Freon 12)	69% (70-130%)	J-, all associated samples
0707341CR1-51A	CCV	Dichlorodifluoromethane (Freon 12)	63% (70-130%)	J-, all associated samples
0707341CR1-51B	CCV	Hexachlorobutadiene	132% (70-130%)	None, recovery was above the QC limits
0707373A-21A	CCV	Naphthalene	68% (70-130%)	J-, all associated samples
0707373A-21B	CCV	Dichlorodifluoromethane (Freon 12)	69% (70-130%)	J-, all associated samples
0707373A-21C	CCV	Dichlorodifluoromethane (Freon 12)	63% (70-130%)	J-, all associated samples

0709236A-22B	CCV	1,2-Dichloro-1,1,2,2-tetrafluroethane	131% (70-130%)	None, recovery was above the QC limits
0709236C-08A	CCV	Methyl tert-butyl ether (MTBE)	64% (70-130%)	J-, all associated samples

2.1.3. Laboratory Control Samples (LCS)

Laboratory Control Samples met the QC limits with the following exceptions.

Lab Sample ID	Client Sample ID	Compound	Recovery (limits)	Qualifier
0707341BR1-41A	LCS	Hexachlorobutadiene	132% (70-130%)	J+, all associated samples
0707341CR1-52B	LCS	Hexachlorobutadiene	136% (70-130%)	J+, all associated samples
0707373BR1-42A	LCS	Hexachlorobutadiene	136% (70-130%)	J+, all associated samples
0707373BR1-42B	LCS	Hexachlorobutadiene	134% (70-130%)	J+, all associated samples
0707390B-39A	LCS	Hexachlorobutadiene	133% (70-130%)	J+, all associated samples
0707390B-39B	LCS	Hexachlorobutadiene	134% (70-130%)	J+, all associated samples
0707407A-09A	LCS	Hexachlorobutadiene	134% (70-130%)	J+, all associated samples
0711373A-18A	LCS	1,2-Dichloro-1,1,2,2-tetrafluroethane	69% (70-130%)	J-, all associated samples
0711373A-18A	LCS	1,2,4-Trichlorobenzene	64% (70-130%)	J-, all associated samples
0711373A-18A	LCS	Hexachlorobutadiene	67% (70-130%)	J-, all associated samples
0711373A-18A	LCS	Naphthalene	60% (70-130%)	J-, all associated samples
0711373B-19A	LCS	1,1,1-Trichloroethane	141% (70-130%)	J+, all associated samples

0711373B-19A	LCS	1,2,4-Trichlorobenzene	139% (70-130%)	J+, all associated samples
0711413C-38A	LCS	1,1,1-Trichloroethane	131% (70-130%)	J+, all associated samples
0711413C-38A	LCS	1,4-Dioxane	143% (70-130%)	J+, all associated samples
0711413C-38A	LCS	2-Hexanone	148% (70-130%)	J+, all associated samples
0711413C-38A	LCS	1,4-Dichlorobenzene	136% (70-130%)	J+, all associated samples

2.1.4. Blank Samples

There were no analytes detected in any of the Laboratory Blanks run under this method. No data are qualified due to laboratory blanks issues. The Equipment Blank 0001 (laboratory ID 0711413A-19A), sampled on 11/17/2007 contained the analytes m,p-xylenes at 2.0 ppbv (.0095 µg/L). The following samples were collected and analyzed in the same batch as this Equipment Blank. Levels of m,p-xylenes in those samples are provided below.

Lab Sample ID	Client Sample ID	m,p-xylenes Concentration (µg/L)	Qualifier
0711413A-05A	SV-69-05a	0.042	none
0711413A-05AA	SV-69-05a Lab Duplicate	0.044	None
0711413A-06A	SV-69-05b	0.025	None
0711413A-07A	SV-69-15	0.2	None
0711413A-11A	SV-53-15	0.064	None
0711413A-12A	SV-54-13	1	None
0711413A-12AA	SV-54-13 Lab Duplicate	1	None
0711413A-15A	SV-45-05	0.084	None
0711413A-16A	SV-45-15	0.0083	J

2.1.5. Other Qualifications

Lab Sample ID	Client Sample ID	Analyte	Qualifier
0707341BR1-38A	SV-38-15	Cyclohexane	E
0709236C-05A	SV-10-15	Chloroform	E

2.2.Summary

Several samples contained surrogates that exceeded the QC limits. However, all of these recoveries were above the limits, indicating a potential for bias high but limited potential for false negatives. The CCV and LCS data show a number of compounds that were below or above the QC limits; however the recoveries were either slightly low or high. This indicates the potential for slight bias as noted with the qualifiers. M,p-Xylenes was detected in one Equipment Blank and also indentified in a number of samples associated with that blank. In most cases the concentration of m,p-xylenes was well above the concentration in the blank. This indicates most samples likely were not contaminated.

3. Modified ASTM D-1946

A total of 100 samples air samples that were analyzed using Modified ASTM Method D-1946 for methane and fixed gases, were validated. No quality assurance or quality control issues were identified with these samples.

4. Elements by ICP, ICP-MS, and Atomic Absorption

A total of 89 soil samples that were analyzed using EPA Methods 6010B, 6020, and 7471A for metals and elements were validated. Quality control results for the metals/elements data included laboratory blanks, laboratory control samples (blank spikes or LCSs), and matrix spikes. No initial or continuing calibration or interference check sample (ICP) data was included with the laboratory reports. None of the sample results were rejected based on holding time or other quality

assurance/control issues. All samples were analyzed within the required holding time of 180 days from date of collection.

4.1. Quality Control Results

4.1.1. Laboratory Control Samples (LCS)

All laboratory Control Sample results were within the QC limits of 80-120% recovery. No data are qualified based on LCS results.

4.1.2. Blank Samples

All analytes were "not detected" in all laboratory blanks samples. No data are qualified based on laboratory blank results.

4.1.3. Matrix Spike and Matrix Spike Duplicate Samples

Matrix Spike and Matrix Spike Duplicate Samples met the QC limits with the following exceptions.

SDG	MS/MSD ID	Analytes	%R /%R of duplicate and limits	Associated Sample	Qualifiers
IQG1327	7G20082-MS1 (07/20/2007) and the MS duplicate 7G20082-MSD1 Method 6010B	Antimony Beryllium Cadmium Cobalt Copper Lead Molybdenum Nickel Selenium Thallium Zinc	19%/ 23% (75-125%) 61%/ 77% (75-125%) 57%/ 73% (75-125%) 58%/73% (75-125%) 63%/ 77% (75-125%) 59%/ 74% (75-125%) 46%/ 59% (75-125%) 63%/ 77% (75-125%) 53%/ 69% (75-125%) 54%/ 70% (75-125%) 61%/ 74% (75-125%)	IQG1327-21	J- None* J- J- J- J- J- None* J- J- J-

* One of two spike recovery percentage was within the QC limit

4.2. Summary

All blanks and LCS samples meet the QC limits. A limited number of matrix spike and MSDs exceeded the QC limits, primarily at a recovery slightly below the limit. This indicates that the matrix may have caused a slight bias for the analytes shown and qualified above.

5. EPA Method 8260: VOLATILE ORGANICS with OXYGENATES by GC/MS

A total of 92 soil samples that were analyzed using EPA Method 8260 for Volatile Organic Compounds with Oxygenates were validated. The laboratory reports do not specify the preparation method used, but it is assumed that EPA Method 5035 was used. Quality control results for the data included laboratory blanks, laboratory control samples (blank spikes or LCSs), and matrix spikes, and surrogate recoveries. No initial or continuing calibration data was included with the laboratory reports. None of the sample results were rejected based on holding time or other quality assurance/control issues. All samples were extracted and analyzed within the required 14 days.

5.1. Quality Control Results

5.1.1. Surrogates

Surrogates were reviewed for each sample. All surrogates were within the QC limits with the following exceptions:

Lab Sample ID	Client Sample ID	Compound	Recovery (limits)	Qualifier
IQG1327-02	SV-63-01	Dibromofluoromethane	127% (80-125%)	J
IQG1327-02	SV-63-01	4-Bromofluorobenzene	69% (80-120%)	J

IQG1730-10	S-1C-01	4-Bromofluorobenzene	58% (80-120%)	J
IQG1730-12	S-40A-01	4-Bromofluorobenzene	61% (80-120%)	J
IQG1730-13	S-40A-03	4-Bromofluorobenzene	74% (80-120%)	J
IQG1730-18	S-38B-01	4-Bromofluorobenzene	70% (80-120%)	J

5.1.2. Laboratory Control Samples (LCS)

A number of LCS samples had recoveries for carbon tetrachloride above the QC limits. Since these recoveries were greater than the limit and the associated samples did not detect this analyte, no data are qualified.

5.1.3. Blank Samples

All analytes were "not detected" in all laboratory blanks samples. No data are qualified based on laboratory blank results.

5.1.4. Matrix Spike and Matrix Spike Duplicate Samples

All sample batches included a matrix spike and matrix spike duplicate. For samples in which the MS and/or MSD recovery was above the QC limit, and the native sample was ND for that analyte, no data was qualified. The following matrix spikes and MSDs had recoveries below the QC limits.

MS/MSD ID	Analytes	%R/%R of duplicate (if also below limit) and limits	Associated Sample	Qualifier
7G17003-MS1/MSD1	1,2,3-Trichlorobenzene	57%/ 42% (45-145%)	IQG1327-12 SV-58-02	None*
7G16021-MS1	n-Butylbenzene	53%/54% (65-135%)	IQG1327-19 SV-36-05	UJ
	sec-Butylbenzene	63%/63% (70-125%)		UJ
	Hexachlorobutadiene	22%/24% (60-135%)		UJ
	p-Isopropyltoluene	64%/ 63% (65-130%)		UJ
	Naphthalene	49%/ 52% (50-140%)		UJ
	1,2,3-Trichlorobenzene	28%/ 30% (60-135%)		UJ
	1,2,4-Trichlorobenzene	34%/ 34% (65-135%)		UJ
	Dichlorodifluoromethane	14%/ 14% (30-160%)	IQG1351-29 SV-08-01	UJ
	Hexachlorobutadiene	48%/ 45% (50-145%)		UJ
	Hexachlorobutadiene	18%/ 19% (50-145%)	IQG1351-16 SV-04-05	UJ
	1,2,3-Trichlorobenzene	27%/ 29% (45-145%)		UJ
	1,2,4-Trichlorobenzene	33%/ 36% (50-140%)		UJ
	Dichlorodifluoromethane	26%/ 24% (30-160%)	IQG1351-26 SV-38-05	UJ

* Only one of two spike recovery exceeded the QC limits.

5.2. Summary

A number of samples had surrogate recoveries that exceeded the QC limits. However, all LCS recoveries met the requirements. A limited number of analytes has low recoveries in the matrix spike which indicates the potential for low bias in this matrix.

6. Volatile Fuel Hydrocarbons (EPA Method 5030/8015M)

A total of 85 soil samples that were analyzed using EPA Method 8015M (preparation by EPA Method 5030) for Volatile Fuel Hydrocarbons (C4-C10) and

Gasoline Range Organics (C4-C12) were validated. Quality control results for the data included laboratory blanks, laboratory control samples (blank spikes or LCSs), and matrix spikes, and surrogate recoveries. No initial or continuing calibration data was included with the laboratory reports. All samples were extracted and analyzed within the required holding times. None of the sample results were rejected based on holding time or other quality assurance/control issues.

6.1. Quality Control Results

6.1.1. Surrogates

The surrogates were reviewed in all samples and they met the QC limits with the following exceptions.

Lab Sample ID	Client Sample ID	Compound	Recovery (limits)	Qualifier
IQG1327-14	SV-60-01	4-Bromofluorobenzene	61% (65-140%)	UJ
IQG1327-15	SV-60-05	4-Bromofluorobenzene	1070% (65-140%)	U
IQG1327-18	SV-36-01	4-Bromofluorobenzene	189% (65-140%)	U
IQG1327-19	SV-36-05	4-Bromofluorobenzene	63% (65-140%)	UJ
IQG1327-21	SV-61-05	4-Bromofluorobenzene	3850% (65-140%)	U
IQG1351-07	S-47-01	4-Bromofluorobenzene	52% (65-140%)	UJ
IQG1351-09	SV-02-01	4-Bromofluorobenzene	46% (65-140%)	UJ
IQG1351-16	SV-04-05	4-Bromofluorobenzene	30% (65-140%)	UJ
IQG1351-17	SV-04-10	4-Bromofluorobenzene	0.08%* (diluted out) (65-140%)	None
IQG1351-25	SV-38-01	4-Bromofluorobenzene	62% (65-140%)	UJ
IQG1730-12	S-40A-01	4-Bromofluorobenzene	14% (65-140%)	UJ
IQG1730-13	S-40A-03	4-Bromofluorobenzene	50% (65-140%)	UJ
IQG1730-14	S-40B-01	4-Bromofluorobenzene	40% (65-140%)	UJ
IQG1730-15	S-40B-03	4-Bromofluorobenzene	52% (65-140%)	UJ
IQG1730-16	S-38A-01	4-Bromofluorobenzene	34% (65-140%)	UJ

6.1.2. Laboratory Control Samples (LCS)

All laboratory control samples were within the QC limits, no data were qualified based on LCS/LCSD results.

6.1.3. Blank Samples

All analytes were "not detected" in all laboratory blanks samples. No data are qualified based on laboratory blank results.

6.1.4. Matrix Spike and Matrix Spike Duplicate Samples

The surrogates were reviewed in all samples and they met the QC limits with the following exceptions.

MS/MSD ID	Analytes	%R/%R of duplicate (if also below limit) and limits	Associated Sample	Qualifier
7G16141-MS1 and MSD1 07/16/2007	Volatile Fuel Hydrocarbons (C4-C10)	-2%/ -20% (60-140%)	IQG1327-10	J-

6.2. Summary

A number of samples had surrogate recoveries that exceeded the QC limits and in many cases there were below the lower limit. However, these recoveries were not significantly below the lower limit.

7. Hydrocarbon Distribution (Methods CADHS/8015 Modified)

A total of 89 soil samples that were analyzed using EPA Method 8015M/CADHS for Extractable Fuel Hydrocarbon Distributions (C8-C40) were validated. Quality control results for the data included laboratory blanks, laboratory control samples, and matrix spikes, and surrogate recoveries. No initial or continuing calibration data was included with the laboratory reports. All samples were extracted and analyzed within the required holding times. None of the sample results were rejected based on holding time or other quality assurance/control issues.

7.1. Quality Control Results

7.1.1. Surrogates

The surrogates were reviewed in all samples and they met the QC limits with the following exceptions. All J qualified samples below had detected levels of Extractable Fuel Hydrocarbons.

Lab Sample ID	Client Sample ID	Compound	Recovery (limits)	Qualifier
IQG1327-02	SV-63-01	n-Octacosane	366% (40-125%)	J
IQG1327-13	SV-58-05	n-Octacosane	164% (40-125%)	J
IQG1327-14	SV-60-01	n-Octacosane	322% (40-125%)	J
IQG1327-15	SV-60-05	n-Octacosane	155% (40-125%)	J
IQG1327-16	SV-62-01	n-Octacosane	545% (40-125%)	J
IQG1327-17	SV-62-05	n-Octacosane	867% (40-125%)	J
IQG1327-18	SV-36-01	n-Octacosane	410% (40-125%)	J
IQG1327-19	SV-36-05	n-Octacosane	207% (40-125%)	J
IQG1327-21	SV-61-05	n-Octacosane	293% (40-125%)	J
IQG1351-16	SV-04-05	n-Octacosane	207% (40-125%)	J
IQG1351-17	SV-04-10	n-Octacosane	194% (40-125%)	J
IQG1351-21	SV-35-01	n-Octacosane	525% (40-125%)	J
IQG1351-25	SV-38-01	n-Octacosane	165% (40-125%)	J
IQG1351-29	SV-08-01	n-Octacosane	143% (40-125%)	J
IQG1351-36	SV-50-01	n-Octacosane	228% (40-125%)	J
IQG1730-12	S-40A-01	n-Octacosane	15% (40-125%)	J
IQG1730-19	S-38B-03	n-Octacosane	143% (40-125%)	J

7.1.2. Laboratory Control Samples (LCS)

All laboratory control sample results for EFH (C8-C40) were within the QC limits. No data was qualified based on the LCS samples.

7.1.3. Blank Samples

All analytes were “not detected” in all laboratory blanks samples. No data are qualified based on laboratory blank results.

7.1.4. Matrix Spike and Matrix Spike Duplicate Samples

All matrix spike sample results for EFH (C8-C40) were within the QC limits. No data was qualified based on the matrix spike samples.

7.2. Summary

All QC results for EFH data met the required limits with the exception of surrogates. Most surrogates exceeded the upper limit. Since the MS/MSD and LCS data met all QC requirements the surrogate recoveries are not considered an indication of significant bias.

8. Semivolatile Organic Compounds by GC/MS (SIM) – PAHs (EPA Method 8270)

A total of 89 soil samples, that were analyzed using EPA Method 8270 (using Single Ion Monitoring) for Polyaromatic Hydrocarbons, were validated. Quality control results for the data included laboratory blanks, laboratory control samples

(blank spikes or LCSs), and matrix spikes, and surrogate recoveries. No initial or continuing calibration data was included with the laboratory reports. All samples were extracted and analyzed within the required holding time. None of the sample results were rejected based on holding time or other quality assurance/control issues.

8.1. Quality Control Results

8.1.1. Surrogates

The surrogates were reviewed in all samples and they met the QC limits with the following exceptions. PAH results were not qualified with respect to surrogate recovery unless two or more semi-volatile surrogates were out of specification. All J qualified samples below had detected levels of PAHs.

Lab Sample ID	Client Sample ID	Compound	Recovery (limits)	Qualifier
IQG1327-02	SV-63-01	2-Fluorobiphenyl	22% (42-140%)	J
IQG1327-02	SV-63-01	Terphenyl-d14	14% (42-151%)	J
IQG1327-14	SV-60-01	Nitrobenzene-d5	231% (38-141%)	J

IQG1351-21	SV-35-01	Nitrobenzene-d5	534% (38-141%)	J
IQG1351-21	SV-35-01	2-Fluorobiphenyl	37% (42-140%)	J
IQG1351-36	SV-50-01	Terphenyl-d14	158% (42-151%)	None*

* Only one surrogate was out of the QC limits.

8.1.2. Laboratory Control Samples (LCS)

For SDG IQG1327 two the LCS/LCSD pairs met the individual recovery limits for all compounds. However, 2-Methylnaphthalene, 1-Methylnaphthalene, Indeno[1,2,3-cd]pyrene, and Dibenz(a,h)anthracene exceeded the RPD limits. No data are qualified since the recoveries met the QC limits.

8.1.3. Blank Samples

All analytes were "not detected" in all laboratory blanks samples. No data are qualified based on laboratory blank results.

8.1.4. Matrix Spike and Matrix Spike Duplicate Samples

All Matrix Spike and Matrix Spike Duplicates met the QC limits with the following exception.

MS/MSD ID	Analytes	%R/%R of duplicate (if also below limit) and limits	Associated Sample	Qualifier
IQG1327: 657518S/D Analyzed 07/25/2007	2-Methylnaphthalene Benzo[g,h,i]perylene Indeno[1,2,3-cd]pyrene	53%/ 93% (65-125%) 38%/ 49% (57-142%) 53%/ 63% (59-139%)	IQG1327-19	None* J- None*
IQG1351: 657718S/D Analyzed 07/28/2007	Naphthalene 2-Methylnaphthalene 1-Methylnaphthalene Chrysene Acenaphthene Fluorene Benzo[a]anthracene	257%/ 261% (64-129%) 188%/ 195% (65-125%) 193%/ 183% (48-148%) 55%/ 47% (71-126%) 66%/ 62% (65-130) 56%/ 48% (68-128%) 57%/ 57% (64-124%)	IQG1351-21	UJ UJ UJ J- None* UJ UJ

* Only one of two spike recovery exceeded the QC limits.

8.2. Summary

A number of samples were qualified based on two or more surrogates exceeding the QC limits in the same direction. This information, combined with the MS/MSD results indicate the matrix may have resulted in some bias as shown in the qualified data above. However, all results are usable as qualified.

9. PARCC

Precision and accuracy assessments were included in each individual section above. The precision and accuracy of the data are considered acceptable with the qualifiers included.
Representativeness: All holding times were met as described at the beginning of each section. Only one set of analyses showed blank contamination and this did not appear to have significant impact upon the associated samples. The representativeness of the project data is considered acceptable.

Comparability: The laboratory used standard analytical methods for all of the analyses, though they did indicate some methods were modified. No method

detection limit information was provided to compare with the reporting limits. No data was flagged by the laboratory due to the results below the reporting limit. This indicates the results were censored at the reporting limit. There is no information provided that would question the comparability of the results. The overall comparability is considered acceptable.

Completeness: No results were rejected based on this data validation. The completeness level attained for the samples was 100 percent.

1. INTRODUCTION

This Data Validation Report has been prepared by Neptune and Company, Inc. to assess the validity of laboratory analytical data associated with the April 2005 Trench Investigation at the Avila Tank Farm Property in Avila Beach, California. Laboratory reports were provided from BC Laboratories, Inc, Bakersfield, California. The BC Laboratories report was provided as an Adobe Acrobat file, with file name "Trench lab data 0425056.pdf." The laboratory report contained the results for solid samples analyzed for Total Petroleum Hydrocarbons (TPH), TPH C10-C25, TPH C25-C40, Total Purgeable Petroleum Hydrocarbons, Polycyclic Aromatic Hydrocarbons (PAHs), Organochlorine Pesticides, PCBs (Aroclors), Semi-Volatile Organic Compounds (Base Neutral and Acid Extractables), and Metals (Title 22).

Analysis	Number of Samples*
TPH (C4-C10), EPA 8260	55
TPH (C10-C25 and C25-C40), EPA 8015	55
PAHs, EPA 8270 SIM	24
Title 22 Metals, EPA 6010B/7471A	24
Organochlorine Pesticides and PCBs (EPA 8080)	3
SVOCs (BNAs using EPA 8270)	3

*Sample count does not include QC samples such as Laboratory Blanks, LCS, CCV, duplicate samples or similar.

The laboratory report included summary results for the samples. This summary information included analyte results and surrogate recovery data (where applicable). Results that did not meet Continuing Calibration Verification (CCV) were qualified by the laboratory but the recovery information was not provided. Other QC results, including LCS/LCSD, MS/MSD, or Method Blank results were provided. QC data and laboratory qualification information is included in this data validation. All data are censored at the practical quantitation limit in the database (Excel spreadsheet). However, Method Detection Limits are reported for each analyte in the laboratory report. This report summarizes the quality assurance evaluation of the data according to precision, accuracy, representativeness, completeness, and comparability (PARCC) relative to the National Functional Guidelines. This report provides an assessment of the data and identifies potential sources of error, uncertainty, and bias that may affect the overall usability.

Qualifiers	
J-	Estimated: The associated numerical value is an estimated quantity with a potentially negative bias. The analyte was detected but the reported value may not be accurate or precise. The "J-" qualification indicates the data fell outside the QC limits, but the exceedance was not sufficient to cause rejection of the data.
J+	Estimated: The associated numerical value is an estimated quantity with a potentially positive bias. The analyte was detected but the reported value may not be accurate or precise. The "J+" qualification indicates the data fell outside the QC limits, but the exceedance was not sufficient to cause rejection of the data.
J	Estimated: The associated numerical value is an estimated quantity. It is not possible to assess the direction of the potential bias. The analyte was detected but the reported value may not be accurate or precise. The "J" qualification indicates the data fell outside the QC limits, but the exceedance was not sufficient to cause rejection of the data.
R	Rejected: The datum is unusable (the compound or analyte may or may not be present). Use of the "R" qualifier indicates a significant variance from functional guideline acceptance criteria.
UJ	Estimated/Nondetected: Analyses were performed for the compound or analyte, but it was not detected. This qualification is used to flag possible false negative results in the case where low bias in the analytical system is indicated by low calibration response, surrogate, or other spike recovery.
E	The analyte exceeded the calibration range of the instrument. There is greater uncertainty associated with the reported value.

PARCC Criteria

Precision is a measure of the agreement or reproducibility of analytical results under a given set of conditions. It is a quantity that cannot be measured directly but is calculated from percent recovery data. Precision is expressed as the relative percent difference
(RPD):

$$RPD = \text{Absolute Value of } (D1-D2)/\{1/2(D1+D2)\} \times 100$$

where D1 and D2 are the reported concentrations for sample and duplicate analyses.

An RPD outside the numerical QC limit in either MS/MSD samples or LCS/LCSD indicates imprecision but does not imply accuracy or allow for directional qualification (e.g. J+ or J-).

Accuracy is a measure of the agreement of an experimental determination and the true value of the parameter being measured. It is used to identify bias in a given measurement system. Recoveries outside acceptable QC limits may be caused by factors such as instrumentation, analyst error, or matrix interference.

Accuracy is assessed through the analysis of spiked matrix samples and laboratory control samples containing analytes of interest and surrogate compounds. Surrogate spikes were added to every environmental sample for the organic analyses; spiked matrix samples or laboratory control sample results were also included in the data package. Accuracy of inorganic analyses is determined using the percent recoveries of MS and LCS analyses; MS or LCS sample results were included in the data package.

Percent recovery (%R) is calculated using the following equation:

$$\%R = (A-B)/C \times 100$$

where:

A = measured concentration in the spiked sample
B = measured concentration of the spike compound in the unspiked sample
C = concentration of the spike

Spike recoveries outside the acceptable QC accuracy limits provide an indication of bias, where the reported data may overestimate or underestimate the actual concentration of compounds detected. This directional bias information can be used to provide J- or J+ qualification, when no other qualifiers complicate the datum.

Representativeness is a qualitative parameter that expresses the degree to which the sample data are characteristic of a population. It is evaluated herein by reviewing the QC results of blanks, samples and holding times. Positive detects of compounds in the blank samples identify compounds that may have been introduced into the samples during sample collection, transport, preparation, or analysis. The QA/QC blanks usually collected and analyzed are method blanks, trip blanks, and field blanks.

Contamination found in both the environmental sample and a laboratory blank sample are usually assumed to be laboratory artifact if the concentration in the environmental sample is less than 10 times the blank value for common laboratory contaminants or 5 times the blank value for other laboratory contaminants.

Holding times are evaluated to assure that the sample integrity is intact for accurate sample preparation and analysis. Holding times will be specific for each method and matrix analyzed. Holding time exceedances can cause loss of sample constituents due to biodegradation, precipitation, volatization, and chemical degradation. In accordance with EPA guidance (USEPA 1999 and 2004), sample results for analyses that are performed after the method holding time but less than two times the method holding time are qualified as estimated

(J- or UJ) and sample results for analyses that are performed after two times the method holding time are qualified as rejected (R).

Comparability is a qualitative expression of the confidence with which one data set may be compared to another. In the data validation context it provides an assessment of the equivalence of the analytical results to data obtained from other analyses. Comparability is also dependent upon other PARCC criteria, because only when precision, accuracy, and representativeness are known can data sets be compared with confidence.

Completeness is defined as the percentage of acceptable sample results compared to the total number of sample results. Completeness equals the total number of sample results for each fraction minus the total number of rejected sample results divided by the total number of sample results multiplied by 100. Percent completeness is calculated using the following equation:

$$\%C = (T - R)/T \times 100$$

where:

%C = percent completeness
T = total number of sample results
R = total number of rejected sample results

Basis for qualifying data**:**

Holding Times: The time between sampling and extraction (where applicable) and extraction and analysis was reviewed for all samples. All steps meet the method required holding times.

Basis for qualifying data**:**

Surrogates: A directional qualifier (e.g. +/-) was not used for surrogate. The sample was J qualified if the recovery exceeded limits (above or below) and sample had detected analytes. Though in some cases professional judgment was use, for example if matrix interference affected surrogate recovery or if the recovery was slightly outside limits the data may not have been qualified. If the sample was ND for all analytes, and the recovery exceeded the upper limit, the sample was qualified with a U. If the sample was ND for all analytes, and the recovery was below the lower limit, the sample was qualified with a UJ. Qualifiers were not applied to individual sets of analytes since the raw data was not available to verify which surrogates were associated with which analytes.

CCV: CCV results were not provided other than a laboratory assigned qualifier. If a result was qualified by the laboratory it is noted in this report. However, since

neither the magnitude nor direction of the CCV recovery was provided the effect cannot be fully assessed and no data were qualified.

LCS: LCS samples were qualified with a J- / J+ for all detected analytes in which the recovery was below/above the QC limit. These qualifiers apply to all samples within the associated batch. Samples were qualified with a UJ if the analytes were ND and the recovery was below limit. Samples that were ND, and the recovery exceeded the QC limit were not qualified.

MS/MSD: LCS samples were qualified with a J- / J+ for all detected analytes in which the recovery was below/above the QC limit. These qualifiers only apply to the samples that were spiked. Samples were qualified with a UJ if the analytes were ND and the recovery was below limit. Samples that were ND, and the recovery exceeded the QC limit were not qualified.

Blanks: Samples were only qualified based upon blank information if the analyte was detected in a sample and its concentration was equal or less than 5X the value in the associated blank.

The following sections present a review of QC data for each analytical method.

2. TPH (C10-C25) and TPH (C25-C40) by EPA Method 8015C

A total of 55 solid samples that were extracted and then analyzed for TPH (C10-C25) and TPH (C25-C40) by EPA Method 8015C were validated. Surrogate recoveries were compared to the lower and upper control limits. QC sample results for CCV, LCS, MS/MSD and blanks were also validated. All holding times were met. QC results not meeting method or laboratory specific criteria are discussed below.

Batch-specific QC:

QC Batch ID BOE0335
Matrix Spike/Matrix Spike Duplicate (MS/MSD) (pp. 172): The MS/MSD percent recoveries and relative percent differences were **all within limits** and a surrogate was included with the sample.

Laboratory Control Sample (LCS) (p. 179): The LCS percent recoveries were **within limits** and a surrogate was included with the sample.

Method Blank (MB) (p. 189): The percent recovery for the MB sample surrogate was low; the recovery was 26.5% and the control limits were 45-142%. The results for the other constituents in the MB were not detected.

No data in this batch were qualified.

