Introduction

The Montrose Chemical Corporation of California (Montrose) operated a DDT manufacturing and formulation facility at 21201 South Normandie Avenue in Los Angeles, California, from 1947 until 1982 when the facility was closed. The Montrose facility (the "Facility") occupied approximately 13 acres (the "Property") located in the City and County of Los Angeles. The Facility was dismantled in 1983. In 1985, without the approval of the U.S. Environmental Protection Agency (USEPA) or the state, Montrose regraded and capped most of the Property with asphalt.

Releases from the Facility to the surrounding environment have occurred via groundwater, air, and surface water. The Montrose site was included on the National Priorities List (NPL) of federal sites on October 4, 1989 (Metcalf and Eddy, 1986). The Montrose Superfund site includes the Property, the surface soil surrounding the Property, the underlying contaminated groundwater, the sanitary sewers, and the stormwater pathway. The stormwater pathway includes the Jones Ditch, Normandie Avenue Ditch, Kenwood Drain, Torrance Lateral, Dominguez Channel, and Consolidated Slip (see Figure 1).

Potential sources of exposure (surface water, sediment, and biota) were sampled in 1994 to obtain representative data that could be used to determine whether Montrose-related contamination in drainages could result in impacts to human health or the environment (CH2M HILL, 1993; CH2M HILL, 1995). Sediments were sampled again in 2002 to obtain samples representative of current conditions (CH2M HILL, 2002).

A Phase I ecological risk assessment (EcoRA) was conducted (CH2M HILL, 1992) as part of the remedial investigation/feasibility study (RI/FS) to address those areas of the site that were potentially affected by environmental releases of chemicals of concern through surface drainage and atmospheric transport. Based on the conclusions and limitations of the Phase I EcoRA, a Phase II investigation was recommended. However, before proceeding with the

Phase 2 EcoRA, it was necessary to determine whether current levels of contamination differ from those observed in 1994.

This need was due to delays between completion of sampling in 1994 and the Phase II EcoRA as well as the occurrence of high rainfall runoff associated with an El Nino event in 1997 to 1998. This technical memorandum summarizes the Fall 2002 supplemental sampling results and compares surface sediment data (0 to 6 inches) collected in 1994 and 2002 from surface drainages and stormwater pathways, and discusses the adequacy of the data for completion of the EcoRA. Samples from sediment collected throughout the depth of the Dominguez Channel (up to 6 feet) as well as up to 3 feet in depth in Consolidated Slip were also collected in 2002. Those results may be used to help identify areas of temporary, in-channel sediment and contaminant storage and to quantify the volume and location of contaminated sediments within the system. The fall 2002 results are summarized below and provided in detail in Appendix A.

Methods

Sediment

Sampling and analysis methods for the two collection events are outlined in the *Sampling and Analysis Plan for Sediment, Surface Water, and Biological Sampling* (CH2M HILL, 1993) and the *Field Sampling Plan for the Montrose Superfund Site Supplemental Sediment Investigation* (CH2M HILL, 2002). Detailed descriptions and results of the sampling conducted in 1994 are presented in the field sampling report (CH2M HILL, 1995).

Data were reduced in several steps as part of this comparative summary of sediment results. Sample-specific method detection limits were averaged by analyte, and half of the average value was used when samples were qualified as nondetects (i.e., qualified as "U" in the database). DDT isomers and metabolites were summed, by sample location, to produce total DDT (tDDT) concentrations. If at least one of the six DDT isomers or metabolites was detected, the tDDT value was calculated. Chemical results with laboratory or validation qualifier "R" were considered rejected and were removed from the database. The maximum value between an original sample and its field duplicate was retained for analysis; the lower value was removed from the database. All other results were retained for quantitative use. Overall detection frequencies for DDT and BHC isomers for 1994 and 2002 are presented here in Tables 1 and 2, respectively.

Geometric means and maxima were calculated by reach for each analyte with a detection frequency \geq 50 percent. Only maxima were calculated for analytes, by reach, when detection frequencies were less than 50 percent. These summary sediment quality statistics are presented by reach in Table 3 and Figures 2 through 8 for 0- to 6-inch depths of sediment, and in Table 5 for all depths of sediment for the 2002 data.

Biota

Water and biological tissue data (fish and aquatic invertebrates) collected in 1994 were not resampled in 2002. Single samples of water (as collected in 1994) are not useful estimates of ecological exposure in a flowing water system such as the Montrose storm drainage pathway. Instead, biota sediment accumulation factors (BSAF) were estimated as a tool to

evaluate ecological exposure. Relationships between co-located tissue and sediment concentrations from 1994 were used to create BSAFs, which could be used to estimate food chain tissue concentrations in 2002.