QC Batch ID BOE0734

Matrix Spike/Matrix Spike Duplicate (MS/MSD) (pp. 172): The MS/MSD percent recoveries and relative percent differences were **within limits** and a surrogate was included with the sample. The surrogate recovery in the CCV was not within limits and apparently this was isolated to the CCV; however, the associated CCV results were not provided.

Laboratory Control Sample (LCS) (p. 179): The LCS percent recoveries were **within limits** and a surrogate was included with the sample. The surrogate recovery in the CCV was not within limits and apparently this was isolated to the CCV; however, the associated CCV results were not provided.

Method Blank (MB) (p. 189): The percent recovery for the MB sample surrogate was within limits. The surrogate recovery in the CCV was not within limits and apparently this was isolated to the CCV; however, the associated CCV results were not provided. The results for the other constituents in the MB were ND. No data in this batch were qualified.

QC Batch ID BOE0735

Matrix Spike/Matrix Spike Duplicate (MS/MSD) (pp. 172): The MS/MSD percent recoveries and relative percent differences were **within limits** and a surrogate was included with the sample. The surrogate recovery in the CCV was not within limits and apparently this was isolated to the CCV; however, the associated CCV results were not provided.

Laboratory Control Sample (LCS) (p. 179) for the Diesel Range TPH: The LCS percent recovery for TPH-Diesel was high; the recovery was 108% and the limits were 64-97%. The surrogate recovery was within limits. The associated samples may be biased high. The surrogate recovery in the CCV was not within limits and apparently this was isolated to the CCV; however, the associated CCV results were not provided.

Method Blank (MB) (p. 189): The percent recovery for the MB sample surrogate was within limits. The surrogate recovery in the CCV was not within limits and apparently this was isolated to the CCV; however, the associated CCV results were not provided. The results for the other constituents in the MB were ND.

Due to the LCS recovery beyond the quality limits, there is a slight chance the sample results are biased high.

Sample-specific QC:

For the two samples, STR-6-1-0.5 and STR-9-1-0.5 the recovery for the only surrogate, Tetracosane, was not reportable due to matrix interference. Because these samples were diluted due to the matrix no data are qualified.

For sample STR-10-4-1.5 the surrogate recovery for the only surrogate, Tetracosane, was 24.3% versus the limits of 45-142%. This sample had levels of TPH at concentrations around the PQL. **These results are qualified with a J.**

For sample STR-5-1-0.5, the surrogate recovery was above the control limits. No data was qualified.

For samples STR-6-5-1.0, STR-10-1-0.5, STR-8-1-0.5, STR-12-2-4.5, STR-12-2-4.5, STR-12-3-1.5, STR-11-3-4.5, STR-11-2-1.5, STR 11-3-4.5, STR-11-4-1.5, STR-13-2-1.5, STR-13-3-5.5, STR-13-4-1.5, STR-14-1-0.5, STR-9-1-0.5, STR 14-1-0.5, STR-14-2-1.5, STR-14-3-4.0, STR-14-4-1.5, STR 1-3-1.5, STR-1-4-1.5, STR-4-1-1.0, STR-4-2-1.5, STR-4-3-2.5, STR-4-4-2.5, STR-2-1-1.5, STR-2-2-7.0, STR-2-3-1.5, STR-3-1-1.5, STR-3-2-5.5, STR-3-3-1.5, STR-7-2-1.5, STR-7-3-5.0,STR-7-4-1.5, STR-5-2-1.5, STR-5-3-1.5, STR-5-5-5.0: The surrogate recovery in the CCV was not within limits and apparently this was isolated to the CCV; however, the associated CCV results were not provided. No data were qualified.

3. PAHs by EPA 8270 SIM

A total of 24 solid samples that were extracted then analyzed using EPA Method 8270 SIM for PAHs were validated. Surrogate recoveries were compared to the lower and upper control limits. QC sample results for CCV, LCS, MS/MSD and blanks were also validated. All holding times were met. QC results not meeting method or laboratory specific criteria are discussed below.

Batch-specific QC:

QC Batch ID BOE0333

Matrix Spike/Matrix Spike Duplicate (MS/MSD) (pp. 170-171): The MS/MSD percent recoveries and relative percent differences were **all within limits** and surrogates were included with the sample.

The Continuing Calibration Verification (CCV) recovery was **not within limits for Benzo[b]fluoranthene**; however, the associated CCV results were not provided. The accuracy of benzo(b)fluoranthene is in question, but since neither the magnitude nor direction of the CCV recovery was provided, the effect cannot be fully assessed.

Laboratory Control Sample (LCS) (p. 178): The LCS percent recoveries were **within limits** and surrogates were included with the sample.

Method Blank (MB) (p. 184): The percent recoveries for the MB sample surrogates were **within limits**. The results for all other analytes in the MB were ND.

Sample-specific QC:

STR-6-1-0.5, STR-8-1-0.5, STR-13-1-0.5, STR-1-2-1.0, STR-4-1-1.0: One of three surrogates, Nitrobenzene-d5, was not reportable due to matrix interference.

STR-1-1-1.0: The recovery of one of three surrogates, Nitrobenzene-d5, was 4.25% and limits were 31-112%.

STR-7-1-0.5: One of three surrogates, Nitrobenzene-d5, was not reportable due to matrix interference. Another surrogate, 2-Fluorobiphenyl, was recovered at 26.5% and the limits were 32-110%.

STR-5-1-0.5: All three surrogates were not within control limits: Nitrobenzene was recovered at 23.5% (limits 31-112%), 2-Fluorobiphenyl was recovered at 15.8% (limits 32-110%) and p-Terphenyl-d-14 was recovered at 20.5% (limits 29-113%).

Low recovery of the surrogates is believed to be due to matrix interference noted by the laboratory. No data were qualified.

4. TPH (C4-C10) by EPA Method 8260

A total of 55 solid samples that were analyzed for VOCs and TPH (C4-C10) by EPA Method 8260 and GC/MS Combination were validated. Surrogate recoveries were compared to the lower and upper control limits. QC sample results for CCV, LCS, MS/MSD and blanks were also validated. All holding times were met. QC results not meeting method or laboratory specific criteria are discussed below.

Batch-specific QC:

QC Batch ID BOE0311

Matrix Spike/Matrix Spike Duplicate (MS/MSD) (p. 167): The MS/MSD percent recoveries and relative percent differences were **all within limits**. However, only surrogates were reported so the precision and accuracy of the analysis for Total Purgeable Petroleum Hydrocarbons could not fully be assessed.

Laboratory Control Sample (LCS) (p. 176): The LCS percent recoveries were **within limits.** However, only surrogates were reported so the accuracy of the analysis for Total Purgeable Petroleum Hydrocarbons could not fully be assessed.

Method Blank (MB) (p. 184): The percent recoveries for the MB sample surrogates were within limits. The result for Total Purgeable Petroleum Hydrocarbons in the MB was a non-detect (ND).

No data were qualified

QC Batch ID BOE0313

Matrix Spike/Matrix Spike Duplicate (MS/MSD) (p. 167): The MS/MSD percent recoveries and relative percent differences were **all within limits**. However, only surrogates were reported so the precision and accuracy of the analysis for Total Purgeable Petroleum Hydrocarbons could not fully be assessed.

Laboratory Control Sample (LCS) (p. 176): The LCS percent recoveries were **within limits**. However, only surrogates were reported so the accuracy of the analysis for Total Purgeable Petroleum Hydrocarbons could not fully be assessed.

Method Blank (MB) (p. 184): The percent recoveries for the MB sample surrogates were within limits. The result for Total Purgeable Petroleum Hydrocarbons in the MB was a non-detect (ND).

No data were qualified

QC Batch ID BOE0314

Matrix Spike/Matrix Spike Duplicate (MS/MSD) (p. 167): The MS/MSD percent recoveries and relative percent differences were **all within limits**. However, only surrogates were reported so the precision and accuracy of the analysis for Total Purgeable Petroleum Hydrocarbons could not fully be assessed.

Laboratory Control Sample (LCS) (p. 176): The LCS percent recoveries were **within limits**. However, only surrogates were reported so the accuracy of the analysis for Total Purgeable Petroleum Hydrocarbons could not fully be assessed.

Method Blank (MB) (p. 184): The percent recoveries for the MB sample surrogates were within limits. The result for Total Purgeable Petroleum Hydrocarbons in the MB was a non-detect (ND).
No data were qualified

5. Title 22 Metals by EPA Method 6010B/7471A

A total of 24 solid samples that were analyzed using EPA Methods 6010B and 7471A for Title 22 metals were validated. QC sample results for CCV, LCS, MS/MSD and blanks were also validated. All holding times were met. QC results not meeting method or laboratory specific criteria are discussed below.

Batch-specific QC:

QC Batch ID BOE0095

Source Duplicate Samples (pp. 173-174): The percent recoveries for the duplicate samples were **within limits**. The relative percent differences for three

analytes (Cadmium, Cobalt, and Molybdenum) were above control limits. However, for these same three analytes, both the source results and duplicate results were less than the practical quantitation limit.

Matrix Spike/Matrix Spike Duplicate (MS/MSD) (pp. 173-174): The MS/MSD percent recoveries were **all within limits**. The MS/MSD relative percent differences were within limits except for zinc. The relative percent difference was 23.2 for zinc, with a control limit of 20.

Laboratory Control Sample (LCS) (p. 180): The LCS percent recoveries were **within limits**.

Method Blank (MB) (p. 190): All MB constituents were NDs except for Barium, Beryllium, and Copper. Barium was detected at 0.0014000 mg/kg and qualified J because it was below the PQL of 0.010 mg/kg. Beryllium was detected at 0.00050000 mg/kg and qualified J because it was below the PQL of 0.010 mg/kg. Copper was detected at 0.015400 mg/kg and qualified J because it was below the PQL of 0.040 mg/kg.

No data were qualified

6. Organochlorine Pesticides and PCBs

A total of 3 solid samples that were extracted and then analyzed using EPA Method 8080 for organochlorine pesticides and PCBs were validated. QC sample results for CCV, LCS, MS/MSD and blanks were also validated. All holding times were met. QC results not meeting method or laboratory specific criteria are discussed below.

Batch-specific QC:

QC Batch ID BOE0332

Matrix Spike/Matrix Spike Duplicate (MS/MSD) (p. 166): The MS/MSD percent recoveries and relative percent differences were **all within limits** and surrogates were included with the sample.

Laboratory Control Sample (LCS) (p. 175): The LCS percent recoveries were **within limits** and surrogates were included with the sample.

Method Blank (MB) (pp. 181-182): The percent recoveries for the MB sample surrogates were within limits. The results for all other analytes in the MB were ND.

No data were qualified

Sample-specific QC:

STR-1-1-1.0: The CCV for 4,4'-DDT and Methoxychlor was out of limits, but no CCV results were provided. The recovery for one of two surrogates, dibutyl chlorendate, was 40.3% and the limits were 47-133%. None of the organochlorine or PCB analytes were detected. Because the surrogate recovery was below the lower control limit these **data are qualified UJ.**

STR-4-1-1.0: The CCV for 4,4'-DDT and Methoxychlor was out of limits, but no CCV results were provided. The recoveries for both surrogates were out of limits: TCMX was recovered at 29.9% (limits 36-106%) and Dibutyl chlorendate was recovered at 24.3% (limits 47-133%). None of the organochlorine or PCB analytes were detected. Because the surrogate recovery was below the lower control limit these **data are qualified UJ.**

STR-7-1-0.5: The CCV for 4,4'-DDT and Methoxychlor was out of limits, but no CCV results were provided. The recoveries for one of two surrogates, TCMX, was 34.4% and the limits were 36-106%. Only gamma-BHC (Lindane) was detected, at the PQL of 0.06 mg/kg. Because the surrogate recovery was only slightly below the lower control limit these data were not qualified.

The accuracy of the associated analytes due to the CCV are in question since the recovery was out of the laboratory limits. However, since neither the magnitude nor direction of the CCV recovery was provided the effect cannot be fully assessed.

7. Semi-Volatile Organic Compounds

A total of 3 solid samples that were extracted and then analyzed using EPA Method 8270 for Base Neutral and Acid-Extractable Semi-Volatile Organic Compounds were validated. QC sample results for CCV, LCS, MS/MSD and blanks were also validated. All holding times were met. QC results not meeting method or laboratory specific criteria are discussed below.

Batch-specific QC:

QC Batch ID BOE0466

Matrix Spike/Matrix Spike Duplicate (MS/MSD) (pp. 168-169): The MS/MSD percent recoveries were all within limits except for 3-&4-Methylphenol, which had a recovery of 140% for the MS (limits 30-121%) and a recovery of 132% for the MSD (limits 30-121%). All relative percent differences were within limits and surrogates were included with the sample.

Laboratory Control Sample (LCS) (p. 175): The LCS percent recoveries were within limits except for 3-&4-Methylphenol and surrogates were included with the sample. The recovery for 3-&4-Methylphenol was 129% with limits of 46-115%.

Method Blank (MB) (pp. 184-187): The percent recoveries for the MB sample surrogates were within limits. The results for all other analytes in the MB were ND.

The CCV recovery for Benzidine, Benzo[k]fluoranthene, 4,4'-DDT, Endosulfan I, Endosulfan II, and 2-Naphthylamine was not within limits; however, the associated CCV results were not provided. The accuracy of the associated analytes due to the CCV are in question since the recovery was out of the laboratory limits. However, since neither the magnitude nor direction of the CCV recovery was provided the effect cannot be fully assessed.

No data were qualified.

8. PARCC

Precision and accuracy assessments were included in each individual section above. The precision and accuracy of the data are considered acceptable with the qualifiers included.

Representativeness: All holding times were met as described at the beginning of each section. Only one set of analyses (metals) showed blank contamination and this did not appear to have significant impact upon the associated samples. The representativeness of the project data is considered acceptable.

Comparability: The laboratory used standard analytical methods for all of the analyses, though they did indicate some methods were modified. All data were censored by the laboratory at the PQL, though the MDL was reported. There is no information provided that would question the comparability of the results. The overall comparability is considered acceptable.

Completeness: No results were rejected based on this data validation. The completeness level attained for the samples was 100 percent.

1. INTRODUCTION

This Data Validation Report has been prepared by Neptune and Company, Inc. to assess the validity of laboratory analytical data associated with the 2005 Surface Water and Sediment Sampling Event at the Avila Tank Farm Property in Avila Beach, California. For this data validation only the sediment data was requested for validation. Laboratory reports were provided from ZymaX envirotechnology, San Luis Obispo, California. The ZymaX envirotechnology laboratory report was provided as an Adobe Acrobat file, with file name "Surface Water & Sediment_022405_Final.pdf." The laboratory report contained the results for sediment samples (the matrix is called "soil" in the laboratory report) analyzed for Total Petroleum Hydrocarbons (TPH) C4-C10, TPH C10-C25, TPH C25-C40, Polycyclic Aromatic Hydrocarbons (PAHs), Volatile Organic Compounds (VOCs), Metals, Moisture Content, Total Organic Carbon (TOC) and Grain Size Distribution. Moisture Content, TOC, and Grain Size Distribution were not within the scope of this data validation because results of these analyses are not used for the risk assessment. The laboratory report also contained the results for water samples analyzed for Total Petroleum Hydrocarbons (TPH) C4-C10, TPH C10-C25, TPH C25-C40, Polycyclic Aromatic Hydrocarbons (PAHs), Volatile Organic Compounds (VOCs), Metals, Minerals, Dissolved Organic Carbon and Ammonia-Nitrogen. The water samples were not within the scope of this data validation.

Analysis	Number of Sediment Samples*
TPH (C4-C10), EPA 8260	12
TPH (C10-C25 and C25-C40), GS/MS Comb.	12
PAHs, EPA 8270 SIM	12
VOCs, EPA 8260B	12
Title 22 Metals, EPA 6010B/7471A	12

*Sample count does not include QC samples such as Laboratory Blanks, LCS, CCV, or similar.

The laboratory report included summary results for the samples. This summary information included analyte results and surrogate recovery data (where applicable), however no surrogate limits were included in the report. No Continuing Calibration Verification (CCV), LCS/LCSD, MS/MSD, or Method Blank results were provided. All data are censored at the practical quantitation limit, with no data reported below this value. This report summarizes the quality assurance evaluation of the data according to precision, accuracy, representativeness, completeness, and comparability (PARCC) relative to the National Functional Guidelines. This report provides an assessment of the data and identifies potential sources of error, uncertainty, and bias that may affect the overall usability.

Qualifiers	
J-	Estimated: The associated numerical value is an estimated quantity with a potentially negative bias. The analyte was detected but the reported value may not be accurate or precise. The "J-" qualification indicates the data fell outside the QC limits, but the exceedance was not sufficient to cause rejection of the data.
J+	Estimated: The associated numerical value is an estimated quantity with a potentially positive bias. The analyte was detected but the reported value may not be accurate or precise. The "J+" qualification indicates the data fell outside the QC limits, but the exceedance was not sufficient to cause rejection of the data.
J	Estimated: The associated numerical value is an estimated quantity. It is not possible to assess the direction of the potential bias. The analyte was detected but the reported value may not be accurate or precise. The "J" qualification indicates the data fell outside the QC limits, but the exceedance was not sufficient to cause rejection of the data.
R	Rejected: The datum is unusable (the compound or analyte may or may not be present). Use of the "R" qualifier indicates a significant variance from functional guideline acceptance criteria.
UJ	Estimated/Nondetected: Analyses were performed for the compound or analyte, but it was not detected. This qualification is used to flag possible false negative results in the case where low bias in the analytical system is indicated by low calibration response, surrogate, or other spike recovery.
E	The analyte exceeded the calibration range of the instrument. There is greater uncertainty associated with the reported value.

PARCC Criteria

Precision is a measure of the agreement or reproducibility of analytical results under a given set of conditions. It is a quantity that cannot be measured directly but is calculated from percent recovery data. Precision is expressed as the relative percent difference (RPD):

$$RPD = \text{Absolute Value of } (D1-D2)/\{1/2(D1+D2)\} \times 100$$

where D1 and D2 are the reported concentrations for sample and duplicate analyses.

An RPD outside the numerical QC limit in either MS/MSD samples or LCS/LCSD indicates imprecision but does not imply accuracy or allow for directional qualification (e.g. J+ or J-). For this data set, there were no samples identified as duplicates and precision could not be determined.

Accuracy is a measure of the agreement of an experimental determination and the true value of the parameter being measured. It is used to identify bias in a given measurement system. Recoveries outside acceptable QC limits may be

caused by factors such as instrumentation, analyst error, or matrix interference. Accuracy is assessed through the analysis of spiked matrix samples and laboratory control samples containing analytes of interest and surrogate compounds. Surrogate spikes were added to every environmental sample for the organic analyses; however no spiked matrix samples or laboratory control sample results were included in the data package. Accuracy of inorganic analyses is determined using the percent recoveries of MS and LCS analyses; however no MS or LCS sample results were included in the data package.

Percent recovery (%R) is calculated using the following equation:

$$\%R = (A-B)/C \times 100$$

where:

A = measured concentration in the spiked sample
B = measured concentration of the spike compound in the unspiked sample
C = concentration of the spike

Spike recoveries outside the acceptable QC accuracy limits provide an indication of bias, where the reported data may overestimate or underestimate the actual concentration of compounds detected. This directional bias information can be used to provide J- or J+ qualification, when no other qualifiers complicate the datum. No QC accuracy limits were provided in the data package.

Representativeness is a qualitative parameter that expresses the degree to which the sample data are characteristic of a population. It is evaluated herein by reviewing the QC results of blanks, samples and holding times. Positive detects of compounds in the blank samples identify compounds that may have been introduced into the samples during sample collection, transport, preparation, or analysis. The QA/QC blanks usually collected and analyzed are method blanks, trip blanks, and field blanks. In the laboratory data package provided, there were no results for blanks.

Contamination found in both the environmental sample and a laboratory blank sample are usually assumed to be laboratory artifact if the concentration in the environmental sample is less than 10 times the blank value for common laboratory contaminants or 5 times the blank value for other laboratory contaminants.

Holding times are evaluated to assure that the sample integrity is intact for accurate sample preparation and analysis. Holding times will be specific for each method and matrix analyzed. Holding time exceedances can cause loss of sample constituents due to biodegradation, precipitation, volatization, and chemical degradation. In accordance with EPA guidance (USEPA 1999 and 2004), sample results for analyses that are performed after the method holding time but less than two times the method holding time are qualified as estimated

(J- or UJ) and sample results for analyses that are performed after two times the method holding time are qualified as rejected (R). There was no holding time data included with the laboratory data package provided.

Comparability is a qualitative expression of the confidence with which one data set may be compared to another. In the data validation context it provides an assessment of the equivalence of the analytical results to data obtained from other analyses. Comparability is also dependent upon other PARCC criteria, because only when precision, accuracy, and representativeness are known can data sets be compared with confidence.

Completeness is defined as the percentage of acceptable sample results compared to the total number of sample results. Completeness equals the total number of sample results for each fraction minus the total number of rejected sample results divided by the total number of sample results multiplied by 100. Percent completeness is calculated using the following equation:

$$\%C = (T - R)/T \times 100$$

where:

%C = percent completeness
T = total number of sample results
R = total number of rejected sample results

Basis for qualifying data**:**

Holding Times: The time between sampling and extraction (where applicable) and extraction and analysis was reviewed for all samples. All steps meet the method required holding times.

Surrogates: Surrogate recoveries were provided with organic data; however, no surrogate recovery limits were provided.

CCV: No CCV sample results were provided.

LCS: No LCS sample results were provided.

MS/MSD: No MS/MSD sample results were provided.

Blanks: No blank sample results were provided.

The following sections present a review of QC data for each analytical method.

2. TPH (C10-C25) and TPH (C25-C40) by GC/MS Combination

A total of 12 sediment samples that were extracted by EPA 3550 and then analyzed for TPH (C10-C25) and TPH (C25-C40) by GC/MS Combination were validated. The only QC sample results provided were surrogate recoveries; however, no surrogate limits were included. No information was provided for other types of QC samples such as CCV, LCS, MS/MSD or blanks. No holding times were reported.

3. PAHs by EPA 8270 SIM

A total of 12 sediment samples that were extracted by EPA 3550 and then analyzed using EPA Method 8270 SIM for PAHs were validated. The only QC sample results provided were surrogate recoveries; however, no surrogate limits were included. No information was provided for other types of QC samples such as CCV, LCS, MS/MSD or blanks. No holding times were reported.

4. VOCs and TPH (C4-C10) by EPA Method 8260 and GC/MS Combination

A total of 12 sediment samples that were analyzed for VOCs and TPH (C4-C10) by EPA Method 8260 and GC/MS Combination were validated. The only QC sample results provided were surrogate recoveries; however, no surrogate limits were included. No information was provided for other types of QC samples such as CCV, LCS, MS/MSD or blanks. No holding times were reported.

5. Title 22 Metals by EPA Method 6010B/7471A

A total of 12 sediment samples that were analyzed using EPA Methods 6010B and 7471A for Title 22 metals were validated. No information was provided for QC samples such as CCV, LCS, MS/MSD or blanks. No holding times were reported.

6. PARCC

The precision and accuracy of the data cannot be determined because of the limited QC results provided.

The representativeness of the data cannot be fully determined because no results of blank QC samples were provided.

Comparability: The laboratory used standard analytical methods for all of the analyses, though they did indicate some methods were modified. Results were censored at the practical quantitation limit.

Completeness: The only QC data provided in the laboratory report were surrogate recovery results; however, no surrogate limits were reported. There is not enough information with which to accept or reject the analytical results for the sediment samples.

Attachment D

Data Usability Report for Avila Tank Farm Events: 2007 Soil and Air Sampling; 2005 Wetland Sampling; 2005 Trench Sampling. March 31, 2008

Prepared for:

Chuck Lambert, McDaniel Lambert, Inc.

Prepared by:

Neptune and Company, Inc.
1505 15th Street, Los Alamos, NM 87544
Point of Contact: David Gratson

The purpose of this document is to evaluate the usability of the Unocal Avila Beach Tank Farm 2007 environmental analytical data, the 2005 trench samples analytical data, and the 2005 wetland samples analytical data (data) for use in the human health risk assessment. The 2007 environmental samples were collected by Avocet Environmental (Irvine, CA) and analyzed by Air Toxics Ltd (Folsom, CA),and TestAmerica (Irvine, CA). The 2005 trench samples were analyzed by BC Laboratories, Bakersfield, California. The 2005 wetland samples were analyzed by ZymaX envirotechnology, San Luis Obispo, California. Evaluation of analytical data, in terms of usability for this assessment, was conducted using the criteria provided by USEPA in the *Guidance for Data Usability in Risk Assessment* (Part A), Final (USEPA, 1992a). These USEPA criteria include:

1. Reports –confirmation that report(s) relied upon are complete and appropriate for use in the HRA;

2. Documentation –confirmation that each analytical result is associated with a specific sample location and that the appropriate sampling procedure is documented;

3. Data Sources – confirmation that the analytical methods used are appropriate to identify the chemicals of potential concern for the media of interest;

4. Analytical Methods and Detection Limits - confirmation that analytical methods appropriately identify the chemical form or species and that the sample detection limit is at or below a concentration appropriate for the risk assessment application;

5. Data Review – confirmation that the quality of analytical results is assessed by a professional knowledgeable in field collection procedures and analytical chemistry and that data quality are adequate to estimate exposure concentrations; and

6. Data Quality Indicators – documentation that sampling and analysis data quality indicators (including precision, accuracy, holding time, and reproducibility) are evaluated using criteria specific to the risk assessment.

An evaluation of the provided analytical data was conducted. A summary of the data analysis relevant to usability criteria for risk assessment is provided in Section 2.0. The Data Validation Reports associated with these data are provided in Appendix A. All tables referenced in this report (highlighted in yellow) are provided in an Excel spreadsheet. Spatial analysis of the sample locations is presented in a separate memorandum (attached).

1.0 Analytical Methods

Samples from multiple sampling events at Avila Beach Tank Farm were analyzed for one or more of the following: metals, volatile fuel hydrocarbons, hydrocarbon distribution, volatile organics with oxygenates, organochlorine pesticides, chlorinated herbicides, and semi-volatile organic hydrocarbons (BNAs, PAHs and PCBs). Samples collected prior to 2005 are referred to as "historical samples". Background samples were also collected and analyzed. The historical samples and background samples are discussed in the Avila Human Health Risk Assessment v2.0 (2005). Trench samples and wetland samples collected in 2005 as well as soil and air samples collected in 2007 are discussed in this data usability report. Because these samples were analyzed by multiple laboratories over multiple years, a review of analytical methods was performed in order to look at the overall comparability of the data. Table 1 provides a summary of the analytical methods used for sample analysis in each of these events.

This data usability evaluation was performed on three sets of data: soil samples collected in 2005 from a trench, sediment samples collected in 2005 from wetlands, and soils samples collected in 2007 from various locations. Historical data and background data are also discussed in this evaluation.

All analytical sample data results for the environmental media of interest were provided in adequate formats. Broad suite analyses were conducted. The laboratory reports that were provided were summary reports that included at least one of the following: a case narrative, a copy of the Chain-of-Custody records, surrogates, blanks, matrix spike and laboratory control sample (and replicate) results. The laboratory reports did not include the raw results or other QC information typically characterized as a Level IV report.

Because data were collected during multiple sampling events and analyzed in different laboratories, the comparability between analytical methods was reviewed for the data sources discussed in this report as well as for the historical data that was presented in the Avila Human Health Risk Assessment v2.0 (2005). Table 1 provides a list of analytical methods used. Approximately 6.5% of the historical data were reported with an analytical method labeled as unknown, so analytical methods were compared when the method information was available. No specific analytical method information was available for the background data presented in Attachment 8, which contains the background evaluation. The analytical methods for arsenic (SW6020), mercury (SW7471), PCBs (SW8080), PAHs (SW8270), VOCs (SW8260), and SVOCs (SW8270) were consistent across sampling events. The 2005 Trench sampling event analyzed for PCBs and pesticides using SW-846 method 8080 according to the laboratory reports. Method 8080 was replaced in 1996 with two methods, 8081 and 8082 which separate the organochlorine pesticides from the PCB analysis. Method 8080 does not provide the cleanup and quantitation procedures designed for PCBs. Method 8080 is subject to false positives and greater quantitative uncertainty due to non-PCB interferences. Samples from the trench, wetland, and samples collected in 2007 were analyzed for metals by SW6010B. Method SW6020 was used to analyze the historical samples for metals. Methods SW6010 and SW6020 are generally comparable when similar digestion

methods (environmentally available digestion, no HF) are used. Method SW6020 can provide more sensitive reporting limits for a number of the analytes. Sensitivity issues are discussed Section 2.0. There were also comparability issues for the TPH analyses. TPH was reported in the ranges of C4-C10, C10-C25, and C25-C40. Method SW8015 was used to analyze samples for all TPH ranges in the 2007 samples as well as the C10-C25 and C25-C40 ranges of the trench and wetland samples. The results for the C4-C10 range for the trench data and wetland samples as well as all of the historical TPH samples were analyzed by SW8260. The 2007 TPH results were reported in C2-C5 carbon intervals above C8. These individual results were combined for final reporting. Both SW 8015 and SW 8260 methods used purge and trap concentrations. However, SW8015 is a GC/FID method compared to SW8260, which is a GC/MS method. Slight differences in quantitation between these methods is likely.

Although analytical methods were comparable with only a few exceptions, it is also noted that the historical data were reported in mg/kg wet weight. The 2007 data were reported in dry weight and are therefore directly comparable to the California Human Health Screening Levels (CHHSLs) and the Region 9 Preliminary Remediation Goals (PRGs). It is not apparent whether wet weight or dry weight results were reported for trench and wetland samples. The laboratory reports only indicate units of mg/kg. Because specific footnotes that specify dry weight results are not present, the results are assumed to be reported in wet weight.

Table 1: Analytical Methods

Suite	2007 Soil	Trench soil	Wetland sediment	Historical soil	Background data
Hexavalent Chromium				7199	Not available
metals	6010B*	6010B	6010B	6020	Not available
Arsenic	6020			6020	Not available
Mercury	7471	7471	7471A	7471	Not available
PCBs		8080		8080	
organochlorine pesticides		8080		8081	
chlorinated herbicides				8151	
VOCs			8260	8260	
PAHs	8270	8270 SIM**	8270 SIM	8270	
SVOCs (Base Neutral and Acid Extractable)		8270C			
TPH C4-C10	8015	8260	8260	8260	
TPH C10-C25	8015	8015	8015	8260	
TPH C25-C40	8015	8015	8015	8260	
Volatile Fuel hydrocarbons	8015				
Air Toxics	TO-15 modified***				

*The method numbers in the table refer to SW-846 analytical methods defined in Test Methods for Evaluating Solid Waste, Physical/Chemical Methods
** SIM=Simple Ion Monitoring
*** TO-15 modified in full scan mode.

2.0 Data Usability

2.1 2007 Soil Matrix Data

Data Usability Criterion	Evaluation Result
I. Reports	Laboratory analytical reports for soil samples collected in 2007 were provided by TestAmerica, Irvine, California. The TestAmerica laboratory reports were provided as Adobe Acrobat files with filenames IQG1327_REVISION, IQG1351_REVISION, and IQG1730_REVISION. Samples associated with each Laboratory Report are provided in Table 2. No site map with sample locations that included soil depths or description of the sampling design and procedures including rationale was provided.
II. Documentation	The chain of custody record was included in all of the Adobe Acrobat files provided by the laboratory.
III. Data Sources	The analytical methods, as discussed in Section 1.0, were appropriate to identify the chemicals of concern in the 2007 soil samples.
IV. Analytical Method and Detection Limit	**2007 Soil Samples** Metals EPA Methods 7471A (mercury), 6020 (Arsenic), and 6010B (all other metals) are considered adequate to characterize metals in soil. Reporting Limits were provided for each sample and analyte. Data in the laboratory reports appear to be censored at the Reporting Limit as no data were flagged due to results below the RL. Some reporting limits were elevated due to sample dilutions for specific metals. Two metals, arsenic and thallium, had RLs that exceeded CHHSLs (details are provided below). All other elements met the applicable CHHSL or EPA Region 9 PRG. The standard reporting limits for the metals are reported Table 3. The reporting limits of arsenic and thallium compared to the screening levels are presented in Table 4. Arsenic: There were six non-detects with a reporting limit of 0.5 mg/kg compared to the Residential CHHSLL, 0.07 mg/kg. The database shows an "MDL" of 0.35 mg/kg, which is also above the CHHSL. There were 83 detects of arsenic with a range of 0.82 to 54 mg/kg. Thallium: All thallium results were non-detects (89 records) with reporting limits of 9.9, 10, or 20 mg/kg. For those samples with a dilution factor of 2, the reporting limit was 20 mg/kg (MDL of 1.6 mg/kg). For those samples with a dilution factor of 1, the reporting limit ranged from 9.9 to 10 mg/kg (MDL of 0.79 to 0.81 mg/kg).The Residential CHHSLL for thallium is 5 mg/kg, so all of the reporting limits are above this level yet the MDLs are below the CHHSLL.

	Total Petroleum Hydrocarbons EPA Method 8015M (preparation by EPA Method 5030) is adequate to characterize volatile fuel hydrocarbons and gasoline range organics (GRO), C4-C10, in soil. Data in the laboratory reports appear to be censored at the Reporting Limit as no data were flagged due to results below the RL. The reporting limit for the volatile fuel hydrocarbons and GRO is 0.40 mg/kg when the sample dilution factor is 1. The range of the majority of the reporting limits was between 0.37 and 0.42 mg/kg. A limited number of reporting limits were higher than 0.42 mg/kg due to elevated levels of hydrocarbons or GRO in those samples. A PRG for volatile fuel hydrocarbons or GRO was not available for comparison to the reporting limits. The reporting limits are adequate based on use of TPH data in HRA (i.e., to identify the need for indicator chemical analysis). Extractable Fuel Hydrocarbons Method CADHS/8015Mod is adequate to characterize extractable fuel hydrocarbon (EFH) distribution (C8-C40) in soil. Data in the laboratory reports appear to be censored at the Reporting Limit as no data were flagged due to results below the RL. The reporting limits were 5 and 10 mg/kg. Some reporting limits were elevated due to sample dilution in samples with high concentrations of particular analytes. The reporting limits are adequate based on use of TPH data in HRA (i.e., to identify the need for indicator chemical analysis). Volatile Organic Hydrocarbons EPA Method 8260B is adequate to characterize VOCs with Oxygenates in soil. The preparation method for these samples was not specified, but is assumed to be EPA Method 5035. Reporting Limits were provided though some reporting limits were elevated due to sample dilution in samples with high concentrations of particular analytes. The standard reporting limit for most of the analytes ranged between 0.002 mg/kg and 0.01 mg/kg when the samples were not diluted. A few analytes, methylene chloride and tert-Butyl alcohol, have slightly higher reporting limits. Results for sample SV-60-05 (dilution factor of 200) and SV-61-05 (dilution factor of 1000) also had elevated reporting limits due to the dilutions. Table 4 shows the comparison of RLs to CHHSLs and PRGs. Semi-volatile Organic Hydrocarbons EPA Modified Method 8270C was utilized in the Single Ion Monitoring mode to measure PAHs in soil matrix. This method is adequate to characterize PAHs in soil and provides improved sensitivity relative to the full scan method. All reporting limits are adequate for HRA. Only one analyte, (Benzo(a)pyrene), exceeded the applicable screening value, as discussed below. Benzo(a)pyrene: There were sixty-five non-detects with a reporting limit range of 0.0049 to 0.0079 mg/kg for those samples with a dilution factor of 1. There is one non-detect sample with a reporting limit of 0.056 mg/kg (dilution factor 10). These

	reporting limits are compared to a Residential CHHSLL of 0.038 mg/kg. There were 23 detects of benzo(a)pyrene with a range of 0.0064 to 0.26 mg/kg. As a note, there were no results for PCB analysis provided either in the databases or laboratory reports. Rationale was not provided for the lack of PCB data in the 2007 sampling event.
V. Data Review	Data review of the laboratory reports and two excel spreadsheets (files *2007-08-13 Data to Append.xls* and *2007-12-18.xls*) was conducted by Neptune and Company. The Data Validation Report prepared by Neptune and Company is provided in Appendix A. The laboratory reports included summary results for both the samples and quality control samples analyzed with the sample batches. This summary information included analyte results, surrogate recovery data (where applicable), Continuing Calibration Verification (CCV) and LCS/LCSD and MS/MSD results (where applicable). No internal standard information (other than qualifiers added by the laboratory), raw data (e.g. chromatograms) ICP Interference Check Sample, ICP Serial Dilution initial or continuing calibration was provided unless noted in the report. The laboratory reports were evaluated based on the following documents: *Contract Laboratory Program National Functional Guidelines for Organic Data Review*, October 1999, *Contract Laboratory Program National Functional Guidelines for Inorganic Data Review*, October 2004. Professional judgment was used in some cases to qualify the results. No results were rejected during the data review and no data gaps are identified based on the analytical data.
VI. Data Quality Indicators	**Precision, Accuracy, Representativeness, Comparability and Completeness (PARCC)** data quality indicator information is provided below. This discussion is provided separately for the analytical data and conceptual site model. The data quality indicators (DQI) address field and analytical data quality aspects as they relate to uncertainties in selection of COPCs, EPCs (exposure point concentrations), and risk characterization. The DQIs are briefly discussed below. Precision is determined by evaluating: (1) the sampling variability; and (2) the measurement error. Assessment of sampling variability is critical to identifying the appropriate statistical measures and the number of required samples. Assessment of measurement error is accomplished by using the results of field duplicate samples. Field duplicates determine total within-batch measurement error (including analytical error if the samples are also analyzed as laboratory duplicates). Accuracy is a measure of overestimation or underestimation of reported concentrations and is evaluated from the results of spiked samples. Accuracy is controlled primarily by the analytical process and is reported as bias. Bias is estimated for the measurement process by calculating the percent recovery (%R) for the spiked or reference compound.

	Completeness is measured, for risk assessment purposes, by the total number of data points available and acceptable for each COPC for each medium of interest. For risk assessment purposes, the adequacy of the number of samples is evaluated in terms of: (1) acceptable uncertainty regarding the identification of COPCs in each environmental medium of interest and within each exposure area; and (2) acceptable uncertainty regarding the estimation of exposure point concentration of each COPC within each exposure area. Comparability is a critical parameter when considering the combination of data sets from different analyses for the same COPCs. Only comparable data sets can readily be combined for the purpose of generating a single risk assessment decision/calculation. The use of standard sampling and analytical methods simplifies the determination of comparability. All non-routine methods should be specifically evaluated for comparability in the DU evaluation. Representativeness of data used in risk assessment should be documented. The results of the risk assessment will be biased to the degree that the data do or do not reflect the chemicals and concentrations present in the exposure area of interest. In cases where sampling was not specifically designed to characterize representative COPCs and exposure concentrations for all potential exposure areas of the site, it is critical to evaluate what the impact on the risk assessment results may be. In addition to sampling strategy issues, analytical data quality should be assessed in regard to representativeness. Holding time, sample preservation, extraction procedures, and results from analyses of blanks affect the representativeness of analytical data. **PARCC parameters in terms of CSM/CEM:** **PARCC parameters are discussed in terms of the analytical data only.** **Soil Matrix Data for Metals**: Precision and accuracy of the metals analysis were assessed by analyzing matrix spikes, matrix spike duplicates, laboratory blanks, and laboratory control samples. With the exception of a limited number of matrix spike and matrix spike duplicates (MSDs) that had recoveries slightly below the QC limit, the quality control parameters were reported by the laboratory to be within acceptable laboratory limits. The exceptions indicate that the matrix may have caused a slight bias for the analytes referenced in the data validation report. QC results that did not meet the limits are discussed below. In general all metal data are considered useable for the HRA. Accuracy for soil samples SV-53-01 and SV-61-05: Recoveries for eleven metals in matrix spikes were slightly below the laboratory target range (75-125%), resulting in estimated values potentially biased low or non-detected values reported with a slight potential for false negatives around the reporting limit (see the Data Validation Report, Section 4.1.3 for details). These data are regarded as usable for HRA, but should be discussed in the uncertainty analysis section of the HRA. Accuracy for soil samples SV-02-10, SV-08-01, and SV-47-10: Recoveries for three metals in matrix spikes were slightly below the laboratory target range (75-125%), resulting in estimated values potentially biased low or non-detected values reported with a slight potential for false negatives around the reporting limit. One barium

	recovery and one mercury recovery for the duplicate were slightly above the laboratory target range, resulting in estimated values potentially biased high (see the Data Validation Report, Section 4.1.3 for details). These data are regarded as usable for HRA, but should be discussed in the uncertainty analysis section of the HRA. Accuracy for soil sample S-1A-03: The recoveries for two metals in matrix spikes were slightly below the laboratory target range (75-125%), resulting in estimated values potentially biased low or non-detected values reported with a slight potential for false negatives around the reporting limit (see the Data Validation Report, Section 4.1.3 for details). These data are regarded as usable for HRA, but should be discussed in the uncertainty analysis section of the HRA. All data quality indicators used to assess precision met the quality limits for the metals suite. **Soil Matrix Data for Volatile Fuel Hydrocarbons:** Precision and accuracy of the volatile fuel hydrocarbons and GRO (C4-C10) analyses were assessed by analyzing laboratory blanks, laboratory control samples, surrogates, and matrix spikes. All results met the quality control limits except those samples described below. Accuracy for soil samples: The surrogate compound 4-Bromoflourobenzene had recoveries below the laboratory target range (65-140%) in eleven samples. Three samples had recoveries for 4-bromofluorobenzene above the laboratory target range (see the Data Validation Report in Appendix A, Section 6.1.1 for details). All of the sample results that were qualified based on surrogate recoveries were reported as not detected. These data are regarded as usable for HRA, but should be discussed in the uncertainty analysis section of the HRA. Sample SV-51-01 had the associated matrix spike and MSD recoveries outside of the laboratory target range (60-140%). This sample was qualified as J- . Due to the severely low recovery of Volatile Fuel Hydrocarbon of -2% and -20% in the MS and MSD respectively, there is a strong potential for low bias with this sample. Due to the severely low recovery of the sample SV-51-01 matrix spike these data should not be used for this HRA. All other data are considered useable for the HRA. Attention should be given to indicator chemical data at this location. All data quality indicators used to assess precision met the quality limits for the volatile fuel hydrocarbons suite. **Soil Matrix Data for Volatile Organics with Oxygenates:** Precision and accuracy of the volatile organics with oxygenates was assessed by analyzing laboratory blanks, laboratory control samples, surrogates, and matrix spikes. With the exception of surrogate recoveries outside of laboratory target range and some low matrix spike recoveries (discussed below), the quality control parameters are within acceptable laboratory limits. Data are considered useable for the HRA. Accuracy for soil samples: A number of samples had surrogate recoveries that were outside of the QC limits, which resulted in estimated values. All of these samples were qualified in the Data Validation Report. Most of these recoveries were just slightly below the lower range of the laboratory target range (see the Data Validation Report, Section 5.1.1 for specific recoveries and laboratory target ranges). These data are regarded as usable for HRA, but should be discussed in the uncertainty analysis section of the HRA.

	A limited number of analytes in five samples (SV-58-02, SV-36-05, SV-08-01, SV-04-05, SV-38-05) had low recoveries in the matrix spike. None of these target analytes were detected in the unspiked samples (see the Data Validation Report, Section 5.1.4 for details). The low recovery of these spiked analytes does indicate the potential for false negatives at concentrations around the reporting limits. For reference, the spike level is approximately 50 ug/kg, with a reporting limit of 2-5 ug/kg. These data are considered usable for the HRA (i.e., soil ingestion route) as risks associated with VOCs are driven by the inhalation route, which will be assessed using soil vapor data. These results should be discussed in the uncertainty analysis section of the HRA. All data quality indicators used to assess precision met the quality limits for the volatile organics with oxygenates suite. **Soil Matrix Data for PAHs:** Precision and accuracy of the PAH analyses were assessed by analyzing laboratory blanks, laboratory control samples, surrogates, and matrix spikes. All quality checks met the requirements with the exceptions discussed below. <u>Precision for the LCS/LCSD pair in SDG IQG1327:</u> The analytes 2-Methylnaphthalene, 1-Methylnaphthalene, Indeno[1,2,3-cd]pyrene, and Dibenz(a,h)anthracene exceeded the RPD limits indicating variability of greater than 30% for these analytes in this sample. Data are considered usable for HRA but these results should be discussed in the uncertainty analysis section of the HRA. <u>Accuracy for soil sample SV-36-05</u>: The matrix spike pair in sample SV-36-05 for Benzo[g,h,i]perylene had recoveries of 38% and 49% which are below the limits of 57-142%. This indicates the concentration of this analyte in this sample is potentially biased low. This data point is regarded as usable for HRA, but should be discussed in the uncertainty analysis section of the HRA. <u>Accuracy for soil sample SV-36-01:</u> The matrix spike pair in sample SV-35-01 for Chrysene had recoveries of 55% and 47% which are below the limits of 71-126%. This indicates the concentration of this analyte in this sample is potentially biased low. Fluorene also had low recoveries of 56%/ 48% below the limits of 68-128% in sample SV-35-01. Benzo[a]anthracene had low recoveries in this sample of 57%/ 57% (limits of 64-124%). Fluorene and Benzo[a]anthracene were not detected in the native sample. These data are regarded as usable for HRA, but should be discussed in the uncertainty analysis section of the HRA. <u>Precision of LCS pair associated with SDG IQG1327</u>: SDG IQG1327 had the LCS/LCSD pairs meet the individual recovery limits for all compounds. However, 2-Methylnaphthalene, 1-Methylnaphthalene, Indeno[1,2,3-cd]pyrene, and Dibenz(a,h)anthracene exceeded the RPD limits. No data are qualified since the recoveries met the QC limits and all associated samples are considered usable. **Soil Matrix Data for Hydrocarbon Distribution :** Precision and accuracy of the Extractable Fuel Hydrocarbons (EFH) (C10-C40) were assessed by analyzing laboratory blanks, laboratory control samples, surrogates, and matrix spikes. With the exception of some surrogate recoveries outside of laboratory target range (discuss below), the quality control parameters are within acceptable laboratory limits. The surrogate recoveries are not considered an indication of significant bias; therefore the

	data are considered useable for HRA. Accuracy for soil samples: The recoveries of the surrogate n-Octacosane in seventeen samples (9 samples from IQG1327, 6 samples from IQG1351, and 2 samples from IQG1730) were outside of the laboratory target range (40-125%). Most of these recoveries were above the upper range of the laboratory target range between 143% and 867% indicating a potential for high bias (see Data Validation Report, Section 7.1.1 for details). The results for the analytes associated with these surrogates and sample numbers are reported as estimated. The data are considered adequate based on use of TPH data in HRA (i.e., to identify the need for indicator chemical analysis) but should be discussed in the uncertainty analysis section of the HRA. All data quality indicators used to assess precision met the quality limits for the EFHs suite. **All Soil Matrix Samples:** Completeness: One analytical results for sample SV-51-01, Volatile Fuel Hydrocarbons and GRO should not be used for HRA, all other results are considered acceptable. Completeness is greater than 99%. Representativeness: The representativeness of these analytical data was evaluated by reviewing the laboratory QC results of the blanks, samples and holding times. There were no data qualified based on the laboratory blanks. Some sample results were qualified based on matrix spikes and surrogate recoveries, but these qualifications do not appear to have a significant impact on the analytical data. All holding times were met. The analytical data are considered useable with respect to representativeness. Comparability: The laboratory used standard analytical methods for all of the analyses. The data reported and reviewed were all obtained in the year 2007 and were analyzed by the same laboratories as described above. The overall comparability of the data is acceptable based on the information that was provided.

*There is a discrepancy between the database and laboratory reports for samples S-50-01, S-50-05, and S-50-10 above. The laboratory report (IQG1351) identifies samples IQG1351-4, 05, and 06 as S-46-01, S-46-05, and S-46-10 respectively. This is also consistent with the analysis data and time included in the database.

Table 3. Nominal Reporting Limits from 2007 Soil Samples and CHHSLs for Metals

Analyte	CAS Number	Reporting Limit* (mg/kg)	CalEPA CHHSL (res) (mg/kg)
Antimony	7440-36-0	10	30
Arsenic	7440-38-2	0.5	0.07
Barium	7440-39-3	1	5200
Beryllium	7440-41-7	0.5	150
Cadmium	7440-43-9	0.5	1.7
Chromium	7440-47-3	1	n/a
Cobalt	7440-48-4	1	660
Copper	7440-50-8	2	3000
Lead	7439-92-1	2	150
Mercury	7439-97-6	0.02	18
Molybdenum	7439-98-7	2	380
Nickel	7440-02-0	2	1600
Selenium	7782-49-2	2	380
Silver	7440-22-4	1	380
Thallium	7440-28-0	10	5
Vanadium	7440-62-2	1	530
Zinc	7440-66-6	5	23000

n/a = Not available
*The RL applies to those samples with a nominal dilution factor of 1. Samples with dilution factors greater than this will have correspondingly higher reporting limits.

Table 4. Comparison of Maximum RLs and Screening Levels from 2007 Soil Samples

Analyte	Max. RL (mg/kg)	CHHSLL Res (mg/kg)	PRG, Res (mg/kg)	NOTES
Arsenic	0.5	0.07	0.390	six non-detect results with RL=0.5 mg/kg which is above CHHSLLs and Res PRG; 83 detected values
Thallium	20	5	5.162	all 89 are non-detect; RLs of 9.9, 10, or 20 mg/kg which are above Residential CHHSLL and Res PRG
1,1,2,2-Tetrachloro-ethane	1	NA	0.408	all 89 are non-detect; one record with DF=1000 and RL=1 mg/kg; range of remaining RLs is 0.0019 to 0.2 mg/kg which is below PRGs
1,1,2-Trichloro-ethane	1	NA	0.729	all 89 are non-detect; one record with DF=1000 and RL=1 mg/kg; range of remaining RLs is 0.0019 to 0.2 mg/kg which is below PRGs
1,2,3-Trichloro-propane	5	NA	0.034	all 89 are non-detect; two records with DFs of 200 and 1000 and RLs 1 and 5 mg/kg; range of remaining RLs is 0.0093 to 0.049 mg/kg; RL of 0.049 is also > Res PRG; all other RLs are below PRGs
1,2-Dibromo-3-chloropropane	2.5	NA	0.460	all 89 are non-detect; one record has RL=0.5 mg/kg (DF=200) and one record has RL= 2.5 (DF= 1000); all other RLs range between 0.0046 and

				0.024 mg/kg which are below PRGs
1,2-Dibromoethane	1	NA	0.032	all 89 are non-detect; one record has RL=0.2 mg/kg (DF=200) and one record has RL= 1 (DF= 1000); all other RLs range between 0.0046 and 0.0097 mg/kg which are below PRGs
1,2-Dichloroethane	1	NA	0.278	all 89 are non-detect; one record has RL=0.2 mg/kg (DF=200 and below PRGs) and one record has RL= 1 (DF= 1000); all other RLs range between 0.0046 and 0.0097 mg/kg which are below PRGs
1,2-Dichloro-propane	1	NA	0.342	all 89 are non-detect; one record has RL=0.2 mg/kg (DF=200 and below PRGs) and one record has RL= 1 (DF= 1000); all other RLs range between 0.0046 and 0.0097 mg/kg which are below PRGs
Benzo(a)-pyrene	0.056	0.038	0.062	66 records are non-detect; one record has RL=0.056 mg/kg (DF=10) which is above the Res CHHSLL; all other RLs range between 0.0049 and 0.0079 mg/kg which are below Ind CHHSLL and PRGs
Bromo-dichloro-methane	1	NA	0.824	all 89 are non-detect; one record has RL=0.2 mg/kg (DF=200 and below PRGs) and one record has RL= 1 (DF= 1000); all other RLs range between 0.0046 and 0.0097 mg/kg which are below PRGs
Carbon tetrachloride	2.5	NA	0.251	all 89 are non-detect; one record has RL=0.5 mg/kg (DF=200) and one record has RL= 2.5 (DF= 1000); all other RLs range between 0.0046 and 0.024 mg/kg which are below PRGs
Chloroform	1	NA	0.221	87 records are non-detect; one record has RL=0.2 mg/kg (DF=200 and below PRGs) and one record has RL= 1 (DF= 1000); all other RLs range between 0.0019 and 0.0097 mg/kg which are below PRGs
Methylene chloride	10	NA	9.107	all 89 are non-detect; one record has RL=2 mg/kg (DF=200 and below PRGs) and one record has RL= 10 (DF= 1000); all other RLs range between 0.0097 and 0.097 mg/kg which are below PRGs
Tetrachloro-ethene	1	NA	0.484	all 89 are non-detect; one record has RL=0.2 mg/kg (DF=200 and below PRGs) and one record has RL= 1 (DF= 1000); all other RLs range between 0.0019 and 0.0097 mg/kg which are below PRGs
Trichloro-ethene	1	NA	0.053	all 89 records are non-detect; one record has RL=0.2 mg/kg (DF=200) and one record has RL= 1 (DF= 1000); all other RLs range between 0.0019 and 0.0097 mg/kg which are below PRGs
Vinyl chloride	2.5	NA	0.079	all 89 are non-detect; one record has RL=0.5 mg/kg (DF=200) and one record has RL= 2.5 (DF= 1000); all other RLs range between 0.0046 and 0.024 mg/kg which are below PRGs

YELLOW shading indicates that the maximum RL exceeded the screening level.

2.2 2005 Wetland Sediment Matrix Data

Data Usability Criterion	Evaluation Result
I. Reports	Laboratory analytical reports for sediment samples collected from wetlands in 2005 were provided by ZymaX envirotechnology, San Luis Obispo, California. The ZymaX envirotechnology reports were provided in an Adobe Acrobat file named "Surface Water & Sediment_022405_Final.pdf". Samples reported in this Laboratory Report are provided in Table 5. No site map with sample locations that included soil depths or description of the sampling design and procedures including rationale was provided.
II. Documentation	The chain of custody record was included in the Adobe Acrobat file provided by the laboratory.
III. Data Sources	The analytical methods, as presented in Table 1, were appropriate for the analytes reported. However, the results appear to be reported in mg/kg wet weight which causes a comparability issue with screening levels.
IV. Analytical Method and Detection Limit	The analytical sample data results for the sediment samples were provided in adequate formats. The sediment samples were classified as soil by the laboratory and were analyzed for TPH, PAHs, VOCs, and metals. The laboratory reports that were provided included surrogate recoveries as the only QC information. However no surrogate limits were included in the report. No Continuing Calibration Verification (CCV), Laboratory Control Sample/Laboratory Control Sample Duplicate (LCS/LCSD), Matrix Spike/Matrix Spike Duplicate (MS/MSD), or Method Blank results were provided. All data were censored at the practical quantitation limit (PQL), with no data reported below this value. The results were also assumed to be reported in mg/kg wet weight, as discussed in Section 1.0. Table 6 presents the maximum reporting limit of analytes which have PQLs greater than 1/10 of the CHHSL or 1/10 of the PRG.
V. Data Review	Data review of the laboratory report and an excel spreadsheet (file *Feb 2005 Wetland Samples_020808.xls*) was conducted by Neptune and Company. The Data Validation Report prepared by Neptune and Company is provided in Appendix A. Since no QC results (other than surrogate information) were provided, the data shouldn't be used for risk assessment purposes. It could be used as screening information to indicate the semi-quantitative values of the analytes. A comparison to 1/10 of appropriate screening levels is provided for information only.
VI. Data Quality Indicators	**Precision, Accuracy, Representativeness, Comparability and Completeness (PARCC)** data quality indicator information is provided below. This discussion is provided separately for the analytical data and conceptual site model. The data quality indicators (DQI) address field and analytical data quality aspects as they relate to uncertainties in selection of COPCs, EPCs (exposure point concentrations), and risk characterization. **Precision and accuracy** could not be determined due to lack of quality control information. The only quality control information provided was for surrogates, but no

	acceptance limits were provided for these recoveries. **Representativeness**: The representativeness of these analytical data was evaluated by reviewing the laboratory QC results. Only surrogate recoveries were reported, but no acceptance criteria were provided for these recoveries. All holding times were met. The analytical data are considered useable only in the context of screening since no quality control information, other than surrogate recoveries, was provided. **Comparability:** The laboratory used standard analytical methods to analyze the wetland samples for metals, VOCs, and PAHs. The analytical methods used to measure total petroleum hydrocarbons were slightly different than other analyses used to analyze for the same carbon ranges in other samples. The overall comparability of the data is acceptable with the exception of TPH. The analytical methods for TPH should be considered when combining data from multiple sampling events. **Completeness:** The analytical results were reported for all of the samples. Due to lack of QC information, it is difficult to assess whether or not these sample results are "complete".

Table 5. Sediment Matrix Samples and Laboratory Reports from 2005 Wetland Samples

Sample Name	Lab Sample ID	Filename
WL-1-1	39095-5	Surface Water & Sediment_022405.pdf
WL-1-2	39095-6	Surface Water & Sediment_022405.pdf

Table 6. Comparison of Maximum RLs and Screening Levels from 2005 Wetland Samples

Analyte	Maximum PQL (mg/kg wet wt*)	1/10 CHHSLL, Res (mg/kg)	1/10 PRG, Res (mg/kg)
1,2,3-Trichloropropane	0.005	NA	0.003
1,2-Dibromoethane	0.005	NA	0.003
Antimony	5	3	3.13
Benzo(a)pyrene	0.005	0.0038	0.01
Cadmium	1	0.17	3.70
Dibenzo(a,h)anthracene	0.01	NA	0.006
Thallium	5	0.5	0.52

* units are assumed to be wet weight, so comparisons are made to 1/10 of the screening level to be conservative.
YELLOW shading indicates that the maximum PQL exceeded 1/10 of the screening level.