BSAFs were estimated within each reach for each sediment and biological tissue sample from the 1994 data set for tDDT as:

$$\text{BSAF (unitless)} = (C_t/f_l)/(C_s/f_{oc}), \text{ where:}$$

C_t = Organism tissue contaminant concentration (milligrams per kilogram [mg/kg])

f_l = Lipid fraction in the tissue sample

C_s = Sediment contaminant concentration (mg/kg)

f_{oc} = Organic carbon fraction in the sediment

Individual biota tissue results were combined with reach-average sediment values to yield the values summarized in Table 4. The BSAF results were compared to standard literature values for DDT and DDE. In addition, BSAFs will be estimated for BHC compounds for the EcoRA.

Results

Analytical data were not collected for BHCs and tDDTs from three segments in 1994 (Torrance Lateral Upgradient, Dominguez Channel Upgradient of Torrance Lateral, and Dominguez Channel Midchannel at Torrance Lateral). In most of the remaining 1994 samples, BHCs were not measured above their sample-specific detection limits (Table 1). Sample-specific detection limits were consistently higher in 1994 data, compared to 2002 data. As a consequence, detection frequency and data availability were generally higher for surface samples collected during 2002 (Table 2). Of all the BHC isomers analyzed in the 1994 samples, only δ -BHC collected at Consolidated Slip had a detection frequency of >50 percent. The comparative BHC data suggest that the contaminant load has moved downgradient during the last 8 years. Surface sediment concentrations for all four isomers are greatest at Consolidated Slip in 2002, but not consistently so in 1994. The data show a buildup in BHC concentrations over time at Consolidated Slip (Figures 5 through 8).

The 2002 concentrations of the other BHC isomers are also highest at Consolidated Slip; mean concentrations of α -BHC and γ -BHC were similar at all depths, whereas mean concentrations of β -BHC and δ -BHC tended to decrease with increasing sediment depth (Table 5). Mean concentrations of each BHC isomer do not change significantly with depth at Dominguez Channel Segment 1 (Table 5).

Two important patterns are shown by tDDT (Figures 3 and 4). Maximum (Figure 3) and mean (Figure 4) tDDT concentrations in 1994 suggested Kenwood Drain was a source, and the Dominguez Channel Intertidal area was a sink (Dominguez Channel Intertidal, the confluence of the Torrance Lateral with the Dominguez Channel, is a sediment depositional area and a zone of freshwater and saltwater mixing). This pattern was not present in the 2002 data; instead, tDDT concentrations were highest at Consolidated Slip, suggesting that sediment concentrations decreased at Kenwood Drain and Dominguez Channel Intertidal,

but increased at Consolidated Slip over time (Figures 3 and 4). This is most likely to have occurred as a result of scouring of drainage channels during high volume stormflows during the past 8 years associated with the concurrent redeposition of sediments in the upper harbor.

The largest increase in 2002 tDDT sediment concentrations was revealed in the maximum surface sediment concentrations, moving downgradient from Torrance Lateral, Kenwood Drain, and Dominguez Channel to Consolidated slip. The highest maximum concentrations were found in Dominguez Channel Segment 3, Consolidated Slip, and the midchannel station at the intersection of Torrance Lateral and Dominguez Channel (see Figure 1 for location). Although minimum, mean, and maximum concentrations decreased with depth at Consolidated Slip, minimum and mean concentrations at Dominguez Channel Segment 1 increased with depth. The maximum concentrations at Dominguez Channel Segment 1 were highest in sediment collected from the 0.5- to 3-foot layer and lowest in the > 3-foot layer.

Preliminary BSAFs for tDDT were estimated for fish and invertebrates based on the 1994 data (Table 4). The 1994 results are variable and generally low, as compared to literature values. Only mosquitofish showed BSAFs over 1.0 (Table 4). In contrast, literature-derived BSAFs for pelagic species average 7.7 versus 1.85 for benthic species (USEPA, 1997). The BSAF values in Table 4, as well as estimates for BHC compounds, can be used to calculate tissue concentrations for the risk assessment using the 2002 sediment data. However, one task of the risk assessment will be to compare these 1994 field estimates to literature results for comparable species to arrive at the best choice of BSAFs for the report. In neither case will additional field sampling of biota be required to complete the risk assessment.

Discussion

The following summary can be applied to the sediment BHC and tDDT results collected in 1994 and 2002:

- The 1994 sediment dataset generally had quantitation limits higher than the 2002 surface sediment (0 to 6 inches) dataset detection limits, although the detection limits from both datasets are similar. This may be an artifact of improved extraction and analytical methodologies.
- DDT and BHC are likely moving downgradient into Consolidated Slip and may eventually continue farther into the Port of Los Angeles. The 2002 data show that the concentration of tDDT and BHC isomers were lower in Kenwood Drain than in Dominguez Channel Intertidal, and greatest in Consolidated Slip as compared to 1994. Specific results showed:
 - Kenwood Drain appeared to be a source of tDDT (and possibly BHC isomers) in 1994, but much less so in 2002.
 - The Dominguez Channel Intertidal zone (at the confluence with the Torrance Lateral), although also appearing to be a source of tDDT and BHC, is known to be a sediment depositional zone, and therefore was likely both a sink and source (depending on flow velocity) in 1994 and 2002.