2.3 2005 Trench Soil Matrix Data

Data Usability Criterion	Evaluation Result
I. Reports	Laboratory analytical reports for sediment samples collected from wetlands in 2005 were provided by ZymaX Envirotechnology, San Luis Obispo, California. The ZymaX Envirotechnology reports were provided in an Adobe Acrobat file named "Surface Water & Sediment_022405_Final.pdf". Samples reported in this Laboratory Report and the associated QC batch numbers are provided in Table 7.
II. Documentation	The chain of custody record was included in the Adobe Acrobat file provided by the laboratory.
III. Data Sources	The analytical methods, as discussed in Section 1.0, were appropriate to identify the chemicals of concern in the 2005 soil samples. The analytical methods, as presented in Table 1, were appropriate for the analytes reported. However, the results appear to be reported in mg/kg wet weight which causes a comparability issue with screening levels.
IV. Analytical Method and Detection Limit	Total Purgeable Petroleum Hydrocarbons Method 8260 is adequate to characterize total purgeable petroleum hydrocarbons (C4-C10) in soil. Data in the laboratory reports appear to be censored at the PQL as no data were flagged below the PQL. The PQL for C4-C10 range results is 0.2 mg/kg. A screening level for TPH is not available for comparison to the PQL. The PQL is adequate based on the use of TPH data in HRA (i.e., to identify the need for indicator chemical analysis). PAHs EPA Modified Method 8270 was utilized in the Single Ion Monitoring mode to measure PAHs in soil matrix. This method is adequate to characterize PAHs in soil

	and provides improved sensitivity relative to the full scan method. The samples analyzed for PAHs had elevated PQLs due to matrix interference, sample dilution, or both. There were three samples in particular (STR-1-1-1.0, STR-4-1-1.0, STR-7-1-0.5) that have high PQLs for PAH results. Maximum PQLs that were reported above CHHSLs are shown in Table 8. <u>TPH</u> EPA modified 8015 was adequate to characterize C10-C25 and C25-C40 ranges of total petroleum hydrocarbons in soil. Data in the laboratory reports appear to be censored at the PQL as no data were flagged due to results below the PQL. The samples without dilutions had reported PQLs of 1 mg/kg. A screening level for TPH is not available for comparison to the PQL. The PQL is adequate based on the use of TPH data in HRA (i.e., to identify the need for indicator chemical analysis). <u>Metals</u> EPA methods 7471 (mercury) and 6010 (all other metals reported) were considered adequate to characterize metals in soil. Non-detected results in the laboratory reports appear to be censored at the PQL as no data were flagged due to results below the PQL. Antimony, cadmium, and thallium had at least one PQL that exceeded CHHSLs (Table 8). Antimony: There were eight non-detected concentrations of antimony ranging between 5 and 100 mg/kg. These PQLs are all above 1/10 of the CHHSL of 3 mg/kg. The detected concentrations range between 0.28 and 1.5 mg/kg, which are below the PQLs. Cadmium: The two non-detected concentrations were reported at 2.5 and 10 mg/kg, which are above 1/10 the CHHSL of .0.17 mg/kg. The detected concentrations range between 0.14 and 0.86 mg/kg, which are below the PQLs. Thallium: The six non-detected concentrations of thallium ranged between 5 and 25 mg/kg. All of these PQLs are above 1/10 of the CHHSL of 0.5 mg/kg. The detected concentrations range between 0.74 and 16 mg/kg. <u>Organopesticides and PCBs</u> EPA method 8080 was utilized to measure organopesticides and PCBs in the soil matrix. This method is adequate to characterize pesticides and PCBs in soil. There were samples with elevated PQLs due to matrix interference, sample dilutions, or both. Multiple Pesticides and PCBs have at least one PQL above the CHHSL (Table 8). <u>Base Neutral and Acid Extractables Organic Chemicals</u> EPA method 8270C was used to measure base neutral and acid extractable organic chemicals. This method is adequate to characterize base neutral and acid extractable

	organic chemicals in soil. There were samples with elevated PQLs due to dilutions of the sample for analysis. Table 8 shows the analytes that had at least one PQL above 1/10 of the CHHSL or 1/10 of the PRG.
V. Data Review	Data review of the laboratory report and an excel spreadsheet (file *April 2005 Trench Samples_020808.xls*) was conducted by Neptune and Company. The Data Validation Report prepared by Neptune and Company is provided in Appendix A. The laboratory reports included summary results for both the samples and quality control samples analyzed with the sample batches. This summary information included analyte results, surrogate recovery data (where applicable), Continuing Calibration Verification (CCV) and LCS/LCSD and MS/MSD results (where applicable). No internal standard information (other than qualifiers added by the laboratory), raw data (e.g. chromatograms) ICP Interference Check Sample, ICP Serial Dilution initial or continuing calibration was provided unless noted in the report. The laboratory reports were evaluated based on the following documents: *Contract Laboratory Program National Functional Guidelines for Organic Data Review*, October 1999, *Contract Laboratory Program National Functional Guidelines for Inorganic Data Review*, October 2004. Professional judgment was used in some cases to qualify the results.
VI. Data Quality Indicators	**Precision, Accuracy, Representativeness, Comparability and Completeness (PARCC)** data quality indicator information is provided below. This discussion is provided separately for the analytical data and conceptual site model. **PARCC parameters in terms of CSM/CEM:** **PARCC parameters are discussed in terms of the analytical data only.** **Soil Matrix data for Total Purgeable Petroleum Hydrocarbons (C4-C10):** Precision and accuracy of the C4-C10 analysis was assessed by analyzing matrix spikes, matrix spike duplicates, laboratory control samples, and method blanks. All three QC batches, including the MS/MSD, LCS, and method blank results, only included surrogate recovery data. All surrogates were within limits indicating good accuracy. However the accuracy of the full range of purgeable petroleum hydrocarbons cannot be fully assessed since they were not reported. **Soil Matrix data for PAHs:** Precision and accuracy of the PAH analysis was assessed by analyzing matrix spikes, matrix spike duplicates, laboratory control samples, and method blanks. Three samples (STR-13-1-0.5, STR-4-1-1.0, and STR8-1-0.5) had detects of PAHs. The CCV recovery was not within limits for benzo(b)fluoranthene. The accuracy of benzo(b)fluoranthene is in question, but since neither the magnitude nor direction of the CCV recovery was provided, the effect cannot be fully assessed. **Soil Matrix data for TPH (C10-C25 and C25-C40):** Precision and accuracy of the C10-C25 and C25-C40 analyses were assessed by analyzing matrix spikes, matrix spike duplicates, laboratory control samples, and method blanks. All of the MS/MSD and LCS percent recoveries, and surrogates were all within limits with the following exceptions. The LCS percent recovery associated with QC batch BOE0735 for TPH-

	Diesel was high; the recovery was 108% and the limits were 64-97%. The associated samples may be biased high. Two samples, STR-6-1-0.5 and STR9-1-0.5, did not have surrogate recoveries reported due to matrix interference. The surrogate for sample STR-10-4-1.5 was low and the results are qualified J. Multiple samples (see Trench validation report in Appendix A for details) had CCV out of limits for the surrogate, Tetracosane, but no CCV results were provided. The accuracy of the associated analytes are in question since neither the magnitude nor direction of the CCV recovery was provided, so the effect cannot be fully assessed. The recovery of tetracosane in sample STR-5-1-0.5 was 510% and the limits were 45-142%. The results for the associated samples may be biased high. **Soil Matrix data for Metals:** Precision and accuracy of the metals analysis was assessed by analyzing source duplicate samples, laboratory control samples, and method blanks. For QC batch BOE0095, all of the percent recoveries were within limits. The MS/MSD relative percent difference for zinc in QC batch BOE0095 (see Table 7 for associated sample numbers) was 23.3 percent with a control limit of 20. Therefore the matrix spike precision is not within control limits, however this exceedance is not significant. All method blank constituents were non-detected concentrations except for Barium, Beryllium, and Copper. Barium was detected at 0.0014 mg/kg and qualified J, the PQL for barium was 0.010 mg/kg. Beryllium was detected at 0.0005 mg/kg and qualified J, the PQL was 0.010 mg/kg. Copper was detected at 0.0154 mg/kg and qualified J, the PQL was 0.040 mg/kg. The results for these samples were not censored. **Soil Matrix data for Organochlorine Pesticides and PCBs:** Precision and accuracy of the metals analysis was assessed by analyzing matrix spikes, matrix spike duplicates, laboratory control samples, and method blanks. All results were within acceptable limits with the following exceptions. Samples STR-1-1-1.0, STR-4-1-1.0, and STR7-1-0.5 showed that the CCV for 4,4'-DDT and methoxyclor was out of limits. The accuracy of the associated analytes are in question since neither the magnitude nor direction of the CCV recovery was provided, so the effect cannot be fully assessed. For sample STR-1-1-1.0: The recovery for one of two surrogates, dibutyl chlorendate, was 40.3% and the limits were 47-133%. None of the organochlorine or PCB analytes were detected. Because the surrogate recovery was below the lower control limit these **data are qualified UJ.** For sampe STR-4-1-1.0: The recoveries for both surrogates were out of limits: TCMX was recovered at 29.9% (limits 36-106%) and Dibutyl chlorendate was recovered at 24.3% (limits 47-133%). None of the organochlorine or PCB analytes were detected. Because the surrogate recovery was below the lower control limit these **data are qualified UJ.** **Soil Matrix data for Base Neutral and Acid Extractables Organic Chemicals:** Precision and accuracy of the SVOC analysis was assessed by analyzing matrix spikes, matrix spike duplicates, laboratory control samples, and method blanks. The MS/MSD and LCS percent recoveries (QC batch BOE0466) for 3-&4-methylphenol were above the upper acceptance limit; however, 3-&4-methylphenol were not detected in client samples. The percent recoveries for the method blank sample surrogates were within limits. The results for all other analytes in the method blank were non-detected concentrations. The CCV recovery for Benzidine, Benzo[k]fluoranthene, 4,4'-DDT,

	Endosulfan I, Endosulfan II, and 2-Naphthylamine was not within limits; however, no information about the magnitude or direction of the CCV results were provided. The sample results for these analytes were reported as non-detected. There is a slight chance of false negatives due to the lack of complete CCV information. **All Soil Matrix Samples:** Representativeness: The representativeness of these analytical data was evaluated by reviewing the laboratory QC results of the blanks, samples and holding times. There were no data qualified based on the laboratory blanks. Some sample results were qualified based on matrix spikes and surrogate recoveries, but these qualifications do not appear to have a significant impact on the analytical data. All holding times were met. The analytical data are considered useable with respect to representativeness. Comparability: The laboratory used standard analytical methods for all of the analyses. The data reported and reviewed were all obtained in the year 2005 and were analyzed by the laboratory described above. The overall comparability within the trench data set is acceptable based on the information that was provided. Completeness: No results were rejected based on the data validation. The completeness level for the data set is 100%.

* units are assumed to be wet weight, so comparisons are made to 1/10 of the screening level to be conservative.
YELLOW shading indicates that the maximum RL exceeded 1/10 of the screening level.

2.4 Air Matrix Data

Data Usability Criteria	Evaluation Result
I. Reports	Results for the Air Toxic Compound analysis (EPA Method TO-15) reports included the laboratory analytical reports provided by Air Toxics Ltd (Table 9). The individual work orders are listed in Table 10. No SAP, QAPP, or other planning information was available to review for this data usability. No site map with sample locations that included soil depths or description of the sampling design and procedures including rationale was provided. **Methane and Fixed Gases:** The results for Methane and Fixed Gases in air using ASTM Method D-1946 is considered usable since no quality issues were identified in the laboratory reports. No SAP, QAPP, or other planning information was available to review for this data usability. This analytical suite is not discussed below since there is no known use of this data for HRA.

II. Documentation	No information on sampling location or sampling information was available for this data usability process. The laboratory reports indicated that a Chain-of-Custody copy was included but none was found.
III. Data Sources	The laboratory data reports provided named analytical methods. Modified method TO-15 was used to measure air toxic chemical in 1-Liter Summa Canisters using GC/MS in the full scan mode. All analytical sample data results for the environmental media of interest (air) were provided in adequate format. These samples were analyzed for air toxics and methane plus fixed gases. The laboratory reports that were provide were summary reports that included a case narrative, a copy of the Chain-of-Custody, surrogates, blanks, matrix spike and laboratory control sample (and replicate) results. The laboratory reports did not include the raw results or other QC information typically characterized as a Level IV report. Data usability, especially representativeness with respect to sample locations could not be assessed due to lack of such documentation.
IV. Analytical Method and Detection Limit	**Air Toxics Samples:** EPA Modified Method TO-15 is generally considered the method of choice for characterization of air toxics. No method detection limit values were provided. All data appear to be censored at the reporting limit, with no data reported below this value. The reporting limit (RL) was not defined in the laboratory reports. It is assumed the RL is greater than the method detection limit. Reporting Limits were compared to the residential CHHSLs and ESLs for shallow soil gas. The Reporting Limits provided were below the CHHSLs and ESLs for shallow soil gas with the exceptions shown in Table 11. Also note, a number of samples were received with significant vacuum remaining in the canister. The residual canister vacuum resulted in elevated reporting limits.
V. Data Review	Data review of the laboratory reports and two excel spreadsheets (files *2007-08-13 Data to Append.xls* and *2007-12-18.xls*) was conducted by Neptune and Company. The Data Validation Report is provided in Appendix A. The laboratory report included a Narrative and Results Sections with quality control information. The reports indicated a Chain-of-Custody was included but none were located in the files provided. The laboratory reports included summary results for both the samples and quality control samples analyzed with the sample batches. This summary information included analyte results, surrogate recovery data (where applicable), Continuing Calibration Verification (CCV) and LCS/LCSD and MS/MSD results (where applicable). No internal standard information (other than qualifiers added by the laboratory), or raw data (e.g. chromatograms) was provided unless noted in the report. The laboratory reports indicated that a Chain-of-Custody copy was included but none was found. The laboratory reports were evaluated based on the following documents: *Contract Laboratory Program National Functional Guidelines for Organic Data Review*, October 1999, *Contract Laboratory Program National Functional Guidelines for Inorganic Data Review*, October 2004. Professional judgment was used in some cases to qualify the results. No results were rejected during the data review and no data gaps are identified based on the analytical data.

VI. Data Quality Indicators	**Air Toxics Data:** Precision and accuracy of the air toxic compound analysis were assessed by analyzing surrogates, matrix spikes, matrix spike duplicates, blanks, and laboratory control samples. The quality control parameters for TO-15 Air Toxics data were reported by the laboratory to be within acceptable laboratory limits with the following exceptions: The surrogate recoveries for seventeen air samples were above the upper control limit indicating a small potential for high bias. Details are provided in Section 2.1.1 of the Data Validation Report (Appendix A). Accuracy for air toxics samples: Twelve continuing calibration verification samples had recoveries that were slightly below (63-69%) the lower (70%) recovery limit indicating a potential for low bias or false negatives. The analytes associated with the low CCV sample were Dichlorodifluoromethane (Freon 12), Naphthalene, 2,2,4-Trimethlypentane, Hexachlorobutadiene, and MTBE (see Section 2.1.2 in Appendix A). Because these recoveries are only slightly below the lower limit the bias associated with these samples is expected to be minimal and the samples are considered usable for HRA. Four laboratory control samples (LCS) had recoveries that were slightly below (60-69%) the lower limit (70%) for 1,2-Dichloro-1,1,2,2-tetrafluroethane, 1,2,4-Trichlorobenzene, Hexachlorobutadiene, and Naphthalene, detail are provided in Section 2.1.3 of Appendix A. These data are regarded as usable for HRA but should be discussed in the uncertainty analysis section of the HRA. Cyclohexane was found in sample SV-38-15 and chloroform was found in sample SV-10-15 at a concentration that exceeded the calibration range for these analytes. The reported values are therefore uncertain and the direction of potential bias is unknown. Without additional information that can be used to assess the magnitude of these calibration range exceedances it is difficult to determine the potential and direction of bias. These data are usable but should be considered highly uncertain. M,p-Xylenes were detection in one Equipment Blank. All associated samples had concentrations of m,p-xylenes well above the value in the blank with the exception of sample SV-45-15. The value of m,p-xylenes in this sample is potentially associated with contamination. These data are regarded as usable for HRA but should be discussed in the uncertainty analysis section of the HRA. **All Air Toxics Samples:** Completeness: No results were rejected, therefore completeness was 100%. Representativeness: The representativeness of these analytical data was evaluated by reviewing the laboratory QC results of the blanks, samples and holding times. One sample was qualified based on the equipment blank. Some sample results were qualified based on matrix spikes and surrogate recoveries, but these qualifications do not appear to have a significant impact on the analytical data. All holding times were met. The analytical data are considered useable with respect to representativeness. Comparability: The laboratory used standard analytical methods for all of the analyses. No method detection limits were reported, so they cannot be compared to the reporting limits. No data was flagged by the laboratory due to results below the reporting limit.

	This indicates the results were censored at the reporting limit. The overall comparability of the data is acceptable based on the information that was provided.

Introduction

This document supports the data validation and data usability reports that have been submitted separately (Attachments A through D). Whereas the data validation and data usability report focuses on chemical analytical issues and data quality indicators (precision, accuracy, representativeness, comparability and completeness), this document focuses only on representativeness in terms of spatial coverage of source terms and land use scenarios. Specifically, the soil and soil vapor sample locations are viewed spatially while overlaid on maps of source terms and land use scenarios, to evaluate adequate representation of the data to both characterize the source terms and to perform risk assessment on the different evaluation areas. The intent, therefore, of this analysis is to identify data gaps in the sampling, if any, that have occurred at the Avila site.

Assumptions made in this analysis are related to the form that the risk assessment will take at this site. Specifically, evaluation areas A through M have been established, in which case it is assumed that risk assessment is intended to be performed separately for each of these evaluation areas. Evaluation areas A through L will be evaluated for commercial use, whereas, Area M will be evaluated for residential use. The entirety of the area in between these evaluation areas will be evaluated for recreational use. Alternate options exist for the risk assessment, including combining some of the evaluation areas that have similar land use scenarios, and merging some of the recreational areas into the commercial areas to create larger contiguous areas for risk assessment. However, if either of these types of combination were to be considered, it would be important to verify that underlying statistical assumptions are supportive. For example, similar statistical distributions should be evident in areas that are combined.

Based on the assumptions described above (separate risk assessment for each evaluation area), the analysis presented herein consists of summary tables by area and depth and spatial plots by depth. For each area and depth, the summary tables provide sample size, number of detects, and the number of samples greater than some statistically-based concentrations. These statistically-based concentrations are used only to evaluate whether some sub-areas exhibit high concentrations more often than other sub-areas for a specific chemical. They are based initially on the 95% upper confidence limit (UCL) of the data for each chemical in turn. Arbitrary multipliers are used to evaluate data further into the upper tail of the data distributions. These multipliers are 125% UCL, 150% UCL, and 200% UCL. The intent is to identify locations where groups of comparatively high concentrations might occur. In this context, high means high relative to the remainder of the samples from the site. The actual concentrations may or may not pose a risk.

Bubbleplots for each chemical and depth interval are used to show samples and concentrations spatially by drawing a circle (area proportional to concentration) at the sample location coordinates. Concentrations greater than the 150% UCL value are plotted as filled triangles for easier identification of higher concentrations.

Note that the evaluation areas are shown first in the figure titled “Avila Site Map.”

Soil Gas Evaluation

The chemicals evaluated here are benzene, chloroform, and naphthalene, which are the VOCs of greatest concern for the risk assessment. Surface soil gas was defined as sample depths 0-10 feet and deep soil gas was defined as sample depths 12-95 feet. Generally speaking, the soil gas sampling locations cover the site uniformly both spatially and with depth, as can be seen in the figure "Soil Gas Sampling Locations."

Benzene and chloroform had detection rates of approximately 50% while naphthalene had only a single detect. The highest concentrations of benzene and chloroform occur in and around Area E in both surface and deep samples. Sample support in and around Area E appears adequate for characterization, especially since the entire surrounding area is designated for commercial land use. Sample support in some of the other evaluation areas could be considered inadequate. Often there are only 1 or 2 samples per evaluation area, upon which the assumption made here is that a risk assessment will be performed. This few samples might be considered inadequate for some evaluation areas. We note, however, that there are many other samples outside the evaluation areas that could be used to offer support to a specific evaluation-area risk evaluation if the statistical properties are comparable between the evaluation area and the other samples. This might require redrawing the evaluation areas.

Soil Evaluation

Surface soil was defined as sample depths 0-1 feet and deep soil was defined as sample depths 1.5-10.5 feet. Generally speaking, the soil sampling locations cover the site reasonably both spatially and with depth, as can be seen in the figure "Soil Sampling Locations", with the possible exception of evaluation area M, which is designated for residential land use. There are only 2 surface soil samples in evaluation area M, upon which a residential risk assessment will be performed.

More generally, by evaluation area, sample support could be considered inadequate. Often there are only 2 or 3 surface or near-surface samples per evaluation area, upon which the assumption made here is that a risk assessment will be performed. These few samples might be considered inadequate to support risk assessment for some evaluation areas. We note, however, that there are many other samples outside the evaluation areas that could be used to offer support to a specific evaluation-area risk evaluation if the statistical properties are comparable between the evaluation area and the other samples. This might require redrawing the evaluation areas.

Additionally, we note that the deepest soil sample from the site is 10.5 feet. This might be reasonable depending on the depth to groundwater and the possibility of transport to groundwater combined with an exposure pathway from groundwater. If contamination of groundwater is a concern, then samples from greater depths might be necessary.

The analytical laboratory labeled "BC" analyzed soil samples collected in April 2005. These are the only samples analyzed by this laboratory. These samples came from the southeast corner of the site between Areas K and L where no known source terms appear to exist. Many of the highest sample values for PAHs (many of them non-detects), all metals, DRO, and ORO occur in this area. The lack of known source terms, the magnitude of the concentrations, and the highly variable RDLs indicate these samples should be investigated for possible data issues or other possible source terms in this area.

Each group of chemicals is discussed in turn below with emphasis on the evaluation areas. Following these discussions is a brief discussion of the area between the evaluation areas, which is termed here the recreational area.

Metals

The metals evaluated here are arsenic, lead, mercury, nickel, vanadium, and zinc, which are the metals of greatest concern for the risk assessment. All metals have comparatively large surface soil values in the southeast corner as mentioned previously. In addition to this:

- Arsenic has high concentrations relative to background concentrations throughout the site in both surface and deep soil.
- Lead concentrations are generally low with only a few surface values above 400 mg/kg.
- Mercury values are relatively low when compared to those from the southeast corner.
- Nickel, Vanadium, and Zinc have some comparatively high surface and deep soil concentrations in and around Area D.
- Nearly all of the Vanadium surface and deep soil concentrations in and around Area M are comparatively high.

BTEX

The BTEX chemicals of interest are benzene, toluene, ethylbenzene, and xylenes (total). There was a single BTEX detect in surface soil which occurred in Area E. The highest BTEX concentrations occurred in deep soil in and around area E, with some others coming from the area of the pipeline that runs directly to the east. The sample support in this area appears adequate to support a risk assessment for these chemicals. However, the number of samples for risk assessment is small in other evaluation areas, particularly in area M which is intended for residential land use.

PAHs

The PAHs of interest are anthracene, benzo(a)pyrene, chrysene, naphthalene, phenanthrene, and pyrene. The site wide detection rates for the PAHs are approximately 33%. A large percentage of the detected results occur in deep soil in Area E, but these are not generally the greatest sample concentrations. The greatest concentrations occur in

the southeast part of the site between Evaluation Areas K and L. By evaluation area the sample sizes are quite small, with as few as 1 or 2 surface soil sample results for some evaluation areas. This is of particular concern for Evaluation Area M, which is intended for residential use.

TPHs

The TPH groups of interest are GRO (C4-C10), DRO (C10-C25), and ORO (C25-C40). In addition to the large DRO and ORO surface soil concentrations in the southeast corner:

- TPH chemicals and groups of TPH chemicals exhibit similar behavior in deep soil with the highest concentrations beginning in and around Area E and then running directly east along the pipelines.
- DRO and ORO have further high concentrations scattered around the commercial land use region.

As with the other chemical groups, the sample support by evaluation area might be deemed insufficient to support risk assessment. This is of greatest concern for Evaluation Area M, which is intended for residential use.

Unaffected Areas

Across all chemicals, areas A, B, and C (the northwest corner of the site) have comparatively low concentrations. The sample support in the recreational area appears more than adequate to support a recreational risk assessment. As noted in the introduction, some realignment of the Evaluation areas and land use scenarios might be considered if these data are to be considered adequate to support the planned risk assessment.

Laboratory Data Package Reviews

OEC Report for Sample Group Number 1102999

Samples collected on 20 June 2011
Analyzed by *Oilfield Environmental and Compliance, Inc.*
Laboratory samples IDs 110299-01 through 1102999-38
Matrix: Soil

	Samples: 4 soil samples collected and submitted for analyses; all within 10 feet bgs Client sample IDs: B-224-5', B-224-10', B-225-5', B-225-10'
	Analyses: Total Petroleum Hydrocarbons (TPH Diesel (C10-C25) and TPH Oil Crude (C25-C40)) via 8015 (all samples) Volatile Organic Compounds (VOCs) and TPH Gasoline (C4-C10) via 8260B/LUFT (all samples)
Yes	Includes all chain of custody forms All requested analyses completed (100% complete)
Yes	Identification of analytical methods and detection limits
Yes Yes No	Results given on a per sample basis – *soil on wet weight basis* Qualified Data Tentatively identified compounds Qualified Data Notes: 1) Detected above MDL but below the RL/PQL; therefore result is an estimated concentration (J): a. TPH Diesel (C10-C25) and TPH Oil Crude (C25-C40) in sample B-224-5'
N/A	Narrative explanation of qualified data Narrative Notes: None
Yes	Includes project quality control data (Blanks, Duplicates, LCS/LCSD, MS/MSD) Quality Control Notes: 1) Blanks: All method blank recoveries and relative percent differences within laboratory-specified control limits except:

Lab Sample ID	Samples in Batch (LabIDs)	Analyte (Analysis)	Result (RL)
A106433-BLK1	4 (1102999-01, 02, 20, and 21)	*Methylene chloride* (VOCs)	0.00208 (0.0050)[1]
A106433-BLK1	4 (1102999-01, 02, 20, and 21)	*1,2,4-Trimethylbenzene* (VOCs)	0.00668 (0.0050)[2]

[1]detected but below the RL/PQL; therefore, result is an estimated concentration; all associated field samples were nondetected for this compound therefore no qualifiers were applied to the data (J)

[2]the method blank contains analyte at a concentration above the RL/PQL (B-06)

2) Duplicates: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits.
3) MS/MSD: All matrix spike recoveries and relative percent differences (RPDs) within laboratory-specified control limits except:

Lab Sample ID	Samples in Batch (LabIDs)	Analyte (Analysis)	Recovery/RPD (limit)
A106433-MS1	4 (1102999-01, 02,	*Toluene* (VOCs)	158% (70-130%)[1]

		20, and 21)		
	A106523-MS2	4 (1102999-01, 02, 20, and 21)	*Oil Crude (C25-C40)* (TPH)	27.9% (70-130%)[2]
	A106523-MSD2	4 (1102999-01, 02, 20, and 21)	*Oil Crude (C25-C40)* (TPH)	31.9 (70-130%)[2]
	[1]the spike level was outside acceptance limits. The batch was accepted based on acceptable recovery of the remaining spikes (QM-12) [2]detected but below the RL/PQL; therefore, result is an estimated concentration (J) 4) LCS/LCSD: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits.			
Yes	Definitions and descriptions of flagged data			
Yes	Hardcopy of laboratory electronic files			
No	Raw laboratory data			

OEC Report for Sample Group Number 1103073

Samples collected on 22 June 2011 Analyzed by *Oilfield Environmental and Compliance, Inc.* Laboratory samples IDs 1103073-01 through 1103073-55 Matrix: Soil	
	Samples: 8 soil samples collected and submitted for analyses; all within 10 feet bgs Client sample IDs: B-226-5', B-226-10', B-227-5', B-227-10', B-228-5', B-228-10', B-229-5', B-229-10'
	Analyses: Total Petroleum Hydrocarbons (TPH Diesel (C10-C25) and TPH Oil Crude (C25-C40)) via 8015 (all samples) Volatile Organic Compounds (VOCs) and TPH Gasoline (C4-C10) via 8260B/LUFT (all samples) Lead via 6010B (2 samples)
Yes	Includes all chain of custody forms All requested analyses completed (100% complete)
Yes	Identification of analytical methods and detection limits
Yes Yes No	Results given on a per sample basis – *soil on wet weight basis* Qualified Data Tentatively identified compounds Qualified Data Notes: 1) Surrogate Recovery: All surrogate recoveries were within laboratory specified control limits except: a. The surrogate recovery for 4-bromorfluorobenzene in sample B-228-5'. The data was accepted based on valid recovery of the remaining surrogates (S-GC)
N/A	Narrative explanation of qualified data Narrative Notes: None
Yes	Includes project quality control data (Blanks, Duplicates, LCS/LCSD, MS/MSD) Quality Control Notes: 1) Blanks: All method blank recoveries and relative percent differences within

<table>
<tr><td></td><td>laboratory-specified control limits.
2) Duplicates: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits except:
a. TPH Diesel (C10-C25) and TPH Oil Crude (C25-C40) in Lab Sample ID A107039-DUP1. No samples within 0-10 ft bgs region are included in batch A107039; data is not affected.
3) MS/MSD: All matrix spike recoveries and relative percent differences (RPDs) within laboratory-specified control limits except:
a. 1,1-Dichloroethene in Lab Sample ID A106583-MS1 and 1103068 and TPH Gasoline (C4-C10) in Lab Sample ID A106607-MS2. No samples within 0-10 ft bgs region are included in batches A106583-MS1 or A106607-MS2; data is not affected.
4) LCS/LCSD: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits except:
<table>

1) Detected above MDL but below the RL/PQL; therefore result is an estimated concentration (J):
    a. Tert-butylbenzene and TPH Oil Crude (C25-C40) in sample B-230-5'; tert-butylbenzene and TPH Oil Crude (C25-C40) in sample B-230-10'; TPH Diesel (C10-C25) and TPH Oil Crude (C25-C40) in sample B-231-5'; and isopropylbenzene and 1,2,4-trimethylbenzene in sample B-231-10'
2) High frequency of "R-06": The reporting limit has been raised to account for the presence of high levels of analytes. Reporting limits for VOCs equal 0.5 mg/kg in samples B-230-5' and B-230-10'.