- The upgradient surface sediment sample results from 2002 (Dominguez Channel Upgradient of the tidal influence) and the Torrance Lateral Upgradient of the Kenwood Drain) both showed greatly reduced concentrations of DDTs relative to the Montrose drainage pathways. These results demonstrate the primary, local (Montrose) source for DDT loading to the channels as superimposed on a low level of background loading.
- The 1994 sediment and tissue chemistry data can be used in conjunction with available literature values for BSAFs to provide new estimates of tissue chemistry using the 2002 surface sediment results.
- The field data collected during 1994 and 2002 provide sufficient information to proceed with the EcoRA for the Montrose surface water pathways. No further data collection will be required.
- The 2002 sediment quality data provide an estimate of total load and stratigraphy of contaminants in the Dominguez Channel and uppermost zones of Consolidated Slip.

Notes:

tDDT calculated by summing isomer concentrations by sample, and averaging the totals for each reach

#DETS = number of samples with concentrations above the detection limit

"--" = Insufficient or no data

CS = Consolidated Slip

DC1 - DC4 = Dominguez Channel Segments 1 through 4

DCM = Dominguez Channel Midchannel Segment

DCT = Dominguez Channel Intertidal Segment

DCU = Dominguez Channel Segment Upgradient of Torrance Lateral

KDD = Kenwood Drain

TLL = Torrance Lateral Lined Segment

TLN = Torrance Lateral Nonlined Segment

TLU = Torrance Lateral Segment Upgradient of KDD

Consolidated Slip - 5	3	10/15/02	33°46'33.4"	118°14'35.0"
Subtotal EPA Samples	72			
QAQC: (Field duplicates: 1 in 10 samples; MS/MSDs: 1 in 20 samples)				

Notes:

Native samples were surface samples only where single analyses are indicated and from surface to 6 feet (or refusal) where 2 to 3 samples are indicated.

In these locations, 3 samples were collected if at least 4.5 feet of sediment is recovered in vibracore; otherwise, only 2 samples were collected.

In Consolidated Slip, sediments were collected from surface to refusal (or max. 20-foot depth) within the following depth intervals: 0 to 6 inches; 6 inches to 3 feet.

NS = not sampled.

MS/MSD = matrix spike/matrix spike duplicate

Notes and Definitions for Table A-2, Raw Sediment Data, October 2002

FIELD	DESCRIPTION
Sample Delivery Group No.	Laboratory deliverable designation (02J030, 02J100, 02J115, 02J151, 02J172)
Station Location	Abbreviated channel name: CS = Consolidated Slip DC1-4 = Dominguez Channel Sections 1 - 4 DCM = Dominguez Channel Midchannel DCT = Dominguez Channel Intertidal DCU = Dominguez Channel Upgradient [of Torrance Lateral] KDD = Kenwood Drain TLL = Torrance Lateral Lined TLN = Torrance Lateral Nonlined TLU = Torrance Lateral Upgradient
Segment	Channel segment (1 to 5)
Top Depth (ft)	Depth (feet) of top of sediment layer (0 = sediment layer 0 - 6 inches; 0.5 = sediment layer 6 - 36 inches max; 3 = sediment >36 inches)
Latitude	Latitude (in decimal degrees)
Longitude	Longitude (in decimal degrees)
Sample ID	Unique sample ID (Station Location-Segment-Top Depth)
Collection Date	Date samples collected (10/1/02, 10/2/02, 10/8/02, 10/9/02, 10/10/02, 10/11/02, 10/12/02, 10/15/02)
Dilution Factor	Dilution factor (1, 5, or 10)
Compound	Analyte name (alpha-BHC; beta-BHC; delta-BHC; gamma-BHC; percent solids; 2,4'-DDD; 2,4'-DDE; 2,4'-DDT; 4,4'-DDD; 4,4'-DDE; 4,4'-DDT)
Result	Measured concentration, includes nondetects
Units	Units of measurement (ug/kg, %). Dry weight basis.
Qualifier	QA qualifier for Result field (J, JL, JU, U)
Final Result	Measured concentration with contract-required quantitation limits (CRQLs) in place of nondetects
Comment	Lab/Review comment codes (A, AB, ABE, AC, AE, AG, B, C, CE, CF, D, E, EF, F, G)
Case No	11-26CO-39.0
Site	Montrose OU2
Lab	Laboratory where analyses conducted (EMAX)
Reviewer	QA/QC reviewer (Santiago Lee, ESAT/LDC)
Date	Review date (January 15, 2003 and January 21, 2003)