N/A

Narrative explanation of qualified data
Narrative Notes: None

Yes

Includes project quality control data (Blanks, Duplicates, LCS/LCSD, MS/MSD)
Quality Control Notes:

1) Blanks: All method blank recoveries and relative percent differences within laboratory-specified control limits.
2) Duplicates: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits except:

Lab Sample ID	Samples in Batch (LabIDs)	Analyte (Analysis)	Recovery/RPD/ Result (limit)
A107005-DUP1	2 (1103124-01 and 1103124-02)	*Benzene* (VOC)	0.139 (0.50)[1] 20.5 (20)[3]
A107005-DUP1	2 (1103124-01 and 1103124-02)	*1,3,5-Trimethylbenzene* (VOC)	21.8 (20)[3]
A107005-DUP1	2 (1103124-01 and 1103124-02)	*Xylenes (total)* (VOC)	21.8 (20)[3]
A107005-DUP1	2 (1103124-01 and 1103124-02)	*tert-Butylbenzene* (VOC)	0.123 (0.50)[1]
A107071-DUP1	6 (1103124-01, 01RE1, 02, 02RE2, 08, and 09)	*Oil Crude (C25-C40)* (TPH)	71.3 (20)[3]
A107071-DUP2	6 (1103124-01, 01RE1, 02, 02RE2, 08, and 09)	*Diesel (C10-C25)* (TPH)	29.5 (20)[2]
A107099-DUP1	2 (1103124-01RE1 and 02RE2)	*4-Bromofluorobenzene* (VOC, surrogate)	132% (70% - 130%)[4]

[1]detected but below the RL/PQL; therefore, result is an estimated concentration (J)
[2]the RPD value for the sample duplicate or MS/MSD was outside of QC acceptance limits due to matrix interference. QC batch accepted based on LCS and/or LCSD recovery and/or RPD values (QR-03)
[3]the RPD exceeded the QC control limits (QR-04)
[4]surrogate recovery outside of control limits. The data was accepted based on valid recovery of the remaining surrogates (S-GC)

3) MS/MSD: All matrix spike recoveries and relative percent differences (RPDs) within laboratory-specified control limits except:

Lab Sample ID	Samples in Batch (LabIDs)	Analyte (Analysis)	Recovery/RPD/ Result (limit)
A106607-MS2	2 (1103124-08 and	*Gasoline (C4-C10)*	63.2% (70% -

		1103124-09)	(TPH)	130%)[2]
	A107005-MS2	2 (1103124-01 and 1103124-02)	*Gasoline (C4-C10)* (TPH)	276% (70% - 130%)[2]
	A107005-MS2	2 (1103124-01 and 1103124-02)	*4-Bromofluorobenzene* (VOC, surrogate)	132% (70% - 130%)[3]
	A107071-MS3	6 (1103124-01, 01RE1, 02, 02RE2, 08, and 09)	*Diesel (C10-C25)* (TPH)	77.3 (100)[1] -594% (70% - 130%)[2]
	A107071-MS4	6 (1103124-01, 01RE1, 02, 02RE2, 08, and 09)	*Oil Crude (C25-C40)* (TPH)	776% (70% - 130%)[2]
	A107071-MSD3	6 (1103124-01, 01RE1, 02, 02RE2, 08, and 09)	*Diesel (C10-C25)* (TPH)	-94% (70% - 130%)[2]
	A107071-MSD4	6 (1103124-01, 01RE1, 02, 02RE2, 08, and 09)	*Oil Crude (C25-C40)* (TPH)	496 (500)[1] 723% (70% - 130%)[2]

[1]detected but below the RL/PQL; therefore, result is an estimated concentration (J)
[2]the spike recovery was outside acceptance limits for the MS and/or MSD. The QC Batch was accepted based on LCS/LCSD percent recoveries and RPD values (QM-08)
[3]surrogate recovery outside of control limits. The data was accepted based on valid recovery of the remaining surrogates (S-GC)

4) LCS/LCSD: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits except:

Lab Sample ID	Samples in Batch (LabIDs)	Analyte (Analysis)	Recovery/RPD/ Result (limit)
A107071-BS2	6 (1103124-01, 01RE1, 02, 02RE2, 08, and 09)	*Oil Crude (C25-C40)* (TPH)	48.3 (50)[1]
A107099-BSD1	2 (1103124-01RE1 and 02RE2)	*Toulene* (VOC)	20.6 (20)[2]
A107099-BSD2	2 (1103124-01RE1 and 02RE2)	*4-Bromofluorobenzene* (VOC, surrogate)	139% (70% - 130%)[3]

[1]detected but below the RL/PQL; therefore, result is an estimated concentration (J)
[2]the RPD exceeded the QC control limits (QR-04)
[3]surrogate recovery outside of control limits. The data was accepted based on valid recovery of the remaining surrogates (S-GC)

OEC Report for Work Order E206093

Report dated July 13, 2012

Samples collected on 20 June 2012 Analyzed by *H&P Mobile Geochemistry, Inc.* Laboratory samples IDs E206093-01 through E206093-31 Matrix: Vapor	
	Samples: 31 soil gas samples submitted for analyses Client Sample IDs: SV-71-5', SV-72-5', SV-73-5', SV-74-5', SV-75-5', SV-76-5', SV-77-5', SV-78-5', SV-79-5', SV-80-5', SV-80-15', SV-81-5', SV-81-15', SV-82-5', SV-82-15', SV-83-5', SV-83-15', SV-84-5', SV-84-15', SV-85-5', SV-85-15', SV-86-15', SV-87-15', SV-88-15', SV-89-15', SV-90-15', SV-91-15', DUP-1, DUP-2, Trip Blank A, Trip Blank B
	Analyses: Volatile Organic Compounds via MA APHm and USEPA Method T0-15 TVPH by USEPA Method TO-15 Modified Fixed Gases by ATSM 1945-96 Methane by USEPA 8015M
Yes	Includes all chain of custody forms All requested analyses completed (100% complete)
Yes	Identification of analytical methods and detection limits 1) All analyses include method detection limits (MDLs; in electronic file) except: a. Fixed Gases (Carbon Dioxide, Nitrogen, and Oxygen) by ATSM 1945-96, Methane by EPA 8015M, and 1,1-Difluoroethane (LCC) by EPA T0-15 2) All analyses include reporting limits (RLs)
Yes Yes No	Results given on a per sample basis Qualified Data Tentatively identified compounds Qualified Data Notes: 1) High frequency of "J"-qualified data: detected but below the RL/PQL; therefore, result is an estimated concentration
No	Narrative explanation of qualified data Narrative Notes: None
Yes	Includes project quality control data (blanks, LCS) Quality Control Notes: 1) Surrogates: All surrogate recoveries within laboratory-specified control limits 2) LCS: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits 3) Trip Blanks: Chloroform was detected in Trip Blank A (12 µg/m_3) and in Trip Blank B (13 µg/m^3)
Yes	Definitions and descriptions of flagged data
Yes	Hardcopy of laboratory electronic files
No	Raw laboratory data

Attachment 10: Laboratory Data Package Review

OEC Report for Sample Group Number 1205657

Samples collected on 08 November 2012 Analyzed by *Oilfield Environmental and Compliance, Inc.* Laboratory samples IDs 1205657-01 through 1205657-29 Matrix: Groundwater	
	Samples: 3 groundwater samples where groundwater was encountered within 15 feet bgs Client sample IDs: B-35-45R, B-57-20, DUP-3
	Analyses: Total Petroleum Hydrocarbons (TPH Gasoline (C4-C10), Diesel (C10-C25) and TPH Oil Crude (C25-C40)) (all samples) Volatile Organic Compounds (VOCs) and oxygenates via Method 8260 Polycyclic Aromatic Hydrocarbons (PAHs) SIM via Method 8270 Metals via 7000/6000
Yes	Includes all chain of custody forms All requested analyses completed (100% complete)
Yes	Identification of analytical methods and detection limits
Yes Yes No	Results given on a per sample basis Qualified Data Tentatively identified compounds Qualified Data Notes: 1) Sample dilution (R-05): Sample B-35-45R was diluted due to the presence of high levels of non-target analytes and resulted in elevated reporting limit for thallium (ND<0.005 mg/kg) 2) Detected above MDL but below the RL/PQL; therefore result is an estimated concentration (J): a. TPH Diesel (C10-C25) and TPH Oil Crude (C25-C40) in sample B-224-5’
N/A	Narrative explanation of qualified data Narrative Notes: None
Yes	Includes project quality control data (Blanks, Duplicates, LCS/LCSD, MS/MSD) Quality Control Notes: 1) Blanks: No blank detections. 2) Duplicates: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits (DUP3) 3) MS/MSD: All matrix spike recoveries and relative percent differences (RPDs) within laboratory-specified control limits. 4) LCS/LCSD: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits.
Yes	Definitions and descriptions of flagged data
Yes	Hardcopy of laboratory electronic files
No	Raw laboratory data

OEC Report for Sample Group Number 1205597

Samples collected on 06 November 2012

Attachment 10: Laboratory Data Package Review

Analyzed by *Oilfield Environmental and Compliance, Inc.* Laboratory samples IDs 11205597-11 through 11205597-13 Matrix: Groundwater	
	Samples: 3 groundwater samples where groundwater was encountered within 15 feet bgs Client sample IDs: AT-B-147, AT-B-202, AT-B-146
	Analyses: Total Petroleum Hydrocarbons (TPH Gasoline (C4-C10), Diesel (C10-C25) and TPH Oil Crude (C25-C40)) (all samples) Volatile Organic Compounds (VOCs) and oxygenates via Method 8260
Yes	Includes all chain of custody forms All requested analyses completed (100% complete)
Yes	Identification of analytical methods and detection limits
Yes Yes No	Results given on a per sample basis Qualified Data Tentatively identified compounds Qualified Data Notes: 1) Detected above MDL but below the RL/PQL; therefore result is an estimated concentration (J): a. Toluene in sample AT-B-147 b. Toluene in sample AT-B-202 c. Toluene in sample AT-B-146
N/A	Narrative explanation of qualified data Narrative Notes: None
Yes	Includes project quality control data (Blanks, Duplicates, LCS/LCSD, MS/MSD) Quality Control Notes: 1) Blanks: No blank detections. 2) Duplicates: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits. 3) MS/MSD: All matrix spike recoveries and relative percent differences (RPDs) within laboratory-specified control limits. 4) LCS/LCSD: All laboratory control spike recoveries and relative percent differences within laboratory-specified control limits.

1.0 INTRODUCTION

To respond to comments from San Luis Obispo County Environmental Health Services (SLO County EHS), a quantitative data quality assessment (DQA) was conducted for the former Avila Tank Farm (the Site) to determine if data used in the Final Human Health Risk Assessment (Final HHRA) are sufficient to support risk-based decisions with the desired confidence. The *Avila Tank Farm Data Validation and Data Usability Report* (DVDU, Neptune and Company, Inc. 2008) determined that the data collected during environmental site investigations were appropriate to use in a human health risk assessment, but did not address the sufficiency of the data to support risk-based decisions. While the Neptune and Company, Inc. (Neptune) DVDU addressed data sufficiency qualitatively through spatial representation of the data, this document focuses on evaluating data sufficiency quantitatively through sample size calculations.

The DQA process used in this evaluation is based on USEPA guidance (USEPA 2006a and b), and was developed in general concurrence with Neptune & Company, Inc. The primary purpose of the DQA process is to verify that data quality objectives (DQOs) were satisfied. When human health risk assessment activities recommenced in 2007, qualitative DQOs were developed for soil and soil gas sampling based on visual inspection of sample coverage and professional judgment. This evaluation provides quantitative DQO statements and a DQA to verify that sufficient data have been collected to support future risk management decisions – that is, to decide on no further action, or on further action. The data sufficiency conclusions summarized in this evaluation are based on the data used in the Final HHRA and exposure areas as defined in the proposed Vision Plan (see main document). As requested by SLO County EHS, this document is an update of the 2011 Data Quality Assessment in order to incorporate changes made to the Vision Plan, supplemental sampling conducted since 2007, and the Final HHRA results.

2.0 DATA QUALITY ASSESSMENT PROCESS

2.1 Data Quality Objectives

The first step of the DQA process is to review the sampling objectives set forth in the DQOs. The DQOs developed during the planning phase of the 2007 site investigations were qualitative statements, and would allow for a qualitative DQA. As requested by SLO County EHS, this DQA is quantitative. Prior to performing sample size calculations in this DQA, it was necessary to develop quantitative DQO statements. Therefore, the seven steps of the DQO process were revisited to specify risk-based concentrations (RBCs), and acceptable performance criteria.

1. *State the Problem*: Both petroleum and non-petroleum chemicals are present in various media on the Site. Although the Site is currently zoned industrial, potentially exposed populations include short-term residents, indoor and outdoor commercial employees, intrusive utility workers, and recreational users.
2. *Identify the Goals of the Study:* Human health risk assessment results are to be used in the development of risk management recommendations in order to protect human health.
3. *Identify the Information Inputs:*
    - Site conceptual model showing potential sources of contamination and dominant exposure pathways.
    - Key chemical-pathway receptor combinations accounting for the majority of cancer risk and noncancer hazard in each exposure area (e.g. benzene in soil gas for short-term residents in Area M).
    - Environmental data to determine sample variability.
    - Risk goals to be achieved (e.g. cancer risk no greater than 10^{-6} for short-term residents, recreational users and offsite residents; 10^{-5} for commercial employees and intrusive utility workers; and hazard quotient no greater than 1.0 for all receptors) and corresponding RBCs.
    - Risk assessment inputs from the Final HHRA to back-calculate soil and soil gas RBCs that will result in achievement of risk goals.
4. *Define the Boundaries of the Study:*
    - Exposure areas outlined in the Vision Plan, as described in the Final HHRA.
    - Site soil gas data used must have been collected after the DTSC 2004 vapor intrusion guidance was published (includes 2007 and 2013 sampling events).
    - Data used includes site data determined valid according to the ATF DVDU (Neptune 2008) and supplemental soil and soil gas sampling collected in 2011 and 2012, as requested by SLO County EHS (Padre 2012a,b).
5. *Develop the Analytical Approach:* For short-term residents and indoor/outdoor employees, if the 95 percent upper confidence limit (UCL) of the average concentration of any chemical of potential concern within the upper 10 feet (ft) of soil is greater than its risk-based goal, then propose remedial action or institutional controls. Recreational users and offsite residents are evaluated using the 0-2 ft soil horizon. If there are not enough data to support a 95 percent UCL calculation, then the maximum detected concentration is compared to risk goals. For intrusive utility workers, risk management decisions are based on the maximum concentration.
6. *Specify Performance or Acceptance Criteria:* To be health protective, the null hypothesis assumes that the mean concentrations are greater than the respective RBCs. Based on agreement with SLO County EHS, the acceptable error rate for incorrectly accepting the

null hypothesis is determined to be 20% (remediate a clean site; Type II error), and for incorrectly rejecting the null is 5% (no further action taken at a contaminated site; Type I error). These error rates are consistent with the USEPA default performance criteria. The acceptable minimum detectable difference (MDD), or the width of the gray region was selected to be 20% of the RBC for each risk-significant chemical.

7. *Optimize the Design:* The final step typically develops the most efficient design to meet the acceptable limits on decision errors specified in Step 6. Because sampling has already occurred, the sample sizes used in the Final HHRA will be compared to the required sample size calculated from the USEPA default error rates. If the Final HHRA sample size does not meet the desired sample size calculated with the above USEPA default performance criteria, a sensitivity analysis was conducted by calculating optimal sample sizes based on a range of limits of decision errors: Type II error range of 15%, 20% and 25%; Type I error range of 5%, 10% and 15%; and MDDs of 10%, 20%, and 30%. Sample sizes were then compared to this range of statistically calculated sample sizes.

2.2 Data Quality Assessment Process

The USEPA's DQA process focuses on evaluating one chemical at a time. In the risk assessment context, the goal is to verify that enough data have been collected for each chemical that contributes significantly to the overall risk (referred to as the risk-significant chemical). This retrospective DQA is applied to a range of possible DQO inputs. As described in the previous section, these inputs include risk-significant chemicals, data variability, risk-based goals and error rates.

2.2.1 Risk-Significant Chemicals

Risk-significant chemicals were identified for soil and soil gas pathways by reviewing the Final HHRA results (McDaniel Lambert 2013), and calculating the percentage of risk accounted for by a single chemical. Risk-significant chemicals were identified as any chemical(s) accounting for a cumulative 40% of the total cancer risk or noncancer hazard for each receptor. Because it is evaluated separately in the Final HHRA, lead also was considered a risk-significant chemical for every exposure area. For risk-significant chemicals other than lead, the chemical-pathway-receptor combinations are summarized in Table 1. Carcinogenic polycyclic aromatic hydrocarbons (except dibenzo[a,h]anthracene and naphthalene) are evaluated collectively as one risk-significant chemical (benzo[a]pyrene toxic equivalents, or BaP TEQ).

2.2.2 Final HHRA Data Variability

In a prospective DQO effort, the anticipated data variability typically is specified based on a combination of historical data and expert opinion. Since this is a retrospective DQO effort and

the Final HHRA dataset is available, the *actual* sample standard deviation was calculated from the site-specific data for each chemical identified as risk-significant. In the case of non-detects, the reporting limit was substituted as the chemical concentration. For each risk-significant chemical, the Final HHRA soil and soil gas datasets were reviewed for elevated reporting limits to avoid skewing the standard deviation. Outlying reporting limits (generally two or more orders of magnitude larger than other reporting limits) were excluded from the datasets. The elevated reporting limits were due to sample dilution as a result of the presence of non-target analytes. Table 2 indicates the reporting limits that were removed and the rationale for exclusion. Although these elevated reporting limits were included in the Final HHRA, they do not significantly affect the risk results.

2.2.3 Risk-based Concentrations

For purposes of the DQA, the desired risk goals (e.g. 10^{-6}/10^{-5} and 1.0) are translated into RBCs for each risk-significant chemical. The RBCs were back-calculated using equations, exposure assumptions, and toxicity criteria presented in Sections 3 and 5 of the Final HHRA (McDaniel Lambert 2013). For potential cancer health effects of risk-significant chemicals in every exposure area, RBCs were calculated using thresholds within the USEPA risk management range. Specifically, a cancer risk threshold of 10^{-6} is used to calculate RBCs for offsite residents, short-term residents and recreational users, and a threshold of 10^{-5} is used for commercial employees and intrusive utility workers (personal communication, June 25, 2013, Aaron LaBarre). For potential noncancer health effects, the RBC corresponds to a chemical-specific hazard quotient of 1.0. Consistent with the Final HHRA, the noncarcinogenic health effects of lead are assessed separately from other COPCs. The lead RBCs for soil are based on the residential California Human Health Screening Level (CHHSL) of 80 mg/kg and the commercial CHHSL of 320 mg/kg (Cal/EPA 2009). The residential CHHSL is used as the RBC to evaluate recreational receptors, and the commercial CHHSL of 320 mg/kg is protective of the short-term resident child (see Final HHRA Attachment 13).

If the same risk-significant chemical was identified for multiple receptors in the same exposure area, then the most conservative RBC was carried forward in the DQA process to be health protective of the most sensitive receptor in each area. The cancer and noncancer RBCs used in the DQA are presented in Table 3. The RBCs calculated in this assessment are intended for the sole purpose of guiding this DQA effort, and it should be noted that these RBCs are not cleanup standards.

2.2.4 Performance and Acceptance Criteria

Similar to the other inputs, tolerable limits on decision errors also are developed as part of quantitative DQOs during the sample design phase. The decision errors are framed in the context of the hypothesis being tested by considering the impacts of falsely rejecting or falsely

accepting the null hypothesis. SLO County EHS has selected acceptable decision errors, which are described below.

For each risk-significant chemical, the null hypothesis is that the mean concentration is above the RBC. In other words, the hypothesis is a health protective assumption that remediation is necessary unless the collected data contain sufficient evidence to conclude otherwise. A false acceptance decision error (Type II) would occur if the results concluded the mean site concentration is above the RBC, when in fact they are below. A false rejection decision error (Type I) would occur if the results concluded that the mean site concentration is not below the RBC, when in fact it is above. In this case, false rejection would be a more serious error in terms of protecting public health; therefore it is important to place more stringent criteria on the probability of this occurring (alpha value). For further action areas, the probability of making a false rejection error equals 5%, and the probability of making a false acceptance error equals 20%. These are consistent with the error rates that EPA guidance generally recommends –5% for the more severe error that would lead to compromising public health, and 20% for the chance of remediating when it is not necessary (USEPA 1994).

The minimum detectable difference (MDD), or the width of the gray region, is typically a specified proportion of the RBC. In this DQA, an MDD equal to 20% of the RBC was selected as an acceptable value in conjunction with SLO County EHS and its consultants.

2.2.5 Sensitivity Analysis

If Final HHRA sample sizes did not meet the default criteria described above, a sensitivity analysis was conducted to calculate optimal sample sizes based on a range of inputs for various acceptance criteria. False rejection errors ranged from 15% to 25%; false acceptance errors ranged from 5% to 15%; and the MDD was set at 10%, 20% and 30% of the RBC. Depending on where the Final HHRA sample size falls within the desired range of statistically calculated sample sizes, the level of confidence in possible risk management decisions varies. If the actual sample size is at the low end of the calculated range, there is a 15% probability that no further action will be taken at a contaminated site and a 25% probability that a clean site will be remediated.

2.3 Sample Size Calculations

Using the DQA inputs identified above, the software package Visual Sample Plan (Version 6.0, Pacific Northwest National Laboratory, 2010) was used to calculate sample sizes. This software includes a module that calculates the sample size required to compare the mean site concentration with an RBC. The formula used in this calculation is based on a non-parametric test; therefore it provides an approach that is robust to datasets such as those in the Final

HHRA exposure areas that deviate from a normal distribution. The formula developed by Pacific Northwest National Laboratory and used in this exercise is as follows:

$$n = 1.16\left[\frac{s^2}{\Delta^2}\left(z_{1-\alpha} + z_{1-\beta(\mu)}\right)^2 + 0.5z_{1-\alpha}^2\right]$$

where,

n = number of samples
s = sample standard deviation of concentrations evaluated in Final HHRA
Δ = width of gray region (difference between the RBC and the point at which β is specified)
α = significance level or Type I error tolerance
β = Type II error tolerance; and
z = quantile from the standard normal distribution

3.0 ARSENIC BACKGROUND DATA

In addition to the DQO and DQA for soil and soil gas risk-significant chemicals identified in the Final HHRA, SLO County Health requested a review of the data sufficiency for arsenic. The *Analysis of Background Metals* (McDaniel Lambert 2009) examined multiple lines of evidence to determine if site concentrations are within background levels, including statistical comparison tests of metal concentrations by geology, and concluded that Site arsenic concentrations are consistent with background levels. SLO County Health previously agreed that the exclusion of arsenic as a COPC was appropriate, and has requested a quantitative DQA to verify that sample sizes were sufficient to complete the statistical comparison tests.

The background evaluation included two sets of comparison tests for arsenic – one for each of the predominant geologies (Obispo and Pismo) at the Site. The DQA was conducted by calculating the sample sizes required for the Student's t-test with independent, unequal group sizes, which was one of the four comparison tests used in the background evaluation. As in the DQA process for risk-significant chemicals at the Site, acceptable performance criteria were selected for this arsenic evaluation. The Type I and Type II error rates are consistent with those discussed in Section 2.2.4, however the MDD values were selected specifically to evaluate background arsenic at the Site. The USEPA guidance (USEPA 2002) discusses several options for establishing an appropriate MDD when testing for differences between background and onsite areas. One of these options was chosen for this analysis, which is to use a specified proportion of the mean background concentrations. Several proportions of the mean background concentrations were considered, including 50%, 100% and 150%. Given the potential human health risk, regional background levels and lack of historical sources, reasonable MDDs were

selected for each geology as described in more detail below: (1) a difference of 100% was considered important for arsenic in the Pismo geologic formation, and (2) a difference of 50% for the Obispo formation. The reason for the different percent MDDs is that the natural concentrations of arsenic in the Obispo formation are greater than those in the Pismo formation. The different percent MDDs for each geology hence correspond to very similar differences in mean concentration for the two geologies.

A reasonable MDD is typically established by considering a contaminant level that does not pose a risk. However, the arsenic residential CHHSL of 0.07 mg/kg is less than reporting limits used by analytical laboratories. Therefore, any positive confirmation of arsenic by a laboratory will be reported at a concentration that exceeds the CHHSL. Nevertheless, the risk concerns support the idea of a small MDD to protect against potentially adverse risk. Other factors to consider, however, include the lack of known historical source term for arsenic, and background concentrations of arsenic in the general area or region of the site. These factors lend themselves to the idea of a larger MDD. The MDD values chosen for the DQA balance the risk, lack of source, and regional background concerns.

Naturally occurring (or background) concentrations of arsenic in California soils are known to exceed the CHHSLs and other risk-based concentrations. The following table presents the range of results from background metal concentration data sets conducted in various California locations, which range from 1.5 to 46 mg/kg. The nearest data source to the Site is Shell Beach, with background arsenic concentrations ranging from 8.1 to 11.9 mg/kg. The Human Health Risk Assessment Working Group[1] agreed that these regional background levels for arsenic are appropriate to use in determining a reasonable MDD.

Table 4. Regional Background Arsenic Data

Source	Background arsenic concentration (mg/kg)
San Miguel, San Luis Obispo County, CA (EIS 2009)	1.5 – 7.1
San Miguel, San Luis Obispo County, CA (DMI 2004)	<1.0 – 46
Paso Robles, San Luis Obispo County, CA (OEC 2008)	3.1 – 5.4
Shell Beach, San Luis Obispo County, CA (Lancaster Laboratories 2008)	8.1 – 11.9

Note: SLO County Health provided these regional arsenic data for various background locations in SLO County (email communication, January 21, 2010, Aaron LaBarre).

[1] The Human Health Working Group consists of members of the Avila Tank Farm Collaborative Assessment Team, including the Regional Water Quality Control Board, the Air Pollution Control District, and the SLO County Health and its consultants.

A difference of 100% of the background mean for arsenic in Pismo soils (3.9 mg/kg) equates to an MDD of 3.9 mg/kg. This means that an inaccurate decision is more likely to be made if the true arsenic concentration onsite is between 3.9 mg/kg (the lower bound of the grey region) and 7.7 mg/kg (the upper bound of the grey region). In other words, the desired error rates apply (i.e., Type II error probability of falsely excluding arsenic as a COPC) if the true arsenic concentration in onsite Pismo soils is above 7.7 mg/kg. Since this concentration is within the range of regional background concentrations, and below the background levels detected at nearby Shell Beach, a difference of 100% of the background mean is considered reasonable.

A difference of 50% of the background mean for arsenic in Obispo soils (6.3 mg/kg) equates to an MDD of 3.2 mg/kg. This means that an inaccurate decision is more likely to be made if the true arsenic concentration onsite is between 6.3 mg/kg (the mean background concentration, and the lower bound of the grey region) and 9.5 mg/kg (the upper bound of the grey region). In other words, the desired error rates apply (i.e., Type II error probability of falsely excluding arsenic as a COPC) if the true arsenic concentration in onsite Obispo soils is above 9.5 mg/kg. Since this concentration is within the range of regional background concentrations, and similar to the background levels detected at nearby Shell Beach, a difference of 50% of the background mean is considered reasonable. Given the propensity for arsenic to occur naturally within the volcaniclastic rocks of the Obispo formation, it is reasonable that the upper bound of the grey region for arsenic in Obispo is greater than that for Pismo. Electron probe analysis of one of the highest arsenic concentrations found in the onsite Obispo formation confirmed its geogenic source (Avocet 2004).

Lastly, potential anthropogenic sources of arsenic (e.g. pesticides) at the Site have been thoroughly investigated since environmental sampling began in 1998. The only available information regarding historical weed management is a report by England & Associates (1998) that cites a 1982 weed abatement contract for the application of oil (also referred to as asphalt) to large portions of the property as a means of weed and erosion control. Analyses of pesticides in Site soils further support the limited use of pesticides; only one pesticide (gamma-BHC) was detected in one of 12 soil samples collected site-wide. Furthermore, arsenic is not a metal usually associated with petroleum products (WHO 1989). There is some evidence of arsenic being present in crude oil in the parts-per-billion range (Stigter 2000), which is nominal compared to the minimum background concentration in Obispo. The absence of operational practices using arsenic further supports the MDDs selected.

The sample size calculations for arsenic in Pismo and Obispo are summarized in Tables 5 and 6 below. In addition to the error rates that correspond to the USEPA default criteria (α = 5% and β = 20%), the tables show a sensitivity analysis with a range of error rates consistent with those

described in Section 2.2.5. Given the regional background data and lack of arsenic sources onsite, the DQA confirmed there are enough arsenic samples to conclude background and site concentrations are similar.

Table 5. Sample Size Calculations for Arsenic in Pismo

Analyte: Arsenic, Pismo		Matrix: Soil		
Null Hypothesis= Site mean ≤ Background		Allocation Ratio: 1 : 25.57		s= 3.73
No. Bkgd Samples=7	No. Site Samples= 179	α = 5%	α = 10%	α = 15%
MDD = 100% (3.87)	β = 15%	7 : 179	6 : 135	5 : 108
	β = 20%	7 : 155	5 : 113	4 : 89
	β = 25%	6 : 135	4 : 97	3 : 75

Table 6. Sample Size Calculations for Arsenic in Obispo

Analyte: Arsenic, Obispo	Matrix: Soil			
Null Hypothesis= Site mean ≤ Background		Allocation Ratio: 1 : 5.14		s= 5.25
No. Bkgd Samples=22*	No. Site Samples=113	α = 5%	α = 10%	α = 15%
MDD = 50% (3.155)	β = 15%	25 : 124	19 : 93	15 : 75
	β = 20%	21 : 108	16 : 78	12 : 62
	β = 25%	19 : 93	13 : 67	10 : 52

α = alpha, probability of correctly concluding that the mean site concentration is within background (Type I error)
β = beta, probability of incorrectly concluding that the mean site concentration is within background (Type II error)
MDD = minimum detectable difference
Grey shading indicates USEPA default performance criteria, α=5% and β=20%
*Two outliers were removed for the sample size calculations. Results of comparison tests with outliers removed suggest background and site data are similar.

The sample size calculations were conducted using the open source statistical software program R (www.r-project.org). The programming code is provided in Attachment 1 for the Pismo scenario. The program uses a 1-sided 2-sample t-test, which compares mean concentrations. The inputs to the program include:

- a range of possible desired Type I and Type II error rates,
- the selected MDDs,
- the standard deviation of the background data (since the intent is to demonstrate that the site arsenic concentrations are similar to the background concentrations), and,
- an allocation ratio of the number of site samples to background samples, which is also based on the actual number of site and background samples taken.

The actual numbers of background and site samples collected for arsenic in the Pismo formation are 7 and 179. For the range of conditions provided in Table 5, the maximum numbers of samples needed are, coincidentally, 7 and 179. The number of samples needed when the default Type I and Type II error rates (5% and 20%) are used are 7 and 155. This suggests that enough samples have been collected to confirm the finding that the site arsenic concentrations in the Pismo formation are close enough to background concentrations. The p-

value for the test of the difference between site and background concentrations in the Pismo formation is 0.22, suggesting that the site and background concentrations are similar. This DQA confirms that there are enough samples to support this conclusion.

The actual numbers of background and site samples collected for arsenic in the Obispo formation are 24 and 179. However, two of the 24 background samples have been removed for this DQA analysis, because their concentrations are considerably greater than the site concentrations (110 and 220 mg//kg compared to the maximum site concentration of 57 mg/kg). Note, these two data points are still considered part of the background dataset, but are removed for this DQA only. For the range of conditions provided in Table 6, the maximum numbers of samples needed are 25 and 124. The number of samples needed when the default Type I and Type II error rates (5% and 20%) are used are 21 and 108. This suggests that enough samples have been collected to confirm the finding that the site arsenic concentrations in the Obispo formation are close enough to background concentrations. The p-value for the test of the difference between site and background concentrations in the Obispo formation is 0.32, suggesting that the site and background concentrations are similar. This DQA confirms that there are enough samples to support this conclusion.

Note that if the two outliers are included, then the background mean concentration is 19.5 mg/kg, which is much larger than the site mean concentration of 7.4 mg/kg, in which case DQA is not necessary, and the conclusion that site concentrations are no greater than background concentrations is appropriate.

4.0 RESULTS

The sample size results determined in this DQA process are presented for risk-significant chemicals and corresponding pathways and receptors for each exposure area. The desired sample sizes are presented as a single value, which is based on the performance criteria that were determined acceptable by SLO County EHS. These correspond to a Type I error of 5%, Type II error of 20%, and a MDD equal to 20% of the RBC. In other words, there is a 5% probability that no further action will be taken at a contaminated site and a 20% probability that a clean site will be remediated. Table 7 summarizes the DQA results for soil and Table 8 presents the DQA results for the soil gas data, which are presented separately for 5 and 15 ft data. As requested by SLO County EHS, sample size results in Tables 7 and 8 are identified with a check mark if the sample size is sufficient based on the USEPA default performance criteria. Results that do not meet these criteria, which are referred to as the default USEPA criteria, are summarized below by exposure area and detailed in Attachment 2. Additionally, when soil results did not meet the sample size criteria, quantile-quantile plots (Q-Q plots) were constructed to determine if the effect could be explained by sample distribution, and whether

the majority of concentrations are below or above the risk-based threshold. The Q-Q plots are included as Attachment 3.

Area D:

- *Lead in soil*: The Final HHRA sample size of 25 does not meet the default USEPA criteria. The Final HHRA sample also does not meet any of the acceptance criteria calculated in the sensitivity analysis (falls below the range of 38 to 822 samples). The wide range of desired sample sizes is due to one elevated concentration above the threshold level of 320 mg/kg, while the other results consist of a well-defined population below the RBC.
- *Ethylbenzene in soil gas*: Potential indoor air health risk estimates are based on four samples collected from 15-ft soil gas samples in Area D. This sample size does not meet the default USEPA criteria for the 10^{-6} cancer risk threshold, although it falls at the low end of the sample size range of 2 to 29. The 5-ft soil gas sample size is sufficient to meet the USEPA criteria.

Area E:

- *Benzene in soil gas:* Potential indoor air health risk estimates were based on eight 15-ft soil gas samples in Area E. These samples do not meet the default USEPA criteria for the 10^{-6} cancer risk threshold. Additionally, the seven 5-ft soil gas samples are not sufficient to meet the default USEPA criteria for the 10^{-6} cancer risk threshold.

Area Ia:

- *Lead in soil:* The Final HHRA sample size of 22 does not meet the default USEPA criteria, although falls towards the low end of the calculated sample size range of 20 to 428. The wide range of desired sample sizes is due to one elevated concentration above the threshold level of 320 mg/kg, while the other results consist of a well-defined population below the RBC.
- *Chloroform in soil gas:* Potential indoor air health risk estimates were based on three 15-ft soil gas samples in Area Ia. These samples do not meet the default USEPA criteria for the 10^{-6} cancer risk threshold, but fall between the calculated sample size range of 2 to 24. The three 5-ft soil gas samples are sufficient to meet default USEPA criteria for the 10^{-6} risk threshold.

Area Ib:

- *Chloroform in soil gas:* Potential indoor air health risk estimates are based on four 15-ft soil gas samples in Area Ib. These samples are not sufficient to meet the default USEPA criteria for the 10^{-6} cancer risk threshold, or the noncancer threshold of 1.0. The 5-ft soil

gas sample size does not meet USEPA criteria for the 10^{-6} cancer risk threshold, however it equals the low end of the range of 4 to 74 samples.

Area J:

- *Chloroform in soil gas:* Potential indoor air health risk estimates are based on eleven 15-ft soil gas samples. These samples are not sufficient to meet the default USEPA criteria for 10^{-6} cancer risk threshold. The ten 5-ft soil gas samples also are not sufficient to meet the default USEPA criteria.

Area K:

- *Chloroform in soil gas:* Potential indoor air health risk estimates are based on nine 15-ft soil gas samples, which do not meet the default USEPA criteria for the 10^{-6} cancer risk thresholds. However, the three 5-ft soil gas samples are sufficient to meet default USEPA criteria for 10^{-6} risk goal.

Area M:

- *Benzene in soil gas:* Since the potential indoor air health risk estimates are based on a single sample collected from 15-ft, the data variability could not be estimated; therefore a desired sample size could not be calculated. However, the six 5-ft soil gas samples are sufficient to meet the default USEPA criteria for the 10^{-6} risk goal.

Open Space:

- *Dibenz(a,h)anthracene in soil:* The Final HHRA sample size of 23 for the 0 to 2 ft soil horizon does not meet the USEPA default criteria for the 10^{-6} risk goal for recreational users in Open Space, however this sample size does fall within the calculated range of 11 to 228 samples. The wide range of desired sample sizes is due to one elevated detected concentration and two elevated non-detected values above the threshold level of 0.15 mg/kg, while the other results consist of a well-defined population below the RBC.
- *Benzene in soil:* Benzene in soil is a risk-driver for recreational users in Open Space for evaluation of the 0 to 10 ft soil horizon, although it is not likely for recreators to be exposed to soil at depths below 2 ft. The 91 soil samples collected in this area do not meet the default USEPA criteria for the 10^{-6} risk goal, although this sample size falls within the calculated range of 47 to 1021 samples. The large number of desired sample sizes is due to three elevated detects (approximately 3% of all the samples) above the threshold level of 1.1 mg/kg, while the other results consist of a well-defined population below the RBC.

Site-Wide:

- *2,4-Dinitrotoluene in soil:* The Final HHRA sample size of five for 2,4-dinitrotoluene does not meet the USEPA default criteria for the 10^{-6} risk goal for recreational users in the no-development scenario. Additionally, this sample size of five falls below the calculated range of 8 to 153 samples.

5.0 CONCLUSIONS

As requested by SLO County EHS, this quantitative DQA was focused on evaluating whether the data used in the Final HHRA were sufficient to make health protective risk-based decisions. The approach used USEPA DQO and DQA guidance to calculate the number of samples needed based on the Final HHRA data and the specified range of acceptable performance criteria. This quantitative DQA supplements the previous data quality evaluations that have been conducted for the Site, including the *Data Validation and Data Usability Report* and the qualitative DQOs and DQA that were initially used. The results presented in this report are limited to the Vision Plan presented in the Final HHRA. If exposure area boundaries or land uses are modified, the data sufficiency for that specific area will need to be reevaluated.

One of the main limitations of this evaluation is the disconnect between USEPA guidance for the classical approach to DQA and that for human health risk assessment. This DQA evaluates whether or not the data are sufficient to determine if the sample mean is below the specified risk-based goal, while health risks for some scenarios in the Final HHRA (e.g. intrusive utility worker and soil gas) were calculated using the maximum detected concentration. Although the maximum concentration is a much less stable measurement than the mean, the use of the maximum to estimate risk in the Final HHRA is common practice and health protective.

Generally, depth horizons of the data used in the Final HHRA and in this DQA are consistent. For most exposure areas, soil risks in the risk assessment are based on the greater of the EPCs (maximum or UCL, as appropriate) calculated for the 0-2 and 0-10 ft depth horizons. Since all of the data collected from the upper 10 ft plays a role in the risk-based decision making process, the soil samples from the entire 0 to 10 ft soil horizon were used to evaluate data sufficiency in this DQA. Consistent with the data used to estimate risks in the Final HHRA, the DQA for the produce pathway is based on soil samples collected from 0-5 ft in the Native Gardens. Also, the DQA sample size calculations for the offsite resident, who is potentially exposed to COPCs in outdoor air in the no development scenario, and the recreational user are based on soil samples collected from 0-2 ft across the Site. The soil gas risks in the risk assessment are based on the greater of the indoor air EPCs that result from the 5 and 15 ft soil gas data. Since there is considerable variability between the 5 and 15 ft soil gas data, the DQA evaluated the 5 and 15 ft

data separately. As discussed in the Final HHRA (see Section 7.4.3.7), indoor air concentrations are generally much lower based on 5-ft samples, suggesting that natural attenuation is occurring.

Overall, the results of this DQA show that the soil and soil gas sampling designs accomplished the sampling objectives to support defensible risk management decisions. Table 9 provides a comprehensive summary of the DQA results for cancer and noncancer risk drivers for each receptor evaluated in the Final HHRA. As requested by SLO County EHS, sample size results in Table 9 are highlighted with orange text when specific performance criteria within the range are not met (α=5%, β=20%, MDD=20%); these alpha and beta values are consistent with the default USEPA criteria (USEPA 2006a,b).

5.1 Soil Risk-Significant Chemicals

The following risk-significant chemicals in soil do not meet the default USEPA criteria, however the respective sample sizes fall within the sample size ranges calculated during the sensitivity analysis:

- Benzene – Open Space
- Dibenz(a,h)anthracene – Open Space
- Lead – Area Ia

The following risk-significant chemicals in soil do not meet the default USEPA criteria, nor do they fall within the desired sample size ranges calculated during the sensitivity analysis:

- Lead - Area D
- 2,4-dinitrotoluene - Site-wide no development scenario

The Q-Q plots of dibenz(a,h)anthracene in Open Space, and lead in Areas D and Ia show that the data are below the risk-based thresholds, with the exception of one outlying detection in each instance. The outlying concentrations in each instance were detected in the upper 1 ft of soil in areas near the former pump house and refinery, where there is a high density of soil sampling. Similarly, the Q-Q plot for benzene in Open Space shows that the data are below the RBC, with the exception of three detects from samples collected at depths of 5 and 10 ft. Two of the three benzene detects were found in the same borehole (BH-230 at 5 and 10 ft bgs), and this sample location is bounded by six nearby soil samples (see Figure 1-7 in the Final HHRA). The third elevated benzene concentration is located in Open Space near the former pump house in a petroleum-impacted area that has been well characterized through historic sampling events. Because the majority of benzene data show little variability below the RBC, and the areas surrounding the elevated benzene concentrations have been well characterized, there is evidence suggesting sufficient data have been collected for this risk driver.

The SVOC 2,4-dinitrotoluene is a risk driver for the Site-wide recreational user based on an evaluation of the 0-10 ft soil horizon, as opposed to the more likely shallow soil exposure scenario (0-2 ft). Only five samples were analyzed for 2,4-dinitrotoluene, because it was included in the analyte list for select samples in the November 2011 soil sampling event. The single detection is a concentration estimated to be below the reporting limit of 1 mg/kg, and is located in Exposure Area E. This was not previously analyzed in other samples, because it is not a chemical typically associated with petroleum-related activities at the Site.

Overall, the results of this DQA show that the soil sampling designs accomplished the objective of collecting data to conduct a risk assessment and support defensible risk management decisions. Several risk drivers with sample sizes that do not meet the USEPA default criteria are summarized above, and any issues related to insufficient samples sizes will be addressed in the Pre-Feasibility and/or Feasibility Study.

5.2 Soil Gas Risk-Significant Chemicals

In the Final HHRA, worst-case indoor air concentrations were derived from the maximum 5- or 15-ft soil gas concentrations that resulted in the highest indoor air concentrations. In most cases, the maximum indoor air concentration resulted from the 15-ft soil gas data. As discussed in the Final HHRA (see Section 7.4.3.7), indoor air concentrations are generally much lower if based on 5-ft samples, suggesting that natural attenuation is occurring. The sufficiency of the 5-ft soil gas data was also evaluated for exposure areas where the Final HHRA indoor air risks are based on 15-ft soil gas data. Table 8 summarizes the DQA results for the 5- and 15-ft soil gas data, and indicates the depth that resulted in the worst-case indoor air concentration used in the Final HHRA.

The following risk-significant chemicals in soil gas do not meet the default USEPA criteria for either the 10^{-6} or the 10^{-5} cancer risk threshold:

- Area D: ethylbenzene (15 ft; data are sufficient for 5-ft soil gas)
- Area E: benzene (5 and 15 ft)
- Area Ia: chloroform (15 ft; data are sufficient for 5-ft soil gas)
- Area Ib: chloroform (5 and 15 foot)
- Area J: chloroform (5 and 15 foot)
- Area K: chloroform (15 foot; data are sufficient for 5-ft soil gas)

To be health protective, the Final HHRA used the maximum estimated indoor air vapor concentrations resulting from *either* the 5- or 15-ft soil gas result, despite the observation of substantial attenuation with depth. Because both depths were considered in the HHRA to

support risk management decisions, it is important to note that there are sufficient samples for 5-ft soil gas in Areas D, Ia, and K.

In summary, the results of this DQA show that the soil gas sampling designs accomplished the objective of collecting data to conduct a risk assessment and support defensible risk management decisions. Areas and depth horizons with insufficient data will be addressed as part of the Pre-Feasibility and/or Feasibility Study. Either remedial action will be required or discussions with the agencies will be needed in order to support a decision of *no further action*.

5.3 Arsenic Background Screen

In addition to the DQA for risk-significant chemicals evaluated in the Final HHRA, an additional evaluation was completed to determine whether there are sufficient samples to support the arsenic background evaluation conclusion that onsite arsenic concentrations are consistent with background. The results presented in Section 3 confirmed there are enough arsenic samples to support this conclusion.

Dermal = Direct contact via dermal exposure to soil

Ing = Direct contact via ingestion of soil

InhP = Inhalation of soil-associated particulates in outdoor air

InhV = Inhalation of vapors in indoor air, as modeled from soil gas

Ing - Produce = Ingestion of produce grown onsite in the Native Gardens

Table 2
Rational for Exclusion of Elevated Reporting Limits

Exposure Area	Chemical	Media	Excluded Reporting Limits	Rationale
M	Benzene	Soil Gas (15 feet)	0.26 ug/L	Excluded RL from SV-04-15 sampled on 7/18/2007 is greater than maximum detect (0.18 ug/L); 2 orders of magnitude greater than all other RL's (0.0041 ug/L)
D	Benzo(a)pyrene	Soil	4, 20 mg/kg	Excluded RL's from B-158-1 and B-158-4.5 sampled on 7/1/1999 are 2 orders of magnitude greater than maximum detect (0.084 mg/kg); 2-4 orders of magnitude greater than other RL's (0.005-0.05 mg/kg)
L	Benzo(a)pyrene	Soil	20 mg/kg	Excluded RL from B-196-5 sampled on 7/1/1999 is 2 orders of magnitude greater than the maximum BaP TEQ result of 0.2 mg/kg; 1-4 orders of magnitude greater than other reporting limits (0.001 to 1 mg/kg)

RL = Reporting Limit

[1]RBCs (Risk-based Concentrations) are derived using sHHRA methodology except for lead. Units are mg/kg for soil, µg/L for soil gas and mg/L for groundwater

[2]Samples with elevated reporting limits were removed from dataset. See Table 2 for a complete list of excluded reporting limits and rationale.

[3]Meets USEPA default criteria and assumptions specified by SLO County EHS: alpha = 5%, beta = 20%, MDD = 20%

CHHSL =California Human Health Screening Level for lead (Cal/EPA 2009)

Notes:

[1]ILCR is the incremental probability of an individual developing cancer over a lifetime as a result of exposure to the potential carcinogen; cancer risk is age-weighted and assumes 6 years of exposure as a child and 24 years as an adult, therefore risk is reported for adult and not applicable (NA) to child receptors; 2E-07 = 0.0000002 = two in ten million.

[2]The shaded boxes in the DQA summary indicate that a more conservative receptor was evaluated in the DQA.

[3]Orange text indicates sample size does not meet USEPA acceptable performance criteria (alpha= 5%, beta= 20%, MDD=20%) for corresponding RBC .

[4]Risk and hazard drivers identified are the chemicals of potential concern (COPCs) accounting for the greatest percentage(s) of the total risk or hazard. For example, for residents in Exposure Area A, exposure to BaP TEQ in soil account for 21% of the total risk and 1,3-butadiene in soil gas (via inhalation of indoor air) accounts for 18% of the total risk. The chemical(s) accounting for at least 40% of the total risk or hazard are identified.

[5]Results for soil presented in mg/kg; for soil gas in ug/L

[6]HI is the noncancer hazard index.

CHHSL = California Human Health Screening Level. The HHRA compared area-specific exposure point concentrations to the residential or commercial CHHSL, as appropriate. As shown in Attachment 13 of the HHRA, the commercial CHHSL for lead in soil (320 mg/kg) is protective of short-term residents.

IUW = Intrusive utility worker

NE = Not evaluated; cannot calculate standard deviation for sample size of one.

1.0 INTRODUCTION

On behalf of Chevron Inc., this report documents the chemical of potential concern (COPC) selection process for metals at the Avila Tank Farm Property (the Site). As requested by San Luis Obispo County Environmental Health Services (SLO County EHS), the August 2008 version of this report compared onsite and background metal concentrations for each individual exposure area at the Site. SLO County EHS and Neptune and Company, Inc. (N&C) commented that the "background comparison tests should be performed first by geology and then by evaluation area if necessary" (N&C, 2008). When multiple geologies are present, background comparison tests may be confounded by the effect of geology on metal concentrations. As described in a June 2009 memorandum to N&C, this revised analysis of background metals includes background comparison tests by geology (McDaniel Lambert, 2009a). The process for the metal COPC selection process includes multiple lines of evidence as summarized below:

Site-wide one-tenth residential CHHSL screen – As recommended by SLO County Health, the maximum site-wide concentration is compared to one-tenth of the residential California Human Health Screening Level (CHHSL). If the maximum site-wide concentration exceeds one-tenth of the residential CHHSL, then the metal is further evaluated using background comparison tests.

Site-wide background comparison tests by geology – N&C commented that the statistical background comparisons should take into account the influence of multiple geologies at the Site (N&C 2008), particularly given the correlations between the Obispo formation and arsenic concentrations established in previous background evaluations for this Site (Avocet 2004, McDaniel Lambert 2008). Background comparison tests are conducted by geology according to the "Gilbert Toolbox" approach, as recommended by N&C (N&C 2008). The Gilbert Toolbox consists of four statistical hypothesis tests: the parametric t-test, non-parametric Wilcoxon Rank Sum/Gehan, quantile and slippage tests.

Spatial intensity plots – Graphical displays of the data using spatial intensity plots may reveal potential source areas of a metal when the statistical tests do not show evidence of elevated concentrations. If the spatial plots show evidence of systematic contamination in specific exposure areas, statistical comparisons will be conducted for individual exposure areas as necessary.

Influence of site geology – Avocet (2004) and England & Associates (1998) have conducted extensive investigations of the Site geology. A striking attribute of the local geology is the Obispo Formation, which is visible at the surface and along the cliffs of the Site. Avocet's background metals evaluation indicates that some metals may occur preferentially in the Obispo Formation, especially arsenic (Avocet 2004). Electron probe microanalysis established a geogenic source for elevated arsenic concentrations found in the onsite Obispo formation at depth; this provides an additional line of evidence in the background evaluation for arsenic.

The statistical methods for the background comparison tests by geology were further clarified in a memorandum to N&C on July 15, 2009 (McDaniel Lambert 2009b). In order to compare the site-wide and background data sets by geologic unit, N&C recommended that statistical evidence be used to justify whether or not (1) Obispo-related and Pismo-related geologies can be grouped together, and (2) onsite data at depth (>10 feet below ground surface, or bgs) can be used to expand the background data set if necessary. As detailed in the July memorandum, there is statistical evidence that Obispo-related and Pismo-related geologies can be grouped together for arsenic (McDaniel Lambert, Inc. 2009b). Also, it is reasonable to expand the area background data for arsenic using onsite Obispo-related samples at depth (McDaniel Lambert, Inc 2009b). N&C agreed that the statistical evidence presented in the July 2009 memorandum indicates arsenic is not elevated above background levels. The results for arsenic using the agreed upon approach, as well as for the other CAM 17 metals, are presented in this report.

2.0 METHODS

A state-certified laboratory analyzed background and site samples from soil and bedrock soil for 19 California Assessment Manual (CAM) metals; 17 of which were collected in the 0-10 ft soil horizon. Since the last background evaluation of metals at the Site (Avocet, 2004), additional sampling has been conducted to provide an updated data set for COPC selection. The onsite data set includes 318 samples for each metal, except 431 samples for lead. The background data set consists of 17 samples for each metal. Utilizing the more recent CAM 17 metals data set, this background evaluation supports the metal COPC selection process for the sHHRA. Unlike the previous version of the metals background evaluation (McDaniel Lambert, Inc. 2008), this report identifies metal COPCs by geology on a site-wide basis. Then, the analysis is refined to specific exposure areas if evidence of systematic contamination is identified on the spatial plots.

2.1 Site-wide Residential CHHSL Screen

As recommended by SLO County EHS during the development of the metals background evaluation for the Avila Tank Farm version 1.1 of the sHHRA (McDaniel Lambert Inc., 2008), the first step in the metals COPC selection process is to compare the maximum site-wide metal concentration detected in the 0-10 foot soil horizon onsite with one-tenth of the residential CHHSL. Metals that have a maximum site-wide concentration below one-tenth of the residential CHHSL are assumed not to pose a human health risk, and therefore are not carried forward as COPCs. Metals for which the maximum detected concentration exceeds one-tenth of the CHHSL are retained for background comparison tests by geology. Metals without an appropriate CHHSL (i.e. total chromium) are also retained for background comparison tests by geology.

2.2 Site-wide Background Comparison Tests by Geology

2.2.1 Geologic Units

Before conducting background comparison tests between site-wide and background data sets, the data is pooled according to similar geology. The Site is directly underlain by bedrock and unconsolidated sediments. At the time of sample collection, each sample was identified as either soil or rock, and as to the likely geogenic source – Pismo or Obispo Formation (Avocet 2004). A small number of soil samples were also identified as containing an asphaltic component. The following descriptions of the geologic units are based on reports by England & Associates (1998) and Avocet (2004).

Miocene Obispo Formation: The older of the two bedrock units, the Obispo Formation, consists of pyroclastic materials and has been subject to considerable faulting, folding and other deformation processes; it outcrops primarily along the south, east and northwest margins. The following three geologic units in the site-wide data are associated with the Obispo Formation:

1. *Obispo* – Obispo Formation
2. *Soil-O* – Soil collected above the Obispo Formation
3. *Asph/Soil-O* – Soil collected above the Obispo Formation that contains a significant asphaltic component.

Pliocene Gragg Member of the Pismo Formation: The Gragg Member unconformably overlies the Obispo Formation; it consists of a basal conglomerate, which grades upward into a poorly bedded, locally diatomaceous, fine-grained silty sandstone and siltstone. The central portion of the Site is underlain by bedrock of the Gragg Member. Similar to the Obispo Formation, the following three geologic units in the site-wide data are associated with the Gragg Member:

1. *Pismo* – Gragg Member of the Pismo Formation
2. *Soil-P* – Soil collected above the Gragg Member
3. *Asph/Soil-P* – Soil collected above the Gragg Member that contains a significant asphaltic component.

Unconsolidated Sediment: Three additional geologic units associated with unconsolidated surficial sediments are described in the site-wide data set. Samples collected from these geologic units represent a small percentage of the total site-wide data set, and are typically confined to one exposure area.

1. *Colluvium* – Colluvium is an admixture of gravel, sand, silt, and clay that forms at the base of slopes, and typically reflects the adjacent geology. Colluvium fills the north-south and east-

west drainages in the central part of the Site. Three colluvium samples at the Site were analyzed for metals, all of which are located in Exposure Area M.

2. *Alluvium* – Unconsolidated alluvium occurs in the northeast corner of the Site where the floodplain of the San Luis Obispo Creek encroaches upon the Site. There are six alluvium samples at the Site that were analyzed for metals, all of which are located in Exposure Area N.
3. *Artificial Fill* – Artificial fill is found in the northwest corner of the Site near the Front Street Gate, where the artificial fill was used as backfill to reconstruct part of the slope in 1984. The source of this fill is unknown. There are a total of nine artificial samples at the Site, which were all collected from Open Space, except for one in Exposure Area I.

Background samples were collected from the Pismo and Obispo Formation, specifically from four of the geologic units described above: *Pismo, Soil-P, Obispo* and *Soil-O*. To conduct the background comparison tests, it is necessary to pool the site-wide and background data according to the two bedrock units – Obispo and Pismo Formations. It is reasonable to assume that *Obispo, Soil-O,* and *Asph/Soil-O* are similar, because they are derived from the same Obispo Formation; and the same assumption can be made for the Pismo Formation geologic units. At the request of N&C, statistical evidence is also presented for each metal to justify pooling data that are associated with the same bedrock unit (see Section 3.2). To test whether metal concentrations are similar between the three Pismo-related geologic units or between the three Obispo-related geologic units, two multisample hypothesis tests are performed: a parametric and a nonparametric analysis of variance.

Single-factor Analysis of Variance (ANOVA): The single-factor ANOVA tests whether the mean metal concentrations are equal across all of the sample groups. Although identical sample sizes are not required for this test, the power of the test is increased by having similar sample sizes. The ANOVA test is fairly robust to deviations from normality, especially as sample size increases. It is assumed that the population variances are equal. If there are severe deviations from the underlying assumptions, then a nonparametric procedure like the Kruskal-Wallis test is more appropriate.

Kruskal-Wallis: The Kruskal-Wallis single-factor ANOVA by ranks may be used in any situation where the parametric single-factor ANOVA is applicable, but the underlying assumptions of normality and equal variances are not met. The test assumes that the sampled populations have the same dispersions and shapes, but is little affected if this is not the case.

The p-values from the analysis of variance tests are compared to a significance level of 0.05. If the p-value exceeds 0.05, then there is statistical evidence supporting that the similar geologic units can be pooled together. Along with these statistical tests exploratory data analysis (EDA), in the form of descriptive statistics, box-plots and normal quantile plots, is also used to examine the relationship between geologic units (see Attachments 1 and 2). If the metal concentrations in the three data sets

differ, then pooling the data may not be appropriate. The statistical and graphical evidence are weighed along with metal-specific source information. Given the small sample size for soils with an asphaltic component, the potential association between trace metals and petroleum production is taken into consideration. Elevated concentrations of antimony, magnesium, nickel, and vanadium have been associated with the asphaltic fraction of crude petroleum (Abu-Elgheit, 1981). A weight-of-evidence argument is presented for each metal to determine the appropriate pooling of data by geology.

2.2.2 Statistical Hypothesis Tests

Once the data are pooled by geology, exploratory data analysis (EDA) is first conducted to gain an understanding of the data and any potential differences between site and background data. The EDA includes descriptive statistics, normal quantile plots, and box-and-whisker plots. The descriptive statistics consist of separate summaries for non-detected and detected values; this allows for a cleaner interpretation of the data. A set of four two-sample statistical hypothesis tests, known as the Gilbert Toolbox, are run concurrently to determine if site concentrations are similar to or greater than background concentrations: the t-test, Wilcoxon Rank Sum, quantile, and slippage tests. The parametric t-test and the nonparametric Wilcoxon Rank Sum statistical analyses compare the central tendencies, while the quantile and slippage tests compare the right tails of the distributions. These four tests are performed in conjunction with EDA, and if any one of the tests is statistically significant, then the metal is considered to be elevated above background levels.

t-test: The two-sample t-test performs a parametric test for a difference between two population means. This test assumes that the two populations are independent and approximately normally distributed or the sample sizes are large (at least 30 samples). If these assumptions are violated, then the non-parametric Wilcoxon Rank Sum test is an appropriate alternative. The t-test is robust to moderate deviations from normality, but sensitive to outliers in the data sets. For these background comparisons, half the detection limit is substituted for non-detect values.

Wilcoxon Rank Sum (WRS)/Gehan test: The WRS test performs a nonparametric test for a difference between two population medians, which relies on the relative ranks of data values. Although the two populations are not assumed to be normally distributed, the distributions are assumed to be similar. The test statistic is computed using the Gehan approach, which accounts for non-detects in the data set. If there are many tied data values (or many non-detects), the WRS test results may be misleading. If there are no non-detects, the Gehan test defaults to the Wilcoxon Rank Sum Test.

Quantile Test: The quantile test performs a test for a difference between the right-tails of two distributions by evaluating if the values in the right-tail of the site distribution are larger than the desired quantile percentage of the background data. The quantile value for these background

comparisons is 0.75. It is assumed that the two populations have similar dispersions and shapes. If the percentage of non-detects is large, then the test cannot be performed.

Slippage test: The slippage test performs a test for a difference between the right-tails of two distributions by evaluating if there are values in the site distribution greater than the maximum value of the background distribution. In comparing extreme tails of the two distributions, large outliers can dramatically affect the results.

These tests are performed separately for Obispo-related and Pismo-related geologies. The unconsolidated sediments at the Site account for only 5% of the site-wide data, therefore they are not subject to statistical hypothesis tests; but rather discussed qualitatively. A p-value is reported for each statistical hypothesis test to determine statistical significance of the result. The reported p-value is compared to the desired significance level, which is determined by assessing the consequences if a decision error is made. There is statistical evidence that site concentrations are elevated relative to background if the reported p-value is less than the desired significance level (typically 0.5). As recommended by Neptune and Company, each comparison test is compared to a significance level of 0.025 to provide an approximate family-wise error rate of 0.05 (email communication, Paul Black, June 28, 2008). Because setting a significance level is somewhat subjective, p-values should not be strictly interpreted. A p-value much smaller than 0.025 indicates that site concentrations are elevated relative to background, while a p-value close to 0.025 may indicate there is insufficient data. If the p-value approaches unity, there is reason to suspect that the background data does not correspond to the site data.

2.2.3 Other Considerations

2.2.3.1 Background Sample Size

The background data set consists of 19 soil samples collected from 11 off-site locations; 17 of which were collected in the top 10 feet below ground surface (bgs). Of these 17 samples, 10 are Obispo-related samples and 7 are Pismo-related samples. Once the background data set is subdivided by geology, sample sizes may be too small to properly conduct the statistical hypothesis tests. If sample size issues become apparent in the EDA, then the background data set is expanded to include onsite samples at depth and offsite samples at depth. A specific example of this is arsenic – arsenic concentrations in the background data set do not correspond to naturally occurring arsenic concentrations observed in the Obispo Formation at the Site. To expand the background data set, 12 onsite Obispo-related samples collected at depth (15 to 180 ft bgs) and 2 offsite Obispo-related samples collected at depth (25 and 45 ft bgs) are added to the original background data set. The possibility of subsurface petroleum contamination near any of these sample locations at depth does not preclude the use of these deep samples as background, because arsenic is not a metal usually

associated with petroleum products (WHO 1989). In a study that assessed the occurrence and concentrations of trace metals in crude oils, arsenic was found to be present in amounts ranging from less than 10 to 37 ppb (Stigter 2000). Based on the lack of arsenic sources at depth, samples below 10 feet bgs at the Site are considered to be representative of background levels for arsenic. To include the onsite Obispo-related samples at depth as background for metals that may be associated with TPH contamination (i.e. nickel, vanadium), the onsite sample locations at depth are examined for impacts from total petroleum hydrocarbon (TPH) contamination. If the expanded background data set is necessary for nickel and vanadium, TPH-impacted samples are excluded.

2.2.3.2 Depth Profile

Before adding the soil samples at depth to the background data set, statistical evidence is required to show that there is not a pattern in metal concentrations across depth. If deeper samples are associated with lower/higher concentrations, then adding deeper samples to the background data set will bias the background comparison test. Regression models are used to test whether or not there is an association between depth and metal concentration. This depth analysis is used for any metal that requires the expanded background data set.

2.2.3.3 Non-detects

For purposes of the graphical analyses and statistical hypothesis tests that require substitution (i.e. t-test), one-half of the detection limit is substituted for non-detect values. For some metals, the frequency of detection is too low to reasonably conduct the statistical hypothesis tests. In such cases, the metal is simply carried forward as a COPC.

2.3 Spatial Intensity Plots

To recognize the potential for systematic contamination, the data for each metal (0-10 ft bgs) are color-coded and plotted on the Site map (Figures 1 through 11). The data are divided into five groups, and color-coded green, blue, yellow, orange and red (in order of increasing concentrations). There are fewer than five groups if there are a large number of non-detects. At data points with multiple samples, the data point is color-coded according to the highest concentration detected. Each plot is examined for evidence of systematic metals contamination in specific exposure areas. If there is a cluster of higher concentrations (orange/red dots) that corresponds with a possible source area, the corresponding exposure area is compared to background data using the statistical hypothesis tests.

2.4 Influence of Site Geology

In addition to the statistical evidence presented in the form of the background comparison test results, a qualitative discussion of geology and its relevance to background levels is presented. This post-hoc

discussion of geology is most relevant to arsenic, for which geochemical analyses show is detected at levels up to 310 mg/kg in the Obispo Formation.

3.0 RESULTS

3.1 Site-wide Residential CHHSL Screen

The comparisons of maximum concentrations to one-tenth of the residential CHHSL are summarized in Table 1. The maximum concentrations of five metals are below one-tenth of the residential CHHSL: beryllium, cobalt, molybdenum, selenium, silver and zinc. Therefore statistical comparisons of site-wide concentrations by geology are necessary for antimony, arsenic, barium, cadmium, chromium, copper, lead, mercury, nickel, thallium and vanadium.

3.2 Additional Metal COPC Selection Steps

To account for multiple geologies at the Site, background comparisons for all metals are conducted initially by geology on a site-wide basis. Summary statistics for Site and background data are presented for each metal by geologic unit in Tables 2 and 3, respectively. The EDA plots that depict comparisons between onsite Obispo-related groups and between onsite Pismo-related groups are presented in Attachments 1 and 2. The associated analysis of variance test results are presented in Attachments 3 and 4. The EDA plots that compare site-wide with background data by geology are presented in Attachments 5 and 6, and the results of the background comparison tests are presented in Table 5. If background comparison tests are required for a specific exposure area, as identified by the spatial analysis, the summary statistics are presented in Table 6. For each metal with a maximum concentration above one-tenth of the CHHSL, the additional metal COPC selection steps include the following lines of evidence:

- Site-wide background comparison tests by geology
- Visual inspection of spatial intensity plots for areas with systematic contamination
- Exposure area background comparison tests by geology, where there is potentially systematic contamination as identified in the spatial analysis.

3.2.1 Antimony

3.2.1.1 Site-wide Background Comparison Tests

Antimony was not detected in background samples above the detection limit of 5 mg/kg. Antimony was detected in six of 318 total Site samples, with results ranging from 0.28 mg/kg to 46 mg/kg. Of these six detections, the maximum detect of 46 mg/kg is the only sample that exceeds 2 mg/kg. The statistical hypothesis tests cannot be reasonably conducted due to the low frequency of detection, therefore it should be included as a COPC in areas where it was detected.

3.2.1.2 Spatial Intensity Plot

Inspection of the antimony spatial intensity plot (Figure 1) reveals that low levels (< 2 mg/kg) are detected in a group of samples collected from the slope in the southwest corner of the Site. Five of the 6 detections occur on this slope area in Open Space and one occurs in Exposure Area D. The maximum detect of 46 mg/kg is Exposure Area D is surrounded by "green dots," representing the lowest range of non-detects (<9 mg/kg). Therefore, antimony should be included as a COPC in Exposure Area D and Open Space.

3.2.2 Arsenic

3.2.2.1 Site-wide Background Comparison Tests

Arsenic was detected in 91% of onsite Obispo-related samples and 78% of onsite Pismo-related samples. Arsenic was detected in all of the background samples. The EDA plots indicate arsenic concentrations are slightly higher in *Asph/Soil-O* than *Obispo* and *Soil-O*, and the Kruskal-Wallis test results confirm that arsenic in the Obispo-related geologic types may be from different populations (p-value = 0.035). However higher arsenic concentrations are not observed in *Asph/Soil-P* when compared to *Pismo* and *Soil-P*, suggesting that the asphaltic component does not confound the presence of arsenic. There is no reason to suspect that arsenic would occur preferentially in samples with an asphaltic component, because petroleum processing is not usually associated with arsenic contamination. For the background data, statistical hypothesis tests do not provide evidence that arsenic concentrations in *Obispo* are different than *Soil-O*, or that those in *Pismo* are different than *Soil-P*. Overall, statistical evidence supports that Obispo-related and Pismo-related samples can be pooled together.

For Obispo-related samples, the EDA plots show that the distribution of Site data is more similar to the expanded background data set than the original background data set. Because onsite data at depth and offsite data at depth are added to the background data set, regression analysis is used to determine whether or not there is a relationship between arsenic concentrations and depth. With

depth as a continuous variable, a linear regression model shows depth is not a predictor for arsenic concentrations (p=0.557) or log-transformed arsenic concentrations (p=0.554). Likewise, when depth is grouped by quartiles, a linear regression model shows no significant association between any of the depth categories and arsenic concentrations. As expected, due to the variable nature of the Obispo rock formation, the regression models do not show depth as a predictor for arsenic concentrations. This lack of association is further illustrated in the plots in Attachment 7 where depth (x-axis) is plotted against arsenic concentration (y-axis). Arsenic concentrations appear to be scattered randomly across depth.

Obispo Formation – With the expanded background data set, there is no evidence of elevated arsenic in the Obispo-related samples.

Pismo Formation – It is not necessary to expand the background data set for samples associated with the Pismo Formation, because the background and site data distributions are similar. There is no evidence of elevated arsenic concentrations in the Pismo-related samples.

Artificial fill - The maximum arsenic concentration in artificial fill is 9 mg/kg and the mean is 6.8 mg/kg. Arsenic in the artificial fill samples is not included as a COPC, because these samples were collected from a slope area in Open Space that is unlikely to be accessed frequently; therefore arsenic is not included as a COPC.

Unconsolidated Colluvium - Colluvium forms at the base of slopes, and typically reflects the adjacent geology. There are a total of 6 samples across the Site labeled as colluviums. The mean arsenic concentration is 1.3 mg/kg and the maximum is 1.6 mg/kg. These arsenic concentrations are considered to be nominal; therefore arsenic is not included as a COPC.

Unconsolidated Alluvium – Alluvium is deposited by flowing water, and may be transported a significant distance prior to deposition. There are only 3 samples across the Site labeled as alluvium. The mean arsenic concentration is 1.3 mg/kg and the maximum is 1.4 mg/kg. These arsenic concentrations are considered to be nominal; therefore arsenic is not included as a COPC.

3.2.2.2 Spatial Intensity Plot

The arsenic spatial plot (Figure 2) demonstrates that most of the higher arsenic concentrations (15 to 30 mg/kg and ≥ 30 mg/kg, shown in orange and red, respectively) are surrounded by lower arsenic concentrations, with the exception of a clustering of higher arsenic concentrations along the northwestern cliffs. Samples in this clustering are labeled as Obispo rock or soil derived, and are located near surface expressions of the Obispo formation. It is important to consider potential anthropogenic sources of arsenic, such as pesticides, that may have been used at the Site. The only

available information regarding historical weed management is a report by England & Associates (1998) that cites a 1982 weed abatement contract for the application of oil (also referred to as asphalt) to large portions of the property as a means of weed and erosion control. Analyses of pesticides in Site soils further support the limited use of pesticides; only one pesticide (gamma-BHC) was detected in one of 12 soil samples collected site-wide. Furthermore, arsenic is not a metal usually associated with petroleum products (WHO 1989). There is some evidence of arsenic being present in crude oil in the parts-per-billion range (Stigter 2000), which is nominal compared to the minimum background concentration in Obispo. The absence of operational practices using arsenic makes it difficult to attribute the arsenic detected along the northwestern cliffside to anthropogenic sources; therefore this subarea of the Site is not further evaluated with background comparison tests.

3.2.2.3 Influence of Site Geology

The three highest arsenic soil concentrations found at any depth onsite (110, 220, and 310 mg/kg) were obtained from a boring in the Obispo formation (B-76, B-76A) at depths of 15 to 25 feet. Because metals contamination rarely reaches substantial depth, it is unlikely that these concentrations are the result of anthropomorphic activities (Avocet, 2004). Electron probe analysis of sample B-76A indicates a geogenic source of one of the highest arsenic concentrations found in the onsite Obispo formation. This geochemical analysis supports the propensity for arsenic to occur naturally within the volcaniclastic rocks of the Obispo formation.

3.2.3 Barium

3.2.3.1 Site-wide Background Comparison Tests

Barium was detected in all Site and background samples. In the EDA, barium concentrations are higher in soil samples with an asphaltic component (*Asph/Soil-O* and *Asph/Soil-P*). The ANOVA and Kruskal-Wallis test results also provide statistical evidence that barium concentrations in Obispo-related geologic units are different (p-value < 0.001), and those in Pismo-related geologic units are different (p-value < 0.001). However, the high variability in the asphalt soil sample data sets makes it difficult to conclude that higher barium concentrations are representative of all soil samples with an asphaltic component. Barium is not a metal typically associated with petroleum products, therefore the asphalt soil samples are not excluded from the Obispo- and Pismo-related groups.

Obispo Formation – There is evidence that background concentrations are greater than site-wide concentrations. The p-values approach unity suggesting that the background data may not be representative of naturally occurring barium concentrations at the Site.

Pismo Formation – There is evidence that background concentrations are greater than site-wide concentrations. The p-values approach unity, suggesting that the background data may not be representative of naturally occurring barium concentrations at the Site.

Artificial Fill – With 9 samples total, barium concentrations in artificial fill range from 48 mg/kg to 210 mg/kg. The mean concentration (106 mg/kg) is less than the background mean for all samples (152 mg/kg).

Unconsolidated Colluvium - With 3 samples total, barium concentrations range from 64 mg/kg to 140 mg/kg. The mean concentration (96 mg/kg) is similar to the mean for onsite Obispo-related samples (90 mg/kg).

Unconsolidated Alluvium – With 6 samples total, barium concentrations range from 91 to 170 mg/kg. The mean concentration (128 mg/kg) is less than the background mean for all samples (152 mg/kg).

3.2.3.2 Spatial Intensity Plot

The spatial intensity plot of barium concentrations (Figure 3) shows a cluster of barium concentrations in Open Space on the slope in the southwest corner of the Site and between Exposure Areas I and M. Therefore, statistical hypothesis tests are used to compare the Open Space and background data according to geology.

Open Space Background Comparisons – Both Obispo and Pismo geologies are prevalent in Open Space. With p-values well above the significance level, there is no statistical evidence to support that Open Space concentrations are elevated above background.

3.2.4 Cadmium

3.2.4.1 Site-wide Background Comparison Tests

Cadmium has a low frequency of detection in onsite and background samples: cadmium was detected in 19% of onsite Obispo-related samples, 10% of onsite Pismo-related samples, 40% of background Obispo-related samples, and 14% of background Pismo-related samples. Statistical hypothesis tests are not valid due to the low frequency of detection.

3.2.4.2 Spatial Intensity Plots

The spatial intensity plot for cadmium (Figure 4) provides evidence that there may be systematic contamination in Exposure Area D. Four of 20 samples in Area D detected cadmium, ranging from 2.3

mg/kg to 4.3 mg/kg. The frequency of detection is too low to conduct the statistical hypothesis tests for Exposure Area D. Cadmium should be included as a COPC in any exposure area that it is detected, including Exposure Area D.

3.2.5 Chromium

3.2.5.1 Site-wide Background Comparison Tests

Chromium was detected in all site and background samples. In the EDA, chromium in *Asph/Soil-O* appears higher than the other Obispo-related geologic units. This difference observed between Obispo-related groups is confirmed by the ANOVA and Kruskal-Wallis test results. Although the range for chromium concentrations in Soil-P is larger than the range for *Pismo* and *Asph/Soil-P*, chromium concentrations in all three of the Pismo-related geologic units generally appear very similar; there is also statistical evidence from the ANOVA and Kruskal-Wallis tests that chromium concentrations are similar between Pismo-related groups. Because chromium is not a metal typically associated with the asphaltic fraction of crude oil, the asphaltic soil samples are not excluded from the geology groups.

Onsite data at depth and offsite data at depth are added to the Obispo-related background data set, because the p-value results suggest there may be insufficient data to make a defensible conclusion. Because data at depth is being added to background, regression analysis is used to determine whether or not there is a relationship between chromium concentrations and depth. With depth as a continuous variable, a linear regression model shows depth is not a predictor for chromium concentrations (p=0.64) or log-transformed chromium concentrations (p=0.15). Graphs of chromium verse depth also depict the lack of association (Attachment 7).

Obispo Formation – Chromium concentrations appear to be elevated onsite using the original offsite background data. The results of the statistical hypothesis tests suggest that there may be insufficient data to conclude whether or not onsite concentrations are elevated. When the expanded background data set is compared to the onsite Obispo-related samples, the statistically hypothesis tests show that the onsite median is higher than the background median. Therefore, the statistical evidence supports that chromium is elevated above background in exposure areas with Obispo Formation present.

Pismo Formation – In the EDA, site and background concentrations do not appear to be different. This is confirmed by the statistical hypothesis tests, which provide evidence that chromium concentrations are not elevated in Pismo-related samples.

Artificial Fill – With 9 samples, chromium concentrations range from 18 mg/kg to 49 mg/kg. The maximum concentration does not exceed the background maximum detect of 69 mg/kg.

Unconsolidated Colluvium – With 3 samples, chromium concentrations range from 13 to 15 mg/kg; these are representative of onsite mean concentrations for Pismo-related samples, which were not found to be elevated above background.

Unconsolidated Alluvium – With 6 samples, chromium concentrations range from 6.7 to 13 mg/kg; these are also representative of onsite mean concentrations for Pismo-related samples, which were not found to be elevated above background.

3.2.6.2 Spatial Intensity Plots

Although the Pismo samples are not elevated across the site, inspection of the spatial intensity plot for chromium (Figure 5) reveals that there may be systematic contamination in Exposure Areas D, E, and Open Space. Therefore Pismo-related samples in these areas are compared to background with the statistical hypothesis tests.

Exposure Area D Background Comparisons – Exposure Area D consists only of Pismo-related samples. With 20 out of 20 detected values, there is no statistical evidence that concentrations are elevated above background.

Exposure Area E Background Comparisons – Exposure Area E consists only of Pismo-related samples. With 27 out of 27 detected values, there is no statistical evidence that concentrations are elevated above background.

Open Space Background Comparisons – Open Space consists of both Obispo-related and Pismo-related samples. Obispo-related samples are considered to be above background based on the site-wide comparison results presented above. With 79 out of 79 detected values, there is not statistical evidence that concentrations in Pismo-related samples are elevated about background. Because the statistical hypothesis tests for one of the two geologies are significant, chromium should be carried forward as a COPC in Open Space.

3.2.6 Copper

3.2.6.1 Site-wide Background Comparison Tests

Copper was detected in the majority of Site and background data. Copper concentrations in soil samples associated with asphalt appear to be elevated, but this is based on a limited number of *Asph/Soil-O* and *Asph/Soil-P* samples. The ANOVA and Kruskal-Wallis tests show statistical evidence that copper concentrations between Obispo-related groups and between Pismo-related groups are not

similar. Because copper is not typically associated with asphalt, the asphaltic samples are not excluded from the Obispo-related or Pismo-related groups.

Obispo Formation – Other than one extreme outlier in the Obispo-related data set (500 mg/kg), background concentrations do not appear to be elevated above background. This is confirmed by the statistical hypothesis tests that report p-values near one, suggesting that the background data set may not be representative of naturally occurring Site concentrations.

Pismo Formation – There is no statistical evidence that Site concentrations are elevated above background.

Artificial Fill – With 9 samples detected onsite, copper concentrations range from 4.5 mg/kg to 23 mg/kg. The mean concentration (16.8 mg/kg) is similar to the mean concentration for background Obispo-related concentrations (17.7 mg/g).

Unconsolidated Colluvium – With 3 samples detected onsite, copper concentrations range from 5.4 mg/kg to 9.7 mg/kg. The mean concentration (7.8 mg/kg) is much lower than the background mean concentrations for Obispo-related and Pismo-related concentrations combined (14.4 mg/kg).

Unconsolidated Alluvium – With 6 samples detected onsite, copper concentrations range from 9.4 mg/kg to 11 mg/kg; this range is much lower than Obispo-related or Pismo-related concentrations typically found onsite, which have been determined not to be elevated compared to background.

3.2.6.2 Spatial Intensity Plots

Although the statistical evidence supports that copper is not elevated across the Site when compared to background, inspection of the spatial intensity plot for copper (Figure 6) suggests there may be systematic contamination in Exposure Area D and Open Space. These areas are compared to background using the statistical hypothesis tests.

Exposure Area D Background Comparisons – Exposure Area D consists only of Pismo-related samples. With 20 out of 20 detected values, there is no statistical evidence that concentrations exceed background.

Open Space Background Comparisons – Open Space consists of Obispo-related and Pismo-related samples, which were tested separately. With 69 out of 71 detected values, there is no evidence that Obispo-related concentrations are elevated above background. With 78 out of 79 detected values, there is no evidence that Pismo-related concentrations are elevated above

background. Because the statistical hypothesis tests were not significant for either geology, copper should not be carried forward as a COPC.

3.2.7 Lead

3.2.7.1 Site-wide Background Comparison Tests

Lead was detected in the majority of Site and background samples. The ANOVA and Kruskal-Wallis tests provide statistical evidence that lead concentrations between Obispo groups and between Pismo groups are not similar. The EDA shows that lead concentrations are higher in *Soil-P*, which is likely a function of contamination; most of the *Soil-P* samples were collected from the central portion of the Site, coinciding with the known areas of lead contamination. Lead concentrations also appear to be elevated in asphaltic Obispo soil samples, but this difference is not as pronounced in asphaltic Pismo soil samples. Considering that lead is not consistently elevated in asphaltic soil samples and differences between groups are likely a result of site-related contamination, Obispo-related and Pismo-related geologies are grouped together for the statistical hypothesis tests.

Obispo Formation – There is statistical evidence that shows Site concentrations are elevated above background.

Pismo Formation – There is statistical evidence that Site concentrations are not elevated above background.

Artificial Fill – With 9 detected values onsite, concentrations range from 6.4 mg/kg to 24 mg/kg; this appears representative of background values which range from 2 mg/kg to 50 mg/kg.

Unconsolidated Colluvium – With 3 detected values onsite, concentrations range from 3 mg/kg to 6.2 mg/kg; this is much lower than the range of detected background values.

Unconsolidated Alluvium – With 6 detected values onsite, concentrations range from 2.7 mg/kg to 5.9 mg/kg; this is much lower than the range of detected background values.

3.2.7.2 Spatial Intensity Plots

Although the Pismo samples are not elevated across the site, inspection of the spatial intensity plot for lead (Figure 7) reveals that there may be systematic contamination in Exposure Areas D, I, J, L and Open Space. These areas are compared to background with the statistical comparison tests for the Pismo Formation.

Exposure Area D Background Comparisons – With 19 out of 20 samples detected, there is no statistical evidence that lead is elevated above background levels.

Exposure Area I Background Comparisons – With 25 out of 25 detected values, there is no statistical evidence that lead is above background.

Exposure Area J Background Comparisons – With 41 out of 41 detected values, there is no statistical evidence that lead is elevated above background levels.

Open Space Background Comparisons – There is no statistical evidence that lead in Pismo-related samples is elevated above background. There is statistical evidence that lead in Obispo-related samples exceeds background, which confirms the site-wide results that lead should be carried forward as a COPC in areas where the Obispo Formation is present.

3.2.8 Mercury

3.2.8.1 Site-wide Background Comparison Tests

Mercury has a low frequency of detection with 32% of onsite samples detected and 14% of background samples detected. The statistical hypothesis tests are not valid due to the low frequency of detection. Although there are a very large number of non-detects, the EDA and analysis of variance tests suggest concentration are not similar between Obispo and between Pismo groups. Mercury concentrations in asphaltic soil samples are considerably higher in both Obispo and Pismo groups. Mercury detection limits range from 0.02 mg/kg to 0.1 mg/kg for site data, and equal 0.1 for background data. Because there is only one sample detected in the background data set, comparison tests cannot be reasonably conducted, and mercury should be included as a COPC.

3.2.8.2 Spatial Intensity Plots

Inspection of the spatial intensity plot for mercury (Figure 8) reveals that higher concentrations of mercury appear to be clustered in Open Space on the slope in the southwest corner of the Site. The frequency of detection in the background data set is too low to allow for comparison tests. Mercury should be carried forward as a COPC in every exposure area that is detected, including Open Space.

3.2.9 Nickel

3.2.9.1 Site-wide Background Comparison Tests

Nickel was detected in the majority of Site and background samples. The EDA plots show that nickel may occur preferentially in soil samples with an asphaltic component, and considering the association between petroleum processing and nickel this observation cannot be considered anomalous. The

ANOVA and Kruskal-Wallis test results provide statistical evidence that nickel concentrations are not similar between Obispo and between Pismo groups. To prevent the effect of asphaltic material from impacting the Obispo and Pismo Formation comparisons, *Asph/Soil-O* and *Asph/Soil-P* are compared separately to background concentrations – the results are below.

Obispo Formation – There is no statistical evidence that Site concentrations exceed background concentrations. The p-values are near unity, indicating that the background data set may not be representative of naturally occurring Site concentrations.

Pismo Formation – There is no statistical evidence that Site concentrations exceed background concentrations.

Asph/Soil-O and Asph/Soil-P – These geologic types are limited to samples collected in the Open Space area. With 9 out of 9 detects, there is no statistical evidence that concentrations in *Asph/Soil-O* samples exceed background. With 4 out of 4 detects, there is no statistical evidence that concentrations in *Asph/Soil-P* samples exceed background. Therefore nickel should not be carried forward as a COPC in Open Space.

Artificial Fill –With 9 detected values in the Site data set, concentrations range from 10 mg/kg to 130 mg/kg; this is very similar to the range detected in the background data set (1.8 mg/kg to 130 mg/kg).

Unconsolidated Colluvium – With 3 detected values in the Site data set, concentrations range from 10 mg/kg to 13 mg/kg; this range is considerably lower than typically background values.

Unconsolidated Alluvium – With 6 detected values in the Site data set, concentrations range from 7.5 mg/kg to 15 mg/kg; this is much lower than typical background values.

3.2.10.2 Spatial Intensity Plots

The spatial intensity plot for nickel (Figure 9) indicates that there may be systematic contamination in Exposure Area D and Open Space. The concentrations in these exposure areas are compared to background using the statistical hypothesis tests.

Exposure Area D Background Comparisons – Exposure Area D consists only of Pismo-related samples. With 20 out of 20 detected values, there is no statistical evidence that site-wide concentrations are above background.

Open Space Background Comparisons – The Open Space exposure area consists of both Pismo-related and Obispo-related samples. With 71 out of 71 detected values for Obispo-related samples and 79 out of 79 detected values for Pismo-related samples, there is no statistical evidence for either geology that concentrations are above background.

3.2.10 Thallium

3.2.10.1 Site-wide Background Comparison Tests

Thallium has a low frequency of detection in both Site and background data sets: only 2% of onsite samples detected thallium and no background samples detected thallium. The statistical hypothesis tests are not valid due to the low frequency of detection.

3.2.11.2 Spatial Intensity Plots

The spatial intensity plot (Figure 10) shows that all seven thallium detections are located in Open Space, which are visually identified on the slope in the southwestern corner of the Site. To address the potential area of contamination, thallium should be evaluated in Open Space. However, the lack of detected values in the background data set prevents the statistical comparison tests from being reasonably performed. There are not enough detected values to conduct valid statistical hypothesis tests; therefore thallium should be carried forward as a COPC in Open Space.

3.2.11 Vanadium

3.2.11.1 Site-wide Background Comparison Tests

Vanadium was detected in all of the Site and background samples. The EDA plots show that vanadium may occur preferentially in soil samples with an asphaltic component; this is supported by the ANOVA and Kruskal-Wallis results that indicate vanadium concentrations are not similar between Obispo and between Pismo groups. Vanadium is also known to be associated with the asphaltic fraction of crude oil (Abu-Elgheit 1981). To prevent the effect of asphaltic material from impacting the Obispo and Pismo Formation comparisons, *Asph/Soil-O* and *Asph/Soil-P* are compared separately to background concentrations – the results are below.

Obispo Formation – There is no statistical evidence that Site concentrations exceed background concentrations.

Pismo Formation – There is statistical evidence that Site concentrations exceed background concentrations.

Asph/Soil-O and Asph/Soil-P – These geology types are limited to samples collected in Open Space. There is no statistical evidence that concentrations in *Asph/Soil-O* exceed background, but the t-test p-value indicates there may not be a large enough sample size to make a conclusion. There is statistical evidence that concentrations in *Asph/Soil-P* exceed background. Regardless, vanadium will be evaluated in Open Space as a COPC as a result of the site-wide statistical hypothesis tests for the Pismo Formation.

Artificial Fill –With 9 detected values in the Site data set, concentrations range from 14 mg/kg to 33 mg/kg. Eight out of 9 artificial fill samples were collected from Open Space, and one was collected from Exposure Area I. Thallium detected in artificial fill samples will be carried forward ito the sHHRA, because the Pismo Formation also occurs in Open Space and Exposure Area I.

Unconsolidated Colluvium – With 3 detected values in the Site data set, concentrations range from 19 mg/kg to 29 mg/kg. Thallium detected in colluvium will be carried forward into the sHHRA, because the Pismo Formation occurs in the same exposure areas as colluvium.

Unconsolidated Alluvium – With 6 detected values in the Site data set, concentrations range from 36 mg/kg to 48 mg/kg; this is higher than the range of background values (3.1 mg/kg to 35 mg/kg). Thallium detected in alluvium will be carried forward into the sHHRA, because the Pismo Formation occurs in the same exposure areas.

3.2.11.2 Spatial Intensity Plots

There does not appear to be systematic contamination, with the exception of Exposure Area D and Open Space. These areas identified on the spatial intensity plot for vanadium (Figure 11) coincide with known source areas – the former refinery area in Exposure Area D and a waste disposal area in Open Space. These areas are further evaluated by comparing the exposure area data sets to background.

Exposure Area D Background Comparisons – This area only consists of samples associated with the Pismo Formation, therefore vanadium will be carried forward as a COPC in this area as a result of the statistical hypothesis tests conducted specifically for the Pismo geology.

Open Space Background Comparisons – This area consists of samples associated with both the Obispo Formation and Pismo Formation. There is no statistical evidence that vanadium concentrations in the Obispo-related samples are above background, but vanadium should be carried forward as a COPC in Open Space based on the site-wide background comparison results for the Pismo Formation.

4.0 CONCLUSIONS

Multiple lines of evidence are used to support the metals COPC selection process, which takes into account the different geologies present at the Site and is summarized in Table 6. These include:

- Comparison to one-tenth of the residential CHHSL
- Site-wide background comparison tests by geology
- Visual inspection of spatial intensity plots for areas with systematic contamination
- Exposure area background comparison tests by geology, where there is potentially systematic contamination as identified in the spatial analysis.

In the first step of the COPC selection process that compares the maximum onsite metal concentration to one-tenth of the residential CHHSL, the following five metals are excluded as COPCs: beryllium, cobalt, molybdenum, selenium, silver and zinc.

Antimony, cadmium, mercury, and thallium have low frequencies of detection, which prevents the statistical hypothesis tests from reasonably being conducted. Due to the low frequency of detection, these metals should simply be carried forward as COPCs in areas where they are detected. Specifically, these metals should be included as COPCs for the following exposure areas:

- *Antimony* – Exposure Area D, Open Space, Site-wide
- *Beryllium* – Exposure Areas B, C, E, F, Ia, L, M, Open Space, Parking and Site-wide
- *Cadmium* – Exposure Areas A, C, D, E, F, Ia, Open Space, Parking, Native Gardens and Site-wide
- *Mercury* – All Exposure Areas except Exposure Area G
- *Thallium* – Open Space, Site-wide

Of the remaining seven metals, the statistical hypothesis tests collectively known as the Gilbert Toolbox provide statistical evidence that onsite metal concentrations are not elevated above background for arsenic, barium, copper, and nickel. Evaluation of spatial intensity plots and the associated exposure area-specific background comparison tests (as appropriate) supports the conclusion that these metals are not elevated above background.

Based on site-wide statistical hypothesis tests, three metals are elevated above background in at least one of the two dominant geologies onsite:

- *Obispo Formation* – Chromium and lead
- *Pismo Formation* – Vanadium

Because site-related activities associated with these metals are not limited to a specific geology, these metals should be carried forward as COPCs in every exposure area at the Site.

TABLES

Table 1. Comparison to one-tenth of the residential CHHSL (California Human Health Screening Level). Grey shading highlights metals with a maximum concentration below one-tenth of the residential CHHSL.

Metals	One-tenth of the Residential CHHSL (mg/kg)*	Site Wide Maximum Detection (mg/kg)	Max below 1/10th CHHSL?
Antimony	3	46	No
Arsenic	0.007	57	No
Barium	520	970	No
Beryllium	15	2	Yes
Cadmium	0.17	4.3	No
Chromium (total)	NA	140	NA
Cobalt	66	46	Yes
Copper	300	500	No
Lead	15	1600	No
Mercury	1.8	72	No
Molybdenum	38	37	Yes
Nickel	160	400	No
Selenium	38	0.5	Yes
Silver	38	0.19	Yes
Thallium	0.5	16	No
Vanadium	53	270	No
Zinc	2300	570	Yes

*CalEPA, 2005. Use of CHHSLs in the Evaluation of Contaminated Properties.

```
##Antimony
Sb.obispo.kw=kruskal.test(Sb.obispo)
> Sb.obispo.kw
Kruskal-Wallis rank sum test
data:  Sb.obispo
Kruskal-Wallis chi-squared = 22.5581, df = 2, p-value = 1.264e-05

> Sb.pismo.kw=kruskal.test(Sb.pismo)
> Sb.pismo.kw
Kruskal-Wallis rank sum test
data:  Sb.pismo
Kruskal-Wallis chi-squared = 1.106, df = 2, p-value = 0.5752

##Arsenic
> As.obispo.kw=kruskal.test(As.obispo)
> As.obispo.kw
data:  As.obispo
Kruskal-Wallis chi-squared = 6.6804, df = 2, p-value = 0.03543

> As.pismo.kw=kruskal.test(As.pismo)
> As.pismo.kw
data:  As.pismo
Kruskal-Wallis chi-squared = 7.8098, df = 2, p-value = 0.02014

##Barium
> Ba.obispo.kw=kruskal.test(Ba.obispo)
> Ba.obispo.kw

data:  Ba.obispo
Kruskal-Wallis chi-squared = 19.6936, df = 2, p-value = 5.292e-05

> Ba.pismo.kw=kruskal.test(Ba.pismo)
> Ba.pismo.kw
data:  Ba.pismo
Kruskal-Wallis chi-squared = 20.9819, df = 2, p-value = 2.779e-05

##Beryllium
> Be.obispo.kw=kruskal.test(Be.obispo)
> Be.obispo.kw
data:  Be.obispo
Kruskal-Wallis chi-squared = 2.9272, df = 2, p-value = 0.2314

> Be.pismo.kw=kruskal.test(Be.pismo)
> Be.pismo.kw
data:  Be.pismo
Kruskal-Wallis chi-squared = 4.4337, df = 2, p-value = 0.1090

##Cadmium
```

Attachment 4. Kruskal-Wallis Output.

```
> Cd.obispo.kw=kruskal.test(Cd.obispo)
> Cd.obispo.kw
data:  Cd.obispo
Kruskal-Wallis chi-squared = 4.6958, df = 2, p-value = 0.09557

> Cd.pismo.kw=kruskal.test(Cd.pismo)
> Cd.pismo.kw

data:  Cd.pismo
Kruskal-Wallis chi-squared = 5.7139, df = 2, p-value = 0.05744

##Chromium
> Cr.obispo.kw=kruskal.test(Cr.obispo)
> Cr.obispo.kw
data:  Cr.obispo
Kruskal-Wallis chi-squared = 11.1792, df = 2, p-value = 0.003736

Potential UCL to Use		Use 95% Approximate Gamma UCL	11.14

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL. These recommendations are based upon the results of the simulation studies summarized in Singh, Singh, and Iaci (2002) and Singh and Singh (2003). For additional insight, the user may want to consult a statistician.

ProUCL Output
Exposure Area C 0 to 10 ft bgs

General UCL Statistics for Data Sets with Non-Detects

User Selected Options

From File	Area C.wst
Full Precision	OFF
Confidence Coefficient	95%
Number of Bootstrap Operations	2000

Benzo(a)anthracene

General Statistics

Number of Valid Data	14	Number of Detected Data	7
Number of Distinct Detected Data	7	Number of Non-Detect Data	7
		Percent Non-Detects	50.00%

Raw Statistics		Log-transformed Statistics	
Minimum Detected	0.013	Minimum Detected	-4.343
Maximum Detected	0.07	Maximum Detected	-2.659
Mean of Detected	0.0329	Mean of Detected	-3.569
SD of Detected	0.0197	SD of Detected	0.605
Minimum Non-Detect	0.005	Minimum Non-Detect	-5.298
Maximum Non-Detect	0.04	Maximum Non-Detect	-3.219

Note: Data have multiple DLs - Use of KM Method is recommended
For all methods (except KM, DL/2, and ROS Methods),
Observations < Largest ND are treated as NDs

Number treated as Non-Detect	12
Number treated as Detected	2
Single DL Non-Detect Percentage	85.71%

Warning: There are only 7 Detected Values in this data
Note: It should be noted that even though bootstrap may be performed on this data set
the resulting calculations may not be reliable enough to draw conclusions

It is recommended to have 10-15 or more distinct observations for accurate and meaningful results.

Phenanthrene

General Statistics

Number of Valid Data	10	Number of Detected Data	5
Number of Distinct Detected Data	3	Number of Non-Detect Data	5
		Percent Non-Detects	50.00%

Raw Statistics

Minimum Detected	0.012
Maximum Detected	0.072
Mean of Detected	0.0268
SD of Detected	0.0255
Minimum Non-Detect	0.005
Maximum Non-Detect	20

Log-transformed Statistics

Minimum Detected	-4.423
Maximum Detected	-2.631
Mean of Detected	-3.881
SD of Detected	0.735
Minimum Non-Detect	-5.298
Maximum Non-Detect	2.996

Note: Data have multiple DLs - Use of KM Method is recommended
For all methods (except KM, DL/2, and ROS Methods),
Observations < Largest ND are treated as NDs

Number treated as Non-Detect	10
Number treated as Detected	0
Single DL Non-Detect Percentage	100.00%

Warning: There are only 3 Distinct Detected Values in this data set
The number of detected data may not be adequate enough to perform GOF tests, bootstrap, and ROS methods.
Those methods will return a 'N/A' value on your output display!

It is necessary to have 4 or more Distinct Values for bootstrap methods.
However, results obtained using 4 to 9 distinct values may not be reliable.
It is recommended to have 10 to 15 or more observations for accurate and meaningful results and estimates.

95% Approximate Gamma UCL 49.46
95% Adjusted Gamma UCL 50.58

Potential UCL to Use Use 95% H-UCL 51.09

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
These recommendations are based upon the results of the simulation studies summarized in Singh, Singh, and Iaci (2002)
and Singh and Singh (2003). For additional insight, the user may want to consult a statistician.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
These recommendations are based upon the results of the simulation studies summarized in Singh, Singh, and Iaci (2002)
and Singh and Singh (2003). For additional insight, the user may want to consult a statistician.

Mercury

General Statistics

Number of Valid Data	40	Number of Detected Data	9
Number of Distinct Detected Data	7	Number of Non-Detect Data	31
		Percent Non-Detects	77.50%

Raw Statistics		**Log-transformed Statistics**	
Minimum Detected	0.03	Minimum Detected	-3.507
Maximum Detected	0.7	Maximum Detected	-0.357
Mean of Detected	0.201	Mean of Detected	-2.018
SD of Detected	0.216	SD of Detected	0.931
Minimum Non-Detect	0.02	Minimum Non-Detect	-3.912
Maximum Non-Detect	0.1	Maximum Non-Detect	-2.303

Note: Data have multiple DLs - Use of KM Method is recommended		Number treated as Non-Detect	34
For all methods (except KM, DL/2, and ROS Methods),		Number treated as Detected	6
Observations < Largest ND are treated as NDs		Single DL Non-Detect Percentage	85.00%

Warning: There are only 9 Detected Values in this data
Note: It should be noted that even though bootstrap may be performed on this data set
the resulting calculations may not be reliable enough to draw conclusions

It is recommended to have 10-15 or more distinct observations for accurate and meaningful results.

99% Chebyshev(Mean, Sd) UCL	133.4

Potential UCL to Use

Use 95% H-UCL 67.06

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
These recommendations are based upon the results of the simulation studies summarized in Singh, Singh, and Iaci (2002)
and Singh and Singh (2003). For additional insight, the user may want to consult a statistician.

Potential UCL to Use		Use 95% H-UCL	91.62

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
These recommendations are based upon the results of the simulation studies summarized in Singh, Singh, and Iaci (2002)
and Singh and Singh (2003). For additional insight, the user may want to consult a statistician.

Benzo(g,h,i)perylene

General Statistics

Number of Valid Data	12	Number of Detected Data	3
Number of Distinct Detected Data	3	Number of Non-Detect Data	9
		Percent Non-Detects	75.00%

Raw Statistics		**Log-transformed Statistics**	
Minimum Detected	0.005	Minimum Detected	-5.298
Maximum Detected	0.093	Maximum Detected	-2.375
Mean of Detected	0.0367	Mean of Detected	-4.032
SD of Detected	0.0489	SD of Detected	1.5
Minimum Non-Detect	0.005	Minimum Non-Detect	-5.298
Maximum Non-Detect	20	Maximum Non-Detect	2.996

Note: Data have multiple DLs - Use of KM Method is recommended		Number treated as Non-Detect	12
For all methods (except KM, DL/2, and ROS Methods),		Number treated as Detected	0
Observations < Largest ND are treated as NDs		Single DL Non-Detect Percentage	100.00%

Warning: There are only 3 Distinct Detected Values in this data set
The number of detected data may not be adequate enough to perform GOF tests, bootstrap, and ROS methods.
Those methods will return a 'N/A' value on your output display!

It is necessary to have 4 or more Distinct Values for bootstrap methods.
However, results obtained using 4 to 9 distinct values may not be reliable.
It is recommended to have 10 to 15 or more observations for accurate and meaningful results and estimates.

99% Chebyshev(Mean, Sd) UCL	199.5

Potential UCL to Use Use 95% H-UCL 82.97

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
These recommendations are based upon the results of the simulation studies summarized in Singh, Singh, and Iaci (2002)
and Singh and Singh (2003). For additional insight, the user may want to consult a statistician.

Naphthalene

General Statistics

Number of Valid Data	18	Number of Detected Data	5
Number of Distinct Detected Data	5	Number of Non-Detect Data	13
		Percent Non-Detects	72.22%

Raw Statistics

Minimum Detected	0.06
Maximum Detected	2.4
Mean of Detected	1.142
SD of Detected	0.913
Minimum Non-Detect	0.005
Maximum Non-Detect	0.1

Log-transformed Statistics

SD of Detected	0.698
Minimum Non-Detect	0.005
Maximum Non-Detect	0.005

Log-transformed Statistics

Minimum Detected	-2.617
Maximum Detected	0.262
Mean of Detected	-1.521
SD of Detected	1.558
Minimum Non-Detect	-5.298
Maximum Non-Detect	-5.298

Warning: There are only 3 Distinct Detected Values in this data set
The number of detected data may not be adequate enough to perform GOF tests, bootstrap, and ROS methods.
Those methods will return a 'N/A' value on your output display!

It is necessary to have 4 or more Distinct Values for bootstrap methods.

However, results obtained using 4 to 9 distinct values may not be reliable.

It is recommended to have 10 to 15 or more observations for accurate and meaningful results and estimates.

Potential UCL to Use Use 95% H-UCL 107.2

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
These recommendations are based upon the results of the simulation studies summarized in Singh, Singh, and Iaci (2002)
and Singh and Singh (2003). For additional insight, the user may want to consult a statistician.

SD of Detected	0.332	SD of Detected	0.241
Minimum Non-Detect	0.5	Minimum Non-Detect	-0.693
Maximum Non-Detect	1	Maximum Non-Detect	0

Note: Data have multiple DLs - Use of KM Method is recommended
For all methods (except KM, DL/2, and ROS Methods),
Observations < Largest ND are treated as NDs

Number treated as Non-Detect	7
Number treated as Detected	4
Single DL Non-Detect Percentage	63.64%

Warning: There are only 3 Distinct Detected Values in this data set
The number of detected data may not be adequate enough to perform GOF tests, bootstrap, and ROS methods.
Those methods will return a 'N/A' value on your output display!

It is necessary to have 4 or more Distinct Values for bootstrap methods.
However, results obtained using 4 to 9 distinct values may not be reliable.
It is recommended to have 10 to 15 or more observations for accurate and meaningful results and estimates.

Anthracene

General Statistics

Number of Valid Data	45
Number of Distinct Detected Data	3
Number of Detected Data	3
Number of Non-Detect Data	42
Percent Non-Detects	93.33%

Raw Statistics

Minimum Detected	0.006
Maximum Detected	0.024
Mean of Detected	0.0137
SD of Detected	0.00929
Minimum Non-Detect	0.0049

Log-transformed Statistics

Minimum Detected	-5.116
Maximum Detected	-3.73
Mean of Detected	-4.452
SD of Detected	0.695
Minimum Non-Detect	-5.319

Maximum Non-Detect	0.2	Maximum Non-Detect	-1.609
Note: Data have multiple DLs - Use of KM Method is recommended		Number treated as Non-Detect	45
For all methods (except KM, DL/2, and ROS Methods),		Number treated as Detected	0
Observations < Largest ND are treated as NDs		Single DL Non-Detect Percentage	100.00%

Warning: There are only 3 Distinct Detected Values in this data set
The number of detected data may not be adequate enough to perform GOF tests, bootstrap, and ROS methods.
Those methods will return a 'N/A' value on your output display!

It is necessary to have 4 or more Distinct Values for bootstrap methods.
However, results obtained using 4 to 9 distinct values may not be reliable.
It is recommended to have 10 to 15 or more observations for accurate and meaningful results and estimates.

General Statistics

Number of Valid Data	66	Number of Detected Data	3
Number of Distinct Detected Data	3	Number of Non-Detect Data	63
		Percent Non-Detects	95.45%

Raw Statistics

Minimum Detected	0.069
Maximum Detected	2.1
Mean of Detected	1.223
SD of Detected	1.043
Minimum Non-Detect	0.0046
Maximum Non-Detect	0.1

Log-transformed Statistics

Minimum Detected	-2.674
Maximum Detected	0.742
Mean of Detected	-0.509
SD of Detected	1.882
Minimum Non-Detect	-5.382
Maximum Non-Detect	-2.303

Note: Data have multiple DLs - Use of KM Method is recommended
For all methods (except KM, DL/2, and ROS Methods),
Observations < Largest ND are treated as NDs

Number treated as Non-Detect	64
Number treated as Detected	2
Single DL Non-Detect Percentage	96.97%

Warning: There are only 3 Distinct Detected Values in this data set
The number of detected data may not be adequate enough to perform GOF tests, bootstrap, and ROS methods.
Those methods will return a 'N/A' value on your output display!

It is necessary to have 4 or more Distinct Values for bootstrap methods.
However, results obtained using 4 to 9 distinct values may not be reliable.
It is recommended to have 10 to 15 or more observations for accurate and meaningful results and estimates.

Potential UCL to Use

Use 95% H-UCL 20.68

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
These recommendations are based upon the results of the simulation studies summarized in Singh, Singh, and Iaci (2002)
and Singh and Singh (2003). For additional insight, the user may want to consult a statistician.

Potential UCL to Use	
Use 95% H-UCL	28.97

ProUCL computes and outputs H-statistic based UCLs for historical reasons only.
H-statistic often results in unstable (both high and low) values of UCL95 as shown in examples in the Technical Guide.
It is therefore recommended to avoid the use of H-statistic based 95% UCLs.
Use of nonparametric methods are preferred to compute UCL95 for skewed data sets which do not follow a gamma distribution.

Note: Suggestions regarding the selection of a 95% UCL are provided to help the user to select the most appropriate 95% UCL.
These recommendations are based upon the results of the simulation studies summarized in Singh, Singh, and Iaci (2002)
and Singh and Singh (2003). For additional insight, the user may want to consult a statistician.

Note: Data have multiple DLs - Use of KM Method is recommended		Number treated as Non-Detect	95
For all methods (except KM, DL/2, and ROS Methods),		Number treated as Detected	1
Observations < Largest ND are treated as NDs		Single DL Non-Detect Percentage	98.96%

Warning: Data set has only 2 Distinct Detected Values.
This may not be adequate enough to compute meaningful and reliable test statistics and estimates.
The Project Team may decide to use alternative site specific values to estimate environmental parameters (e.g., EPC, BTV).

Unless Data Quality Objectives (DQOs) have been met, it is suggested to collect additional observations.

The number of detected data may not be adequate enough to perform GOF tests, bootstrap, and ROS methods.
Those methods will return a 'N/A' value on your output display!

It is necessary to have 4 or more Distinct Values for bootstrap methods.
However, results obtained using 4 to 9 distinct values may not be reliable.
It is recommended to have 10 to 15 or more observations for accurate and meaningful results and estimates.

Construction Worker Volatilization Factor (and apparent diffusivity): calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqns 5-14 and 5-15

Where: $Q/Csa = A \times \exp\left[\frac{(\ln \text{Asite} - B)^2}{C}\right.$

Input Parameters

VFsc=		calculated	m^3/kg	Construction worker subchronic volatilization factor (Eqn 5-14)
Da=		calculated	cm2/s	Apparent diffusivity (Eqn 5-14)
T =	7.78E+06	site-specific	sec	Total time over which construction activities occurs (including time not worked)
rhob=	1.41	site-specific	g/cm^3	Dry soil bulk density; average of Obispo samples (see Table 5-34)
Q/Csa=	11.58	calculated	$(g/m^2/sec)/(kg/m^3)$	Subchronic dispersion factor for a ground level area emission source - construction worker (USEPA Eqns 5-15 and E-15)
Fd=	0.188	calculated	unitless	Dispersion correction factor for averaging times less than one year (default = 0.185, Eqns 5-14, E-16)
Thours =	2.16E+03	site-specific	hours	Total time over which construction activities occurs, in hours (for Fd calculation; Eqn E-16)
q_{as} =	0.21	qt-qws	unitless	Air-filled soil porosity (USEPA 2002)
q_T =	0.41	1-(rhob/rhos)	unitless	Total soil porosity (USEPA 2002)
q_{ws} =	0.202	site-specific	unitless	Water-filled soil porosity; average of Obispo samples (see Table 5-34)
rhos=	2.38	site-specific	g/cm3	Soil particle density; average of Obispo samples (Avocet 2008b)
Di=	chemical specific		cm2/sec	Diffusivity in air
Dw=	chemical specific		cm2/sec	Diffusivity in water
Ho=	chemical specific		unitless	Henry's Law Constant
Kd=	chemical specific	Koc*foc (orgs)	cm3/g	Soil-water partition coefficient
Koc=	chemical specific		ml/g (l/kg)	Organic carbon partition coefficient
Foc =	0.002	site-specific	unitless	Fraction organic carbon; average of Obispo samples (Avocet 2008b)
A_{site} =	1.550	site-specific	acres	Areal extent of contamination
A =	*2.4538*	*constant - default*	unitless	constant (USEPA 2002) - default for Q/Csa calc (see App E, E-15)
B =	*17.566*	*constant - default*	unitless	constant (USEPA 2002) - default for Q/Csa calc (see App E, E-15)

Construction Worker Particulate Emission Factor, Wind Erosion and Dumping of Excavated Soils: calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqns E-25 and E-26

$PEF_{sc} = Q/Csa \times 1/Fd \times 1/Jt$

$Jt = (Mwind + Mexcav + Mdoz + Mgrade + Mtill) / (Asite(meters) \times T)$

Where:

PEF_{sc} =	3.65E+07	calculated	m^3/kg	Construction worker particulate emission factor due to activities other than unpaved road traffic
Q/C_{sa} =	11.58	calculated	$(g/m^2/sec)/(kg/m^3)$	Subchronic dispersion factor for a ground level area emission source - construction worker (USEPA Eqns 5-15 and E-15)
Fd =	0.188	calculated	unitless	Dispersion correction factor (default = 0.185, Eqns 5-5 and E-16)
T =	2.6E+06	site-specific	sec	Duration of construction during which workers may be exposure; active work time
Jt =	1.69E-06	calculated	g/m^2-sec	Total time-averaged PM10 unit emission flux for construction activities other than unpaved road traffic
A_{site} =	1.55	site-specific	acres	Areal extent of contamination
Asite meters =	6272.70	calculated	m^2	Areal extent of contamination

Construction Worker Non-traffic PEF: Mass from wind erosion: calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqn E--20

Mwind =	2.72E+04	calculated	grams	Mass emitted from wind erosion
RPF =	*0.036*	*default*	$g/m^2/hr$	Respirable particle fraction
V =	*0.0*	*default*	unitless	Fraction vegetative cover
Um =	*4.69*	*default*	m/sec	Mean annual wind speed (default, USEPA 2002)
Ut =	*11.32*	*default*	m/sec	Equivalent threshold value of wind speed at 7 m (default USEPA 2002)
x =	2.138	calculated	unitless	Function of Ut/Um; x = 0.886 × (Ut/Um)
Fx =	0.193	calculated	unitless	Function of x; Fx = 0.18 × ($8x^3 + 12x$) × $\exp(-x^2)$
ED =	8760	default	hours	Exposure duration

Construction Worker Non-traffic PEF: Mass from dumping of excavated soils: calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqn E--21

Mexcav =	2.50E+02	calculated	grams	Mass emitted from dumping of excavated soils
PM =	*0.35*	*default*	unitless	PM10 particle size multiplier (default, USEPA 2002)
Um =	*4.69*	*default*	m/sec	Mean annual wind speed (default, USEPA 2002)
M =	14	site-specific	%	Gravimetric soil moisture content; average of Obispo samples (Avocet 2008b)
rhos=	1.61	site-specific	Mg/m^3	In situ soil density (includes water); average of Obispo samples (Avocet 2008b)
A_{excav} =	0.10	site-specific	acres	Areal extent of excavation; site-specific assumption for trenching
A_{excav} =	404.69	calculated	m^2	Areal extent of excavation
d_{excav} =	2	site-specific	m	Average depth of excavation
N =	*2*	*default*	unitless	Number of times soil is dumped (default, USEPA 2002)

Construction Worker Particulate Emission Factor, Wind Erosion and Dumping of Excavated Soils: calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqns E-25 and E-26

$PEF_{sc} = Q/Csa \times 1/Fd \times 1/Jt$

$Jt = (Mwind + Mexcav + Mdoz + Mgrade + Mtill) / (Asite(meters) \times T)$

Where:

PEF_{sc} =	3.73E+07	calculated	m^3/kg	Construction worker particulate emission factor due to activities other than unpaved road traffic
Q/C_{sa} =	11.78	calculated	$(g/m^2/sec)/(kg/m^3)$	Subchronic dispersion factor for a ground level area emission source - construction worker (USEPA Eqns 5-15 and E-15)
Fd =	0.188	calculated	unitless	Dispersion correction factor (default = 0.185, Eqns 5-5 and E-16)
T =	2.6E+06	site-specific	sec	Duration of construction during which workers may be exposure; active work time
Jt =	1.68E-06	calculated	g/m^2-sec	Total time-averaged PM10 unit emission flux for construction activities other than unpaved road traffic
A_{site} =	1.41	site-specific	acres	Areal extent of contamination
Asite meters =	5706.13	calculated	m^2	Areal extent of contamination

Construction Worker Non-traffic PEF: Mass from wind erosion: calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqn E--20

Mwind =	2.48E+04	calculated	grams	Mass emitted from wind erosion
RPF =	*0.036*	*default*	$g/m^2/hr$	Respirable particle fraction
V =	*0.0*	*default*	unitless	Fraction vegetative cover
Um =	*4.69*	*default*	m/sec	Mean annual wind speed (default, USEPA 2002)
Ut =	*11.32*	*default*	m/sec	Equivalent threshold value of wind speed at 7 m (default USEPA 2002)
x =	2.138	calculated	unitless	Function of Ut/Um; x = 0.886 × (Ut/Um)
Fx =	0.193	calculated	unitless	Function of x; Fx = 0.18 × ($8x^3 + 12x$) × $\exp(-x^2)$
ED =	8760	default	hours	Exposure duration

Construction Worker Non-traffic PEF: Mass from dumping of excavated soils: calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqn E--21

Mexcav =	1.46E+02	calculated	grams	Mass emitted from dumping of excavated soils
PM =	*0.35*	*default*	unitless	PM10 particle size multiplier (default, USEPA 2002)
Um =	*4.69*	*default*	m/sec	Mean annual wind speed (default, USEPA 2002)
M =	20	site-specific	%	Gravimetric soil moisture content; average of Psimo samples (Avocet 2008b)
rhos=	1.46	site-specific	Mg/m^3	In situ soil density (includes water); average of Pismo samples (Avocet 2008b)
A_{excav} =	0.10	site-specific	acres	Areal extent of excavation; site-specific assumption for trenching
A_{excav} =	404.69	calculated	m^2	Areal extent of excavation
d_{excav} =	2	site-specific	m	Average depth of excavation
N =	*2*	*default*	unitless	Number of times soil is dumped (default, USEPA 2002)

Construction Worker Volatilization Factor (and apparent diffusivity): calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqns 5-14 and 5-15

Where: $\frac{Q}{Csa} = A \times \exp\left[\frac{(\ln Asite - B)^2}{C}\right.$

Input Parameters

VFsc=		calculated	m^3/kg	Construction worker subchronic volatilization factor (Eqn 5-14)
Da=		calculated	cm2/s	Apparent diffusivity (Eqn 5-14)
T =	7.78E+06	site-specific	sec	Total time over which construction activities occurs (including time not worked)
rhob=	1.41	site-specific	g/cm^3	Dry soil bulk density; average of Obispo samples (see Table 5-34)
Q/Csa=	12.74	calculated	$(g/m^2/sec)/(kg/m^3)$	Subchronic dispersion factor for a ground level area emission source - construction worker (USEPA Eqns 5-15 and E-15)
Fd=	0.188	calculated	unitless	Dispersion correction factor for averaging times less than one year (default = 0.185, Eqns 5-14, E-16)
Thours =	2.16E+03	site-specific	hours	Total time over which construction activities occurs, in hours (for Fd calculation; Eqn E-16)
q_{as} =	0.21	qt-qws	unitless	Air-filled soil porosity (USEPA 2002)
q_T =	0.41	1-(rhob/rhos)	unitless	Total soil porosity (USEPA 2002)
q_{ws} =	0.202	site-specific	unitless	Water-filled soil porosity; average of Obispo samples (see Table 5-34)
rhos=	2.38	site-specific	g/cm3	Soil particle density; average of Obispo samples (Avocet 2008b)
Di=	chemical specific		cm2/sec	Diffusivity in air
Dw=	chemical specific		cm2/sec	Diffusivity in water
Ho=	chemical specific		unitless	Henry's Law Constant
Kd=	chemical specific	Koc*foc (orgs)	cm3/g	Soil-water partition coefficient
Koc=	chemical specific		ml/g (l/kg)	Organic carbon partition coefficient
Foc =	0.002	site-specific	unitless	Fraction organic carbon; average of Obispo samples (Avocet 2008b)
A_{site} =	0.92	site-specific	acres	Areal extent of contamination
A =	*2.4538*	*constant - default*	unitless	constant (USEPA 2002) - default for Q/Csa calc (see App E, E-15)
B =	*17.566*	*constant - default*	unitless	constant (USEPA 2002) - default for Q/Csa calc (see App E, E-15)
C =	*189.0426*	*constant - default*	unitless	constant (USEPA 2002) - default for Q/Csa calc (see App E, E-15)

Construction Worker Particulate Emission Factor, Wind Erosion and Dumping of Excavated Soils: calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqns E-25 and E-26

$PEF_{sc} = Q/Csa \times 1/Fd \times 1/Jt$

$Jt = (Mwind + Mexcav + Mdoz + Mgrade + Mtill) / (Asite(meters) \times T)$

Where:

PEF_{sc} =	3.99E+07	calculated	m^3/kg	Construction worker particulate emission factor due to activities other than unpaved road traffic
Q/C_{sa} =	12.74	calculated	$(g/m^2/sec)/(kg/m^3)$	Subchronic dispersion factor for a ground level area emission source - construction worker (USEPA Eqns 5-15 and E-15)
Fd =	0.188	calculated	unitless	Dispersion correction factor (default = 0.185, Eqns 5-5 and E-16)
T =	2.6E+06	site-specific	sec	Duration of construction during which workers may be exposure; active work time
Jt =	1.70E-06	calculated	g/m^2-sec	Total time-averaged PM10 unit emission flux for construction activities other than unpaved road traffic
A_{site} =	0.92	site-specific	acres	Areal extent of contamination
Asite meters =	3739.34	calculated	m^2	Areal extent of contamination

Construction Worker Non-traffic PEF: Mass from wind erosion: calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqn E--20

Mwind =	1.62E+04	calculated	grams	Mass emitted from wind erosion
RPF =	*0.036*	*default*	$g/m^2/hr$	Respirable particle fraction
V =	*0.0*	*default*	unitless	Fraction vegetative cover
Um =	*4.69*	*default*	m/sec	Mean annual wind speed (default, USEPA 2002)
Ut =	*11.32*	*default*	m/sec	Equivalent threshold value of wind speed at 7 m (default USEPA 2002)
x =	2.138	calculated	unitless	Function of Ut/Um; x = 0.886 × (Ut/Um)
Fx =	0.193	calculated	unitless	Function of x; Fx = 0.18 × ($8x^3 + 12x$) × $\exp(-x^2)$
ED =	8760	default	hours	Exposure duration

Construction Worker Non-traffic PEF: Mass from dumping of excavated soils: calculated according to USEPA (2002a) Supplemental Soil Screening Guidance, Eqn E--21

Mexcav =	2.50E+02	calculated	grams	Mass emitted from dumping of excavated soils
PM =	*0.35*	*default*	unitless	PM10 particle size multiplier (default, USEPA 2002)
Um =	*4.69*	*default*	m/sec	Mean annual wind speed (default, USEPA 2002)
M =	14	site-specific	%	Gravimetric soil moisture content; average of Obispo samples (Avocet 2008b)
rhos=	1.61	site-specific	Mg/m^3	In situ soil density (includes water); average of Obispo samples (Avocet 2008b)
A_{excav} =	0.10	site-specific	acres	Areal extent of excavation; site-specific assumption for trenching
A_{excav} =	404.69	calculated	m^2	Areal extent of excavation
d_{excav} =	2	site-specific	m	Average depth of excavation
N =	*2*	*default*	unitless	Number of times soil is dumped (default, USEPA 2002)
